20.3.9.5.2 HT greenfield format Short Training field (HT-GF-STF)

The HT greenfield format short training field (HT-GF-STF) is placed at the beginning of a greenfield format frame. The time domain waveform for the HT-GF-STF on transmit chain i_{TX} is:

$$r^{(i_{TX})}_{HT-GF-STF}(t) = \frac{1}{\sqrt{N_{STS} \cdot N^{Tone}_{HT-GF-STF}}} w_{T_{HT-GF-STF}}(t) \cdot \sum_{k=-N_{SR}}^{N_{SR}} \sum_{i_{STS}=1}^{N_{STS}} [Q_k]_{i_{TX}, i_{STS}} [P_{HTLTF}]_{i_{STS}, 1} \Upsilon_k S_k \exp(j2\pi k \Delta_F (t - T^{i_{STS}}_{CS})) \quad (20\text{-}28)$$

where

$T^{i_{STS}}_{CS}$ represents the cyclic shift for the space time stream i_{STS} and takes values from Table n62 (Cyclic shift values of HT portion of the packet)

Q_k is defined in 20.3.10.10.1 (Spatial mapping)

P_{HTLTF} is defined in Equation (20-27)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000844

S_k is defined in Non-HT Short Training field (L-STF), Equation (20-8) for 20 MHz operation and Equation (20-9) for 40 MHz operation.

The waveform defined by Equation (20-28) has a period of 0.8 μs, and the HT-GF-STF includes ten such periods, with a total duration of $T_{HT-GF-STF} = 8$ μs.

Insert the following new subclause:

20.3.9.5.3 HT SIGNAL field

The content and format of the HT SIGNAL field of a greenfield format frame is identical to the HT SIGNAL field in an HT mixed format frame, as described in 20.3.9.4.3 (The HT SIGNAL field). The placement of the HT SIGNAL field in a greenfield format frame is shown in Figure n62 (PPDU frame format). The time-domain waveform is generated according Equation (20-29) and Equation (20-30).

The following equation gives the time domain waveform for the signal field on transmit chain i_{TX} with 20 MHz operation.

$$r_{HT-SIG}^{i_{TX}}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-SIG}^{Tone}}} \sum_{n=0}^{1} w_{T_{SYM}}(t - nT_{SYM}) \cdot \sum_{k=-26}^{26} \sum_{i_{STS}=1}^{N_{STS}} [Q_k]_{i_{TX}, i_{STS}} [P_{HTLTF}]_{i_{STS}, 1} (jD_{k,n} + p_n P_k) \cdot \exp(j2\pi k\Delta_F (t - nT_{SYM} - T_{GI} - T_{CS}^{i_{STS}})) \quad (20\text{-}29)$$

where

P_k and p_n are defined in 17.3.5.9

$D_{k,n}$ is defined in 20.3.9.4.3 (The HT SIGNAL field)

$T_{CS}^{i_{STS}}$ represents the cyclic shift for space time stream i_{STS} and takes values from Table n62 (Cyclic shift values of HT portion of the packet)

Q_k is defined in 20.3.10.10.1 (Spatial mapping)

P_{HTLTF} is defined in Equation (20-27).

The following equation gives the time domain waveform for the signal field on transmit chain i_{TX} with 40 MHz operation.

$$r_{HT-SIG}^{i_{TX}}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-SIG}^{Tone}}} \sum_{n=0}^{1} w_{\mathrm{T}_{SYM}}(t - nT_{SYM}) \cdot \sum_{k=-26}^{26} \sum_{i_{STS}=1}^{N_{STS}} [P_{HTLTF}]_{i_{STS},1}(jD_{k,n} + p_n P_k) \cdot ([Q_{k-32}]_{i_{TX},i_{STS}} \exp(j2\pi(k-32)\Delta_F(t - nT_{SYM} - T_{GI} - T_{CS}^{i_{STS}})) + j[Q_{k+32}]_{i_{TX},i_{STS}} \exp(j2\pi(k+32)\Delta_F(t - nT_{SYM} - T_{GI} - T_{CS}^{i_{STS}})))$$ (20-30)

where

p_n and P_k are defined in 17.3.5.9

$D_{k,n}$ is defined in 20.3.9.4.3 (The HT SIGNAL field)

$T_{CS}^{i_{STS}}$ represents the cyclic shift for space time stream i_{STS} and takes values from Table n62 (Cyclic shift values of HT portion of the packet)

Q_k is defined in 20.3.10.10.1 (Spatial mapping)

P_{HTLTF} is defined in Equation (20-27)

Insert the following new subclause:

20.3.9.5.4 HT Long Training field

The format of the long training field portion of the preamble in a greenfield format frame is identical to that of the HT long training field in an HT mixed format frame, as described in 20.3.9.4.6 (The HT-LTF long training field), with the exception of the first HT-LTF (HT-LTF1), which is twice as long (8 μs) as the other HT-LTFs. The time domain waveform for the long training symbol on transmit chain i_{TX} for the first HT-LTF in a greenfield format frame is

$$r_{HT-LTF}^{1,i_{TX}}(t) = \frac{1}{\sqrt{N_{STS} \cdot N_{HT-LTF}^{Tone}}} w_{\mathrm{T}_{HT-LTF1}}(t) \cdot \sum_{k=-N_{SR}}^{N_{SR}} \sum_{i_{STS}=1}^{N_{STS}} [Q_k]_{i_{TX},i_{STS}} [P_{HTLTF}]_{i_{STS},1} \Upsilon_k HTLTF(k) \exp(j2\pi k\Delta_F(t - T_{GI2} - T_{CS}^{i_{STS}}))$$ (20-31)

where

$T_{CS}^{i_{STS}}$ represents the cyclic shift for space time stream i_{STS} and takes values from Table n62 (Cyclic shift values of HT portion of the packet)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000846

Q_k is defined in 20.3.10.10.1 (Spatial mapping)

P_{HTLTF} is defined in Equation (20-27)

The first HT-LTF (HT-LTF1) consists of two periods of the long training symbol, preceded by a double-length (1.6 μs) cyclic prefix. The placement of the first and subsequent HT-LTFs in a greenfield format frame is shown in Figure n62 (PPDU frame format).

Insert the following new subclause:

20.3.10 The Data field

The Data field consists of the 16-bit SERVICE field, the PSDU, either six or twelve tail bits, depending on whether there are one or two encoding streams, and pad bits.

The number of OFDM symbols in the data field when BCC encoding is used is computed using the formula:

$$N_{SYM} = m_{STBC}\left\lceil \frac{8 \cdot length + 16 + 6 \cdot N_{ES}}{m_{STBC} \cdot N_{DBPS}} \right\rceil \quad (20\text{-}32)$$

where

m_{STBC} is 2 if STBC is used and 1 otherwise (making sure that the number of symbols is even when STBC is used)

length is the value of the Length field in the HT-SIG field defined in Table n63 (Fields of HT SIGNAL field)

N_{DBPS} can take the values defined in Table n82 (Rate dependent parameters for mandatory 20 MHz, NSS =1 MCSs, NES = 1) through Table n96 (Rate-dependent parameters for optional 40 MHz, NSS = 4 MCSs)

The symbol $\lceil x \rceil$ denotes the smallest integer greater than or equal to x

The number of "zero" pad bits is thus $N_{SYM} \cdot N_{DBPS} - 8 \cdot length - 16 - 6 \cdot N_{ES}$. The number of symbols in the data field when LDPC encoding is used is described in 20.3.10.6 (Low density parity check (LDPC) codes).

For LDPCC encoding, the number of encoded data bits, N_{avbits}, is given by Equation (20-39), the number of OFDM symbols, N_{SYM}, is given by Equation (20-41), and the number of repeated encoded bits for padding, N_{rep}, is given by Equation (20-42), in 20.3.10.6.5 (LDPC PPDU encoding process).

Insert the following new subclause:

20.3.10.1 The SERVICE field

The SERVICE field is used for scrambler initialization. The service field is composed of 16 bits, all set to zero before scrambling. In non-HT and non-HT duplicate transmissions the service field is the same as in 17.3.5.1. In HT frames, the service field is composed of 16 zero bits, scrambled by the scrambler, as defined in 20.3.10.2 (Scrambler).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000847

Insert the following new subclause:

20.3.10.2 Scrambler

The data field is scrambled by the scrambler defined in 17.3.5.4.

Insert the following new subclause:

20.3.10.3 Coding

The data are encoded using either the binary convolutional code (BCC) defined in 17.3.5.5, or the low density parity check (LDPC) code defined in 20.3.10.6 (Low density parity check (LDPC) codes). The encoder is selected by the LDPC coding field in the High Throughput Signal Field, as described in 20.3.9.4.3 (The HT SIGNAL field). A single FEC encoder is always used when LDPC coding is used. When the BCC FEC encoder is used, a single encoder is used, except that two encoders shall be used when the selected MCS has a PHY rate greater than 300 Mb/s calculated based on 800 ns GI. The operation of the BCC FEC is described in 20.3.10.5 (Binary convolutional coding and puncturing). The operation of the LDPC coder is described in 20.3.10.6 (Low density parity check (LDPC) codes).

20.3.10.4 Encoder parsing operation

If two encoders are used, the scrambled data bits are divided between the encoders by sending alternating bits to different encoders. The ith bit to the jth encoder, denoted $x_i^{(j)}$, is:

$$x_i^{(j)} = b_{N_{ES} \cdot i + j} \quad ; \quad 0 \le j \le N_{ES} - 1 \tag{20-33}$$

Following the parsing operation, 6 scrambled "zero" bits following the end of the message bits in each FEC input sequence are replaced by unscrambled "zero" bits, as described in 17.3.5.2.

The replaced bits are:

$$x_i^{(j)} \quad : \qquad 0 \le j \le N_{ES} - 1 \quad ; \quad \frac{length \cdot 8 + 16}{N_{ES}} \le i \le \frac{length \cdot 8 + 16}{N_{ES}} + 5 \tag{20-34}$$

Insert the following new subclause:

20.3.10.5 Binary convolutional coding and puncturing

When BCC encoding is used, the encoder parser output sequences $\{x_i^0\}$, and $\{x_i^1\}$ where applicable, are each encoded by the rate-½ convolutional encoder defined in 17.3.5.5. After encoding, the encoded data is punctured by the method defined in 17.3.5.6 to achieve the rate selected by the modulation and coding scheme.

In the case that rate 5/6 coding is selected, the puncturing scheme is defined in Figure n72 (Puncturing at rate 5/6).

Insert the following new heading:

20.3.10.6 Low density parity check (LDPC) codes

Insert the following new subclause:

20.3.10.6.1 Introduction

Subclauses 20.3.10.6.2 (LDPC code rates and codeword block lengths) to 20.3.10.6.6 (LDPC parser) describe the LDPC codes to be optionally used in the HT system as a high-performance ECC technique, instead of the convolutional code (20.3.10.5 (Binary convolutional coding and puncturing)). The rate-dependent parameters in Table n82 (Rate dependent parameters for mandatory 20 MHz, NSS =1 MCSs, NES = 1) to Table n96 (Rate-dependent parameters for optional 40 MHz, NSS = 4 MCSs) shall still apply.

Support for LDPC codes is optional.

Insert the following new subclause:

20.3.10.6.2 LDPC code rates and codeword block lengths

The supported code rates, information block lengths, and codeword block lengths are described in Table n67 (LDPC parameters).

Table n67—LDPC parameters

Code rate (R)	LDPC information block length (bits)	LDPC codeword block length (bits)
1/2	972	1944
1/2	648	1296
1/2	324	648
2/3	1296	1944
2/3	864	1296
2/3	432	648
3/4	1458	1944
3/4	972	1296
3/4	486	648
5/6	1620	1944
5/6	1080	1296
5/6	540	648

Insert the following new subclause:

20.3.10.6.3 LDPC encoder

For each of the three available codeword block lengths, the LDPC encoder supports rate-1/2, rate-2/3, rate-3/4 and rate-5/6 encoding. The LDPC encoder is systematic, i.e., it encodes an information block, c=(i_0,i_1,..., $i_{(k-1)}$), of size *k,* into a codeword, **c,** of size *n,* **c**=(i_0,i_1,... $i_{(k-1)}$, p_0, p_1,..., $p_{(n-k-1)}$), by adding *n*-*k* parity bits obtained so that $\mathbf{H}\cdot\mathbf{c}^T = \mathbf{0}$, where **H** is an (*n*-*k*)×*n* parity-check matrix. The selection of the codeword block length (*n*) is achieved via the LDPC PPDU encoding process described in 20.3.10.6.5 (LDPC PPDU encoding process).

Insert the following new subclause:

20.3.10.6.4 Parity check matrices

Each of the parity-check matrices can be partitioned into square subblocks (submatrices) of size $Z \times Z$. These submatrices are either cyclic-permutations of the identity matrix or null submatrices.

The cyclic-permutation matrix P_i is obtained from the $Z \times Z$ identity matrix by cyclically shifting the columns to the right by *i* elements. The matrix P_0 is the $Z \times Z$ identity matrix. Figure n73 (Examples of cyclic-permutation matrices with Z=8. The matrix Pi is produced by cyclically shifting the columns of the identity matrix to the right by i places.) illustrates examples (for a subblock size of 8 × 8) of cyclic-permutation matrices P_i.

$$P_0 = \begin{bmatrix} 1&0&0&0&0&0&0&0\\ 0&1&0&0&0&0&0&0\\ 0&0&1&0&0&0&0&0\\ 0&0&0&1&0&0&0&0\\ 0&0&0&0&1&0&0&0\\ 0&0&0&0&0&1&0&0\\ 0&0&0&0&0&0&1&0\\ 0&0&0&0&0&0&0&1 \end{bmatrix}, P_1 = \begin{bmatrix} 0&1&0&0&0&0&0&0\\ 0&0&1&0&0&0&0&0\\ 0&0&0&1&0&0&0&0\\ 0&0&0&0&1&0&0&0\\ 0&0&0&0&0&1&0&0\\ 0&0&0&0&0&0&1&0\\ 0&0&0&0&0&0&0&1\\ 1&0&0&0&0&0&0&0 \end{bmatrix}, P_5 = \begin{bmatrix} 0&0&0&0&0&1&0&0\\ 0&0&0&0&0&0&1&0\\ 0&0&0&0&0&0&0&1\\ 1&0&0&0&0&0&0&0\\ 0&1&0&0&0&0&0&0\\ 0&0&1&0&0&0&0&0\\ 0&0&0&1&0&0&0&0\\ 0&0&0&0&1&0&0&0 \end{bmatrix}$$

Figure n73—Examples of cyclic-permutation matrices with Z=8. The matrix P_i is produced by cyclically shifting the columns of the identity matrix to the right by *i* places.

Table R.1 of Annex R displays the "matrix prototypes" of parity-check matrices for all four code rates at block length *n*=648 bits. The integer *i* denotes the cyclic-permutation matrix P_i, as illustrated in Figure n73 (Examples of cyclic-permutation matrices with Z=8. The matrix Pi is produced by cyclically shifting the columns of the identity matrix to the right by i places.). Vacant entries of the table denote null (zero) submatrices.

Table R.2 of Annex R displays the matrix prototypes of parity-check matrices for block length *n*=1296 bits, in the same fashion.

Table R.3 of Annex R displays the matrix prototypes of parity-check matrices for block length *n*=1944 bits, in the same fashion.

Insert the following new subclause:

20.3.10.6.5 LDPC PPDU encoding process

To encode an LDPC PPDU, steps a) to g) defined below are performed in sequence.

a) Compute the number of available bits, N_{avbits}, in the minimum number of OFDM symbols in which the Data field of the packet may fit.

$$N_{\text{pld}} = length \times 8 + 16 \tag{20-35}$$

$$N_{\text{avbits}} = N_{\text{CBPS}} \times m_{STBC} \times \left\lceil \frac{N_{\text{pld}}}{N_{\text{CBPS}} \times \text{R} \times m_{STBC}} \right\rceil , \tag{20-36}$$

where

m_{STBC} is 2 if STBC is used and 1 otherwise

length is the value of the Length field in the HT-SIG field defined in Table n63 (Fields of HT SIGNAL field)

$\lceil x \rceil$ denotes the smallest integer greater than or equal to x

N_{pld} is the number of bits in the PSDU and SERVICE field

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000851

b) Compute the integer number of LDPC codewords to be transmitted, N_{CW}, and the length of the codewords to be used, L_{LDPC} from Table n68 (PPDU encoding parameters).

Table n68—PPDU encoding parameters

Range of N_{avbits} (bits)	Number of LDPC codewords (N_{CW})	LDPC codeword length L_{LDPC} (bits)
$N_{avbits} \le 648$	1	1296, if $N_{avbits} \ge N_{pld} + 912 \times (1\text{-}R)$ 648, otherwise
$648 < N_{avbits} \le 1296$	1	1944, if $N_{avbits} \ge N_{pld} + 1464 \times (1\text{-}R)$ 1296, otherwise
$1296 < N_{avbits} \le 1944$	1	1944
$1944 < N_{avbits} \le 2592$	2	1944, if $N_{avbits} \ge N_{pld} + 2916 \times (1\text{-}R)$ 1296, otherwise
$2592 < N_{avbits}$	$\left\lceil \frac{N_{pld}}{1944 \cdot R} \right\rceil$	1944

c) Compute the number of shortening bits, N_{shrt}, to be padded to the N_{pld} data bits before encoding, as follows.

$$N_{shrt} = (N_{CW} \times L_{LDPC} \times R) - N_{pld} \quad (20\text{-}37)$$

When $N_{shrt} \le 0$, shortening is not performed. When $N_{shrt} > 0$, shortening bits shall be equally distributed over all N_{CW} codewords with the first $\text{rem}(N_{shrt}, N_{CW})$ codewords being shortened one bit more than the remaining codewords. Define $N_{spcw} = \lfloor N_{shrt} / N_{CW} \rfloor$. Then, when $N_{shrt} > 0$, the shortening is performed by setting information bits $(i(k - N_{spcw} - 1), \ldots, i(k-1))$ to 0 in the first $\text{rem}(N_{shrt}, N_{CW})$ codewords and, provided $N_{shrt} > 0$, setting information bits $(i(k - N_{spcw}), \ldots, i(k-1))$ to 0 in the remaining codewords. For all values of N_{shrt}, encode each of the N_{CW} codewords using the LDPC encoding technique described in 20.3.10.6.2 (LDPC code rates and codeword block lengths) through 20.3.10.6.4 (Parity check matrices). When $N_{shrt} > 0$, the shortened bits shall be discarded after encoding.

d) Compute the number of bits to be punctured, N_{punc}, from the codewords after encoding, as follows.

$$N_{punc} = \max(0, (N_{CW} \times L_{LDPC}) - N_{avbits} - N_{shrt}) \quad (20\text{-}38)$$

If $\left(\left(N_{punc} > 0.1 \times N_{CW} \times L_{LDPC} \times (1-R)\right) \text{ AND } \left(N_{shrt} < 1.2 \times N_{punc} \times R/(1-R)\right)\right)$ is true OR if $\left(N_{punc} > 0.3 \times N_{CW} \times L_{LDPC} \times (1-R)\right)$ is true, then increment N_{avbits} and recompute N_{punc} by the following:

$$N_{avbits} = N_{avbits} + N_{CBPS} \times m_{STBC} \quad (20\text{-}39)$$

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000852

$$N_{\text{punc}} = \max(0, (N_{\text{CW}} \times L_{\text{LDPC}}) - N_{\text{avbits}} - N_{\text{shrt}}) \quad (20\text{-}40)$$

The punctured bits shall be equally distributed over all N_{CW} codewords with the first $\text{rem}(N_{\text{punc}}, N_{\text{CW}})$ codewords being punctured one bit more than the remaining codewords. Define $N_{\text{ppcw}} = \lfloor N_{\text{punc}} / N_{\text{CW}} \rfloor$. When $N_{\text{ppcw}} > 0$, the puncturing is performed by discarding parity bits $(p(n-k-N_{\text{ppcw}}-1), \ldots, p(n-k-1))$ of the first $\text{rem}(N_{\text{punc}}, N_{\text{CW}})$ codewords and discarding parity bits $(p(n-k-N_{\text{ppcw}}), \ldots, p(n-k-1))$ of the remaining codewords after encoding. The number of OFDM symbols to be transmitted in the PPDU can be computed per:

$$N_{\text{SYM}} = N_{\text{avbits}} / N_{\text{CBPS}} \quad (20\text{-}41)$$

e) Compute the number of coded bits to be repeated, N_{rep}, as follows.

$$N_{\text{rep}} = \max(0, N_{\text{avbits}} - N_{\text{CW}} \times L_{\text{LDPC}} \times (1-R) - N_{\text{pld}}) \quad (20\text{-}42)$$

The number of coded bits to be repeated shall be equally distributed over all N_{CW} codewords with one more bit repeated for the first $\text{rem}(N_{\text{rep}}, N_{\text{CW}})$ codewords than for the remaining codewords.

NOTE—When puncturing occurs, the coded bits are not repeated, and vice versa.

The coded bits to be repeated for any codeword shall be copied only from that codeword itself, starting from information bit i(0) and continuing sequentially through the information bits and, when necessary, into the parity bits, until the required number of repeated bits are obtained for that codeword. Note that these repeated bits are copied from the codeword after the shortening bits have been removed. If for a codeword the required number of repeated bits cannot be obtained in this manner (i.e. repeating the codeword once), the procedure is repeated until the required number is achieved. These repeated bits are then concatenated to the codeword after the parity bits in their same order. The is process is illustrated in Figure n74 (LDPC PPDU encoding padding and puncturing of a single codeword). In this figure, the outlined arrows indicate the encoding procedure steps, while the solid arrows indicate the direction of puncturing and padding with repeated bits.

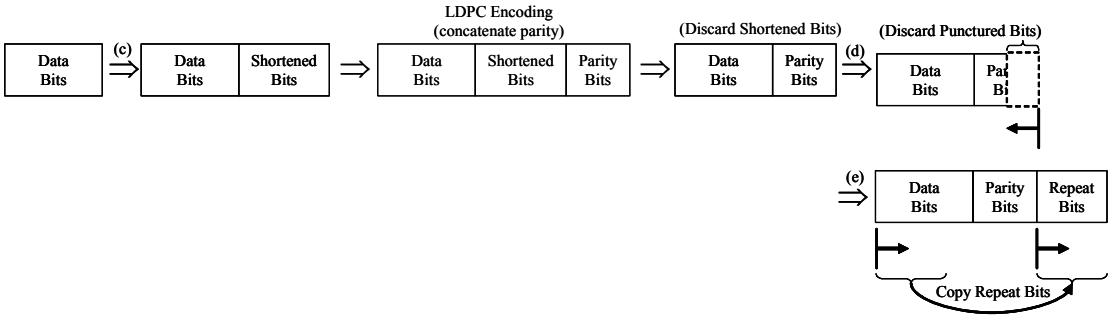

Figure n74—LDPC PPDU encoding padding and puncturing of a single codeword

f) Encode the data per, 20.3.10.6.3 (LDPC encoder), 20.3.10.6 (Low density parity check (LDPC) codes), and 20.3.10.6.4 (Parity check matrices) using the number of shortening bits per codeword as computed in step c), and puncture or repeat bits per codeword as computed per step d) and e), as illustrated in Figure n74 (LDPC PPDU encoding padding and puncturing of a single codeword).

g) Aggregate all codewords and parse per 20.3.10.6.6 (LDPC parser).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000853

Insert the following new subclause:

20.3.10.6.6 LDPC parser

The LDPC shortened and punctured codewords that result from the encoding process shall be sent in sequential fashion. Within each codeword, bit i_0 is sent first. The parsing of this encoded data stream into spatial streams shall follow exactly the parsing rules defined for the BCC encoder, as defined in 20.3.10.7.1 (Overview). However, the frequency interleaver is bypassed in 20.3.10.7.3 (Frequency interleaver).

Insert the following new subclause heading:

20.3.10.7 Data interleaver

Insert the following new subclause:

20.3.10.7.1 Overview

After coding and puncturing, the data bit streams at the output of the FEC encoders are re-arranged into blocks of $N_{CBPSS}(i_{SS})$ bits, where $i_{SS} = 1, 2, \ldots N_{SS}$ is the spatial stream index. This operation is referred to as "stream parsing" and is described in 20.3.10.7.2 (Stream parser). If BCC encoding was used, each of these blocks is then interleaved by an interleaver that is a modification of the Clause 17 interleaver.

Insert the following new subclause:

20.3.10.7.2 Stream parser

The number of bits assigned to a single axis (real or imaginary) in a constellation point in spatial stream i_{SS} is denoted by

$$s(i_{SS}) = \max\left\{1, \frac{N_{BPSCS}(i_{SS})}{2}\right\} \quad (20\text{-}43)$$

The sum of these over all streams is: $S = \sum_{i_{SS}=1}^{N_{SS}} s\left(i_{SS}\right)$.

NOTE—if equal MCS is used for all spatial streams this becomes $N_{SS} \cdot s$, where s is the number of bits for an axis common to all streams.

Consecutive blocks of $s\left(i_{SS}\right)$ bits are assigned to different spatial streams in a round robin fashion.

If two encoders are present, the output of each encoder is used alternately for each round robin cycle, i.e., at the beginning S bits from the output of first encoder are fed into all spatial streams, and then S bits from the output of second encoder are used and so on.

Input k to spatial stream i_{SS} is $y_i^{(j)}$, which is output bit i of the encoder j,

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000854

$$j = \left\lfloor \frac{k}{s(i_{SS})} \right\rfloor \bmod N_{ES} \tag{20-44}$$

$$i = \sum_{i'=1}^{i_{SS}-1} s(i') + S \cdot \left\lfloor \frac{k}{N_{ES} \cdot s(i_{SS})} \right\rfloor + k \bmod s(i_{SS}) \tag{20-45}$$

$1 \le i_{SS} \le N_{SS}$

$\lfloor x \rfloor$ is the largest integer less than or equal to x

$s \bmod t$ is the remainder resulting from the division of integer s by integer t

For $i_{SS} = 1$, the first term in Equation (20-45) has a value of 0.

Insert the following new subclause:

20.3.10.7.3 Frequency interleaver

The bits at the output of the stream parser are divided into blocks of $N_{CBPSS}(i_{SS})$, $i_{SS} = 1, 2, \ldots N_{SS}$ bits, and if BCC encoding was used, each block is interleaved by an interleaver based on the Clause 17 interleaver. This interleaver, which is based on entering the data in rows and reading it out in columns, has a different number of columns and rows depending on whether a 20 MHz channel or a 40 MHz channel is used. Table n69 (Number of rows and columns in the interleaver) defines the interleaver parameters. If LDPC encoding was used, no interleaving is performed, hence skip to 20.3.10.8 (QAM mapping) in order to map the parsed streams.

Table n69—Number of rows and columns in the interleaver

Parameter	20 MHz	40 MHz
N_{COL}	13	18
N_{ROW}	$4 \times N_{BPSCS}(i_{SS})$	$6 \times N_{BPSCS}(i_{SS})$
N_{ROT}	11	29

After the Clause 17 like operations have been applied, if more than one spatial stream exists, a third operation called frequency rotation is applied to the additional spatial streams. The parameter for the frequency rotation is N_{ROT}.

The interleaving is defined using three permutations. The first permutation is defined by the rule:

$$i = N_{ROW}\left(k \bmod N_{COL}\right) + \text{floor}\left(k / N_{COL}\right) \qquad k = 0,1,\ldots, N_{CBPSS}(i_{SS}) - 1 \tag{20-46}$$

The second permutation is defined by the rule

Not for Resale,2024-01-29 21:52:11 UTC
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000855

$$j = s(i_{SS}) \times \text{floor}\left(i / s(i_{SS})\right) + \left(i + N_{\text{CBPSS}}(i_{SS}) - \text{floor}\left(N_{\text{COL}} \times i / N_{\text{CBPSS}}(i_{SS})\right)\right) \bmod s(i_{SS}); \quad i = 0,1,\ldots, N_{\text{CBPSS}}(i_{SS}) - 1 \tag{20-47}$$

The value of $s(i_{SS})$ is determined by the number of coded bits per sub carrier:

$$s(i_{SS}) = \max(N_{BPSCS}(i_{SS})/2, 1) \tag{20-48}$$

If more that one spatial stream exists, a frequency rotation is applied to the output of the second permutation

$$r = \left(j - \left(\left((i_{ss}-1)\times 2\right) \bmod 3 + 3 \times \text{floor}\left(\left.(i_{ss}-1)\right/3\right)\right) \times N_{ROT} \times N_{BPSCS}(i_{SS})\right) \bmod N_{CBPSS}(i_{SS}); \quad j = 0,1,\ldots, N_{\text{CBPSS}}(i_{SS}) - 1 \tag{20-49}$$

where

$i_{SS} = 1, 2, \ldots, N_{SS}$ is the index of the spatial stream on which this interleaver is operating.

The deinterleaver uses the following operations to perform the inverse rotation. The index of the bit in the received block (per spatial stream) is denoted by *r*. The first permutation reverses the third (frequency rotation) permutation of the interleaver

$$j = \left(r + \left(\left((i_{ss}-1)\times 2\right) \bmod 3 + 3 \times \text{floor}\left(\left.(i_{ss}-1)\right/3\right)\right) \times N_{ROT} \times N_{BPSCS}(i_{SS})\right) \bmod N_{CBPSS}(i_{SS}); \quad r = 0,1,\ldots, N_{\text{CBPSS}}(i_{SS}) - 1 \tag{20-50}$$

The second permutation reverses the second permutation in the interleaver.

$$i = s(i_{SS}) \times \text{floor}\left(j / s(i_{SS})\right) + \left(j + \text{floor}\left(N_{COL} \times j / N_{\text{CBPSS}}(i_{SS})\right)\right) \bmod s(i_{SS}); \quad j = 0,1,\ldots, N_{\text{CBPSS}}(i_{SS}) - 1 \tag{20-51}$$

where $s(i_{SS})$ is defined in Equation (20-48).

The third permutation reverses the first permutation of the interleaver:

$$k = N_{COL} \times i - \left(N_{CBPSS}(i_{SS}) - 1\right) \times \text{floor}\left(i / N_{ROW}\right) \qquad i = 0,1,\ldots, N_{CBPSS}(i_{SS}) - 1 \tag{20-52}$$

Insert the following new subclause:

20.3.10.8 QAM mapping

The mapping between bits at the output of the interleaver and complex constellation points for BPSK, QPSK, 16-QAM and 64-QAM follows exactly the rules defined in 17.3.5.7.

Not for Resale,2024-01-29 21:52:11 UTC

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000856

The streams of complex numbers are denoted:

$$d_{k,l,n},\ k = 0,1,\ldots,N_{\mathrm{SD}}-1,\ l = 1,\ldots,N_{\mathrm{SS}},\ n = 0,1,\ldots,N_{\mathrm{SYM}}-1 \tag{20-53}$$

Insert the following new subclause:

20.3.10.8.1 Space-Time Block Coding (STBC)

This subclause defines a set of optional robust transmission rates that are applicable only when N_{STS} is greater than N_{SS} spatial streams are mapped to N_{STS} space time streams, which are mapped to N_{TX} transmit chains. These rates are based either on Space-Time Block Coding (STBC) or hybrid STBC /SM schemes. When the use of STBC is indicated in the STBC field of the HT-SIG, a symbol operation shall occur between the constellation mapper and the spatial mapper (see Figure n64 (Transmitter block diagram for the greenfield format packet and HT portion of the mixed format packet except HT signal field)) as defined in this Clause.

Denote the complex modulator symbol transmitted on data subcarrier *k* of OFDM symbols 2*m* and 2*m*+1 in spatial stream *i* as $d_{k,\,i,\,2m}$ and $d_{k,\,i,\,2m+1}$, respectively, where *m* = 0, 1, ...

Table n70 (Constellation mapper output to spatial mapper input for STBC) indicates, for each combination of N_{STS} and N_{SS}, which modulator symbol shall be transmitted during OFDM symbol period (2*m*) and (2*m*+1) from space time stream $i_{STS} = 1,\ldots,N_{STS}$.

In the following description, the complex-valued modulation symbol at the output of the STBC encoder, as given in Table n70 (Constellation mapper output to spatial mapper input for STBC), in data subcarrier *k* of OFDM symbol *m* of space time stream *i* is denoted $\tilde{d}_{k,\,i,\,m}$. If space time block coding is not applied, then $\tilde{d}_{k,\,i,\,m} = d_{k,\,i,\,m}$ and $N_{SS} = N_{STS}$.

NOTE—The specific STBC schemes for single spatial streams ($N_{SS} = 1$) with $N_{TX} \geq 3$ are not detailed in this subclause since they can be covered through the use of spatial expansion as detailed in 20.3.10.10.1 (Spatial mapping).

Insert the following new subclause:

20.3.10.9 Pilot subcarriers

In the case of 20 MHz, 4 pilot tones are inserted in the same sub-carriers used in Clause 17, i.e., in sub-carriers -21, -7, 7 and 21. The pilot sequence for the nth symbols and $i_{STS}{}^{th}$ space time stream is defined as follows:

$$\begin{aligned} P^{-28,28}_{(i_{STS},n)} = \{&0,0,0,0,0,0,0,\Psi^{(N_{STS})}_{i_{STS},n\oplus 4},0,0,0,0,0,0,0,0,0,0,0,0,0,0,\Psi^{(N_{STS})}_{i_{STS},(n+1)\oplus 4},0,0,0,0,0,0,0,\\ &0,0,0,0,0,0,\Psi^{(N_{STS})}_{i_{STS},(n+2)\oplus 4},0,0,0,0,0,0,0,0,0,0,0,0,0,\Psi^{(N_{STS})}_{i_{STS},(n+3)\oplus 4},0,0,0,0,0,0,0\} \end{aligned} \tag{20-54}$$

In the case of 40 MHz transmission (excluding MCS 32, see 20.3.10.10.4 (Transmission in HT duplicate format)), pilot signals are inserted in sub-carriers -53, -25, -11, 11, 25, 53. The pilot sequence for the nth symbols and $i_{STS}{}^{\mathrm{th}}$ space time stream is defined as follows

Exhibit 1014
Page 000858

NOTE—For each space time stream there is a different pilot pattern and the pilot patterns are cyclically rotated over symbols.

The basic patterns are also different according to the total number of space time streams for the packet.

The patterns $\Psi_{i_{STS},n}^{(N_{STS})}$ are defined in Table n71 (pilot values for 20 MHz transmission) and Table n72 (Pilots values for 40 MHz transmission (excluding MCS 32)). The first table (Table n71 (pilot values for 20 MHz transmission)) defines the values for 20 MHz transmission and the second table (Table n72 (Pilots values for 40 MHz transmission (excluding MCS 32))) defines the values for 40 MHz transmission.

Table n71—pilot values for 20 MHz transmission

N_{STS}	i_{STS}	$\Psi_{i_{STS},0}^{(N_{STS})}$	$\Psi_{i_{STS},1}^{(N_{STS})}$	$\Psi_{i_{STS},2}^{(N_{STS})}$	$\Psi_{i_{STS},3}^{(N_{STS})}$

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000859

Insert the following new subclause:

20.3.10.10 OFDM modulation

The time domain signal is composed from the stream of complex numbers

$$\tilde{d}_{k,l,n},\ k = 0,1,\ldots,N_{\mathrm{SD}}-1,\ l = 1,\ldots,N_{\mathrm{STS}},\ n = 0,1,\ldots,N_{\mathrm{SYM}}-1 \qquad (20\text{-}56)$$

and from the pilot signals. In the case of 40 MHz transmission, the upper sub-carriers are rotated 90° relative to the lower sub-carriers.

Insert the following new subclause:

20.3.10.10.1 Spatial mapping

The transmitter may choose to rotate and/or scale the constellation mapper output vector (or the space time block coder output, if applicable). This is useful in the following cases:

— there are more transmit chains than space time streams, $N_{STS} < N_{TX}$,
— as part of (an optional) sounding packet,
— as part of (an optional) calibration procedure,
— when the packet is in (an optional) beamforming mode.

If the data to be transmitted on sub-carrier k on space time stream i_{STS} is $X_k^{(i_{STS})}$, then the transmitted data on the transmit chain i_{TX} shall be:

$$r_{Field}^{(i_{TX})}(t) = \frac{1}{\sqrt{N_{STS}\cdot N_{Field}^{Tone}}}\, w_{T_{Field}}(t) \sum_k \sum_{i_{STS}=1}^{N_{STS}} \left[Q_k\right]_{i_{TX},i_{STS}} X_k^{(i_{STS})} \exp\left(j2\pi k\Delta_F \left(t - T_{CS}^{i_{STS}}\right)\right) \qquad (20\text{-}57)$$

where

$\left[Q_k\right]_{i_{TX},i_{STS}}$ is the element in the i_{TX}'th row and i_{STS}'th column in a matrix Q_k with N_{TX} rows and N_{STS} columns. Q_k may be frequency dependent.

