Shooters – A “Fracking” History

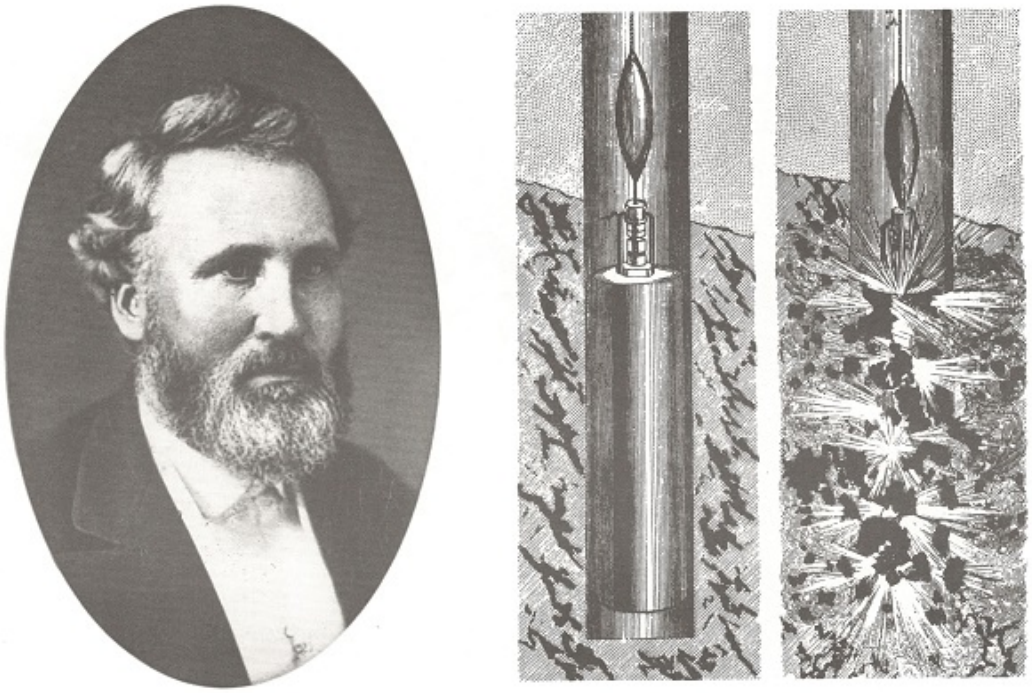

Petroleum Technology

The evolution of technologies for fracturing geologic formations to increase oil and natural gas production.

Since America’s earliest oil discoveries, detonating dynamite or nitroglycerin downhole helped increase a well’s production. The geologic “fracking” technology commonly used in oilfields after the Civil War would be significantly enhanced when hydraulic fracturing arrived in 1949.

Modern hydraulic fracturing — popularly known as petroleum well “fracking” — can trace its roots to April 1865, when Civil War Union veteran Lt. Col. Edward A. L. Roberts received the first of his many patents for an “exploding torpedo.”

In May 1990, Pennsylvania’s Otto Cupler Torpedo Company “shot” its last oil well with liquid nitroglycerin as the company abandoned using nitro while continuing to pursue a fundamental oilfield technology. Company President Rick Tallini credited Col. Roberts’ original patents for leading to the modern fracturing systems.

In 1862, E.A.L. Roberts was appointed Lieutenant Colonel of the Union Army. In December he "conceived the idea of opening the veins and crevices in oil-bearing rock by exploding an elongated shell or torpedo therein." Images courtesy Drake Well Museum, Early Days of Oil, Princeton University Press.

