(57) **ABSTRACT**

A wireless telecommunications terminal employing both an IEEE 802.11 radio and a Bluetooth radio is disclosed. The illustrative embodiment employs a novel preemption scheme that ensures that Bluetooth preemptions of the 802.11 radio are not fatal to the 802.11 media access control (MAC) error-correction mechanism. The illustrative embodiment thus enables what appears to be concurrent 802.11 and Bluetooth activity by a single wireless telecommunications terminal. The preemption scheme does not require any changes to the 802.11 and Bluetooth protocols, or to the radios. It will be clear to those skilled in the art how to make and use alternative embodiments of the present invention for protocols other than IEEE 802.11 and Bluetooth that might interfere with each other.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of:

[0002] 1. U.S. provisional application Serial No. 60/409,356, filed Sep. 9, 2002, entitled "A Mechanism For Collaboration And Interference Prevention Between 802.11 And Bluetooth Using The 802.11 Power Save Mechanism," (Attorney Docket: 680-023us), and

[0003] 2. U.S. provisional application Serial No. 60/411,848, filed Sep. 18, 2002, entitled "Coordinating A Plurality Of Medium Access Control Protocols That Share A Common Communications Channel," (Attorney Docket: 680-017us),

[0004] both of which are also incorporated by reference.

[0005] The following patent application is incorporated by reference:

[0006] 1. U.S. patent application, entitled "Multi-Protocol Interchip Interface," (Attorney Docket: 680-021us).

FIELD OF THE INVENTION

[0007] The present invention relates to telecommunications in general, and, more particularly, to a telecommunications terminal with two radios operating in accordance with competing respective protocols (i.e., respective protocols that might interfere with each other).

BACKGROUND OF THE INVENTION

[0008] FIG. 1 depicts a schematic diagram of a portion of wireless communication system 100 in the prior art. Wireless communication system 100 comprises wireless terminals 101-1 through 101-6, all communicating with each other by using one or more air interfaces in the same, shared radio frequency band. As an example, IEEE 802.11 (i.e., "802.11") wireless terminals 101-1, 101-2, and 101-4 communicate using an 802.11 air interface, Bluetooth wireless terminals 101-5 and 101-6 communicate using a Bluetooth air interface, and 802.11/Bluetooth wireless terminal 101-3 communicates using either an 802.11 or a Bluetooth air interface.

[0009] As depicted in FIG. 1, wireless terminal 101-2 is transmitting a signal with wireless terminal 101-3 as the intended recipient. Also, wireless terminal 101-6 is transmitting a signal with wireless terminal 101-5 as the intended recipient. Wireless terminals 101-2 and 101-6 can transmit simultaneously, although in order to do so, either (1) their respective transmissions have to be coordinated, or (2) wireless terminals 101-2 and 101-6 have to be situated far enough apart from each other to minimize interference. If, however, a wireless terminal supports two air interface protocols (e.g., wireless terminal 101-3, etc.), a mechanism must exist to prevent interference (i.e., the effect of two radios transmitting simultaneously in the same frequency band), since spatial separation of two air interfaces within the same wireless terminal is not an option.

[0010] In accordance with a first technique in the prior art, FIG. 2 depicts a block diagram of the salient components of wireless terminal 101-3. Wireless terminal 101-3 comprises

host 201, A/B switch 202, 802.11 radio 203, Bluetooth radio 204, antenna switch 205, and antenna 206. Host 201 comprises a microprocessor. At any given time, host 201 communicates with 802.11 radio 203 or Bluetooth radio 204, both not both, by means of A/B switch 202. 802.11 radio 203 communicates in accordance with the 802.11 air interface, and Bluetooth radio 204 communicates in accordance with the Bluetooth air interface. Antenna switch 205 directs a signal to be transmitted to antenna 206 from either 802.11 radio 203 or Bluetooth radio 204. Antenna switch 205 also directs a received signal from antenna 206 to either 802.11 radio 203 or Bluetooth radio 204. Antenna switch 205 is coordinated with A/B switch 202.

[0011] The first technique in the prior art controls contention for the shared frequency band through A/B switch 202. In addition to providing contention-free access to the shared frequency band, the first technique provides a low-cost solution. As a disadvantage, however, the air interface in use must remain in either 802.11 or Bluetooth mode for relatively long periods of time. Also, contention resolution requires manual intervention on the part of a user whenever wireless terminal 101-3 has to make a transmission over the air interface that is not presently active. Finally, the inactive air interface might miss a transmission by some other wireless terminal.

[0012] In accordance with a second technique in the prior art, FIG. 3 depicts a block diagram of wireless terminal 101-3. Wireless terminal 101-3 comprises host 301, 802.11 radio 302, Bluetooth radio 303, antenna switch 304, and antenna 305. Host 301 comprises a microprocessor. At any given time, host 301 communicates with 802.11 radio 302 or Bluetooth radio 303, but not both, by means of an internal switch. Typically, the internal switch requires the user of wireless terminal 101-3 to select the air interface to be used (e.g., from a menu, etc.). Alternatively, host 301 chooses between the air interfaces based on the type of communication it needs to send or expects to receive. 802.11 radio 302 communicates in accordance with the 802.11 air interface, and Bluetooth radio 303 communicates in accordance with the Bluetooth air interface. Antenna switch 304 directs a signal to be transmitted to antenna 305 from either 802.11 radio 302 or Bluetooth radio 303. Antenna switch 304 also directs a received signal from antenna 305 to either 802.11 radio 302 or Bluetooth radio 303. Antenna switch 304 is coordinated with the selection of the air interface.

