ABSTRACT

A method and system for managing transmission resources in a wireless communications network includes receiving a packet and determining a time duration for transmission of the packet. A power level for transmission of the packet over the time duration is further determined. Based on the time duration and the power level, a wireless resource impact is determined for the packet. Transmission resources are allocated based on the wireless resource impact.

METHOD AND SYSTEM FOR MANAGING TRANSMISSION RESOURCES IN A WIRELESS COMMUNICATION NETWORK

RELATED PATENT APPLICATIONS

This application claims the benefit of U.S. patent application Ser. No. 60/122,012 entitled "Method and Apparatus for Policing, Shaping, and Controlling Bandwidth in a Wireless Multi-media Network" which was filed on Mar. 1, 1999. This application is also related to U.S. patent application Ser. No. 09/513,912 entitled "Method and System for Queuing Traffic in a Wireless Communications Network," U.S. patent application Ser. No. 09/513,592 entitled "Method and System for Brokering Bandwidth in a Wireless Communications Network," U.S. patent application Ser. No. 09/513,914 entitled "Wireless Router and Method for Processing Traffic in a Wireless Communications Network," and U.S. patent application Ser. No. 09/513,090 entitled "Method and System for Configuring Wireless Routers and Networks," all filed on Feb. 25, 2000 and incorporated herein by reference.

TECHNICAL FIELD OF THE INVENTION

The present invention relates generally to the field of wireless communications, and more particularly to an improved method and system for managing transmission resources in a wireless communications network.

BACKGROUND OF THE INVENTION

Wireline and wireless Internet protocol (IP) networks have traditionally supported a best effort delivery of all traffic. To support enhanced services, multiple types, or classes, of services have been established and assigned certain quality of service (QoS) parameters that manage queues for each service type. The QoS parameters include delay, jitter, error rates, and throughput. The QoS parameters can be provisioned on a per IP connection or per flow basis through mechanisms such as resource reservation protocol (RSVP) or can be provisioned on aggregate flow which are classified into service classes. Internet service providers (ISPs) can utilize the service classes, their associate QoS behavior and QoS provisioning to provide multiple service offerings to their business and consumer customers.

The IP QoS architecture provides congestion control tools that work closely with traffic shaping, admission control and coordinated policing tools to control and shape the traffic of various IP flows and to insure QoS behavior for each class of service. The goal of congestion control is to adapt the sending rate of data at its source to match the bandwidth available at a network node. Thus, as the bandwidth availability or the demand for bandwidth changes in a network, the data sources are controlled to adapt their sending rate to the bandwidth changes.

Traffic shaping and policing are performed at the network nodes. Traffic shaping is typically implemented using a token, or leaky bucket. The token bucket is sized in accordance with a burst rate of the traffic and is filled with tokens at a long-term average rate of the available supply or bandwidth. Traffic is policed by requiring packets to check-out tokens from the bucket for transmission.

To support flows having disparate QoS parameters, multiple token buckets have been used in a network node to police and control the disparate QoS flows. Each token bucket is sized and configured at a rate corresponding to the QoS parameters of an associated flow. While the use of

2

multiple token buckets supports disparate flow types, the token buckets are not sensitive to the characteristics of the radio frequency (RF) wireless environment in which different flow types have different impact on the media/physical layer and have a different interference impact based on location of the flow.

SUMMARY OF THE INVENTION

The present invention provides an improved method and system for managing transmission resources in a wireless communications network that substantially eliminate or reduce problems and disadvantages associated with previous methods and systems. In particular, transmission power usage and/or inter geo-location interference are taken into account in allocating transmission resources in a wireless network in order to effectively police, shape and control traffic flows.

In accordance with one embodiment of the present invention, a method and system for managing transmission resources in a wireless communications network includes receiving an internet protocol (IP) or other data packet. A duration time for transmission of the packet is determined. A power level for transmission of the packet over the time duration is also determined. A wireless resource impact is determined for the packet based on the time duration and the power level. Transmission resources are allocated based on the wireless resource impact.

More specifically, in accordance with a particular embodiment of the present invention, the wireless resource impact is a sector impact representing the impact of transmitting the packet in a sector of the wireless network. In this embodiment, a geographic interference impact of transmitting the packet in the sector is determined for a neighboring or other sector based on the sector impact. A network impact is determined based on and accounts for the sector impact and the geographic interference impact. Transmission resources are allocated based on the network impact.

In accordance with another aspect of the present invention, a method and system for managing transmission resources in a wireless communications network includes receiving a packet and providing a token bucket comprising a plurality of tokens representing power available for transmission of the packet. A transmission token is generated representing a time duration for transmission of the packet and a power level for transmission of the packet over the time duration. The sufficiency of available tokens in the token bucket for the transmission token is determined and the packet transmitted if sufficient tokens are available.

Technical advantages of the present invention include providing an improved method and system for managing transmission resources in a wireless communications network. In particular, the varying impact of transmitting data packets on a wireless physical layer is accounted for in allocating queuing, forwarding and other transmission resources in the wireless network. The varying impact may be determined based on the time, power, and geo location constraints of the packet on the physical layer. Thus, conflicts between calls or other types of flows and the resulting excessive interference impact within the system due to over allocation are minimized.

Another technical advantage of the present invention includes providing an improved multi-media wireless network. In particular, the network employs a multi-dimensional allocation system that allows multiple users and multiple services types with differing bandwidth requirements to use a shared wireless transmission resource without

3

conflict. The multiple service types may be different quality of service (QoS) classes such as premium, assured, and best effort.

Yet another technical advantage of the present invention includes providing an improved method and system for controlling, shaping, and policing data flows in a wireless network. In particular, the full impact of packet transmission on the wireless network is evaluated in allocating bandwidth resources. As a result, traffic flows may be more accurately policed and shaped to account for limitations of the wireless system.

Yet another technical advantage of the present invention includes providing a method and system to account for the specific impact of each data packet on the physical layer resource in a wireless network. In particular, transmission power for the packet is taken into account when evaluating the impact of packet transmission in a cell site or other location of the wireless network. In addition, impact on neighboring and other cell sites is also accounted for to conform the packet to specific physical layer traffic characteristics of the network.