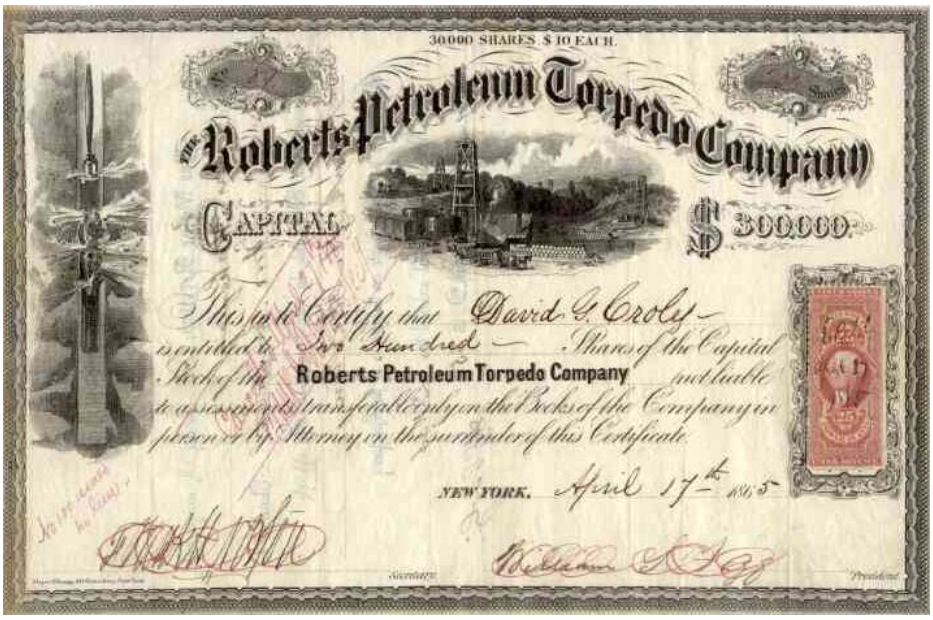

When the Roberts patent expired in 1883, his company was sold to former employee Adam Cupler Jr. (who died in a 1903 nitro explosion). The Cupler Torpedo Company became Otto Cupler Torpedo Company in 1937 after Otto Torpedo Company purchased it.

"Our business since Colonel Roberts' day has concerned lowering high explosives charges into oil wells in the Appalachian area to blast fractures into the oil bearing sand," Tallini said.

Roberts' torpedo company operated in the Allegheny region of Titusville, where the U.S. petroleum industry began in August 1859 with the first American well specifically drilled for oil. His explosive method for fracking wells in Pennsylvania's oil-bearing geologic formations would be adopted as other states made their first oil discoveries.

Civil War Veteran's "Torpedo"

Civil War veteran Col. Edward A.L. Roberts led a New Jersey Regiment at the bloody 1862 Battle of Fredericksburg, Virginia. Amid the chaos of the battle, he saw the results of explosive Confederate artillery rounds plunging into the narrow millrace (canal) that obstructed the battlefield.

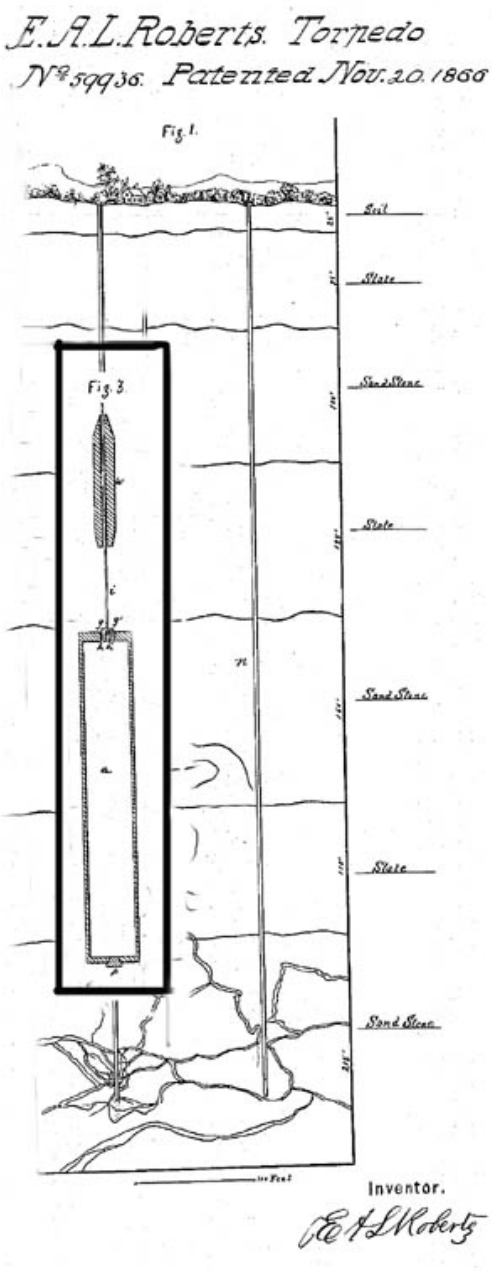

When E.A.L. Roberts founds his company in 1865, his many patents give him a monopoly on torpedoes needed by the oil industry.

