(57) **ABSTRACT**

A pluggable optical connector with a lock and release mechanism having a slider. The slider includes a handle, two spaced apart longitudinal arms extending from the handle and along two opposite sidewalls of a housing of the connector, two wedges formed at two free ends of the two arms respectively for forcing two deflectable locking tabs formed on a cage outwards when the connector is plugged into the cage and locked therein, and a bridge extending between the two arms. A single transverse leaf spring is positioned between the bridge and a transverse vertical wall extending inwardly from the housing of the connector. The leaf spring exerts spring force in a longitudinal direction, and locking of the connector is released with a reverse movement of the connector countering the spring force.

PLUGGABLE OPTICAL CONNECTOR, LOCK AND RELEASE MECHANISM THEREFOR

FIELD OF THE TECHNOLOGY

The present application relates to a pluggable optical connector, and a lock and release mechanism for a pluggable optical connector.

BACKGROUND

Electronic systems and communications have increased their applications in the recent years. There is also an increase in data transfer to improve the performance and the complexities in processing communication data. Optical connectors are used to transfer data signals for long or short distances between electronic peripherals or even more circuit connections. Higher data transfer rate is in demand for high speed optical signals to replace electrical connection to achieve the needed data transfer rate.

The mechanical integrity of assembly of this kind of electronic device is important as optical fiber is used for data transfer and higher data rate is required.

The above description of the background is provided to aid in understanding the pluggable optical connector, but is not admitted to describe or constitute pertinent prior art to the pluggable optical connector, or consider the cited documents as material to the patentability of the claims of the present application.

SUMMARY

According to one aspect, there is provided a pluggable optical connector including (a) a two-part housing having a top housing part and a bottom housing part; (b) a slider having a handle, two spaced apart longitudinal arms extending from the handle and along two opposite sidewalls of the housing respectively, two wedges formed at two free ends of the two arms respectively for forcing two deflectable locking tabs formed on a cage outwards when the connector is plugged into the cage and locked therein, and a bridge connected to and extending between the two arms; and (c) a single transverse leaf spring positioned between the bridge and a transverse vertical wall extending inwardly from the top housing part. The leaf spring may be made of metal and can exert spring force against the bridge and the vertical wall in a longitudinal direction, whereby locking of the connector can be released with a reverse movement of the connector countering the spring force of the leaf spring.

In one embodiment, the leaf spring can be positioned in a space defined by the bridge, the vertical wall, the top housing part from which the vertical wall extends, and a cap provided on the bottom housing part.

In one embodiment, the bridge may include a first wing portion extending inwardly from one arm and a second wing portion extending inwardly from the other arm, and wherein free ends of the two wing portions can be connected to each other at midway of the bridge. The free ends of the two wing portions can be in the form of two interlocking tabs. A cutout may be formed at a middle portion of the bridge to receive therein a middle convex portion of the leaf spring to thereby prevent transverse movement thereof.

In one embodiment, the leaf spring can be in the form of a strip having a middle convex portion pressing against the bridge, and two legs extending in opposite directions from the middle convex portion and having two convexly curved end portions pressing against the vertical wall. The leaf spring

2

may further include two extended convexly curved portions extending from the two convexly curved end portions respectively for pressing against the two opposite sidewalls of the housing when the leaf spring is pressed and transversely extends.

In another embodiment, the leaf spring can be in a form of a J-shaped spring member having a transverse elongate portion pressing against the transverse vertical wall, a semi-circular convex portion extending from one end of the elongate portion and pressing against one of the two opposite sidewalls of the housing, and a middle convex portion extending from the semi-circular convex portion and pressing against the bridge at a middle portion thereof.

In one embodiment, a lower edge of the leaf spring may be positioned on a top surface of a cap which is mounted on a receptacle support for supporting two optical receptacle modules, and wherein the two optical receptacle modules can be connected respectively to two optical fibers extending from an optical module mounted on a printed circuit board sub-assembly.