Still another technical advantage of the present invention includes providing a multiple dimension token and token bucket for allocating resources in a wireless network. In particular, each packet may be represented by a transmission token specifying packet transmission time in a first dimension, transmission power in a second dimension, and interference impact on neighboring and other cell sites in a third dimension. This multi-dimensional token fully accounts for the impact of the packet on the physical wireless system. In addition, the multiple dimension token bucket may be filled at a static or dynamic rate based on system loading or available bandwidth.

Other technical advantages of the present invention will be readily apparent to one skilled in the art from the following figures, description, and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention and its advantages, reference is now made to the following description taken in conjunction with the accompanying drawings, wherein like reference numerals represent like parts, in which:

FIG. 1 is a block diagram illustrating a wireless network in accordance with one embodiment of the present invention;

FIG. 2 is a block diagram illustrating details of the mobile gateway of FIG. 1 in accordance with one embodiment of the present invention;

FIG. 3 is a block diagram illustrating the multiple dimension token bucket of FIG. 2 in accordance with one embodiment of the present invention;

FIG. 4 is a block diagram illustrating filling of an exemplary multiple dimension token bucket in accordance with one embodiment of the present invention;

FIG. 5 is a block diagram illustrating a multiple dimension token for use in conjunction with the multiple dimension token bucket of FIG. 3 in accordance with one embodiment of the present invention;

FIG. 6 is a flow diagram illustrating a method for packet check-in at the queue of FIG. 2 in accordance with one embodiment of the present invention;

FIG. 7 is a flow diagram illustrating a method for packet check-out from the queue of FIG. 2 using the multiple dimension token and token bucket of FIGS. 3 and 5 in accordance with one embodiment of the present invention;

4

FIGS. 8A–E are a series of block diagrams illustrating check-out of exemplary packets in accordance with one embodiment of the present invention;

FIG. 9 is a block diagram illustrating the multiple dimension token bucket of FIG. 2 in accordance with another embodiment of the present invention;

FIG. 10 is a block diagram illustrating a multiple dimension token for use in conjunction with the multiple dimension token bucket of FIG. 9 in accordance with one embodiment of the present invention;

FIG. 11 is a flow diagram illustrating a method for packet check-out from the queue of FIG. 2 using the multiple dimension token and token bucket of FIGS. 9 and 10 in accordance with one embodiment of the present invention;

FIG. 12 is a flow diagram illustrating a method for communicating token availability between the queue managers of FIG. 2 in accordance with one embodiment of the present invention; and

FIG. 13 is a block diagram illustrating check-out of exemplary packets in accordance with one embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 illustrates a wireless network 10 in accordance with one embodiment of the present invention. In this embodiment, the wireless network 10 is a cellular network in which terrestrial wireless transmission originates in geographically delimited cells. It will be understood that the present invention may be used in connection with satellite and other suitable wireless and other dynamic bandwidth networks.

Referring to FIG. 1, the wireless network 10 covers a contiguous area that is broken down into a series of overlapping cells 12. Each cell 12 has a base station, or server, 14 and may be subdivided into a plurality of geo-location areas 16. The geo-location areas 16 are each a defined area in which bandwidth may be allocated to mobile devices. The geo-location areas 16 may have a resolution greater than, less than, or equal to cell size. In a particular embodiment, the geo-location areas 16 are substantially square in shape to form a contiguous grid over the coverage area. Thus, the geo-locations 16 may be shared by one or more cells 12. Further information regarding the geo-location and allocation of bandwidth in the geo-locations is described in co-owned U.S. patent application Ser. No. 09/466,308, titled Method and System for Allocating Bandwidth in a Wireless Communications Network, filed Dec. 17, 1999, and incorporated herein by reference.

Each server 14 provides a radio frequency (RF) link for mobile devices 18 within its cell 12. The wireless RF link to the mobile devices 18 in the cell 12 may be based on established standard such as IS-54 (TDMA), IS-95 (CDMA), GSM and AMPS, 802.11 based WLAN, or new upcoming standards such as CDMA 2000 and W-CDMA or proprietary radio interfaces. The mobile devices may be cell phones, data phones, data devices, portable computers, or any other suitable device capable of communicating information over a wireless link. Due to the nature of the RF airlink, the interference generated by the usage of various mobile devices 18 is inter-dependent. That is, the interference generated by the usage of a mobile device 18 including transmitting and receiving signals is not only dependent on its geo-location, but is also dependent on the geo-location of surrounding mobile devices 18 and the usage of those devices. Thus, the cellular network is an inherently

5

interference-limited network with bandwidth usage in a particular location impacting the interference in specific areas of the neighborhood. In the complete spectrum sharing systems such as CDMA and W-CDMA, bandwidth usage in a particular area directly impacts the bandwidth available at different locations in the neighborhood.

The servers **14** each have a defined bandwidth with which to communicate with the mobile devices **18** in the cells **12**. The bandwidth is used by the server **14** and the mobile devices **18** to communicate voice and data information. The supported bandwidth is a function of various factors such as frequency reuse, carrier to interface ratio, bit-energy to noise ratio, effective bit-rate per connection and the like. As described in more detail below, the bandwidth available to allocate to certain flows is geo-location dependent, and time dependent based on current usage of other flows in the geo-neighborhood.

The servers **14** are each connected to a mobile gateway **20** that allocates bandwidth within the wireless network **10**, routes traffic, and tracts the location of the mobile devices **18** in the cells **12**. The position of a mobile device **18** may be determined using network-assist, global position systems (GPS) and radio frequency fingerprinting. Preferably, the positioning technique provides fast and accurate information with respect to the location of the mobile device **18** to minimize acquisition time for position information. As mobile users move from cell **12** to cell **12**, a hand-off operation between base stations **14** is performed by the mobile gateway **20**.

The mobile gateway **20** provides connectivity from the wireless portion of the network **10** to a wireline portion **24** of the network **10** via circuit switched and packet switch wireless data protocols. The wireline portion **24** may be the Internet, intranet, extranet, or other suitable local or wide area network. For the Internet, the mobile gateway **20** provides an access, or entry point for all transport control protocol/Internet protocol (TCP/IP) data connections to the wireless portion of the network **10**. Each mobile gateway **20** may serve one or more servers **14**, include the RF front end and other functionality of a server **14**, and/or may be wireless router as described in co-owned U.S. patent application Wireless Router and Method for Processing Traffic in a Wireless Communications Network previously incorporated by reference. In the later case, the wireless router may be self-configuring as described in co-owned U.S. patent application Method and System for Configuring Wireless Routers and Networks also previously incorporated by reference. Bandwidth allocation and other functionality of the mobile gateways **20** may instead be implemented by a mobile switching center (MSC), data interworking function (IWF) devices, and other suitable network devices without departing from the scope of the present invention.

