(57) **ABSTRACT**

Providing information as to location of a mobile station involves receiving a mobile station location request from a requesting software application at an API gateway of a wireless communications network. The API gateway provides a network-initiated request to the wireless communications network for the location of the mobile station after determining that the requesting application is authorized to receive the location of the specified mobile station. The location of the mobile station can be determined, according to either a coarse or granular location position resolution, or accuracy, based on the request of the application and/or the conditions of the wireless communication network. Information as to location of the mobile station can be produced, and provided to the requesting software application, which can be resident on the mobile station itself or at a different location/platform.

SYSTEMS AND METHODS FOR PROVIDING MOBILE HANDSET POSITION TO SOFTWARE APPLICATIONS

TECHNICAL FIELD

The present subject matter relates to systems and methods for providing information regarding the location of mobile stations to authorized software applications. The software applications can be resident on a target mobile station or another platform.

BACKGROUND

In recent years, mobile stations have become “must have” devices for most people, in many countries. The communications that such devices offer, via wireless mobile communications network, enable users to talk and exchange various types of messages for business and personal reasons and to access information, all from or while traveling through any location where a network provides service. As the technology has advanced, the size of mobile stations has decreased, so that today most can be carried in a pocket or purse, clipped to a belt, etc. There are situations where it is desirable to determine the location of a mobile station, and various industry players have developed technologies to meet such demands. For example, in the US today, most mobile devices are equipped with Global Positioning Satellite (GPS) receivers/processors sufficient to enable emergency services to obtain information as to the location of a device as part of the processing of an emergency call, e.g., to 911. The advanced location capabilities of such mobile stations, however, have also enabled service providers to offer services and applications today that will allow a user of a mobile station to learn their present location and possibly obtain information about that locale and/or related navigation information, via the mobile station itself.

Situations arise where it is desirable for another person to learn the location of a mobile station, and the service providers have developed technologies for many such situations. For example, mobile network service providers today offer at least some types of Mobile Location-Based Service (MLBS) that enable a user of or associated with one mobile station to locate a user of another mobile station, based on the location of the second mobile station. Examples of such services today include Family Locator (formerly Chaperone) offered by Verizon Wireless®, and Boost Loop offered by BoostMobile™.

Family Locator is a simple and secure method for parents to keep a closer tab on their children. The mobile stations are GPS enabled. Family Locator allows a customer (e.g., a parent) to view on a map a location of the Family Locator enabled phone of another customer (e.g., a child) and to receive alerts when the Family Locator enabled phone enters or leaves a particular zone.

Boost Loop expanded this type of location service to include keeping tabs on a wider range of friends and family member. In this connection, Boost Loop is another location-based social service that uses a mobile phone with built-in GPS to automatically update a customer location for a private list of friends. To illustrate, the customer downloads the Boost Loop software onto her mobile phone and publishes its location on a Boost Loop map. Thereafter, the customer may invite other friends who have installed Boost Loop to join the customer's networks. If friends accept such invitation, their locations will also be published on the map. As such, the

2

customer can identify the locations of her friends in real-time on a map display on the customer's mobile station.

Although these mobile station location technologies allow a requesting device, as operated by a user, to monitor or learn the current location of a mobile station that is the “target” of a location information request or procedure, the existing technologies do not allow software applications to make a request for and be giving access to the location of a mobile station for performing software functions based on the location of that mobile station.

Hence, there is still a need for an improved/simplified technique for obtaining information as to the location of a mobile station.

SUMMARY

The teachings herein provide improved methods and equipment (e.g., mobile station and/or programming for the station) to provide a quick effective way to provide an software application with information as to the location of a mobile station connected to a wireless network.

For example, in one aspect the detailed description and drawings disclose a method of providing information as to location (position) of a mobile station, which involves receiving a mobile station location request message from a requesting application, over a communications link, at an API gateway (API GW) of a wireless communications network. The communications link can be any suitable link such as a part of a wireless communications network or the Internet. A number of further steps can be taken once it is determined that the software application is authorized to receive the location of the mobile station. These further steps can include the API gateway (API GW) providing a network-initiated request to the wireless communications network for the location of the mobile station after determining that the requesting application is authorized to receive the location of the specified mobile station. The location of the mobile station can be determined at one of two position accuracies, or resolutions, i.e., coarse or granular, based on the request made by the software application and/or the conditions of the wireless communication network. For position determination, the request from the API GW can be sent to a location gateway (LGW) that is connected to a wireless data network (WDN) of the wireless network. The LGW can query the WDN as to the granular position of the mobile station. The LGW is also connected to a mobile position center (MPC), which is connected to one or more mobile switching centers (MSCs) and home location registers (HLRs) of the wireless network. The LGW can query the MPCs and HLRs for the coarse location of mobile station. Information as to location of the mobile station can be produced, and provided to the requesting software application at the lesser of the requested position accuracy and the position accuracy made available by the network.

Another aspect of the detailed description and drawings disclose an infrastructure for providing one or more location based services through a wireless network. The infrastructure can include an API gateway (API GW) that serves as an interface between the wireless network and one or more software applications, such as third-party applications relative to the wireless network provider. The API GW is connected to a location gateway (LGW) that is connected to a wireless data network (WDN) of the wireless network. The API GW sends the request to the LGW. The LGW can query the WDN as to the granular position of the mobile station. The LGW is also connected to a mobile position center (MPC), which is connected to one or more mobile switching centers (MSCs) and home location registers (HLRs) of the wireless network. The

3

LGW can query the MPCs and HLRs for the coarse location of mobile station. The coarse or granular location of the mobile station can be determined, based on the request of the application and/or the wireless communication network. Information as to location of the mobile station can be produced, and provided to a software application, which can be resident on the mobile station itself or at a different location/platform.

It should be noted that any of the approaches to providing granular location information, as outlined herein, may be facilitated by a mobile station configured with a location agent application to provide granular location information and/or in the form of a product or article of manufacture typically including a computer-readable storage medium bearing a location agent program that may configure a mobile station so that the station is capable of providing the granular location information as discussed herein.

Additional advantages and novel features will be set forth in part in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following and the accompanying drawings or may be learned by production or operation of the examples. The advantages of the present teachings may be realized and attained by practice or use of various aspects of the methodologies, instrumentalities and combinations set forth in the detailed examples discussed below.

BRIEF DESCRIPTION OF THE DRAWINGS

The drawing figures depict one or more implementations in accord with the present teachings, by way of example only, not by way of limitation. In the figures, like reference numerals refer to the same or similar elements.

FIG. 1 is a functional block diagram that depicts various components of an exemplary mobile communications network.

FIG. 2 is a functional block diagram that depicts various components of an exemplary mobile communications network as used for mobile station position determination.

FIG. 3 is a flowchart showing various aspects of a call flow for a coarse location request as utilized for mobile station position determination.

FIG. 4 is a flowchart showing various further aspects of a call flow for a granular location request as utilized for mobile station position determination.