Despite heroic actions during the battle, he was cashiered from Union Army in 1863. But the Virginia battlefield observation gave him an idea that would evolve into what he described as “superincumbent fluid tamping.”

Roberts received his first patent for an “Improvement in Exploding Torpedoes in Artesian Wells” on April 25, 1865. His oilfield invention of fracturing to improve a well would vastly improve oil production from America’s young petroleum industry. Many more of the technology patents would follow.

The Roberts torpedo system eclipsed earlier oilfield methods, including black powder or dropping sticks of dynamite down a well, which often collapsed boreholes and ruined production.

The same month Roberts was awarded his first exploding torpedo patent, an actor with a failed Pennsylvania oil well assassinated President Lincoln. In June 1864, John Wilkes Booth left Pennsylvania’s oilfields after a botched fracturing attempt at an oil well drilled by his Dramatic Oil Company.

Early “torpedoes” were set off by a weight dropped along a suspension wire.

Roberts received another U.S. Patent (No. 59,936) in November 1866. This improved device would become widely known as the “Roberts Torpedo.” The advanced petroleum production technology used a column of water on top of an explosive device downhole to more effectively breakup rock formations at the oil-producing depths of wells.

Shooting Oil Wells

The Titusville Morning Herald newspaper reported: *Our attention has been called to a series of experiments that have been made in the wells of various localities by Col. Roberts, with his newly patented torpedo. The results have in many cases been astonishing.*

The torpedo, which is an iron case, containing an amount of powder varying from fifteen to twenty pounds, is lowered into the well, down to the spot, as near as can be ascertained, where it is necessary to explode it. It is then exploded by means of a cap on the torpedo, connected with the top of the shell by a wire.

Filling the borehole with water provided Roberts his "fluid tamping" to concentrate concussion and more efficiently fracture surrounding oil strata.

Support the American Oil & Gas Historical Society

The downhole technique had an immediate impact — production from some wells increased 1,200 percent within a week of being shot – and the Roberts Petroleum Torpedo Company flourished.

Roberts charged $100 to $200 per torpedo and a royalty of one-fifteenth of the increased flow of oil. Attempting to avoid Roberts' fees, some oilmen hired unlicensed practitioners who operated by "moonlight" with their own devices. The inventor was outraged.