FIG. 2 illustrates details of the mobile gateway **20** in accordance with one embodiment of the present invention. In this embodiment, the mobile gateway **20** includes local queuing and queue management functionality for processing traffic in the wireless network **10**. It will be understood that the queue and queue management functionality of the mobile gateway **20** may be suitably distributed within the wireless network **10**. In a particular embodiment, the queuing and queue management functionality may be separately implemented for each of a plurality of virtual groups as described in co-owned U.S. Application Method and System for Queuing Traffic in a Wireless Communication Network previously incorporated by reference.

Referring to FIG. 2, the mobile gateway **20** includes a wireless interface **30**, a wireline interface **32**, an ingress

6

transmission control system **34**, and an egress transmission control system **36**. The wireless interface **30** includes a transceiver or other suitable system for communicating RF signals with mobile devices **18** in the network **10**. The wireline interface **32** comprises a conventional or other suitable interface for communicating traffic with the wireline portion of the network **10**. The interfaces **30** and **32** may also be remote from the mobile gateway **20**.

As described in more detail below, the ingress and egress transmission control systems **34** and **36** each account for the varying impact of packet transmissions and/or the system loading on the physical layer in allocating transmission resources in the network **10**. As a result, conflicts between calls due to over allocation are minimized. The ingress and egress transmission control systems **34** and **36** may each be implemented in hardware, software stored in a computer-readable medium, and/or a combination of hardware and software. The hardware may comprise a field programmable gate array (FPGA) programmed to perform the functionality of the transmission control systems **34** and **36**, an application specific integrated circuit (ASIC) designed to perform the functionality of the transmission control systems **34** and **36**, and/or a general purpose processor programmed by software instructions to perform the functionality of the transmission control systems **34** and **36**.

In one embodiment, the ingress and egress transmission control systems **34** and **36** each include a queue **40**, a queue manager **42**, and a multiple dimension token bucket **44**. Packets received by the wireless interface **30** are checked-in to the ingress queue **40** from which they are checked-out by the ingress queue manager **42** as transmission resources become available. The packets may each be a packetized or other suitable signal transmitted or received in discrete units. Each means every one of at least a subset of the identified items. As the ingress packets are checked-out of the ingress queue **40**, they are passed to the wireline interface **32** for transmission in the wireline portion **24** of the network **10**. Similarly, egress packets received by the wireline interface **32** are checked-in to the egress queue **40** from which they are checked-out by the egress queue manager **42** as transmission resources become available. As the egress packets are checked-out by the egress queue manager **42**, they are passed to the wireless interface **30** for transmission in the wireless portion of the network **10**. In this way, the ingress and egress queue managers **42** together control traffic transmitted from and to the mobile devices **18** in an associated sector **12** of the network **10**.

The multiple dimension token buckets **44** provide the available impact level and/or supply bandwidth for packet transmissions in the associated sector **12** at each unit in time. In particular, the ingress token bucket **44** is sized in accordance with transmission resources available for the mobile devices **18** in the sector **12**. Similarly, the egress token bucket **44** is sized in accordance with reception resources available for the mobile devices **18**. Available resources in the transmit and receive directions will vary depending on the size of the sectors **12**, the various access technologies deployed in the sectors **12** system loading parameters, type of flows in the geo-neighborhood and other suitable operating parameters of the system.

To support multiple service levels, multi-media, and customer groups, packet flows in the mobile gateway **20** may be organized into a plurality of discrete groups. In this case, a separate set of multiple dimension token buckets **44** may be used to police and control flows in each group. As used herein, each means everyone of at least a subset of the identified items. Available resources in the sector **12** are

statically or dynamically allocated between the groups. Each set of the multiple dimension token buckets **44** is sized in accordance with the resources allocated to the group. Further information regarding the organization of flows into groups and the disparate treatment of groups is described in co-owned U.S. Patent Application entitled "Method and System for Queuing Traffic in a Wireless Communications Network", which has been previously incorporated by reference.

FIG. 3 illustrates the multiple dimension token bucket **44** in accordance with one embodiment of the present invention. In this embodiment, the multiple dimension token bucket **44** is a two-dimensional token bucket **50**. The token buckets **44** and **50** are implemented in software, ASIC, FPGA, or other suitable processor. It will be understood that the multiple dimension token bucket **44** may include additional dimensions to conform a flow or aggregation of flows to specific physical layer characteristics of the wireless network **10**.

Referring to FIG. 3, the two-dimensional token bucket **50** comprises a plurality of two-dimensional tokens **52**. The two-dimensional token bucket **50** is sized based on the average data rate, burst rate, transmission power, interference characteristics, or other suitable parameters of a corresponding flow, group of flows or location.

The two-dimensional token bucket **50** is updated for each unit of time to account for the token fill rate and the token use rate. Tokens are filled at a static or dynamic rate per unit time based on defined parameters such as historical data, system loading, available bandwidth, and system interference. The token use rate is dependent on transmission activity. Thus, some or all of the tokens may be used for each unit time. Further information regarding filling of the token bucket **50** is described in more detail below in connection with FIG. 4. Further information regarding use of tokens from the token bucket **50** is described in more detail below in connection with FIGS. 7-8.

In one embodiment, the two-dimensional token bucket **50** represents power level **54** as depth of the bucket **50** and time duration **56** as width of the bucket **50**. In this embodiment, each token **52** represents impact on RF resources of transmitting or receiving a packet at one power level unit per unit time. The power and time units are units based or associated directly or indirectly with transmission power and duration, respectively. In a particular embodiment, the power level unit is one watt and the time unit is one-tenth of a second. It will be understood that the two-dimensional token bucket **50** may comprise other suitable units that represent impact of a transmission on RF resources.

FIG. 4 illustrates filling of an exemplary token bucket **60** in accordance with one embodiment of the present invention. In this embodiment, the exemplary token bucket **60** is a two-dimensional token bucket as previously described in connection with FIG. 3. The token bucket **60** is filled during each unit time at a variable rate in accordance with defined parameters which are based on real-time and other dynamic parameters of the network **10**. The real-time and variable parameters may include system loading, system interference, call statistics, and soft handoff percentages.

