(57) **ABSTRACT**

Electronic modules having complex contact structures may be formed by encapsulating panels containing pluralities of electronic modules delineated by cut lines and having conductive interconnects buried within the panel along the cut lines. Holes defining contact regions along the electronic module sidewall may be cut into the panel along the cut lines to expose the buried interconnects. The panel may be metallized, e.g. by a series of processes including plating, on selected surfaces including in the holes to form the contacts and other metal structures followed by cutting the panel along the cut lines to singulate the individual electronic models. The contacts may be located in a conductive groove providing a castellated module.

METHOD OF ELECTRICALLY INTERCONNECTING CIRCUIT ASSEMBLIES

FIELD OF THE INVENTION

This invention relates to the field of encapsulating electronic assemblies and more particularly to forming edge connections and other conductive features on and through encapsulated electronic assemblies including encapsulated power converters.

BACKGROUND

Contemporary electronic power systems require power converters capable of deployment at the point of load. Competing considerations require increasing power density, decreasing mounting area on customer motherboard, and lower cost.

An encapsulated electronic module, such as an electronic power converter module for example, may comprise a printed circuit assembly over-molded with an encapsulant to form some or all of the package and exterior structure or surfaces of the module. Encapsulation in this manner may aid in conducting heat out of the over-molded components, i.e., components that are mounted on the printed circuit assembly and covered with encapsulant. In the case of an electronic power converter module, the printed circuit assembly may include one or more inductive components, such as inductors and transformers. Encapsulated electronic power converters capable of being surface mount soldered to a customer motherboard are described in Vinciarelli et al., *Power Converter Package and Thermal Management*, U.S. Pat. No. 7,361,844, issued Apr. 22, 2008, (the "SAC Package Patent") (assigned to VLT, Inc. of Sunnyvale, Calif., the entire disclosure of which is incorporated herein by reference). Encapsulated electronic modules having at least one surface of a magnetic core structure exposed and methods for manufacturing the same are described in Vinciarelli et al., *Encapsulation Method and Apparatus for Electronic Modules*, U.S. Pat. No. 8,427,269 issued Apr. 23, 2013, (the "Exposed Core Patent") (assigned to VI Chip Inc. of Andover, Mass., the entire disclosure of which is incorporated herein by reference).

Methods of over-molding both sides of a printed circuit board assembly while leaving opposing regions on both sides of the printed circuit board free of encapsulant are described in Saxelby, et al., *Circuit Encapsulation Process*, U.S. Pat. No. 5,728,600, issued Mar. 17, 1998 and Saxelby, et al., *Circuit Encapsulation*, U.S. Pat. No. 6,403,009, issued Jun. 11, 2002 (collectively the "Molding Patents") (both assigned to VLT, Inc. of Sunnyvale, Calif. and incorporated by reference in their entirety).

Leads for connecting the encapsulated power converter substrate to the customer motherboard are described in Vinciarelli et al., *Surface Mounting A Power Converter*, U.S. Pat. No. 6,940,013, issued Sep. 6, 2005 (the "J-Lead Patent") (assigned to VLT, Inc. of Sunnyvale, Calif., the entire disclosure of which is incorporated herein by reference).

Encapsulation of electronic assemblies as panels and forming electrical contacts, e.g. bar codes, along vertical edges of portions of the panels, e.g. during singulation into modules, for establishing electrical connections to the circuitry inside each module are described in Vinciarelli et al., *Panel-Molded Electronic Assemblies*, U.S. Pat. No. 8,966,747, issued on Mar. 3, 2015 (the "Bar Code Patent"); and in Vinciarelli et al., *Panel-Molded Electronic Assemblies*, U.S.

2

patent application Ser. No. 14/116,642, filed on Nov. 8, 2013, which is a national stage application of PCT/US2012/037495, filed on May 11, 2012 (the "PM CIP"), now U.S. Pat. No. 9,402,319, issued on Jul. 26, 2016; and three-dimensional contacts for establishing robust solder connections to the bar codes is described in Vinciarelli et al., *Electronic Assemblies Having Components With Edge Connectors*, U.S. patent application Ser. No. 14/596,914, filed on Jan. 14, 2015 (the "3D Bar Code Application"); collectively "the Panel Mold Disclosures") (all of which are assigned to VLT, Inc. of Sunnyvale, Calif., and are incorporated in their entirety herein by reference).

SUMMARY

In general, in one aspect, a method of electrically interconnecting circuit assemblies is provided. The method includes assembling an encapsulated panel including a substrate having electronic components mounted to the substrate and one or more conductive features enclosed within the panel and unexposed to an exterior surface of the panel, the panel including one or more electronic modules having boundaries defined by one or more predetermined cut lines, and the one or more conductive features having portions that are located along the cut lines. The method includes selectively forming holes in the panel at predetermined locations along the cut lines exposing within selected holes respective portions of the one or more conductive features; selectively forming one or more conductive metal layers on selected surfaces of the panel including within the selected holes, each selected hole having a respective portion of the one or more conductive metal layers within the selected holes being in electrical contact with the respective portions of the one or more conductive features; and cutting the panel through the holes and along the one or more cut lines singulating the one or more electronic modules, each electronic module having electrical contacts formed along a perimeter edge of the module.

Implementations of the method may include one or more of the following features. The method can include preparing one or more surfaces of the encapsulated panel. Preparing one or more surfaces can include lapping the panel before selectively forming the holes. Preparing one or more surfaces can include lapping the panel after selectively forming the holes. Preparing one or more surfaces can include cleaning the panel ultrasonically in an aqueous solution before selectively forming the one or more metal layers. Preparing one or more surfaces can include laser etching the panel before selectively forming the one or more metal layers. Selectively forming one or more conductive metal layers can further include: (a) applying a seed layer including conductive particles to the surfaces of the panel, and subsequently (b) plating a layer of metal onto the seed layer. Applying the seed layer can include sputter coating the encapsulated panel with conductive particles. The sputtering can include sputtering copper particles. The sputtering can further include sputtering chromium particles. The method can further include coating the encapsulated panel with colloidal graphite and curing the graphite before the plating. The method can further include patterning the metal before cutting the panel. The patterning can include masking and subsequently etching the metal layer. The patterning can further include using a laser to expose or remove portions of the mask. The method can further include applying one or more finishing layers on top of the metal layer. Applying the seed layer can include applying conductive epoxy. Applying the seed layer can further include applying the conductive