[0013] The second technique in the prior art integrates the switch into host 301, so the intervention by the user is more convenient, even though the intervention is still possibly manual. In addition to providing contention-free access to the shared frequency band, the second technique provides a more convenient way of allowing the user to change between air interfaces. As a disadvantage, however, the air interface in use must remain in either 802.11 or Bluetooth mode for relatively long periods of time. Also, contention resolution still possibly requires manual intervention on the part of a user whenever wireless terminal 101-3 has to make a transmission over the air interface that is not presently active. Finally, the inactive air interface might miss a transmission by some other wireless terminal.

[0014] In accordance with a third technique in the prior art, FIG. 4 depicts a block diagram of wireless terminal 101-3. Wireless terminal 101-3 comprises host 401, 802.11/

Bluetooth radio **402**, antenna switch **403**, and antenna **404**. Host **401** comprises a microprocessor. Host **401** maintains an interface with the 802.11 part of 802.11/Bluetooth radio **402** and an interface with the Bluetooth part of 802.11/Bluetooth radio **402**. 802.11/Bluetooth radio **402** is a single integrated circuit that communicates in accordance with the 802.11 air interface and with the Bluetooth air interface. 802.11/Bluetooth radio **402** coordinates transmissions to some extent between its 802.11 part and its Bluetooth part. Antenna switch **403** directs a signal to antenna **404** to be transmitted from either the 802.11 part of 802.11/Bluetooth radio **402** or the Bluetooth part of 802.11/Bluetooth radio **402**. Antenna switch **403** also directs a received signal from antenna **404** to either the 802.11 part of 802.11/Bluetooth radio **402** or the Bluetooth part of 802.11/Bluetooth radio **402**.

[0015] In the prior art, approaches of integrating and dynamically coordinating multiple wireless protocols on a single platform have focused on integration into a single integrated circuit. This control necessitates coordinating the contention for the same frequency band between the two air interfaces. If the two air interface protocols are 802.11 and Bluetooth, the control must be imposed on the two air interfaces, since there is no standardized interoperability between the two air interface protocols. When the individual wireless technologies, however, are on a rapid evolutionary path, "same chip" integration can increase cost and can cause the integrated circuit development to lag behind that of separate circuits. Also, the market demand for a dual-interface solution within a single integrated circuit can be considerably smaller than the demand for either integrated circuit supporting a single protocol only (i.e., 802.11 or Bluetooth, but not both). Furthermore, even same chip integration by itself does not inherently guarantee a tight, efficient contention control between the two air interfaces.

[0016] Therefore, the need exists for multiple radios supporting different air interface protocols, possibly on separate integrated circuits, to coordinate the use of a shared frequency band.

SUMMARY OF THE INVENTION

[0017] The present invention enables both an IEEE 802.11 radio and a Bluetooth radio to be employed in a single wireless telecommunications terminal (e.g., wireless telephone, personal digital assistant (PDA), etc.) without interference. In particular, the illustrative embodiment enables standard "off-the-shelf" 802.11 and Bluetooth radios to work in concert in a single telecommunications terminal.

[0018] In the illustrative embodiment, the Bluetooth radio distinguishes between more "time-critical" packets that have a lower latency tolerance (for example, synchronous connection-oriented [SCO] packets, as are well-known in the art), and packets with a higher latency tolerance (for example, some asynchronous connection-less [ACL] packets, as are well-known in the art). The Bluetooth radio "preempts" the operation of the 802.11 radio to transmit the former, and waits until the 802.11 radio is in power-save mode, which is an inactive "sleep" mode employed to conserve power, to transmit the latter. By coordinating the occurrence and duration of the Bluetooth preemptions, the illustrative embodiment ensures that the preemptions are not fatal to the 802.11 medium access control (MAC) error-

correction mechanism, thereby enabling what appears to be concurrent operation of 802.11 and Bluetooth by the wireless telecommunications terminal.

[0019] In this specification, the illustrative embodiment is disclosed in the context of the IEEE 802.11 and Bluetooth protocols; however, it will be clear to those skilled in the art how to make and use alternative embodiments of the present invention for other combinations of competing protocols (i.e., protocols that might interfere with each other). In addition, although the illustrative embodiment is disclosed in the context of radios, it will be clear to those skilled in the art how to make and use alternative embodiments of the present invention for non-RF wireless radios and/or wireline transceivers that might interfere with each other.

[0020] The illustrative embodiment comprises: a first transmitter for transmitting a first data block through a communications band in accordance with an automatic-repeat-request error-correction mechanism; and a second transmitter for (i) preventing the first transmitter from outputting at least a portion of the first data block into the communications band while the second transmitter transmits a second data block through the communications band, and (ii) allowing the first transmitter to output into the communications band before the error-correction mechanism for the first data block fails.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] FIG. 1 depicts a schematic diagram of wireless telecommunications system **100** in the prior art.

[0022] FIG. 2 depicts a block diagram of a dual protocol wireless terminal that uses a first technique in the prior art.

[0023] FIG. 3 depicts a block diagram of a dual protocol wireless terminal that uses a second technique in the prior art.

[0024] FIG. 4 depicts a block diagram of a dual protocol wireless terminal that uses a third technique in the prior art.

[0025] FIG. 5 depicts a block diagram of wireless terminal **500** in accordance with the first illustrative embodiment of the present invention.

[0026] FIG. 6 depicts a block diagram of multi-radio card **600** in accordance with the second illustrative embodiment of the present invention.

[0027] FIG. 7 depicts a diagram of the salient components of radio **502-1** in accordance with the third illustrative embodiment of the present invention.

[0028] FIG. 8 depicts a block diagram of wireless terminal **800** in accordance with the fourth illustrative embodiment of the present invention.

[0029] FIG. 9 depicts a graph of signals transmitted and their interrelationship in the illustrative embodiment of the present invention.

[0030] FIG. 10 depicts a diagram of the salient components of radio **502-1** in accordance with another variation of the third illustrative embodiment of the present invention.