FIG. 5 is a flowchart showing various further aspects of a call flow for geographic notification as utilized for mobile station position determination.

FIG. 6 is a flowchart showing various further aspects of a call flow for cancellation of geographic notification as utilized for mobile station position determination.

FIG. 7 is a flowchart showing various further aspects of a call flow for scheduled notification as utilized for mobile station position determination.

FIG. 8 is a high-level block diagram of an exemplary mobile station device.

DETAILED DESCRIPTION

In the following detailed description, numerous specific details are set forth by way of examples in order to provide a thorough understanding of the relevant teachings. However, it should be apparent to those skilled in the art that the present teachings may be practiced without such details. In other instances, well known methods, procedures, components, and/or circuitry have been described at a relatively high-level,

4

without detail, in order to avoid unnecessarily obscuring aspects of the present teachings.

Functionality, systems, and methods for determining the location of a mobile station are shown and described. By use of such, the location of a mobile station can be determined and provided to one or more software applications, such as local weather forecasting and asset tracking applications.

Reference now is made in detail to the examples illustrated in the accompanying drawings and discussed below. FIG. 1 illustrates a mobile communication network 100 as may be operated by a carrier or service provider to provide a wide range of mobile communication services and ancillary services or features to its subscriber customers and associated mobile station (MS) users. The elements collectively indicated by the reference numeral 100 generally are elements of the network and are operated by or on behalf of the carrier, although the mobile stations may be sold to and owned by the carrier's customers. The mobile communication network 100 provides communications between mobile stations as well as communications for the mobile stations with networks and stations (not shown) outside the mobile communication network 100.

The wireless mobile communication network 100 might be implemented as a network conforming to the code division multiple access (CDMA) IS-95 standard, the 3rd Generation Partnership Project 2 (3GPP2) wireless IP network standard or the Evolution Data Optimized (EVDO) standard, the Global System for Mobile (GSM) communication standard, a time division multiple access (TDMA) standard or other standards used for public mobile wireless communications. The mobile stations 113 may be capable of conventional voice telephone communications and data communications.

For purposes of later discussion, several mobile stations 113 appear in the drawing, to represent examples of the mobile stations that may receive various services via the mobile communication network 100.

Mobile stations 113 can take the form of portable handsets, smart-phones or personal digital assistants, although they may be implemented in other form factors. Mobile stations 113 can include media content. The media content can be configured to execute on many different types of mobile stations 113. For example, a mobile station application can be written to execute on a binary runtime environment for mobile (BREW-based) mobile station. In further instances, a mobile station application can be written to execute on a Windows Mobile based mobile station, Android, I-Phone, Java Mobile, or RIM based mobile station such as a BlackBerry or the like.

The mobile communication network 100 can be implemented by a number of interconnected networks. Hence, the overall network 100 may include a number of radio access networks (RANs), as well as regional ground networks interconnecting a number of RANs and a wide area network (WAN) interconnecting the regional ground networks to core network elements. A regional portion of the network 100, such as that serving mobile stations 113, can include one or more RANs and a regional circuit and/or packet switched network and associated signaling network facilities.

Physical elements of a RAN operated by one of the mobile service providers or carriers, include a number of base stations represented in the example by the base stations (BSs) 119. Although not separately shown, such a base station 119 can include a base transceiver system (BTS), which can communicate via an antennae system at the site of base station and over the airlink with one or more of the mobile stations 113, when the mobile stations are within range. Each base station can include a BTS coupled to several antennae mounted on a

radio tower within a coverage area often referred to as a "cell." The BTS is the part of the radio network that sends and receives RF signals to/from the mobile stations 113 that are served by the base station 119.

The radio access networks can also include a traffic network represented generally by the cloud at 121, which carries the user communications and data for the mobile stations 113 between the base stations 119 and other elements with or through which the mobile stations communicate. In some examples, the mobile traffic network 121 includes network elements that support mobile station media content transfer services such as mobile switching centers (MSCs) 130, signal transfer points (STPs) 134, and an application server (App. Server) 132. The network can also include other elements that support functionality other than media content transfer services such as messaging service messages and voice communications. Examples of other network elements that may be used in support of messaging service message communications include, but are not limited to, message centers (MCs) 139, home location registers (HLRs) 138, simple messaging service point-to-point (SMPP) gateway 140, and other network elements such as wireless interne gateways (WIGs), and visitor location registers (VLRs) (not shown). Other individual elements such as switches and/or routers forming the traffic network 121 are omitted here for simplicity. It will be understood that the various network elements can communicate with each other and other aspects of the mobile communications network 110 and other networks, e.g., the public switched telephone network (PSTN) and the Internet, either directly or indirectly.

The mobile switching center (MSC) 130 is responsible for managing communications between the mobile station and the other elements of the network 110. In addition, the MSC 130 is responsible for handling voice calls and messaging service message requests as well as other services (such as conference calls, FAX and circuit switched data, messaging service communications, Internet access, etc.). The MSC 130 sets up and releases the end-to-end connection or session, and handles mobility and hand-over requirements during the call. The MSC 130 also routes messaging service messages to/from the mobile stations 113, typically from/to an appropriate MC 139. The MSC 130 is sometimes referred to as a "switch". The MSC 130 manages the cell sites, the voice trunks, voicemail, and SS7 links.

The message center (MC) 139, in some examples, allows messaging service messages to be exchanged between mobile telephones and other networks. For SMS messaging, for example, the MC 139 receives packet communications containing text messages from originating mobile stations and forwards the messages via the signaling resources and the signaling channels to the appropriate destination mobile stations. The MC 139 may receive messages from external devices for similar delivery to mobile stations, and the MC 139 may receive similar messages from the mobile devices and forward them to servers or terminal devices, in either case, via an Internet Protocol (IP) packet data network.

In some examples, the MC 133 can also be considered or include functionality that may be considered that of a Short Messaging Service Message Center (SMSC) or a Message Register (MR). Wireless carriers developed the short message service (SMS) to transmit text messages for display on the mobile stations. In many existing network architectures, the SMS traffic uses the signaling portion of the network 121 to carry message traffic between a Short Message Service Center (SMSC) 139 and the mobile stations. The SMSC 139 supports mobile station to mobile station delivery of text messages. However, the SMSC 139 also supports communi-

cation of messages between the mobile stations and devices coupled to other networks. For example, the SMSC 139 may receive incoming IP message packets from the Internet 129 for delivery via the network 121, one of the base stations 119 and a signaling channel over the air link to a destination mobile station. For this later type of SMS related communications, the network 110 also includes one or more Short Message Peer-to-Peer (SMPP) protocol gateways 140.

In other examples, the MC 139 can include functionality related to the Enhanced Messaging Service (EMS) or Multimedia Messaging service (MMS). An EMS message can have special text formatting (e.g., such as bold or italic), animations, pictures, icons, sound effects and special ring tones. MMS messages support the sending and receiving of multimedia messages (e.g., images, audio, video and their combinations) to (or from) MMS-enabled mobile stations. In some examples, the MC 139 can be considered in whole or in part a multimedia messaging service center (MMSC).