3

epoxy in a predetermined pattern. The method can further include coating the encapsulated panel with colloidal graphite and curing the graphite before the plating. The method can further include applying one or more finishing layers on top of the metal layer. The method can further include configuring the holes to provide gaps between adjacent contacts, in which the holes establish a pattern in the conductive metal layers along the perimeter edge of the one or more electronic modules. The method can further include patterning the one or more metal layers to form conductive pads on a selected surface of the one or more electronic modules, the pads providing a surface mounting area for one or more components. Patterning the metal layer can further include establishing electrical connections between respective ones of the pads to respective ones of the electrical contacts. The method can further include selectively forming auxiliary holes in the panel at predetermined locations spaced away from the cut lines; and selectively forming one or more conductive metal layers within the auxiliary holes to form thermal conduits for conducting heat from respective interior portions of the one or more electronic modules to an exterior surface. The auxiliary holes can be cut to a controlled depth without exposing within the auxiliary holes any components in the one or more electronic modules. The auxiliary holes can be cut through the entire thickness of the panel without exposing within the auxiliary holes any components in the one or more electronic modules. The cutting the auxiliary holes can expose within selected ones of the auxiliary holes respective portions of one or more auxiliary conductive features. The method can further include selectively forming auxiliary holes in the panel at predetermined locations spaced away from the cut lines exposing within selected ones of the auxiliary holes respective portions of one or more auxiliary conductive features; selectively forming one or more conductive metal layers within the auxiliary holes to form electrical connections to the auxiliary conductive features; and patterning the one or more metal layers to form conductive pads on a selected surface of the one or more electronic modules and electrical connections between selected ones of the pads and the one or more auxiliary conductive features, the pads providing a surface mounting area for one or more components.

In general, in another aspect, an apparatus includes a first circuit assembly having a first modular package including a first circuit board disposed between a top encapsulant and a bottom encapsulant, the first modular package having a perimeter edge connecting a top surface of the top encapsulant and a bottom surface of the bottom encapsulant, the perimeter edge having at least a first electrical contact electrically coupled to one or more conductive features embedded in the first circuit board. The first electrical contact extends along the perimeter edge from the first circuit board toward the top surface of the top encapsulant or toward the bottom surface of the bottom encapsulant such that the first electrical contact occupies a portion of the top or bottom encapsulant along the perimeter edge.

Implementations of the apparatus may include one or more of the following features. The first electrical contact can extend to the top surface of the top encapsulant or to the bottom surface of the bottom encapsulant. The first electrical contact can further include a side contact surface generally parallel to the perimeter edge, and a first contact surface generally parallel to the top surface of the top encapsulant or a second contact surface generally parallel to the bottom surface of the bottom encapsulant. The apparatus can include a second circuit board having a top surface that has a conductive pad, in which the first electrical contact

4

includes the second contact surface, the conductive pad of the second circuit board is electrically coupled to the second contact surface of the first electrical contact of the first circuit assembly, the top surface of the second circuit board faces the bottom surface of the first modular package and is generally parallel to the bottom surface of the first modular package, and the perimeter edge of the first modular package is generally perpendicular relative to the top surface of the circuit board. The first electrical contact can include the first contact surface, and the first circuit assembly can further include an inductive component and the first contact surface can cover a surface of the inductive component. The first contact surface can extend over 50% of the top surface of the top encapsulant. The second contact surface can extend over 50% of the bottom surface of the bottom encapsulant. The first electrical contact can extend to both the top surface of the top encapsulant and the bottom surface of the bottom encapsulant. The first circuit board can include a multilayer circuit board, and the first electrical contact of the first circuit assembly can be electrically coupled to conductive features in multiple layers of the multilayer circuit board. The first circuit assembly can further include a second electrical contact that extends along the perimeter edge from the first circuit board toward the top surface of the top encapsulant or toward the bottom surface of the bottom encapsulant such that the second electrical contact occupies a portion of the top or bottom encapsulant along the perimeter edge, the second electrical contact can be electrically coupled to one or more conductive features embedded in the first circuit board, in which the first electrical contact can include an input contact configured to receive an input signal for the first circuit assembly, and the second electrical contact can include an output contact configured to provide an output signal from the first circuit assembly. The apparatus can further include a second circuit assembly having a second modular package including a second circuit board disposed between a top encapsulant and a bottom encapsulant, the second modular package can have a perimeter edge connecting a top surface of the top encapsulant and a bottom surface of the bottom encapsulant, the perimeter edge can have at least a second electrical contact electrically coupled to one or more conductive features embedded in the second circuit board, wherein the second electrical contact of the second modular package can extend to the top surface of the top encapsulant of the second modular package and can include a first contact surface generally parallel to the top surface of the top encapsulant, wherein the first electrical contact of the first modular package can extend to the bottom surface of the bottom encapsulant of the first modular package and can include a second contact surface generally parallel to the bottom surface of the bottom encapsulant, wherein the first contact surface of the second electrical contact can be electrically coupled to the second contact surface of the first electrical contact, the top surface of the second modular package can face the bottom surface of the first modular package and be generally parallel to the bottom surface of the first modular package, and the perimeter edge of the second modular package can be generally parallel to the perimeter edge of the first modular package. In some examples, the top surface of the second modular package can have a length and a width that are larger than corresponding length and width of the bottom surface of the first modular package. In some examples, the top surface of the second modular package can have a length and a width that are the same as corresponding length and width of the bottom surface of the first modular package. The first electrical contact can further include a side contact surface

5

generally parallel to the perimeter edge, and the side contact surface can be recessed from the perimeter edge.

The details of one or more embodiments of the invention are set forth in the accompanying drawings and description below. Other features, objects, and advantages of the invention will be apparent from the description and drawings, and from the claims.

DESCRIPTION OF DRAWINGS

FIG. 1 shows an isometric view of a leadless panel-molded power converter module having castellated electrical-connections and integral heat-spreading EMI-shields.

FIG. 2 shows an exploded isometric view of the leadless panel-molded power converter module of FIG. 1 with a printed circuit board.

FIG. 3 shows an isometric view of the leadless panel-molded power converter module of FIG. 1 mounted to the printed circuit board.

FIG. 4 shows an encapsulated panel assembly comprising a plurality of power converters prior to singulation.