According to another aspect, there is provided a lock and release mechanism for a pluggable optical connector. The lock and release mechanism may include (a) a slider having a handle, two spaced apart longitudinal arms extending from the handle and along two opposite sidewalls of a housing of the connector, two wedges formed at two free ends of the two arms respectively for forcing two deflectable locking tabs formed on a cage outwards when the connector is plugged into the cage and locked therein, and a bridge connected to and extending between the two arms; and (b) a single transverse leaf spring positioned between the bridge and a transverse vertical wall extending inwardly from the housing of the connector. The leaf spring can exert spring force against the bridge and the vertical wall in a longitudinal direction, whereby locking of the connector can be released with a reverse movement of the connector countering the spring force of the leaf spring. The housing of the connector can be a two-part housing having a top housing part and a bottom housing part.

In one embodiment, the leaf spring can be positioned in a space defined by the bridge, the vertical wall, the top housing part from which the vertical wall extends, and a cap provided on the bottom housing part.

In one embodiment, the bridge may be formed by a first wing portion extending inwardly from one arm and a second wing portion extending inwardly from the other arm, and wherein free ends of the two wing portions can be connected to each other at midway of the bridge. The free ends of the two wing portions can be in the form of two interlocking tabs. A cutout may be formed at a middle portion of the bridge to receive therein a middle convex portion of the leaf spring to thereby prevent transverse movement thereof.

In one embodiment, the leaf spring can be in the form of a strip having a middle convex portion pressing against the bridge, and two legs extending in opposite directions from the middle convex portion and having two convexly curved end portions pressing against the vertical wall. The leaf spring may further include two extended convexly curved portions extending from the two convexly curved end portions respectively for pressing against the two opposite sidewalls of the housing when the leaf spring is pressed and transversely extends.

In another embodiment, the leaf spring can be in the form of a J-shaped spring member having a transverse elongate portion pressing against the transverse vertical wall, a semi-circular convex portion extending from one end of the elongate portion and pressing against one of the two opposite

3

sidewalls of the housing, and a middle convex portion extending from the semi-circular convex portion and pressing against the bridge at a middle portion thereof.

In one embodiment, a lower edge of the leaf spring may be positioned on a top surface of a cap which is mounted on a receptacle support for supporting an optical receptacle module, and wherein the optical receptacle module is connected to an optical fiber extending from an optical module mounted on a printed circuit board sub-assembly.

Although the pluggable optical connector is shown and described with respect to certain embodiments, it is obvious that equivalents and modifications will occur to others skilled in the art upon the reading and understanding of the specification. The pluggable optical connector in the present application includes all such equivalents and modifications, and is limited only by the scope of the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Specific embodiments of the pluggable optical connector will now be described by way of example with reference to the accompanying drawings wherein:

FIG. 1 is a perspective view of a pluggable optical connector according to an embodiment thereof.

FIG. 2 is an exploded view of the optical connector shown in FIG. 1.

FIG. 2a is an exploded view of the optical connector shown in FIG. 1, showing another embodiment of a leaf spring.

FIG. 3 is a bottom perspective view of a top housing part with a single transverse leaf spring.

FIG. 3a is a bottom perspective view of a top housing part with the transverse leaf spring shown in FIG. 2a.

FIG. 4 is a perspective view of the transverse leaf spring according to an embodiment thereof.

FIG. 4a is an enlarged perspective view of the leaf spring shown in FIG. 2a.

FIG. 5 is a perspective view of a slider of the optical connector according to an embodiment thereof.

FIG. 6 is a bottom perspective view of the top housing part showing a vertical wall and sidewalls of the top housing part.

FIG. 7 is an enlarged perspective view of the cage according to an embodiment thereof.

FIG. 8 is an exploded view of an optical module assembly according to an embodiment thereof.

FIG. 9 is a perspective view of the optical module assembly shown in FIG. 8.

FIG. 10 is a cross sectional view of the optical connector.

DETAILED DESCRIPTION

Reference will now be made in detail to a preferred embodiment of the pluggable optical connector, examples of which are also provided in the following description. Exemplary embodiments of the pluggable optical connector are described in detail, although it will be apparent to those skilled in the relevant art that some features that are not particularly important to an understanding of the pluggable optical connector may not be shown for the sake of clarity.