Below are some examples of spatial mapping matrices that can be used. There exist many other alternatives, implementation is not restricted to the spatial mapping matrices shown.

a) *Direct Mapping*: in this case Q_k is a diagonal matrix of unit magnitude complex values that can take two forms:
   1) $Q_k = \mathbf{I}$, the identity matrix
   2) A CSD matrix in which the diagonal elements represent cyclic shifts in the time domain: $\left[Q_k\right]_{i,i} = \exp(-j2\pi k\Delta_F \tau_{CS}^{i})$, where tau τ_{CS}^{i} represents the CSD applied.

b) *Spatial Expansion:* in this case Q_k is the product of a CSD matrix and a square matrix formed of orthogonal columns. As an illustration:
   1) Q_k may be the product of a CSD matrix and a square unitary matrix such as the Hadamard matrix or the Fourier matrix.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000860

2) the spatial expansion may be performed by duplicating some of the N_{STS} streams to form the N_{TX} streams, with each stream being scaled by the normalization factor $\sqrt{\frac{N_{STS}}{N_{TX}}}$. The spatial expansion may be performed by using for instance one of the following matrices, denoted D, left multiplied by a CSD matrix, denoted $M_{CSD}(k)$, and/or possibly multiplied by any square unitary matrix. The resulting spatial mapping matrix is then $Q_k = M_{CSD}(k) \cdot D$, where D may take on one of the following values:

i) N_{TX}=2, N_{STS}=1, $D = \frac{1}{\sqrt{2}}\begin{bmatrix}1 & 1\end{bmatrix}^T$

ii) N_{TX}=3, N_{STS}=1, $D = \frac{1}{\sqrt{3}}\begin{bmatrix}1 & 1 & 1\end{bmatrix}^T$

iii) N_{TX}=4, N_{STS}=1, $D = \frac{1}{2}\begin{bmatrix}1 & 1 & 1 & 1\end{bmatrix}^T$

iv) N_{TX}=3, N_{STS}=2, $D = \sqrt{\frac{2}{3}}\begin{bmatrix}1 & 0\\ 0 & 1\\ 1 & 0\end{bmatrix}$

v) N_{TX}=4, N_{STS}=2, $D = \frac{1}{\sqrt{2}}\begin{bmatrix}1 & 0\\ 0 & 1\\ 1 & 0\\ 0 & 1\end{bmatrix}$

vi) N_{TX}=4, N_{STS}=3, $D = \frac{\sqrt{3}}{2}\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\\ 1 & 0 & 0\end{bmatrix}$

3) Different Spatial Expansion over sub-carriers—this should be used in HT mixed format only and with the smoothing bit set to 0:

i) N_{TX}=2, N_{STS}=1, $\left[Q_k\right]_{N_{STS}} = \begin{bmatrix}1 & 0\end{bmatrix}^T$ *or* $\left[Q_k\right]_{N_{STS}} = \begin{bmatrix}0 & 1\end{bmatrix}^T$

ii) N_{TX}=3, N_{STS}=2, $\left[Q_k\right]_{N_{STS}} = \begin{bmatrix}1 & 0\\ 0 & 0\\ 0 & 1\end{bmatrix}, \begin{bmatrix}1 & 0\\ 0 & 1\\ 0 & 0\end{bmatrix}$ *or* $\begin{bmatrix}0 & 0\\ 1 & 0\\ 0 & 1\end{bmatrix}$

iii) N_{TX}=4, N_{STS}=2, $[Q_k]_{N_{STS}} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix}$ *or* $\begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}$

iv) N_{TX}=4, N_{STS}=3, $[Q_k]_{N_{STS}} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ *or* $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

c) *Beamforming Steering Matrix:* In this case, Q_k is any matrix that improves the reception in the receiver based on some knowledge of the channel between the transmitter and the receiver. With transmit beamforming with explicit feedback, the steering matrix Q_k is determined using either H_{eff} for CSI feedback or V_k for Non-Compressed and Compressed Matrices feedback from the STA to which the beamformed packet is addressed.

In the case where there are fewer space time streams than transmit chains, the first N_{STS} columns of the matrices above that are square can be used.

The same matrix Q_k shall be applied to subcarrier k during all parts of the packet in greenfield format and all parts of the packet following and including the HT-STF field in an HT mixed format packet. This operation is transparent to the receiver.

If 95 percent of the sum of the energy from all impulse responses of the time domain channels between all space time streams and all transmit chain inputs, induced by the CSD added according to Table n62 (Cyclic shift values of HT portion of the packet) and the frequency-dependence in the matrix Q_k, is contained within 800 ns, the smoothing bit should be set to 1, otherwise it shall be set to 0.

The CSD of Table n62 (Cyclic shift values of HT portion of the packet) shall be applied at the input of the spatial mapper.

If no spatial mapping is applied, the matrix Q_k is equal to the identity matrix and $N_{STS} = N_{TX}$.

Sounding PPDUs using spatial expansion shall use unitary Q_k.

Insert the following new subclause:

20.3.10.10.2 Transmission in 20 MHz HT format

Exhibit 1014
Page 000865

Insert the following new subclause:

20.3.11 Beamforming

Beamforming is a technique in which the transmitter utilizes the knowledge of the MIMO channel to generate a steering matrix Q_k that improves reception in the receiver.

The equivalent complex baseband MIMO channel model is one in which when a vector $\mathbf{x}_k = \left[x_1, x_2, \ldots, x_{N_{TX}} \right]^T$ is transmitted in subcarrier k the received vector $\mathbf{y}_k = \left[y_1, y_2, \ldots, y_{N_{RX}} \right]^T$ is modeled as:

$$\mathbf{y}_k = H_k \mathbf{x}_k + \mathbf{n} \tag{20-62}$$

where

H_k is channel matrix of dimensions $N_{RX} \times N_{TX}$

n is white (spatially and temporally) Gaussian noise. This is illustrated in Figure n75 (The beamforming MIMO channel model).

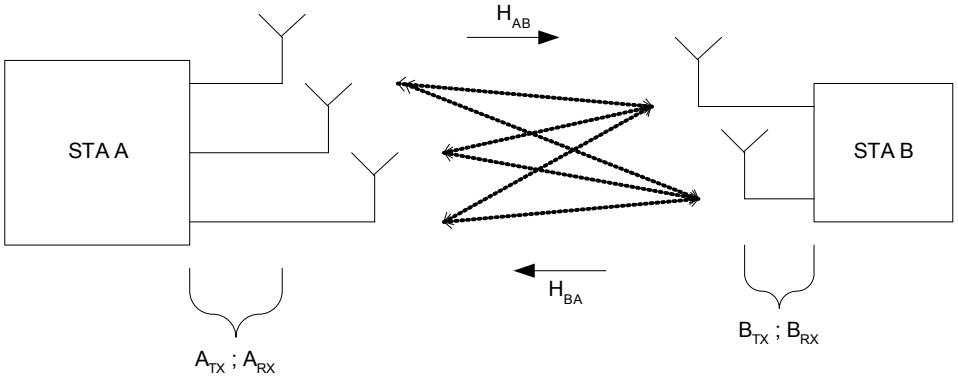

Figure n75—The beamforming MIMO channel model

When beamforming is used, the transmitter replaces $\mathbf{x}_k$, which in this case has $N_{STS} \le N_{TX}$ elements, with $Q_k \mathbf{x}_k$, where Q_k has N_{TX} rows and N_{STS} columns, so that the received vector is

$$\mathbf{y}_k = H_k Q_k \mathbf{x}_k + \mathbf{n} \tag{20-63}$$

The beamforming steering matrix that is computed (or updated) from a new channel measurement replaces the existing Q_k for the next beamformed data transmission. There are several methods of beamforming, differing in the way the transmitter acquires the knowledge of the channel matrices H_k and on whether the transmitter or the receiver generates Q_k.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000866

Insert the following new subclause:

20.3.11.1 Implicit feedback beamforming

Implicit beamforming is a technique that relies on reciprocity in the time division duplex channel to estimate the channel that a device is transmitting over based on MIMO reference received from the device to which it plans to transmit. This allows the transmitting device to calculate a set of transmit steering matrices, Q_k, one for each subcarrier, which are intended to optimize the performance of the link.

Referring to Figure n75 (The beamforming MIMO channel model) beamforming transmissions from a STA A to a STA B using implicit techniques are enabled when STA B sends STA A a sounding PPDU, allowing STA A to form an estimate of the MIMO channel from STA B to STA A, for all subcarriers. For a TDD channel in which the forward and reverse channels are reciprocal, the channel from STA A to STA B in subcarrier k is the matrix transpose of the channel from STA B to STA A in subcarrier k, to within a complex scaling factor, i.e., $H_{\mathrm{AB},\,k} = \rho H_{\mathrm{BA},\,k}$. Here $H_{\mathrm{AB},\,k}$ is the MIMO channel matrix from STA A to STA B at subcarrier k, and $H_{\mathrm{BA},\,k}$ is the channel matrix from STA B to STA A at subcarrier k. STA A uses this relationship to compute transmit steering matrices that are suitable for transmitting to STA B over $H_{\mathrm{AB},\,k}$.

When the over-the-air channel between the antenna(s) at one STA and the antenna(s) at a second STA is reciprocal, the observed baseband-to-baseband channel used for communication may not be, as it includes the transmit and receive chains of the STAs. Differences in the amplitude and phase characteristics of the transmit and receive chains associated with individual antennas degrade the reciprocity of the over-the-air channel, and cause degradation of performance of implicit beamforming techniques. The over-the-air calibration procedure described in subclause 9.17.2.4 (Calibration) may be used to restore reciprocity. The procedure provides the means for calculating a set of correction matrices that can be applied at the transmit side of a STA to correct the amplitude and phase differences between the transmit and receive chains in the STA. If this is done in both the STAs that are communicating with each other, reciprocity is restored in the baseband-to-baseband response of the forward and reverse channels.

Figure n76 (The baseband-to-baseband channel) illustrates the observed baseband-to-baseband channel, including reciprocity correction. The amplitude and phase responses of the transmit and receive chains can be expressed as diagonal matrices with complex valued diagonal entries, of the form $A_{\mathrm{TX(RX)},\,k}$. The relationship between the baseband-to-baseband channel, $\tilde{H}_{\mathrm{AB},\,k}$, and the over-the-air channel, $H_{\mathrm{AB},\,k}$, is

$$\tilde{H}_{\mathrm{AB},\,k} = B_{\mathrm{RX},\,k} H_{\mathrm{AB},\,k} A_{\mathrm{TX},\,k} \tag{20-64}$$

and, similarly, the relationship between $\tilde{H}_{\mathrm{BA},\,k}$ and $H_{\mathrm{BA},\,k}$ is

$$\tilde{H}_{\mathrm{BA},\,k} = A_{\mathrm{RX},\,k} H_{\mathrm{BA},\,k} B_{\mathrm{TX},\,k} \tag{20-65}$$

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000867

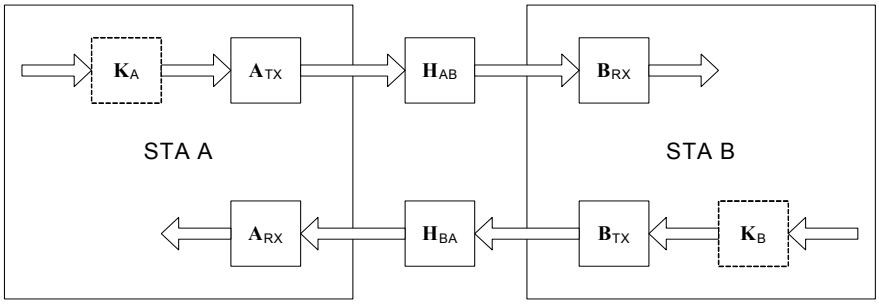

Figure n76—The baseband-to-baseband channel

As an example, consider the case where calibration is performed at both STA A and STA B. The objective is to compute correction matrices, $K_{\mathrm{A},\,k}$ and $K_{\mathrm{B},\,k}$, that restore reciprocity such that

$$\tilde{H}_{\mathrm{AB},\,k}K_{\mathrm{A},\,k} = \rho[\tilde{H}_{\mathrm{BA},\,k}K_{\mathrm{B},\,k}]^{\mathrm{T}} \tag{20-66}$$

The correction matrices are diagonal matrices with complex valued diagonal entries. The reciprocity condition above is enforced when

$$K_{\mathrm{A},\,k} = \alpha_{\mathrm{A},\,k}[A_{\mathrm{TX},\,k}]^{-1}A_{\mathrm{RX},\,k} \tag{20-67}$$

and

$$K_{\mathrm{B},\,k} = \alpha_{\mathrm{B},\,k}[B_{\mathrm{TX},\,k}]^{-1}B_{\mathrm{RX},\,k} \tag{20-68}$$

where $\alpha_{\mathrm{A},\,k}$ and $\alpha_{\mathrm{B},\,k}$ are complex valued scaling factors.

Using these expressions for the correction matrices, the calibrated baseband-to-baseband channel between STA A and STA B is expressed as

$$\hat{H}_{\mathrm{AB},\,k} = \tilde{H}_{\mathrm{AB},\,k}K_{\mathrm{A},\,k} = \alpha_{\mathrm{A},\,k}B_{\mathrm{RX},\,k}H_{\mathrm{AB},\,k}A_{\mathrm{RX},\,k} \tag{20-69}$$

and if both sides apply the correction matrices, then we have that

$$\hat{H}_{\mathrm{BA},\,k} = \alpha_{\mathrm{B},\,k}A_{\mathrm{RX},\,k}H_{\mathrm{BA},\,k}B_{\mathrm{RX},\,k} = \frac{\alpha_{\mathrm{B},\,k}}{\alpha_{\mathrm{A},\,k}}[\hat{H}_{\mathrm{AB},\,k}]^{\mathrm{T}} \tag{20-70}$$

Focusing on STA A, the procedure for estimating $K_{\mathrm{A},\,k}$ is as follows:

a)STA A sends STA B a sounding PPDU, allowing STA B to estimate the channel matrices $\tilde{H}_{\mathrm{AB},\,k}$.

b)STA B sends STA A a sounding PPDU, allowing STA A to estimate the channel matrices $\tilde{H}_{\mathrm{BA},\,k}$.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000868

c)STA B sends the quantized estimates of $\tilde{H}_{\mathrm{AB},\,k}$ to STA A.

d)STA A uses its local estimates of $\tilde{H}_{\mathrm{BA},\,k}$ and the quantized estimates $\tilde{H}_{\mathrm{AB},\,k}$ received from STA B to compute the correction matrices $K_{\mathrm{A},\,k}$.

Steps a) and b) occur over a short time interval to ensure that the channel changes as little as possible between measurements. A similar procedure is used to estimate $K_{\mathrm{B},\,k}$ at STA B. The details of the computation of the correction matrices is implementation specific, and beyond the scope of this document.

Insert the following new subclause:

20.3.11.2 Explicit feedback beamforming

In explicit beamforming, in order for STA A to transmit a beamformed packet to STA B, STA B measures the channel matrices and sends STA A, either the effective channel, $H_{\mathrm{eff},k}$, or the beamforming feedback matrix, V_k for STA A to determine a steering matrix, $Q_{\mathrm{steer},k} = Q_k V_k$, with V_k found from $H_k Q_k$, where Q_k is the orthonormal spatial mapping matrix which was used to transmit the sounding packet that elicited the V_k feedback. When new steering matrix $Q_{\mathrm{steer},\,k}$ is found, $Q_{\mathrm{steer},\,k}$ may replace Q_k for the next beamformed data transmission.

Note - $Q_{\mathrm{steer},\,k}$ is a mathematical term to update a new steering matrix for Q_k in the next beamformed data transmission.

Insert the following new subclause:

20.3.11.2.1 CSI Matrices feedback

In CSI Matrices feedback the transmitting STA receives the quantized MIMO channel matrix, H_{eff}, from the receiving STA. The transmitting STA then may use this matrix to compute a set of transmit steering matrices, Q_k. The CSI matrix, H_{eff}, shall be determined from the transmitter spatial mapper input to the receiver FFT outputs (the beamformee removes the CSD in table n67 from the measured channel matrix).

The matrices $H_{eff}(k)$, where k is the subcarrier index, are encoded so that applying the procedure below will optimally reconstruct the matrix.

The received, quantized, matrix $H^{q}_{eff}(k)$ (of a specific subcarrier, k) shall be decoded as follows:

d) The real and imaginary parts of each element of the matrix $H^{q(R)}_{eff(m,\,l)}(k)$ and $H^{q(I)}_{eff(m,\,l)}(k)$ shall be decoded as a pair of two's complement numbers to create the complex element. Each element in the matrix of subcarrier k is then scaled using the value in the carrier matrix amplitude field (3 bits), $M_H(k)$, interpreted as a positive integer in dB, as follows:

   1) Calculate the linear value as defined in Equation (20-71), and
   2) Calculate decoded values of the real and imaginary parts of the matrix element as defined in Equation (20-72) and Equation (20-73).

$$r(k) = 10^{M_H(k)/20}. \quad (20\text{-}71)$$

$$\mathrm{Re}\{\tilde{H}_{eff(m,l)}(k)\} = \frac{H^{q(R)}_{eff(m,l)}(k)}{r(k)} \quad (20\text{-}72)$$

$$\mathrm{Im}\{\tilde{H}_{eff(m,l)}(k)\} = \frac{H^{q(I)}_{eff(m,l)}(k)}{r(k)} \quad (20\text{-}73)$$

The following is an example of an encoding process:

a) The maximum of the real part and the imaginary part of each element of the matrix in each subcarrier are found, as defined by Equation (20-74).

$$m_H(k) = \max\left\{\max\left\{\left|\mathrm{Re}(H_{eff(m,l)}(k))\right|_{m=1,l=1}^{m=N_r,l=N_c}\right\}, \max\left\{\left|\mathrm{Im}(H_{eff(m,l)}(k))\right|_{m=1,l=1}^{m=N_r,l=N_c}\right\}\right\} \quad (20\text{-}74)$$

b) The scaling ratio is calculated and quantized to 3 bits as defined by Equation (20-75) and its linear counterpart is given by Equation (20-76).

$$M_H(k) = \min\left\{7, \left\lfloor 20\log_{10}\left(\frac{\max\{m_H(k)\}_{k=-N_{SR}}^{k=N_{SR}}}{m_H(k)}\right)\right\rfloor\right\}, \quad (20\text{-}75)$$

where

$\lfloor x \rfloor$ is the largest integer smaller than or equal to x.

$$:M^{\mathrm{lin}}_H(k) = \frac{\max\{m_H(k)\}_{k=-N_{SR}}^{k=N_{SR}}}{10^{M_H(k)/20}} \quad (20\text{-}76)$$

c) The real and imaginary parts of each element in the matrix $H_{eff(m,l)}(k)$ are quantized to N_b bits in two's complement encoding as defined by Equation (20-77) and Equation (20-78).

$$H^{q(R)}_{eff(m,l)}(k) = \mathrm{round}\left(\frac{\mathrm{Re}\{H_{eff(m,l)}(k)\}}{M^{\mathrm{lin}}_H(k)}(2^{N_b-1}-1)\right) \quad (20\text{-}77)$$

$$H^{q(I)}_{eff(m,l)}(k) = \mathrm{round}\left(\frac{\mathrm{Im}\{H_{eff(m,l)}(k)\}}{M^{\mathrm{lin}}_H(k)}(2^{N_b-1}-1)\right) \quad (20\text{-}78)$$

Each matrix is encoded using $3 + 2 \times N_b \times N_r \times N_c$ bits, where N_r and N_c are the number of rows and

columns, respectively, in the channel matrix estimate computed by the receiving station, and N_b may have the value of 4, 5, 6, 8 bits.

Insert the following new subclause:

20.3.11.2.2 Non-compressed beamforming matrix feedback

In non compressed beamforming matrix feedback, the receiving STA removes the space-time stream CSD in 62 (Cyclic shift values of HT portion of the packet) from the measured channel before computing a set of matrices for feedback to the transmitter. These matrices are sent to the transmitter. The transmitter can use these matrices to determine the steering matrices Q_k.

The beamformee shall encode the matrices $V(k)$ so a beamformer applying the procedure below will optimally reconstruct the matrix.

The received matrix $V^q(k)$ (of a specific subcarrier k) shall be decoded as follows:

d) The real and imaginary parts of each element of the matrix, $V_{m,l}^{q,R}$ and $V_{m,l}^{q,I}$, shall be decoded as a pair of two's complement numbers to create the complex element.

The dimensions of the beamforming matrices is $N_r \times N_c$, where N_r and N_c are the number of rows and columns, respectively, in the beamforming matrix computed by the receiving station. Each matrix is encoded using $2 \times N_b \times N_r \times N_c$ bits. N_b may have the value of 4, 5, 6, 8 bits.

Columns $1 \ldots Nc$ of the beamforming feedback matrix correspond to spatial streams $1 \ldots Nc$, respectively. Spatial stream to modulation mapping is defined in the MCS Tables in 20.6 (Rate dependent parameters for HT Modulation and Coding Schemes (MCS)). A transmitter shall not re-order the columns of the beamforming feedback matrices.

Insert the following new subclause:

20.3.11.2.3 Compressed beamforming matrix feedback

In compressed beamforming matrix feedback, the receiving STA removes the space-time stream CSD in Table n62 (Cyclic shift values of HT portion of the packet) from the measured channel before computing a set of matrices for feedback to the transmitter. These matrices are compressed in the form of angles, which are sent to the transmitter. The transmitter can use these angles to de-compress the matrices and determine the steering matrices Q_k.

The matrix compression is defined as follows. The unitary beamforming $N_r \times N_c$ matrix V found by the beamformee shall be represented as:

$$V = \left[\prod_{i=1}^{\min(N_c, N_r - 1)} \left[D_i \left(1_{i-1} \quad e^{j\phi_{i,i}} \quad \ldots \quad e^{j\phi_{N_r-1,i}} \quad 1 \right) \prod_{l=i+1}^{N_r} G_{li}^T \left(\psi_{li} \right) \right] \right] \tilde{I}_{N_r \times N_c} \tag{20-79}$$

The matrix $D_i \left(1_{i-1} \quad e^{j\phi_{i,i}} \quad \ldots \quad e^{j\phi_{N_r-1,i}} \quad 1 \right)$ is an $N_r \times N_r$ diagonal matrix, where 1_{i-1} represents a

sequence of ones with length of *i*-1, as follows:

$$D_i\left(1_{i-1} \quad e^{j\phi_{1,i}} \quad \ldots \quad e^{j\phi_{N_r-1,i}} \quad 1\right)=\begin{bmatrix} I_{i-1} & 0 & \cdots & \cdots & 0 \\ 0 & e^{j\phi_{1,i}} & 0 & \cdots & 0 \\ \vdots & 0 & \ddots & 0 & 0 \\ \vdots & \vdots & 0 & e^{j\phi_{N_r-1,i}} & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \tag{20-80}$$

The matrix $G_{li}(\psi)$ is an $N_r \times N_r$ Givens rotation matrix:

$$G_{li}(\psi)=\begin{bmatrix} I_{i-1} & 0 & 0 & 0 & 0 \\ 0 & \cos(\psi) & 0 & \sin(\psi) & 0 \\ 0 & 0 & I_{l-i-1} & 0 & 0 \\ 0 & -\sin(\psi) & 0 & \cos(\psi) & 0 \\ 0 & 0 & 0 & 0 & I_{N_r-l} \end{bmatrix} \tag{20-81}$$

where each I_m is an $m \times m$ identity matrix, and $\cos(\psi)$ and $\sin(\psi)$ are located at l^{th} and i^{th} row and column. $\tilde{I}_{N_r \times N_c}$ is an identity matrix padded with zeros to fill the additional rows or columns when $N_r \neq N_c$.

For example, a 4x2 V matrix has the following representation:

$$V=\begin{bmatrix} e^{j\phi_{11}} & 0 & 0 & 0 \\ 0 & e^{j\phi_{21}} & 0 & 0 \\ 0 & 0 & e^{j\phi_{31}} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\times\begin{bmatrix} \cos\psi_{21} & \sin\psi_{21} & 0 & 0 \\ -\sin\psi_{21} & \cos\psi_{21} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}^T\begin{bmatrix} \cos\psi_{31} & 0 & \sin\psi_{31} & 0 \\ 0 & 1 & 0 & 0 \\ -\sin\psi_{31} & 0 & \cos\psi_{31} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}^T\begin{bmatrix} \cos\psi_{41} & 0 & 0 & \sin\psi_{41} \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\sin\psi_{41} & 0 & 0 & \cos\psi_{41} \end{bmatrix}^T$$
$$\times\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & e^{j\phi_{22}} & 0 & 0 \\ 0 & 0 & e^{j\phi_{32}} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\times\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\psi_{32} & \sin\psi_{32} & 0 \\ 0 & -\sin\psi_{32} & \cos\psi_{32} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}^T\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\psi_{42} & 0 & \sin\psi_{42} \\ 0 & 0 & 1 & 0 \\ 0 & -\sin\psi_{42} & 0 & \cos\psi_{42} \end{bmatrix}^T\times\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \tag{20-82}$$

The procedure for finding a compressed V matrix is described as follows:

A unitary $N_r \times N_c$ beamforming matrix V is column-wise phase invariant because the steering matrix needs a reference in phase per each column. This means V may be equivalent to $\tilde{V}\tilde{D}$, where $\tilde{D}$ is a column-wise phase shift matrix such as $\tilde{D}=\text{diag}\left(e^{j\theta_1}, e^{j\theta_2}, \ldots, e^{j\theta_{N_c}}\right)$. When the beamformee estimates the chan-

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000872

nel, it may find $\tilde{V}$ for the beamforming matrix for the beamformer, but it should send $\tilde{V}\tilde{D}$ back to the beamformer, where $V = \tilde{V}\tilde{D}$. The angle, θ_i, in $\tilde{D}$ is found to make the last row of $\tilde{V}\tilde{D}$ to be non-negative real numbers.

The angles $\phi_{1,1} \ldots \phi_{N_r-1,1}$ in the diagonal matrix $D_1\left(e^{j\phi_{11}} \quad \ldots \quad e^{j\phi_{N_r-1,1}} \quad 1\right)^*$ may be found to make the first column of $D_1^* V$ to all be non-negative real numbers. Now, the first column of $(G_{N_r 1} \ldots G_{31} G_{21} D_1^*) \times V$ can be $\begin{bmatrix}1 & 0 & \ldots & 0\end{bmatrix}^T$ by Givens rotation G_{l1} 's such as.

$$\begin{bmatrix} \cos\psi_{N_r 1} & 0 & 0 & \sin\psi_{N_r 1} \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\sin\psi_{N_r 1} & 0 & 0 & \cos\psi_{N_r 1} \end{bmatrix} \cdots \begin{bmatrix} \cos\psi_{31} & 0 & \sin\psi_{31} & 0 \\ 0 & 1 & 0 & 0 \\ -\sin\psi_{31} & 0 & \cos\psi_{31} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos\psi_{21} & \sin\psi_{21} & 0 & 0 \\ -\sin\psi_{21} & \cos\psi_{21} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} e^{j\phi_{11}} & 0 & 0 & 0 \\ 0 & \ddots & 0 & 0 \\ 0 & 0 & e^{j\phi_{N_r-1,1}} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}^* \times V = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & & & \\ 0 & & V_2 & \\ 0 & & & \end{bmatrix} \tag{20-83}$$

For a new $(N_r - 1) \times (N_c - 1)$ submatrix V_2, this process may be applied in the same way. Then, the angles $\phi_{2,2} \ldots \phi_{N_r-1,2}$ in the diagonal matrix $D_2\left(1 \quad e^{j\phi_{22}} \quad \ldots \quad e^{j\phi_{N_r-1,2}} \quad 1\right)^*$ may be found to make the second column of $D_2^* \times \mathrm{diag}(1, V_2)$ to be all non-negative real numbers. Now, the first two columns of $(G_{N_r 2} \ldots G_{32} D_2^*)(G_{N_r 1} \ldots G_{31} G_{21} D_1^*) \times V$ can be $\tilde{I}_{N_r \times 2}$ by Givens rotation G_{l2}s such as

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\psi_{N_r 2} & 0 & \sin\psi_{N_r 2} \\ 0 & 0 & 1 & 0 \\ 0 & -\sin\psi_{N_r 2} & 0 & \cos\psi_{N_r 2} \end{bmatrix} \cdots \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\psi_{32} & \sin\psi_{32} & 0 \\ 0 & -\sin\psi_{32} & \cos\psi_{32} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & e^{j\phi_{22}} & 0 & 0 \\ 0 & 0 & e^{j\phi_{N_r-1,2}} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}^* \times G_{N_r 1} \ldots G_{31} G_{21} D_1^* \times V = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & & \\ 0 & 0 & V_3 & \end{bmatrix} \tag{20-84}$$

This process may continue until the first N_c columns of the right side matrix become $\tilde{I}_{N_r \times N_c}$. When $N_c < N_r$, this process does not need to continue because V_{N_c+1} will be nulled out by $\tilde{I}_{N_r \times N_c}$. Then, by multiplying the complex conjugate transpose of the products of the D_i 's and G_{li} 's on the left, V can be expressed as

$$V = D_1 G_{21}^T G_{31}^T \ldots G_{N_r 1}^T \times D_2 G_{32}^T G_{42}^T \ldots G_{N_r 2}^T \times \ldots \times D_p G_{p+1,p}^T G_{p+2,p}^T \ldots G_{N_r p}^T \times \tilde{I}_{N_r \times N_c}, \tag{20-85}$$

where $p = \min(N_c, N_r - 1)$, which can be written in short form as in Equation (20-79).

The angles found from the decomposition process above, e.g., ψ 's and ϕ 's, shall be quantized as described in 7.4.9.8 (MIMO Compressed Beamforming frame format).

Columns $1 \ldots N_c$ of the beamforming feedback matrix correspond to spatial streams $1 \ldots N_c$, respectively. Spatial stream to modulation mapping is defined in the MCS Tables in 20.6 (Rate dependent parameters for HT Modulation and Coding Schemes (MCS)). A transmitter shall not re-order the columns of the beamforming feedback matrices in determining steering matrices.

Insert the following new subclause:

20.3.12 HT Preamble format for sounding PPDUs

The MIMO channel measurement takes place in every PPDU as a result of transmitting the HT-LTFs as part of the PLCP preamble. At a minimum, the number of HT-LTFs transmitted shall be equal to the number of space time streams transmitted, and these are transmitted using the same spatial transformation that is used for the HT-Data. This enables the computation of the spatial equalization at the receiver.

When the number of space time streams, N_{STS}, is less than the number of transmit antennas, or less than $\min(N_{TX}, N_{RX})$, sending only N_{STS} HT-LTFs does not allow the receiver to recover a full characterization of the MIMO channel, even though the resulting MIMO channel measurement is sufficient for receiving the HT-Data.

However, there are several cases where it is desirable to obtain as full a characterization of the channel as is possible, thus requiring the transmission of a sufficient number of HT-LTFs to sound the full dimensionality of the channel, which is in some cases N_{TX}, and in other cases $\min(N_{TX}, N_{RX})$. These cases of MIMO channel measurement are referred to as MIMO channel sounding. A sounding packet may be used to sound available channel dimensions. A sounding PPDU is identified by setting the Not Sounding field in the HT-SIG to zero. A sounding PPDU may have any allowed number of HT-LTFs satisfying $N_{LTF} \geq N_{STS}$. In general, if the Not Sounding field in the HT-SIG is set to zero and $N_{LTF} > N_{STS}$, extension HT-LTFs are used, except for the case where $N_{SS} = 3$ and $N_{LTF} = 4$ or in an NDP.

Even if N_{ESS} =0 in a sounding packet, the Not Sounding field shall be set to zero.

20.3.12.1 Sounding with a Null Data Packet

An STA may sound the channel using a Null Data Packet (NDP) (indicated by zero in the Length field in the HT-SIG) with the Not Sounding field set to 0. The number of LTFs is the number implied by the MCS, which shall indicate two or more spatial streams. The last HT-LTF of an NDP shall not be followed by a Data field (see Figure n77 (Example of an NDP used for sounding)).

It is optional for a STA to process an NDP.

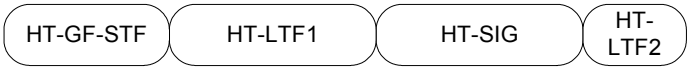

Figure n77—Example of an NDP used for sounding

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000874

Insert the following new subclause:

20.3.12.2 Sounding PPDU for calibration

In the case of a bidirectional calibration exchange, two STAs exchange sounding PPDUs, enabling the receiving STA to compute an estimate of the MIMO channel matrix H_k for each sub-carrier *k*. In general, in an exchange of calibration messages, the number of spatial streams is less than the number of transmit antennas, necessitating the use of extension HT-LTFs. In the case of sounding PPDUs for calibration, the antenna mapping matrix shall be

$$Q_k = C_{CSD}(k)P_{CAL} \tag{20-86}$$

where

$C_{CSD}(k)$ is a diagonal cyclic shift matrix in which the diagonal elements carry frequency-domain representation of the cyclic shifts given in Table n61 (Cyclic shift for non-HT portion of the packet) and

P_{CAL} is one of the following unitary matrices:For $N_{TX} = 1, P_{CAL} = 1$

For $N_{TX} = 2, P_{CAL} = \frac{\sqrt{2}}{2}\begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}$

For $N_{TX} = 3, P_{CAL} = \frac{\sqrt{3}}{3}\begin{bmatrix} 1 & 1 & 1 \\ 1 & e^{-j2\pi/3} & e^{-j4\pi/3} \\ 1 & e^{-j4\pi/3} & e^{-j2\pi/3} \end{bmatrix}$

For $N_{TX} = 4, P_{CAL} = \frac{1}{2}\begin{bmatrix} 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \\ -1 & 1 & 1 & 1 \end{bmatrix}$.

Insert the following new subclause:

20.3.12.3 Sounding PPDU for channel quality assessment

In response to the reception of an MCS Request (MRQ), sent by STA A to STA B, the responding STA B returns to the initiating STA A an MCS selection that the responding STA B determines to be a suitable MCS for the initiating STA A to use in subsequent transmissions to the responding STA B. In determining the MCS, the responding STA B performs a channel quality assessment, which entails using whatever information the responding STA B has about the channel, such as an estimate of the MIMO channel derived from the sounding PPDU that carries the MRQ. To enable this calculation, the MRQ should be sent in conjunction with a sounding PPDU (either in a sounding PPDU, or in a PPDU in which the NDP announcement bit in the HT Control field is set to 1, and which is followed by an NDP.)

The STA sending the MRQ (STA A) determines how many HT-LTFs to send, and whether to use extension HT-LTFs or an NDP, based on the number of space time streams used in the PPDU carrying the MRQ, the

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000875

number of transmit chains it is using (N_{TX}), whether or not the transmit and receive stations support STBC, and in some cases, the number of receive chains at the responding STA (N_{RX}).

The maximum number of available space-time streams is set by the number of transmit and receive chains, and the STBC capabilities of the transmitter and receiver, as is shown in Table n73 (Maximum available space-time streams). While the number of receive chains at a STA is not communicated in a capabilities indicator, the maximum number of space time streams supported may be inferred from the MCS capabilities and the STBC capabilities of the receiving STA. When the number of receive chains is known at the transmitter, the number of HT-LTFs sent to obtain a full channel quality assessment is determined according to the maximum number of space-time streams indicated in Table n73 (Maximum available space-time streams). The number of HT-LTFs to use in conjunction with the indicated number of space time streams is determined according to 20.3.9.4.6 (The HT-LTF long training field)

If the initiating STA A sends an MRQ in a PPDU that uses fewer space time streams in the data portion than

Table n73—Maximum available space-time streams

N_{TX}	N_{RX}	$N_{STS,\max}$ **without STBC**	$N_{STS,\max}$ **with STBC**
1	1	1	N/A
2	1	$\min(N_{TX}, N_{RX})$	2
3	1	1	2
3	2	$\min(N_{TX}, N_{RX})$	3
4	1	1	2
4	2	$\min(N_{TX}, N_{RX})$	4

are available on the channel, the channel quality assessment made by responder STA B may be based on the Data HT-LTFs alone, but in this case the MCS feedback will be limited to MCSs using the number of streams used in the data portion of the PPDU, or fewer. To determine whether an MCS should be chosen that uses more spatial streams than the PPDU containing the MRQ, it is necessary for the initiating STA A to either use extension HT-LTFs (send the MRQ in a staggered sounding PPDU), or use an NDP (send the MRQ in a PPDU in which the NDP announcement bit in the HT Control field is set, and which is followed by an NDP.)

The sounding PPDU may have non-identity spatial mapping matrix Q_k. Over different RAs, Q_k may vary.

Insert the following new subclause:

20.3.13 Regulatory requirements

Wireless LANs implemented in accordance with this standard are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The PMD specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision, or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PMD specification. Regulatory re-

quirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Annex I for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

Insert the following new subclause:

20.3.14 Channel numbering and channelization

The STA may operate in the 5GHz band and/or 2.4GHz band. When using 20 MHz channels it uses channels defined in 17.3.8.3 (5 GHz band) or 18.4.6 (2.4 GHz band). When using 40 MHz channels, it can operate in the channels defined in 20.3.14.1 (Channel allocation in the 2.4 GHz Band) and 20.3.14.2 (Channel allocation in the 5 GHz band).

Insert the following new subclause:

20.3.14.1 Channel allocation in the 2.4 GHz Band

Channel center frequencies are defined at every integral multiple of 5 MHz in the 2.4 GHz band. The relationship between center frequency and channel number is given by the following equation:

$$\text{Channel center frequency} = 2407 + 5 \times n_{ch}(\text{MHz}) \quad (20\text{-}87)$$

where

$$n_{ch} = 1, 2, \ldots, 13$$

Insert the following new subclause:

20.3.14.2 Channel allocation in the 5 GHz band

Channel center frequencies are defined at every integral multiple of 5 MHz above 5 GHz. The relationship between center frequency and channel number is given as follows:

$$\text{Channel center frequency} = \text{Channel starting frequency} + 5 \times n_{ch}(\text{MHz}) \quad (20\text{-}88)$$

where

$$n_{ch} = 0, 1, \ldots, 200$$

Channel starting frequency is defined as dot11ChannelStartingFactor × 500 kHz or is defined as 5 GHz for systems where dot11RegulatoryClassesRequired is false or not defined

Insert the following new subclause:

20.3.14.3 40 MHz channelization

The set of valid operating channel numbers by regulatory domain is defined in Annex J.