Referring to FIG. 4, ten tokens are added at each 0.1 second time interval (100 milliseconds) for the first ten time intervals. In response to changing conditions in the network **10**, five tokens are added at each of the next five time intervals between time 1.0 and time 1.5. Starting at time 1.5, due to again changing conditions in the network **10**, the full ten tokens are added at the next time interval. During the

reduced fill rate interval, the queue manager **42** will be forced to check-out and transmit a reduced rate and/or size of packets. In this way, bandwidth between flow groups may be dynamically re-allocated based on available resources within the access network.

FIG. 5 illustrates a two-dimensional transmission token **70** for packets for use in connection with the two-dimensional token bucket **50**. The two-dimensional transmission token **70** comprises a token depth **72** and a token width **74** together defining a number and configuration of tokens **52** (area of transmission token **50**) needed for transmission of a corresponding packet. The token depth **72** indicates the impact of power usage for transmission of the corresponding packet. The token width **74** indicates the duration of the impact. Thus, the full impact of transmitting the packet is represented by the transmission token **70** to allow full resource allocation for transmission of the packet. It will be understood that transmission tokens may be otherwise suitably configured to correspond to the multiple dimension token bucket **44**.

FIG. 6 is a flow diagram illustrating a method for checking-in packets to the queue **40** in accordance with one embodiment of the present invention. In this embodiment, packets are queued in the order in which they are received. Congestion control may be applied prior to queuing as described in co-owned U.S. Patent Application entitled Method and System for Queuing Traffic in a Wireless Communications Network previously incorporated by reference.

Referring to FIG. 6, the method begins with the queue manager **42** in an Idle state **100** while no packets are being received by the wireless or wireline interface **30** or **32**. In response to receiving a packet, the queue manager **42** transitions from the Idle state **100** to step **102**. An action is in response to an event when it directly or indirectly follows from the event. Thus, one or more steps may intervene and/or be necessary for the action to occur. At step **102**, the packet is queued at the tail end of the queue **40**. Step **102** returns to state **100** in which the queue manager **42** awaits receipt of additional packets. Thus, the queue manager **42** will continuously queue packets in a first-in first-out (FIFO) order. It will be understood that incoming packets may be otherwise suitably queued in the mobile gateway **20** while awaiting transmission to a destination device.

FIG. 7 is a flow diagram illustrating the method for checking-out packets from the queue **40** using the multiple dimension token bucket **44** in accordance with one embodiment of the present invention. In this embodiment, the token bucket is a two-dimensional token bucket **50** and packets are represented by two-dimensional tokens **70**. As described in more detail below, packets are checked-out in the order in which they are received in accordance with available resources. Thus, if available resources do not exist to transmit a first packet in the queue **40**, later queued packets for which sufficient resources are available will be transmitted to maximize use of available resources.

Referring to FIG. 7, the method begins with the queue manager **42** in the Idle state **110** while the queue **40** is empty. In response to the queuing of one or more packets, the queue manager **42** transitions to step **112**. At step **112**, the queue manager **42** determines a size of a transmission token **70** for the first queued packet. As previously described, the transmission token **70** includes one or more tokens **52** and represents the full impact of transmitting the packet in the sector **12**.

Proceeding to decisional step **114**, the queue manager **42** determines whether sufficient tokens **52** are available in the

token bucket 50 for transmission of the first packet based on the size of the transmission token 70. In one embodiment, sufficient tokens 52 are available in the token bucket 50 when a set of tokens 52 spanning the power level are available over the duration of the transmission time. If sufficient tokens 52 are available in the token bucket 50, the tokens 52 are allocated to the first packet and the Yes branch of decisional step 114 leads to step 116. At step 116, the first packet is removed from the queue 40. Next, at step 118, the first packet is transmitted to the wireless or wireline portion of the network 10 for delivery to a destination device. At step 120, the token bucket 50 is updated to remove the tokens 52 allocated to the packet as that bandwidth and power (impact) has been used and is no longer available.

Proceeding to decisional step 122, the queue manager 42 determines whether additional packets exist in the queue 40. If additional packets do not exist, the queue manager 42 has no additional packets to transmit and the No branch of decisional step 122 returns to the Idle state 110. If additional packets are queued, the Yes branch of decisional step 122 leads to step 124. At step 124, the queue manager 42 determines the size of a transmission token 70 for the new first packet. Step 124 returns to decisional step 114 where, as previously described, the queue manager 42 determines whether sufficient tokens 52 are available in the token bucket 50 to transmit the first packet. If sufficient tokens 52 are available, the packet is transmitted and the token bucket 50 updated as previously described.

If sufficient tokens are not available in the token bucket 50, then sufficient bandwidth is not available in the sector 12 to transmit the first packet. Accordingly, the No branch of decisional step 114 leads to decisional step 130 in which the queue manager 42 determines whether additional packets are queued and may be transmitted in the limited bandwidth that is currently available. If additional packets are not queued, then the No branch of decisional step 130 returns to decisional step 114 to determine if sufficient tokens 52 have become available due to filling of the token bucket 50 to transmit the first packet. If sufficient tokens 52 have become available, the first packet will be transmitted and the token bucket 50 updated as previously described. If sufficient tokens are still not available, the queue manager 42 will continue to check for and try to transmit additional packets until sufficient resources become available to transmit the first packet in the queue 40.

At decisional step 130, if additional packets exist in the queue 40, the Yes branch leads to step 132. At step 132, the queue manager 42 determines a size of a transmission token 70 for the next packet in the queue 40. At decisional step 134, the queue manager 42 determines whether sufficient tokens 52 are available in the token bucket 50 for transmission of the next packet in the queue 40. If sufficient tokens 52 are not available, the No branch of decisional step 134 leads to decisional step 142 where a resource change is determined.

At decisional step 134, if sufficient tokens 52 are available in the token bucket 50 to transmit the packet under consideration, the tokens 52 are allocated to the packet and the Yes branch leads to step 136. At step 136, the next packet is removed from the queue 40. Next, at step 138, the next packet is transmitted to the wireline or wireless network for delivery to a destination device. At step 140, the token bucket 50 is updated to remove tokens 52 allocated to the packet as that bandwidth and power (impact) has been used and is no longer available.