Furthermore, it should be understood that the pluggable optical connector is not limited to the precise embodiments described below and that various changes and modifications thereof may be effected by one skilled in the art without departing from the spirit or scope of the protection. For example, elements and/or features of different illustrative embodiments may be combined with each other and/or substituted for each other within the scope of this disclosure and appended claims.

4

In addition, improvements and modifications which may become apparent to persons of ordinary skill in the art after reading this disclosure, the drawings, and the appended claims are deemed within the spirit and scope of the protection.

For illustration purposes, the terms “upper”, “lower”, “vertical”, “horizontal”, “top”, “bottom” appeared hereinafter relate to the invention as it is oriented in the drawings. It is understood that the invention may assume various positions, except where expressly specified to the contrary. Furthermore, it is understood that the specific devices shown in the drawings, and described in the following description, are simply exemplary embodiments of the invention. Hence, specific dimensions and other physical characteristics related to the embodiments disclosed hereinafter are not to be considered as limiting.

It should be noted that throughout the specification and claims herein, when one element is said to be “coupled” or “connected” to another, this does not necessarily mean that one element is fastened, secured, or otherwise attached to another element. Instead, the term “coupled” or “connected” means that one element is either connected directly or indirectly to another element or is in mechanical or electrical communication with another element.

FIG. 1 is a perspective view of a pluggable optical connector with a lock and release mechanism according to an embodiment thereof. The lock and release mechanism of the pluggable optical connector may include a bottom housing part 100, a top housing part 200, a handle 300, and a slider 400. The optical connector can be pluggable into a cage 700. The cage 700 may be permanently mounted on a printed circuit board. The bottom housing part 100 and the top housing part 200 together may form a two-part housing of the optical connector. Optical cables 800 can be attached to the optical connector. The slider 400 and the handle 300 may be attached to each other as over molded parts.

The slider 400 and the handle 300 can only travel longitudinally forwards in a plug-in direction or backwards within guiding slots formed at opposite sides of the optical connector, as it is pulled by a user or it is pushed by the leaf spring 500 inside the optical connector.

Although it is shown and described that the pluggable connector is pluggable optical connector, it is understood that the pluggable connector can be any pluggable electronic connectors with the lock and release mechanism disclosed herein.

FIG. 2 is an exploded view of the optical connector shown in FIG. 1. The optical connector includes a single transverse leaf spring 500 which may be positioned on a support or cap 600. An optical module 670 may be mounted on a printed circuit board (PCB) sub-assembly 640. The PCB sub-assembly 640 can be mounted on the bottom housing part 100. As used herein, the term “leaf spring” means a spring member made of a flat piece of metal.

FIG. 3 is a bottom perspective view of the top housing part 200 with the single transverse leaf spring 500 provided thereon. The single transverse leaf spring 500 can be positioned transversely between the bridge 406 and a transverse vertical wall 201 extending inwardly from the top housing part 200 and facing the bridge 406.

The leaf spring 500 can exert spring force against the bridge 406 and the vertical wall 201 in a longitudinal direction. The locking of the optical connector can be released with a reverse movement of the optical connector countering the spring force of the leaf spring 500.

FIG. 4 is a perspective view of the transverse leaf spring 500 according to an embodiment thereof. The leaf spring 500

5

may be in the form of a strip having a middle convex portion **502** pressing against the bridge **406**, and two legs **503** extending in opposite directions from the middle convex portion **502** and having two convexly curved end portions **501** pressing against the vertical wall **201** of the top housing part **200**. The leaf spring **500** may be made of metal or any other suitable material.

The leaf spring **500** may further include two extended convexly curved portions **504** extending from the two convexly curved end portions **501** respectively for pressing against two opposite sidewalls **202** of the top housing part **200** when the leaf spring **500** is pressed and transversely extends.