FIG. 5 is an exploded view showing details of the encapsulated panel assembly of FIG. 4.

FIG. 6 is an exploded view showing details of the encapsulated panel assembly of FIG. 4 after slots are cut.

FIG. 7 is an exploded view showing details of the encapsulated panel assembly of FIG. 6 after metallization.

FIG. 8 is an exploded view showing details of the encapsulated panel assembly of FIG. 6 after the metal is patterned.

FIG. 9 is an exploded view showing details of the encapsulated panel assembly of FIG. 8 after singulation.

FIG. 10 (reproduced from FIG. 35 of the PM CIP) shows a heat-sinkless power converter made using the Center Plate Molding or Direct Molding techniques described in the PM CIP.

FIG. 11 shows an isometric view of a leadless panel-molded power converter module having castellated electrical-connections, integral heat-spreading EMI-shields, and a thermal conduit for conducting heat away from a central portion of the converter.

FIG. 12 shows an isometric view of a stacked module assembly including a leadless panel-molded electronic module mounted on top of a second leadless panel-molded electronic module which is mounted onto a printed circuit board.

FIG. 13 is an exploded view of the stacked module assembly of FIG. 12.

Like references symbols in the various drawings indicate like elements.

DETAILED DESCRIPTION

I. Leadless Panel-Molded Module

Referring to FIG. 1, a leadless electronic module 100 is shown having a plurality of electrical contacts, e.g. 120-1, 120-2, 121, 122-1, and 123, situated in grooves located along all four perimeter edges of the module. As shown, the electrical contacts extend onto the top and bottom surfaces of the module 100. As shown in FIG. 1, wider electrical contacts (occupying greater perimeter length along the sidewalls), e.g. contacts 120-1, 120-2, 121, and 122-1 provide greater interconnect surface area and thus provide higher current carrying capacity, making them amenable for use as power connections. In the example shown, contacts 120-1 and 120-2 may be used for input power connections, 121-1 through 121-8 may be used for output power connections,

6

and contact 122-1 may be used for a common connection for the output (or in a non-isolated example, for the input and output). As shown, the common connection extends laterally along a substantial portion of one side of the module 100 forming contact 122-1 and also extends over much (e.g., 50% or more) of the top and bottom surfaces of the module forming shields 122-2 and 122-3 either or both of which may also be used to establish electrical connections thus increasing the surface area and current carrying capacity. A plurality of narrower connections (occupying less perimeter length along the sidewalls) 123-1, 123-2, 123-3, 123-4, 123-5, 123-6, having less interconnect area and lower current carrying capacity, may be provided for signal connections, such as control and communication signals.

As shown in FIG. 1, the electronic module 100 includes a printed circuit board 101 (which can be, e.g., a multilayer printed circuit board) disposed between cured layers of encapsulant 102 and 103. The contacts 120-1, 120-2, 121, 122-1, and 123 extend vertically from the top surface of the cured encapsulant 102 to the bottom surface of the cured encapsulant 103. Because the encapsulant layers 102 and 103 cover the components mounted on the printed circuit board 101, the top surface of the encapsulant 102 and the bottom surface of the encapsulant 103 may provide smooth surfaces allowing multiple modules 100 (either of the same size or different sizes) to be stacked together (see FIGS. 12 and 13).

FIG. 10 (reproduced from FIG. 35 of the PM CIP) shows for comparison a heat-sinkless power converter 800 (PM CIP: ¶¶0137-0138) made using the Center Plate Molding or Direct Molding techniques described in the PM CIP (¶¶0139-0145 and 0146-0150 respectively). The horizontal-mount component 800 as shown includes a singulated module 815 and two adapters 803A, 803B, suitable for through-hole mounting to a motherboard. Other adapters are described in the PM CIP. As described in the Bar Code Patent and the PM Disclosures, the Center Plate and Direct Molding Techniques produce singulated modules, e.g. 815 (FIG. 10) that include a circuit board (which may be a multilayer printed circuit board) disposed between cured layers of encapsulant, e.g. encapsulant layers 805 and 806 (FIG. 10). The singulated module 815 also includes exposed interconnects ("bar codes"), e.g. bar codes 811 and 812 as shown in FIG. 10, and described in greater detail in the PM CIP (¶¶0100-0104) and the Bar Code Patent (Col. 15, ln 40-col. 17, ln 2). The top 815A and bottom 815B surfaces of the singulated module 815 may be defined by the cured encapsulant 805, 806 in which the magnetic core surfaces 815C, 815D are exposed.

Leadless modules such as leadless module 100 shown in FIGS. 1-3 may be more amenable to reductions in size and cost compared to the lead-frame modules, e.g. heat-sinkless module 800 in FIG. 10, described in the Panel Mold Disclosures. In addition, the leadless process described below allows as many surfaces of the singulated modules as desired to be used for forming electrical connections. In the example of FIG. 1, the electrical connections extend from the bar codes up and down the sidewalls and onto selected portions of the top and top and bottom surfaces of the module. As shown, all four sidewalls and the top and bottom surfaces of module 100 have metallized contacts.

Referring to FIGS. 2 and 3, the module 100 of FIG. 1 is shown in relation to a customer printed circuit board 900 having conductive pads 920, 921, 922, and 923 arranged to mate with corresponding contacts 120, 121, 122, and 123 on the module 100. Although conductive pad 922 is shown in FIG. 2 as mating with only a small portion of the common

contacts **122-3** on the bottom surface of the module **100**, it will be appreciated that contact **922** may be enlarged to extend below module **100** to provide greater contact area with the contact **122-3** on the bottom of the module. The castellated module **100** may be surface mount soldered to PCB **900**. As shown in FIGS. 1-3, all four perimeter edges and selected portions of the bottom surface of the module **100** may be used to establish electrical connections between the module and an external PCB **900**. While the top surface may also be used for electrical connections, the added complexity of establishing such top-surface connections may in many applications outweigh the incremental benefits.

Additionally portions of the top and bottom surfaces of the module **100**, optionally including areas covering the magnetic cores (e.g., similar to **815C** in FIG. 10), may be coated with electrically (and thermally) conductive material such as copper to provide electromagnetic shielding (e.g. for EMI reduction), improve heat distribution over the large surfaces of the module (e.g. provide isothermal planes), improved thermal coupling to the module (e.g. by conducting heat through a mounting board or substrate), and solder-mount options (e.g. shields/contacts **122-2** and **122-3** in FIG. 1). Additionally, the plated conductive layer may slow moisture absorption by the encapsulant (e.g., **102**, **103**), protect the magnetic cores, and help control leakage inductance in internal transformers.