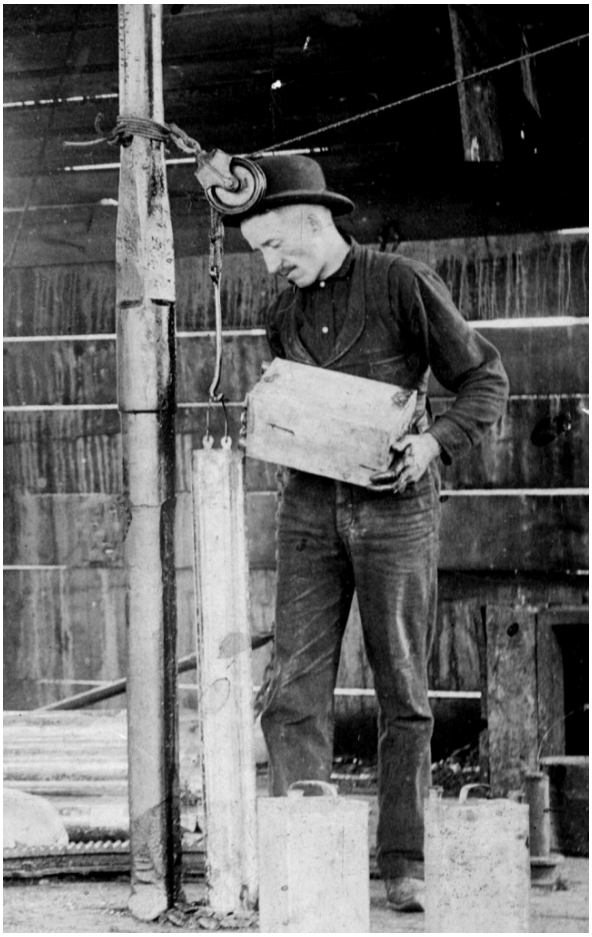

Roberts hired Pinkerton detectives and lawyers to protect his patent — and is said to have been responsible for more civil litigation in defense of a patent than anyone in U. S. history. He spent more than $250,000 to stop the unlawful "torpedoists" or "moonlighters."

Pouring nitro into a canister to prepare a "shooting" of a well drilled using a cable-tool rig powered with a nearby steam boiler.

Applied legally or illegally, by 1868 nitroglycerin was preferred to black powder, despite its frequently fatal tendency to detonate accidentally.

“A flame or a spark would not explode Nitro-Glycerin readily, but the chap who struck it a hard rap might as well avoid trouble among his heirs by having had his will written and a cigar-box ordered to hold such fragments as his weeping relatives could pick from the surrounding district,” noted John J. McLauren in 1896 in his book *Sketches in Crude Oil — Some Accidents and Incidents of the Petroleum Development in all parts of the Globe*.

Pouring nitroglycerin was risky enough in late 19th century oilfields. Doing it for an illegal well “shooting” led to the term “moonlighting.”

Roberts died a wealthy man on March 25, 1881, in Titusville. His heirs sold Roberts Petroleum Torpedo Company to its employees, who continued in business as the Independent Explosives Company. By then, the Civil War Union veteran’s revolutionary “fracking” technology was being applied by the petroleum industry worldwide.

Otto Cupler Torpedo Company

Rick Tallini’s historic Otto Cupler Torpedo Company at one time produced its own nitroglycerin in plants near Titusville — until the last of the company’s plants exploded in

1978. They continued using liquid nitroglycerin for more than a decade. Then the company's final nitroglycerine supplier's plant exploded in Moosic, Pennsylvania, in 1990.

A century earlier, farther east of the oilfields at Oil City and Titusville (and the notorious boom town of Pithole), the giant Bradford oilfield had its own nitroglycerine manufacturers and fracturing service companies. A notable well fracking operation was run by an astute business woman (see Mrs. Alford's Nitro Factory).

At the Drake Well Museum, this 1948 Dodge Power Wagon once hauled hundreds of pounds of liquid nitroglycerin in ten-quart copper cans. The Department of Transportation in 1990 ended the era of hauling liquid nitroglycerin over U.S. roadways. Photo by Bruce Wells.

Tallini's final well shooting on May 5, 1990, used up the last of his company's liquid nitro reserves on nitroglycerine. His company would continue shooting wells, but with safer modern explosives and procedures.

The Otto Cupler Company would established a small museum in East Titusville to preserve documents from its earliest "fracking" of wells. The company's 1948 Dodge truck in 2008 was put on display at the Drake Well Museum and Park in Titusville. Thanks to Rick Tallini, the museum's park hosts realistic-looking "Nitro Shows" for visitors and school groups.

At the end of the 19th century in Indian Territory, a crowd gathered in Bartlesville to watch a real nitro fracturing of a discovery well. The driller's young stepdaughter, a Delaware Indian, dropped a "go devil" — the weighted detonating device — down the wire line in well bore to set off the canister of nitroglycerin.

The downhole explosion of April 15, 1897, caused the Nellie Johnstone No.1 well to erupt a geyser of "black gold" that impressed onlookers and launched the Oklahoma petroleum

industry (see First Oklahoma Oil Well).

Support the American Oil & Gas Historical Society

Related to petroleum formation fracturing, development of well perforation was another important downhole oilfield technology.