DETAILED DESCRIPTION

[0031] FIG. 5 depicts a block diagram of wireless terminal **500** in accordance with the first illustrative embodiment

of the present invention. Wireless terminal **500** is a computer that supports two distinct wireless air interface protocols concurrently for the purpose of sending and receiving data over the air on a shared frequency band. The frequency band, when used for communications purposes, is also referred to as a “communications band,” comprising one or more “channels” of communication. The object referred to generically as a “data block” conveys data across a transmission medium (e.g., air, wire, etc.). A data block constitutes a message, in which the message typically comprises a header part and the data in a payload part. A data block can be also referred to as a “frame” or as a “packet.” The term “frame,” as is known in the art, is commonly used in an IEEE 802.11 protocol context when referring to the medium access control data blocks that are communicated across over the air. The term “packet,” as is known in the art, is commonly used in a Bluetooth protocol context when referring to the data blocks that are communicated over the air.

[0032] A wireless telecommunications terminal, or “wireless terminal,” as described in this specification (e.g., wireless terminal **500**, etc.), is a type of telecommunications terminal. The wireless protocols supported by wireless terminal **500** can be, for example, 802.11 and Bluetooth. Wireless terminal **500** comprises host **501**, radio **502-1**, radio **502-2**, antenna switch **503**, and antenna **504**, interconnected as shown.

[0033] Host **501** is a computing platform (e.g., laptop, workstation, wireless terminal, etc.) comprising a general-purpose or special-purpose processor that is capable of storing data into a memory, retrieving data from a memory, and executing programs stored in a memory. The memory constituting host **501** might be random-access memory (RAM), flash memory, disk drive, etc. Host **501** processes higher-layer applications that use data that are transmitted over the air and data received over the air. Alternatively, host **501** can be the motherboard of a computer comprising a processor. Host **501** provides overall control of wireless terminal **500**, and the remainder of wireless terminal **500** provides the wireless communication function of host **501**. It will be clear to those skilled in the art how to make and use host **501**.

[0034] Host **501** also comprises an output device and an input device. The output device (e.g., display, speaker, etc.) is a transducer that receives signals from the processor and converts the received signals to an output signal (e.g., visual, auditory, etc.) in well-known fashion. The input device receives input from a user and sends the input to the processor. As is well-known in the art, the input device can take on a variety of forms, such as a keypad, pressure-sensitive touch screen, etc.

[0035] Radio **502-1** provides the channel-access control for communicating in accordance with a first air interface (e.g., 802.11, etc.). Radio **502-1** provides this service for data blocks arriving from host **501** via host data link **506** that are to be transmitted over the air and for data blocks arriving from antenna switch **503** via path **510-1-1** that are to be sent to host **501**. Radio **502-1** also receives data blocks from radio **502-2** and transmits data blocks to radio **502-2**. Radio **502-1** exchanges data blocks with radio **502-2** via collateral radio data link **507**, which will be described later. Radios **502-1** and **502-2** comprise a receiving function and a transmitting function and, as such, are transceivers.

[0036] Radio **502-1** receives signals from radio **502-2** and transmits signals to radio **502-2**. Radio **502-1** exchanges signals with radio **502-2** via signaling link **508-1**, a bus comprising M lines, and signaling link **508-2**, a bus comprising N lines. Signaling links **508-1** and **508-2** will be described later.

[0037] Radio **502-1** interfaces with host **501** through host data link **506**. Host data link **506** is a peripheral bus providing signaling, messaging, and control between those devices connected to the bus. It will be clear to those skilled in the art how to make and use the bus constituting host data link **506**. In the illustrative embodiment, host **501** is one such device connected to the bus, and radio **502-1** is another device. Radio **502-1** can interface with the bus mechanically, as well as electrically, through a removable circuit card designed for such an application. Alternatively, radio **502-1** can be hardwired directly to host **501** via the bus constituting host data link **506**. Examples of standardized busses include PCI, MiniPCI, and CardBus, all well known in the art. It will be clear to those skilled in the art how to make and use an interface that constitutes host data link **506**.

[0038] Radio **502-2** provides the channel-access control for communicating in accordance with a second air interface (e.g., Bluetooth, etc.). Radio **502-2** provides this service for data blocks arriving from host **501**—via host data link **506**, radio **502-1**, and collateral radio data link **507**—to be transmitted over the air and for data blocks arriving from antenna switch **503** via path **510-2-1** to be sent to host **501**. Radio **502-2** exchanges data blocks with radio **502-1** via collateral radio data link **507**.

[0039] Radio **502-2** receives signals from radio **502-1** and transmits signals to radio **502-1**. Radio **502-2** exchanges signals with radio **502-1** via signaling link **508-1** and signaling link **508-2**. Each of radios **502-1** and **502-2** might or might not constitute its own integrated circuit.

[0040] Antenna switch **503** exchanges signals with radio **501-1** via paths **510-1-1** and **510-1-2**, with radio **502-2** via paths **510-2-1** and **510-2-2**, and with antenna unit **504**. Antenna switch **503** enables antenna unit **504** to be shared, or switched, between radios **501-1** and **502-2**, reducing the required number of antennas. Antenna unit **504** provides coupling for transmitted and received signals between antenna switch **503** and the air. Antenna unit **504** can consist of a single antenna or it can consist of multiple antennas (e.g., one antenna for transmit, two antennas for receive, etc.). Antenna unit **504** can support receive diversity, transmit diversity, or both. Radio **501-1**, radio **502-2**, or host **501** can control the antenna switching. FIG. 5 depicts radio **501-1** providing control of antenna switching via path **511-1**. It will be clear to those skilled in the art how to make and use antenna switch **503** and antenna unit **504**. It will also be clear to those skilled in the art how to make and use a wireless terminal (e.g., wireless terminal **500**, etc.) without antenna switch **503**.