II. Leadless Panel Mold Process

The preferred processes for making the leadless modules build upon the panel molding processes described in the Panel Mold Disclosures and will be described starting with an encapsulated PCB panel, such as panel **150** shown in FIG. 4. (See also, encapsulated panel **890** shown in FIGS. 43-44 of the PM CIP Application). The Panel Mold Disclosures describe making pluralities of electronic modules in panels having interconnection features buried within a substrate or PCB within the encapsulated panel, preferably along the boundaries of the individual circuits, so that electrical contacts are at least in part formed by or exposed by cutting the panel along the boundaries. (See e.g., cut lines **129** in FIG. 9A of the Bar Code Patent; and the description of buried interconnects and bar codes in the PM CIP at ¶¶0100-0104, and in the Bar Code Patent at col. 15, ln 40-col. 17, ln 2.)

The preferred method of making the encapsulated PCB panel for use in the leadless panel mold process described herein is called direct molding as described in the PM CIP Application (PM CIP: ¶¶0139-0149). Direct molding may include preparing one or more surfaces of the encapsulated panel. For example, as described below, the optional lapping finishing described in the PM CIP (PM CIP: ¶0150) may be used before (or after) the first step (cutting slots and holes) in the leadless panel mold process. Lapping before cutting the slots and holes may be preferred for establishing rounded edges between the top and bottom surfaces and the sidewall contacts, e.g. improving adhesion of the metal layers on the edges.

Referring to FIG. 4, positional accuracy during the below-described process may be achieved by providing one or more holes, e.g. holes **151**, in the substrate for generally registering the substrate with the mold during encapsulation and providing one or more fiducials, e.g. fiducials **152**, on the substrate for precise registration during subsequent processing steps, such as the slot and hole cutting, patterning, and singulation steps. The fiducials **152** may be protected during encapsulation, e.g. using mold ejector pins or other features in the mold, to prevent the fiducials from being obscured by molding compound. Additional panel identifying information may be placed on the substrate in regions,

e.g. region **154** or **153**, where portions of the mold engage with, and prevent encapsulant from covering, the substrate. Additional examples of fiducials **891D** for positioning and other panel identifying information are shown in FIG. 43 of the PM CIP. FIG. 42 of the PM CIP shows a cross-sectional view of the encapsulated panel assembly through one of the holes **871** in the encapsulant (which may be preferably formed by the presence of an ejector pin or other mold feature during encapsulation) exposing the fiducial mark **872** on the PCB panel.

Referring to FIG. 5, which is a close-up view of a portion of the encapsulated panel **150**, several cut lines **131**, **132**, **133**, **134**, **135** are shown forming boundaries between a plurality of un-singulated modules, **100A**, **100B**, **100C**, **100D**, **100E**, **100F**, **100G**, **100H**, **100I**. The modules **100A-100I** remain integral parts of the encapsulated panel throughout the process until separated from the panel by singulation cuts as described in more detail below. In order to preserve legibility, the top surface **102-1** of the panel is shown in FIG. 5 without the details of any exposed magnetic cores, e.g. core **815C** shown in FIG. 10, however it should be understood that magnetic cores may be exposed at the top and bottom surfaces of the un-singulated modules. As shown in FIG. 5, one of the features **153** where the mold may have supported the PCB during encapsulation is retained for reference continuity in FIGS. 5-8.

In a first example which will be described in connections with FIGS. 5-9, the process for making the castellated leadless modules (starting with an encapsulated and preferably lapped panel), may include: (a) forming slots or holes in or through the encapsulated panel, preferably perpendicular to one of the large planar surfaces, which produce the grooved contours in the sidewalls of the castellated modules, and in the process, exposes the buried interconnects, i.e. the bar codes, in the slots; (b) depositing a conductive seed layer; (c) plating a thicker conductive metal layer over the seed layer; (d) patterning the conductive layers; (e) applying one or more metallic finish layers; and (f) singulation, i.e. cutting the panel along the cut lines to form one or more individual modules. The above steps are described in greater detail below including optional steps. Additional options may include ultrasonic cleaning before application of the seed layer, or cutting the slots and holes before lapping and then ultrasonically cleaning the panel before applying the seed layer.

A. Castellation

Referring to FIG. 6, an encapsulated and slotted panel **150-1** has slots, e.g. slotted openings **160**, **161**, **162**, **163** formed along the cut lines, e.g. cut lines **131**, **132**, **133**, **134**, **135**, which separate the un-singulated modules, **100A-100I**. The slots or holes **160-163** preferably extend completely through the panel and are cut to produce the desired contours (castellations) in the singulated module. The slots or holes, e.g. **160**, **161**, **162**, **163**, may preferably be cut vertically down, from a surface, e.g. top surface **102-1** or bottom surface **103-1** (not shown) of the encapsulated panel **150** along the cut-lines in the areas where the contacts will be formed preferably before the panel is singulated to facilitate bulk processing of common sized panels compared with individual modules of varying sizes and shapes. The castellation process of forming slots or holes exposes buried contacts to form electrical connections, i.e. the buried interconnect features situated along the cut-lines which are exposed when the slots or holes are cut into the panel, i.e. along the cut lines as described in the Bar Code Patent (See FIG. 11, Col. 15, ln 61-col. 17, ln 2). However, the present castellation process differs in that the buried interconnects or

bar codes are exposed within the slot or hole (during the slot or hole cutting step), which is preferably before the encapsulated panel is actually singulated.

The slots and holes may be formed using a high pressure water jet to cut away the encapsulant and substrate layers. Alignment of the water jet to the panel may be achieved using the exposed PCB fiducials or tooling holes or both. Abrasives in the water may be used to facilitate cutting quality, accuracy, and speed. The cutting of slots and holes may be optimized from either the top **102-1** or bottom **103-1** sides of the panel. Preferably, the holes and slots are cut to have the desired castellation contours and extending completely through the panel which may facilitate cleaning, plating, and finishing in subsequent steps. Although the slots and holes may be cut using a water jet, the speed and accuracy of the process may be improved by first establishing a pilot hole, e.g. a 0.010" diameter pilot hole using a laser. To avoid potential reflection of the laser by the buried interconnects, clearance holes may be provided in the buried interconnects in the region of the pilot hole, e.g. a 0.020-0.025" diameter clearance. As described earlier, formation of the slots in the encapsulated panel **150** exposes the buried interconnects in the sidewall of the slots which are metalized in subsequent steps to form electrical contacts.