Although a single MC 139 is shown, a network 10 can have many geographically dispersed MCs 139. The MCs 139 can include destination routing tables (DRTs). In essence the DRTs are databases within the MCs 139. A DRT contains a list of the MDNs which are associated with the various MCs 139. For example, a first MDN is associated with a MC 139 in California while a second MDN is associated with a MC 139 in Virginia. The DRTs are used to determine which MC 139 should attempt to deliver an incoming messaging service message to the destination MDN. For example, if a user associated with the MC in California sends an SMS to a user associated with the MC 39 in Virginia, the California MC 139 sends the SMS to the Virginia MC 133 for delivery to the destination MDN. The communication among the MCs 139 occurs using known protocols such as SMPP and the like.

The HLR 138, in some examples, stores a subscriber profile for each of the wireless subscribers and their associated mobile stations 113, 115, and 117. The HLR 138 may reside in an MSC 130 or in a centralized service control point that communicates with the MSC(s) 130 via an out-of-band signaling system such as an SS7 network. The HLR 138 stores for each mobile subscriber the subscriber's mobile directory number (MDN), the mobile identification number (MIN), and information specifying the wireless services subscribed to by the mobile subscriber, such as numeric paging or text-based paging, data communication services, etc. Of course, the HLR 138 can also be a stand-alone device. The HLR also tracks the current point of attachment of the mobile station to the network, e.g., the identification of the MSC 130 with which the mobile station is currently registered to receive service.

The visitor location register (VLR) (not shown) is, in some examples, a temporary database of the mobile stations that have roamed into the particular area which it serves. The VLRs for a region often are implemented in or in association with a MSC 130. Each base station 119 in the network is served by a single VLR, hence a subscriber cannot be present in more than one VLR at a time. The data stored in the VLR has either been received from the HLR 138, or collected from the mobile station.

The SMPP gateway 140 provides functionality to transport messaging service messages to other mobile communication networks and also receive messaging service messages from other networks. The SMPP gateway 140 supports communications using the SMPP protocol. SMPP gateways 140 are Short Message Peer-to-Peer (SMPP) gateways 140 used to connect the wireless communication network (such as an Internal Protocol IP network on the left of the SMPP Gateway 140 in FIG. 1) to another network (such as a public Internet

7

network on the right of the SMPP Gateway **140** in FIG. 1). The SMPP Gateway **140** allows the MC **139** to receive and send messages in IP packet format. The SMPP Gateway **140** is an entity within the wireless network **100** that acts as an intermediary between the wireless service provider network and other networks. For example, the SMPP Gateway **140** converts messages in protocol(s) used by other applications and devices, e.g. Extensible Markup Language (XML), Hypertext Mail Protocol (HTMP), etc., to and from the SMPP protocol. The SMPP messages ride on IP transport, e.g., between the SMPP Gateway **140** and the MC **139**.

In addition, the traffic network portion **121** of the mobile communications network **110** connects to a private data network **136**. The private data network **36** connects to the traffic network portion **121** via a gateway (not shown). The gateway can provide protocol conversions between the protocols used by the traffic network **121** and the protocols used by the private data network **136**.

The private data network **136** can be in communication with various auxiliary services servers, e.g., such as those providing additional services to the users of the network **100**, and/or to operations support personnel of the service provider or carrier that operates the network **100**. For example, the carrier can also offer its subscribers on-line access to a variety of functions related to the subscribers' accounts, such as review of billing statements and usage data, on-line payment, subscription changes, password control or the like. For that purpose, the carrier can operate a customer account web server **141**, offering a "MyAccount" type subscriber interface via the Internet, e.g., a "My Verizon" page for a user having a Verizon Wireless account. Hence, a user's terminal, such as PC **131**, may be used to access on-line information about a subscriber's account, which the mobile carrier makes available via the carrier's MyAccount web site accessible through the Internet **129**.

In addition, a group provisioning manager device (GPMD) **142**, a zone provisioning device (ZPD) **143**, and a service creation manager device (SCMD) **144** can be provided in communication with the private data network **136** media content transfer functions, e.g., downloading of media content. The GPMD **142** can also be referred to as a group provisioning manager network device. For discussion purposes, each of the GPMD **142**, ZPD **143**, and SCMD **144** can be a stand alone computing device such as a server. The functionality described below with respect to each of the GPMD **142**, ZPD **143**, and SCMD **144** can, however, be provided by one or multiple different computing devices. In other words, the GPMD **142**, ZPD **143**, and SCMD **144** need not be a stand-alone computing device in various configurations. The SCMD **144** can maintain provisioning information for a particular end user and mobile station **13**. As explained in further detail below for FIG. 2, a network can be provided with various elements for determining the location of a mobile and allowing software applications to make use of such position information.

An example of a wireless work with location based services infrastructure (LBSI) for support of granular and coarse location via a network-initiated request is shown FIG. 2. Network **200** includes elements similar to those of network **100** of FIG. 1, including one or more mobile stations **202**. The mobile device or station **202** can be an advanced device, e.g., a Blackberry/RIM, Android, Palm, LiMo, Java, or Linux device. API gateway (API GW) **208** functions to allow software applications, e.g., third-party applications (shown by application server **204**), to send requests to locate mobile handsets. Such software applications can be resident on the mobile station **202** itself or resident on another platform.

8

Examples of such software applications include but are not limited to weather forecasting/reporting applications and asset or person tracking and/or location applications. The API GW **208** is interfaced with a location gateway (LGW) **210** for supporting location requests from the software application(s) **204**. The API GW **208** and LGW are connected to a wireless data network (WDN) **220** of the network **200**, which can include SMPP Gateway (GW) **224**, AAA server/cache **226**, and position determining entity (PDE) **222**. The LGW **210** is also connected to a mobile position center (MPC), which is connected to one or more mobile switching centers (MSCs) and home location registers (HLRs) of the wireless network **200**. After verifying that the requesting software application (indicated by **204**) is authorized to receive the position information for the mobile station **202**, the request can be processed and the position information can be determined at different resolutions, or accuracies, based on the request itself and/or network conditions. One position resolution of location, or position accuracy, is "coarse," which is cell ID-based position of a mobile using the latitude/longitude of the centroid of a cell in which the mobile station is operating. Another resolution, or accuracy, is "granular," which can offer a more precise location of the mobile station, e.g., based on GPS determined latitude and longitude of the mobile station. Assisted GPS, Advanced Forward Link Triangulation (AFLT), or other suitable techniques can be used for facilitating granular position determination, as is described in further detail below.