The 40 MHz channels are specified by two fields: (Nprimary_ch, Secondary). The first field represents the channel number of the primary channel, and the second one indicates whether the secondary channel is above or below the primary channel (1 -> above, -1 -> below). The secondary channel number shall be Nprimary_ch

+ Secondary*4.

For example, a 40 MHz channel consisting of 40 MHz channel number 36 and Secondary 1 specifies the primary channel is 36 and the secondary channel is 40.

Insert the following new subclause:

20.3.15 Transmit and receive in-band and out-of-band spurious transmissions

The OFDM PHY shall conform to in-band and out-of-band spurious emissions as set by regulatory bodies.

Insert the following new subclause:

20.3.16 Transmitter RF delay

The transmitter RF delay shall follow 17.3.8.5.

Insert the following new subclause:

20.3.17 Slot time

The slot time shall follow 17.3.8.6 for 5 GHz bands and 19.4.4 for 2.4 GHz bands.

Insert the following new subclause:

20.3.18 Transmit and receive port impedance

The transmit and receive antenna port impedance for each transmit and receive antenna shall follow 17.3.8.7.

Insert the following new subclause:

20.3.19 Transmit and receive operating temperature range

The transmit and receive temperature range shall follow 17.3.8.8.

Insert the following new subclause heading:

20.3.20 PMD Tx specification

Insert the following new subclause:

20.3.20.1 Transmit spectrum mask

In the absence of other regulatory restrictions, when transmitting in a 20 MHz channel, the transmitted spectrum shall have a 0 dBr (dB relative to the maximum spectral density of the signal) bandwidth not exceeding 18 MHz, –20 dBr at 11 MHz frequency offset, –28 dBr at 20 MHz frequency offset and –45 dBr at 30 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure n78 (Transmit spectral mask for 20 MHz transmission). The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

of the constellations in each of the spectral lines –16 to –1 and +1 to +16 shall deviate no more than ± 2 dB from their average energy. The average energy of the constellations in each of the spectral lines –28 to –17 and +17 to +28 shall deviate no more than +2/–4 dB from the average energy of spectral lines –16 to –1 and +1 to +16.

In a 40 MHz transmission (excluding HT duplicate format and non-HT duplicate format) the average energy of the constellations in each of the spectral lines –42 to –2 and +2 to +42 shall deviate no more than ± 2 dB from their average energy. The average energy of the constellations in each of the spectral lines –43 to –58 and +43 to +58 shall deviate no more than +2/–4 dB from the average energy of spectral lines –42 to –2 and +2 to +42.

In HT duplicate format and non-HT duplicate format the average energy of the constellations in each of the spectral lines -42 to -33, -31 to -6, +6 to +31, and +33 to +42 shall deviate no more than ± 2 dB from their average energy. The average energy of the constellations in each of the spectral lines -43 to -58 and +43 to +58 shall deviate no more than +2/-4 dB from the average energy of spectral lines -42 to -33, -31 to -6, +6 to +31, and +33 to +42.

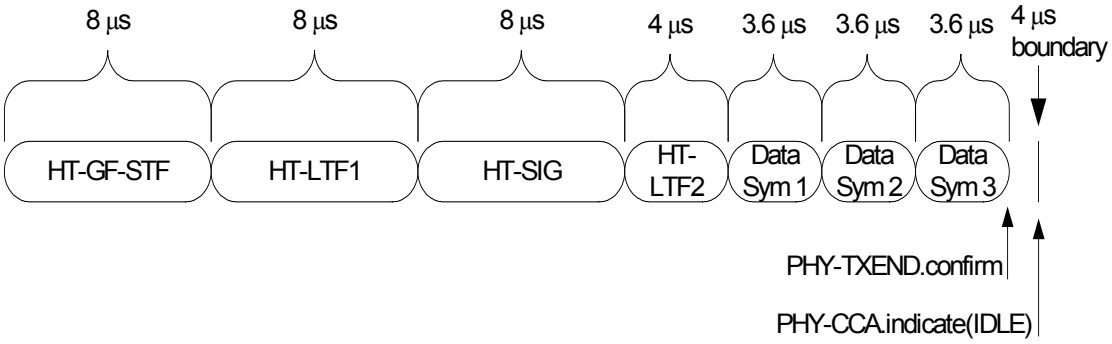
Insert the following new subclause:

20.3.20.3 Transmit power

The maximum allowable transmit power by regulatory domain is defined in Annex I.

Insert the following new subclause:

20.3.20.4 Transmit center frequency tolerance



The transmitter center frequency tolerance shall be ±20 ppm maximum for the 5GHz band and ±25 ppm maximum for the 2.4GHz band. The different transmit chain center frequencies (LO) and each transmit chain symbol clock frequency shall all be derived from the same reference oscillator.

Insert the following new subclause:

20.3.20.5 Packet alignment

The receiver asserts PHY-CCA.indication(idle) (see 12.3.5.10) at the 4μs boundary following the reception of the last symbol of the packet. This is illustrated for the case of a greenfield format packet using short GI in Figure n80 (Packet alignment example (greenfield format packet with short GI)).

The transmitter asserts PHY-TXEND.confirm (12.3.5.7) at the trailing boundary of the last symbol of the packet on the air as illustrated in Figure n80 (Packet alignment example (greenfield format packet with short GI)).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000880

Figure n80—Packet alignment example (greenfield format packet with short GI)

Insert the following new subclause:

20.3.20.6 Symbol clock frequency tolerance

The symbol clock frequency tolerance shall be ±20 ppm maximum for 5 GHz bands and ±25 ppm for 2.4 GHz bands. The transmit center frequency and the symbol clock frequency for all transmit antennas shall be derived from the same reference oscillator.

Insert the following new subclause:

20.3.20.7 Modulation accuracy

20.3.20.7.1 Introduction to Modulation accuracy tests

Transmit modulation accuracy specifications are described in 20.3.20.7.2 (Transmit center frequency leakage) and 20.3.20.7.3 (Transmitter constellation error). The test method is described in 20.3.20.7.4 (Transmitter modulation accuracy (EVM) test).

Insert the following new subclause:

20.3.20.7.2 Transmit center frequency leakage

The transmitter center frequency leakage shall follow 17.3.9.6.1 for all transmissions in a 20 MHz channel width. For transmissions in a 40 MHz channel width, the center frequency leakage shall not exceed -20 dB relative to overall transmitted power, or, equivalently, 0 dB relative to the average energy of the rest of the subcarriers. The transmit center frequency leakage is specified per antenna.

Insert the following new subclause:

20.3.20.7.3 Transmitter constellation error

The relative constellation RMS error, averaged over subcarriers, OFDM frames, and spatial streams shall not exceed a data-rate dependent value according to Table n74 (Allowed relative constellation error versus constellation size and code rate). In this table, the number of spatial streams is equal to the number of transmit antennas. The same requirement applies both to 20 MHz channels and 40 MHz channels.

Insert the following new subclause:

20.3.20.7.4 Transmitter modulation accuracy (EVM) test

The transmit modulation accuracy test shall be performed by instrumentation capable of converting the transmitted signals into a streams of complex samples at 40 Msample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, analog to digital quantization noise, etc. Each transmit chain is connected directly through a cable to the setup input port. A possible embodiment of such a setup is converting the signals to a low IF frequency with a microwave synthesizer, sampling the signal with a digital oscilloscope and decomposing it digitally into quadrature components. The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps, or an equivalent procedure:

a) Start of frame shall be detected.

b) Transition from short sequences to channel estimation sequences shall be detected, and fine timing (with one sample resolution) shall be established.

Table n74—Allowed relative constellation error versus constellation size and code rate

Modulation	Code Rate	Relative constellation error (dB)
BPSK	1/2	-5
QPSK	1/2	-10
QPSK	3/4	-13
16-QAM	1/2	-16
16-QAM	3/4	-19
64-QAM	2/3	-22
64-QAM	3/4	-25
64-QAM	5/6	-28

c) Coarse and fine frequency offsets shall be estimated.

d) The packet shall be derotated according to estimated frequency offset.

e) The complex channel response coefficients shall be estimated for each of the subcarriers and each of the transmit chains.

f) For each of the data OFDM symbols: transform the symbol into subcarrier received values, estimate the phase from the pilot subcarriers in all spatial streams, derotate the subcarrier values according to estimated phase, group the results from all the receiver chains in each subcarrier to a vector, multiply the vector by a zero-forcing equalization matrix generated from the channel estimated during the channel estimation phase.

g) For each data-carrying subcarrier in each spatial stream, find the closest constellation point and compute the Euclidean distance from it.

h) Compute the average of the RMS of all errors in a packet. It is given by:

$$Error_{RMS} = \frac{\sum_{i_f=1}^{N_f} \sqrt{\frac{\sum_{i_s=1}^{N_{SYM}} \left[\sum_{i_{ss}=1}^{N_{SS}} \left(\sum_{i_{sc}=1}^{N_{ST}} \left(\left(I\left(i_f, i_s, i_{ss}, i_{sc}\right) - I_0\left(i_f, i_s, i_{ss}, i_{sc}\right) \right)^2 + \left(Q\left(i_f, i_s, i_{ss}, i_{sc}\right) - Q_0\left(i_f, i_s, i_{ss}, i_{sc}\right) \right)^2 \right) \right) \right]}{N_{SYM} \times N_{SS} \times N_{ST} \times P_o}}{N_f} \tag{20-89}$$

where

Nf is the number of frames for the measurement;

$I_0\left(i_f, i_s, i_{ss}, i_{sc}\right), Q_0\left(i_f, i_s, i_{ss}, i_{sc}\right)$ denotes the ideal symbol point of the i_f'th frame, i_s'th OFDM symbol of the frame, i_{ss}'th spatial stream, i_{sc}'th subcarrier of the OFDM symbol in the complex plane;

$I\left(i_f, i_s, i_{ss}, i_{sc}\right), Q\left(i_f, i_s, i_{ss}, i_{sc}\right)$ denotes the observed point of the i_f'th frame, i_s'th OFDM symbol of the frame, i_{ss}'th spatial stream, i_{sc}'th subcarrier of the OFDM symbol in the complex plane (see Figure 256;

P_0 is the average power of the constellation.

The vector error on a phase plane is shown in Figure 256.

The test shall be performed over at least 20 frames (*Nf*), and the average of the RMS shall be taken. The packets under test shall be at least 16 OFDM symbols long. Random data shall be used for the symbols.

Insert the following new subclause heading:

20.3.21 HT PMD receiver specification

Insert the following new subclause:

20.3.21.1 Receiver minimum input sensitivity

The packet error rate (PER) shall be less than 10% for a PSDU length of 4096 octets with the rate-dependent input levels listed in Table n75 (Receiver minimum input level sensitivity) or less. The minimum input levels are measured at the antenna connectors and are referenced as the average power per receive antenna. The number of spatial streams under test shall be equal to the number of utilized transmitting STA antenna (output) ports and also equal to the number of utilized Device Under Test input ports. Each output port of the transmitting STA shall be connected through a cable to one input port of the Device Under Test.

Table n75—Receiver minimum input level sensitivity

Modulation	Rate (R)	Adjacent channel rejection (dB)	Non-adjacent channel rejection (dB)	Minimum sensitivity (dBm) (20 MHz channel spacing)	Minimum sensitivity (dBm) (40 MHz channel spacing)
BPSK	1/2	16	32	-82	-79
QPSK	1/2	13	29	-79	-76
QPSK	3/4	11	27	-77	-74
16-QAM	1/2	8	24	-74	-71
16-QAM	3/4	4	20	-70	-67
64-QAM	2/3	0	16	-66	-63
64-QAM	3/4	–1	15	-65	-62
64-QAM	5/6	–2	14	-64	-61

Insert the following new subclause:

20.3.21.2 Adjacent channel rejection

The adjacent channel rejection shall follow 17.3.10.2 in the 5 GHz band or 19.5.2 in the 2.4 GHz band for all transmissions in a 20 MHz channel width with the exception that 10% PER is required for 4096 octet packets rather than 10% PER for 1000 octet packets. For all transmissions in a 40 MHz channel width, the adjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate dependent sensitivity specified in Table n75 (Receiver minimum input level sensitivity) and raising the power of the interfering signal until 10% PER is caused for a PSDU length of 4096 octets. The power difference between the

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000883

interfering and the desired channel is the corresponding adjacent channel rejection. The adjacent channel center frequencies shall be separated by 40 MHz. The interfering signal in the adjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For a conformed OFDM PHY, the corresponding rejection shall be no less than specified in Table n75 (Receiver minimum input level sensitivity). The interference signal shall have a minimum duty cycle of 50%.

Insert the following new subclause:

20.3.21.3 Non-adjacent channel rejection

The non-adjacent channel rejection shall follow 17.3.10.3 in the 5 GHz band for all transmissions in a 20 MHz channel width with the exception that 10% PER is required for 4096 octet packets rather than 10% PER for 1000 octet packet. For all transmissions in a 40 MHz channel width, the non-adjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table n75 (Receiver minimum input level sensitivity), and raising the power of the interfering signal until a 10% PER occurs for a PSDU length of 4096 octets. The power difference between the interfering and the desired channel is the corresponding non-adjacent channel rejection. The non-adjacent channel center frequencies shall be separated by 80 MHz or more. The interfering signal in the non-adjacent channel shall be a conformant OFDM signal, unsynchronized with the signal in the channel under test. For a conformed OFDM PHY, the corresponding rejection shall be no less than specified in Table n75 (Receiver minimum input level sensitivity). The interference signal shall have a minimum duty cycle of 50%. The non-adjacent channel rejection for transmissions in a 40 MHz channel width is applicable only to 5 GHz band.

Insert the following new subclause:

20.3.21.4 Receiver maximum input level

The receiver shall provide a maximum PER of 10% at a PSDU length of 4096 octets, for a maximum input level of –30 dBm in the 5 GHz band, and -20 dBm in the 2.4 GHz band, measured at each antenna for any baseband modulation.

Insert the following new subclause:

20.3.21.5 Clear Channel Assessment (CCA) sensitivity

On the start of a valid non-HT transmission on the primary channel refer to Clause 17 and 19.

20.3.21.5.1 Clear channel assessment (CCA) sensitivity in 20 MHz

The following paragraph describes the CCA sensitivity requirements for an HT-STA with the operating channel width set to 20 MHz.

The start of a valid 20 MHz HT transmission at a receive level equal to or greater than the minimum modulation and coding rate sensitivity of -82 dBm shall cause the PHY to set PHY-CCA.indicate(BUSY) with a probability > 90% within 4 μs. The receiver shall hold the CCA signal busy for any signal 20 dB or more above the minimum modulation and coding rate sensitivity (-62 dBm) in the 20 MHz channel.

20.3.21.5.2 Clear channel assessment (CCA) sensitivity in 40 MHz

The following paragraphs describe the CCA sensitivity requirements for an HT-STA with the operating channel width set to 40 MHz.

The receiver of a 20/40 MHz STA with the operating channel width set to 40 MHz shall provide CCA on both the primary and secondary channels.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000884

When the secondary channel is idle, the start of a valid 20 MHz HT transmission in the primary channel at a receive level equal to or greater than the minimum modulation and coding rate sensitivity of -82 dBm shall cause the PHY to set PHY-CCA.indicate(BUSY) with a probability > 90% within 4 μs. The start of a valid 40 MHz HT transmission that occupies both the primary channel and the secondary channel at a receive level equal to or greater than the minimum modulation and coding rate sensitivity of -79 dBm shall cause the PHY to set PHY-CCA.indicate(BUSY) for both the primary channel and the secondary channel with a probability per channel > 90% within 4 μs.

The receiver shall hold the 20 MHz primary channel CCA signal busy for any signal 20 dB or more above the minimum modulation and coding rate sensitivity (-62 dBm) in the 20 MHz primary channel. When the primary channel is idle, the receiver shall hold the 20 MHz secondary channel CCA signal busy for any signal 20 dB or more above the minimum modulation and coding rate sensitivity (-62 dBm) in the 20 MHz secondary channel. The receiver shall hold both the 20 MHz primary channel CCA and the 20 MHz secondary channel CCA busy for any signal present in both the primary and secondary channel that is 20 dB or more above the minimum modulation and coding rate sensitivity (-59 dBm).

Insert the following new subclause:

20.3.21.6 Received channel power indicator (RCPI) measurement

The RCPI indicator is a measure of the received RF power in the selected channel. This parameter shall be a measure by the PHY sublayer of the received RF power in the channel measured over the data portion of the received frame. The received power shall be the average of the power in all receive chains. RCPI shall be a monotonically increasing, logarithmic function of the received power level defined in dBm. The allowed values for the Received Channel Power Indicator (RCPI) parameter shall be an 8 bit value in the range from 0 through 220, with indicated values rounded to the nearest 0.5 dB as follows:

- 0: Power < -110 dBm
- 1: Power = -109.5 dBm
- 2: Power = -109.0 dBm
- and so on up to
- 220: Power > 0 dBm
- 221-254: reserved
- 255: Measurement not available

where

$$RCPI = \text{int}\{(\text{Power in dBm} + 110) * 2\} \text{ for } 0 \text{ dbm} > \text{Power} > -110 \text{ dBm} \quad (20\text{-}90)$$

RCPI shall equal the received RF power within an accuracy of +/- 5 dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel bandwidth multiplied by 1.1.

20.3.21.7 Reduced interframe Space (RIFS)

The receiver shall be able to decode a packet that was transmitted by a STA with a RIFS separation from the previous packet.

Insert the following new subclause:

20.3.22 PLCP transmit procedure

There are three options for transmit PLCP procedure. The first two options, for which typical transmit proce-

dures are shown in Figure n81 (PLCP transmit procedure (HT mixed format PPDU)) and Figure n82 (PLCP transmit procedure (HT greenfield format PPDU)), are selected if the FORMAT field of PHY-TXSTART.request(TXVECTOR) is set to HT_MF or HT_GF respectively. These transmit procedures do not describe the operation of optional features, such as LDPC. The third option is to follow the transmit procedure as in Clause 17 or 19 if the FORMAT field is set to NON_HT. Additionally, if the FORMAT field is set to NON_HT, CW indicates NON_HT_CBW20, and NON_HT_MODULATION indicates OFDM, follow the transmit procedure as in Clause 17. If the FORMAT field is set to NON_HT, CH_BANDWIDTH indicates NON_HT_CBW20, and NON_HT_MODULATION indicates other than OFDM, follow the transmit procedure as in Clause 19. And furthermore, if the FORMAT field is set to NON_HT and CH_BANDWIDTH indicates NON_HT_CBW40, follow the transmit procedure as in Clause 17 duplicated on both channels. In all these options, in order to transmit data, PHY-TXSTART.request shall be enabled so that the PHY entity shall be in the transmit state. Further, the PHY shall be set to operate at the appropriate frequency through station management via the PLME. Other transmit parameters, such as MCS Coding types and TX power, are set via the PHY-SAP with the PHY-TXSTART.request(TXVECTOR), as described in 20.2.2 (TXVECTOR and RXVECTOR parameters).

A clear channel shall be indicated by PHY-CCA.indication(IDLE). The MAC considers this indication before issuing the PHY-TXSTART.request. Transmission of the PPDU shall be initiated after receiving the PHYTXSTART.request(TXVECTOR) primitive. The TXVECTOR elements for the PHY-TXSTART.request are specified in Table n56 (TXVECTOR and RXVECTOR parameters).

The PLCP shall issue the parameters in the following PMD primitives to configure the PHY:

— PMD_TXPWRLVL
— PMD_TX_PARAMETERS
— PMD_EXPANSIONS_MAT
— PMD_EXPANSIONS_MAT_ON

The PLCP shall then issue a PMD_TXSTART.request, and transmission of the PLCP preamble may start, based on the parameters passed in the PHY-TXSTART.request primitive. The data shall then be exchanged between the MAC and the PHY through a series of PHY-DATA.request(DATA) primitives issued by the MAC, and PHY-DATA.confirm primitives issued by the PHY. Once PLCP preamble transmission is started, the PHY entity shall immediately initiate data scrambling and data encoding. The encoding method shall be based on the LDPC_CODING, CH_BANDWIDTH, and MCS parameter of the TXVECTOR. A modulation rate change, if any, shall be initiated starting with the SERVICE field data, as described in 20.3.2 (PLCP frame format).

The PHY proceeds with PSDU transmission through a series of data octet transfers from the MAC. The SERVICE field and PSDU are encoded by the encoder selected by the LDPC_CODING, CH_BANDWIDTH, and MCS parameters of the TXVECTOR as described in 20.3.3 (Transmitter block diagram). At the PMD layer, the data octets are sent in bit 0–7 order and presented to the PHY through PMD_DATA.request primitives. Transmission can be prematurely terminated by the MAC through the primitive PHY-TXEND.request. PHY-TXSTART shall be disabled by the issuance of the PHY-TXEND.request. Normal termination occurs after the transmission of the final bit of the last PSDU octet, according to the number supplied in the LENGTH field.

The packet transmission shall be completed and the PHY entity shall enter the receive state (i.e., PHYTXSTART shall be disabled). Each PHY-TXEND.request is acknowledged with a PHY-TXEND.confirm primitive from the PHY. If the coded PSDU (C-PSDU) is not multiples of the OFDM symbol, bits shall be stuffed to make the C-PSDU length multiples of the OFDM symbol.

In the PMD, the GI or short GI shall be inserted in every OFDM symbol as a countermeasure against delay spread.

procedures and state machine do not describe the operation of optional features, such as LDPC or STBC. If the detected format indicates Non_HT PLCP format, refer to the receive procedure and state machine in Clause 17 or 19. In order to receive data, PHY-TXSTART.request shall be disabled so that the PHY entity is in the receive state. Further, through station management (via the PLME) the PHY is set to the appropriate frequency. Other receive parameters, such as RSSI and indicated DATARATE, may be accessed via the PHY-SAP.

Upon receiving the transmitted PLCP preamble, PMD_RSSI.indication shall report a busy channel to the PLCP. This indicates activity to the MAC via PHY-CCA.indication. PHY-CCA.indication(BUSY) shall be issued for reception of a signal prior to correct reception of the PLCP frame. The PMD primitive PMD_RSSI is issued to update the RSSI and parameter reported to the MAC.

After PHY-CCA.indication(BUSY) is issued, the PHY entity shall begin receiving the training symbols and searching for SIGNAL and HT-SIG in order to set the length of the data stream, the demodulation type, code type, and the decoding rate. If signal loss occurs before validating L-SIG and/or HT-SIG, the HT PHY shall maintain PHY-CCA.indication(BUSY) until the received level drops below the CCA sensitivity level (for a missed preamble) in 21.3.21.5. If the check of the HT-SIG CRC is not valid, a PHY-RXSTART.indication is not issued. The PHY shall issue the error condition PHY-RXEND.indication(FormatViolation). The HT PHY shall maintain PHY-CCA.indication(BUSY) until the received level drops below the CCA sensitivity level (for a missed preamble) in 21.3.21.5.

If the PLCP preamble reception is successful and a valid HT-SIG CRC is indicated:

— Upon reception of an HT mixed format preamble, the HT PHY shall maintain PHY-CCA.indication(BUSY) for the predicted duration of the transmitted frame, as per TXTIME in 21.4.3, for all supported and unsupported modes except Reserved HT-SIG Indication.

— Upon reception of a GF preamble by an HT STA which does not support GF, PHY-CCA.indication(BUSY) shall be maintained until either the predicted duration of the packet from the contents of the HT-SIG field, as per TXTIME in 21.4.3, except Reserved HT-SIG Indication, or until the received level drops below the receiver minimum sensitivity level of BPSK, R=1/2 in Table n75 (Receiver minimum input level sensitivity) + 10 dB (-72 dBm for 20 MHz, -69 dBm for 40 MHz)

— Upon reception of a GF preamble by an HT STA which supports GF, the HT PHY shall maintain PHY-CCA.indication(BUSY) for the predicted duration of the transmitted frame, as per TXTIME in 21.4.3, for all supported and unsupported modes except Reserved HT-SIG Indication.

— If the HT-SIG indicates a Reserved HT-SIG Indication, the HT PHY shall maintain PHY-CCA.indication(BUSY) until the received level drops below the CCA sensitivity level (minimum modulation and coding rate sensitivity + 20 dB) in 21.3.21.5. Reserved HT-SIG Indication is defined as an HT-SIG with MCS field in the range 77-127 or Reserved field = 0 or STBC field = 3.

Subsequent to an indication of a valid HT-SIG CRC, a PHY-RXSTART.indication(RXVECTOR) shall be issued. The RXVECTOR associated with this primitive include the parameters specified in Table n63 (TXVECTOR and RXVECTOR parameters). Upon reception of a GF preamble by an HT STA which does not support GF, the FORMAT field of RXVECTOR is set to HT_GF and the remaining fields may be empty, and the PHY shall issue the error condition PHY-RXEND.indication(FormatViolation). If the HT-SIG is not completely recognizable and supported the PHY shall issue the error condition PHY-RXEND.indication(UnsupportedRate).

Following training and signal fields, the PLCP SERVICE field and PSDU shall be received. If signal loss occur during reception prior to completion of the PSDU reception, the error condition PHY-RXEND.indication(CarrierLost) shall be reported to the MAC. After waiting for the intended end of the PSDU, the PHY shall set PHY-CCA.indication(IDLE) and return to RX IDLE state.

The received PSDU bits are assembled into octets, decoded, and presented to the MAC using a series of PHY-DATA.indication(DATA) primitive exchanges. The number of PSDU octets is indicted in the LENGTH field

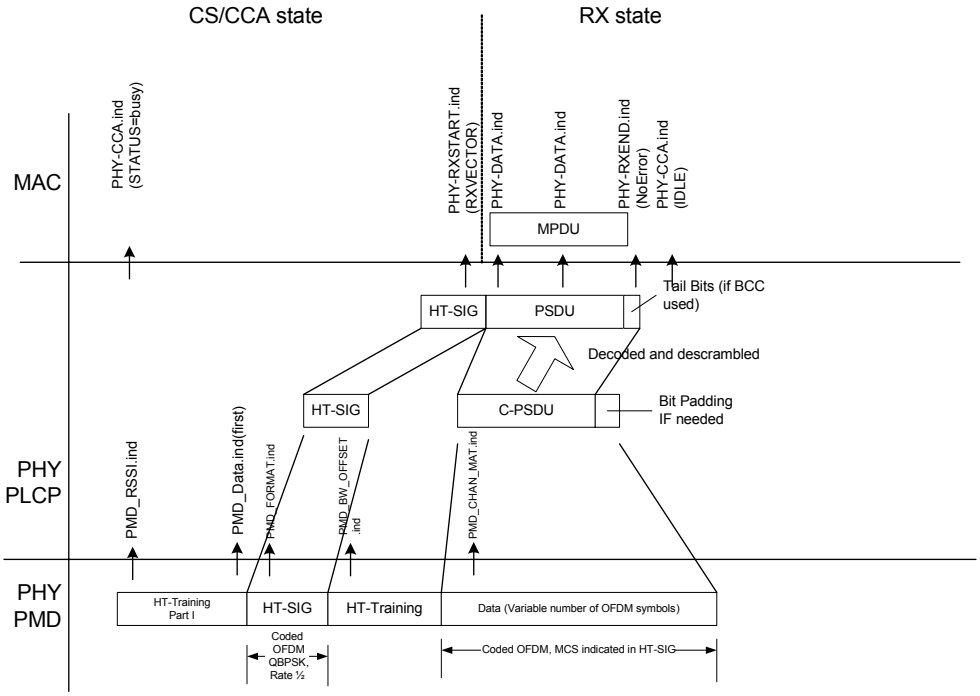
of the HT-SIG. The PHY shall proceed with PSDU reception. After the reception of the final bit of the last PSDU octet the receiver shall be returned to the RX IDLE state, as shown in Figure n86 (PLCP receive state machine). A PHY-RXEND.indication(NoError) primitive shall be issued.



If the binary convolutional code is used, any data received after the indicated data length are considered pad bits (to fill out an OFDM symbol) and should be discarded.

Note: procedure does not describe the operation of optional features, such as LDPC or STBC

Insert the following new subclause:

20.4.3 TXTIME calculation

The value of the TXTIME parameter returned by the PLME-TXTIME.confirm primitive shall be calculated for HT mixed format according to the Equation (20-91) and Equation (20-92) for short and regular GI, and for greenfield format according to Equation (20-93) and Equation (20-94) for short and regular GI respectively:

$$TXTIME = T_{LEG\_PREAMBLE} + T_{L\_SIG} + T_{HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYM} \times \text{Ceiling}\left(\frac{T_{SYMS} \times N_{SYM}}{T_{SYM}}\right) \quad (20\text{-}91)$$

$$TXTIME = T_{LEG\_PREAMBLE} + T_{L\_SIG} + T_{HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYM} \times N_{SYM} \quad (20\text{-}92)$$

$$TXTIME = T_{GF\_HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYMS} \times N_{SYM} \quad (20\text{-}93)$$

$$TXTIME = T_{GF\_HT\_PREAMBLE} + T_{HT\_SIG} + T_{SYM} \times N_{SYM} \quad (20\text{-}94)$$

where

$T_{LEG\_PREAMBLE} = T_{L-STF} + T_{L-LTF}$ is the duration of the non-HT preamble,

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000899

$T_{HT\_PREAMBLE}$ is the duration of the HT preamble in HT mixed format. This duration is $T_{HT-STF} + T_{HT-LTF1} + (N_{LTF} - 1)T_{HT-LTFs}$,

$T_{HT\_PREAMBLE}$ is the duration of the preamble in HT greenfield format. This duration is $T_{HT-GF-STF} + T_{HT-LTF1} + (N_{LTF} - 1)T_{HT-LTFs}$,

T_{SYM}, T_{SYMS}, T_{HT-SIG}, T_{L-STF}, T_{HT-STF}, T_{L-LTF}, $T_{HT-LTF1}$ and $T_{HT-LTFs}$ are defined in Table n58 (Timing related constants),

N_{SYM} is the total number of data symbols in the data portion, which may be calculated according to Equation (20-95).

$$N_{SYM} = m_{STBC} \times Ceil\left(\frac{8 \cdot length + 16 + 6 \cdot N_{ES}}{m_{STBC} \cdot N_{DBPS}}\right) \quad \text{When BCC is used}$$
$$N_{SYM} = N_{avbits} / N_{CBPS} \quad \text{When LDPC is used} \qquad (20\text{-}95)$$

where

length is the number of octets in the data portion of the PPDU;

m_{STBC} is equal to 2 when space time block code (STBC) is used, and otherwise 1;

N_{ES} and N_{CBPS} are defined in Table n59 (Frequently used parameters);

N_{DBPS} is defined in Table n81 (Symbols used in rate dependent parameter tables);

N_{avbits} is defined in Equation (20-39).

For non-HT modes of operation refer to Clause 17 and Clause 19 for TXTIME calculations.

Insert the following new subclause:

20.4.4 PHY characteristics

The static HT PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive, are

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000901

The HT PHY introduces these new characteristics:

— aSTFOneLength is the length of the non-HT Short Training Field

— aSTFTwoLength is the length of the HT Short Training Field

— aLTFOneLength is the length of the First Long Training Field

— aLTFTwoLength is the length of the Additional HT Long Training Fields.

— The aPLCPSigTwoLength is the length of the HT SIGNAL Field.

For non-HT modes of operation refer to Clause 17 and Clause 19 for PHY characteristics.

Insert the following new subclause heading:

20.5 HT PMD sublayer

Insert the following new subclause:

20.5.1 Scope and field of application

Subclause 20.5 (HT PMD sublayer) describes the PMD services provided to the PLCP for the High Throughput (HT) PHY. Also defined in this subclause are the functional, electrical, and RF characteristics required for interoperability of implementations conforming to this specification. The relationship of this specification to the entire HT PHY is shown in Figure n87 (PMD layer reference model).

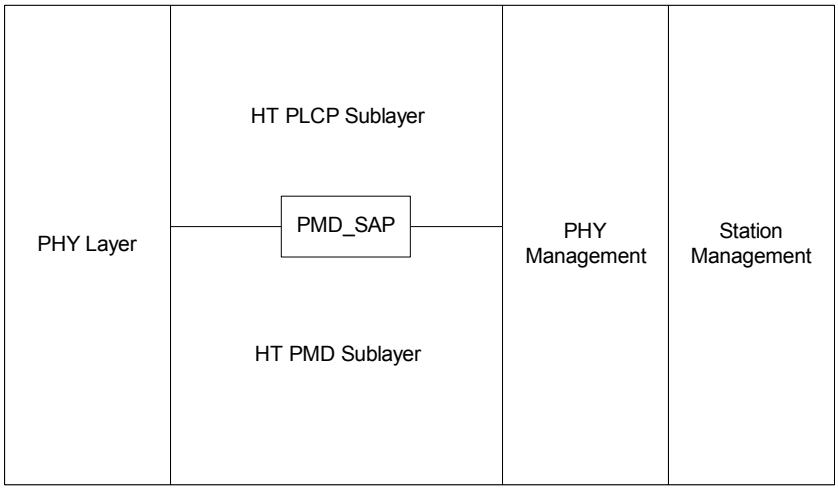

Figure n87—PMD layer reference model

Insert the following new subclause:

20.5.2 Overview of service

The HT PMD sublayer accepts PLCP sublayer service primitives and provides the actual means by which data are transmitted or received from the medium. The combined function of the HT PMD sublayer primitives and parameters for the receive function results in a data stream, timing information, and associated receive signal parameters being delivered to the PLCP sublayer. A similar functionality is provided for data transmission.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000902

Insert the following new subclause:

20.5.3 Overview of interactions

The primitives provided by the HT PMD fall into two basic categories:

a) Service primitives that support PLCP peer-to-peer interactions;

b) Service primitives that have local significance and support sublayer-to-sublayer interactions.

Insert the following new subclause heading:

20.5.4 Basic service and options

Insert the following new subclause:

20.5.4.1 Status of service primitives

All of the service primitives described in 20.5.4 (Basic service and options) are mandatory, unless otherwise specified.

Insert the following new subclause:

20.5.4.2 PMD_SAP peer-to-peer service primitives

Table n78 (PMD_SAP peer-to-peer service primitives) indicates the primitives for peer-to-peer interactions.

Table n78—PMD_SAP peer-to-peer service primitives

Primitive	Request	Indicate	Confirm	Response
PMD_DATA	X	X	—	—

Insert the following new subclause:

20.5.4.3 PMD_SAP sublayer-to-sublayer service primitives

Table n79 (PMD_SAP sublayer-to-sublayer service primitives) indicates the primitives for sublayer-to-sublayer interactions.

Insert the following new subclause:

20.5.4.4 PMD_SAP service primitive parameters

Table n80 (List of parameters for the PMD primitives) shows the parameters used by one or more of the PMD_SAP service primitives.

20.5.5 PMD_SAP detailed service specification

Insert the following new subclause:

20.5.5.1 Introduction to PMD_SAP service specification

20.5.5.2 (PMD_DATA.request) to 20.5.5.13 (PMD_FORMAT.indication) describe the services provided by each PMD primitive.

Insert the following new subclause:

20.5.5.2 PMD_DATA.request

Insert the following new subclause:

20.5.5.2.1 Function

This primitive defines the transfer of data from the PLCP sublayer to the PMD entity.

Insert the following new subclause:

20.5.5.2.2 Semantics of the service primitive

This primitive shall provide the following parameters: PMD_DATA.request (TXD_UNIT)

The TXD_UNIT parameter shall be the n-bit combination of 0 and 1 for one symbol of OFDM modulation. If the length of a coded PSDU (C-PSDU) is shorter than n bits, 0 bits are added to form an OFDM symbol. This parameter represents a single block of data that, in turn, shall be used by the PHY to be encoded into an OFDM transmitted symbol.

Page 000904

Table n80—List of parameters for the PMD primitives

Parameter	Associate primitive	Value
TXD_UNIT	PMD_DATA.request	One(1), Zero(0): one OFDM symbol value
RXD_UNIT	PMD_DATA.indication	One(1), Zero(0): one OFDM symbol value
TXPWR_LEVEL	PMD_TXPWRLVL.request	1 to 8 (max of 8 levels)
MCS	PMD_TX_PARAMETERS.request	0 to 76, MCS index defined in 20.6 (Rate dependent parameters for HT Modulation and Coding Schemes (MCS))
CH_BANDWIDTH	PMD_TX_PARAMETERS.request PMD_CBW_OFFSET.indication	Set to 0 for HT_CBW20 (20 MHz), Set to 1 for HT_CBW40 (40 MHz), Set to 2 for HT_CBW_20DN (Non-HT duplicate) Set to 3 for HT_CBW_20DH (HT duplicate)
CH_OFFSET	PMD_TX_PARAMETERS.request PMD_CBW_OFFSET.indication	Set to 0 for CH_OFF_40 (whole 40 MHz channel) Set to 1 for CH_OFF_20U (Upper 20 MHz in 40 MHz) Set to 3 for CH_OFF_20L (Lower 20 MHz in 40 MHz)
STBC	PMD_TX_PARAMETERS.request	Set to a non-zero number, indicates the difference between the number of space time streams N_{STS} and the number of spatial streams N_{SS} indicated by the MCS Set to 00 indicates no STBC ($N_{STS}=N_{SS}$)
SHORT_GI	PMD_TX_PARAMETERS.request	Set to 0 indicates Short GI is not used in the packet Set to 1 indicates Short GI is used in the packet
ANTENNA_SET	PMD_TX_PARAMETERS.request	Bit field with 8 bits
EXPANSION_MAT	PMD_EXPANSIONS_MAT.request	$(N_{SD}+N_{SP})$ complex matrices of size $N_{TX}\times N_{STS}$
RSSI	PMD_RSSI.indication	0 to 255
RCPI	PMD_RCPI.indication	0 to 255
CHAN_MAT	PMD_CHAN_MAT.indication	$(N_{SD}+N_{SP})$ complex matrices of size $N_{RX}\times N_{STS}$
FORMAT	PMD_FORMAT.indication	Set to 0 for NON_HT Set to 1 for HT_MF Set to 2 for HT_GF

Insert the following new subclause:

20.5.5.2.3 When generated

This primitive shall be generated by the PLCP sublayer to request transmission of one OFDM symbol. The data clock for this primitive shall be supplied by the PMD layer based on the OFDM symbol clock.