The two extended convexly curved portions **504** can be used to further increase the spring force of the leaf spring **500**. When a user pulls the handle **300** further backwards opposite to the plug-in direction, the legs **503** of the leaf spring **500** spread or flatten and extend transversely until the two extended convexly curved portions **504** are in contact with the sidewalls **202** of the top housing part **200**. The two extended convexly curved portions **504** compress and perform its spring action, and then release or expand after release of the handle **300**.

Although one embodiment of the leaf spring **500** has been shown and described, it is understood by one skilled in the art that the leaf spring **500** can be in any other possible shape and configuration so long as it can perform the functions described herein. Another embodiment of the leaf spring **500** is shown in FIGS. **2a**, **3a** and **4a**.

FIG. **2a** is an exploded view of the optical connector of FIG. **1**, showing a second embodiment of the leaf spring. A single generally J-shaped transverse leaf spring **900** may be positioned on the support or cap **600**. Similarly, the optical module **670** may be mounted on the printed circuit board (PCB) sub-assembly **640**. The PCB sub-assembly **640** can be mounted on the bottom housing part **100**.

FIG. **3a** is a bottom perspective view of the top housing part **200** with the single transverse leaf spring **900** provided thereon. The single transverse leaf spring **900** can be positioned between the bridge **406** and the transverse vertical wall **201** extending inwardly from the top housing part **200** and facing the bridge **406**.

The leaf spring **900** can exert spring force against the bridge **406** and the vertical wall **201** in a longitudinal direction. The locking of the optical connector can be released with a reverse movement of the optical connector countering the spring force of the leaf spring **900**.

FIG. **4a** is a perspective view of the leaf spring **900**. The leaf spring **900** may be in the form of a J-shaped spring member having a transverse elongate portion **901** pressing against the transverse vertical wall **201**, a semi-circular convex portion **902** extending from one end of the elongate portion **901** and pressing against one of the two opposite sidewalls **202** of the housing, and a middle convex portion **904** extending from the semi-circular convex portion **902** and pressing against the bridge **406** at a middle portion thereof. A concave portion **903** may be formed between the semi-circular convex portion **902** and the middle convex portion **904**. The semi-circular convex portion **902** can generate a spring action, and then release or expand after release of the handle **300**.

The J-shaped spring member **900** can be assembled in either direction as long as the transverse elongate portion **902** with a longer length is in contact with the transverse vertical wall **201** of the housing. In other words, when assembled, the semi-circular convex portion **902** can be pressing against one of the two opposite sidewalls **202** of the housing and facing one direction, or the semi-circular convex portion **902** can be

6

pressing against the other one of the two opposite sidewalls **202** of the housing and facing the other direction.

FIG. **5** is a perspective view of the slider **400** of the optical connector according to an embodiment thereof. The handle **300** can be connected to an outer end of the slider **400**. The slider **400** may include two spaced part longitudinal arms **405** extending from the handle **300** and along two opposite sidewalls **202** of the top housing part **200**.

Two wedges **403** may be formed at two free ends of the two arms **405** respectively for forcing two deflectable tabs **701** (FIG. **7**) formed on the cage **700** outwards when the optical connector is plugged into the cage **700** and then locked therein. A bridge **406** may be connected to and extending between the two arms **405**. The slider **400** may be made of metal or any other suitable material.

The bridge **406** may be formed by a first wing portion **402** extending inwardly from one arm **405** and a second wing portion **408** extending inwardly from the other arm **405**. The ends of the two wing portions **402**, **408** can interlock each other at midway of the bridge **406**.

In the illustrated embodiment, the free ends of the two wing portions **402**, **408** may include two tabs **404** interlocking with each other to make the bridge **406** stronger.

A cutout **401** may be formed at a middle portion of the bridge **406** to receive therein the middle convex portion **502** of the leaf spring **500** to thereby prevent transverse movement thereof, as illustrated in FIG. **3**.

FIG. **6** is a bottom perspective view of the top housing part **200** showing the vertical wall **201**, the sidewall **202** and an inner surface **203** of the top housing part **200** with the slider **400** and the leaf spring **500** being removed therefrom.