[0041] Collateral radio data link **507** provides a path through which radio **502-2** exchanges data blocks with host **501**. Essentially, collateral radio data link **507** provides the host interface for radio **502-2**. This “daisy-chaining” of host **501**, radio **502-1**, and radio **502-2** is necessary, since multiple integrated circuits with host interfaces that use certain bus standards, such as PCI, cannot be located on the same card because of the loading requirements of the bus. PCI,

however, supports a multiple function model, in which more than one logical host interface is combined into a single physical integrated circuit. Radio 502-1 uses the ability to host more than one logical host interface and uses collateral radio data link 507 to provide radio 502-2 with access to host 501. It will be clear to those skilled in the art how to host more than one logical host interface for a given physical interface.

[0042] FIG. 6 depicts a block diagram of wireless terminal 600 in accordance with the second illustrative embodiment of the present invention. Wireless terminal 600 supports two distinct wireless air interface protocols concurrently. The wireless protocols supported by wireless terminal 600 can be, for example, 802.11 and Bluetooth. Wireless terminal 600 comprises host 501, radio 502-1, radio 502-2, antenna switch 503, and antenna unit 504, interconnected as shown.

[0043] Radio 502-1, radio 502-2, antenna switch 503, antenna unit 504, and printed circuit board 602 constitute multi-radio card 601. Each of radios 502-1 and 502-2 might or might not constitute its own integrated circuit. Multi-radio card 601 is mechanically separable from host 501 and is electrically connected to host 501 using a card bus standard, in well-known fashion. The set of possible standards comprises PCI, MiniPCI, and CardBus. Printed circuit board 602, constituting multi-radio card 601, plugs into a card bus interface that electrically connects host 501 and radio 502-1, and can be physically removed from that interface as needed. It will be clear to those skilled in the art how to make and use printed circuit board 602 as part of multi-radio card 601.

[0044] The relationship and interaction between the elements depicted in FIG. 6 differ from that in FIG. 5 only in that the elements constituting multi-radio card 601 are mechanically separable from (i.e., not hardwired to) host 501. Elements common to both FIGS. 5 and 6 have been described above.

[0045] FIG. 7 depicts a block diagram of radio 502-1 in accordance with the third illustrative embodiment of the present invention. As is well known in the art, radio 502-1 might or might not constitute its own integrated circuit. Channel-access controller 701 provides the medium access control (MAC) functionality for communicating in accordance with a first air interface (e.g., 802.11, etc.). Note that the term "medium access control," as used in this specification, denotes the functionality that determines which wireless terminal transmits next on a multi-access (shared) channel, constituting a communications band, for a given air interface. Channel-access controller 701 accepts host data from multi-radio host interface 702 via path 711. It provides data from host 501 to baseband controller 703 via path 712 for preparation for transmission. Channel-access controller 701 also provides data received over the air from baseband controller 703 via path 712 to host 501 through path 711 and multi-radio host interface 702. Channel-access controller 701 can track whether it has control or radio 502-2 has control of the frequency band at any given moment. Consequently, channel-access controller 701 can control antenna switching at antenna switch 503 via path 511-1. Alternatively, channel-access controller 701 can operate uninformed of the status of radio 502-2.

[0046] Channel access controller 701 can pass to radio 502-2 via signaling link 508-1 information representative of

receiver 704-1 and transmitter 705-1, received through path 715. Channel access controller 701 can pass to receiver 704-1 and transmitter 705-1 via path 715 information representative of radio 502-2, received through signaling link 508-2. It will be clear to those skilled in the art how to make and use channel-access controller 701.

[0047] In accordance with the illustrative embodiment of the present invention, multi-radio host interface 702 provides the interface between host 501 and radio 502-1. Multi-radio host interface 702 accepts data blocks from host 501 via host data link 506. Multi-radio interface 702 then determines whether it should (1) transfer each data block to channel-access controller 701 via path 711, if the data block is meant for radio 502-1, or (2) relay the data blocks over to radio 502-2 via link collateral radio data link 507. Multi-radio host interface 702 accepts data blocks from channel-access controller 701 and transfers them to host 501. In other words, multi-radio host interface 702 provides multiple logical channel interfaces on a single physical channel interface to host 501. After reading this specification, it will be clear to those skilled in the art how to make and use multi-radio host interface 702.

[0048] Baseband controller 703 exchanges signals with channel-access control 701 via path 712. It also exchanges signals with receiver 704-1 and transmitter 705-1 via paths 713 and 714, respectively. In the receive direction, baseband controller 703 accepts the demodulated signal from receiver 704-1 and converts the signal into a format that can be used by channel-access controller 701. In the transmit direction, baseband controller 703 takes the signal from channel-access controller 701 and converts the signal into a format that is ready for modulation to the transmit frequency, the modulation being performed by transmitter 705-1. It will be clear to those skilled in the art how to make and use baseband controller 703.

[0049] In addition to exchanging signals with baseband controller 703, receiver 704-1 and transmitter 705-1 exchange signals with antenna switch 503 via paths 510-1-1 and 510-1-2, respectively. Transmitter 705-1 provides part of the functionality of the physical layer of communication—that is, modulation of the baseband signals, representing data blocks, received from baseband controller 703 to characteristics consistent with the particular air interface protocol supported by radio 502-1. Transmitter 705-1 can accomplish modulation through an intermediate frequency (IF) section, or stage, and a radio frequency section. It then amplifies the signal to be transmitted via a power amplifier section. Transmitter 705-1 transmits the modulated and amplified signal over the air through antenna switch 503 and antenna unit 504. Receiver 704-1 receives, amplifies, and demodulates signals from antenna switch 503 and antenna unit 504, providing the signals to baseband controller 703. Respectively, receiver 704-1 and transmitter 705-1 receives and transmits signals at a radio frequency communications band, such as, for example, the 2.4 GHz Industrial, Scientific, and Medical (ISM) band or the 5.0 GHz ISM band. It will be clear to those skilled in the art how to make and use receiver 704-1 and transmitter 705-1.