Insert the following new subclause:

20.5.5.2.4 Effect of receipt

The PMD performs transmission of the data.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000905

Insert the following new subclause header:

20.5.5.3 PMD_DATA.indication

Insert the following new subclause:

20.5.5.3.1 Function

This primitive defines the transfer of data from the PMD entity to the PLCP sublayer.

Insert the following new subclause:

20.5.5.3.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_DATA.indication(RXD_UNIT)

The RXD_UNIT parameter shall be 0 or 1, and shall represent either a SIGNAL field bit or a data field bit after the decoding of the FEC by the PMD entity.

Insert the following new subclause:

20.5.5.3.3 When generated

This primitive, generated by the PMD entity, forwards received data to the PLCP sublayer. The data clock for this primitive shall be supplied by the PMD layer based on the OFDM symbol clock.

Insert the following new subclause:

20.5.5.3.4 Effect of receipt

The PLCP sublayer interprets the bits that are recovered as part of the PLCP or passes the data to the MAC sublayer as part of the PSDU.

Insert the following new subclause heading:

20.5.5.4 PMD_TXSTART.request

Insert the following new subclause:

20.5.5.4.1 Function

This primitive, generated by the PHY PLCP sublayer, initiates PPDU transmission by the PMD layer.

Insert the following new subclause:

20.5.5.4.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_TXSTART.request

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000906

Insert the following new subclause:

20.5.5.4.3 When generated

This primitive shall be generated by the PLCP sublayer to initiate the PMD layer transmission of the PPDU. The PHY-TXSTART.request primitive shall be provided to the PLCP sublayer prior to issuing the PMD_TXSTART command.

Insert the following new subclause:

20.5.5.4.4 Effect of receipt

PMD_TXSTART initiates transmission of a PPDU by the PMD sublayer.

Insert the following new subclause heading:

20.5.5.5 PMD_TXEND.request

Insert the following new subclause:

20.5.5.5.1 Function

This primitive, generated by the PHY PLCP sublayer, ends PPDU transmission by the PMD layer.

Insert the following new subclause:

20.5.5.5.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_TXEND.request

Insert the following new subclause:

20.5.5.5.3 When generated

This primitive shall be generated by the PLCP sublayer to terminate the PMD layer transmission of the PPDU.

Insert the following new subclause:

20.5.5.5.4 Effect of receipt

PMD_TXEND terminates transmission of a PPDU by the PMD sublayer.

Insert the following new subclause heading:

20.5.5.6 PMD_TXPWRLVL.request

Insert the following new subclause:

20.5.5.6.1 Function

This primitive, generated by the PHY PLCP sublayer, selects the power level used by the PHY for transmission.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000907

Insert the following new subclause:

20.5.5.6.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_TXPWRLVL.request (TXPWR_LEVEL)

TXPWR_LEVEL selects which of the transmit power levels should be used for the current packet transmission. The number of available power levels shall be determined by the MIB parameter aNumberSupportedPowerLevels. See 20.3.20.3 (Transmit power) for further information on the OFDM PHY power level control capabilities.

Insert the following new subclause:

20.5.5.6.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific transmit power. This primitive shall be applied prior to setting PMD_TXSTART into the transmit state.

Insert the following new subclause:

20.5.5.6.4 Effect of receipt

PMD_TXPWRLVL immediately sets the transmit power level to that given by TXPWR_LEVEL.

Insert the following new subclause heading:

20.5.5.7 PMD_RSSI.indication

Insert the following new subclause:

20.5.5.7.1 Function

This primitive, generated by the PMD sublayer, provides the receive signal strength to the PLCP and MAC entity.

Insert the following new subclause:

20.5.5.7.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_RSSI.indication (RSSI)

The RSSI shall be a measure of the RF energy received by the HT OFDM PHY. RSSI indications of up to 8 bits (256 levels) are supported.

Insert the following new subclause:

20.5.5.7.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP that, in turn, shall provide the parameter to the MAC entity.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000908

Insert the following new subclause:

20.5.5.7.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RSSI may be used as part of a CCA scheme.

Insert the following new subclause heading:

20.5.5.8 PMD_RCPI.indication

Insert the following new subclause:

20.5.5.8.1 Function

This primitive, generated by the PMD sublayer, provides the received channel power indicator to the PLCP and MAC entity.

Insert the following new subclause:

20.5.5.8.2 Semantics of the service primitive

The primitive shall provide the following parameter: PMD_RCPI.indication(RCPI).

The RCPI shall be a measure of the channel power received by the OFDM PHY. RCPI indications of 8 bits are supported.

Insert the following new subclause:

20.5.5.8.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be continuously available to the PLCP that, in turn, provides the parameter to the MAC entity.

Insert the following new subclause:

20.5.5.8.4 Effect of receipt

This parameter shall be provided to the PLCP layer for information only. The RCPI may be used in conjunction with RSSI to measure input signal quality.

Insert the following new subclause heading:

20.5.5.9 PMD_TX_PARAMETERS.request

Insert the following new subclause:

20.5.5.9.1 Function

This primitive, generated by the PHY PLCP sublayer, selects the related parameters used by the PHY for transmission.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000909

Insert the following new subclause:

20.5.5.9.2 Semantics of the service primitive

This primitive shall provide the following parameter:

PMD_TX_PARAMETERS.request (MCS, CH_BANDWIDTH, CH_OFFSET, STBC, SHORT_GI, ANTENNA_SET)

Insert the following new subclause:

20.5.5.9.3 When generated

This primitive shall be generated by the PLCP sublayer to select a specific transmit parameter. This primitive shall be applied prior to setting PMD_TXSTART into the transmit state.

Insert the following new subclause:

20.5.5.9.4 Effect of receipt

PMD_TX_PARAMETERS immediately sets the transmit parameters. The receipt of these parameters selects the values that shall be used for all subsequent PPDU transmissions

Insert the following new subclause heading:

20.5.5.10 PMD_EXPANSIONS_MAT.request

Insert the following new subclause:

20.5.5.10.1 Function

This primitive, generated by the PHY PLCP sublayer, defines the steering matrices used by the PHY for transmission.

Insert the following new subclause:

20.5.5.10.2 Semantics of the service primitive

This primitive shall provide the following parameter:

PMD_EXPANSIONS_MAT.request (EXPANSION_MAT)

EXPANSION_MAT selects which steering matrices should be used for the current packet transmission.

Insert the following new subclause:

20.5.5.10.3 When generated

This primitive shall be generated by the PLCP sublayer to define specific steering matrices. This primitive shall be applied prior to setting PMD_TXSTART into the transmit state.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000910

Insert the following new subclause:

20.5.5.10.4 Effect of receipt

PMD_EXPANSIONS_MAT immediately sets the transmission steering matrices to that given by EXPANSION_MAT. The receipt of PMD_EXPANSIONS_MAT selects the steering matrices that shall be used for all subsequent PPDU transmissions.

Insert the following new subclause:

20.5.5.11 PMD_CBW_OFFSET.indication

Insert the following new subclause:

20.5.5.11.1 Function

This primitive, generated by the PMD sublayer, provides the bandwidth and channel offset of the received frame to the PLCP and MAC entity.

Insert the following new subclause:

20.5.5.11.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_CBW_OFFSET.indication (CH_BANDWIDTH, CH_OFFSET)

CH_BANDWIDTH represents channel width (20 MHz or 40 MHz) and the transmission format (non-HT duplicate or HT duplicate). CH_OFFSET indicates a 20 MHz sub-channel of the 40 MHz channel (upper or lower).

Insert the following new subclause:

20.5.5.11.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP that, in turn, shall provide the parameter to the MAC entity.

Insert the following new subclause:

20.5.5.11.4 Effect of receipt

The PLCP sublayer passes the data to the MAC sublayer as part of the RXVECTOR.

Insert the following new subclause heading:

20.5.5.12 PMD_CHAN_MAT.indication

Insert the following new subclause:

20.5.5.12.1 Function

This primitive, generated by the PMD sublayer, provides the channel response matrices to the PLCP and MAC entity.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000911

Insert the following new subclause:

20.5.5.12.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_CHAN_MAT.indication (CHAN_MAT)

The CHAN_MAT parameter contains the channel response matrices that were measured during the reception of the current frame.

Insert the following new subclause:

20.5.5.12.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP that, in turn, shall provide the parameter to the MAC entity.

Insert the following new subclause:

20.5.5.12.4 Effect of receipt

The PLCP sublayer passes the data to the MAC sublayer as part of the RXVECTOR.

Insert the following new subclause heading:

20.5.5.13 PMD_FORMAT.indication

Insert the following new subclause:

20.5.5.13.1 Function

This primitive, generated by the PMD sublayer, provides the format of the received frame to the PLCP and MAC entity.

Insert the following new subclause:

20.5.5.13.2 Semantics of the service primitive

This primitive shall provide the following parameter: PMD_FORMAT.indication (FORMAT).

The format indicates one of the PPDU formats: non HT, HT mixed format or greenfield format.

Insert the following new subclause:

20.5.5.13.3 When generated

This primitive shall be generated by the PMD when the OFDM PHY is in the receive state. It shall be available continuously to the PLCP that, in turn, shall provide the parameter to the MAC entity.

Insert the following new subclause:

20.5.5.13.4 Effect of receipt

The PLCP sublayer passes the data to the MAC sublayer as part of the RXVECTOR.

20.6 Rate dependent parameters for HT Modulation and Coding Schemes (MCS)

Table n81 (Symbols used in rate dependent parameter tables) defines the symbols used in the rate dependent parameter tables.

Table n81—Symbols used in rate dependent parameter tables

Symbol	Explanation
N_{SS}	Number of spatial streams
R	Code rate
N_{BPSC}	Number of coded bits per single carrier (total across spatial streams)
$N_{BPSCS}(i_{SS})$	Number of coded bits per single carrier for each spatial stream, $i_{SS} = 1,...,N_{SS}$
N_{SD}	Number of data subcarriers
N_{SP}	Number of pilot subcarriers
N_{CBPS}	Number of coded bits per OFDM symbol
N_{DBPS}	Number of data bits per OFDM symbol
N_{ES}	Number of FEC encoders
N_{TBPS}	Total bits per subcarrier

Annex A (normative) PICS

A.4 PICS proforma–IEEE Std 802.11, 2006 Edition

A.4.3 IUT configuration

Change PICS items CF10 and CF11 as follows and insert CF15 at the end of the table:

Item	IUT configuration	References	Status	Support
*CF10	Is spectrum management operation supported?	7.3.1.4, 11.6	(CF6 OR CF15):O	Yes ☐ No ☐
*CF11	Is regulatory classes capability implemented?	7.3.2.12, 17.3.8.3.2, 17.3.8.6, 17.4.2, Annex I, Annex J	(CF6 OR CF15)& CF8&CF10:O	Yes ☐ No ☐
*CF15	Enhancements for Higher Throughput	7.3.2.49 (HT Capabilities element)	O	Yes ☐ No ☐

A.4.14 QoS base functionality

Change PICS item QB4 and insert the following two rows immediately below it as follows:

Item	Protocol capability	References	Status	Support
QB4	Block Acknowledgements (Block Acks)	~~7.2.1.7, 7.2.1.8, 7.4.4, 9.10, 11.5~~	~~CF12:O~~	~~Yes ☐ No ☐ N/A ☐~~
QB4.1	Immediate Block Ack	7.2.1.7, 7.2.1.8, 7.4.4, 9.10, 11.5	CF12:O	Yes ☐ No ☐ N/A ☐
QB4.2	Delayed Block Ack	7.2.1.7, 7.2.1.8, 7.4.4, 9.10, 11.5	CF12:O	Yes ☐ No ☐ N/A ☐

Insert the following new subclause heading:

A.4.17 Enhancements for Higher Throughput

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000924

Insert the following new subclause:

A.4.17.1 MAC enhancements for Higher Throughput

Item	Protocol capability	References	Status	Support
	Are the following MAC protocol enhancements supported?			
HTM1	HT capabilities signaling			
HTM1.1	HT capabilities element	7.3.2.49.1 (HT Capabilities element structure)	CF15:M	Yes ☐ No ☐ N/A ☐
HTM1.2	Signaling of STA capabilities in Probe Request, Association Request and Reassociation Request frames	7.3.2.49 (HT Capabilities element), 7.2.3.8 (Probe Request frame format), 7.2.3.4 (Association Request frame format), 7.2.3.6 (Reassociation Request frame format)	(CF15 AND CF2):M	Yes ☐ No ☐ N/A ☐
HTM1.3	Signaling of STA and BSS capabilities in Beacon, Probe Response, Association Response and Reassociation Response frames	7.3.2.49 (HT Capabilities element), 7.2.3.1 (Beacon frame format), 7.2.3.9 (Probe Response frame format), 7.2.3.5 (Association Response frame format), 7.2.3.7 (Reassociation Response frame format)	(CF15 AND CF1):M	Yes ☐ No ☐ N/A ☐
HTM2	Signaling of HT Information	7.3.2.50 (HT Information element)	(CF15 AND CF1):M	Yes ☐ No ☐ N/A ☐
HTM3	MPDU aggregation

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 000951

Annex D(normative) ASN.1 encoding of the MAC and PHY MIB

Insert in the list of IMPORTS from SNMPv2-SMI the following:

```
Counter64
```

In Annex D, insert the following comment to the end of SMT attributes after dot11FastBSSTransitionTable:

```
-- dot11HTStationConfigTable ::= { dot11smt 16 }
```

In Annex D, insert the following comment to the end of dot11phy after dot11PhyERPTable:

```
-- dot11PhyHTTable ::= {dot11phy 15 }
-- dot11HTSupportedMCSTxTable ::= { dot11phy 16 }
-- dot11HTSupportedMCSRxTable ::= { dot11phy 17 }
-- dot11TxBFConfigTable ::= { dot11phy 18 }
```

In the dot11StationConfig table of Annex D, change the dot11StationConfigEntry sequence by inserting a comma and the new entry at the end of the existing entries (which are represented below by "…") as follows:

```
Dot11StationConfigEntry ::=
    SEQUENCE {
          … ,
          dot11HighThroughputOptionImplemented TruthValue
}
```

Change the definition of dot11OperationalRateSet as shown below:

```
dot11OperationalRateSet OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(1..126))
MAX-ACCESS read-write
STATUS current
DESCRIPTION
              "This attribute shall specify the set of non-HT data rates at
which the station may transmit data. The attribute that specifies the set of
HT data rates is dot11HTOperationalMCSSet. Each octet contains a value
representing a rate. Each rate shall be within the range from 2 to 127,
corresponding to data rates in increments of 500 kbit/s from 1 Mb/s to 63.5
Mb/s, and shall be supported (as indicated in the supported rates table) for
receiving data. This value is reported in transmitted Beacon, Probe Request,
Probe Response, Association Request, Association Response, Reassociation
Request, and Reassociation Response frames, and is used to determine whether
a BSS with which the station desires to synchronize is suitable. It is also
used when starting a BSS, as specified in 10.3."
::= { dot11StationConfigEntry 11 }
```

               dot11PCO20MinDuration INTEGER
                }
```

(Ed: CID 8119) Change the entry for dot11RTSThreshold as follows:

```
dot11RTSThreshold OBJECT-TYPE
       SYNTAX INTEGER (0..3000)
       MAX-ACCESS read-write
       STATUS current
       DESCRIPTION
              "This attribute shall indicate the number of octets in an MPDUPSDU,
              below which an RTS/CTS handshake shall not be performed, except as
              RTS/CTS is used as a cross modulation protection mechanism as
              defined in 9.10. An RTS/CTS handshake shall be performed at the
              beginning of any frame exchange sequence where the MPDUPSDU is of
              type Data or Management, the MPDUPSDU has an individual address in
              the Address1 field, and the length of the MPDUPSDU is greater than
              this threshold. (For additional details, refer to Table 21 in 9.7.)
              Setting this attribute to be larger than the maximum MSDUPSDU size
              shall have the effect of turning off the RTS/CTS handshake for
              frames of Data or Management type transmitted by this STA. Setting
              this attribute to zero shall have the effect of turning on the RTS/
              CTS handshake for all frames of Data or Management type transmitted
```

```
            by this STA. The default value of this attribute shall be
            3000 65535."
        ::= { dot11OperationEntry 2 }
```

Change the entry for dot11FragmentationThreshold as follows:

```
dot11FragmentationThreshold OBJECT-TYPE
        SYNTAX INTEGER (256..2340 8000)
        MAX-ACCESS read-write
        STATUS current
        DESCRIPTION
            "This attribute shall specify the current maximum size, in
            octets, of the MPDU PSDU that may be delivered to the PHY.
            This maximum size does not apply in the case of A-MPDU. An
            MSDU, A-MSDU or MMPDU shall be broken into fragments if its
            size exceeds the value of this attribute after adding MAC
            headers and trailers. An MSDU, A-MSDU or MMPDU shall be
            fragmented when the resulting frame has an individual address
            in the Address1 field, and the length of the frame is larger
            than this threshold. The default value for this attribute
            shall be the lesser of 3000 8000 or the aMPDUMaxLength or the
            aPSDUMaxLength of the attached PHY and shall never exceed the
            lesser of 3000 8000 or the aMPDUMaxLength or the
            aPSDUMaxLength of the attached PHY. The value of this
            attribute shall never be less than 256."
        ::= { dot11OperationEntry 5 }
```

Exhibit 1014
Page 000997

Annex G (informative) An example of encoding a frame for OFDM PHY

Change G.2 as follows:

G.2 The message for the BCC example

The message being encoded consists of the first 72 characters (shown in **bold** font) of the well-known "Ode to Joy" by F. Schiller:

Change the first 72 characters of the text quoted from G.2 to a bold font as follows:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header and a CRC32 is added. The resulting 100 octets PSDU is shown in Table G.1.

EDITORIAL NOTE—There are four changes: (1) The header for the left column has changed; (2) seven entries in the left column have been corrected; (3) the last 4 entries of the bottom row have the corrected CRC32 value; and (4) the caption indicates the example is specific to BCC.

Replace Table G.1 with the following:

Table G.1—The message for the BCC example

Octet ##	Val	Val	Val	Val	Val
1...5	04	02	00	2E	00
6...10	60	08	CD	37	A6
11...15	00	20	D6	01	3C

91...95	65	20	74	72	65
96...100	61	67	33	21	B6

Change the heading of G.5 as follows:

G.5 Generating the DATA bits <u>for the BCC example</u>

G.5.1 Delineating, SERVICE field prepending, and zero padding

Change G.5.1 as follows:

The transmitted message shown in Table G.1 contains 100 octets or, equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits and are appended by 6 tail bits. The resulting 822 bits are appended by zero bits to yield an integer number of OFDM symbols. For the 36 Mb/s mode, there are 144 data bits per OFDM symbol; the overall number of bits is ceiling (822/144) × 144 = 864. Hence, 864 – 822 = 42 zero bits are appended.

~~The data bits are shown in Table G.13 and Table G.14. For clarity, only the first and last 144 bits are shown.~~ <u>The DATA bits are shown in Table G.13. Note that the bit-ordering of the octets is most significant bit first.</u>

Change the heading of G.5.2 as follows:

G.5.2 Scrambling the BCC example

Change G.5.2 as follows:

The 864 bits are scrambled by the scrambler of Figure 117 (in 17.3.5.4). The initial state of the scrambler is the state 1011101. The generated scrambling sequence is given in Table G.15.

After scrambling, the 6 bits in location 816 (i.e. bit 817) to 821 (bit 822) are zeroed. ~~The first and last 144 scrambled bits are show in Table G.16 and G.17, respectively.~~ The scrambled DATA bits are shown in Table G.16, with the bit-ordering being most significant bit first.

Change the heading of G.6 as follows:

G.6 Generating the first DATA symbol for the BCC example

Change G.6.1 as follows:

G.6.1 Coding the DATA bits

The scrambled bits are coded with a rate 3/4 convolutional code. ~~The first 144 scrambled bits of Table G.16 are mapped into the 192 bits of G.18.~~ The DATA encoded bits are shown in Table G.18, with the bit-ordering being most significant bit first.

Change G.8 as follows:

G.8 The entire packet for the BCC example

The packet in its entirety is shown in Table G.24 to Table G.32. ~~The short sequences section, the long sequences section, the SIGNAL field, and the DATA symbols are separated by double lines.~~ These tables illustrate the short training sequence section (Table G.24), the long training sequence section (Table G.25), the SIGNAL field (Table G.26), and the six DATA symbols (Table G.27 to G.32).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001014

Insert the following new subclause:

G.9 Generating encoded DATA bits — LDPC example 1

LDPC example 1 is similar to the BCC Example. This example illustrates LDPC shortening, encoding, and puncturing of a single codeword.

Input TXVECTOR parameters for LDPC example 1:

- TxVectorCW = 0(TXVECTOR ChannelWidth = 0 => 20 MHz)
- TxVectorMCS = 4(MCS = 4; QAM 16; Code Rate = 3/4)
- Code Rate R = 3/4
- TXVectorLength = 100 octets(with 16-bit SERVICE field becomes 102 Octets = 816 bits to scramble and encode)
- m_STBC = 1(STBC = OFF)

G.9.1 The message for LDPC example 1

The message being encoded consists of the first 72 characters (shown in **bold** below) of the well-known "Ode to Joy" by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header and a CRC32 is added. The resulting 100 octets PSDU is shown in Table G.33.

NOTE 1—the message for LDPC example 1 is identical to the corrected message for the BCC example, meaning that the FCS field (octets 97-100) has the correct CRC 32 value.

NOTE 2—the DurationID field (i.e., octets 3 and 4) remains 0x02E = 46 μs.

G.9.2 Prepending the SERVICE field for LDPC example 1

The transmitted message shown in Table n33 (The message for LDPC example 1) contains 100 octets, or equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits (bits 0-15 in Table n34 (The DATA bits for LDPC example 1 before scrambling)), as defined in 20.3.10.1 (The SERVICE field), but tail bits and padding bits are not appended as in the BCC Example. The resulting 816 bits are shown in Table G.34.

NOTE—the CRC32 value is correct in bits 784-815. Bit-ordering of octets is most significant bit first.

G.9.3 Scrambling LDPC example 1

The 816 bits are scrambled by the scrambler of Figure 117. The initial state of the scrambler is the state 1011101 binary (0x5D hexadecimal). The scrambled sequence is given in Table G.35, with the bit-ordering being most significant bit first.

G.9.4 Inserting the shortening bits for LDPC example 1

The equations of 20.3.10.6.5 (LDPC PPDU encoding process) are solved to calculate the following derived parameters for LDPC example 1 from the input TXVECTOR parameters:

— $N_{CW} = 1$ (number of codewords)
— $L_{LDPC} = 1944$ (size of codeword)
— $N_{CBPS} = 208$ (number of coded bits per symbol)
— $N_{avbits} = 1248$ (number of available bits)
— $N_{shrt} = 642$ (number of bits to be shortened)
— $N_{punc} = 54$ (number of bits to be punctured)
— $N_{SYM} = 6$ (number of OFDM symbols)
— $N_{rep} = 0$ (number of bits to be repeated)

The results of applying shortening bits, as prescribed in paragraph (c) of 20.3.10.6.5 (LDPC PPDU encoding process) is given in Table G.36, with the bit-ordering being most significant bit first.
NOTE—N_{shrt} = 642 shortening bits have been inserted as zeroes in bits 816-1457.

G.9.5 Encoding the data for LDPC example 1

The DATA with shortening bits are LDPC encoded as a single ($N_{CW} = 1$) codeword ($L_{LDPC} = 1944$; R = 3/

1896-1919	00100011	10011011	00110110	0x23	0x9B	0x36
1920-1943	00111110	00010101	00010001	0x3E	0x15	0x11

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 20.3.10.6.5 (LDPC PPDU encoding process). Finally, either puncturing is applied as described in paragraph (d) of the same subclause or the copying of repeated bits are applied as described in paragraph (e) of the same subclause. In LDPC example 1, because $N_{punc} = 54$ is non-zero and $N_{rep} = 0$, puncturing is prescribed, completing the LDPC encoding process.

The results are given in Table G.38, with the bit-ordering being most significant bit first.

NOTE—the $N_{shrt} = 642$ shortening bits have been removed and that the $N_{punc} = 54$ bits have been punctured from Table G.37 to produce bits 816-1247 of Table G.38.

G.10 Generating encoded DATA bits — LDPC example 2

LDPC example 2 exercises the alternative branches of the LDPC encoding procedure not exercised in LDPC example 1, employs multiple codewords, and diversifies the TXVECTOR parameters, without making the length of this example cumbersome.

This example exhibits LDPC shortening, encoding, and padding by repetition. The length of the text of the message was increased by 40 octets from 72 characters to 144 characters, in order to illustrate padding (rather than puncturing) and encoding of multiple codewords.

Input TXVECTOR parameters for LDPC example 2:

- TxVectorCW = 1 (TXVECTOR ChannelWidth = 1 => 40 MHz)
- TxVectorMCS = 1 (MCS = 1; QPSK; Code Rate = 1/2)
- Code Rate R = 1/2

— TXVectorLength = 140 Octets (with 16-bit SERVICE field becomes 142 Octets = 1136 bits to scramble and encode)

— m_STBC = 2 (STBC = ON)

G.10.1 The message for LDPC example 2

The message being encoded consists of the first 112 characters (shown in **bold** below) of the well-known "Ode to Joy" by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers

Exhibit 1014
Page 001026

Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header and a CRC32 is added. The resulting 100 octets PSDU is shown in Table G.39.

Because of the additional 40 characters, note that the message for LDPC example 2 has a different FCS field (octets 137-140) than the previous examples, and that the DurationID field (i.e., octets 3 and 4) changes to 0x036 = 54 μs.

136...140	74	3B	DB	B5	22

G.10.2 Prepending the SERVICE field for LDPC example 2

The transmitted message shown in Table G.39 contains 140 octets, or equivalently, 1120 bits. The bits are prepended by the 16 SERVICE field bits (bits 0-15 in Table G.40), as defined by 20.3.10.1 (The SERVICE field), but tail bits and padding bits are not appended as in the BCC Example. The resulting 1136 bits are shown in Table G.40. Bit-ordering is most significant bit first.

Table G.40—The DATA bits for LDPC example 2 before scrambling

G.10.3 Scrambling LDPC example 2

The 1136 bits are scrambled by the scrambler of Figure 117. The initial state of the scrambler is the state 1011101 binary (0x5D hexadecimal). The scrambled sequence is given in Table G.41, with the bit-ordering being most significant bit first.

G.10.4 Inserting the shortening bits for LDPC example 2

The equations of 20.3.10.6.5 (LDPC PPDU encoding process) are solved to calculate the following derived parameters for LDPC example 2 from the input TXVECTOR parameters:

— $N_{CW} = 2$ (number of codewords)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001031

- $L_{LDPC} = 1296$ (size of codeword)
- $N_{CBPS} = 216$ (number of coded bits per symbol)
- $N_{avbits} = 2592$ (number of available bits)
- $N_{shrt} = 160$ (number of bits to be shortened)
- $N_{punc} = 0$ (number of bits to be punctured)
- $N_{SYM} = 12$ (number of OFDM symbols)
- $N_{rep} = 160$ (number of bits to be repeated)

The results of applying shortening bits, as prescribed in paragraph (c) of 20.3.10.6.5 (LDPC PPDU encoding process) is given in Table G.42, with the bit-ordering being most significant bit first.

NOTE— $N_{shrt} = 160$ shortening bits have been inserted as zeroes, 80 zeroes at bits 568-647 and 80 zeroes at bits 1216-1295, which equally distributes the shortening bits across the $N_{CW} = 2$ codewords.

Table G.42—The DATA bits for LDPC Example #2 after insertion of shortening bits

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001033

The DATA with shortening bits are LDPC encoded as two (N_{CW} = 2) codewords (L_{LDPC} = 1296; R = 1/2) as prescribed by paragraph (c) of 20.3.10.6.5 (LDPC PPDU encoding process) . The results are given in Table G.43, with the bit-ordering being most significant bit first.

NOTE—the LDPC encoder appends 648 bits as follows: bits 648-1295 after the first shortened codeword; and another 648 bits, bits 1944-2591, after the second shortened codeword.

Table G.43—The DATA bits for LDPC example 2 after LDPC encoding

G.10.6 Removing the shortening bits and repetition for LDPC example 2

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 20.3.10.6.5 (LDPC PPDU encoding process). Finally, either puncturing is applied as described in paragraph (d) of the same subclause or the copying of repeated bits are applied as described in paragraph (e) of the same subclause. In LDPC example 1, because $N_{punc} = 0$ and $N_{rep} = 160$ is non-zero, repetition is prescribed, completing the LDPC encoding process.

The results are given in Table G.44, with the bit-ordering being most significant bit first.

NOTE 1—$N_{shrt} = 642$ shortening bits have been removed and $N_{punc} = 54$ bits have been punctured from Table G.37 to produce bits 816-1247 of Table G.38.

NOTE 2—The first 80 shortening bits (bits 568-647 from Table G.43) have been removed from the first codeword between bit 567 and 568 of Table G.44, and that the second 80 shortening bits (bits 1864-1943 of Table G.43) have been removed between bits 1215 and 1216 of Table G.44. Also, 80 bits have been repeated from the beginning of the first codeword (bits 0-79) to the end of the first codeword (bits 1216-1295), and 80 bits have been repeated from the beginning of the second codeword (bits 1296-1375) to end of the second codeword (bits 2512-2591) in Table G.44.

Annex I (informative) Regulatory Classes

Insert a new row after the tenth Behavior limits set row, and change the last row of Table I.3 as shown:

Table I.3—Behavior limits sets

Behavior limits set	USA	Europe	Japan
13 40 MHz Primary channel with Secondary = 1 and also 20 MHz operation on primary channel	Reserved	Reserved	Reserved
14 40 MHz Primary channel with Secondary = -1 and also 20 MHz operation on primary channel	Reserved	Reserved	Reserved
15~~11~~ – 255	Reserved	Reserved	Reserved
NOTE—For 20 MHz operation where the regulatory class signifies 40 MHz channel spacing, the 20 MHz channel corresponds to the channel number indicated.

Annex J(normative) Country information element and regulatory classes

Insert new penultimate rows, change the last row and insert the note after the last row of Table J.1 as shown:

Table J.1—Regulatory classes in the USA

Regulatory Class	Channel Starting Frequency (GHz)	Channel Spacing (MHz)	Channel set	Transmit Power limit (mW)	Emissions Limits set	Behavior Limits set
22	5	40	36, 44	40	1	1,2,13
23	5	40	52, 60	200	1	1,13
24	5	40	100, 108, 116, 124, 132	200	1	1,13
25	5	40	149, 157	800	1	1,13
26	5	40	149, 157	1000	4	10,13
27	5	40	40, 48	40	1	1,2,14
28	5	40	56, 64	200	1	1,14
29	5	40	104, 112, 120, 128, 136	200	1	1,14
30	5	40	153, 161	800	1	1,14
31	5	40	153, 161	1000	4	10,14
32	2.407	40	1-7	1000	4	10,13
33	2.407	40	5-11	1000	4	10,14
~~12~~31-255	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
NOTE—The Channel Spacing for Regulatory Class 22-33 is for the supported bandwidth rather than the operating bandwidth. In these regulatory classes, the AP operates in 20/40 MHz mode, and the operating bandwidth for a non-AP STA is either 20 MHz or 40 MHz.						

Insert new penultimate rows and change the last row of Table J.2 as shown:

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001047

Insert the following new Annex heading:

Annex S (Informative) Frame exchange sequences

EDITORIAL NOTE—Editing instructions in 9.12 move that subclause into this informative annex. Editing instructions in this Annex assume that this repositioning has taken place.

Change the first paragraph as follows:

The allowable frame exchange sequences are defined using an extension of the EBNF format as defined in ISO/IEC 14977: 1996(E). The elements of this syntax that are used here are:

- [a] = a is optional
- {a} = a is repeated zero or more times
- n{a} = a is repeated *n* or more times. For example, 3{a} requires 3 or more "a".
- a|b = a xor b
- () = grouping, so "a (b|c)" is equivalent to "a b | a c"
- (* a *) = "a" is a comment. Comments are placed before the text they relate to.
- ~~<> = order of frames not relevant.~~*e.g.*. For example, ~~<a b> is either "a b" or "b a"~~
- A rule is terminated by a semicolon ";"
- Whitespace is not significant, but ~~it~~is used to highlight the nesting of grouped terms.

Change the second paragraph as follows:

Two types of terminals are defined:

- *Frames*: A frame is shown in Bold, and identified by its type/subtype. For example, **Beacon** and **Data.** Frames are shown in an initial capital letter.
- *Attributes*: Attributes are shown in italic. An attribute is introduced by the "+" character. The attribute specifies a condition that applies to the frame that precedes it. Where there are multiple attributes applied, they are generally ordered in the same order of the fields in the frame they refer to. The syntax a+(b|c) where b and c are attributes is equivalent to (a+b) | (a+c).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001048

Change Table 76 appropriately renumbered following its move to this annex as follows:.

Table 76—Attributes applicable to frame exchange sequence definition

Attribute	Description
ampdu	Frame is part of an A-MPDU aggregate
ampdu-end	Frame is the last frame in an A-MPDU aggregate
block-ack	QoS Data frame has Ack Policy set to Block Ack
broadcast	Frame RA is the broadcast address
CF	Beacon contains a CFP element
CF-Ack	Data type CF-Ack subtype bit set to 1 or CF-End+CF-Ack frame
CF-Poll	Data type CF-Poll subtype bit set to 1
csi	A Management Action frame carrying channel state feedback (either channel state information, uncompressed or compressed beamforming matrices).
csi-request	A +HTC frame with the Feedback Request field set to a value > 0
delayed	BlockAck or BlockAckReq under a delayed policy
delayed-no-ack	BlockAck or BlockAckReq frame has No Ack Ack Policy
DTIM	Beacon is a DTIM
frag	Frame has its More Fragments field set to 1
group	Frame RA has Individual/Group bit set to 1
HTC	+HTC frame, i.e., a QoS Data or Control frame with the Order field of the Frame Control field set to 1
implicit-bar	QoS Data frame in an A-MPDU with Normal Ack Ack Policy
individual	Frame RA has i/g bit set to 0
last	Frame has its More Fragments field set to 0
L-sig	L-sig duration not equal to PPDU duration
action-no-ack	Management frame of subtype Action No Ack
mfb	A +HTC frame with the MFB field is not set to all ones
more-psmp	A PSMP frame with the More PSMP field set to 1
mrq	A +HTC frame with the MRQ field set to 1
mtba	Ack Policy of QoS data frame is set to MTBA
ndp-announce	A +HTC frame with the NDP Announcement field set to 1
no-ack	QoS Data frame has Ack Policy set to No Ack
no-more-psmp	A PSMP frame with the More PSMP field set to 0
normal-ack	QoS Data frame has Ack Policy set to Normal Ack
non-QAP	Frame is transmitted by a non-AP QSTA

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001049

Table 76—Attributes applicable to frame exchange sequence definition *(continued)*

Attribute	Description
non-stbc	PPDU TXVECTOR STBC parameter is set to 0
null	Data type Null Data subtype bit set
pifs	Frame is transmitted ~~using~~following a PIFS
QAP	Frame is transmitted by a QAP
QoS	Data type QoS subtype bit set
RD	Frame includes an HT control field in which the RD subfield is set to 1
self	Frame RA = TA
sounding	PPDU TXVECTOR NOT_SOUNDING parameter present and set to 0
stbc	PPDU TXVECTOR STBC parameter is set to a value >0
trq	Frame is a +HTC frame with the TRQ field set to 1

Change the txop-sequence term as follows:

(* A TXOP (either polled or EDCA) may be filled with txop-sequences, which are initiated by the TXOP holder. *)

txop-sequence = (((**RTS CTS**) | **CTS**+*self*) **Data**+*individual*+*QoS*+(*block-ack*|*no-ack*)) |
[**RTS CTS**] (TXOP-part-requiring-ack TXOP-part-providing-ack) |
[**RTS CTS**] (**Management**|(**Data**+QAP))+*individual* **Ack** |
[**RTS CTS**] (**BlockAckReq BlockAck**) |
ht-txop-sequence;

Delete the term poll-sequence as shown:

~~(* A poll-sequence is the start of a polled TXOP, in which the HC delivers a polled TXOP to a QSTA. The poll may or may not piggyback a CF-Ack according to whether the previous frame received by the HC was a Data frame. *)~~

~~poll-sequence = non-cf-ack-piggybacked-qos-poll-sequence |~~

~~cf-ack-piggybacked-qos-poll-sequence;~~

Modify the term txop-part-requiring-ack as follows:

(* These frames require acknowledgement *)

txop-part-requiring-ack = **Data**+*individual*[+*null*] |
Data+*individual*[+*null*]+*QoS*+*normal-ack* |
BlockAckReq+*delayed* |
BlockAck+*delayed*;

Modify the term txop-part-providing-ack as follows:

(* These frames provide acknowledgement to the TXOP-part-requiring-ack *)

txop-part-providing-ack= **Ack** |

(* An HC responds with a new polled TXOP on expiry of current TXOP *)
cf-ack-piggybacked-qos-poll-sequence |

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001050

(* An HC responds with CF-Ack and its own data on expiry of TXOP *)
cf-ack-piggybacked-qos-data-sequence |
Data+*CF-Ack*;

Insert the following paragraphs after the term starting "cf-ack-piggybacked-qos-data-sequence":

(* The ht-TXOP-sequence describes the additional sequences that may be initiated by an HT STA that is the holder of a TXOP *)
ht-TXOP-sequence = L-sig-protected-sequence |
long-nav-protected-sequence |
nav-protected-sequence |
dual-cts-protected-sequence |
1{initiator-sequence};

(* an L-sig-protected-sequence is a sequence protected using the L-sig TXOP protection feature *)
L-sig-protected-sequence = L-sig-protection-set 1{initiator-sequence} eifs-reset;

(* An eifs-cancellation sequence is transmitted at the end of an L-sig-protected-sequence in order to reset the EIFS state of non-HT STA. The L-sig duration expires before the eifs-cancellation sequence starts. *)
eifs-reset = **CF-End** | (**CF-End**+*non-QAP* **CF-End**+*QAP*);

(* a long-nav-protected sequence consists of setting the NAV, performing one or more initiator-sequences and then resetting the NAV if time permits, or resetting EIFS if non-HT devices are present. *)
long-nav-protected-sequence = nav-set 1{initiator-sequence} [nav-reset | eifs-reset];

(* nav-protected-sequence starts with a sequence that sets the NAV, followed by sequences initiated by the TXOP holder, followed by an eifs-reset sequence if non-HT devices are present. *)
nav-protected-sequence = nav-set 1{initiator-sequence} [eifs-reset];

(* a dual-cts-protected-sequence is a sequence protected using the dual CTS protection feature *)
dual-cts-protected-sequence = dual-cts-nav-set 1{initiator-sequence};
(* a dual-cts-nav-set is an initial exchange that establishes NAV protection using dual CTS protection.
dual-cts-nav-set = (* A dual CTS initiated by a non-AP STA that is not STBC capable *)
(**RTS**+*non-stbc*+*non-QAP* **CTS**+*non-stbc*+*QAP* **CTS**+*stbc*+*pifs*+*QAP*) |

(* A dual CTS initiated by a non-AP STA that is STBC capable *)
(**RTS**+*stbc*+*non-QAP* **CTS**+*stbc*+*QAP* **CTS**+*non-stbc*+*QAP*) |

(* An STBC initiator-sequence (i.e., containing STBC PPDUs) transmitted by the QAP is protected by non-STBC CTS to self *)
(**CTS**+*self*+*non-stbc*+*QAP*) |

(* A non-STBC initiator-sequence transmitted by the QAP is protected by STBC CTS to self *)
(**CTS**+*self*+*stbc*+*QAP*);

(* an ma-no-ack-htc represents a Management Action No Ack + HTC frame *)
ma-no-ack-htc = **Management**+*action-no-ack*+*HTC;*

(* This is the sequence of frames that establish protection using the L-sig TXOP protection method *)
L-sig-protection-set = (**RTS**+*L-sig*[+*HTC*] **CTS**+*L-sig*[+*HTC*]) |
(**RTS**+*L-sig*[+*HTC*] **CTS**+*L-sig*[+*HTC*]+*ampdu*
ma-no-ack-htc+*ampdu*+*ampdu-end*) |

) **NDP**
);

(* During operation of explicit txbf, there are three encodings of feedback information. These are not distinguished here and are all identified by the *csi* attribute. The feedback position may be: immediate, aggregate or unsolicited. Immediate feedback follows a SIFS after a CSI request, identified by the *csi-request* attribute. Aggregate feedback occurs during an aggregate within the same TXOP, and may accompany Data frames in the same PPDU. Unsolicited feedback occurs during a subsequent TXOP during which the CSI responder is TXOP intiator. Only immediate feedback is described in the syntax below. The frame indicating any *csi-request* is carried in a sounding PPDU or followed by an NDP. The CSI response is

Insert the following Annex:

Annex T (Informative) Additional High Throughput information

T.1 Waveform Generator Tool

Add the following text:

As an informative extension to the specification, the Waveform Generator Tool has been written to model the PHY transmission process described in Clauses 17, 19, and 20.

The waveform generator can be downloaded from the public IEEE web site.

The purpose of the Tool is to promote common understanding of complex PHY algorithms, facilitate device interoperability by providing reference test vectors, and assist researchers in industry and academia to develop next generation wireless solutions.

The code is written in the MATLAB computing language, and can be configured to generate test vectors for most PHY configurations, defined by the specification. Instructions on how to configure and run the Tool are specified in the documentation files that are supplied with the code. A command line interface and GUI interface exist to configure the tool. For consistency with specification, the configuration interface is made very similar to the TXVECTOR parameters defined in 20.2.2 (TXVECTOR and RXVECTOR parameters).

The Waveform Generator Tool produces test vectors for all transmitter blocks, defined in Figure n63 (Transmitter block diagram for the non-HT portion and the HT signal field of the HT mixed format packet) and Figure n64 (Transmitter block diagram for the greenfield format packet and HT portion of the mixed format packet except HT signal field), generating reference samples in both frequency and time domains. Outputs of the Tool are time domain samples for all transmitting chains.

T.2 Summary of the use of HT Protection Signalling

This subclause contains a summary of typical use of the OBSS Non-HT STAs Present field, NonERP_Present bit and Use_Protection bit.

Separate fields and bits are used for status reporting (OBSS Non-HT STAs Present and NonERP_Present) and for protection (Operating Mode and Use_Protection) so that protection extends to the BSS directly detecting the non-HT STAs and to the nearby BSSs, but not beyond. Table T.1 describes typical uses of these fields and bits. A first AP has non-HT STAs associated to its BSS or directly observes a non-HT BSS, and reports this status to its neighbors (Layer 1c). A second AP's BSS overlaps the first AP's BSS, and may respond to the status report by requiring protection (Layer 2b or 2c). The second AP does not relay the status report further. A third AP's BSS overlaps the second AP's BSS but not the first, and so the third AP sees no report of non-HT STAs and so requires no protection (Layer 3).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001058

Table T.1—Summary of typical use of the OBSS Non-HT STAs Present field, NonERP_Present bit and Use_Protection bit

Layer	Indication from overlapping BSS		Indication to Associated STAs		Indication to overlapping BSSs		Typical Use
	OBSS Non-HT STAs Present from overlapping BSS	ERP IE is present and NonERP_Present equals 1 from overlapping BSS	Operating Mode	ERP IE is present and Use_Protection equals 1	OBSS Non-HT STAs Present	ERP IE is present and NonERP_present equals 1	
1a	0	0	1	0	0	0	Non-HT STAs may be present in both the primary and the secondary channel, but protection by overlapping BSSs is determined to not be necessary.
1b	0	0	3	0, 1	0	0	Non-HT STAs are associated to and protected by the BSS, but protection by overlapping BSSs is determined to not be necessary.
1c	0	0	3	0, 1	1	0, 1	Non-HT STAs are associated to and protected by the BSS, and protection by overlapping BSSs is determined to be necessary.
1d	1	0	3	0	1	0	Both the BSS and an overlapping BSS have determined that protection by the BSS is necessary, and protection by overlapping BSSs is determined to be necessary.
		0		1		1	
		1		0		1	
		1		1		1	
2a	1	0, 1	1	0	0	0	An overlapping BSS has determined that protection by the BSS is necessary, but the BSS is advising that there may be non-HT STAs, rather than requiring protection.
2b	1	0, 1	3	0, 1	0	0	An overlapping BSS has determined that protection by the BSS is necessary, the BSS has no associated non-ERP STAs, and the BSS is requiring the determined protection.
2c	1	0, 1	3	1	0	0	An overlapping BSS has determined that protection by the BSS is necessary, the BSS has associated non-ERP STAs, and the BSS is requiring protection.
3	0	0	0, 2	0	0	0	No non-HT STAs are present. (Layer 3)
Various	Other combinations of values						None or unusual.

If you have trouble reading or printing our PDF documentation with the version of Acrobat Reader you are currently using, or if you don't have Acrobat Reader installed on your computer, you can download the latest version of Acrobat Reader from Adobe or by clicking the icon above now.

The IEEE-SA has created an easy to use Online Standards Development web site that has a wealth of information that details the whole standards process flow, from creation of the initial PAR, to balloting to final draft, and beyond. It even includes, tutorials, and online forms of the various processes evolved. This site is recommended for all Member's and Chair's involved.

IEEE 802.11 WLAN CONFERENCE CALL SCHEDULES

TGy	Tue	08/15/06	Once	13:00

HAVE ACCESS TO THE 802.11 PRIVATE AREA OF THIS WEB SITE ?

. . . you have direct access to the 802.1, 802.15, 802.16, 802.17, 802.18, 802.19, 802.20, 802.21, 802.22, & ETSI-BRAN private areas as well, by using your existing assigned 802.11 user name and password.

Having this ability enables us to freely access each others working documentation online. This is over and above the existing privilege of accessing ETSI-BRAN documentation.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001066

IEEE 802 STANDARDS AVAILABLE FOR FREE DOWNLOAD !

On 15 May 2001, the IEEE made available published 802 standards for free download. This being Six months after the initial publication of a standard, under this program.

All relevant IEEE 802.11 Standard, Amendments, and Recommended Practices are listed here.

IEEE 802.11 STANDARD INTERPRETATIONS

Interpretations are issued to explain and clarify the intent of the standard and are not intended to constitute an alteration to the original standard or to supply consulting information. Any changes to the standard are made only through revisions or supplements to the standard.

It is recognized that requests are frequently received that are partially or totally requests for information rather than requests for an interpretation. It is inappropriate to issue an official interpretation to answer such requests.

- IEEE Standards Interpretations
- Procedure for Requesting an Interpretation
- Current IEEE 802.11 WG Interpretations
- Available IEEE Standards Interpretations Online

To view the 802.1, 802.11, 802.15, 802.16, 802.17, 802.18, 802.19, 802.20, 802.21, 802.22, or the ETSI-BRAN documentation, you only have to enter your normally attended IEEE Working Group or Technical Advisory Group "Members Only -Username \ Password" to access all these private areas. Therefore, it is imperative that you do not allow your Username or Password to be misused as per the rules that cover the issuance of these parameters in the first place from the WG and as detailed in the operating rules.

From the WG's perspectives, it is mainly due in part to the close working relationship that the 802 Wireless WGs, TAGs & ETSI-BRAN have with each other that has allowed us to achieve this unprecedented step. Going forward it will be an invaluable resource to all groups concerned. We hope this relationship will be one of many within IEEE and other International standards bodies around the world.

802.11 members access to ETSI-BRAN INFO:

To view the ETSI-BRAN information, or alternatively use the hyperlink on the contents menu on this page. Please note, you will have to enter the normal IEEE 802.11 WG Members Only Username \ Password to access this area. For our colleagues from 802.1, 802.15, 802.16, 802.17, 802.18, 802.19, 802.20, 802.21, and 802.22 WGs \ TGs they may use their groups own assigned Members Only Username \ Password.

This page is maintained by Stuart J. Kerry. Comments are welcome.

IEEE Std 802.11, 802.11a, 802.11b, 802.11b-Cor1, 802.11d, 802.11e, 802.11F, 802.11g, 802.11h, 802.11i, 802.11j, 802.11k, 802.11m, 802.11-REVma, 802.11n, 802.11p, 802.11r, 802.11s, 802.11T, 802.11v, 802.11u, 802.11w, 802.11y, 802.11.1 and 802.11.2 are trademarks of the IEEE. Name	Company	Address	Phone	email
R. R. Miller	AT&T	180 Park Ave, Florham Park NJ	973-236-6920	rrm@att.com

Abstract

This document records minutes of the 802.11 meeting of March 2007 at Orlando, Florida.

Notice: This document has been prepared to assist IEEE 802.11. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.

Release: The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.11.

Patent Policy and Procedures: The contributor is familiar with the IEEE 802 Patent Policy and Procedures <http://ieee802.org/guides/bylaws/sb-bylaws.pdf>, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair <stuart@ok-brit.com> as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.11 Working Group. **If you have questions, contact the IEEE Patent Committee Administrator at <patcom@ieee.org>.**

1. Monday Afternoon Opening Plenary, March 12, 2007

1.2. Opening

1.2.1. Call to Order

1.2.1.1. Number of people in the room: 177

1.2.1.2. Stuart Kerry (Stuart): I call the meeting to order.

1.2.1.3. Meeting convened at 1339 hours.

1.2.1.4. Stuart: There is some difficulty with the attendance system. We are attempting to fix the problem. Will the first person who notices the system is working again, please advise?

1.2.1.5. This is 102nd meeting. Our agenda (document number 07/0075r2) is shown. There is a notice asking you to switch off your phones. Use of any recording device is prohibited. Still photography is allowed only by permission of the chair. Both of these prohibitions are covered in the rules and procedures. Is everyone aware of these procedures? Yes.

1.2.1.6. Notification from floor: Attendance now working.

1.3. Process

1.3.1. Review/Modify the Agenda

1.3.1.1. Stuart: I ask that we approve the agenda as shown. [reviews items]. Is there any objection? Yes.

1.3.1.2. Adrian Stevens: We started a discussion at last session regarding process improvements. I would like to ask that we continue this discussion.

1.3.1.3. Stuart: I acknowledge your suggestion, and suggest that we schedule this for the Wednesday session. OK? Yes. Added to agenda for Wednesday.

1.3.1.4. Stuart: Any further modifications? Any objection to approving unanimously? None. So moved and approved. Adopted unanimously.

1.3.2. Review/Approve Minutes

1.3.2.1. Stuart: We need to approve the London minutes. Is there any objection to approving unanimously? None. Moved and approved unanimously.

1.3.3. Poll of First-Time Attendees

1.3.3.1. Stuart: Who is attending for first time? 7 attendees.

1.3.4. Financial Summary

1.3.4.1. Al Petrick: I show the document 07/0355r0 on the screen. [reviews] We show a healthy balance. We are using a new auditing form, required for non-profit organizations. Historical attendance is shown as well. Questions? None.

1.3.5. Review of LMS Policy

1.3.5.1. Stuart: Introduces people on the dais. Bob Miller will be substituting as secretary for this session. You have been issued a voting token. If your token does not indicate you are a qualified voter and you think you should be qualified to vote, see Harry Worstell. We operate under the LMSC P&P.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001082

06/812r3 shows our policies. We operate under Robert's Rules of Order. Voting can be obtained by attending two of the last 4 plenary meetings, or one plenary and one interim. Once you reach voter status, you must contact the appropriate vice-chair requesting voting rights 14 days in advance of the session. Once you receive your voting rights, you may attend study groups and task groups, with the voting token required to vote when motions are offered. See 07/344r0 which is new participant orientation.

1.3.5.2. Comments to media/press: Comments will be provided only by chairs and vice-chairs, and only on the week's activities.

1.3.5.3. Regarding reflector services: The reflector can be invoked for your use via ieee802.com/11. Click the task bar for reflector access. There is a confidentiality disclaimer. If you submit, you will be added. Attendees are responsible for maintaining accurate contact information; see Harry for questions. 5.2.11 of the rules requires declaration of affiliation. The affiliation is now required and will be shown on the minutes:

1.3.5.4. Stuart Kerry: NXP Semiconductor

1.3.5.5. Al Petrick: WiDefi

1.3.5.6. Harry Worstell: AT&T

1.3.5.7. Bob Miller (Temporary Secretary): AT&T

1.3.6. Review of Patent Policy

1.3.6.1. Stuart: Review of patent policy. [reads]

1.3.7. Review of Inappropriate Topics

1.3.7.1. Stuart: I'd like to review inappropriate topics. Contact the patent committee if you know of any violation. Anti-trust laws forbid certain discussions. Under U.S. copyright law, all submissions become the property of the IEEE. We represent individually, so no references to companies should be used. Any questions? None.

1.3.7.2. Gunther: How are we doing on attendance this week?

1.3.7.3. Stuart: Harry Worstell will explain.

1.3.7.4. Stuart: Al Petrick will now cover changes to code of ethics.

1.3.8. Review of Ethics Requirement Changes

1.3.8.1. Al Petrick: The SA has indicated that significant changes will occur with respect to patent policy. There has been rich input and legal counsel, leading to these policy changes. The patent group is now editing the patent policy. You can get access to some material on the IEEE site. In the April time-frame, the changes will be made final. I would like to cover them [reads]. Policy highlights were covered, including letters of assurance. Use of LOA form, which is now mandatory. Flexible licensing terms are now allowed. Questions? None.

1.3.8.2. Stuart: There is a tutorial tonight (tutorial #1) covering this material. Harry, Al, and I will attend. Chairs of task groups are urged to attend as well. Representatives of the SA patent committee and legal counsel will be present for questions.

1.3.8.3. Stuart: Does the chair need to be informed about any letters of assurance? None. Is everyone aware of the patent policy? No dissent. Any questions? No. We shall be operating as per these rules.

1.3.8.4. I have received an e-mail regarding a possible patent overlay for 802.11. I have talked to the IEEE patent secretary regarding CSIRO, which submitted a letter of assurance for 802.11. I have also requested a letter for 802.11n. This request will be sent to the appropriate contact.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001083

1.3.9. Other Announcements

1.3.9.1. Stuart: Discussion on process. LMSC rules regarding 15 and 30 day ballots.

1.3.9.2. The TGT chair has requested to step down. Suman has volunteered.

1.3.9.3. The TGv chair, Pat Calhoun, is stepping down. I am seeking nominations. Joe Epstein has volunteered. I will act on Wednesday or Friday depending on feedback from groups.

1.3.9.4. Regarding the Working Group secretary: Tim Godfrey could not attend this meeting. Bob Miller is stepping in.

1.3.9.5. Task Group "r" Appeal: The review judgment was issued, with the right to appeal which closed 3/10. Dan, will there be any appeal? No. There will be no appeal from Dan. Clint, will you choose to appeal? No. Gentlemen, thank you for abiding by the decision of the review.

1.3.9.6. An "Open Office" will be held this meeting. Use the opportunity to ask questions.

1.3.9.7. Are there any other announcements from the table? No. Any other announcements from the floor? No.

1.3.9.8. Caution: Book now for hotel in Montreal.

1.3.9.9. Regarding the Montreal schedule: Due to a previously-scheduled function, there will be no tutorials next time in Montreal on Monday night.

1.3.9.10. In September we shall meet at Waikoloa, HI. For November, Asia and the Far East are being considered. Auckland and Singapore appear too expensive. Taipai currently tops the list. Taipai is expensive, but we will draw down the treasury to partially subsidize the attendance fee. The break point will be 450 people. This will be the last international event, as discussed last time. In subsequent years only one international event will be held per year.

1.3.9.11. In May 2008 we are scheduled to meet in Jacksonville. March 2008 had been scheduled for New Orleans, however Hyatt has informed us that they cannot hold the event. Other choices by Hyatt were provided in other cities. The Caribe Royale also gave a good rate. The choices are, accordingly, Chicago, San Francisco, or Orlando. I'd like a poll to sample member view:

1.3.9.12. Anyone in room can vote (once).

1.3.9.13. Chicago: 30

1.3.9.14. San Francisco: Many (no count)

1.3.9.15. Orlando: Many (no count)

1.3.9.16. Andrew: Are we not having multiple international sessions?

1.3.9.17. Stuart: One per year has been decided by the group.

1.3.9.18. Stuart: I'd like to review PAR activities: QAW, 1AX, .3rev, .16c, .17c I'd appreciate feedback on these PARs. Are there any comments on these? No comments, no positions. You should reply by Wednesday if you have any comments.

1.3.9.19. Al Petrick: I shall post for a meeting to discuss. Watch poster board.

1.3.9.20. Stuart: Tutorials: Monday #1 Patent Policy, #2 Video over 802.11, Tuesday #3 Emergency Services for IEEE 802.

1.3.9.21. Harry: Wireless Update - We have over 50 APs here. Coverage should be complete. We have also gained free wireless access. Login: "IEEE", Password "802". Hotel has limited BW into our area, and we are negotiating to expand that.

1.3.9.22. Stuart: Harry will cover attendance.

1.3.9.23. Harry Worstell: Attendance update. See document 07/0369r1. It shows details of this gathering with TG credits for sessions. Tutorials count for 1 meeting if you attend both. You have to attend 12 meetings this week to get 75% credit. You can go to http://newton.events.ieee.org and select 802.11 or

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001084

go to http://newton.events.ieee.org/bin/attendance.cgi/802.11. You must sign in initially with your badge number before claiming credit. [runs through sign-in and attendance processes]. It is your responsibility to sign in. No corrections will be made after the fact, per Stuart's and CAC's policy. Newton.events.ieee.org can also be used to access documents, with years shown. Any new draft will be in the "drafts" area. Those drafts have not been entered yet, but will be shortly.

1.3.9.24. Floor: For tutorials, which session should be chosen? Tutorials aren't listed.

1.3.9.25. Harry: We will correct to add that.

1.3.9.26. Floor: Is there a way to log attendance as a function of time?

1.3.9.27. Harry: We are working on that. We have been selected as the beta test org for new features. For documentation, there is a new system that has been built. It is being trialed by chairs now. When tested thoroughly, it will replace 802wirelessworld.com. Hope to have it on line soon. Bob LaBelle is working on this with his team.

1.3.9.28. Stuart: A new web site is being prepared as well. [shows]

1.3.9.29. Harry: Voter Summary - 325 voters, with potential new voters at this meeting 34, nearly voters (haven't asked for rights yet) 36, aspirants 177, lost privileges 24. By not voting on letter ballots, many are losing their voting rights.