Step 140 leads to decisional step 142 in which a resource change is determined. If additional resources have become

available due to bucket fill or resource release, the Yes branch of decisional step 142 returns to decisional step 114 in which the queue manager 42 continues to determine whether sufficient tokens 52 have become available in the token bucket 50 to transmit the first queued packet. The No branch of decisional step 142 returns to decisional step 130 where further packets are examined. Thus, the queue manager 42 will continue to check each packet in the queue 40 in the order in which they are queued until a packet is found for which sufficient resources are currently available for transmission. In this way, packet flows in a sector 12 are effectively policed and shaped where the packets have a varying level of impact on the physical RF layer. Thus, the specific impact of each packet is accounted for to conform the flows to specific physical layer traffic characteristics of bandwidth and power usage.

FIGS. 8A-E are a series of block diagrams illustrating management of exemplary traffic resources in accordance with one embodiment of the present invention. In this embodiment, the traffic resources are managed using the two-dimensional token bucket 50 of FIG. 3 with a static fill rate at 10 tokens 52 per unit time. Packets are only transmitted when sufficient tokens 52 are available in the token bucket 50 for the power level and duration of a transmission token 70 representing the packet.

Referring to FIG. 8A, packet 1 has a peak rate of 1000 bytes per second using power level 1 and is thus represented by a transmission token 150 having a depth of 1 and a width of 10 0.1 seconds (1 second). Packet 2 has a peak rate of 4000 bytes per second using power level 4 and is represented by a transmission token 152 having a depth of 4 and width of 0.25 seconds. Packet 4 has a peak rate of 4000 bytes per second using power level 2 and is represented by transmission token 154 having a depth of 2 and a width of 0.25 seconds. Packet 3 has a peak rate of 10,000 bytes per second using power level 10 for 0.1 seconds and is thus represented by a transmission token 156 having a depth of 10 and a width of 0.1 seconds. Each of the packets will be transmitted in the order received so long as sufficient tokens 52 are available in the token bucket 50 to check-out the corresponding transmission token 150, 152, 154 or 156.

Referring to FIG. 8B, the queue manager 42 checks the two-dimensional token bucket 50 to determine if sufficient tokens 50 are available to support transmission of packet 1 as represented by transmission token 150. Half and other fractional tokens may be rounded up to a full token. Sufficient tokens are available in the bucket 50 and accordingly packet 1 is sent out to the wireless link or network and the token bucket 50 updated.

Referring to FIG. 8C, the queue manager 42 determines whether sufficient tokens 52 are available in the token bucket 50 to support transmission of packet 2, the current first packet in the queue 40, having a transmission token 152 with a power level of 4 for a duration of 0.25 seconds. Because sufficient tokens 52 are available in the bucket 50, packet 2 is sent out and the token bucket 50 updated.

Referring to FIG. 8D, packet 3 is advanced to the front of the queue 40. The queue manager 42 determines whether sufficient tokens 52 are available in the token bucket 50 to support transmission of packet 3 as represented by a transmission token 154 having a power level 10 for 0.1 seconds. Because the necessary tokens 152 are not available, packet 3 is not sent out and remains in the queue 40. Packet 3 will be sent out from the queue 40 by the queue manager 42 when sufficient resources become available. Alternatively, transmission may be scheduled based on known token availability at a later start time in the bucket 50.

Referring to FIG. 8E, the queue manager 42 moves on to packet 4, the next packet in the queue 40, and determines whether sufficient tokens 52 are available in the token bucket 50 to support transmission of packet 4 as represented by the transmission token 156. Because sufficient tokens 52 are available, packet 4 is sent out to wireless or wireline link and the token bucket 50 updated. In this way, shared bandwidth is allocated between packet flows while insuring that the traffic characteristics do not violate bucket configuration.

In another embodiment, the ingress and egress transmission control systems 34 and 36 may each be implemented based on an allocation algorithm without use of the token buckets 44. In this embodiment, packet check-out is scheduled based on available transmission resources. The time to check-out each packet may be calculated as follows:

$$tts=ct+L/I/R$$

where: tts is the time to send the next packet;

ct is the current time;

L is the packet size;

I is the impact coefficient; and

R is the average available transmission rate.

The inclusion of the impact coefficient in the scheduling algorithm allows a full impact of packet transmission to be accounted for in managing transmission resources. The impact coefficient may be predefined for a particular flow or group of flows, dynamically based on operating conditions in the network 10, based on the transmission power or other suitable characteristic of the packet. Thus, the specific impact of each data packet on the physical layer resource of a sector 12 is taken into account in evaluating and allocating transmission resources. As a result, traffic flows are more accurately policed and shaped to account for resource limitations in the sector 12.

FIG. 9 illustrates a three-dimensional token bucket 200 in accordance with one embodiment of the present invention. In this embodiment, the three-dimensional token bucket 200 comprises a two-dimensional token bucket 202 for a sector 12 in which traffic will be transmitted and a plurality of two-dimensional token buckets 204 for disparate sectors 12. The transmission sector token bucket 202 may include transmission resources for the entire sector 12 or for one of a plurality of flow groups within the sector 12. Each disparate sector token bucket 204 may comprise transmission resources for the entire sector 12 or may be a supplementary token bucket dedicated to providing transmission resources to packet transmissions in other sectors. As previously described in connection with two-dimensional token bucket 50, each two-dimensional token bucket 202 and 204 is sized based on the average data rate, burst rate, transmission power, interference characteristic or other suitable parameter of a corresponding flow or groups of flows at an associated location. The two-dimensional token buckets 202 and 204 may each have a static or dynamic fill rate.

Referring to FIG. 9, the three-dimensional token bucket 200 represents power level 212 as depth of the bucket 200, time duration 214 as width of the bucket 200, and location 216 as length of the bucket 200. Each token 218 represents impact on RF resources in a location of transmitting or receiving a packet in that or another location at one power level unit per unit time. In a particular embodiment, the power level unit is one watt, the time unit is one tenth of a second, and the location is at the sector level. It will be understood that the three-dimensional token bucket 200 may comprise other suitable units that represent the impact on transmission resources at each location in the network 10.