[0050] Radio 502-1 communicates with radio 502-2 via collateral radio data link 507, signaling link 508-1, and signaling link 508-2. Collateral radio data link 507 serves to exchange data blocks between host 501 and radio 502-2, in

well-known fashion. In accordance with the illustrative embodiment of the present invention, signaling link **508-1** and signaling link **508-2** provide the signaling interface between radio **502-1** and radio **502-2**, conveying transmitting/receiving status and specifying control. Signaling link **508-1** provides inter-MAC messaging from radio **502-1** to radio **502-2**. Similarly, signaling link **508-2** provides inter-MAC messaging from radio **502-2** to radio **502-1**.

[0051] Signaling links **508-1** and **508-2** comprise a communication and coordination protocol. Signaling links **508-1** and **508-2** also provide time synchronization functions between radio **502-1** and **502-2** for the purposes of determining time intervals corresponding to transmit opportunities for either air interface (i.e., the air interface served by radio **502-1** and the air interface served by radio **502-2**). These characteristics are described below.

[0052] Signaling link **508-1** conveys a first set of signals from radio **502-1** to radio **502-2**. In some embodiments, this first set of signals comprises a first transmitting indication signal, a first receiving indication signal, and a first idle indication signal. The transmit indication signal indicates when radio **502-1** is transmitting signals over the air. The receive indication signal indicates when radio **502-1** is receiving (or attempting to receive) signals from over the air. The idle indication signal indicates when radio **502-1** is neither in transmit mode nor in receive mode (but is still powered on). The idle indication signal, for example, can be used to indicate when radio **502-1** is in a power save mode, possibly an opportunity in time when radio **502-2** can control the shared frequency band. It will be clear to those skilled in the art how to determine which signal levels indicate what condition.

[0053] Signaling link **508-2** transfers a second set of signals from radio **502-2** to radio **502-1**. In some embodiments, this second set of signals comprises a first transmit inhibit signal. The transmit inhibit signal specifies that radio **502-2** is commanding radio **502-1** to inhibit transmitter **705-1** of radio **502-1**. In an illustrative scenario, radio **502-2** has time-critical information to transmit over the air and needs to “cut in” to radio **502-1**’s usage of the communications band. Use of the transmit inhibit signal in this scenario forces the radio frequency and intermediate frequency sections of transmitter **705-1** (within radio **502-1**) out of transmit mode or turns off the power amplifier section or both, whatever ensures that no signal is transmitted by transmitter **705-1**. It will be clear to those skilled in the art how to turn off the transmitter **705-1** of radio **502-1** so that no signal is radiated over the air. It will be clear to those skilled in the art how to determine which signal levels indicate which conditions.

[0054] In some other embodiments, radio **502-2** also uses signaling link **508-2** to send a polite request signal to radio **502-1** as part of the second set of signals. The polite request signal indicates to radio **502-1** that radio **502-2** has a data block to transmit, but does not necessarily have to send it at that moment. Correspondingly, radio **502-1** understands that it does not have to turn off its transmitter the moment it receives a polite request signal. The polite request signal can also be used to indicate level of urgency or importance of the data block requiring transmission, the time by which the data block has to be transmitted (i.e., latency tolerance), or other time-sensitive characteristics of the data blocks. The par-

ticular usage of the polite request signal depends on the relationship of the respective air interfaces of radios **502-1** and **502-2**. It will be clear to those skilled in the art how to customize the usage of the polite request signal. It will be clear to those skilled in the art how to determine which signal levels indicate which conditions.

[0055] Radio **502-1** continually monitors the second set of signals sent on signaling link **508-2**. Radio **502-1** uses the signals to make decisions as to when to transmit, when not to transmit, and when to communicate status or control or both back to radio **502-2** along signaling link **508-1**.

[0056] In some embodiments, all signals sent across signaling links **508-1** and **508-2** apply bi-directionally—that is, each signal described thus far can also be sent in the direction opposite to what has been described. Signaling link **508-1** can also send, as the first set of signals, a second transmit inhibit signal and a polite request signal. Furthermore, signaling link **508-2** can also send, as the second set of signals, a second transmitting indication signal, a second receiving indication signal, and a second idle indication signal. This fully reciprocal sharing between radios **501-1** and **501-2** of status and control signals can be used, for example, in applications where master control of the radios—functionality essentially residing in radio **502-1** in the illustrative embodiments has to be reassigned to a different radio (e.g., radio **502-2**, etc.).

[0057] FIG. 8 depicts a block diagram of wireless terminal **800** in accordance with the fourth illustrative embodiment of the present invention. Wireless terminal **800** supports two distinct wireless air interface protocols concurrently. The wireless protocols supported by wireless terminal **800** can be, for example, 802.11 and Bluetooth. Wireless terminal **800** comprises host **501**, radio **502-1**, radio **502-2**, antenna switch **503**, and antenna unit **504**, interconnected as shown. Radio **502-1** comprises receiver **704-1**, transmitter **705-1**, and host interface **801-1**. Radio **502-2** comprises receiver **704-2**, transmitter **705-2**, and host interface **801-2**. Other elements constituting radios **502-1** and **502-2** have been depicted earlier and for clarity are not depicted in FIG. 8.

[0058] Each of host data links **802-1** and **802-2** is a peripheral bus providing signaling, messaging, and control between those devices connected to the bus. It will be clear to those skilled in the art how to make and use the bus constituting each of host data links **802-1** and **802-2**. In the illustrative embodiment, host **501** is one such device connected to the bus, radio **502-1** is another device regarding host data link **802-1**, and radio **502-2** is yet another device regarding host data link **802-2**. Each of radios **502-1** and **502-2** can interface with its bus mechanically, as well as electrically, through a removable circuit card designed for such an application. Examples of standardized busses include PCI, MiniPCI, and CardBus, all well known in the art. It will be clear to those skilled in the art how to make and use an interface that constitutes host data link **802-1** and an interface that constitutes host data link **802-2**.