1.3.9.30. Stuart: You must click on voter request to request voting privileges, after you are convinced that you have met qualifications.

1.3.9.31. Stuart: Policy and Procedures Update will be provided by Al Petrick.

1.3.9.32. Al Petrick: We have been collecting input since last July. We have document 07/362r0 showing proposed changes to P&P. Document 07/360r0 contains the redlined version. I shall post these shortly. I would like you to forward comments to me. In the future, I also request that you e-mail me comments on an ongoing basis. Absent comments, the new policy will go into effect soon. We reviewed the changes proposed to CAC last night, with only one spotlighted issue. There is proposed text, current text, and the rationale for the change. [reviews each change]. Special consideration from last evening, treasurer's activities: If an ad-hoc meeting is happening external to 802.11, then none of the expenses will be reported to the working group or be assigned to the IEEE. I removed the text that relates to such meetings. All of these requirements are mandated by the LMSC. Please read through the documents and forward comments to me. Any questions? Yes.

1.3.9.33. Stuart: What happens next?

1.3.9.34. Al: Assuming no comments, the changes will be voted in at next meeting in July and become active.

1.3.9.35. David Hunter: Robert' Rules allow a chair to temporarily step down to allow him/her to make a technical comment, with the vice-chair continuing as chair until he/she is finished.. This appears to have been removed. Is that the intention?

1.3.9.36. Al: Let's take that off-line.

1.3.9.37. Stuart: Working Group Publicity - Al Petrick will cover publicity this week if issues arrive.

1.3.9.38. Stuart: Richard Paine will cover timelines.

1.3.9.39. Richard Paine: Timeline - Chairs must deliver timeline estimates to me by Thursday. Editors must reference the version of the .pdf document. Harry will run the editors' meeting.

1.3.9.40. Harry: Editors' Meeting Substituting for Terry Cole. At the editors' meeting, we shall resolve TBD use, update the "Editor's Best Practices" document, include reports on internationalization status, timelines, updates to the format in baseline, and discuss whether timeline is for WG or SA. The meeting is at 7 am tomorrow.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001085

1.3.9.41. Stuart: ANA Assignment - Bob O'Hara. I would like to thank Bob and his team for completing the Rev-ma product. It will be published in July of this year. We have a difference between the ma draft and its issue. I am working on authorization to vend the draft until then. Draft 9.0 will be available in the members' area.

1.3.9.42. Bob O'Hara: Draft 9.0 is already in the members' area. There has been no ANA activity since last plenary. There is no indication that "n" will be asking for numbers this session, if not, ANA will have nothing to do.

1.3.9.43. Clint Chaplin: The only draft 9.0 posted is the redlined version.

1.3.9.44. Stuart: That will be fixed.

1.3.9.45. Stuart: Under "ma", Bob has being doing interpretations. There have been none.

1.3.9.46. Stuart: Next, we have a WMM-802.11e study group reaffirmation vote. We did not have a quorum in the previous meeting. Is there any discussion on this? No. We shall vote to reaffirm the vote to approve WMM-802.11e study group formation at the last meeting. Voters only, please hold up your tokens.

1.3.9.47. Approve: 70, Disapprove: 17, Abstain: 28 (80.46% Approval). The motion to approve the vote passes.

1.3.9.48. Similar motion:

1.3.9.49. Reaffirmation: To approve the vote on WMM-802.11e task group formation:

1.3.9.50. Approve: 81, Disapprove: 1, Abstain: 10 (Approval 98.7%) The motion to approve the vote passes.

1.3.9.51. Steve McCann: We shall be meeting to discuss IMT Advanced as well as supporting the tutorial on Video.

1.3.9.52. Richard Paine: TGk Summary. LB86 closed Feb 15th, with comments in 07253r4. This week we will create more comment resolutions. Document 07/376r0 shows the agenda.

1.3.9.53. Stuart: Regarding the 802.11n LB97 ballot results: 83.4% approved of the "n" draft. Statistics:

1.3.9.54. Qualified Voters: 325

1.3.9.55. Participant Voters: 306

1.3.9.56. [Secretarial Note: The participant voter count was found after the session to have been in error. The correct number is 305. The other data, including percentages was found to be correct]

1.3.9.57. Return Ratio: 94.2%

1.3.9.58. Approve Votes: 231

1.3.9.59. Approve %: 83.4%

1.3.9.60. Do Not Approve Votes: 46

1.3.9.61. Do Not Approve %: 16.6%

1.3.9.62. Abstain Votes: 28

1.3.9.63. Abstain %: 9.2%

1.3.9.64. Invalid Votes: 4

1.3.9.65. Stuart: One individual showed a "no" vote but with no comment attached. I ask that his input be considered. I have arranged that draft 2.0 will be available for sale at the end of this week ($90 Non-member, $70 IEEE-Member)

1.3.9.66. Bruce Kraemer: Assembled comments from the letter ballot. 3163 comments received, some duplicates. 1141 were editorial, with 1635 technical. We shall be busy doing comment resolution. Questions? None.

1.3.9.67. Stuart: Adrian, please change document cover from 2006 to 2007.

1.3.9.68. TGp: Lee Armstrong. Still resolving comments

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001086

1.3.9.69. TGr: Clint Chaplin. 22 comments remaining from last meeting. Some others due to internal work. Document 06/1895r18 shows resolutions. Document 07/244r13 shows internally-adopted work items.

1.3.9.70. Stuart: This contains all comments, right?

1.3.9.71. Clint: Yes.

1.3.9.72. Stuart: There was some criticism on "n", where there was no consolidated resolution sheet.

1.3.9.73. TGs: Donald Eastlake. Concluded LB93. 07/213r3 shows agenda, Document shows 07/23r20 with resolutions. If a PAR change happens, we will have to revise the draft document.

1.3.9.74. TGT: Charles Darwin. Looking for nominee for TG as new chair. Will then hear proposals for remaining comments. No questions.

1.3.9.75. TGu: Allocation sheet is being corrected. 802.21 is shown as having an ad-hoc with TGu today in error. TGu will have a joint meeting with .21 tomorrow. Liaison and comment resolution.

1.3.9.76. TGv: Bob O'Hara for Pat Calhoun. Complete comment processing from internal review and proposals for additions to draft.

1.3.9.77. TGw: Jesse Walker. Finish resolving LB88 comments. Request WG send next version of draft for recirculation.

1.3.9.78. Stuart: You are also the JTC SC6 representative?

1.3.9.79. Jesse Walker, Yes, submitting comments on liaison statement for meeting in Xian, China in April.

1.3.9.80. TGy: Peter Ecclesine: Recirculation approved. Joint meetings with other groups to explore coexistence protocols.

1.3.9.81. DLS–SG: Suman Sharma. [Inaudible]

1.3.9.82. Darwin Engwer: I shall cover document 374r1 - IMT Advanced. I was asked to investigate. Bruce Kramer helped. IMT uses different nomenclature and process from us. The document shows an overview. What I believe should happen is that we should indicate we'll produce a response. We should send the response by May, 2007. We should work this week. If not, it could be done by executive e-mail letter ballot. We alternatively could produce a more detailed response, with an early indication now. I suggest Tuesday night or Thursday night to work the response, and on Friday that we form a team to work on more advanced topics. Assuming approval by 802.18, we could approve in the closing plenary. Reference document 375 and 202 (introduction)

1.3.9.83. Steven McCann: I agree.

1.3.9.84. Gunther: Why is 802.16 not mentioned?

1.3.9.85. Darwin: Wasn't mentioned because this is 802.11. We shall meet with a variety of other groups along with 802.18 (RR-TAG) and other groups on Tuesday. Questions? Yes.

1.3.9.86. Stuart: Can you remain our representative?

1.3.9.87. Darwin Yes. Tuesday and Thursday.

1.3.9.88. Stuart: Are you a voting member of 802.18? No. I would like both of you in there as well as myself as I am the only voting member.

1.3.9.89. Al Petrick: FYI, I have posted the P&P documents.

1.4. Closing

1.4.1. Recess

1.4.1.1. Stuart: We are recessed.

1.4.1.2. Recess at 1530 hours.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001087

2. Wednesday Morning Mid-Session Plenary, March 14, 2007

2.2. Opening

2.2.1. Call to Order

2.2.1.1. Stuart Kerry (Stuart): I call the meeting to order.

2.2.1.2. Meeting convened at 1032 hours.

2.3. Process

2.3.1. Review/Modify the Agenda

2.3.1.1. Stuart: The only change in r2 is the cellphone notice, shown on the screen. Audio and video recording is prohibited according to the operating manual, the only exception being approval of the chair who will announce any exceptions. The Adrian Stevens discussions, John Barr discussion, and joint discussions on IMT Advance have been added. Are there any other changes to the agenda? No.

2.3.1.2. May we approve by unanimous consent? Yes. So moved and approved.

2.3.1.3. Patent policy: Are there any questions on the patent policy of the IEEE. No. We shall be operating under these rules. Are there any LOAs that the chair should no about? No.

2.3.1.4. The chair confirms that a letter has been sent to CSIRO regarding the request for an LOA. [the item was mentioned in the Monday session]

2.3.1.5. Harry: Attendance Recording - You must sign in with 5 minutes grace. You must achieve 75%. The server has been working, so you should be having no problems.

2.3.1.6. Stuart: Any announcements from the table? Yes.

2.3.1.7. Al: I have received no comments on the PARs.

2.3.1.8. On the P&P: One comment from Dave Bagby. The draft had removed specific empowerment motions, they are now added back in. No other comments on proposed changes. Documents are 362.r1 draft, 360r1redline, 363r1 summary. If there is a 360r2, it will be voted in April.

2.3.1.9. Stuart: Is Nuraj Sharma in the room? No. Darwin? Yes. Please ensure that Sharma will be in the room Friday.

2.3.1.10. Chair positions: Epstein and Stanley for TGv. Any others? No.

2.3.1.11. March Plenary in 2009. Want to get view of group of suitability of Israel. Straw poll: Yes 62, No. 25

2.3.1.12. I will pass that back to the executive secretary.

2.3.1.13. Just before our meeting in Montreal, Steve Mills, SA Chair, would also like to hold an IEEE-sponsored event in Tunisia. I'd like to see if anyone could represent the WG at that meeting. Please notify me by Friday.

2.3.1.14. Stuart: Any other announcements from floor? No.

2.3.1.15. Last announcement from table.

2.3.1.16. Al: Joint meeting with TGy yesterday. Notes will be available after this meeting.

2.3.1.17. Stuart: There seems to be a network problem (possible rogue DHCP server), which the contractor is working.

2.3.1.18. Presentation: Richard Kennedy, Oak tree Networks, presented document 07/425r0 (.18). Richard is the 802.11 Liaison for 802.18, which is the RR-Tag between various agencies and IEEE. organization. At the meeting, Radio Frequency Medical Devices were discussed. Meeting yesterday with

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001088

802.16h and 11y discussing possible collaboration in 3650 – 3700 MHz band. Also IMT Advanced meeting, for collaborating all working groups to 8F. This session we shall be evaluating white space proposals and reviewing.

2.3.1.19. Peter Ecclesine: There is another meeting IMT Advanced PM1 Thursday

2.3.1.20. Stuart: Any votes? No.

2.3.1.21. Floor: Between 16h and 11y any conclusions? No.

2.3.1.22. Eldad Perahia,: Intel, discussed 802.19. Reviewed text for coordination between 802.16h and 802.11y 802.19 agreed to host. See documents S802.16-07/017r1, C802.16H-07-38 and C802.16H-07-39

2.3.1.23. Room count: 192 in room.

2.3.1.24. David Hunter: 802.21, Panasonic, 07/0450r0. Chair of 802.21 will present shortly. Interfacing 802.11 with cellular network operators. Representation in TGu and other groups. Now working with EC projects. Security an important issue, coordination difficult. Paging technologies also being worked. In Draft D4, 66% approval. If you are interested, use your 802.11 user ID and password to access the draft. July planned for LB.

2.3.1.25. Questions? None.

2.3.1.26. Wi-Fi Alliance Liaison: Andrew Myles, Cisco, Document 07/447r0. Preparing presentation in May. 802.11 Chair challenged Wi-Fi Alliance to review process between 802.11 and Wi-Fi. General presentation planned in Montreal. Seeking questions from group. Much work in Alliance is based on work in 802.11. Congratulates body on 802.11n, and making draft available. Activities related to WMM Michigan Trials, thank working group to transition to 11r and 11k also useful for voice and video. Mesh also important. Joining

2.3.1.27. Dorothy Stanley: IETF Liaison. Aruba Networks. Document 07/423r0. There are two items highlighted. 1) ECRIT two outstanding items: request for review of ECRIT framework document in TGu, request for overview presentation of 802.11 Emergency Services approach, also being addressed in TGu. Steven developing presentation. and 2) CAPWAP documents for review in April, with response in may. I need a time slot at next meeting to deal with that response.

2.3.1.28. Questions? No.

2.3.1.29. Stuart: Which day for IETF slot?

2.3.1.30. Dorothy: Will take off line.

2.3.1.31. JTC1 SC6 Jesse Walker Intel. The joint development agreement SC6 and IEEE has been under review. Disposition of comments received by international bodies looks favorable to continuation of relationship. Will be voted on April 9-13 in Xian China. Previous meeting worked on presentation for Xian, where IEEE endorsed going-forward.

2.3.1.32. Questions. None.

2.3.1.33. Stuart: 3GPP Liaison is Open Volunteers for position? None. Third call. Removed by P&P

2.3.1.34. TIA Liaison is Open. 1st call for volunteers. Steve Whitesell, VTech. Currently chair of TR41 future premises terminal equipment. Have done liaison duty in the past.

2.3.1.35. Stuart: Are you a regular attendee? Yes.

2.3.1.36. Stuart: Is there any objection to appointing Steve? None. Very well, Steve will be the liaison.

2.3.1.37. Stuart: We now have Old business from Monday Plenary

2.3.1.38. 802.11s PAR discussion

2.3.1.39. Donald Eastlake: Document 1107/391r1, Motorola. Chair of TGs. Amend PAR of 802.11s. Current PAR written too narrowly. Donald gave several examples of situations where an enlarged PAR would allow mesh solutions

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001089

to be used in the context of ESS infrastructure, home networking and 802.11 for first responders. No reason why all of these applications have to be APs. This tends to force the mesh into operation in an environment with less-restrictive beacons, etc. Specific Text 07/149r5 with tracked changes. Replaces "access point" with "station" and a few other changes. Discussion covered three scenarios for proceeding and the changed PAR was viewed as the best. Low attendance in London. Failed vote at plenary by one vote. Intend to bring forward again.

2.3.1.40. Stuart: Questions?

2.3.1.41. Bob O'Hara: Since this needs to be approved by EC, has the 5-criteria also been updated as well as the coexistence document?

2.3.1.42. Donald: The 5 criteria update is included in the referenced document.

2.3.1.43. Bob O'Hara: The larger number of devices will not impact coexistence with 802.11 devices in the same environment?

2.3.1.44. Garth Hillman: What is the difference between APs and mesh points?

2.3.1.45. Donald: Mesh points provide a peer-peer like relationship. People can roam on a peer-peer level with multi-hop forwarding. Two or more peer relationship between nodes.

2.3.1.46. Discussion of Ballot Timing

2.3.1.47. Adrian Stevens, Intel UK Limited, showing document 377r1. I'd like to bring forward an issue with 802.11n task group. 400 comments from ballot, and would like to go to recirculation. P&P allows 15 day procedural ballot with 30 day technical ballot. To meet timing, we must operate in "hero" mode. The chart shows no slack between session activities. 15 day ballot comes from LMSC with no difference between regular and recirculation ballots. Could either change LMSC rules to 10 day ballot, (may be hard-LMSC just went from 10-15 days). Task group chair could "pre-authorize" the ballot after examining the edits. Point is that task group chair is required to determine that draft is complete. This would be a continuation of that technique. I would ask for two straw polls. First no discussion, 2nd with discussion.

2.3.1.48. Stuart: OK.

2.3.1.49. Should we attempt to modify the LMSC rules to allow a 10 day ballot that do not affect the contents of a draft standard?

2.3.1.50. Stuart: Will voters please rise?

2.3.1.51. Yes 110, No 7, Abstain 26.

2.3.1.52. Question: Jim if we pass this it is just a straw poll. All the chairs have to certify the quality of the document.

2.3.1.53. Charles Wright, Azimuth Systems: How does this affect the time on the server rule? I believe that the rules say that a task group can move as fast as it wants to but someone can ask to see the draft. Seems like a good idea to go that way.

2.3.1.54. Jesse Walker, Intel. We should move the ballot along as fast as possible. I would like the group to recommend that the draft is ready for ballot.

2.3.1.55. Adrian: I would not propose to ruin the normal process.

2.3.1.56. Steve McCann: When you say there would be a "motion against the task group chair" to start the ballot.

2.3.1.57. Adrian: Haven't thought about details.

2.3.1.58. Steve: This would seem to place some responsibilities on the chair.

2.3.1.59. Jim Petranovich, Conexant: I'd like to understand the history of this, having had a process in place. Why was the LMSC rule changed in the first place?

2.3.1.60. Adrian: As I recall it was caused where a draft clearly went to letter ballot without proper inspection. The trust with the editor was broken once, and must be repaired.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001090

2.3.1.61. Darwin Engwer: We have good reasons for the four-hour rule. I am concerned that your new process would open the opportunity for abuse. For myself, I could endorse this if we required a checklist that drafts would have to meet before going out to review.

2.3.1.62. Adrian: The four-hour rule may need to apply to certain documentation, because they could determine the proper outcome of changes. WRT the checklist it seems like a good idea.

2.3.1.63. Stuart: Recess for 30 seconds [discusses poll with Adrian].

2.3.1.64. Stuart: In session again.

2.3.1.65. Straw Poll on screen:
Should we attempt to modify our rules to allow something like the following strawman sequence (details TBD):
– Editing instructions are approved by motion in a TG (e.g. comment resolutions).
–The TG determines it wants to ballot the draft after editing instructions are executed by motion.
–The TG chair declares the completeness of the draft, given that the editing instructions are incorporated
–The WG approves going to letter ballot, contingent on the determination of the TG chair that the editing instructions have been properly applied
–The editor does the editing and produces a draft
–The TG chair determines if the edits have been properly applied
–The TG chair informs the WG chair of this determination and the WG chair starts the ballot if satisfied.

2.3.1.66. Stuart: Let us vote. There can be abstains.

2.3.1.67. Yes 37, No 13, Abstain 72

2.3.1.68. Stuart: Is there any new business? We have 4 items with 15 minutes left. I must reduce the times of presentations? [negotiates]. OK with all presenters? Yes.

2.3.1.69. John Barr, Motorola, presented 07/419r1 outlining the very high throughput study group. New market requirements suggest a 1Gbps LAN should be considered. To keep up with activities elsewhere, we should create a PAR. There has been a call to collaborate with IMT Advanced and there has been discussion in the next-generation group. 802.11 is close to finishing. Wi-Fi Alliance is already preparing products. Market opportunities for streaming video, etc. and IMT Advanced would suggest work on this should begin soon, aiming at standard in 2009. We would like to move that 802.11 approve a study group.

2.3.1.70. Motion:

2.3.1.71. IEEE 802.11 WG requests approval by IEEE 802 LMSC to form a study group to address requirements for >Gbps… (Harry to provide motion text)

2.3.1.72. Bruce Kraemer Marvel Semiconductor

2.3.1.73. Stuart: Questions? Yes. Let us alternate, in-favor, against.

2.3.1.74. Bruce Kraemer: In favor. Seems a stretch, but mirrors 11g while considering 11n. Past history suggests a never-ending need to have more throughput.

2.3.1.75. Steven McCann: Speak against. From the WNG point of view, we may be in the position of having two groups asking ExCom to consider two study groups at the same time, because of the Video group.

2.3.1.76. The video group is headed for incremental improvement on what we have now. Here we are looking at very high throughputs that would probably required more restructuring.

2.3.1.77. Darwin Engwer Nortel Networks In favor. Presentation in WNG. 412r1 explained reasons. This is the right time to start the next thing. This is not related to IMT Advanced, however.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001091

2.3.1.78. Jim Petranovich, Conexant: The way the motion is worded, it is independent of other initiatives.

2.3.1.79. Andrew Myles: I speak against. This is difficult. It takes time for a standard.

2.3.1.80. T. K. Tan: I have been approached by several other people, and I speak in favor.

2.3.1.81. Stuart: Comments on motion? None remaining.

2.3.1.82. Members come to rest for 30 seconds. [discussion with Barr]

2.3.1.83. Back to order

2.3.1.84. Stuart: Vice-Chair suggests changing to greater-than-or-equal than 1 Gbps.

2.3.1.85. Any objection to the modification to changing the motion before you? No objections. Change inserted.

2.3.1.86. Voting members only, please rise. 75% required

2.3.1.87. Yes 123, No 1, Abstain 12. The motion passes.

2.3.1.88. I shall be requesting a volunteer to chair the study group.

2.3.1.89. Stuart: Can we begin the presentations? Can we go with NIST first? No objection. Agenda item 6.3 moving to Friday with approval of presenter.

2.3.1.90. Nader Moayeri/Michael Souryal NIST presented 07/297 Real time Deployment of Reliable Multihop Networks. Describes need for a “drop in” solution for radio communication with first responders and mobile users. Target requirements: Self-configuration, adaptation to maintain links. Looking beyond simulation platform, looked at a different platform from 802.11 at 900 MHz, low power sensor network solution. Studies done to understand PHY attributes. Fashioned deployment algorithm. Looked at link quality with single transmitter, multiple receiver scenarios. Two learnings: 1) the deployment is not “can you hear me now” because there is no time when EOR occurs. Instead “how loud do you hear me”. Second, topology-related, large multipath fades, require deployment algorithm and diversity. OFDM frequency adaptation and diversity could also be used. Real time examination of link integrity with multiple connections offered as valuable deployment tool (drop one here). Resulting data from studies were presented. Presented a demo to 802.15, not enough time here. Test system set up in building on NIST campus. NIST is neutral on what standard/solution arises, but would like to gauge interest in 802.11.

2.3.1.91. Stuart: Questions/discussion? None. Appreciate presentation.

2.3.1.92. Darwin Engwer, Nortel Networks, presented document 452r1, Summary of 802.18 IMT-Advanced Joint Meeting. Not much progress. Saw a number of documents, including 802.16 docs with Roger Marks. The document was not yet approved. 802.20 had a document but not shown. Timelines involved May and Jan 2008 with some confusion. Different parts of IMT Technology part in January. There is not requirement for technical input before January. Plan to continue discussions. There may not be time to complete work this week. Talking about ways to keep work going external to meeting. Perhaps team in 802.11 to allow local activities.

2.3.1.93. Questions? Yes.

2.3.1.94. John Noter 802.18. There is information on the 802.18 web site in the public area.

2.3.1.95. Stuart: More discussion? No.

2.3.1.96. Stuart: The 802.21 presentation has been moved to Friday. Is that OK with the presenters? Yes.

2.3.1.97. Is there any other business? None.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001092

2.4. Closing

2.4.1. Recess

2.4.1.1. Stuart: We are recessed.

2.4.1.2. Recess at 1222.

3. Friday Morning Closing Plenary, March 16, 2007

3.2. Opening

3.2.1. Call to Order

3.2.1.1. Stuart Kerry (Stuart): I call the meeting to order.

3.2.1.2. Meeting convened at 0811 hours.

3.3. Process

3.3.1. Review/Modify the Agenda

3.3.1.1. Stuart: I ask that we approve the agenda as shown. [reviews agenda r3 items].

3.3.2. Business/Motions

3.3.2.1. Stuart: For the record, I have sent the request for an LOA to CSIRO. I have not yet received a response.

3.3.2.2. Stuart: Is everyone familiar with the patent policy? Are there any questions? No. We are operating under these rules.

3.3.2.3. Stuart: Item 1.2. We previously approved the minutes from the London meeting, but these did not have a document reference number. The document number for the minutes is 07/0504-00-0000. TK Tan flew in Thursday from Korea and back on Wednesday. Steve McCann as agreed to cover WNG this time.

3.3.2.4. Stuart: The chair position of the WMM study group is open. Bob O'Hara has volunteered. Are there any others? No. Are there any announcements from the table?

3.3.2.5. Al Petrick: There is a press release document, 05/0003r0.

3.3.2.6. Stuart: Are there any floor announcements? Yes.

3.3.2.7. Bob O'Hara, Cisco, presented a contribution on congestion control. The presentation reviewed 802.11 progress, including applications of CSMA. What would be needed to support the mechanism in other regimes? Outlines CSMA procedure applied to letter balloting process.

3.3.2.8. Stuart: Are there any other announcements? No.

3.3.2.9. Harry: Documentation. The new server is expected to be on line shortly. It will look a lot like we have now, but it should be much easier to find individual documents. We shall retire "wirelessworld" at that point.

3.3.2.10. Petrick: P&P. Refer to document 812/r3 for the set of changes. I received one input from Dave Bagby. Proposed procedures may be found in 362r1; 360r1 contains the current text. 07/360r2 will issue in July.

3.3.2.11. Publicity: Al Petrick. Approval of the previously-mentioned press release will be requested as motion from TGn from Bruce Kraemer/Sheung Lee.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001093

3.3.2.12. Work Load Timeline, Richard Paine: [shows on screen] Comments on changes in timeline. Note the addition of editor's columns in the new version, along with a name-change for 802.11ma version9 to 802.11 2000. TGk had one change for sponsor ballot recirculation. TGn had no changes. TGs has changed. TGr had no changes. TGT had no changes. TGu slipped a whole session. Tgv has no changes this time. Tgw has no changes. TGy changed by two months. Questions? No.

3.3.2.13. Stuart: 802.11ma Rev d will now show 802.11 2007.

3.3.2.14. Harry Worstell: Editors' meeting. We covered guidelines for TBDs, including a list of TBDs for drafts leading to ANA. This should reduce confusion for drafts. Mandatory Editorial board attendance. Representative of SA attended (Michelle) and she has given a lot of assistance. Staff will provide checklist for sponsor ballot up through the approval chain. The timeline has been updated to show what version and what file type what is available. We have now expanded the document to show what the format is (e.g. frame, Word etc.). We also created a document baseline template.

3.3.2.15. Bob O'Hara: ANA. A few identifiers and a single bit have been preserved for TGn pending a motion later this morning.

3.3.2.16. Stuart: I'd like a straw poll:

3.3.2.17. Did you like this hotel with these facilities?

3.3.2.18. "Yes", many. "No", few. Majority "Yes".

3.3.2.19. Steven McCann: See document 07/460r0 for WNG. Five presentations. Video streaming over 802.11 SG motion. High speed broadband wireless initiative begun. Darwin Engwer will speak further on future initiatives. Questions? Yes.

3.3.2.20. Darwin: Darwin document is 412r0 not 460r0

3.3.2.21. Stuart: May I have task group chairs to the microphone?

3.3.2.22. TGk Richard Paine: See document 497r1. The task group has been resolving LB 96 comments. Want to go to recirculation ballot. Have resolved all comments. Will have a motion to request conditional sponsor ballot. We held teleconferences and consolidated the "no" voter list. We also conducted an e-mail campaign to convert "no" votes. Objectives for May: Comment resolution on sponsor ballot. Will hold teleconferences at noon Thursdays beginning 29 March. Our goal is to go to sponsor ballot recirculation ballot. There will be a motion offered for recirculation LB. There are no changes in this draft. The WG motion will request conditional approval under clause 20 for approval for LB. Are there any questions? None.

3.3.2.23. TGn Bruce Kraemer. Refer to document 07/496r0. The group just closed LB #97, which passed. There were 3163 total ballot returns. 95 duplicates, 1470 unique, 1594 were technical. Matched volunteers to resolution topics. All but 97 are assigned. Distribution by topic graphic was shown. Most comments were on Coexistence. We revised the ad-hoc structure to adjust for new leaders. We are targeting separate spreadsheets with a composite comment sheet in document 07/336. We shall also produce a set of ad-hoc reports with PowerPoint status files. For major technical ad-hoc sessions, tracking for sessions and progress will be provided. We shall be concentrating primarily on how to get to draft 3.0. Schedule: Trying for LB3 in July. Anticipate ad-hoc in SF. Overall timeline. LB in Fall, followed by sponsor ballot cycle. Timeline was moved to September.

3.3.2.24. Stuart: Must report draft 2.0 is now available. Please take back to WFA, Andrew Myles? Yes.

3.3.2.25. Questions for TGn? None.

3.3.2.26. TGp, Lee Armstrong. See document 07/499r0. 174 comments addressed, 134 resolved. 9 presentations. 1060 comments, 649+ still to be resolved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001094

Draft 2.01 is on the site. Weekly telecons Thursday at 1400. Potential for using TGs-like beacon exploration via teleconferences.

3.3.2.27. Stuart: Questions? None.

3.3.2.28. TGr, Clint Chaplin. See document 07/495r0. Comments for LB91: (691), 23 comments addressed at meeting. No comments left. Will authorize ad-hoc Apr 24-26 and June 21 in Toronto. The 5.0 draft is available. Motion to approve comments and resolutions was passed. Motion to go to letter ballot passed. Goals: Recirculation, then possibly another.

3.3.2.29. Stuart: Questions? None.

3.3.2.30. TGs, Donald Eastlake: See document 07/464r0. TGs is making progress on comments from LB93. There were 5713 originally. All editorial comments have been resolved as well as about half of the technical. Motion to amend PAR will be offered. We shall be holding teleconferences as well as an ad-hoc in Eindhoven in April and Hillsboro, Oregon in June.

3.3.2.31. Stuart: Questions? None. Acknowledges Charles' work on TGT.

3.3.2.32. TGT, Charles Wright: See document 0322r0. Recommendation for new chair: Nuraj Sharma.

3.3.2.33. Stuart. I ask that we appoint Nuraj as chair of TGT by acclamation. Unanimously approved by acclamation.

3.3.2.34. Charles: There are 29 remaining deferred comments from our internal review. Presentations for resolving 22 of them were made. 7 difficult ones were declined. We will move on to letter ballot D0.14 draft to be produced. Will move for LB this time. Motion to instruct editor to create draft. Motion for confirmation ballot, and to the authorize 30 day letter ballot to request sponsor ballot. Plans for next meeting: LB comment resolutions. Recirculation planned after September. Telecons are set for Thursday from now to May meeting starting 29 March.

3.3.2.35. Stuart: Questions? None.

3.3.2.36. TGu, Steven McCann: See document 07/490r0. We re-approved all comments from the ad-hoc. Presentations were heard. We tried to tackle liaison issues. Liaison letters for NENA 3GPP, etc. also joint meeting with 802.21. Teleconferences are planned. We also plan to have an ad hoc meeting 25-27 March in Singapore.

3.3.2.37. TGw, Jesse Walker: See document 07/483. Our goal was to complete LB88 comment resolution, which was completed. All comments are resolved. Document 06/1729r22 contains the comment resolutions. We shall be offering a motion to approve a 15 day e-mail ballot on draft output from this session on draft 1.03, and then a 15 day recirculation on draft 2.0. We plan no ad-hoc meetings. Goal for next meeting is to resolve comments from the recirculation.

3.3.2.38. Stuart: Questions? None.

3.3.2.39. TGy, Peter Ecclesine: See document 07/487r1. Document 07/008r12 contains comment resolutions. We shall be offering the motion shown [shows]. We held joint meeting with 802.16h and 802.19. Document 07/0395 contains the joint minutes. We shall also offer a motion to ask for ANA element IDs. The schedule is for executive committee approval in July instead of March, sliding two months. We shall make a motion for a 15 day recirculation ballot.

3.3.2.40. Secretarial Note: Attendance is 165 people in room.

3.3.2.41. Stuart: Questions? None.

3.3.2.42. DLS-SG, Suman Sharma. See document 07/493r0. Goal to Prepare PAR and 5 criteria. Prepared document and study group 07/225r2. Motion to extend study group. Presentations. Motion to approve PAR will be coming to WG. Another to extend study group. Motion to approve telecons for 3 April and 1 May. Plan to hear technical presentations.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001095

3.3.2.43. TGv, Bob Miller for Pat Calhoun. See document 07/485. All 446 internal review comments have been addressed with comment resolutions and normative text to be applied to 0.1 draft. Dorothy Stanley recommended by TG as next chair.

3.3.2.44. Stuart: May we accept Dorothy as chair of TGv by acclamation? Yes. Dorothy approved unanimously.

3.3.2.45. Al Petrick: I would like to make a bulk motion to empower telecons. See slide.

Motion

Move to empower the following TG(s)/SG(s)/Ad-Hoc(s) to hold teleconference calls beginning no sooner than March 25, 2007 through 15 days past the end of the July 2007 Plenary Session.

Group	Start Date	Frequency	Time
Task Group "k"	March 29, 2007	Weekly	12:00 ET
Task Group "n"	April 4, 2007	Weekly	11:00 ET
Task Group "p"	March 29, 2007	Weekly	14:00 ET
Task Group "r"	April 4, 2007	Weekly	11:00 ET
Task Group "s"	March 28, 2007	Weekly	10:00 ET
Task Group "T"	March 29, 2007	Bi-Weekly	12:00 ET
Task Group "u"	April 19, 2007 May 2, 2007	Once Once	10:00 ET
Task Group "v"	N/A	N/A	N/A
Task Group "w"	N/A	N/A	N/A
Task Group "y"	March 27, 2007 July 10, 2007	Bi-weekly Once	13:00 ET 13:00 ET
BLS SG	April 3, 2007 May 1, 2007	Once Once	11:00ET
IMT-Advanced	April 6, 2007	Weekly	11:00 ET

3.3.2.46. Move: Al Petrick (as individual)

3.3.2.47. Second: Clint Chaplin.

3.3.2.48. Stuart: Any objection to approving unanimously? None. Moved and approved unanimously.

3.3.2.49. Move to empower the 802.11 WG, Task Groups, SGs, and SCs to hold meetings during the May 2007 Interim Session to conduct business as deemed necessary.

3.3.2.50. Moved on behalf of all groups.

3.3.2.51. Move: Harry Worstell

3.3.2.52. Second. Bruce Kraemer

3.3.2.53. Stuart: Discussion? Yes.

3.3.2.54. Bruce Kraemer: Request a change for IMT Advance from 1100-1200.

3.3.2.55. Stuart: Any objection to approving unanimously? No objection. Unanimously approved.

3.3.2.56. Publicity motion. Al [shows release]

3.3.2.57. Move to approve doc: 07/0503r0 as a suggested IEEE 802.11n press release and forward to IEEE 802 Excom approval for immediate Media release by the IEEE staff.

3.3.2.58. Move: Al Petrick (as individual)

3.3.2.59. Second: Bruce Kraemer

3.3.2.60. Stuart: Discussion? None. May we have a 30 second rest?

3.3.2.61. Secretarial Note: 165 in room

3.3.2.62. Stuart: Let us vote.

3.3.2.63. For 88, Against 0, Abstain 2.

3.3.2.64. IMT Advanced 1 Motion

3.3.2.65. No other agenda items in WG to do.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001096

3.3.2.66. Report on document 07/488 Darwin Engwer

3.3.2.67. In 11 opening report, mid-week report, closing report. Tuesday joint meeting, second joint on Thursday constructed response (1 page letter: 802 is interested). Work plan process. Document expected to be approved in 802EC. A correspondence process was fashioned to maintain progress. Individual working groups will produce individual docs then harmonize through 802.18. Approved 18/7-19r2 as draft doc. Needed: more research, input to technical requirements. Submit to 18 with consensus. As needed provide input to 802.11 Gigabit wireless effort.

3.3.2.68. Stuart: Questions? None.

3.3.2.69. Bruce Kraemer provided an overview of technical requirements outline 07/506r1 provides technology background. ITU technical document covers table of contents show issues. The TOC will have appendices that will be forced upon us. Higher spectral efficiencies, higher data rates, ranges, mobility---good match to 802.11. Output letter from .18. No motion.

3.3.2.70. Stuart: Observation on presentation: no disclaimer notice? Ad-hoc group dealing with Darwin and Bruce formed in London. Teleconferences. 2 hour slot in Montreal.

3.3.2.71. WNG-SC Motion Steven McCann

3.3.2.72. Move to form an IEEE 802.11 Study Group (recommended by the WNG SC) to examine issues related to Audio/Video Streaming over 802.11 (ref: IEEE 802.11-07-400r1), with the intent to create a PAR and five criteria to form a new Task Group.

3.3.2.73. TG moved by Ganesh Venkatesan

3.3.2.74. TG Second Ed Royce

3.3.2.75. Moved on behalf of WNG SC (WNG result 59-3-11) Steve McCann standing in for TK Tan.

3.3.2.76. Stuart: The EC had understood “Video” only. We now understand group wants it to be “Audio/Video?

3.3.2.77. EdReuss: In discussions during presentations it was recognized that there are problems beyond video. Expect streaming for audio and video, but usually audio sync’d to video. We should coordinate.

3.3.2.78. Stuart: The motion says “Audio/Video”. Are any other members of the group present? No other members of group present. Ganesh, can you represent at Excom? Yes.

3.3.2.79. Move to form IEEE SG for Audio/.Video Streaming 07/0400r1.

3.3.2.80. Stuart: Discussion? Yes. Ed Reuss.

3.3.2.81. Ed Reuss: I think I was the seconder, which resulted in confusion with the name.

3.3.2.82. Who seconded? Modify seconder from Royce to Reuss. Any objection? None.

3.3.2.83. Further discussion?

3.3.2.84. Peter: Did the motion in the SG contain “audio”? Yes.

3.3.2.85. Steve: These slides came from WNG.

3.3.2.86. Myron Heading, Intel: I speak against the motion. 802.1 concerns.

3.3.2.87. Suman: Can we amend to remove “Audio”?

3.3.2.88. Stuart: We just went through that. Were you member of WNG? Yes.

3.3.2.89. Suman: Audio was added later. I suggest only video streaming.

3.3.2.90. Stuart: Rest [discussion with Bob O’Hara] If we do this change it will be a motion to amend the motion before us. Dictate to Harry how to amend.

3.3.2.91. Suman: Delete “Audio/”

3.3.2.92. Harry: There is a motion to remove audio.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001097

3.3.2.93. Move to amend, removing audio

3.3.2.94. Suman: I so move.

3.3.2.95. Second Peter Ecclesine

3.3.2.96. Stuart: Discussion? Yes.

3.3.2.97. Bruce. Any reasonable use would include both audio and video. If this is just a general thing, then OK.

3.3.2.98. Peter: Issue of A/V is the result of the study group's recommendation.

3.3.2.99. Ganesh Intel: I'd like to clarify. We meant to include video with audio part of the stream. The idea was to have audio and video together, rather as separate streams. I speak in favor.

3.3.2.100. EdReuss: I'm torn on this. Don't want to step on other orgs. 802.1 looking more at routing issues, etc. This group would be working MAC issues in .11. The streams contain audio and video components. I have no resolution for voting.

3.3.2.101. Bruce: Complementary to Ed. If we document in minutes that the video includes audio, if this comes into question, then the minutes can serve to amplify.

3.3.2.102. Harry: Is that the intent of the group? Intend that video includes audio?

3.3.2.103. Straw poll

3.3.2.104. Petranovich: Point of order. What are we voting for? Motion should be clear.

3.3.2.105. Darwin: Seeking clarification on what group is going to do. Wonder if group will be looking at streams in general. If they are focusing on video only, there are pieces missing.

3.3.2.106. John: Speak in favor of keeping the motion as is, dumping revision. I was in WNG when the motion was created. The intent was not to limit the scope. We should not limit the scope in the working group. Should leave open.

3.3.2.107. EdReuss: Not just audio and video, but also supplementary data. I suggest streaming over 802.11. The motion may not have been framed correctly, but everyone seems to understand the intent. Suggest related to streaming.

3.3.2.108. Petranovich: I don't know what we are voting for. I object to the whole process.

3.3.2.109. Steve McCann: We should agree with what Ed said, meaning that we should use "multimedia streaming". We are arguing over semantics. Change to multimedia streaming, and carry on.

3.3.2.110. Stuart. No changing these words at this point. The exact words can be changed as the group works forward. Two more speakers only.

3.3.2.111. Bob O'Hara: I've heard a number of people that video is OK; others say multimedia streaming, which seems too broad. The tutorial seemed to center on delivery of a video transport stream.

3.3.2.112. Art Aspen: Concern is for chair sent to ExCom with this motion and can envision motion from wired groups saying, "Why is this an issue only for wireless?" Why not an issue for 802.3, etc?

Harry: Any further discussion? No.

Amendment to motion. Remove "Audio/"

[shows on screen without Audio/]

3.3.2.113. Move to form an IEEE 802.11 Study Group (recommended by the WNG SC) to examine issues related to Video Streaming over 802.11 (ref: IEEE 802.11-07-400r1), with the intent to create a PAR and five criteria to form a new Task Group.

3.3.2.114. For 31, Against 38, Abstain 19, 44%

3.3.2.115. The motion to amend fails.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001098

3.3.2.116. We are now back to the original motion: [shows, with Audio/Video]

3.3.2.117. Move to form an IEEE 802.11 Study Group (recommended by the WNG SC) to examine issues related to Audio/Video Streaming over 802.11 (ref: IEEE 802.11-07-400r1), with the intent to create a PAR and five criteria to form a new Task Group.

3.3.2.118. Discussion:

3.3.2.119. Suman Sharma: I suggest we alter it to be "…delivery of Video Transport Streaming."

3.3.2.120. Move to form an IEEE 802.11 Study Group (recommended by the WNG SC) to examine issues related to delivery of Video Transport Streaming over 802.11 (ref: IEEE 802.11-07-0400-r1), with the intent to create a PAR and five criteria to form a new Task Group.

3.3.2.121. Move Suman Sharma

3.3.2.122. Second Charles Cook

3.3.2.123. Suman: Want to change from Streaming to "Streams"?

3.3.2.124. Harry: Does everyone agree? Yes.

3.3.2.125. Harry: Let's have short discussions.

3.3.2.126. Bagby: I am not sure it is the chair's prerogative to foreclose debate, rather the group's.

3.3.2.127. Harry: Only 1 minute per person. OK? Yes.

3.3.2.128. Bruce: For, think this is a good change.