In 1939, Ira McCullough of Los Angeles received a U.S. patent for his design of a multiple bullet-shot casing perforator, "in which projectiles or perforating elements are shot through the casing and into the formation."

The innovation of firing at several levels through a borehole's casing enhanced the flow of oil from geologic formations. Learn more in Downhole Bazooka.

Hydraulic "Fracking"

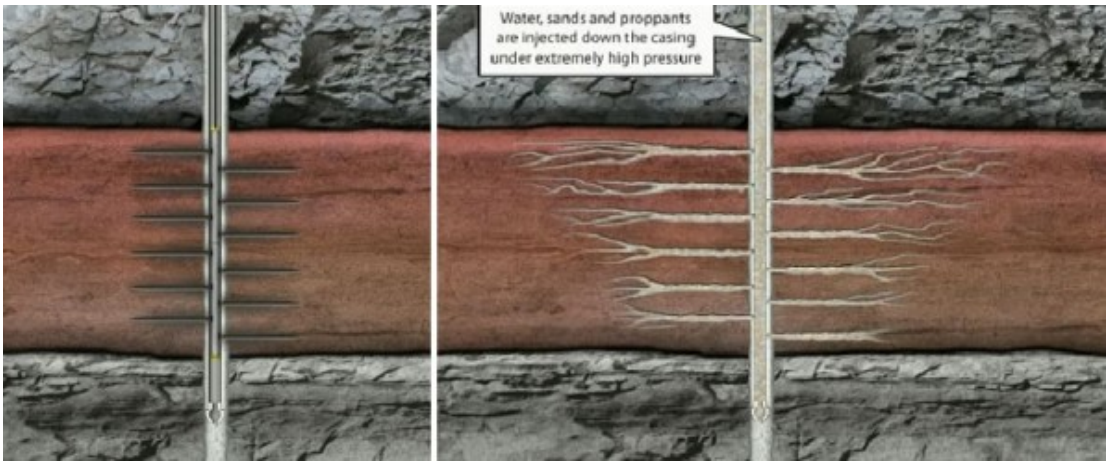

On March 17, 1949, a team of petroleum production experts converges on an oil well about 12 miles east of Duncan, Oklahoma — to perform the first commercial application of hydraulic fracturing. Later that day, Halliburton and Stanolind company personnel successfully fractured another oil well near Holliday, Texas.

The first commercial hydraulic fracturing of an oil well took place in 1949 about 12 miles east of Duncan, Oklahoma.

A fracking well experiment two years earlier in Hugoton, Kansas — home of a massive natural gas field — had proven the possibility of hydraulic fracturing for increased gas well productivity. Erle Halliburton (1892-1957) had patented an improved method for cementing oil wells in 1921, two years after founding his well service company in Ardmore, Oklahoma.

By 1988, the technology will have been applied nearly one million times. The technique had been developed and patented by Stanolind (later known as Pan American Oil Company) and an exclusive license issued to Halliburton to perform the process. In 1953, the license was extended to all qualified service companies.

To complete a new well, explosive charges are lowered by a wire line to perforate the steel casing, cement and producing formation. After the charges are electronically fired, hydraulic fracturing greatly enhances oil and natural gas production.

According to a spokesman from Pinnacle, a Halliburton service company:

Since that fateful day in 1949, hydraulic fracturing has done more to increase recoverable reserves than any other technique, and Halliburton has led the industry in developing and applying fracturing technology.

The company representative also noted, "In the more than 60 years following those first treatments, more than two million fracturing treatments have been pumped with no documented case of any treatment polluting an aquifer — not one."

An Erle Halliburton statue was dedicated in 1993 in Duncan, Oklahoma.

Issues concerning water withdrawals for hydraulic fracturing in areas of low availability, spills during the handling of fracturing fluids, and injection of the fluids with inadequate mechanical integrity were among issues raised by the Environmental Protection Agency in its 2016 report, Hydraulic Fracturing For Oil And Gas.

Shale Fracturing Technology

In the 1980s, a sudden technological advance in fracturing shale formations led to the U.S. vastly increasing its oil and especially natural gas production that continues to this day.