As an overview of a process by which a third party application is provided with the location of a mobile station **202** by way of the LBSI (API GW **208**, LGW **210**, and MPC **212**), the API GW **208** of FIG. 2 provides the single point of interface to third party applications, shown by **204**. The API GW **208** receives requests for location from third party applications **204**, translates them into mobile location protocol (MLP) commands toward the LGW **210**, receives responses from the LGW **210** and responds to third party applications **204** with the location of the mobile station **202**. The LGW **210** provides an interface to the API GW **208** to extract device positions in a user plane positioning environment. The LGW **210** can be connected to the WDN **220** via, e.g., two dedicated T1 connections. MPC **212** is provided for coarse location determination and interfaces with the LGW **210** for determining the status of the mobile station **202** (e.g., available or unavailable), identifying the network location of the mobile station (i.e., by way of the Serving Mobile Switching Center **234**) and determining the coarse location of the mobile station **202**. The MPC is preferably provisioned with the following data: MDN range to HLR address mapping data; MSC identifiers to lat/long mapping data; cell ID to lat/long mapping data; and, MSC Point Code/SSN to MSCID data. In FIG. 2, physical connectivity between network elements is indicated by solid lines while logical interfaces are indicated by dashed lines, suitable examples of which are describe below.

As for interfaces between the location-specific network elements of network **200**, the interface between the API GW **208** and LGW **210** can be based on OMA Mobile Location Protocol (MLP) v. 3.2 over HTTP. The API GW **208** can be connected to the WDN **220**, so existing WDN connectivity to the LGW **210** can be utilized for this interface. This interface can be and preferably is secured using SSL. The interface between the MPC **212** and LGW **210** can be based on Open Mobile Alliance (OMA) Mobile Location Protocol (MLP) v. 3.2. The MPC **212** can interface with the home location registers (HLRs) using, e.g., TIA-41-D, and the MSCs **234**, which can include visitor location registers (VLRs), using,

e.g., TIA/EIA/IS-881 links, respectively. The API GW **208** itself can interface with the software application(s) via Parlay-X 2.1 Web Services API.

PDEs **222** have resulted from the mobile telecom industry developing a number of technologies to locate mobile stations, both for emergency services (e.g., 911) and for location based applications. In an increasingly common network implementation, the mobile station has the capability to take GPS signal measurements and communicate those measurements to one or more network elements or software applications **204** for processing, depending on the particular application. Typically, a PDE communicates with an appropriately equipped mobile station (MS) to determine the location of the MS, and for non-emergency services, a Location gateway (LGW) makes that information accessible to various user applications, including some applications that reside on mobile stations. Hence, the location determination software in the mobile station **202** enables that station to obtain the location information by working with elements of a location based service (LBS) platform of the mobile wireless communication network, such as a location gateway (LGW) **210** and a PDE **222**.

The PDE **222** is a network element that manages the position or geographic location determination of each mobile station. For discussion purposes at this point, it can be assumed that exemplary network **200** utilizes an assisted GPS (AGPS) approach to the determination of mobile station location, in which the mobile station **202** takes measurements of signals from a number of GPS satellites **250** (only three of which are shown, for convenience) and interacts with the PDE **222** to process those measurements so as to determine the latitude and longitude (and possibly altitude) of the current location of the mobile station **202**. The PDE system **222** is essentially a general purpose programmable device with an interface for data communication via the network **200** running server software and running programming for implementation of the PDE functions. The PDE **222** stores (e.g., in cache memory) or has access to a complete and up to date set of the satellite data for the constellation of GPS satellites **250** needed to allow computation of position based on pseudorange measurements from satellite signals. The data may include that associated with the entire constellation but will at least include the data for the satellites expected to be broadcasting into the geographic region serviced by the network **200**.

When a mobile station such as **202** attempts a GPS position fix, the mobile station provides information allowing the PDE **222** to perform a pre-fix. Typically, the mobile station will provide data identifying the base station **240** through which it is receiving service (and possibly the serving sector). In some implementations, the PDE **222** may receive data regarding several base stations/sectors and signal strengths thereof, for trilateration. The PDE **222** uses information about base station location(s) to process the data received from the mobile station so as to determine a region (e.g., area of the cell or sector, or a general area triangulated based on signals from several base stations) that the mobile station is likely located within. The PDE **222** then uses the pre-fix location to parse the satellite data down, to assistance data that the mobile station at the particular location needs in order to take GPS readings. The PDE **222** sends the parsed satellite data to the mobile station, e.g., to target mobile station **202**, for use in taking measurements of signals from appropriate satellites **250**. The GPS assistance data may contain selected satellite almanac, satellite visibility, Doppler and clock correction information.

The mobile station **202**, in turn, uses this information (also known as acquisition assistance records) to take multiple

satellite pseudorange measurements. Depending on the device/network configuration, the mobile station such as **202** or the PDE **222** can then calculate a final fix using these pseudorange measurements. The final fix computation provides latitude and longitude (and possibly altitude) coordinates for the current location of the mobile station **202**. If the mobile station **202** has full GPS computation capability, the station **240** would know its current latitude and longitude and would communicate that data to the PDE **222** through the network **200**. In many cases, however, the mobile station has only measurement capability, and the mobile station forwards the measurement data to the PDE **222** to determine the final fix. In either case, the GPS processing leads to a situation in which the PDE **222** knows the latitude and longitude of the mobile station, that is to say **202** in the given example. If necessary, the PDE **222** can provide coordinates to the mobile station **202**.

For many location based applications today, further processing or access is needed. To provide access to general users, e.g., mobile subscribers and authorized third party users, the carrier also operates a location gateway (LGW) **210**. The LGW **210** is essentially a general purpose programmable device with an interface for data communication via the network **200** running server software and running programming for implementation of the LGW functionality. In the example, the server platform runs a queue manager for managing communications and access to the various LGW program modules. The LGW program modules can include a thin API proxy client, for client-server proxy communications with the mobile stations, such as the target mobile station **202**. The LGW program modules can also include a PDE adapter, for communications through the network with the PDE **222**, e.g., for situations in which the LGW **210** needs to obtain mobile station position data from the PDE **222**.

Continuing with the description of network **200**, upon receipt of a location request from a third-party application, the API GW **208** sends a request for location to the LGW **210**. The LGW **210** makes a determination if coarse or granular location is needed. If granular location is required, the LGW **210** uses user plane location technology. For supporting granular location, a Location Agent (LA) client can be installed on the mobile handset **202**. If coarse location is requested, the LGW **210** sends a request to the Control Plane Mobile Position Center (MPC) **212**. As indicated, the MPC **212** can interface with a pre-existing SS7 **230** network for communicating with HLRs and MSCs.