3.3.2.129. Harry: Any objection to calling the question on the amendment? No.

3.3.2.130. Move to form an IEEE 802.11 Study Group (recommended by the WNG SC) to examine issues related to delivery of Video Transport Streams over 802.11 (ref: IEEE 802.11-07-0400-r1), with the intent to create a PAR and five criteria to form a new Task Group.

3.3.2.131. For 58 Against 2 Abstain 28 96% approval

3.3.2.132. Any objection to limiting debate to 1 minute/person?

3.3.2.133. Donald Eastlake: Call the question.

3.3.2.134. Read the motion:

3.3.2.135. "…Video Transport Streams"

3.3.2.136. Move to form an IEEE 802.11 Study Group (recommended by the WNG SC) to examine issues related to delivery of Video Transport Streams over 802.11 (ref: IEEE 802.11-07-0400-r1), with the intent to create a PAR and five criteria to form a new Task Group.

3.3.2.137. For 76, Against 1, Abstain 25, 98.7%

3.3.2.138. The motion passes.

3.3.2.139. Stuart: Any other motions for WNG?

3.3.2.140. Steven: Do you need nominations for the study group?

3.3.2.141. Clint: Not formed yet.

3.3.2.142. Stuart: In order, any nominations for SG? Ganesh Venkatesan Intel. Are there any other nominations? Thank you.

3.4. Closing

3.4.1. Recess

3.4.1.1. Stuart: I think that we should break until 1025 hours.

3.4.1.2. Recess at 1003 hours.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001099

3.5. Opening

3.5.1. Call to Order

3.5.1.1. Stuart Kerry (Stuart): I call the meeting to order.

3.5.1.2. Meeting convened at 1035 hours.

3.6. Process

3.6.1. Business/Motions

3.6.1.1. Stuart: Let us resume with motions.

3.6.1.2. Richard Paine: Motion to go to recirculation of draft 7.0 with no changes from last recirculation.

3.6.1.3. *Believing that comment responses in 07/253r7 and the draft mentioned below satisfy WG 802.11 rules for letter ballot recirculation,*

3.6.1.4. Move to authorize a 15-day WG recirculation LB of 802.11k draft 7.0.

3.6.1.5. TGK Moved by: Joe Kwak

3.6.1.6. TGK 2nd: Brian Hart

3.6.1.7. Richard: Moved on behalf of the Task Group (7-0-1)

3.6.1.8. For 67, Against 0, Abstain 8

3.6.1.9. Richard: I'd like to take the opportunity to relate the history of the ballot. [recounts ballot results]. We went through a campaign to convert no votes. 10 carried-over no voters, so 371 affirmative, 20 remaining "no" votes. With e-mail conversion 95% 21/404 remain "no". We are recirculating draft 7.0 with no changes, editorial or technical. Shows summary of no voters. Included carry-over of "no" votes. See 502r1. Shows track of no voters. Of the 21 comments active, one can see the categories. The carryover "no" votes are also listed.

3.6.1.10. Next, I have a motion go to sponsor ballot.

3.6.1.11. To approve document 07/0502r1 as the report to the 802 Executive Committee (EC) on the requirements for conditional approval to forward 802.11k D7.0 to sponsor ballot, requesting the chair of 802.11 to forward this report to the EC on behalf of the working group.

3.6.1.12. Richard: Moved on behalf of task group

3.6.1.13. Second Brian Hart

3.6.1.14. Stuart: Any objection to calling the question No.

3.6.1.15. For 66, Against 0, Abstain 8

3.6.1.16. Richard: Move to request conditional approval, under clause 20 of the IEEE 802 policies and procedures, to forward the P802.11k draft 7.0 to Sponsor Ballot

3.6.1.17. Moved by Richard Paine on behalf of the Task Group (8-0-1).

3.6.1.18. Stuart. Are clause 20 requirements complete? Yes. Discussion on the motion? Yes.

3.6.1.19. Al Petrick: I need a first and second from task group.

3.6.1.20. Vote was 8-0-1 in the TG.

3.6.1.21. Stuart: Is there any further discussion? None.

3.6.1.22. For 61, Against 0, Abstain 10.

3.6.1.23. The motion passes

3.6.1.24. Stuart: TGn motions. Bruce Kramer

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001100

3.6.1.25. Move to request TGn be authorized to conduct an ad hoc meeting for the purpose of resolving comments received during WG letter ballot 97 on TGn Draft 2.0

3.6.1.26. to be held Wednesday May 9 thru Friday, May11, 2007

3.6.1.27. (just prior to the May Interim in Montreal Canada)

3.6.1.28. at the Fairmont Hotel in Montreal Canada

3.6.1.29. Approved unanimously in TGn

3.6.1.30. Move Bruce Kraemer on behalf of TG

3.6.1.31. Stuart: Discussion? None.

3.6.1.32. OK to approve by unanimous consent? Yes. Approved unanimously.

3.6.1.33. Move to Request TGn be authorized to conduct an ad hoc meeting for the purpose of resolving comments received during WG letter ballot 97 on TGn Draft 2.0

3.6.1.34. to be held Wednesday July 11 thru Friday, July 13, 2007

3.6.1.35. (just prior to the July Plenary in San Francisco, CA)

3.6.1.36. with the preferred option being the Hyatt Regency Embarcadero in San Francisco, CA

3.6.1.37. Approved unanimously in TGn

3.6.1.38. Moved by Bruce on Behalf of TG

3.6.1.39. Stuart: Discussion? None. Any objection to approving unanimously? None.

3.6.1.40. Unanimously Approved

3.6.1.41. Move to have the ANA assign values for the following items found in Draft P802.11n_D2.0.pdf:

- An element ID for the Extended Channel Switch Announcement Element
- An element ID for the Supported Regulatory Classes element
- An extended capabilities bit for the HT Information Exchange Support capability

3.6.1.42. Move to have the ANA assign values for the following items found in draft P802.11n_D2.0.pdf.

3.6.1.43. References:

3.6.1.44. Draft P802.11n_D2.0.pdf

3.6.1.45. 11-07-0336-00-000n-tgn-lb97-comments.xls

3.6.1.46. See CID 210, 223, 224

3.6.1.47. Unanimous in TG

3.6.1.48. Moved by Bruce on behalf of task group

3.6.1.49. Stuart: Discussion? Yes

3.6.1.50. Peter: We have ANA motion coming forward so that all task groups will get to use numbers jointly.

3.6.1.51. Bruce: I will request the same.

3.6.1.52. Stuart: Please minute that ANA should share all numbers among the relevant groups.

3.6.1.53. Further discussion? None.

3.6.1.54. For 68, Against 1, Abstain 4.

3.6.1.55. Stuart: The chair requests to incorporate into ANA database. Bob O'Hara do you accept? Yes.

3.6.1.56. TGr, Clint.

3.6.1.57. Move to authorize a 15-day Working Group Recirculation Letter Ballot of 802.11r draft 5.0, asking the question "Should the 802.11r draft 5.0 be forwarded to sponsor ballot?"

3.6.1.58. By (TGr): Kapil Sood

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001101

3.6.1.59. Second (TGr): Michael Montemurro

3.6.1.60. TGr Result: Yes - 12; No - 0; Abstain - 2.

3.6.1.61. Moved on behalf of TG by Clint Chaplin

3.6.1.62. Stuart: Discussion? None.

3.6.1.63. For 67, Against 0, Abstain 3.

3.6.1.64. Move to authorize an IEEE 802.11 TGr ad-hoc meeting on June 19th through June 21st, 2007, in Toronto, Canada

3.6.1.65. By (TGr): Michael Montemurro

3.6.1.66. Second (TGr): Kapil Sood

3.6.1.67. TGr Result: Yes - 10; No - 0; Abstain - 5.

3.6.1.68. Moved b y Clint on behalf of TG

3.6.1.69. Stuart: Any objection to approving unanimously? None. So moved an approved. Is there a sponsor in Toronto? Yes.

3.6.1.70. TGs, Donald Eastlake.

3.6.1.71. Move to request that the 802.11 WG authorize an ad hoc on 13-15 June 2007 (to be cancelled if TGs goes to Letter Ballot again from the May meeting) in Hillsboro, Oregon, to work on comment resolution.

3.6.1.72. In TGs:
Moved: Steve Conner Seconded: Michelle Gong

3.6.1.73. Yes: 23 No: 0 Abstain: 1

3.6.1.74. Stuart: Discussion? None. May we approve by unanimous consent? Yes. So moved and approved.

3.6.1.75. Move to approve the amendment in 11-07/149r5 to the P802.11s PAR and 5 Criteria and forward this PAR and 5 Criteria amendment to the 802 Executive Committee for their approval and further transmission.

3.6.1.76. In TGs:
Moved: Guido Hiertz Seconded: Steve Conner

3.6.1.77. Yes: 26 No: 0 Abstain: 2

3.6.1.78. Note by Stuart: 30 day Executive Committee requirement.

3.6.1.79. Moved by Donald on behalf of TG

3.6.1.80. For 53, Against 5, Abstain 11.

3.6.1.81. TGT, Charles Wright Azimuth Systems

3.6.1.82. Question: Necessary to include language when ballot should finish? No.

3.6.1.83. Believing that the P802.11.2 draft D0.13 and all motions and resolutions adopted during the Orlando plenary will satisfy all 802.11 WG rules for letter ballot, Moved,

- To instruct the editor to create D0.14 incorporating all approved motions and resolutions,
- To request the 802.11 WG chair to conduct a 15-day confirmation ballot on D0.14,
- To request the 802.11 Working Group to renumber 802.11.2 Draft D0.14, if the confirmation ballot succeeds, as D1.0 and authorize a 30-day Letter Ballot asking the question “Should P802.11.2 draft D1.0 be forwarded to Sponsor Ballot?”

3.6.1.84. Moved/Seconded: S.Tolpin/M.Emmelmann

3.6.1.85. Yes/No/Abstain: 4/1/4 (technical; passes)

3.6.1.86. Moved on behalf of TG by Charles Wright

3.6.1.87. For 48, Against 1, Abstain 8.

3.6.1.88. TGu, Steven McCann.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001102

3.6.1.89. Move to approve liaison document 07/0489r1 and then request the IEEE 802.11 WG chair to forward it to 3GPP SA2 as the response to their request for information from IEEE 802.11u.

3.6.1.90. Moved by Steven McCann on behalf of TG

3.6.1.91. Stuart: Secretary of TGu, do you have TG vote? Yes 9-0-0

3.6.1.92. Stuart: Discussion. None. Vote due to output document.

3.6.1.93. For 51, Against 0, Abstain 11

3.6.1.94. Move to approve liaison document 11-07-0476r1 and then request the IEEE 802.11 WG chair to forward it to IETF ECRIT as the response to their request fro information from IEEE 801.11

3.6.1.95. Moved Steven McCann on behalf of TG
10-0-1 in TG vote in task group

3.6.1.96. Stuart: Any discussion? No.

3.6.1.97. For 50, Against 0, Abstain 8

3.6.1.98. Stuart: Forward the first letter in my name. Dorothy will present the second.

3.6.1.99. Move to approve an IEEE 802.11u ad-hoc from April 25 to April 27th 2007 in Singapore

3.6.1.100. Steven McCann for TG

3.6.1.101. Stuart: Is there a sponsor? Yes. Panasonic.

3.6.1.102. Stuart: May we approve unanimously? Yes. Passes unanimously.

3.6.1.103. TGw, Jesse Walker

3.6.1.104. Move that the IEEE 802.11 Working Group conduct a 15 day e-mail ballot reviewing TGw draft P802.11w D1.03. Upon successful completion, the draft shall be renamed as P802.11w D2.0 and a Working Group Recirculation Ballot initiated.

3.6.1.105. Moved by Jesse Walker on behalf of TG. 10-0-1 vote in TG

3.6.1.106. Stuart: Ask that e-mail be changed to electronic ballot instead of e-mail. Accepted? Yes.

3.6.1.107. For 60, Against 0, Abstain 3

3.6.1.108. TGy, Peter Ecclesine

3.6.1.109. Peter Ecclesine 7 voting in room + me so 7-0-0 on votes.

3.6.1.110. Move to authorize a 15-day Working Group Recirculation Letter Ballot of P802.11y draft 2.0, asking the question “Should the P802.11y draft 2.0 be forwarded to sponsor ballot?”

3.6.1.111. TG Moved Dan Lubar

3.6.1.112. TG Second Yasuhiko Inoue

3.6.1.113. TG Results: Unanimously approved

3.6.1.114. Moved by Peter Ecclesine on behalf of TG

3.6.1.115. Stuart: Discussion? No.

3.6.1.116. For 56, Against 0, Abstain 4

3.6.1.117. Move to request that the 802.11 WG approve requests for assignment by the ANA of three Element IDs, one Spectrum management Action Value, and Regulatory Class values for 5-, 10- and 20-MHz channel bandwidths.

3.6.1.118. TG Moved Rich Kennedy

3.6.1.119. TG Seconded Roger Durand

3.6.1.120. TG Results: Unanimously approved

3.6.1.121. Moved by Peter Ecclesine on behalf of the Task Group.

3.6.1.122. Stuart: Discussion? None.

3.6.1.123. For 61, Against 1, Abstain 1

3.6.1.124. DLS SG, Suman Sharma

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001103

3.6.1.125. Move to request the IEEE 802.11 Working Group approve the PAR and 5 Criteria document IEEE 802.11-07/0225r2 and forward it to ExCom for Approval.

3.6.1.126. SG Moved: Menzo Wentink

3.6.1.127. SG Second: Michael Livshitz

3.6.1.128. SG Vote: 22/0/2

3.6.1.129. Moved by Suman Sharma on behalf of TG

3.6.1.130. For 43, Against 2, Abstain 18

3.6.1.131. Move to request the IEEE 802.11 Working Group to extend the DLS Study Group through the July 2007 meeting and forward to the Executive Committee for Approval.

3.6.1.132. SG Moved: Kevin Hayes

3.6.1.133. SG Second: James Yee

3.6.1.134. SG Vote: 21/0/1

3.6.1.135. Stuart: Discussion? None.

3.6.1.136. For 51, Against 0, Abstain 10

3.6.1.137. Stuart: Item 4.5.1 - 802.21 Update. I spoke to StephenMcCann who agreed to remove this item and transfer it to the May meeting. New business? None

3.6.1.138. Item 6? Any other business from table? No. Do we have volunteers for 1Gbps? No. 802.11 WMM? Bob O'Hara. Video over 802.11? Ganesh. Any other nomination for 1Gbps SG? John Barr? Not present.

3.6.1.139. Stuart: For WMM, any objections, Bob O'Hara? Bob accepts. Accept by acclamation? Yes.

3.6.1.140. Video Transport Streams. Ganesh. Others? No. Appoint Ganesh? By acclamation. Yes.

3.6.1.141. Other items to be done later. 1 Gbps. The Volunteer is John Barr, but he is not here.

3.6.1.142. Stuart: Reviews letter ballots. Total 7 ballots. On behalf of memberships announced at CAC on Thursday night. Trying not to stifle innovation and movement, some comments coming in are not pertinent to ballot.

3.6.1.143. Stuart: Any other business? Table? Yes

3.6.1.144. Al Petrick: Received P&P comments. Now 07/360r2 is the P&P document. P&P proposed changes may be found in document 07/362r2. 360r3 will constitute the new document draft following inclusion of the latest proposed changes.

3.6.1.145. Bagby: In old days we said we would never run more groups in parallel.

3.6.1.146. Stuart: We authorized 5 sessions in parallel two years ago and we are not going to change

3.6.1.147. [Secretarial Note: The secretary wishes to acknowledge and thank Garth Hillman for capturing the minutes from this point on.]

3.6.1.148. Adrian: ANA info on IEEE 802.11 web site is not up to date

3.6.1.149. Adrian: wants to form a group of volunteers to change P&P regarding letter balloting; Volunteers were requested and Stuart appointed Al Petrick and the following people volunteered – Don Eastlake III, Bill Marshall, and Harry Worstell.

3.6.1.150. Jim Petranovich: what is policy affiliation?

3.6.1.151. Chairs' put slide 15 from 11-07-0340r1 on the screen from Bob Groh slide set at 802 plenary; affiliation must be stated if requested to do so.

3.6.1.152. Jim Petranovich: Can we simply make stating affiliation mandatory to save time?

3.6.1.153. Stuart: I believe members should automatically state affiliation. Chair will take advice from SA and 802.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001104

3.6.1.154. Dave Bagby: Recommend we stick to LMSC rules and not have to state affiliation automatically.

3.6.1.155. Stuart: LMSC affiliation rules are indeed vague.

3.6.1.156. Steve McCann – does every name in minutes need to have affiliation attached? Chair – no because they will be in the consolidated minutes with the affiliations attached.

3.6.1.157. No more business.

3.7. Closing

3.7.1. Recess

3.7.1.1. Stuart: Next meeting May 13-18 at Fairmont in Montreal; suggest you book now! We are adjourned.

3.7.1.2. Chair adjourned at 11:49 AM

Abstract

This document constitutes the tentative minutes of the IEEE 802.11 full working group for the May, 2007 interim session at Montreal, Quebec, Canada.

Notice: This document has been prepared to assist IEEE 802.11. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.

IEEE 802.11 Interim Meeting – Session #103
Fairmont Hotel, Montreal, Quebec, Canada
May 14th-18th, 2007

Monday, 14 May 2007

Joint Wireless Opening Plenary

802.11, 802.15, 802.18, 802.19, 802.20, 802.21, and 802.22 Chairs called the joint meeting to order. Presiding chair : Stuart Kerry, NXP Semiconductors.

1. Approve/modify joint opening agenda (11-07-0348r3)

- Following neither discussion nor dissent the agenda was approved.

Review and approve joint minutes from the London meeting

- Upon neither discussion nor objection the joint minutes were approved.

, asked for those attending for the first time, 14 responded out of a total of 178 people in the room.

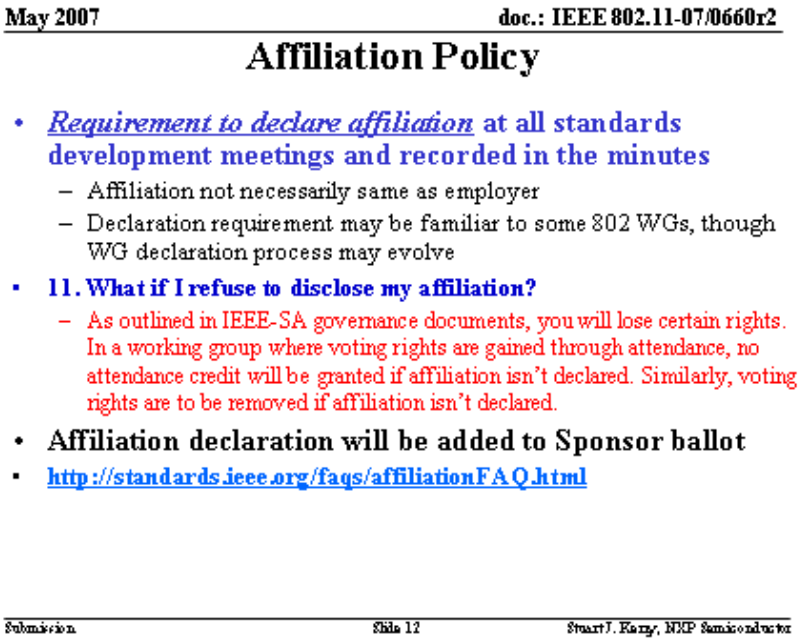
2. Financial report (15-07-711r0)

- March balance was $143,606.51
- May 14 balance was $136,876.51
- Funds in Face-to-Face Events account were $72,234.21
- Meeting reserve funds of $209,110.72
- Montreal status:
    - 407 attendees registered as of 13 May
    - Estimated meeting surplus of about $1,700

3. Review of IEEE, 802 LMSC, 802.11 Policies & Procedures (11-07-0660r2)

- Member affiliation requirement that has been added by the IEEE SA as included in doc 07/660r2

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001108



Member Affiliation

- It is defined in the *IEEE-SA Standards Board Bylaws*, 5.2.1.5 as: "An individual is deemed "affiliated" with any *individual or entity that has been, or will be, financially or materially supporting that individual's participation in a particular IEEE standards activity*. This includes, but is not limited to, his or her employer and any individual or entity that has or will have, either directly or indirectly, requested, paid for, or otherwise sponsored his or her participation.
- http://standards.ieee.org/faqs/affiliationFAQ.html

Declaration of Affiliation

- Revision: May 2007 Standards Board Bylaw 5.2.1.1
  - 5.2.1.1 Openness
    - Openness is defined as the quality of being not restricted to a particular type or category of participants. All meetings involving standards development an all IEEE Sponsor ballots shall be open toa all interested parties. *Each individual participant in IEEE Standards activities shall disclose his or her affiliations when requested.* A person who knows or reasonably should know, that a participant's disclosure is materially incomplete or incorrect should report that fact to the Secretary of the IEEE-SA Standards Board and the appropriate Sponsors.

Al Petrick read highlights of the IEEE-SA patent policy as included in doc 07/660r2

Highlights of the *IEEE-SA Standards Board Bylaws* on Patents in Standards

- Participants have a duty to tell the IEEE if they know (based on personal awareness) of potentially Essential Patent Claims they or their employer own
- Participants are encouraged to tell the IEEE if they know of potentially Essential Patent Claims owned by others
  - This encouragement is particularly strong as the third party may not be a participant in the standards process
- Working Group required to request assurance
- Early assurance is encouraged
- Terms of assurance shall be either:
  - Reasonable and nondiscriminatory, with or without monetary compensation; or,
  - A statement of non-assertion of patent rights
- Assurances
  - Shall be provided on the IEEE-SA Standards Board approved LOA form
  - May optionally include not-to-exceed rates, terms, and conditions
  - Shall not be circumvented through sale or transfer of patents
  - Shall be brought to the attention of any future assignees or transferees
  - Shall apply to Affiliates unless explicitly excluded
  - Are irrevocable once submitted and accepted
  - Shall be supplemented if Submitter becomes aware of other potential Essential Patent Claims
- A "Blanket Letter of Assurance" may be provided at the option of the patent holder
- A patent holder has no duty to perform a patent search
- Full policy available at http://standards.ieee.org/guides/bylaws/sect6-7.html#6

http://standards.ieee.org/board/pat/pat-slideset.ppt

6.2 Policy *IEEE-SA Standards Board Bylaws* on Patents in Standards

IEEE standards may be drafted in terms that include the use of Essential Patent Claims. If the IEEE receives notice that a [Proposed] IEEE Standard may require the use of a potential Essential Patent Claim, the IEEE shall request licensing assurance, on the IEEE Standards Board approved Letter of Assurance form, from the patent holder or patent applicant. The IEEE shall request this assurance without coercion.

The Submitter of the Letter of Assurance may, after Reasonable and Good Faith Inquiry, indicate it is not aware of any Patent Claims that the Submitter may own, control, or have the ability to license that might be or become Essential Patent Claims. If the patent holder or patent applicant provides an assurance, it should do so as soon as reasonably feasible in the standards development process. This assurance shall be provided prior to the Standards Board's approval of the standard. This assurance shall be provided prior to a reaffirmation if the IEEE receives notice of a potential Essential Patent Claim after the standard's approval or a prior reaffirmation. An asserted potential Essential Patent Claim for which an assurance cannot be obtained (e.g., a Letter of Assurance is not provided or the Letter of Assurance indicates that assurance is not being provided) shall be referred to the Patent Committee.

A Letter of Assurance shall be either:

a) A general disclaimer to the effect that the Submitter without conditions will not enforce any present or future Essential Patent Claims against any person or entity making, using, selling, offering to sell, importing, distributing, or implementing a compliant implementation of the standard; or

b) A statement that a license for a compliant implementation of the standard will be made available to an unrestricted number of applicants on a worldwide basis without compensation or under reasonable rates, with reasonable terms and conditions that are demonstrably free of any unfair discrimination. At its sole option, the Submitter may provide with its assurance any of the following: (i) a not-to-exceed license fee or rate commitment, (ii) a sample license agreement, or (iii) one or more material licensing terms.

http://standards.ieee.org/board/pat/pat-slideset.ppt

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001119

IEEE-SA Standards Board Bylaws on Patents in Standards

The assurance is irrevocable once submitted and accepted and shall apply, at a minimum, from the date of the standard's approval to the date of the standard's withdrawal.

The IEEE is not responsible for identifying Essential Patent Claims for which a license may be required, for conducting inquiries into the legal validity or scope of those Patent Claims, or for determining whether any licensing terms or conditions are reasonable or non-discriminatory.

Nothing in this policy shall be interpreted as giving rise to a duty to conduct a patent search. No license is implied by the submission of a Letter of Assurance.

In order for IEEE's patent policy to function efficiently, individuals participating in the standards development process: (a) shall inform the IEEE (or cause the IEEE to be informed) of the holder of any potential Essential Patent Claims of which they are personally aware and that are not already the subject of an existing Letter of Assurance, owned or controlled by the participant or the entity the participant is from, employed by, or otherwise represents; and (b) should inform the IEEE (or cause the IEEE to be informed) of any other holders of such potential Essential Patent Claims that are not already the subject of an existing Letter of Assurance.

http://standards.ieee.org/board/pat/pat-slideset.ppt

IEEE-SA Standards Board Bylaws on Patents in Standards

Copies of an Accepted LOA may be provided to the working group, but shall not be discussed, at any standards working group meeting.

The Submitter and all Affiliates (other than those Affiliates excluded in a Letter of Assurance) shall not assign or otherwise transfer any rights in any Essential Patent Claims that are the subject of such Letter of Assurance that they hold, control, or have the ability to license with the intent of circumventing or negating any of the representations and commitments made in such Letter of Assurance.

The Submitter of a Letter of Assurance shall agree (a) to provide notice of a Letter of Assurance either through a Statement of Encumbrance or by binding any assignee or transferee to the terms of such Letter of Assurance; and (b) to require its assignee or transferee to (i) agree to similarly provide such notice and (ii) to bind its assignees or transferees to agree to provide such notice as described in (a) and (b).

This assurance shall apply to the Submitter and its Affiliates except those Affiliates the Submitter specifically excludes on the relevant Letter of Assurance.

If, after providing a Letter of Assurance to the IEEE, the Submitter becomes aware of additional Patent Claim(s) not already covered by an existing Letter of Assurance that are owned, controlled, or licensable by the Submitter that may be or become Essential Patent Claim(s) for the same IEEE Standard but are not the subject of an existing Letter of Assurance, then such Submitter shall submit a Letter of Assurance stating its position regarding enforcement or licensing of such Patent Claims. For the purposes of this commitment, the Submitter is deemed to be aware if any of the following individuals who are from, employed by, or otherwise represent the Submitter have personal knowledge of additional potential Essential Patent Claims, owned or controlled by the Submitter, related to a [Proposed] IEEE Standard and not already the subject of a previously submitted Letter of Assurance: (a) past or present participants in the development of the [Proposed] IEEE Standard, or (b) the individual executing the previously submitted Letter of Assurance.

Submission Slide 18 Stuart J. Kerry, NXP Semiconductor

- Comment: Rolf de Vogt, affiliation of Qualcomm; read the following statement "That Qualcomm may have intellectual property underlying a contribution that, if adopted, could be essential to the practice of the standard. If we do, we will timely comply with all IEEE requirements regarding IPRs and disclosure"
    - 802.11 Chair asked the commenter if this was a comment to his particular WG or to all WG / TAG Chairs present
        - Answer: general statement to all Chairs present
- 802.11 Chair noted that it is the WG chair's responsibility upon hearing of required IP, to find out the general counsel of the noted company and send them a LOA request
- Question : Ask the chair to repeat obligations of the TG chairs as to their procedures. Reply was that the patent sections were to be read to each TG at least once this week.
- IEEE antitrust statement was read.

4. LoA Requests

- No response was heard from any attendee

5. Review Interim meetings

- September 16 -21, 2007: Hilton Waikoloa Village, Big Island, HI,USA
    - Hotel rate expires 1st August 2007
- January 13-18, 2008 Taipei, Taiwan
    - Taipei convention center or Howard hotel TBD
- 11-16 May, 2008: Hyatt Regency in Jacksonville, FL, USA
- 7 - 12 Sept, 2008 US Midwest location TBD

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001121

- 802.15 chair noted that after 2008 one plenary per year will be an international venue
- Question asked as to Jan 2009 venue with the reply that it had not been decided as of yet

6. Agenda review

- 802.11 chair noted that all WG / TAG chairs are considering changes to the joint meeting in future interims

7. Summary of key working group/802 events/activities

7.1. 802.11 Wireless Local Area Networks

Attendance announced 802.11 record (802.11-06/1736r3)

- 802.11 WG voter summary: 327 voters, 16 potential, 84 nearly, 227 aspirants
- Went on to delineate the procedures for recording attendance to 802.11 meetings
- Question: As to 802.11 attendance, how can we know when we have crossed the 75% attendance threshold? Response was that there was no way with the current software so concerned would need to ask IEEE 802.11 attendence vice-chair, until the new attendance software is in place. Due July 2007
- Question: is the server working? Response: yes

802.11 Policies and Procedures (IEEE 802.11 -07/675 r0)

- Document IEEE 802.11 -07/360r3 is not available. IEEE 802.11 vice-chair responded that he will check upon this later

802.11 Chair reviewed any modifications or changes to the IEEE 802.11 agenda for the session, IEEE 802.11 07/348 rev 4

- Upon neither discussion nor dissent the agenda was approved
- Group chairs
    - WNG SC: 2 presentations are scheduled this week
    - TGk (IEEE 802.11 -07/662 r1)
        - Letter ballot 103 results (5th recirculation): out of 514 total: 363/29/30
        - received authorization to go to sponsor ballot
    - TGmb: set up process for interpretation requests
    - TGn: working on comments from LB2, expecting draft 3.0 to be complete by Sept timeframe
    - TGp: resolving comments from LB92 noting that the beacons are key to the resolutions
    - TGr: focus on comment resolution from LB98
    - TGs: focus on comment resolution from LB93
    - TGT: Intel: focus on comment resolution on LB 101
        - Question: LB 101 is not closed, how can we resolve comments? Reply: some comments are known and those that might be withdrawn

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001122

are expected to be few

- Question: How do we deal with amended draft before the LB is closed? Reply: We won't change the draft before close of LB
- Question: Is there a precedent for this procedure? Reply: Yes

- TGu: sorting out draft document try to go to LB after session
- TGv: plan is to go to LB after session
- TGy: discussion extended channel switch announcement. LB 104 process comments amend draft go to lb before July.
- DLS SG: IEEE 802.11 -07/657r2 technical presentation on DLS
- VTS-SG: writing the PAR and 5C
- QES-SG: discussion of PAR and 5C for QoS enhancements
- VHT SG: first meeting for this group, review processes,
  - Question: I note that two meetings had been canceled
  - There are two nominees seeking to be chair of this SG.
- IMT Advanced Ad Hoc:
  - no comments were received from LB
  - No need for time slots this session
- IETF Ad Hoc:
  - Meeting slots have been canceled due to lack of comments
  - IEEE 802.11 -07/665r0 document will be liaison report

7.2. 802.15 Wireless Personal Area Networks

- Member update: 140 voters, 19 nearly, 74 aspirants
- 15 WNG: two presentations are expected this week
- 15.3c, 18 proposals received:
- 15.4d alternate low rate PHY, status of Japanese regulatory, coexistence, channel models, asked for .11n channel model assistance from group
- 15.4c SG: sub GHz for China, CWPAN review
- 15 MBAN: review regulatory issues, applications, channel models of human body
- 15.5, focus on low data rate mesh

7.3. 802.18 Regulatory TAG (802.18-07-036)

- 19 voters
- Competed comments on FDA RF guidelines
- Completed response to FCC on 60 GHz issues
- Held 2 meetings on 802 input to ITU-R
  - IMT advanced with EC ballot 16/0/0

7.4. 802.19 Wireless Coexistence TAG (19-07/013)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001123

- 19 voting members
- Discussion and presentations on coexistence of 802.11y/802.16h/80.21

7.5. 802.20 Mobile Broadband Wireless Access

- 146 voters.
- Round 1 of practice ballot due to possible issues on draft document
- Draft is a result of merging numerous proposals

7.6. 802.21 Media Independent Handoff

- 64 voters, 5 nearly voters.
- Passed 75% threshold on LB

7.7. 802.22 Wireless Regional Area Networks

- 63 voters, 7 nearly voters, 31 aspirants
- WG effort will be spent wrap details to move from pre-draft to draft 1.0 and onto WG LB
- TG1 is working on pre-draft and expects to go to draft 1.0 and onto LB

8. AoB Business

9. Adjourned

Joint 802.11, 802.15, 802.18, 802.19, 802.20, 802.21, and 802.22 meeting

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001124

Mid-Week Plenary: Wednesday, May 16, 2007

1. Introduction

1.1. The mid-week plenary is called to order by Stuart J. Kerry (NXP Semiconductors) at 10:32 ET
1.2. This session will run from 10:30-12:30.
1.3. Tentative agenda of 802.11 is in doc 11-07-0348r5.
1.4. The attendance is 149 individuals.

2. Modifications to Agenda

2.1. Chair: Any modifications to agenda?
2.2. Comment: Yes : TGr does not need two certain meeting slots
2.3. Comment: TGs would like the request these TGr slots please.
2.4. Any objection to changing the agenda unanimously?
  2.4.1. No. 11-07-0348r5r5 moved and approved by unanimous consent.
2.5. Question. I have another issue about the agenda.
2.6. Chair: Please can we leave it until Friday.

3. Patent Issues

3.1. Chair: The chair needs to be aware of any patent issues/letters of assurance. Is everyone familiar with patent policy, are there any questions?
3.2. Scott Henderson: RIM, I would like to make a statement "In conformance to the IEEE Patent Policy, RIM is please to declare that it may have Intellectual Property which may be essential to 802.11 and will conform to section 6.2.b of the Patent Policy"
3.3. No more questions/comments.
3.4. Chair: will send blanket forms covering all active approved PARs to both Qualcomm and RIM for completion

4. Attendance

4.1. Please remember to use the Attendance system. You require 75% attendance for the week, to count towards voting status.

5. March 2007 WG Minutes

5.1. Approval of Orlando minutes 11-07-0500r0
5.2. No comments
5.3. Unanimous approval

6. Other Announcements

6.1. Patent Policy

6.1.1. Chair: Not giving a legal point of view.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001125

6.1.2. There is no duty to read all these slides. There is just a duty to "Call for Patents". The reading of this call is what must then be recorded in all minutes by all groups. Please can all chairs be made aware of this.
6.1.3. The following statement has been made from Dave Ringle, IEEE legal council:

"There is no duty to use/read the patent slides developed by PatCom. They are a tool that was created to aid WGs in doing the Call for Patents.

The important thing is that the Call for Patents must occur at every standards developing meeting. The minutes must record that the Call occurred and any responses.

Please see the following:

- *IEEE-SA Standards Board Operations Manual 6.3.2 at http://standards.ieee.org/guides/opman/sect6.html#6.3.2*
- *FAQ 4 and 5 at http://standards.ieee.org/board/pat/faq.pdf"*

6.1.4. Chair: This is now IEEE 802.11 policy.

6.2. E911 802 Ad Hoc

6.2.1. Chair: I have appointed Stephen McCann as chair for the IEEE 802 Emergency Services Ad Hoc, which will be held during the IEEE 802 July Plenary.

6.3. Canadian French P&P

6.3.1. Issue about policies and procedures in French to comply with Canadian Law.
6.3.2. Dave Ringle replied to this question, stating that this meeting complies with all applicable laws.

6.4. Attendance server

6.4.1. 11-07-0767r0 is the document describing the new documentation system.

6.4.2. The IEEE 802.11 vice-chair will send out an email later to inform the membership that this will come on line next week. Please note that the existing http://www.802wirelessworld.com will cease to be used after 22nd May 2007 @23:59 ET. Hence please be careful with new numbers over the weekend, as these may not exist within the new system. The system will be shut down until 24th May 2007 @23:59 ET, when the new system will come online. The 802wirelessworld.com website will then automatically re-direct to the new one.

Questions:
6.4.3. What about revisions to document numbers.
6.4.4. Answer: These will not be affected.
6.4.5. Thank you all very much for doing this. What about external/local servers at future meetings.
6.4.6. Answer: Similar to how it is now.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001126

6.4.7. What about the ftp site?
6.4.8. Answer: Not sure about this, but ftp will not be allowed by the IEEE because of security concerns.
6.4.9. May I have a straw poll: "Delay the switch to the new document system, until ftp is allowed".
6.4.10. Chair: No, I'm going to disallow that, as we have to move on with the documentation system. I respectfully decline your request for your straw poll, as it is imperative that we move to the new system because the existing system is seriously failing and members cannot be disenfanchised
6.4.11. I know that IEEE staff are working hard, but I now have to switch methods as I cannot use ftp downloads.
6.4.12. Chair: I will ask IEEE directly about this situation.
6.4.13. Subsequent email from IEEE 802.11 vice-chair, on chair's behalf: "As we have discussed earlier, this is an official request from the 802.11 membership, as recorded in the minutes of the mid-day plenary, to ask the IEEE IT Staff to respond to our request for a bulk download mechanism. We know that FTP has some security issues but we are now committed to respond back to our membership within 30 days with an answer for the timeline of implementation."
6.4.14. So, I can not receive a date for this?
6.4.15. Will document 07/767 be put on the server please.
6.4.16. IEEE 802.11 vice-chair: Sure, but I wanted to make the announcement first.

7. Liaisons

7.1.802.18

7.1.1. Report is 18-07-0045r0
7.1.2. There are some issues raised from Ofcom (UK), so the group will be drafting a liaison to them at some point.

7.2.802.19

7.2.1. Report is 11-07-0771r0
7.2.2. There have been some Teleconferences since the last meeting

Questions:
7.2.3. Is there any indication of joint meetings for the July meeting
7.2.4. Answer: No, not as yet. Will send information when we have it.

7.3.Bluetooth

7.3.1. Chair: Would now like to elect John Barr (Motorola) as Bluetooth SIG liaison officer.
7.3.2. Any other candidates. None seen, so John is duly appointed by the WG Chair .
7.3.3. Bluetooth SIG Liaison
7.3.4. Report is 11-07-0747r0

Questions:
7.3.5. Do you want to modify the existing MAC and PHY?

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001127

7.3.6. Answer: No, we just want to use the IEEE 802.11 system, Bluetooth profiles would run over the top.
7.3.7. Chair: Would you be prepared to come and talk to us during the mid-week plenary in September 2007.
7.3.8. Yes.

7.4.IETF

7.4.1. Report 11-07-777r0

7.4.2. **IETF ECRIT**
7.4.3. Discussions ongoing. Possible liaison this week from TGu.

7.4.4. SDO Emergency Services Workshop was held in April 2007. IEEE 802.11 was represented by the IEEE 802.11 vice-chair.

7.4.5. **IETF CAPWAP**
7.4.6. 665
7.4.7. Liaison response. No comments were received from IEEE 802.11 and this is what the liaison letter states.

Motion
7.4.8. **Move to approve liaison document 11-07-0665r0 and request the IEEE 802.11 WG chair to forward it to IETF CAPWAP as the response to the request for review comments on the draft-ietf-capwap-protocol-specification-06 and draft-ietf-capwap-protocol-binding-ieee80211-03 internet drafts**

7.4.9. Moved by: Dorothy Stanley (Aruba Networks)
7.4.10. 2nd: Jesse Walker (Intel Corporation)
7.4.11. Results: For 87, Against 0, Abstain 7. The motion passes.

7.4.12. Please note the next IETF meeting in Chicago,

7.5.TIA

7.5.1. Report 11-07-697r0
7.5.2. The new liaison officer has now been approved by the TIA committee.
7.5.3. Next TIA meeting is in Ottawa in August.

7.6.JTC1 SC6

7.6.1. SC 6 met in Chiang China in April.
7.6.2. Review of the collaborative working agreement, The SC 6 members will vote on this, up to December, so that decision will be done in at the next meeting in Geneva in April 2008.

8. Inter-change Activity

8.1. None

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001128

WiFi Alliance

8.2. Presentation : 11-07-0764

Questions:

8.3. Chair: Please note that registered trademarks are contained within this presentation

8.4. WiFi Alliance has been of great help to 11i. One thing that is missing are plug fests and interop-tests etc. The WPA experiences was essential to remove some fatal flaws form 802.11i

8.5. Answer: Yes, and indeed this happens in the IETF. It's part of their culture. Perhaps WiFi and 802.11 should form this culture

8.6. Slide #29, I disagree with the lesions stated in this slides. Perhaps it should say users want non-standard mechanisms, not proprietary. Additionally there are many groups working in parallel. However, if the scopes are smaller, then this will generate more groups!

8.7. There is a big difference between IEEE and WiFi Alliance. Academia can not really attend WiFi. We would be missing many important developments. Also one still has to purchase WiFi documents, why cannot they be free after a certain time, like IEEE. The relationship is more complex than what is appears on the surface.

8.8. Answer: The goals of academia and industry are different. A balance is required, but IEEE currently generates too much bloat. WiFi documents are not that expensive, so hopefully most academics can afford them.

8.9. It would be also useful to allow people to "play" with the initial standards. In nature systems come and go.

8.10. There are some good points in the presentation, but there are some blind spots. Throwing things over the wall is not so true. If you do not get your way in one forum, you then go to the other forum. WiFi tends to assume that it is the market. 11n seems to be a case of certification before standardization. WiFi should not confuse markets with vendor interests. There are many vendor interests here.

8.11. Answer: I agree, especially with WMM. Vendors were pushing this. However, for 11n, I'm sure that this is market driven, as opposed to vendor driven.

8.12. I buy a widget for the wireless connectivity, as opposed to 11n certification.

8.13. Answer: It's a difficult balance

8.14. The second to last slide. If WiFi was able to provide an input to the VHT SG that would be wonderful.

8.15. Answer: During the initial days of 11n, this did happen, but the advice was essentially ignored.

9. Another other business

9.1. Reminder of the social at the Pub St. Paul (http://www.pubstpaul.com). There are walking maps and busses.

9.2. No other business

10. Recess

10.1. Chair: We are now in Recess until Friday.

10.2. Recessed at 12:23

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001129

Closing Plenary 18th May 2007

1. Introduction

1.1. Chair: Call to order at 08:00
1.2. 105 attendees present.
1.3. Any modifications to agenda r5
1.4. No changes

2. Patent Policy

2.1. Does the chair need to be aware of any LoAs. No.
2.2. Hence as a reminder we are still operating under IEEE-SA P&P rules, as discussed and reviewed in the opening plenary

3. Announcements

3.1. CAC dates please for all the chairs. Next CAC call is 11th June 2007. Next graphic available by 25th May 2007. There are big issues with space and availability during the July meeting. Please be aware.
3.2. Please book the hotel for July 2007 now. There are other events in San Francisco at that time.
3.3. Also be aware that the Hawai'i meeting hotel is now available for reservations

3.4. Document Server

3.4.1. The current 802wirelessworld server will cease to exist next week, as described in the mid week plenary.
3.4.2. It will not be available for 2 days next week, and please remember that unused numbers will be lost.
3.4.3. You will now require an IEEE members account which is free to all whether an IEEE member or not; all details are in document 767r0. Emails will be sent to the email reflectors next week.

4. Policies and Procedures

4.1. IEEE 802.11 vice-chair presented document 11-07-675r2
4.2. The vice-chair responsibie for the WG P&P has received no comments this week.
4.3. Hence he will bring a motion later to adopt this document.

Question
4.4. I sent a comment to the IEEE 802.11 vice-chair.
4.5. Chair: Please can we move this to later after discussion with the member concerned.

5. Timelines

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001130

5.1. Please go and have a look at the new timelines, there have been several changes as present on the screen to the audience.

6. Technical Editor

6.1. Report : 07/788r2
6.2. Revisions MA-rev9.0 is now being professionally edited by the IEEE at this moment.
6.3. They can no longer commit themselves to a 2 month publication cycle.

6.4. ANA Function

6.4.1. This has now been transferred to the technical editor by a directive from the WG Chair.
6.4.2. Please see 827r0 for the revised ANA procedure.