FIG. 10 illustrates a three-dimensional transmission token 220 for packets for use in connection with the three-dimensional token bucket 200. The three-dimensional transmission token 220 comprises a token depth 222, token width 224, and token length 226 that together define a number of tokens 208 (volume of transmission token 220) needed for transmission of the corresponding packet. The token depth 222 indicates the impact power usage for transmission of the packet. The token width 224 indicates the duration of the impact. The token length 226 indicates the impact on a set of neighboring or other disparate sectors 12, which may be adjacent or all sectors 12 in the network 10. In one embodiment, the three-dimensional transmission token 220 includes a two-dimensional transmission token 240 for the transmit sector 12 and a two-dimensional geo-location interference token 242 for each of the disparate sectors 12. The transmission token 240 represents the impact in a sector 12 of transmitting a token in the sector 12. Each of the geo-location interference token 242 represents the impact of that transmission in the associated disparate sector. Thus, the three-dimensional transmission token 220 is a network token representing the full impact on network resources of transmitting the packet, which allows the full network impact to be evaluated and necessary resources allocated.

FIG. 11 is a flow diagram illustrating a method for checking-out packets from the queue 40 using the multiple, dimension token bucket 44 in accordance with another embodiment of the present invention. In this embodiment, the multiple dimension token bucket 44 is the three-dimensional token bucket 200 and packets are represented by the three-dimensional transmission token 220. Packets are checked-out in the order in which they are received in accordance with available transmission resources. Thus, if available resources do not exist to transmit a first packet in the queue 40, later queued packets for which sufficient resources are available will be transmitted to maximize use of available resources.

Referring to FIG. 11, the method begins with a queue manager 42 in the Idle state 250 while the queue 40 is empty. In response to the queuing of one or more packets, the queue manager 42 transitions to step 252. At step 252, the queue manager 42 determines a size of a transmission token 240 for the first queued packet. At step 254, the queue manager 42 determines a size of a geographic interference token 242 at each neighboring sector for the first packet. Together, the transmission and geographic interference tokens form a network token indicating the full impact on network resources of transmitting the packet.

Proceeding to decisional step 256, the queue manager 42 determines whether sufficient tokens 218 are available in the token bucket 200 for transmission of the first packet based on the size of the three-dimensional transmission network token 220. In one embodiment, sufficient tokens 218 are available in the token bucket 200 when a set of tokens 218 spanning the power level are available over the duration of the transmission time in each of the two-dimensional transmit and disparate buckets 202 and 204. If sufficient tokens are available in the token buckets 202 and 204, the tokens 218 are allocated to the first packet and the Yes branch of decisional step 256 leads to step 258. At step 258, the first packet is removed from the queue 40. Next, at step 260, the first packet is transmitted to the wireless or wireline portion of the network 10 for delivery to a destination device. At step 262, the token buckets 202 and 204 are updated to remove tokens 218 allocated to the packet as that bandwidth and power (impact) has been used and is no longer available.

Proceeding to decisional step 264, the queue manager 42 determines whether additional packets exist in the queue 40.

If additional packets do not exist, the queue manager 42 has no additional packets to transmit and the No branch of decisional step 264 returns to the Idle state 250. If additional packets are queued, the Yes branch of decisional step 264 leads to step 266.

At step 266, the queue manager 42 determines the size of a transmission token 240 for the new first packet. At step 268, the queue manager 42 determines a size of a geographic interference token 242 for each sector for the new first packet. Step 268 returns to decisional step 256 where, as previously described, the queue manager 42 determines whether sufficient tokens 218 are available in the token bucket 200 to transmit the first packet based on the network token formed by the transmission token 240 and the geographic interference tokens 242. If sufficient tokens 218 are available, the packet is transmitted and the token bucket 200 updated as previously described.

If sufficient tokens are not available in the token bucket 200, then sufficient transmission resources not available in one or more of the sectors 12 to transmit the packet. Accordingly, the No branch of decisional step 256 leads to decisional step 270 in which the queue manager 42 determines whether additional packets are queued and may be transmitted in the limited resources that are currently available. If additional packets are not queued, then the No branch of decisional step 270 returns to decisional step 256 to determine if sufficient tokens 218 have become available due to the filling of the token bucket 200 to transmit the first packet. If sufficient tokens 218 have become available, the first packet will be transmitted and the token bucket 200 updated as previously described. If sufficient tokens are still not available, the queue manager 42 will continue to check for and try to transmit other packets until sufficient resources become available to transmit the first packet in the queue 40.

At decisional step 270, if additional packets exist in the queue, the Yes branch leads to step 272. At step 272, the queue manager 42 determines a size of a transmission token 240 for the next packet in the queue 40. At step 274, the queue manager 42 determines a size of a geographic interference token for each of the neighboring or other sectors 12 and creates the network token for the next packet in the queue 40.

At decisional step 276, the queue manager 42 determines whether sufficient tokens 218 are available in the token bucket 200 for transmission of the next packet in the queue 40 based on the network token formed by the transmission token 240 and the geographic tokens 242. If sufficient tokens 208 are not available, the No branch of decisional step 276 leads to decisional step 284 where a resource change is determined.

At decisional step 276, if sufficient tokens 218 are available in the token bucket 200 to transmit the next packet, the tokens 218 are allocated to the next packet and the Yes branch leads to step 278. At step 278, the next packet is removed from the queue. Next, at step 280, the next packet is transmitted to the wireline or wireless network for delivery to a destination device. At step 282, the token bucket 200 is updated to remove tokens 218 allocated to the next packet as that bandwidth and power (impact) has been used is no longer available.

Step 282 leads to decisional step 284 in which a resource change is determined. If additional resources have become available due to bucket fill or resource release, the Yes branch of decisional step 284 returns to decisional step 256 in which the queue manager 42 determines whether sufficient tokens 218 have become available in the token bucket 200 to transmit the first queued packet. The No branch of decisional step 284 returns to decisional step 270 where further packets are examined. Thus, the queue manager 42 will continue to check each packet in the queue 40 in the order in which they are queued until a packet is found for

which sufficient resources are currently available for transmission. In this way, packet flows in each sector are efficiently policed and shaped where the packets have a varying level of impact on the physical RF layer. Thus, the specific impact of each packet is accounted for in each sector to conform the flows to specific physical layer traffic characteristics of bandwidth and power usage.

In another embodiment of the three-dimensional system, each queue manager 42 may itself determine the availability of tokens in a corresponding token bucket. In this embodiment, each queue manager 42 will respond to a request from disparate queue managers 42 in the network 10 in order to evaluate and allocate interference resources for transmission of packets in the neighboring sectors. FIG. 12 illustrates interactions between queue managers 42 in accordance with this embodiment of the present invention.