Although credit should be shared with others, America's first "shale boom" began with the innovative thinking from independent producers, especially from Galveston, Texas, George P. Mitchell, (1919 – 2013). Shale fracturing advancements began with steering a well horizontally into producing geological formations.

In the 1980s, Mitchell Energy & Development began experimenting with hydraulic fracturing in horizontal wells in the Barnett Shale near Fort Worth. The company was among the few that began finding ways to extract large amounts of natural gas from shale formations.

More innovations would follow as geologists recognized the potential of natural gas rich shales in Arkansas and Pennsylvania — and oil shale North Dakota (learn more in First North Dakota Oil well).

America's modern shale boom began in the 1980s when independent producers like George Mitchell experimented with ways to produce natural gas from the Barnett shale in Texas. May 2011 map courtesy Energy Information Administration.

In the historic Williston Basin of North Dakota, producing oil since 1951, billions of barrels of new production came from the Bakken shale. Read more in First North Dakota Oil Well.

Earthquakes

The largest earthquake in Oklahoma known to be induced by hydraulic fracturing came in 2019, according to the United States Geological Survey, adding that the majority of the state's earthquakes since 2009 have resulted from injected wastewater, not fracturing fluids.

"Wastewater disposal is a separate process in which fluid waste from oil and gas production is injected deep underground far below ground water or drinking water aquifers," USGS explained. "In Oklahoma over 90 percent of the wastewater that is injected is a byproduct of oil extraction process and not waste frack fluid."

Support the American Oil & Gas Historical Society

In the Permian Basin of West Texas, a major U.S. location of production from shale fields, the Texas Railroad Commission (RRC) in September 2021 reported six earthquakes since February 2020 registered at least a 3.5 magnitude on the Richter scale. The RRC identified the disposal of the large amounts of water used to break apart rock formations as a likely contributor to seismic activity.

The commission, "asked drillers to cut back on the amount of wastewater they're pumping underground," according to *World Oil*. "It's a fairly unusual move by the regulator, which hasn't been as active as its counterpart in Oklahoma in trying to prevent earthquakes linked to fracking."

Industry Perspective

Petroleum industry trade groups have established websites to educate a skeptical public about geologic fracturing technologies — "fracking" wells. According to one, "There is no shortage of questions about domestic energy production — what technologies are used? What does it mean for our environment? How does it create jobs? What is hydraulic fracturing, anyway?"

Hydraulic fracturing has been used to increase production on millions of oil and natural gas wells since 1949.

Energy in Depth — offers links to the industry's research and has long maintained: "While the first commercial fracturing job was conducted in the 1940s, the technique has been applied to the vast majority of U.S. oil and natural gas wells to enhance well performance, minimize drilling, and recover otherwise inaccessible resources."

The website, a project of the Independent Petroleum Association of America (IPAA), reports that about 90 percent of operating U.S/ wells have been fractured — "and the process continues to be applied to boost production in unconventional formations — such as tight gas sands and shale deposits."

For another perspective about down-hole explosives to increase production, see Project Gasbuggy tests Nuclear "Fracking."

Col. Roberts at Battle of Fredericksburg

Some Civil War historians might know of Col. Edward A. L. Roberts leading one of the many ill-fated Union charges up Marye's Heights. Below are American Oil & Gas Historical Society research documenting little-known details from his service records at the National Archives, Washington, D.C.

Oil well "shooting" or "fracking" torpedo inventor Col. Edward A.L. Roberts (1829-1881) was buried in Woodlawn Cemetery at Titusville, Pennsylvania. A simple headstone includes only by his name and the military rank he held at the Battle of Fredericksburg 19 years earlier.

"We went into action under a most galling and deadly fire of shot and shell," reported Col. Edward Roberts. An 1888 lithograph depicts the Army of the Potomac crossing the Rappahannock at the Battle of Fredericksburg in December 1862. Image courtesy Library of Congess.

For four months during the Civil War, the man who would someday revolutionize oil and natural gas production technology served as Lt. Colonel with the 28th New Jersey Volunteer Infantry Regiment. He fought at Fredericksburg in December 1862 – while awaiting results from his court martial, which had convened just weeks earlier.