FIG. **7** is an enlarged perspective view of the cage **700** according to an embodiment thereof. The two deflectable tabs **701** can be formed on two opposite sidewalls of the cage **700** respectively.

FIG. **8** is an exploded view of an optical module assembly according to an embodiment thereof, and FIG. **9** is a perspective view of the optical module assembly shown in FIG. **8**. The cap **600** may be mounted on a receptacle support **641** to form an enclosure for supporting an optical receptacle module **671** therein. The optical receptacle module **671** can be connected to an optical fiber **672** extending from an optical module **670**, such as Transmitter and Receiver devices, mounted on a printed circuit board (PCB) sub-assembly **640**. This assembling arrangement can prevent any assembly issue such as broken optical parts that may affect the overall performance of the optical connector.

In the illustrated embodiment, the cap **600** is snap-fitted on a receptacle support **641** for supporting two optical receptacle modules **671**. The two optical receptacle modules **671** are connected respectively to two optical fibers **672** extending from the optical module **670**.

FIG. **10** is a cross sectional view of the pluggable optical connector. The top and bottom housing parts **200**, **100** can be tightly connected by two screws or any other suitable fastening means after all the components of the optical connector are assembled together. It can be seen that the leaf spring **500** can be positioned in a space defined by the bridge **406**, the vertical wall **201**, the top housing part **200** from which the vertical wall **201** extends, and the cap **600** provided on the bottom housing part **100**.

It is appreciated that the leaf spring **500** may have tendency to move vertically up or down during release action. However, its vertical movement can be prevented by the inner surface **203** of the top housing part **200** and the top surface of the cap **600**. These surfaces can limit vertical movement of the leaf spring **500** and help to maintain constant and reliable spring

force during release action. The cap **600** is also useful to prevent the leaf spring **500** from coming out from its desired position.

The space inside the existing pluggable connector with two compression springs is not enough when more electronic components are added to achieve the required functions. The single leaf spring **500** can replace the traditional two compression springs and can maintain the function of the release mechanism of the connector.

The use of the single leaf spring **500** can reduce one part assembly in the process of assembling the connector. The assembling of a single leaf spring is quicker and easier than assembling the traditional two compression springs. Furthermore, the single leaf spring **500** requires a shorter vertical space than two compression springs. The single leaf spring **500** is smaller in size than that of two compression springs, and yet it can perform the same function as two compression springs. The spring force at each side of the single leaf spring **500** is more balance than the spring force of two separate compression springs.

While the pluggable optical connector has been shown and described with particular references to a number of preferred embodiments thereof, it should be noted that various other changes or modifications may be made without departing from the scope of the appended claims.

What is claimed is:

1. A pluggable optical connector comprising:

a two-part housing having a top housing part and a bottom housing part;

a slider comprising a handle, two spaced apart longitudinal arms extending from the handle and along two opposite sidewalls of the housing respectively, two wedges formed at two free ends of the two arms respectively for forcing two deflectable locking tabs formed on a cage outwards when the connector is plugged into the cage and locked therein, and a bridge connected to and extending between the two arms; and

a single transverse leaf spring positioned between the bridge and a transverse vertical wall extending inwardly from the top housing part;

wherein the leaf spring exerts spring force against the bridge and the vertical wall in a longitudinal direction, and locking of the connector is released with a reverse movement of the connector countering the spring force of the leaf spring; and

the leaf spring is positioned in a space defined by the bridge, the vertical wall, the top housing part from which the vertical wall extends, and a cap provided on the bottom housing part.

2. The pluggable optical connector as claimed in claim 1, wherein the bridge comprises a first wing portion extending inwardly from one arm and a second wing portion extending inwardly from the other arm, and wherein free ends of the two wing portions connected to each other at midway of the bridge.

3. The pluggable optical connector as claimed in claim 2, wherein the free ends of the two wing portions are in the form of two interlocking tabs.

4. The pluggable optical connector as claimed in claim 1, wherein a cutout is formed at a middle portion of the bridge to receive therein a middle convex portion of the leaf spring to thereby prevent transverse movement thereof.