Referring to FIG. 12, the method begins with the queue manager 42 in the idle state 298 while waiting for a request from disparate queue managers 42. In response to a request to provide a geographic interference token for packet transmission in another sector 12, the Idle state 250 transitions to decisional step 300. At decisional step 300, the queue manager 42 determines whether the sufficient tokens 218 are available for the geographic interference token 242. The geographic interference token 242 is sized based on the size of the transmission token 240 and interference between the sectors 12. Thus, the geographic interference token 242 may be a fraction of the transmission token 240 based on an intersector interference value. Alternatively, the geographic interference token 242 may be a defined portion of the transmission token 240 based on layout and access technology of the network 10. Further still, the geographic interference token 242 may be an on/off state for each of the neighboring or other sectors 12. The geographic interference token 242 may be sized by the requesting queue manager 42, or sized by the responding queue manager 42 in response to the request and information on the transmission characteristics of the packet. If sufficient tokens 218 are not available, the No branch of decisional step 300 leads to step 302. At step 302, the request is denied as sufficient resources are not available. Step 302 returns to the Idle state 50. Thus, a packet will not be transmitted in the adjacent sector 12 if such transmission would cause degrading interference in the present sector 12.

Returning to decisional step 300, if sufficient tokens are available, the Yes branch leads to step 304. At step 304, the queue manager 42 informs the requesting queue manager 42 that the requested tokens 218 are available. Next, at decisional step 306, the queue manager 42 determines whether the requested tokens should be allocated based on instructions from the requesting queue manager 42. If the requesting queue manager 42 is informed that sufficient resources exist in each of the neighboring sectors 12, then it will instruct those sectors 12 to allocate the geographic impact tokens. If the tokens 218 are to be and are allocated, the Yes branch of decisional step 306 leads to step 308 in which the token bucket 200 is updated to remove the allocated tokens 218 as they will be used by transmission of a packet in another sector and are not available. Step 308 returns to the Idle state 250.

Returning to decisional step 306, if the tokens 218 are available but not allocated, the No branch returns to the Idle state 250. In this way, the queue manager 42 interacts with neighboring sectors 12 to determine whether sufficient resources are available in those sectors 12 in order to accommodate interference caused by transmission of a packet in the sector 12 and responds to request from the neighboring sectors 12 for similar information.

FIG. 13 is a block diagram illustrating management of exemplary traffic resources in accordance with one embodiment of the present invention. In this embodiment, three-

15

dimensional tokens 220 including a geographic interference token 242 for each neighboring sector 12 are used to determine whether sufficient network resources are available to transmit a packet.

Referring to FIG. 13, a transmission sector 330 has a plurality of neighboring sectors 332. The neighboring sectors 332 may be adjacent, proximate to, impacted or suitable sectors 12 in the network 10. A two-dimensional token bucket 344 is used in each of the transmission sector and the neighboring sectors 330 and 332. Together, the two-dimensional token buckets 334 form a three-dimensional token bucket 200. In each of the sectors 330 and 332, a buffer 336 queues traffic and a token-check system 338 checks the traffic out of the buffer 336 when sufficient resources are available in the network 10.

In the transmission sector 330, in response to queuing of a packet having a transmission token 340 with a power level of 4 and a time duration of 0.4 seconds, the token check-out system 338 determines that sufficient resources are immediately available in the sector 12. The token check-out system 338 also checks with neighboring sectors 12 to determine if sufficient resources are available in those sectors 12 to handle the impact caused by transmission of the packet. At a first neighboring sector 342, the packet has geographic interference token 242 with a power level of 2 over the duration time, for which resources are currently available. At a second neighboring sector 344, the packet has an geographic interference token 242 with a power level of one over the duration time. Sufficient tokens are not available at the current time, but will become available in 0.1 seconds. At a third neighboring sector 346, the packet has an geographic interference token 242 with a power level of 3 over the duration time. Again, sufficient tokens are not available but will become available in 0.1 seconds. At a fourth neighboring sector 348, the packet has no interference and accordingly may be transmitted without regard to the token bucket in that sector. Because sufficient resources are not available in all of the neighboring sectors 12, the packet will not be currently transmitted, but will remain queued. Transmission of the packet may be scheduled to begin in 0.1 seconds based on the current state of the system or other packets may be immediately transmitted and transmission resources rechecked at a later time for the packet.

In another embodiment, the three-dimensional resource allocation system may be deployed without the three-dimensional token bucket 200. In this embodiment, packet check-out may be scheduled based on available resources and resource impact. The radio resource impact in a sector may be calculated as follows:

$$\text{impact}_i = I_i / R_1$$

where: I is the impact coefficient in the sector; and

R_1 is the average available transmission rate in the transmission sector; and

i is the sector.

In another embodiment, the radio resource impact in sector may be calculated as follows:

$$\text{impact}_i = \max_i(I_i / R_i)$$

where: I is the impact coefficient in the sector;

R_i is the available transmission rate in the sector; and

i is the sector.

The time to check-out each packet may then be calculated based on the impact as follows:

$$tts_1 = ct + L(\text{impact}_i)$$

$$tts_2 = ct + L(\text{impact}_i)$$

$$tts_n = ct + L(\text{impact}_i)$$

16

where: tts is the time to send the next packet for a sector;

ct is the current time;

L is the packet size; and

i is the sector.

As previously described in connection with the two-dimensional system, inclusion of the impact coefficient in the scheduling algorithm allows the full impact of packet transmission to be accounted for in managing transmission resources in a sector. The impact coefficient may be independently varied depending on the interference caused in the sector by packet transmission in another sector. The impact coefficient may be static based on the layout of the sectors 12 or dynamic based on operating conditions of the network 10. Thus, the specific impact of each data packet on the physical layer resource in the network is taken into account in evaluating and allocating transmission resources. As a result, traffic flows are more accurately policed and shaped to account for resource limitations in the wireless network 10. In addition, because the available bandwidth may be accurately determined, it may be brokered as described in co-owned U.S. patent application Method and System for Brokering Bandwidth in a Wireless Communications Network previously incorporated by reference.

Although the present invention has been described with several embodiments, various changes and modifications may be suggested to one skilled in the art. It is intended that the present invention encompass such changes and modifications as fall within the scope of the appended claims.