The LGW **210** determines whether granular or coarse location is required by examining the requested horizontal accuracy of the location request. If the requested horizontal accuracy is less than a specified threshold, e.g., 500 meters, 1000 meters, 1,500 meters, granular location may be attempted. Of course, the specified threshold can be selected as desired, and may be based on operational parameters of the wireless network and/or the GPS system. If the requested horizontal accuracy is equal to or more than a specified threshold, e.g., 1000 meters or 1,500 meters, coarse location may be attempted. In various examples described below, the following location capabilities can be available for supporting network-initiated location requests: single-shot location (granular location with automatic fallback to coarse location, or coarse location); and triggered location, including (i) geographic notification (or "geofencing"); (ii) scheduled notification (granular location with automatic fallback to coarse location, or coarse location). Additionally, the subscriber's location privacy can be managed by an API GW-resident

11

Privacy Engine (PE), which can validate all location requests from third-party applications against the subscriber's privacy profile.

An example of the call flow for coarse location request scenario **300** is shown in FIG. 3, with reference to network elements of network **200** shown and described for FIG. 2. The scenario shown is for when the mobile station **202** in question is within network and idle. Upon receipt of a request for location from a third-party application, the API GW **208** sends a Standard Location Immediate Request (SLIR) command to the LGW **210**, as shown at step **301**. The MLP message posted to the LGW, and as referenced elsewhere herein, can be written in suitable HTTP script. The SLIR message identifies the third-party application. The LGW/MPC **210/212** pair stores the third-party application ID. LGW/MPC **210/212** determines that cached location information for this mobile does not meet the criteria specified in the request in step **301**, and sends an SMSREQ message to the home location registry (HLR) **232** associated with the identified mobile, as shown at step **302**.

A SMSREQ or an LPREQ message can be used for SMSC-to-HLR queries for short messaging applications. In the scenario depicted in FIG. 3, the MPC **212** uses the SMSREQ message to query the HLR **232** for the MSC **234** that is currently serving the targeted mobile station **202**.

The HLR **232** can respond with a smsreq message, as shown at step **303**, providing the SS7 network address of the MSC **234** serving the targeted mobile station **202**.

Following step **303**, the MPC **212** sends an ISPOSREQ to the MSC **234** serving the mobile **202**, as shown at step **304**. Coarse location is not necessarily supported when the target mobile **202** is outside the (e.g., VZW) network. The MPC **212** can make this determination by comparing the SS7 network address of the serving MSC **234** returned by the HLR **232** against provided SS7 network addresses of all MSCs provisioned on the MPC. If the serving MSC address provided by the HLR **232** is not in the MPC records, the MPC **212** can conclude that the handset or mobile station **202** is outside the network, and can return an error code, e.g., 500 "MS Roamed Out" via the LGW **210** to the API GW **208**.

The serving MSC **234** establishes radio contact with the MS **202** (e.g., pages the MS) to obtain the current serving cell information, as shown at step **305**. The serving MSC **234** can then send an isposreq message to the MPC **212** including the serving cell ID and MSC ID information as shown at step **306**.

If the serving MSC **234** is a Wireless SoftSwitch (WSS), it can additionally return POSINFO parameter containing the location (latitude/longitude) of the, e.g., Femto cell (a.k.a. Network Extender) in the isposreq message.

Continuing with the description of the example, the MPC **212** will look up the cell centroid latitude/longitude for the serving cell ID received in isposreq. To facilitate such, the network provider or third parties can prepare and supply Base Station Almanac (BSA) data for provisioning on the MPC **212**. If the isposreq includes the POSINFO parameter, the MPC **212** can use the latitude/longitude information provided in the POSINFO parameter instead. The LGW **210** returns a Standard Location Immediate Answer (SLIA) message to the API GW **208**, as shown at step **307**. The pos_method attribute can be returned in the SLIA message. Communication between the MPC **212** and HLR **232** is indicated at **320** while communication between the MPC and the MSC/VLR **234** is indicated at **321**.

An example of the call flow for granular location request scenario **400** is shown in FIG. 4, with reference to network elements of network **200** shown and described for FIG. 2. Step **401** is the same as step **301** in FIG. 3 with the caveat the

12

requested accuracy in this scenario is 100 m. Steps **402-406** are the same as steps **302-306** in FIG. 3. Steps **402-406** are executed to support fallback to coarse location in the event that granular location (position determination) is unavailable.

Continuing with the description of FIG. 4, at step **407**, the LGW **210** now has the status of the mobile **202** (available) and has the coarse location of the mobile **202**. The LGW **210** will provide the coarse location if granular location cannot be determined for any reason. The LGW **210** sends a mobile-terminated (MT) SMS message to the Location Agent in the mobile handset **202**. If the name of the third-party application is provided in step **401**, the LGW **210** will include it in the MT SMS message to allow the Location Agent to display it on the mobile handset **202**. The Location Agent sends a StartPositionProcessRequest message to the LGW via HTTPS, as described at step **408**.

At step **409**, the LGW **210** checks in the AAA cache (indicated by **226**) for availability of MIN, IP pair in cache. If cache is not available, a request is made to an AAA server (also indicated by **226**) to authenticate client. The response can be cached at the LGW **210** with SPPRequest. As part of this authentication process, the IP, MDN, MIN and carrier ID for the device **202** are extracted from the AAA server. The LGW **210** can consider a request as authorized if the IP, MDN, MIN from AAA server match the IP, MIN, and MDN as part of the SPPRequest, and if the carrier ID returned by the AAA server for the device is of a supported/authorized carrier. If "null" is returned as a carrier ID or if no value is returned for carrier ID by the AAA server, the request is considered as authorized.

At step **410**, the LGW **210** returns an SPPResponse to the handset **202** containing IP address of the PDE. At step **411**, upon receipt of the PDE IP addresses in the SPPResponse message, the Location Agent invokes the native IPOSDET_GetGPSInfo() function. The mobile device or station **202** can be an advanced device, e.g., a Blackberry/RIM, Android, Palm, LiMo, Java, or Linux device. For example, if the mobile station **202** is a BREW device, the BREW OS connects to the PDE **222** (on IS-801 Authenticator port) to begin the IS-801 session. At step **412**, the PDE **222** calls the LGW **210** to do (IP, MIN) authentication (IS-801 Auth Req) to make sure the requester is a valid handset, a corresponding SPPRequest exist and if the device is on an authorized network (if roaming). At step **413**, the LGW **210** validates that an SPPRequest exist corresponding to this request. IS-801 Authentication result (IS-801 Auth Resp) is sent to the PDE asynchronously.

As shown a step **414**, the PDE **222** completes the IS-801 session. After the IS-801 session is completed successfully, the MS **202** has the current location information. At step **415**, the Location Agent (LA) sends the updated location to the LGW **210** in a Position Report message. At step **416**, the LGW **210** updates its local cache with position from position report and sends a response to the Location Agent (LA). This position information can be made available for any future location requests. The call flow **400** ends at step **417**, where the LGW **210** returns a Standard Location Immediate Answer (SLIA) message to the API GW **208**, as shown at step **307**. The pos_method attribute can be returned in the SLIA message for use by the API GW **208** in providing the requested mobile station location to the software **204**. Communication between the MPC **212** and HLR **232** is indicated at **420** while communication between the MPC and the MSC/VLR **234** is indicated at **421**.