Starting at the pilot hole, slots having the desired length (length along the cut lines), width (thickness of the slot perpendicular to the cut line), and contours may be cut using the water jet to establish the desired castellation grooves in the modules. For example, slots **160** along cut lines **131**, **132**, and **133** are relatively long (along the cut lines) to produce contacts **120-1**, **120-2** (FIGS. 1, 9) in adjacent modules **100A**, **100B**, **100E**, **100F**, following singulation. Similarly, slots **161** along cut lines **131**, **132**, and **133** which also are relatively long (along the cut lines) to produce contacts **121** (FIGS. 1, 9) in adjacent modules **100A**, **100B**, **100E**, **100F** following singulation. In contrast, the slots along cut lines **134** and **135** are asymmetrical, having a smooth contour **162** recessed from the cut line on one side to produce the single very large contact **122-1** (FIG. 1, 9) in modules **100A**, **100B**, **100E**, **100F**, **100G**; and having a saw tooth type contour on the other side. The saw tooth contour includes short (along the cut line) openings **163** which increase the width of the slot at the opening separated by short (along the cut line) teeth protruding toward the cut line. The openings **163** produce the small signal contacts **123** (FIGS. 1, 9) in modules **100A**, **100B**, **100C**, **100H**, **100I** following singulation with the teeth forming the insulated areas between the contacts **123**.

B. Seed layer

To facilitate metalizing the slotted panel **150-1** (FIG. 6), a conductive seed layer may be deposited on the surfaces of the slotted panel including in the slots and holes. One way of applying the conductive coating includes sputter coating a thin layer of chromium, e.g. 600 Angstroms, followed by a thin layer of copper, e.g. 2 microns. The chromium seed layer may help adhering the sputter copper layer to the panel. Applying thicker seed layers by sputtering may not be practical with currently available technology. Preferably, the panel should be cleaned following the slot cutting (and lapping if performed), before the seed layers are applied to improve adhesion to the panel. For example, an ultrasonic water bath may be used to remove any particles which may interfere with adhesion from the panel surfaces. Additional or alternative cleaning or adhesion promoting processes may include de-ionized water pressure washing, plasma etching, and specialized baking cycles, e.g. including vacuum (<200 milli-Torr) baking or ultraviolet assisted baking.

Optionally, a graphite or carbon layer may be deposited either selectively in the slots and holes or over the entire panel for enhancing subsequent plating on the edges, i.e. the sidewalls of the slots and holes, between the buried interconnects (bar codes), which have been exposed within the slots and holes, and the metal on the top and bottom surfaces of the panel. For example, the panel may be dipped in a colloidal graphite solution (available from Electrochemicals Inc., Maple Plain, Minn. under the Shadow Graphite tradename; MacDermid, Inc., Waterbury, Conn. under the Black-hole tradename) which may then be cured prior to plating.

C. Plating

Using the seed layer, a thicker metal layer may be electrolessly or electrolytically plated onto the panel. However, a sputtered seed layer may be too porous to protect ferrite cores which may be exposed on the top and bottom surfaces of the panel (e.g. exposed ferrite core **815C** in FIG. 10) and other potentially sensitive portions of the panel from acid solutions during the primary plating and subsequent etching processes. Sputtering a non-porous copper seed layer would take inordinately long using currently available technology. Therefore, a protective layer of copper, e.g. 5 microns thick, preferably may be electrolessly or electrolytically plated onto the seed layer using an alkaline solution. The ferrite cores are not as sensitive to the alkaline solution compared with an acid solution.

After a first protective copper layer is applied, the rest of the metal layer, e.g. 0.006" of copper (approximately 6 oz equivalent), may be electrolytically plated onto the existing copper layers in an acid solution. Referring to FIG. 7, the metalized panel **150-2** is shown with the top surface **102-1**, bottom surface **103-1** (not shown), and interior walls of the slots **160**, **161**, **162**, **163**, coated with metal, preferably copper, e.g. metal **170**. It will be appreciated that the conductive surfaces of the metalized panel **150-2** need to be patterned to provide the discrete conductive regions required for each module following singulation.

D. Patterning

The metal layer **170** (FIG. 7) may be patterned using traditional photoresist techniques, such as application, exposure using typical ultraviolet exposure tools or preferably using a laser to expose the panel e.g. in a dot matrix exposure pattern, and rinsing away photoresist to create an etch-resistant mask. The masked panel may then be immersed in an etchant to remove the metal, copper and chromium, in the areas in which it is not desired, e.g. to provide spacing between conductors or shields. Afterward, the etch resistant-mask may be stripped from the panel.

In an alternate additive patterning method, photo resist, which is resistant to plating solutions, may be applied over a continuous, or electrically connective, layer of copper. The photo resist may be patterned to expose the areas of copper which are to remain. Then an additional plating step may be used to deposit copper onto the exposed copper, i.e. through the mask openings, after which tin plating or other metals may be used on top of the exposed copper as an etch-resistant mask instead of or in addition to photoresist layer, e.g. to create finer features or spacing. A subsequent etch step removes the unprotected copper and leaves intact the tin plated or otherwise masked copper that was deposited in the intervening plating operation.

Referring to FIG. 8, a patterned panel **150-3** is shown with the metal layer **170** etched back to form the desired discrete conductive regions. For example referring to un-singulated module **100A** of patterned panel **150-3** in FIG. 8, top shield **122-2** is shown separated from the input contacts **120-1** and **120-2**, output contacts **121-1**, **121-2**, **121-3**, **121-4**, **121-5**,

11

121-6, 121-7, and 121-8, and control contacts 123-1, 123-2, 123-3, 123-4, 123-5, and 123-6 but connected to common contact 122-1. Note that spacing (setback) from the top shield 122-2 and the input 120-1, 120-2 and control 123 contacts is greater than to the output contacts 121.

E. Finish Plating

A finish such as gold may be plated onto the copper areas as is customary in the electronics industry. For example an electroless nickel-immersion gold ("ENIG") plating process may be used to plate nickel, e.g. 200 μ " thick, and then gold, e.g. 1 μ " thick over the remaining metal.