What is claimed is:

1. A method for managing transmission resources in a wireless communications network, comprising:

receiving a packet;

providing a token bucket comprising a plurality of tokens representing power available for transmission of the packet at discrete units of time;

generating a transmission token representing an impact of transmitting the packet based on a time duration for transmission of the packet and a power level for transmission of the packet over the time duration;

determining whether sufficient tokens are available in the token bucket for the transmission token; and

transmitting the packet if sufficient tokens are available in the token bucket.

2. The method of claim 1, further comprising queuing the packet until sufficient tokens are available in the token bucket.

3. The method of claim 1, if sufficient tokens are available in the token bucket, further comprising:

allocating a number of tokens corresponding to the size of the transmission token for the packet; and

updating the token bucket to remove the allocated tokens.

4. The method of claim 1, wherein tokens in the token bucket represent power available for transmission of the packet in a sector of a wireless network and the transmission token represents a sector impact of transmitting the packet in the sector, further comprising:

determining a geographic interference impact token representing impact in a disparate sector of transmitting the packet in the sector;

determining whether a token bucket for the disparate sector includes sufficient tokens for the geographic interference impact token; and

transmitting the packet if sufficient tokens are available in the token bucket for the sector for the transmission token and sufficient tokens are available in the token bucket for the disparate sector for the geographic interference impact token.

17

5. The method of claim 4, further comprising:
determining a plurality of geographic interference impact
tokens each representing impact in a disparate sector of
transmitting the packet in the sector;
determining whether a token bucket for each of the
disparate sectors includes sufficient tokens for a corre- 5
sponding geographic interference impact token; and
transmitting the packet if sufficient tokens are available in
the token bucket for the sector for the transmission
token and sufficient tokens are available in each of the 10
token buckets for the disparate sectors for a corre-
sponding geographic interference impact token.

6. A system for managing transmission resources in a
wireless communications network, comprising:
a queue operable to store a packet; and
a transmission control system operable to provide a token
bucket comprising a plurality of tokens representing
power available for transmission of the packet at discrete
units of time, to generate a transmission token repre- 20
senting an impact of transmitting the packet based
on a time duration for transmission of the packet and a
power level for transmission of the packet over the time
duration, to determine whether sufficient tokens are
available in the token bucket for the transmission
token, and to check-out the packet from the queue for
transmission if sufficient tokens are available in the
token bucket.

7. The system of claim 6, if sufficient tokens are available
in the token bucket, the transmission control system further
operable to allocate a number of tokens corresponding to a
size of the transmission token to the packet and to remove
the allocated tokens from the token bucket.

8. The system of claim 6, wherein tokens in the token
bucket represent power available for transmission of the
packet in a sector of a wireless network and the transmission
token represents a sector impact of transmitting the packet in
the sector, the transmission control system further operable
to determine a geographic interference impact token repre- 35
senting impact on a disparate sector of transmitting the
packet in the sector, to determine whether a token bucket for
the disparate sector includes sufficient tokens for the geo-
graphic interference impact token, and to transmit the packet
if sufficient tokens are available in the token bucket for the
sector for the transmission token and sufficient tokens are
available in the token bucket for the disparate sector for the
geographic interference impact token.

9. The system of claim 8, wherein tokens in the token
bucket represent power available for transmission of the
packet in a sector of a wireless network and the transmission
token represents a sector impact of transmitting the packet in
the sector, the transmission control system further operable
to determine for each of a plurality of disparate sectors a
geographic interference impact token representing an impact
in the disparate sector of transmitting the packet in the
sector, to determine whether a token bucket for each of the
disparate sector includes sufficient tokens for the corre- 40
sponding geographic interference impact token, and to trans-
mit the packet if sufficient tokens are available in the token
bucket for the sector for the transmission token and sufficient
tokens are available in each of the token buckets for the
disparate sectors for a corresponding geographic interfer- 45
ence impact token.

18

10. A method for managing transmission resources in a
wireless communications network, comprising:
receiving a packet;
providing a token bucket comprising a plurality of mul-
tiple dimension tokens representing allowable impact
for transmission of the packet at discrete units of time;
generating a multiple dimension transmission token rep-
resenting impact of transmitting the packet;
determining whether sufficient multiple dimension tokens
are available in the token bucket for the multiple
dimension transmission token; and
transmitting the packet if sufficient tokens are available in
the token bucket.

11. The method of claim 10, further comprising:
allocating a number of multiple dimension tokens corre-
sponding to the size of the multiple dimension trans-
mission token for the packet; and
updating the token bucket to remove the allocated mul-
tiple dimensions tokens.

12. The method of claim 10, further comprising filling the
token bucket with multiple dimension tokens at a static rate.

13. The method of claim 10, further comprising filling the
token bucket with multiple dimension tokens at a dynamic
rate based on available bandwidth of the wireless commu-
nications network.

14. The method of claim 10, wherein multiple dimension
tokens in the token bucket represent impact available for
transmission of the packet in a sector of a wireless network
and the multiple dimension transmission token represents a
sector impact of transmitting the packet in the sector, further
comprising:
providing a token bucket for a disparate sector comprising
a plurality of multiple dimension tokens representing
allowable impact for transmission of the token in the
sector;
determining a multiple dimension geographic interference
impact token representing impact in the disparate sector
of transmitting the packet in the sector;
determining whether sufficient tokens are available in the
token bucket for the disparate sector for the geographic
interference impact token; and
transmitting the packet if sufficient tokens are available in
the token bucket for the sector for the multiple dimen-
sion transmission token and sufficient tokens are avail-
able in the token bucket for the disparate sector for the
multiple dimension geographic interference impact
token.

15. The method of claim 14, further comprising:
allocating the number of tokens in the token bucket for the
sector corresponding to the size of the multiple dimen-
sion transmission token;
updating the token bucket for the sector to remove the
allocated tokens;
allocating the number of tokens in the token bucket for the
disparate sector corresponding to the size of the geo-
graphic interference impact token for the packet; and
updating the token bucket for the disparate sector to
remove the allocated token.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 6,522,628 B1
DATED : February 18, 2003
INVENTOR(S) : Achal R. Patel et al.

Page 1 of 1

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Title page, Item [54] and Column 1, line 3,

After “**WIRELESS**”, delete “**COMMUNICATION**”, and insert
-- **COMMUNICATIONS** --.

Signed and Sealed this

Twenty-sixth Day of August, 2003

A handwritten signature in black ink, appearing to read 'James E. Rogan', with a horizontal line drawn underneath it.