An example of the call flow for geographic notification scenario **500** is shown in FIG. 5, with reference to network elements of network **200** shown and described for FIG. 2. At step **501**, the API GW **208** sends a Triggered Location Report-

13

ing Request (TLRR) command to the LGW 210. Steps 502-505 as the same as steps 402-405 of FIG. 4. At step 506, the LGW 210 sends a Triggered Location Reporting Answer (TLRA) message to the API GW 208. At step 507, the geographic notification criteria is indicated as being met on the LA resident on the mobile station 202. Steps 508-513 are the same as steps 411-416 of FIG. 4. These steps are executed by the Location Agent/Handset 202 when the trigger criteria for the requested geographic notification is met. As shown as step 514, the LGW 210 returns a TLREP message to the API GW 208.

An example of the call flow for cancellation of geographic notification scenario 600 is shown in FIG. 6, with reference to network elements of network 200 shown and described for FIG. 2. At step 601, a periodic notification is successfully established using the triggered location reporting call flow in FIG. 5. At step 602, the API GW 208 sends a TLRSR message to the LGW 210. At step 603, the LGW 210 sends a Cancel periodic notification SMS trigger message to Location Agent/MS 202. At step 604, the Location Agent/MS 202 sends a PositionReport message to the LGW 210. The ReportReason parameter is set to PositionReportCancelConfirmation (00000110), and the Status Indicator parameter is set to Success (00000000). At step 605, the LGW 210 does an IP, MIN check to validate that the sender of the PositionReport message is a valid subscriber. At step 606, the LGW 210 sends a PositionReportResponse message to the MS 202. Finally, as indicated at step 607, the LGW returns TRLSA response to the API GW.

The call flow for a scheduled or triggered notification scenario 700 is shown in FIG. 7, with reference to network elements of network 200 shown and described for FIG. 2. As indicated at step 701, the API GW 208 sends a TLRR command to the LGW 210. As indicated at step 702, the LGW 210 sends a TLRA message in response to acknowledge the TLRR command. At step 703, the scheduled notification criteria is indicated as being met on the LGW. Communication between the MPC 212 and HLR 232 is indicated at 720 while communication between the MPC and the MSC/VLR 234 is indicated at 721. Steps 704-718 are the same as steps 502-514 of FIG. 5. At step 719, the PLS 610 returns a TLRP message to the API GW 208, which in turn provide position information of the mobile station 202 to the requesting application.

For purposes of such a discussion, FIG. 8 provides a block diagram illustration of an exemplary wireless device 800, which may be used as mobile station 102 shown in FIG. 1. Although the wireless device 800 may be a smart-phone or may be incorporated into another device, such as a personal digital assistant (PDA) or the like, for discussion purposes, the illustration shows the wireless device 800 in the form of a handset. The handset embodiment of the wireless device 800 functions as a normal digital wireless telephone station. For that function, the station 800 includes a microphone 802 for audio signal input and a speaker 804 for audio signal output. The microphone 802 and speaker 804 connect to voice coding and decoding circuitry (vocoder) 806. For a voice telephone call, for example, the vocoder 806 provides two-way conversion between analog audio signals representing speech or other audio and digital samples at a compressed bit rate compatible with the digital protocol of wireless telephone network communications or voice over packet (Internet Protocol) communications.

For digital wireless communications, the handset 800 also includes at least one digital transceiver (XCVR) 808. The handset 800 can be configured for digital wireless communications using one or more of the common network technology types. For example, the handset 800 may be a dual mode

14

device capable of utilizing either or both of CDMA (IS-95, 1XRTT or EV-DO) technologies and/or 3GPP (LTE/GSM/UMTS) technologies. For that purpose, the transceiver (XCVR) 808 can be a multimode transceiver, or the handset 800 may include two or more transceivers, each of which supports a subset of the various technologies or modes. The concepts discussed here encompass implementations of the station 800 that can utilize any digital transceivers that conform to current or future developed digital wireless communication standards. The mobile station 800 may also be capable of analog operation via a legacy network technology.

The transceiver 808 functions to provide two-way wireless communication of information, such as vocoded speech samples and/or digital message information, in accordance with the technology of the associated network, e.g., network 100 of FIG. 1. The transceiver 808 also sends and receives a variety of signaling messages in support of the various voice and data services provided via the station 800 and the communication network. Each transceiver 808 connects through RF send and receive amplifiers (not separately shown) to an antenna 810. In the example, the transceiver 808 is configured for RF communication in accord with a digital wireless protocol, such as the current CDMA and 3GPP protocols. Of note for purposes of this discussion, the transceiver also supports mobile messaging service message communications to and from the handset 800. In the example, the transceiver supports at least SMS type messaging although it may also support other mobile messaging such as EMS and/or MMS.

The station 800 includes a display 818 for displaying messages, menus or the like, call related information dialed by the user, calling party numbers, etc. A keypad 820 enables dialing digits for voice and/or data calls as well as generating selection inputs, for example, as may be keyed-in by the user based on a displayed menu or as a cursor control and selection of a highlighted item on a displayed screen. The display 818 and keypad 820 are the physical elements providing a textual or graphical user interface. Various combinations of the keypad 820, display 818, microphone 802 and speaker 804 may be used as the physical input output elements of the graphical user interface (GUI), for multimedia (e.g., audio and/or video) communications. Of course other user interface elements may be used, such as a stylus and touch sensitive display screen, as in a PDA or smart phone.

In addition to normal telephone and data communication related input/output (including message input and message display functions), the user interface elements also may be used for display of menus and other information to the user and user input of selections, including any needed during a device location operation. For example, if used as the requesting mobile station 832, the keypad would be used to input the MDN of the target station 831 as well as the requisite code (activation code and password) and then initiate transmission. Then, based on the response from the mobile station 831, the device 800 would display the current location information on display 818.

A microprocessor 812 serves as a programmable controller for the wireless device 800, in that it controls all operations of the wireless device 800 in accord with programming that it executes, for all normal operations, and for operations involved in the device location procedure under consideration here. In the example, the wireless device 800 includes flash type program memory 814, for storage of various "software" or "firmware" program routines and mobile configuration settings, such as mobile directory number (MDN) and/or mobile identification number (MIN), etc. The wireless device 800 may also include a non-volatile random access memory (RAM) 816 for a working data processing memory. Of

15

course, other storage devices or configurations may be added to or substituted for those in the example. In a present implementation, the flash type program memory **814** stores firmware such as a boot routine, device driver software, an operating system, call processing software and vocoder control software, and any of a wide variety of other applications, such as client browser software and short message service software. The memories **814**, **816** also store various data, such as telephone numbers and server addresses, downloaded data such as multimedia content, and various data input by the user. Programming stored in the flash type program memory **814**, sometimes referred to as "firmware," is loaded into and executed by the microprocessor **812**.