After the finish plating, the panel may be labeled, e.g. using a laser, to mark each module with safety agency, manufacturer, serial number, lot number, and any desired information prior to singulation.

F. Singulation

After the panel is metalized in the above described manner, it may be cut along the cut lines to separate individual modules from the panel. It will be appreciated that the grooves or castellations in the sidewalls of the singulated modules, e.g. 100A, 100B (FIG. 9) are formed by cutting, e.g. during singulation, through the slots or holes, e.g. slots 160, 161, 162, 163, in the encapsulated panel. For example, FIG. 9 shows a singulated panel 150-4 having been cut along cut lines 131, 132, 133, 134, 135 with modules 100E and 100F removed but other modules left in place to show the resulting castellated signal contacts 123 on modules 100A and 100B and input 120-1 and output 121-1, 121-2, 121-3 and 121-4 contacts on module 100A. Each of the signal contacts 123, input contact 120-1, and output contacts 121-1, 121-2, 121-3, and 121-4 may extend from a top surface of the top encapsulant to a bottom surface of the bottom encapsulant as shown. Alternatively, the contacts may extend from the PCB toward one or both of the top surface of the top encapsulant and the bottom surface of the bottom encapsulant. Preferably a thin saw, e.g. 0.012" blade, may be used for singulation to avoid requiring unnecessarily large slots and holes and to maintain panel utilization. It will be appreciated that the width of the slots in the area of the desired contacts should be greater than the width of the saw cuts along the cut lines, which should be narrower than the metalized slots in the area of the desired contacts to avoid removing the metal contacts during singulation. Conversely, the width of the slots, to the extent there is a cut, between individual contacts should be narrower than the saw cut to ensure the metal between individual contacts is completely removed to electrically isolate each contact. Referring for example to the slots along cut line 135, contours 162 and the indentations of contour 163 are set back from the cut line 135 sufficiently to provide slot widths that prevent the saw from removing the metal along the intended contact walls. The saw tooth features of contours 163 that extend toward the cut line are close enough to the cut line to ensure that the saw removes metal between the individual contacts 123 (FIG. 9), i.e. removes the metal on the tips of the saw teeth and optionally a portion of the teeth themselves. Small vertical strips of copper, e.g. 0.006" thick, will be left exposed along the vertical edges of the plated castellations as the saw cuts through the thickness of the plating on the walls of the slots and holes at the edges of each metal contact. However, the thin strips, accounting for less than 10% of the contact area, which is within industry standards, should not be problematic.

III. Modifications and Alternatives

Many modifications of the above described process are possible. For example, a grid pattern may optionally be etched, e.g. by laser, into the panel surface before the

12

optional ultrasonic cleaning and subsequent seed layer steps to improve adhesion of the metal layers to the panel surfaces.

A. Conductive Epoxy Seed Alternative

In a first alternative example, step (b) above may be modified by applying a layer of conductive epoxy, e.g. a 0.0002-0.0006 inch thick layer of silver epoxy, instead of sputtering. In such an example, the process flow may include: (a) cutting the slots and holes; (b) applying a patterned layer of silver epoxy on the major surfaces of the panel (adjacent to but not in the slots or holes); (c) coat the panel with graphite or carbon, either the entire surface or selectively in the holes and groves; (d) electrolytic copper plating, e.g. 0.001-0.003 inches; (e) apply a patterned plating-resistant mask; (f) plate copper preferably 0.003 or thicker and then tin in unmasked areas; (g) remove mask; (h) etch exposed copper (copper without tin covering) (i) remove tin; (j) plate nickel, e.g. 200 μ ", and gold, e.g. 1 μ "; and (k) singulate. Additional optional steps include ultrasonic cleaning before application of the conductive epoxy, and optionally plating copper, e.g. electrolessly, onto the epoxy layer before applying graphite.

B. Direct Metallization Alternative

In a second alternative example, the panel may be directly metallized instead of sputtering or applying conductive epoxy as seed layers. Such a process may include the following steps (after the encapsulated panel is lapped and cleaned): (a) polymer coat/treat the panel; (b) direct metallization of 0.5 mils copper layer; (c) cut the slots and holes; (d) apply shadow graphite; (e) copper plate to a desired thickness, e.g. 6 mils; (f) pattern the copper, e.g. using the photolithographic etch processes described above; (g) finish plate the remaining copper, e.g. ENIG and laser mark the panel; (h) cut the panel along the cut lines to singulate the modules.

A typical polymer coating process may include a plasma cleaning activation of the encapsulated panel; application of an adhesion promoter; application of a polymer layer, e.g. having a thickness of 1,000 angstroms to a few microns; thermal treatment of the polymer and adhesion promoter; activation of the polymer for electroless metal deposition, e.g., by application of a catalyst or oxidation of the polymer; and electroless metal deposition.

C. Improved Bar Code Connections

In a third alternative example in which the top and bottom surfaces of the panel need not be plated, the process described above may be used to form contacts over the bar codes only. Alternatively, the holes may be cut by drill or laser; the walls of the hole may be de-smeared; sensitize the walls of the hole, e.g. using chemicals, to attract a catalyst; activate the walls of the holes with a catalyst such as a Palladium based chemical; electrolessly plate copper or nickel metal; finish the plated metal, e.g. using ENIG plating.

Alternatively, the exposed interconnects of singulated modules [e.g., singulated module 815 (FIG. 10)] may be plated, e.g. by placing the singulated modules in plating bath resistant trays or fixtures, in a typical ENIG or similar electroless baths to form an ENIG surface over the exposed interconnects (bar codes). The plating, which may bridge adjacent layers of the buried interconnects to form a continuous metal layer over each bar code or may simply plate the individual bar code elements without bridging. The ENIG plating may provide a non-copper surface for soldering, e.g. to adapter leads 808, 809 (FIG. 10).