[0059] Host interface **801-1** provides the interface between host **501** and radio **502-1**, in well-known fashion. Host interface **801-1** accepts data blocks from host **501** via host data link **802-1**. Host interface **801-1** is also connected to channel-access controller **701** (described earlier) in radio **705-1** via a path equivalent to path **711** and accepts data

blocks from channel-access controller **701**, transferring them to host **501**. Note that host interface **801-1** is identical to multi-radio host interface **702**, except that host interface **801-1** does not have to sort out data blocks for or from radio **502-2**. It will be clear to those skilled in the art how to make and use host interface **801-1**.

[0060] Host interface **801-2** provides the interface between host **501** and radio **502-2**, in well-known fashion. Host interface **801-2** accepts data blocks from host **501** via host data link **802-2**. Host interface **801-2** is also connected to channel-access controller **701** (described earlier) in radio **705-2** via a path equivalent to path **711** and accepts data blocks from channel-access controller **701**, transferring them to host **501**. It will be clear to those skilled in the art how to make and use host interface **801-2**.

[0061] FIG. 9 depicts a timing diagram of an exemplary communication sequence for receiver **704-1**, transmitter **705-1**, and transmitter **705-2**, in accordance with the illustrative embodiment of the present invention. This timing diagram serves to illustrate the operation of radio **502-1** and radio **502-2** in accordance with the fifth illustrative embodiment of the present invention. For illustrative purposes, radio **502-1** operates in accordance with the 802.11 air interface protocol and radio **502-2** operates in accordance with the Bluetooth air interface protocol. It will be clear, however, to those skilled in the art that radios **502-1** and **502-2** can operate in accordance with other protocols.

[0062] FIG. 9 shows two sequences related to transmitter **705-1**. Signal stream **901** represents the input signal into transmitter **705-1** provided on path **714**, and signal stream **902** represents what actually is transmitted by transmitter **705-1** (i.e., the transmitter's "output" on path **510-1-2**). The distinction between transmitter **705-1**'s input and its output will be made clear below.

[0063] The first frame intended for transmission is frame **911**, provided to transmitter **705-1**. Since transmitter **705-1** is active, transmitted frame **921** (corresponding to frame **911**) is equivalent to frame **911** (i.e., all of frame **911** reaches antenna unit **504**), except for the fact that frame **911** is an unmodulated signal while frame **921** is modulated.

[0064] The next transmission in the sequence is acknowledgement frame **931** of signal stream **903**, which is received, in well-known fashion, by receiver **704-1** from the station to which frame **921** was directed.

[0065] The next frame intended for transmission in the sequence is frame **912**, provided to transmitter **705-1**. As shown in FIG. 9, at time t_1 during transmission of corresponding frame **922**, transmitter **705-2** transmits, as part of signal stream **905**, lower latency-tolerant packet **951** (e.g., a synchronous connection-oriented [SCO] packet, etc.), while simultaneously, the transmit inhibit signal (described earlier), represented by signal **906**, is set high. The transmit inhibit signal is provided on signaling link **508-2**.

[0066] For the purposes of discussion of the illustrative embodiments of the present invention, it is assumed that setting a signal high indicates that control is being exercised and that resetting a signal low indicates that control is no longer being exercised by the particular signal line. It will be clear to those skilled in the art how to indicate control in a way that is suitable to the particular design.

[0067] The transmit inhibit signal indicated to radio **502-1** and, more particularly, to transmitter **705-1**, ultimately controls the signal radiated by radio **502-1**. In order to suppress radiation of a signal, it might be necessary to turn off or turn low the power amplifier and the RF/IF sections of transmitter **705-1**, as described earlier. It will be clear to those skilled in the art how to suppress output from transmitter **705-1**.

[0068] Setting the transmit inhibit signal prevents the remainder of frame **912** from reaching antenna unit **504**, as shown by frame **922**. When transmitter **705-2** completes lower latency-tolerant packet **951**, the transmit inhibit signal resets low, thereby allowing input to transmitter **705-1** to once again reach antenna unit **504**. The transmit inhibit signal, in combination with any intermediate logic gates required to format the control signal actually provided to transmitter **705-1**, acts as a preemption signal that effectively suppresses output from transmitter **705-1** during transmitter **705-2**'s transmissions, thereby avoiding interference.

[0069] Meanwhile, transmitter **705-1**, unaware that frame **912** did not fully reach antenna unit **504**, waits for an acknowledgement in accordance with automatic repeat request (ARQ) error correction, as is well understood in the art. Since frame **912** was effectively interrupted, transmitter **705-1** does not receive such an acknowledgement, and, after a timeout in accordance with the protocol, retries frame **912** (in the form of frame **913**). As illustrated in FIG. 9, as long as Bluetooth packet **951** is kept sufficiently short, transmitter **705-1** is no longer suppressed by transmitter **705-2** when transmitting frame **913**. Consequently, frame **913** in its entirety reaches antenna unit **504** (shown by frame **923**), and receiver **704-1** subsequently receives acknowledgement **932**. Recalling the 802.11/Bluetooth nature of the example depicted by FIG. 9, the IEEE 802.11 ARQ error correction thus automatically compensates for sufficiently-short Bluetooth interruptions (i.e., interruptions that are not "fatal") without any changes to the protocols.

[0070] It will be clear to those skilled in the art that ARQ error correction will also automatically compensate for sufficiently-short transmissions from transmitter **705-2** of radio **502-2** that overlap receiver **704-1**'s receiving of data. In addition, it will be clear to those skilled in the art how to make and use alternative embodiments of the present invention for protocols that use other methods of error correction (e.g., forward error correction, etc.) In the case of forward error correction, for example, the interruption of a transmission is not fatal as long as the interruption is kept short enough so that the number of suppressed bits is below the particular error correction threshold.