For position determination and associated location based functions, the mobile station **800** can also include a GPS receiver **822**. Under control of the microprocessor **812**, the GPS receiver **822** receives and processes signals from one or more satellites of the GPS constellation, e.g., represented by satellites **250** in FIG. 2. From its processing, the GPS receiver **822** supplies GPS data to the microprocessor **812**, such as pseudorange measurements and associated PN codes for measured satellite signals. Associated computations may be performed in the microprocessor or by a processor or the like included in the GPS receiver.

If the receiver **822** or the combination of the receiver and the microprocessor **812** are configured to provide a fully functional GPS position determination device, the station **800** could process the pseudorange measurements, absolute times of transmission of the GPS signals, and satellite position data to compute at least the station's latitude and longitude and possibly translate that data into location information such as street address. However, because of size/space/cost constraints on the design of the mobile stations, the GPS receiver **822** in the mobile station **800** often will have only reception capability, not the full GPS processing capability to resolve position from signals received from the satellites, e.g., satellites **250** in FIG. 2. Hence, the receiver **822** supplies the GPS measurement and code data to the microprocessor **812**, which in turn formats the data and sends it to a PDE, e.g., PDE **222** of FIG. 2, using the wireless transceiver **808**. As outlined above, the PDE **822** performs the data processing necessary to determine the latitude and longitude of the station **800** and transmits that data where needed, e.g., for use by LGW **210** in FIG. 2 to provide the street address or the like back to the mobile station **100** for inclusion in the location response message sent at S4.

As outlined above, the mobile station **800** includes a processor, and programming stored in the flash memory **814** configures the processor so that the mobile station is capable of performing various desired functions, including in this case the functions involved in the technique for providing location information.

In the example, the executable programming stored in the flash memory **814** includes at least some minimal location determination software **824**. The location determination software **824** in the example can control the checking of the user password; and that programming controls the operation of the GPS receiver **822**, the processing of the GPS measurements and the interactions through the network, e.g. with LGW **210** and PDE **222** of FIG. 2, to determine location essentially as discussed above. The executable programming also includes SMS message communication programming **826**, for recognizing the activation code to start the program **824** and to receive/send the various SMS messages. Hence, the executable programming **824**, **826** configures the microprocessor so

16

that the mobile station **800** is capable of providing the location information, as did the target mobile station **202** in the example of FIG. 2.

The structure and operation of the mobile station **800**, as outlined above, were described to by way of example, only.

As shown by the above discussion, functions relating to the automated locating of a mobile station may be implemented on programmable mobile stations configured for wireless communication via a mobile communication network, operating as an one of the mobile stations as shown by way of example in FIGS. 1-2.

The software functionalities involve programming, including executable code as well as associated stored data, e.g., files used for the code recognition. The programming code is executable by the processor (microprocessor or the like) that functions as the control element of the particular mobile station device. In operation, the code is stored within the memory of the mobile station for loading and execution by the processor. At other times, however, the executable code may be stored at other locations and/or transported for loading into the mobile station. Execution of such code by the processor of the mobile station enables the mobile station to implement the methodology for providing location information, in essentially the manner performed in the examples discussed and illustrated herein.

Hence, aspects of the methods of providing location information outlined above may be embodied in programming. Program aspects of the technology may be thought of as "products" or "articles of manufacture" typically in the form of executable code and/or associated data that is carried on or embodied in a type of machine readable medium. "Storage" type media include any or all of the non-transitory, tangible memory of the computers, processors, mobile stations or the like, or associated modules thereof, such as various semiconductor memories, tape drives, disk drives and the like, which may provide non-transitory storage at any time for the software programming. All or portions of the software may at times be communicated through the Internet or various other telecommunication networks. Such communications, for example, may enable loading of the software from a computer or processor into the mobile station to add or update the functionality to that device. Thus, another type of media that may bear the software elements includes optical, electrical and electromagnetic waves, such as used across physical interfaces between local devices, through wired and optical landline networks and over various air-links. The physical elements that carry such waves, such as wired or wireless links, optical links or the like, also may be considered as media bearing the software. As used herein, "storage" media relates to tangible, non-transitory media for storing programming and/or data, and unless restricted to such "storage" media, terms such as computer or machine "readable medium" refer to any medium that participates in providing instructions to a processor for execution.

Such a machine readable medium may take many forms, including but not limited to, a tangible storage medium, a carrier wave medium or physical transmission medium. Non-volatile storage media include, for example, optical or magnetic disks, such as any of the storage devices in the mobile stations illustrated in the drawings. Volatile storage media include dynamic memory, such as main memory of such a computer platform. Tangible transmission media include coaxial cables; copper wire and fiber optics, including the wires that comprise a bus within a computer system. Carrier-wave transmission media can take the form of electric or electromagnetic signals, or acoustic or light waves such as those generated during radio frequency (RF) and infrared

17

(IR) data communications. Common forms of computer-readable media therefore include for example: a floppy disk, a flexible disk, hard disk, magnetic tape, any other magnetic medium, a CD-ROM, DVD or DVD-ROM, any other optical medium, punch cards paper tape, any other physical storage medium with patterns of holes, a RAM, a ROM, a PROM and EPROM, a Flash-EPROM, any other memory chip or cartridge, a carrier wave transporting data or instructions, cables or links transporting such a carrier wave, or any other medium from which a computer can read programming code and/or data. Many of these forms of computer readable media may be involved in carrying one or more sequences of one or more instructions to a processor for execution.

While the foregoing has described what are considered to be the best mode and/or other examples, it is understood that various modifications may be made therein and that the subject matter disclosed herein may be implemented in various forms and examples, and that the teachings may be applied in numerous applications, only some of which have been described herein. It is intended by the following claims to claim any and all applications, modifications and variations that fall within the true scope of the present teachings.

APPENDIX

Acronym List

The description above has used a large number of acronyms to refer to various services, messages and system components. Although generally known, use of several of these acronyms is not strictly standardized in the art. For the convenience of the reader, the following list correlates terms to acronyms, as used in the detailed description above.