As the military court deliberated specifications of "intoxication on dress parade," Roberts' regiment marched into the bloody fields and town Fredericksburg, Virginia. On December 13, the 28th New Jersey was the center of Gen. Ambrose Burnside's first doomed assault on the fiercely defended Marye's Heights. Fourteen more failed assaults would follow.

Col. Edward A. L. Roberts is buried in Titusville, Pennsylvania — where the U.S. oil industry began in 1859.

The 28th charged into carefully positioned cannons. Confederate Col. Edward Porter Alexander had declared: “A chicken could not live on that field when we open on it.”

Alexander was right. No Union soldiers would reach Marye’s Heights that cold December day. Crossing a canal and open ground, brigade after brigade could not dislodge the Confederates from their defenses behind a sunken road and stone wall. Union casualties exceeded 12,000.

When his commander was shot in the face during the 28th’s charge, Roberts assumed command. In his after action report, Roberts wrote, “We went into action under a most galling and deadly fire of shot and shell, and continued in action until near dark. Officers and men conducted themselves well.”

A month later, Roberts’ court martial verdict was published under General Order No. 2. Despite his heroic actions during the battle, among the Civil War’s bloodiest, he was found guilty and ordered to be cashiered, effective January 12, 1863. Prior to the court’s verdict,

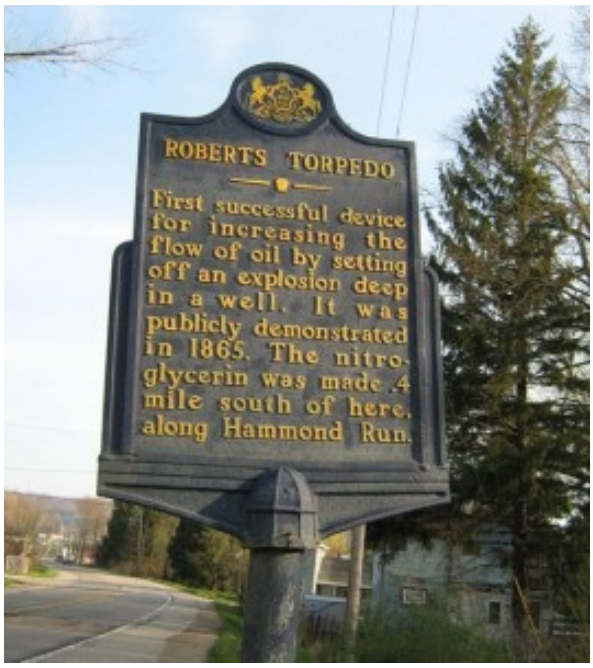

Roberts had attempted to resign, but a superior officer characterized this as “tendering resignation in face of enemy.”

Support the American Oil & Gas Historical Society

Roberts’ service as a Union officer ended in 1863. He soon would be transforming the Pennsylvania oilfields — and the young U.S. petroleum industry.

Moonlighters shoot Wells

Andrew Dalrymple secretly shot his last well on February 5, 1873, when he and his wife were killed in a nitroglycerin explosion at Dennis Run, Pennsylvania. He allegedly had been “moonlighting” — illegal oil well shooting — in the Tidioute oilfield.

A Pennsylvania historical marker notes the 1865 demonstration of the invention Union Col. E.A.L. Roberts.

Nitroglycerine was a powerful but dangerous means of fracturing oil-producing rock formations. The technology had been patented, its use rigorously protected. Pouring nitroglycerin was risky enough in the late 19th century. Doing it illegally at night made it more so.

“The Dalrymple torpedo accident at Tidioute brings to light the fact that nitroglycerine, or other dangerous explosives, are used, stored and manipulated secretly in places little suspected by the general public,” reported the Titusville Morning Herald.

"A large amount of this dangerous material has lately been stolen from the various magazines throughout the country, " the newspaper added. "This species of theft is winked at by some parties, who are opposed to the Roberts torpedo patent."

this article claims fracking does not pollute water sources but here in UK and jus
immense opposition to it by claiming awful pollution.
So waht is the truth about pollution by fracking?