13

D. Thermal Conduits

The leadless panel mold process described above in connection with FIGS. 5-9 may be readily adapted to form thermal conduits in the singulated modules. A singulated leadless panel-molded power-converter module **200** is shown in FIG. 11 having an input power contact **220**, an output power contact **221**, two common contacts **222-1**, a conductive shield **222-2** on the top of the module which may as shown be electrically and connected to the common contacts **222-1**, and a plurality of control signal contacts **223**. In addition, the module **200** is shown having a thermal conduit **265** for conducting heat away from a central portion of the module to the top shield **222-2**. The three-terminal power converter module **200** of FIG. 11 may be fabricated using the same leadless panel mold processes described above in connection with FIGS. 5-9. For example, a slot (or one or more auxiliary holes) may be cut, e.g. by laser, water jet, or machining such as milling or drilling, in the desired location and having the desired dimensions during the slot cutting process and then metallized as described above to form the thermal conduit **265**. The thermal conduit slot may extend entirely through the panel to provide a thermal conduit that extends between the top and bottom surfaces. The thermal conduit slot may expose conductive features to provide thermal, and optionally electrical, connections between the substrate and the top and/or bottom conductive layers. The thermal conduit slot may alternatively be formed to controlled depths to provide thermal pathways to selected components. For example, the slot may be cut partially through the encapsulant above selected components, maintaining the electrical insulation provided by the encapsulant between the selected components and the thermal conduit **265**. In one example a 6 mil wide slot may be cut to a controlled depth above selected electronic switches, such as MOSFETS, in the module and then metallized along with the remainder of the panel. If cut by laser such as a typical carbon dioxide laser, a metal shield, e.g. copper, may be provided on or above the surface of the component to limit the depth of the cut. The metallization may partially or completely fill the thermal conduit slot, e.g. with copper, depending upon the thickness of the deposited metal layer. In either approach the metal provides thermal and optionally electrical pathways from selected interior portions of the module **200** to the top or bottom, or both top and bottom surfaces. Although a straight long thermal conduit **265** is shown in FIG. 11, it will be appreciated that any desired shape or size thermal conduit may be provided using the above process.

E. Carrier Surface Connections

Although the leadless module **100** has been described having surface metal (e.g. top and bottom shields **122-2** and **122-3**) well adapted for improving electromagnetic shielding and thermal performance, it should be appreciated by those of skill in the art that many variations are possible. For example, the metal on one or more surfaces, e.g. preferably the top surface, may be patterned in a manner that would allow one or more components to be mounted onto and electrically connected to the module or to external circuitry via the module. Referring to FIG. 12 (and the exploded view of FIG. 13), a stacked module arrangement is shown having the leadless electronic module **100** shown in FIGS. 1-3 mounted onto and electrically connected, e.g. by solder, onto another leadless carrier module **300**, which is in turn mounted onto and electrically connected, e.g. by solder, to a printed circuit board **900**.

In some implementations, the carrier module **300** includes a circuit board **301** disposed between cured encapsulants

14

302 and **303**. The metallization layer **322** on the top surface **302-1** of carrier module **300** may be patterned to provide pads aligned with respective electrical contacts on the leadless electronic module **100**. For example, pads **322-0**, **322-1**, **322-2**, **322-3** as shown (FIG. 13) on the top surface **302-1** of module **300** align with electrical contacts **120**, **121**, **122-1**, and **123** on module **100** when stacked on top of (FIG. 12) of module **300**. The electrical contacts may be soldered to the pads to provide both thermal and electrical connections. Although all of the electrical contacts along the sides of module **100** are shown in FIGS. 12 and 13 as having respective pads on the top surface of module **300**, it should be appreciated, that a one to one correlation of pads to contacts need not be established, e.g. some contacts may have no corresponding pad or some pads may have no corresponding contact.

As shown, the pads **322** may be connected to, or form part of, conductive runs that connect to respective contacts along the side of module **300** which may in turn be electrically connected to lands on the printed circuit board **900**. For example, pads **322-1** are shown connected to side contacts **322-1A** which in turn may be connected to respective lands **921A** on PCB **900**. Similarly, pads **322-0**, **322-2** and **322-3** are configured to connect to respective lands **920**, **922**, and **923** on PCB **900**. The side contacts of module **300** may, or may not, be electrically connected to circuitry within module **300** and not all side contacts need to connect to a respective pads on top of module **300**, e.g., side contacts **321** are shown connecting to lands **921** on PCB **900** but not to any pads on top of module **300**. Although the details of the conductive runs of PCB **900** are not shown for simplicity, it is understood that each land provided on PCB **900** for module **300** may be connected to external circuitry via conductive runs in PCB **900**, may be connected to other selected lands on PCB **900** providing a bridge between side contacts, or remain isolated from other lands and circuitry providing mechanical support without further electrical connection within the system. Thus, each electrical contact on the side of module **300** may be used to connect to module **100**, to PCB **900**, to both module **100** and PCB **900**, or neither, flexibly allowing each contact in module **100** to be connected directly to PCB **900** without any connection to circuitry in module **300**, or to be connected to circuitry in module **100**, either with a connection to PCB **900** or without.

A number of embodiments of the invention have been described. Nevertheless, it will be understood that various modifications may be made without departing from the spirit and scope of the invention. For example, the grooves may be completely filled during the metallization process to form smooth sidewalls on the module after singulation by electrolytically plating leads to the holes (using above process), then plating up electrolytically to fill the hole, and cutting through the filled hole to leave a smooth sidewall. Although the stacked arrangement is shown with the lower module **300** having a larger footprint, i.e. larger in length and width, than the upper module **100**, it should be appreciated that the stacked modules may have similarly or identically sized footprints. The thermal conduits may alternatively form electrical connections to pads on the surface of the module. In FIGS. 12 and 13, the pad **322-1** is shown electrically connecting the four output contacts **121-1**, **121-2**, **121-3**, and **121-4** of module **100** to the three contacts **321B** of module **300**, but other arrangements are also possible. For example, in some implementations, the pad **322-1** can be configured such that each of the contacts **321B** can be connected to one or more of the output contacts **121-1**, **121-2**, **121-3**, and **121-4**. The terms "top" and "bottom" are used to describe

15

relative positions of items shown in the drawings. It is understood that the modules and devices described in this document can be placed in various orientations such that, e.g., a "top surface" may be facing downwards or sideways, and a "bottom surface" may be facing upwards or sideways.

Accordingly, other embodiments are within the scope of the following claims.