[0071] So far throughout the exemplary sequence depicted in FIG. 9, radio **502-1** has been active, as shown by the "low" value of signal **904**, corresponding to the first idle indication signal of radio **502-1**, which is provided by signaling link **508-1** to radio **502-2**. After acknowledgement frame **932**, radio **502-1** enters power-save (i.e., idle) mode, as shown in FIG. 9 by the transition of first idle indication signal (signal **904**) from low to high. Transmitter **705-2**, upon detecting this transition, takes advantage of this situation by transmitting higher latency-tolerant packet **952** (e.g., an asynchronous connection-less [ACL] packet, etc.). Thus, instead of preempting transmitter **705-1**, as is done for transmissions with a lower latency tolerance (e.g., transmission **951**, etc.), transmitter **705-2** waits for radio **502-1** to

enter power-save mode before initiating transmissions with a higher latency tolerance (e.g., 952, etc.).

[0072] When radio 502-1 exits power-save mode (i.e., “wakes up”), it executes a “warm-up sequence” before transmitting any frames, as is well known in the art. If radio 502-1 happens to wake up while transmitter 705-2 is still transmitting, radio 502-2, which detects that radio 502-1 has awakened, terminates transmitter 705-2’s transmissions. As will be clear to those skilled in the art, the warm-up sequence of radio 502-1, operating in the example in accordance with the Bluetooth protocol, gives transmitter 705-2 plenty of time to gracefully terminate any in-progress transmissions. Any “left-over” information that transmitter 705-2 was unable to transmit before radio 502-1 awoke is queued for the next time that radio 502-1 enters power-save mode; this postponement is not problematic since, by definition, the information has a higher latency tolerance. If, instead, the information had a lower latency tolerance, transmitter 705-2 would have previously preempted transmitter 705-1, as described above;

[0073] FIG. 10 depicts a block diagram of radio 502-1 in another variation of the third illustrative embodiment of the present invention. FIG. 10 is similar to FIG. 7, except that the signaling links between radios 502-1 and 502-2 are interfaced directly to multi-radio host interface 1002. Consequently, channel-access controller 1001, multi-radio host interface 1002, and path 1005 are different from channel-access controller 701, multi-radio host interface 702, and path 705, respectively.

[0074] Channel-access controller 1001 provides the medium access control functionality for communicating in accordance with a first air interface (e.g., 802.11, Bluetooth, etc.). In this regard, it provides the same functionality as channel-access controller 701. It accepts host data from multi-radio host interface 1002 via path 1005. It provides data from host 501 to baseband controller 703 via path 712 for preparation for transmission. Channel-access controller 1001 also provides data received over the air from baseband controller 703 via path 712 to host 501 through path 1005 and multi-radio host interface 1002. Channel-access controller 1001 can track whether it has control of radio 502-2 has control of the communications band at any given moment. Consequently, channel-access controller 1001 can control antenna switching at antenna switch 503 via path 511-1. Alternatively, channel-access controller 1001 can operate uninformed of the status of radio 502-2.

[0075] Channel access controller 1001 can pass to radio 502-2 via signaling link 508-1 information representative of receiver 704-1 and transmitter 705-1, received through path 1006. Channel access controller 1001 can pass to receiver 704-1 and transmitter 705-1 via path 1006 information representative of radio 502-2, received through signaling link 508-2. It will be clear to those skilled in the art how to make and use channel-access controller 1001.

[0076] In accordance with the illustrative embodiment of the present invention, multi-radio host interface 1002 provides the interface between host 501 and radio 502-1. Multi-radio host interface 1002 accepts data blocks from host 501 via host data link 506. Multi-radio host interface 1002 then determines whether it should (1) transfer each data block to channel-access controller 1001 via path 1005, if the data block is meant for radio 502-1, or (2) relay the

data block over to radio 502-2 via link collateral radio data link 507. Multi-radio host interface 1002 accepts data blocks from channel-access controller 1001 and transfers them to host 501. In other words, multi-radio host interface 1002 provides multiple logical channel interfaces on a single physical channel interface to host 501. After reading this specification, it will be clear to those skilled in the art how to make and use multi-radio host interface 1002.

[0077] Multi-radio host interface 1002 terminates one end of collateral radio data link 507, as well as signaling links 508-1 and 508-2. Collateral radio data link 507 and signaling links 508-1 and 508-2 can be different interfaces to radio 502-2 physically, or they can be the same interface. It will be clear to those skilled in the art how to combine collateral radio data link 507 and signaling links 508-1 and 508-2 into one interface. Each of the interfaces with radio 502-2 can be a serial interface or a parallel interface. It will be clear to those skilled in the art how to make and use a serial or parallel interface. If one or more of collateral radio data link 507 and signaling links 508-1 and 508-2 are serial, the serial interface characteristics can comprise SERDES, IEEE1394 style data/strobe encoding, or RFF(2,5) coding, in well-known fashion.

[0078] The signaling information that is exchanged between radio 502-1 and 502-2 can be represented in any of a variety of formats. Signals from radio 502-1 can be communicated to radio 502-2 along signaling link 508-1 via a single high or low electrical signal, one signal value per state, in well-known fashion. For example, when radio 502-1 wants to indicate that it is transmitting, it can set the transmitting indication signal line to “high” and maintain that signal value for as long as radio 502-1 is in the transmitting state. When radio 502-1 stops transmitting, it can reset the transmitting indication signal line to “low”, and maintain that signal value for as long as radio 502-1 is not transmitting. Similarly, signals from radio 502-2 can be communicated to radio 502-1 along signaling link 508-2 via a single high or low electrical signal, one signal value per state, in well-known fashion.