5. The pluggable optical connector as claimed in claim 1, wherein the leaf spring is in the form of a strip comprising a middle convex portion pressing against the bridge, and two

legs extending in opposite directions from the middle convex portion and having two convexly curved end portions pressing against the vertical wall.

6. The pluggable optical connector as claimed in claim 5, further comprising two extended convexly curved portions extending from the two convexly curved end portions respectively for pressing against the two opposite sidewalls of the housing when the leaf spring is pressed and transversely extends.

7. The pluggable optical connector as claimed in claim 1, wherein the leaf spring is in a form of a J-shaped spring member comprising a transverse elongate portion pressing against the transverse vertical wall, a semi-circular convex portion extending from one end of the elongate portion and pressing against one of the two opposite sidewalls of the housing, and a middle convex portion extending from the semi-circular convex portion and pressing against the bridge at a middle portion thereof.

8. The pluggable optical connector as claimed in claim 1, wherein a lower edge of the leaf spring is positioned on a top surface of a cap which is mounted on a receptacle support for supporting two optical receptacle modules, and wherein the two optical receptacle modules are connected respectively to two optical fibers extending from an optical module mounted on a printed circuit board sub-assembly.

9. The pluggable optical connector as claimed in claim 1, wherein the leaf spring is made of metal.

10. A lock and release mechanism for a pluggable optical connector, the lock and release mechanism comprising:

a slider comprising a handle, two spaced apart longitudinal arms extending from the handle and along two opposite sidewalls of a housing of the connector, two wedges formed at two free ends of the two arms respectively for forcing two deflectable locking tabs formed on a cage outwards when the connector is plugged into the cage and locked therein, and a bridge connected to and extending between the two arms; and

a single transverse leaf spring positioned between the bridge and a transverse vertical wall extending inwardly from the housing of the connector;

wherein the leaf spring exerts spring force against the bridge and the vertical wall in a longitudinal direction, and locking of the connector is released with a reverse movement of the connector countering the spring force of the leaf spring;

the housing of the connector is a two-part housing having a top housing part and a bottom housing part; and

the leaf spring is positioned in a space defined by the bridge, the vertical wall, the top housing part from which the vertical wall extends, and a cap provided on the bottom housing part.

11. The lock and release mechanism as claimed in claim 10, wherein the bridge is formed by a first wing portion extending inwardly from one arm and a second wing portion extending inwardly from the other arm, and wherein free ends of the two wing portions connected to each other at midway of the bridge.

12. The lock and release mechanism as claimed in claim 11, wherein the free ends of the two wing portions are in the form of two interlocking tabs.

13. The lock and release mechanism as claimed in claim 10, wherein a cutout is formed at a middle portion of the bridge to receive therein a middle convex portion of the leaf spring to thereby prevent transverse movement thereof.

14. The lock and release mechanism as claimed in claim 10, wherein the leaf spring is in the form of a strip comprising a middle convex portion pressing against the bridge, and two

legs extending in opposite directions from the middle convex portion and having two convexly curved end portions pressing against the vertical wall.

15. The lock and release mechanism as claimed in claim 14, further comprising two extended convexly curved portions extending from the two convexly curved end portions respectively for pressing against the two opposite sidewalls of the housing when the leaf spring is pressed and transversely extends.

16. The lock and release mechanism as claimed in claim 10, wherein the leaf spring is in the form of a J-shaped spring member comprising a transverse elongate portion pressing against the transverse vertical wall, a semi-circular convex portion extending from one end of the elongate portion and pressing against one of the two opposite sidewalls of the housing, and a middle convex portion extending from the semi-circular convex portion and pressing against the bridge at a middle portion thereof.

17. The lock and release mechanism as claimed in claim 10, wherein a lower edge of the leaf spring is positioned on a top surface of a cap which is mounted on a receptacle support for supporting an optical receptacle module, and wherein the optical receptacle module is connected to an optical fiber extending from an optical module mounted on a printed circuit board sub-assembly.