What is claimed is:

1. A method of electrically interconnecting circuit assemblies, the method comprising:

assembling an encapsulated panel including a printed circuit board having electronic components mounted to the printed circuit board and one or more conductive features enclosed within the panel and unexposed to an exterior surface of the panel, the encapsulated panel comprising one or more electronic modules having boundaries defined by one or more predetermined cut lines, and the one or more conductive features having portions that are located along the cut lines and unexposed to an exterior surface of the panel;

selectively forming holes in the panel at predetermined locations along the cut lines exposing within selected holes respective portions of the one or more conductive features;

selectively forming one or more conductive metal layers on selected surfaces of the panel including along sidewalls within the selected holes, each selected hole having a respective portion of the one or more conductive metal layers along sidewalls within the selected holes being in electrical contact with the respective portions of the one or more conductive features; and cutting the panel through the holes and along the one or more cut lines singulating the one or more electronic modules, leaving each singulated electronic module with electrical contacts that include portions of the sidewalls of the selected holes along a perimeter edge of the module.

2. The method of claim 1, further comprising preparing one or more surfaces of the encapsulated panel.

3. The method of claim 2 wherein the preparing one or more surfaces comprises lapping the panel before selectively forming the holes.

4. The method of claim 2 wherein the preparing one or more surfaces comprises lapping the panel after selectively forming the holes.

5. The method of claim 2 wherein the preparing one or more surfaces comprises cleaning the panel ultrasonically in an aqueous solution before selectively forming the one or more metal layers.

6. The method of claim 2 wherein the preparing one or more surfaces comprises laser etching the panel before selectively forming the one or more metal layers.

7. The method of claim 2 wherein the selectively forming one or more conductive metal layers further comprises: (a) applying a seed layer including conductive particles to the surfaces of the panel, and subsequently (b) plating a layer of metal onto the seed layer.

8. The method of claim 7 wherein applying the seed layer comprises sputter coating the encapsulated panel with conductive particles.

9. The method of claim 8 wherein the sputtering comprises sputtering copper particles.

10. The method of claim 9 wherein the sputtering further comprises sputtering chromium particles.

11. The method of claim 10 further comprising coating the encapsulated panel with colloidal graphite and curing the graphite before the plating.

16

12. The method of claim 10 further comprising patterning the metal before cutting the panel.

13. The method of claim 12 wherein the patterning comprises masking and subsequently etching the metal layer.

14. The method of claim 13 wherein the patterning further comprises using a laser to expose or remove portions of the mask.

15. The method of claim 12 further comprising applying one or more finishing layers on top of the metal layer.

16. The method of claim 7 wherein applying the seed layer comprises applying conductive epoxy.

17. The method of claim 16 wherein applying the seed layer further comprises applying the conductive epoxy in a predetermined pattern.

18. The method of claim 17 further comprising coating the encapsulated panel with colloidal graphite and curing the graphite before the plating.

19. The method of claim 17 further comprising applying one or more finishing layers on top of the metal layer.

20. The method of claim 1 further comprising configuring the holes to provide gaps between adjacent contacts; and wherein the holes establish a pattern in the conductive metal layers along the perimeter edge of the one or more electronic modules.

21. The method of claim 1 further comprising patterning the one or more metal layers to form conductive pads on a selected surface of the one or more electronic modules, the pads providing a surface mounting area for one or more components.

22. The method of claim 21 wherein patterning the metal layer further comprises establishing electrical connections between respective ones of the pads to respective ones of the electrical contacts.

23. The method of claim 1 further comprising: selectively forming auxiliary holes in the panel at predetermined locations spaced away from the cut lines; and selectively forming one or more conductive metal layers within the auxiliary holes to form thermal conduits for conducting heat from respective interior portions of the one or more electronic modules to an exterior surface.

24. The method of claim 23 wherein the auxiliary holes are cut to a controlled depth without exposing within the auxiliary holes any components in the one or more electronic modules.

25. The method of claim 24 wherein the auxiliary holes are cut through the entire thickness of the panel without exposing within the auxiliary holes any components in the one or more electronic modules.

26. The method of claim 25 wherein the cutting auxiliary holes exposes within selected ones of the auxiliary holes respective portions of one or more auxiliary conductive features.

27. The method of claim 1 further comprising: selectively forming auxiliary holes in the panel at predetermined locations spaced away from the cut lines exposing within selected ones of the auxiliary holes respective portions of one or more auxiliary conductive features;

selectively forming one or more conductive metal layers within the auxiliary holes to form electrical connections to the auxiliary conductive features; and

patterning the one or more metal layers to form conductive pads on a selected surface of the one or more electronic modules and electrical connections between selected ones of the pads and the one or more auxiliary

17

conductive features, the pads providing a surface mounting area for one or more components.

28. The method of claim **1** further comprising:

selectively forming auxiliary holes in the panel at prede-
termined locations spaced away from the cut lines; and
selectively forming one or more conductive metal layers
within the auxiliary holes of the one or more electronic
modules to an exterior surface.

29. The method of claim **28** wherein the auxiliary holes
are cut to a controlled depth in the one or more electronic
modules.

30. The method of claim **29** wherein the cutting auxiliary
holes exposes within selected ones of the auxiliary holes
respective portions of one or more auxiliary conductive
features.

31. The method of claim **30** further comprising forming a
pad on the exterior surface adjacent one or more of the
auxiliary holes and wherein the one or more conductive
layers in the one or more auxiliary holes forms an electrical
connection between the respective portions of the one or
more auxiliary conductive features and the pad.

32. The method of claim **28** wherein the auxiliary holes
are cut through the entire thickness of the panel in the one
or more electronic modules.

18

33. The method of claim **32** wherein the cutting auxiliary
holes exposes within selected ones of the auxiliary holes
respective portions of one or more auxiliary conductive
features.

34. The method of claim **33** further comprising forming a
pad on the exterior surface adjacent one or more of the
auxiliary holes and wherein the one or more conductive
layers in the one or more auxiliary holes forms an electrical
connection between the respective portions of the one or
more auxiliary conductive features and the pad.

35. The method of claim **1** further comprising:

selectively forming auxiliary holes in the panel at prede-
termined locations spaced away from the cut lines
exposing within selected ones of the auxiliary holes
respective portions of one or more auxiliary conductive
features;

selectively forming one or more conductive metal layers
within the auxiliary holes to form electrical connections
to the auxiliary conductive features; and

patterning the one or more metal layers to form conduc-
tive pads on a selected surface of the one or more
electronic modules and electrical connections between
selected ones of the pads and the one or more auxiliary
conductive features, the pads providing an electrical
connection to the one or more auxiliary conductive
features.