[0079] Alternatively, signals can be communicated between radio 502-1 and radio 502-2 via a packet format (i.e., a format using blocks of data to represent information), as opposed to using individual electrical signal levels to directly represent information. For example, when radio 502-1 wants to indicate that it is transmitting, it can prepare and transfer a packet message to radio 502-2 indicating “transmitting” when the state change from “not transmitting” to “transmitting” occurs. When radio 502-1 stops transmitting, it can prepare and transfer a packet message to radio 502-2 indicating “not transmitting” when the state change from “transmitting” to “not transmitting” occurs. The packet message also specifies the type of message being sent, such as control (e.g., transmit inhibit, etc.), status (e.g., idle indication, etc.), or host interface-related (e.g., data message for radio 502-2 from host 501, etc.). The packet format can be transferred in full-duplex, bidirectional fashion between radios 502-1 and 502-2. It will be clear to those skilled in the art how to make and use a packet format to convey signals and to do so in full-duplex, bidirectional fashion.

[0080] FIG. 10 depicts signaling link 508-1 as comprising M lines and signaling link 508-2 as comprising N lines. This

is for illustrative purposes only, since signaling links **508-1** and **508-2** can be combined with collateral radio data link **508** in practice. The values for M and N depend on several factors, including (in no particular order):

[0081] 1. Whether each of signaling link **508-1** and **508-2** is a serial or parallel interface;

[0082] 2. How wide the parallel interface is;

[0083] 3. If communication is full-duplex, bidirectional;

[0084] 4. If the information is sent in packet format; and

[0085] 5. If collateral radio data link **507**, signaling link **508-1**, and signaling link **508-2** are combined into one interface.

[0086] Values for M and N are determined in well-known fashion. If the three links are combined into one serial interface that is full-duplex, bidirectional with packet format, the number of lines required by that interface is as little as two, consistent with the notion of low cost, low complexity.

[0087] It is to be understood that the above-described embodiments are merely illustrative of the present invention and that many variations of the above-described embodiments can be devised by those skilled in the art without departing from the scope of the invention. It is therefore intended that such variations be included within the scope of the following claims and their equivalents.

What is claimed is:

1. A telecommunications terminal comprising:

a first transmitter for transmitting a first data block through a communications band in accordance with an error-correction mechanism; and

a second transmitter for:

(i) preventing said first transmitter from outputting at least a portion of said first data block into said communications band while said second transmitter transmits a second data block through said communications band, and

(ii) allowing said first transmitter to output into said communications band before said error-correction mechanism for said first data block fails.

2. The telecommunications terminal of claim 1 wherein:

said second transmitter is also for transmitting a third data block when said first transmitter is in an idle mode; and

said third data block has a higher latency tolerance than said second data block.

3. The telecommunications terminal of claim 2 wherein said second transmitter receives a signal from said first transmitter that indicates said idle mode.

4. The telecommunications terminal of claim 1 wherein said error-correction mechanism is an automatic-repeat-request mechanism.

5. A telecommunications terminal comprising:

an IEEE 802.11 transmitter for wirelessly transmitting a frame in accordance with an 802.11 automatic-repeat-request error-correction mechanism; and

a Bluetooth transmitter for:

(i) preventing said IEEE 802.11 transmitter from transmitting at least a portion of said frame while said Bluetooth transmitter transmits a packet, and

(ii) allowing said IEEE 802.11 transmitter to transmit before said 802.11 automatic-repeat-request error-correction mechanism for said frame fails.

6. The telecommunications terminal of claim 5 wherein:

said Bluetooth transmitter is also for transmitting another packet when said IEEE 802.11 transmitter is in power-save mode; and

said other packet has a higher latency tolerance than said packet.

7. The telecommunications terminal of claim 6 wherein said other packet is an asynchronous connectionless link packet.

8. The telecommunications terminal of claim 6 wherein said Bluetooth transmitter receives a signal from said IEEE 802.11 transmitter that indicates said power-save mode.

9. A telecommunications terminal comprising:

a first transmitter for transmitting a first data block through a communications band in accordance with an error-correction mechanism;

a second transmitter for:

(i) preventing said first transmitter from outputting at least a portion of said first data block into said communications band while said second transmitter transmits a second data block through said communications band, and

(ii) allowing said first transmitter to output into said communications band before said error-correction mechanism for said first data block fails; and

a processor for generating said first data block and said second data block.

10. The telecommunications terminal of claim 9 wherein said error-correction mechanism is an automatic-repeat-request mechanism.

11. The telecommunications terminal of claim 9 further comprising a display.

12. The telecommunications terminal of claim 9 further comprising a memory.

13. The telecommunications terminal of claim 9 wherein:

said second transmitter is also for transmitting a third data block when said first transmitter is in an idle mode; and

said third data block has a higher latency tolerance than said second data block.

14. The telecommunications terminal of claim 13 wherein said second transmitter receives a signal from said first transmitter that indicates said idle mode.

15. A telecommunications terminal comprising:

an IEEE 802.11 transmitter for wirelessly transmitting a frame;

a Bluetooth transmitter for:

(i) preventing said IEEE 802.11 transmitter from transmitting at least a portion of said frame while said Bluetooth transmitter transmits a packet, and

- (ii) allowing said IEEE 802.11 transmitter to transmit before an IEEE 802.11 automatic-repeat-request error-correction mechanism for said frame fails; and a processor for generating said frame and said packet.
- 16. The telecommunications terminal of claim 15 further comprising a display.
- 17. The telecommunications terminal of claim 15 further comprising a memory.
- 18. The telecommunications terminal of claim 15 wherein:
 - said Bluetooth transmitter is also for transmitting another packet when said IEEE 802.11 transmitter is in power-save mode; and
 - said other packet has a higher latency tolerance than said packet.
- 19. The telecommunications terminal of claim 18 wherein said other packet is an asynchronous connectionless link packet.
- 20. The telecommunications terminal of claim 15 wherein said Bluetooth transmitter receives a signal from said IEEE 802.11 transmitter that indicates said power-save mode.