3GPP2:	3rd generation partnership project 2
AAA:	authentication-authorization-accounting
ADS:	application download server
AGPS:	assisted global positioning system
API:	application programming interface
BREW:	binary runtime environment for wireless
BS:	base station
BTS:	base transceiver system
CDMA:	code division multiple access
CD-ROM:	compact disc read-only memory
CLNR:	certified like-new replacement
DNDA:	do not disturb application
DVD:	digital video disc
DVD-ROM:	digital versatile (video) disc read-only memory
EPROM:	erasable programmable read-only memory
EV-DO:	evolution-data optimized
ESN:	electronic serial number
GPM:	group provisioning manager
GPMD:	group provisioning manager device
GPS:	Global Positioning System
GSM:	global system for mobile communications
GW:	gateway
HA:	home agent
HLR:	home location register
IP:	Internet protocol
IR:	infrared
LBS:	location based services
LBSI:	location based services infrastructure
LCD:	liquid crystal display
LDAP:	lightweight directory access protocol
LTE:	long-term evolution
MC:	message center
MDN:	mobile directory number
MIN:	mobile identification number
MPC:	mobile positioning center
MS:	mobile station
MSC:	mobile switching center

18

-continued

MT:	mobile traffic
PC:	personal computer
PDE:	position determining entity
PN:	pseudo-random noise
PROM:	programmable read-only memory\
PSDN:	packet data serving node
PSTN:	public switched telephone network
RAM:	random access memory
RAN:	radio access network
RF:	radio frequency
SCM:	service creation manager
SCMD:	service creation manager device
SIF:	standard interchange format
SMPP:	short message peer-to-peer
SMS:	short messaging service
SS7:	signaling system 7
STP:	signaling transfer points
TCP:	transmission control protocol
TDMA:	time-division multiple access
UMTS:	universal mobile telecommunications system
USB:	universal serial bus
VLR:	visitor location register
WAN:	wide area network
XCVR:	transceiver
ZPD:	zone provisioning device

What is claimed is:

1. A method of providing information as to location of a mobile station connected to a wireless mobile communications network, the method comprising:

receiving a mobile station location request from a software application, the location request including a position accuracy;

upon determining that the software application is authorized to receive position information about the mobile station,

(a) determining the requested position accuracy of the request;

(b) determining the location of the mobile station within a position accuracy made available by the network,

wherein determining the location of the mobile station comprises:

(b1) in response to receiving the mobile station location request, causing a mobile switching center to establish radio contact with the mobile station to obtain serving cell information for the mobile station; and

(b2) determining a coarse location of the mobile station based on the serving cell information for the mobile station obtained using the established radio contact;

(b3) determining whether an accuracy of the coarse location is less than the requested position accuracy; and

(b4) upon determining that the accuracy of the coarse location is less than the requested position accuracy, transmitting a mobile-terminated SMS message to the mobile station to cause the mobile station to obtain a granular location of the mobile station;

(c) producing the information as to location of the mobile station based on the determined location at the lesser of the requested position accuracy and the position accuracy made available by the network, based on the determined location; and

(d) sending a message to the software application through the wireless mobile communication network, the sent message containing the information as to location of the mobile station.

2. The method of claim 1, wherein:

the software application is resident on the mobile station.

19

3. The method of claim 1, further comprising:
notifying the user of the mobile station that the software
application has requested the position of the mobile
station.

4. The method of claim 3, further comprising: 5
providing the user of the mobile station the option of deny-
ing the software application access to the location infor-
mation for the mobile station.

5. The method of claim 1, wherein:
receiving a mobile station location request from a software 10
application comprises an API gateway receiving the
request, wherein the API gateway is connected to a wire-
less data network of the wireless communications net-
work.

6. The method of claim 1, wherein the mobile station 15
implements the step (a) of determining the location of the
mobile station by a technique from the group consisting of:
(I) standalone global positioning satellite (GPS) location
determination;
(II) assisted GPS location determination; and 20
(III) triangulation using a signal from any one or more
receivable base stations.

7. The method of claim 1, wherein the generated informa-
tion as to location of the mobile station sent to the software 25
application includes the latitude and longitude of the location
of the mobile station.

8. The method of claim 7, wherein the latitude and longi-
tude of the location of the mobile station are sent in response
to a determination that the requested position accuracy of the
request is below a specified threshold. 30

9. The method of claim 8, wherein the specified threshold
is 1000 m.

10. The method of claim 5, wherein the generated infor-
mation as to location of the mobile station sent to the software 35
application includes the latitude and longitude of the centroid
of a cell of the wireless mobile communications network in
which the mobile station is located.

11. The method of claim 10, wherein the latitude and
longitude of the location of the centroid are sent in response to
a determination that the requested position accuracy of the 40
request is above a specified threshold.

12. The method of claim 11, wherein the specified thresh-
old is 1000 m.

13. The method of claim 5, further comprising:
translating the request into a mobile location protocol 45
(MLP) command; and
sending the MLP command to a Location gateway (LGW),
wherein the LGW is linked to the wireless data network
of the wireless mobile communications network and
configured to query the wireless data network for and 50
receive information as to the latitude and longitude of
the mobile station.

14. The method of claim 13, wherein the LGW is further
linked to a mobile position center (MPC) that is configured to
query the wireless network for and receive information as to 55
the latitude and longitude of the centroid of a cell of the
wireless mobile communications network in which the
mobile station is located.

20

15. An infrastructure for providing one or more location
based services through a wireless network, the location based
services infrastructure comprising:
an API gateway connected to the wireless network and
configured to provide an interface between the wireless
network and one or more software applications, wherein
the API gateway is configured to receive one or more
requests for the position of a mobile station from the one
or more software applications and provide information
as to the requested position in response;
a location gateway connected to the API gateway and a
wireless data network of the wireless network, and con-
figured to query the wireless data network as to the
granular location of a mobile station and to receive the
granular location when available, wherein the location
gateway is configured to determine whether an accuracy
of the coarse location is less than the requested position
accuracy, and upon determining that the accuracy of the
coarse location is less than the requested position accu-
racy, cause a mobile-terminated SMS message to be
transmitted to the mobile station to cause the mobile
station to obtain a granular location of the mobile sta-
tion; and
a mobile position center connected to the location gateway
and one or more mobile switching centers of the wireless
network, and configured to, in response to the API gate-
way receiving a request for the position of the mobile
station, cause radio contact to be established by the one
or more mobile switching centers with the mobile sta-
tion to obtain serving cell information for the mobile
station and determine a coarse location of the mobile
station based on the serving cell information for the
mobile station.

16. The location based services infrastructure of claim 15,
wherein the mobile position center is further connected to one
or more home location registers that are each connected to
one or more of the mobile switching centers.

17. The location based services infrastructure of claim 15,
wherein the one or more mobile switching centers include
one or more visitor location registers.

18. The location based infrastructure of claim 15, wherein
each request includes a requested position accuracy.

19. The location based infrastructure of claim 18, wherein
the API gateway is configured to provide a requesting soft-
ware application the information as to location of the mobile
station at the lesser of the requested position accuracy and the
position accuracy made available by the network, based on
the determined location of the mobile station.

20. The location based infrastructure of claim 15, wherein
the location gateway is configured to determine the requested
position accuracy of each request as being either for coarse or
granular, based on an accuracy threshold.

21. The location based infrastructure of claim 20, wherein
the accuracy threshold is 1000 m.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 8,391,886 B1
APPLICATION NO. : 12/836290
DATED : March 5, 2013
INVENTOR(S) : Atul Thaper

Page 1 of 1

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

In the Specification:

Column 8, lines 24-26, should read as follows:

--station. Assisted GPS, Advanced Forward Link Trilateration (AFLT)--

Signed and Sealed this
Fourth Day of June, 2013

Teresa Stanek Rea
Acting Director of the United States Patent and Trademark Office