6.4.3. The updated ANA database is now on the server as 11-07-1942r5.

Questions:
6.4.4. TGn passed a motion yesterday to ask for ANA numbers. Can ANA handle these numbers
6.4.5. Answer: Yes, and in the future this type of motion is no longer required.
6.4.6. What has happened with 1942r5. This is an odd number.
6.4.7. Answer: It was due to a 06/07 year bug in the document server in January 2007.
6.4.8. Document also covers the creation of redline documents. This process has now been rationalized. Generally we are also trying to sort out all the editors. Looking at communications, timelines and a harmonized approach to going forward with editorial duties. There will be a new chairs guide, which will also contain guidelines for secretaries and editors. Please don't worry about draft numbering in the future and also don't worry too much about trivial typos.

7. Location Straw Poll

7.1. Would you like to come back again to this hotel? Unanimous approval to come back.

8. Group reports

8.1. WNG SC

8.1.1. 11-07-803r0
8.1.2. No motions

8.2. TGk

8.2.1. 11-07-822r1
8.2.2. Completed LB #103 comments. Now headed towards sponsor ballot.
8.2.3. Ad Hoc in San Jose just before July 2007 meeting.

8.3. TGmb

8.3.1. 11-07-804r0
8.3.2. 1st session for TGmb.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001131

8.3.3. Extracted some negative vote issues (items deemed out-of-scope) from TGma and will take these forward in TGmb.

8.4. TGn

8.4.1. 11-07-780r0

8.4.2. Started with about 3000 comments, now finished the editorial ones. Completed 450 technical ones. Roughly one third of the way through the technical comments. Hence should be ready to go to 3rd letter ballot in September 2007.

8.4.3. There was 1 interpretation request from the IEEE, due to the fact that unadopted IEEE 802.11n D2.0 has been made for sale . This has now been rolled into the comment resolution process within TGn.

8.4.4. It has also been noticed that the IEEE-SA has mis-placed part of the TGn PAR on the website. This was with regard to section 12 "notes". The bottom half was missing. This has now been retrieved and re-posted on the NesCom website.

8.5. TGp

8.5.1. 11-07-817r0

8.5.2. Resolving comments from LB #92. All technical comments basically sorted out. Hope to be ready for re-circulation letter ballot in July 2007.

8.6. TGr

8.6.1. 11-07-807r0

8.6.2. LB #98 comment resolution. All comments now resolved. New draft D6.0 available.

8.6.3. The Sponsor Ballot invitation has now been sent out via the IEEE MyBallot system. This is open for 30 days.

8.7. TGs

8.7.1. 11-07-823r1

8.7.2. Also resolved 500 remaining comments from LB #93. Hope to resolve comments at next meeting

8.8. TGT

8.8.1. 11-07-810r0

8.8.2. Resolving comments from LB #101 after closing on Wednesday this week.

8.9. TGu

8.9.1. 11-07-804r0

8.9.2. Motions approved by the TG for initial WG letter ballot.

8.9.3. Announcement that 802 emergency ad-hoc, and its an 802 issue not just an 802.11. an 802 ad-hoc will be hosted in the July plenary

8.10. TGv

8.10.1. 11-07-784r0

8.10.2. All but 20 informal comments were resolved. Will wait until July 2007 until trying to go to letter ballot.

8.11. TGw

8.11.1. 11-07-818r0

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001132

8.11.2. Comments resolutions from LB #102. Resolved 68 technical comments this week and many editorial comments.

8.12. TGy

8.12.1. 11-07-821r0

8.12.2. LB #104 comment resolution. Will go out to re-circulation ballot later today and hope to use procedure 20 during the July 2007 meeting, going into Sponsor Ballot.

8.13. DLS SG

8.13.1. 11-07-809r0

8.13.2. 3 technical presentations this week.

8.14. QES SG

8.14.1. 11-07-663r3

8.14.2. Review of the purpose of the study group. Bringing together the 802.11e and Wi-Fi Alliance WMM specifications. Approved a PAR and 5 Criteria document

8.14.3. There are proposed changes which have suggested in 802.1Qav which have changed some aspects of 802.11e. Members should be aware of this.

Questions

8.14.4. How are you going to reconcile differences if you do not remove anything from 802.11

8.14.5. Answer: The TG will try to incorporate new changes, but will not make existing 802.11e devices obsolete.

8.15. VHT SG

8.15.1. 11-07-819r0

8.15.2. Eldad Perahia (Intel Corporation) was recommnet as a future chair by the SG. A draft PAR and 5Criteria was presented.

8.15.3. Chair: I appoint Eldad by acclamation as chair of VHT SG.

8.16. VTS SG

8.16.1. 11-07-812r0

8.16.2. Various introductory presentations including an overview of 802.1 aspects, which are relevant to this study group. Also discussed potential PAR and 5Criteria.

8.17. IMT Advanced Ad Hoc

8.17.1. We did not hold a session this time. But on 23rd May 2007 Kyoto, there will be 802.11 representation there. The IEEE 802.18 chair may then provide some feedback, so there will be some IMT Advanced teleconferences

9. P&P 15 Day Letter Ballots

9.1. 11-07-828r0

9.2. Clarification of output documents to higher level groups, e.g. from task groups to working group. This is rationalization of the letter ballot process, based on that of the IEEE-SA sponsor ballot process.

9.3. Chair: 15 day procedural process has now been changed. Please be aware.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001133

Questions:
9.4. We made a change during last nights CAC. This is not in this version.
9.5. Answer: Yes, and that will come out in r1
9.6. Chair: The CAC has reviewed this the WG Chair's changes and supports them and this is now the IEEE 802.11 WG policy.

10. Motions (Old Business)

10.1. Working Group

10.1.1. **Policies and Procedures**

10.1.2. **Move that the 802.11 working group approve doc:07/0360r3 (redline) as the 802.11WG policies and procedures and renumber the document to doc:07/0360r4, and reaffirm at the opening of the July 2007 IEEE 802.11 plenary session.**
10.1.3. Moved by: Al Petrick (WiDeFi)
10.1.4. 2nd: Harry Worstell (AT&T)

10.1.5. Debate:
10.1.6. Why has the approval level changed from 66% to 75%? Hence 360r2 should change to reflect this.
10.1.7. Why are we empowering interims 2-3 meetings in advance.
10.1.8. Answer: The change from 66% to 75% are based on the current 802 ExCom rules. However, we are still operating under the Jan 06 rules and they will change again in July 07.
10.1.9. Regarding the empowerment of the interims, we have to do this during the plenaries.
10.1.10. For 62, Against 1, Abstain 8 (Motion passes)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001134

10.1.11. **Teleconference Empowerment Motion**

Motion

Move to empower the following TG(s)/SG(s)/Ad-Hoc(s) to hold teleconference calls beginning no sooner than March 25, 2007 through 15 days past the end of the July 2007 Plenary Session.

Group	Start Date	Frequency	Time
Task Group "u"	May 30, 2007 June 19, 2007	Once Once	10:00 ET
Task Group "v"	June 14, 2007 June 28, 2007	Once	10:00 ET
Task Group "w"	June 14, 2007 July 9, 2007	Once	12:30 ET
VHT-SG	June 7, 2007 June 21, 2007 July 5, 2007	Once	11:00 ET
DLS SG	May 29, 2007 to July 13, 2007	Weekly	11:00ET

Moved by: Harry Worstell Second: Al Petrick
WG Results: Yes No Abstain

10.1.12. Motion passes by unanimous consent

10.2. Groups

10.2.1. **TGk**

10.2.2. **Move to request the Working Group to empower TGk to hold an ad-hoc meeting in San Jose, Ca for 2007-7-11 to 2007-7-13 as required to conduct business necessary to progress the Sponsor Ballot process, including creating and issuing drafts for Sponsor Ballot and handling other business necessary to progress through the IEEE standards process.**

10.2.3. On behalf of the TG (Ganesh/Hart Unanimous)
10.2.4. Motion passes by unanimous consent

10.2.5. **TGn : #1**

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001135

10.2.6. **Move to request the ANA to assign Regulatory Class and Behaviour Limit Set numbers as used in Draft IEEE P802.11n D2.0, which has been published externally.**

10.2.7. Approved in TGn: Unanimously

10.2.8. Note: The 3 informational slides attached to this motion are reproduced below:

Table I.3—Behavior limits sets

Behavior limits set	USA	Europe	Japan
13 40 MHz Primary channel with Secondary = 1 and also 20 MHz operation on primary channel	Reserved	Reserved	Reserved
14 40 MHz Primary channel with Secondary = -1 and also 20 MHz operation on primary channel	Reserved	Reserved	Reserved
15~~11~~ – 255	Reserved	Reserved	Reserved
NOTE—For 20 MHz operation where the regulatory class signifies 40 MHz channel spacing, the 20 MHz channel corresponds to the channel number indicated.			

Table J.1—Regulatory classes in the USA

Regulatory Class	Channel Starting Frequency (GHz)	Channel Spacing (MHz)	Channel set	Transmit Power limit (mW)	Emissions Limits set	Behavior Limits set
22	5	40	36, 44	40	1	1,2,13
23	5	40	52, 60	200	1	1,13
24	5	40	100, 108, 116, 124, 132	200	1	1,13
25	5	40	149, 157	800	1	1,13
26	5	40	149, 157	1000	4	10,13
27	5	40	40, 48	40	1	1,2,14
28	5	40	56, 64	200	1	1,14
29	5	40	104, 112, 120, 128, 136	200	1	1,14
30	5	40	153, 161	800	1	1,14
31	5	40	153, 161	1000	4	10,14
32	2.407	40	1-7	1000	4	10,13
33	2.407	40	5-11	1000	4	10,14
~~12~~31-255	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
NOTE—The Channel Spacing for Regulatory Class 22-33 is for the supported bandwidth rather than the operating bandwidth. In these regulatory classes, the AP operates in 20/40 MHz mode, and the operating bandwidth for a non-AP STA is either 20 MHz or 40 MHz.						

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001136

Table J.2—Regulatory classes in Europe

Regulatory Class	Channel Starting Frequency (GHz)	Channel Spacing (MHz)	Channel set	Transmit Power limit (mW)	Emissions Limits set	Behavior Limits set
5	5	40	36, 44	200	1	2,3,13
6	5	40	52, 60	200	1	1,3,4,13
7	5	40	100, 108, 116, 124, 132	1000	1	1,3,4,13
8	5	40	40, 48	200	1	2,3,14
9	5	40	56, 64	200	1	1,3,4,14
10	5	40	104, 112, 120, 128, 136	1000	1	1,3,4,14
11	2.407	40	1-9	100	4	10,13
12	2.407	40	5-13	100	4	10,14
413-255	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved

NOTE—The Channel Spacing for Regulatory Class 5-12 is for the supported bandwidth rather than the operating bandwidth. In these regulatory classes, the AP operates in 20/40 MHz mode, and the operating bandwidth for a non-AP STA is either 20 MHz or 40 MHz.

10.2.9. Motion passes by unanimous consent

10.2.10. **#2**

10.2.11. **Ad Hoc in Hawai'i in Sept 2007**

10.2.12. **Request TGn be authorized to conduct an ad hoc meeting for the purpose of resolving comments received during WG letter ballot 97 on TGn Draft 2.0 to be held Wednesday Sep 12 thru Friday Sep 14 2007 (just prior to the Sep Interim in Waikoloa, HI) with the preferred venue being the Hilton Waikoloa Village in Waikoloa, HI**

10.2.13. Approved in TGn: 21/0/2

10.2.14. Motion passes by unanimous consent

10.2.15. **#3**

10.2.16. PAR Extension

10.2.17. Extension text captured in 11-07-0814r0

10.2.18. **Motion: Approve submission 11-07-0814r0 PAR Extension Request to 802.11 WG requesting submission to NesCom with any required editorial changes. Approved inTGn: 30/0/0**

10.2.19. Chair: This will require re-affirmation at the July 2007, as there is no quorum at this meeting.

10.2.20. For: 76, Against: 0, Abstain: 1 (Motion passes)

10.2.21. **TGr**

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001137

10.2.22. **Move to authorize a 15-day Working Group Recirculation Letter Ballot of 802.11r draft 6.0, asking the question "Should the 802.11r draft 6.0 be forwarded to sponsor ballot?"**
10.2.23. By (TGr): Kapil Sood, Second (TGr): Michael Montemurro
10.2.24. TGr Result: Yes - 12; No - 0; Abstain - 2.
10.2.25. For: 70, Against: 0, Abstain: 3 (Motion passes)

10.2.26. **TGs : #1**

10.2.27. **Moved, to request that the 802.11 WG authorize an ad hoc in Munich, Germany, 1-3 August 2007, to work on comment resolution.**
10.2.28. In TGs: Moved: Guido Hiertz, Seconded: Jan Kruys, Yes: 11 No: 0 Abstain: 5
10.2.29. Note: This will be hosted by Siemens AG
10.2.30. Motion passes by unanimous consent

10.2.31. **#2**

10.2.32. **Moved, to request that the 802.11 WG authorize an ad hoc in Kaua'i, Hawai'i, 12-14 September 2007, to work on comment resolution.**
10.2.33. In TGs: Moved: Malik Audeh, Seconded: Jesse Walker, Yes: 17 No: 0 Abstain: 1
10.2.34. No location is specified for this ad-hoc
10.2.35. Motion passes by unanimous consent

10.2.36. **TGu**

10.2.37. Couple of friendly amendments to text:
10.2.37.1. Delete 1st paragraph of motion
10.2.37.2. Change TGu in the text to IEEE P802.11u
10.2.38. **Request the IEEE 802.11 WG to authorise a 30-day letter ballot asking the question "should IEEE 802.11u D1.0 be forwarded to Sponsor Ballot?"**
Debate:
10.2.39. What is the difference between D0.06 and D1.0.
10.2.40. Answer: It is just the change in the number.
10.2.41. For: 72, Against: 0, Abstain: 4

10.2.42. **TGw**

10.2.43. **Move to authorize a TGw ad hoc meeting, to be held June 25-26, 2007, in Hillsboro, OR, for the purpose of proposing resolutions to comments received during LB 102.**
10.2.44. TGw : Moved: Kapil Sood, Second: Matthew Gast, approved by unanimous consent
10.2.45. Motion passes by unanimous consent

10.2.46. **TGy**

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001138

10.2.47. **Move to authorize a 15-day Recirculation Letter Ballot of 802.11 TGy, draft 3.0 asking the question "Should the P802.11y draft 3.0 be forwarded to sponsor ballot?"**
10.2.48. Task Group Vote: Moved Bill Marshall, Second Rich Kennedy, Unanimous (3-0-0)
10.2.49. For: 67, Against: 1, Abstain: 3 (Motion passes)

10.2.50. **QES SG**

10.2.51. Comment: Please can we do any letter ballots in sequential order this time.
10.2.52. Chair: There are 3 letter ballots. We will try to accommodate no overlap between these letter ballots. They will start in order and be performed serially.
10.2.53. Comment: I object. I wish to appeal the chair's decision.
10.2.54. **Appeal of Chair's decision**: Chair hands over to vice-chair
10.2.55. Comment: TGy and TGr both have 15 day LBs. After that TGu has a 30 day. Hence TGy will start at the end of June and hence we will have no time to process comments during the July meeting.
10.2.56. IEEE 802.11 vice-chair: Just checking the dates. There are 49 days between now and the start of the next meeting. If we do things serially than that is 60day duration, which will take TGy into the next meeting.
10.2.57. Comment: I don't think that the original statement really meant for the chair to make this policy.
10.2.58. Comment: I think the chair went beyond what I actually requested.
10.2.59. IEEE 802.11 vice-chair: This is really hard work and please can we have some latitude.
10.2.60. Comment: I have no problem changing the order to TGr, TGy and then TGu. Perhaps we can have a small overlap please.
10.2.61. Comment: Perhaps we can adopt a small overlap between TGy and TGu.
10.2.62. **Motion to move in favor of the chair's ruling**.
10.2.63. For 4, Against: 45, Abstain: 19 (Motion fails)

10.2.64. The ruling is that the chair's decision was overturned.
10.2.65. **End of Appeal**
10.2.66. IEEE 802.11 vice-chair hands back to Stuart Kerry as chair

10.2.67. **Moved: to approve document 07/0029r4 adding to the scope statement the following clause: "and will not deprecate any operational mode or feature introduced in 802.11e-2005" as the PAR and Five Criteria for the QSE Study Group and forward for Executive Committee approval.**
10.2.68. **(note: see 07/0029r5 for updated PAR form with 5 criteria statements)**
10.2.69. Passed in study group 23-6-4

Debate:
10.2.70. Can you please clarify that r5 contains the updated scope. Hence isn't r5 that will actually go to ExCom?
10.2.71. Answer: Yes.
10.2.72. I speak against the formation of a task group, as I think this activity should occur within the TGmb group. I know that I helped craft the PAR and 5Criteria, but I am still against this motion.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001139

10.2.73. I speak against this motion, as I'm not happy about possible feature removal from the IEEE 802.11 standard. I think the PAR scope is restrictive.
10.2.74. I speak for the motion and I think this PAR is a good step towards harmonization between IEEE and WiFi Alliance. Speaking as chair of WiFi Alliance I will try to allow the WMM specification to be freely available.

10.2.75. Can we possibly use the new PAR for the adoption of an external standard?
10.2.76. Answer: I don't believe that WMM is actually a standard. To remove features from the IEEE 802.11 standard is not useful to the whole industry. The PAR limitation protects the task group from doing this.
10.2.77. Yes, but we must be given the ability to make any changes it so desires. This is a very unusual precedent.

10.2.78. For: 37, Against: 14, Abstain: 20 (motion fails 72.55%)

10.2.79. Please may I ask for a re-count
10.2.80. Chair: Yes

10.2.81. For: 41, Against: 16, Abstain: 17 (motion fails 71.93%)

10.2.82. Comment: Please can the chair not announce the initial results, before a re-count.
10.2.83. Chair: Yes, so noted.

10.2.84. Comment: Aren't members bound to vote the same way in a re-count.
10.2.85. Chair: Can not answer that, as it's a legal issue.

11. Motions (New Business)

11.1. Individual Motions

11.1.1. **Moved: To approve document 07/0815r0 as an output liaison letter to 802.1.**

11.1.2. The member read through the liaison letter to explain what the issue is between 802.11 and 802.1.

Comment:
11.1.3. I think we need to mention IEEE P802.11 (i.e. addition of the P)
11.1.4. Chair: Yes, I will allow this offline.

11.1.5. Moved Bob O'Hara (Cisco Corporation)
11.1.6. Second: Roger Durand (RIM)

Debate:
11.1.7. Has anyone had a look at the 802.1 PAR project, to see if they are compatible with existing standards?
11.1.8. Answer: No it's the other way around. 802.11 has to be compatible with 802.1
11.1.9. There is a discussion going on the 802.1 group and it has been mentioned within 802.11 WNG. Perhaps we can make these discussions more formal.
11.1.10. If this motion passes, when will the letter going out.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001140

11.1.11. Answer: It's up to the chairman to do this.
11.1.12. Chair: I will endeavor to do this today.

11.1.13. For : 60, Against : 0, Abstain : 0 (Motion passes)

11.1.14. **Liaison to request IETF EAP Update Method (EMU) working group to recommend a suitable EAP method for Emergency Service Authentication in conjunction with IEEE 802.11u.**
Move to approve liaison document 11-07-0826r0 and attached documents 11-07-0508r1 and 11-07-0290r2 request the IEEE 802.11 WG chair to forward it to IETF EMU WG
11.1.15. Moved by: Stephen McCann (Nokia Siemens Networks GmbH & Co. KG)
11.1.16. 2nd: Harry Worstell
11.1.17. For 54, Against 1, Abstain 5 (Motion passes)

11.1.18. **Liaison to respond to NENA's (National Emergency Number Association) request for a review by IEEE 802.11 of their i3 framework document, performed by IEEE 802.11u. (Note: National = USA).**
Move to approve liaison document 11-07-0825r0 and request the IEEE 802.11 WG chair to forward it to NENA
11.1.19. Moved by: Stephen McCann, 2nd: Al Petrick (WiDeFi)
11.1.20. No discussion
11.1.21. For 52, Against 0, Abstain 3 (Motion passes)

11.1.22. **Move to approve an IEEE 802.11u ad-hoc meeting from July 13th -15th 2007 in the Bay Area, CA**
11.1.23. Moved: Stephen McCann, Seconded Clint Chaplin (Symbol Technologies)
11.1.24. Unanimous approval

11.1.25. **Move to conduct a WG electronic ballot on the question "to approve document 11-07-0029r5 as the PAR and 5Criteria for the QSE Study Group and forward to ExCom for approval."**

11.1.26. Moved: Bob O'Hara, Seconded: Andrew Myles (Cisco Corporation)
Debate:
11.1.27. Does this document include the earlier restriction?
11.1.28. Answer: Yes
11.1.29. I think this will allow the IEEE 802.11 membership to consider this issue. think this will hinder future standardization
11.1.30. Isn't this a motion to re-consider?
11.1.31. Chair: The document number is different. What is the difference please.
11.1.32. I think that is irrelevant, as this motion is for a ballot.
11.1.33. Chair: Hence I think this is a valid motion
11.1.34. Is this technical or editorial?
11.1.35. Chair: Technical hence 75%
11.1.36. Can you make comments in the ballot.
11.1.37. Chair: Yes. January 2006 EC P&P states that all ballots have to be 75%.
11.1.38. This motion on the floor is a 50% vote.
11.1.39. Chair: All ballots are now 75%. Hence this motion is 75%.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001141

11.1.40. So, are all motions on the floor 75%?
11.1.41. Chair: Yes.
11.1.42. I am really shocked about this.
11.1.43. Ok, how are the comments going to be resolved from this ballot.
11.1.44. Chair: The comment resolution committee will be run by the IEEE 802.11 vice-chair
11.1.45. Regarding the motion on the floor, I think we have to check all decisions this week.
11.1.46. If this ballot passes, would all the comments be forwarded to ExCom.
11.1.47. Chair: ExCom will possibly only consider the result of the letter ballot. Above and beyond that I'm not sure.
11.1.48. Since we have no quorum, none of these ballots have any binding status. What do we do? I would prefer more discussion in this instance before we go to this electronic ballot.
11.1.49. I speak for the motion, as I think it's better to ask the larger membership this question. Can the chair initiate a ballot himself.
11.1.50. Chair: I decline to answer.

11.1.51. For: 27, Against: 24, Abstain 14 (motion fails 52.94%)

11.1.52. **Request for Action**

11.1.53. I would like to request an action. There is some confusion about this 75% ruling and I don't think all decisions made this week have followed this. Please can all minutes be re-viewed to ensure that all decisions have indeed met the 75% rule. Since we are not in Quorum today, this cannot be effectively done now and I request that this is done at the start of the July 2007 meeting. I think we have a problem.
11.1.54. Chair: The issue has been known for quite a while since January 2006. We know that the LMSC rules are rather confusing. Please can Al Petrick check all minutes.
11.1.55. Please can we generate some results of this analysis and have this presented at the start of the July 2007.
11.1.56. Chair: Yes, and I would like to re-ask the IEEE 802.11 P&P vice chair to do this. This needs to go to the reflector before the July meeting. Please can all chairs be aware of this.

12. Any other business

12.1. Next Meeting is July 15-20th 2007, Hyatt Regency in San Francisco and the Agenda for the July meeting is 11-07-1953r0

13. Meeting Adjourned at 11:15

APPENDIX 1004F

IEEE Draft Standards Online

IEEE *Xplore*® Digital Library Add-On Subscription Option

Add IEEE Draft Standards to your IEL subscription to gain an edge on the competition

With easily searchable access via IEEE *Xplore*, immediate updates, and automatic alerts, **IEEE Draft Standards Online will maximize research and development and provide your organization with the competitive advantage it needs.**

By adding IEEE Draft Standards Online, your organization can see a standard before it is published to help facilitate early compliance and implementation. Gain an early understanding of standards under development and get advanced insight into solutions and practices being proposed.

IEEE Draft Standards delivers key benefits for your research team:

- **Access the full text** of all IEEE Draft Standards
- **Increased productivity** by having all your standards in one place
- **Real-time updates** to the most vital standards in your industry
- **Trace the evolution of a standard** with a collection of approximately 5,000 drafts documents

For a complete listing of all IEEE Draft Standards in IEEE *Xplore:*

- Go to www.ieee.org/ieeexplore
- Click on the number above the search bar
- Refine your search by content type "standards"
- Further refine by "standard status"
- Lastly, refine by "standard modifier"

Quick Facts

Add IEEE Draft Standards to your IEL subscription* and get the information you need:

Unapproved Drafts—a combination of revisions of previous standards and brand new ideas that are still in the standards development process

Approved Drafts awaiting standard publication (it usually takes 3 to 6 months for approved standards to be published)

Approved and Archived Standards that have been superseded by a published standard provide the complete history of a standard's evolution

*Available exclusively to IEL subscribers

For a custom quote, contact an IEEE Sales Representative.

Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications:

Amendment <number>: Enhancements for Higher Throughput

EDITORIAL NOTE—the amendment number will be inserted by IEEE-SA editorial staff in the publication preparation phase.

The editing instructions are shown in bold italic. Four editing instructions are used: change, delete, insert, and replace. Change is used to make corrections in existing text or tables. The editing instruction specifies the location of the change and describes what is being changed by using strikethrough (to remove old material) and underscore (to add new material). Delete removes existing material. Insert adds new material without disturbing the existing material. Insertions may require renumbering. If so, renumbering instructions are given in the editing instruction. Replace is used to make changes in figures or equations by removing the existing figure or equation and replacing it with a new one. Editorial notes will not be carried over into future editions because the changes will be incorporated into the base standard.

About IEEE Standards

The IEEE is the leading developer of global standards in a broad range of industries including:

- Biomedical and Healthcare
- Information Assurance
- Information Technology
- Nanotechnology
- Power and Energy
- Telecommunications
- Transportation

What's in *Xplore*?

IEEE approved standards, unapproved and approved draft standards are available online to IEEE Standards Online and IEL subscribers.

You can get the standards in topically related collections, as subscriptions. For example, if you are interested in the Local and Metropolitan Area Network standards, you would subscribe to IEEE Standards Online, LAN/MAN subscription. You can also purchase standards individually through IEEE *Xplore*.

Important Information Regarding Drafts

Unapproved and Approved draft standards are included as part of the IEEE Standards Online subscription package at no additional cost. IEL subscribers can purchase an add-on package that contains draft standards.

About IEEE Standards

The IEEE is the leading developer of global standards in a broad range of industries including:

- Biomedical and Healthcare
- Information Assurance
- Information Technology
- Nanotechnology
- Power and Energy
- Telecommunications
- Transportation

What's in *Xplore*?

IEEE approved standards, unapproved and approved draft standards are available online to IEEE Standards Online and IEL subscribers.

You can get the standards in topically related collections, as subscriptions. For example, if you are interested in the Local and Metropolitan Area Network standards, you would subscribe to IEEE Standards Online, LAN/MAN subscription. You can also purchase standards individually through IEEE *Xplore*.

Important Information Regarding Drafts

Unapproved and Approved draft standards are included as part of the IEEE Standards Online subscription package at no additional cost. IEL subscribers can purchase an add-on package that contains draft standards.

Not all versions of drafts are made available and drafts consisting of only updated text may be included. Therefore, the latest complete draft under development may not be provided.

Unapproved drafts are proposed IEEE Standards. As such, these documents are subject to change and should be used at your own risk. Because these drafts are unapproved, they must not be utilized for any conformance / compliance purposes.

Important Information Regarding Archived Standards

Archived standards are not current IEEE standards and may be either withdrawn, replaced or superseded by other standards.

Archived standards may have value as historical documents, but they are not valid or approved IEEE standards. The IEEE shall not be liable for any damages resulting from the subscriber's or register user's practice of this unapproved, archived IEEE standard.

For more information about current, revised or withdrawn standards, please consult the IEEE Standards Status report.

Learn more about Subscriptions

802.3aj-2003	**Archived -** IEEE standard for information technology - telecommunications and information exchange between systems - local and metropolitan area networks - specific requirements part 3: carrier sense multiple access with collision detection (CSMA/CD)access method and physical layer specifications amendment: maintenance 7
802.3ak-2004	**Archived -** IEEE standard for information technology-telecommunications and information exchange between systems-local and metropolitan area networks-specific requirements. Part 3: carrier sense multiple access with method and physical layer specifications. Amendment: physical layer and management parameters for 10 Gb/s operation, type 10 GBASE-CX4 **An Errata is available**
802.3j-1993	**Archived -** Fiber Optic Active and Passive Star-Based Segments, Type 10BASE-F (Section 15-18) **Superseded by 802.3-2002**
802.3k-1992	**Archived -** Layer management for 10 Mb/s baseband repeaters (section 19). Supplement to carrier sense multiple access with collision detection (CSMA/CD)access method and physical layer specifications **Superseded by 802.3-2002**
802.3p and Std 802.3q	**Archived -** Guidelines for the Development of Managed Objects, Layer Management for MAUs
802.3r-1996	**Archived -** Information technology - telecommunications and information exchange between systems - local and metropolitan area networks - specific requirements. Supplement to Carrier Sense Multiple Access with Collision Detection (CSMA/CD) access method and physical layer specifications - Type 10BASE5 Medium Attachment Unit (MAU) Protocol Implementation Conformance Statement (PICS) proforma (subclause 8.8)
802.3u-1995	**Archived -** IEEE Standards for Local and Metropolitan Area Networks: Supplement to Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications Media Access Control (MAC) Parameters, Physical Layer, Medium Attachment Units, and Repeater for 100 Mb/s Operation, Type 100BASE-T (Clauses 21-30)
802.3x-1997	**Archived -** IEEE Standards for Local and Metropolitan Area Networks: Supplements to Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications - Specification for 802.3 Full Duplex Operation and Physical Layer Specification for 100 Mb/s Operation on Two Pairs of Category 3 or Better Balanced Twisted Pair Cable (100BASE-T2)
802.3 Drafts	
P802.3-2005/Cor 1/D2.0, Mar 2006	**Archived Unapproved Draft -** Information technology-Telecommunications and information exchange between systems-Local and metropolitan area networks-Specific requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications--Corrigendum 1(Draft Corrigendum to IEEE Std 802.3-2005)
P802.3-2005/Cor2/D2.0, Mar 2007	**Active Unapproved Draft -** Unapproved Draft IEEE Standard for Information Technology - Telecommunications and Information Exchange Between Systems - Local and Metropolitan Area Networks - Specific Requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications - Corrigendum 2: IEEE Std 802.3an-2006 10GBASE-T Correction (Corrigendum to IEEE Std 802.3-2005)
P802.3/Cor1/D2.0, Mar 2006	**Archived Unapproved Draft -** Unapproved Draft Corrigendum of:Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications: Corrigendum 1 Replaced by approved draft
P802.3ab/D6.0, Mar 1999	**Archived Unapproved Draft -** Unapproved Draft Supplement to Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications-Physical Layer Parameters and Specification-for 1000 Mb/s Operation over 4-pair of Category 5 Balanced Copper Cabling, Type 1000 BASE-T (Superseded by 802.3:2002)
P802.3ad/D3.1, Jan 2000	**Archived Approved Draft -** IEEE Approved Draft Supplement to Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications- Aggregation of Multiple Link Segments (Superseded by 802.3:2000)
P802.3ae/D5.0, May 2002	**Archived Unapproved Draft -** Supplement to Carrier Sense Multiple Access with Collision Detection (CSMA/CD)A ccess Method & Physical Layer Specifications Media Access Control (MAC)Para meters, Physical Layer, and Management Parameters for 10 Gb/s Operation (Superseded by 802.3:2003)
P802.3af/D4.3, Apr 2003	**Archived Unapproved Draft -** Amendment to Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific requirements Part 3: Carrier sense multiple access with collision detection (CSMA/CD) access method and physical layer specificationsAmendment: Data Terminal Equipment (DTE) Power via Media Dependent Interface (MDI) (Amendment to IEEE Std. 802.3-2002)
P802.3ah/D3.3, Apr 2004	**Archived Unapproved Draft -** Draft Amendment to Carrier Sense Multiple Access with Collision Detection (CSMA/CD) access method and physical layer specifications Draft amendment to - Information technology - Telecommunications and information exchange between systems - Local and metropolitan area networks - Specific requirements - Part 3: Carrier sense multiple access with collision detection (CSMA/CD) access method and physical layer specifications - Media Access Control Parameters, Physical Layers and Management Parameters for subscriber access networks (Amendment to 802.3-2002)
P802.3aj/D3.1, Jul 2003	**Archived Unapproved Draft -** Draft Amendment to IEEE Standard for Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific Requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications Amendment Maintenance #7 (Amendment to IEEE Std 802.3-2003 including IEEE Std 802.3ae-2002 and IEEE Std 802.3af-2003)
P802.3ak/D5.3, Nov 2003	**Archived Unapproved Draft -** Draft Amendment to IEEE Standard for Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) AccessMethod and Physical Layer Specifications Amendment: Physical Layer and Management Parameters for 10Gb/s Operation, Type 10GBASE-CX4 (Amendment to IEEE Std 802.3-2002)
P802.3an/D3.0, 2005	**Archived Unapproved Draft -** Unapproved Draft Amendment of: IEEE Standard for Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications: Amendment: Physical Layer and Management Parameters for 10 Gb/s Operation, Type 10GBASE-T (Draft amendment to IEEE Std 802.3-2005) Superseded by P802.3an/D3.1
P802.3an/D3.1, 2006	**Archived Unapproved Draft -** Unapproved Draft Amendment of: IEEE Standard for Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications: Amendment: Physical Layer and Management Parameters for 10 Gb/s Operation, Type 10GBASE-T (Draft amendment to IEEE Std 802.3-2005) Superseded by P802.3an/D4.0
P802.3an/D3.2, 2006	**Archived Unapproved Draft -** Unapproved Draft Amendment of: IEEE Standard for Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific requirements Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications: Amendment: Physical Layer and Management Parameters for 10 Gb/s Operation, Type 10GBASE-T (Draft amendment to IEEE Std 802.3-2005) Superseded by P802.3an/D3.1
P802.3an/D4.0, Apr 2006	**Archived Approved Draft -** Approved Draft Amendment of: IEEE Standard for Information technology Telecommunications and information exchange between systems Local and metropolitan area networks Specific

Abstract: This revision specifies technical corrections and clarifications to IEEE Std 802.11 for wireless local area networks (WLANS) as well as enhancements to the existing medium access control (MAC) and physical layer (PHY) functions. It also incorporates Amendments 1 through 8 including a corrigendum.

IEEE Standards documents are developed within the IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. The IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of the Institute and serve without compensation. While the IEEE administers the process and establishes rules to promote fairness in the consensus development process, the IEEE does not independently evaluate, test, or verify the accuracy of any of the information contained in its standards.

Use of an IEEE Standard is wholly voluntary. The IEEE disclaims liability for any personal injury, property or other damage, of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this, or any other IEEE Standard document.

The IEEE does not warrant or represent the accuracy or content of the material contained herein, and expressly disclaims any express or implied warranty, including any implied warranty of merchantability or fitness for a specific purpose, or that the use of the material contained herein is free from patent infringement. IEEE Standards documents are supplied "**AS IS**."

The existence of an IEEE Standard does not imply that there are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to the scope of the IEEE Standard. Furthermore, the viewpoint expressed at the time a standard is approved and issued is subject to change brought about through developments in the state of the art and comments received from users of the standard. Every IEEE Standard is subjected to review at least every five years for revision or reaffirmation. When a document is more than five years old and has not been reaffirmed, it is reasonable to conclude that its contents, although still of some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that they have the latest edition of any IEEE Standard.

In publishing and making this document available, the IEEE is not suggesting or rendering professional or other services for, or on behalf of, any person or entity. Nor is the IEEE undertaking to perform any duty owed by any other person or entity to another. Any person utilizing this, and any other IEEE Standards document, should rely upon the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

Interpretations: Occasionally questions may arise regarding the meaning of portions of standards as they relate to specific applications. When the need for interpretations is brought to the attention of IEEE, the Institute will initiate action to prepare appropriate responses. Since IEEE Standards represent a consensus of concerned interests, it is important to ensure that any interpretation has also received the concurrence of a balance of interests. For this reason, IEEE and the members of its societies and Standards Coordinating Committees are not able to provide an instant response to interpretation requests except in those cases where the matter has previously received formal consideration. At lectures, symposia, seminars, or educational courses, an individual presenting information on IEEE standards shall make it clear that his or her views should be considered the personal views of that individual rather than the formal position, explanation, or interpretation of the IEEE.

Comments for revision of IEEE Standards are welcome from any interested party, regardless of membership affiliation with IEEE. Suggestions for changes in documents should be in the form of a proposed change of text, together with appropriate supporting comments. Comments on standards and requests for interpretations should be addressed to:

Secretary, IEEE-SA Standards Board
445 Hoes Lane
Piscataway, NJ 08854
USA

Authorization to photocopy portions of any individual standard for internal or personal use is granted by the Institute of Electrical and Electronics Engineers, Inc., provided that the appropriate fee is paid to Copyright Clearance Center. To arrange for payment of licensing fee, please contact Copyright Clearance Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923 USA; +1 978 750 8400. Permission to photocopy portions of any individual standard for educational classroom use can also be obtained through the Copyright Clearance Center.

Introduction

This introduction is not part of IEEE Std 802.11-2007, IEEE Standard for Information Technology—Telecommunications and information exchange between systems—Local and metropolitan area network—Specific requirements—Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications.

This revision gives users, in one document, the IEEE 802.11 standard for wireless local area networks (WLANS) with all the amendments that have been published to date. The original standard was published in 1999 and reaffirmed in 2003. The following documents have been rolled into this revision and are, therefore, now retired along with the original, reaffirmed edition of IEEE Std 802.11:

— IEEE Std 802.11a™-1999 (Amendment 1)
— IEEE Std 802.11b™-1999 (Amendment 2)
— IEEE Std 802.11b-1999/Corrigendum 1-2001
— IEEE Std 802.11d™-2001 (Amendment 3)
— IEEE Std 802.11g™-2003 (Amendment 4)
— IEEE Std 802.11h™-2003 (Amendment 5)
— IEEE Std 802.11i™-2004 (Amendment 6)
— IEEE Std 802.11j™-2004 (Amendment 7)
— IEEE Std 802.11e™-2005 (Amendment 8)

In addition, this revision specifies technical corrections and clarifications to IEEE Std 802.11 as well as enhancements to the existing medium access control (MAC) and physical layer (PHY) functions. Such enhancements include improved data link security, codified vendor-specific extensions to the protocol, and incorporated interpretation requests.

Notice to users

Errata

Errata, if any, for this and all other standards can be accessed at the following URL: http://standards.ieee.org/reading/ieee/updates/errata/index.html. Users are encouraged to check this URL for errata periodically.

Interpretations

Current interpretations can be accessed at the following URL: http://standards.ieee.org/reading/ieee/interp/index.html.

Patents

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE shall not be responsible for identifying patents for which a license may be required by an IEEE standard or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention. A patent holder has filed a statement of assurance that it will grant licenses under these rights without compensation or under reasonable rates and nondiscriminatory, reasonable terms and conditions to all applications desiring to obtain such licenses. The IEEE makes no representation as to the reasonableness of rates and/or terms and conditions of the license agreements offered by patent holders. Further information may be obtained from the IEEE Standard Department.

Participants

At the time the draft of this revision was sent to sponsor ballot, the IEEE 802.11 Working Group had the following officers:

Stuart J. Kerry, *Chair*
Al Petrick, *Vice-Chair and Treasurer*
Harry R. Worstell, *Vice-Chair*
Tim Godfrey, *Secretary*
Nanci Vogtli, *Publicity Standing Committee*
Teik-Kheong Tan, *Chair, Wireless Next Generation Standing Committee*
Terry L. Cole and **Simon Barber**, *Technical Editors*

Richard H. Paine, *Chair, Task Group k*
Bruce P. Kraemer, *Chair, Task Group n*
Sheung Li, *Vice-Chair, Task Group n*
Lee Armstrong, *Chair, Task Group p*
Clint Chaplin, *Chair, Task Group r*
Donald E. Eastlake III, *Chair, Task Group s*
Charles R. Wright, *Chair, Task Group t*
Stephen McCann, *Chair, Task Group u*
Pat R. Calhoun, *Chair, Task Group v*
Jesse Walker, *Chair, Task Group w*
Peter Ecclesine, *Chair, Contention-Based Protocol Study Group*

When the IEEE 802.11 Working Group approved this revision, Task Group m had the following membership:

Robert O'Hara, *Chair*
Terry L. Cole, *Editor*

When the IEEE-SA Standards Board approved this revision on 8 March 2007, it had the following membership:

Steve M. Mills, *Chair*
Robert M. Grow, *Vice Chair*
Don Wright, *Past Chair*
Judith Gorman, *Secretary*

Richard DeBlasio
Julian Forster*
Alex Gelman
William R. Goldbach
Arnold M. Greenspan
Joanna N. Guenin
Kenneth S. Hanus
William B. Hopf
Richard H. Hulett
Hermann Koch
Joseph L. Koepfinger*
John Kulick
David J. Law
Glenn Parsons
Ronald C. Petersen
Tom A. Prevost
Narayanan Ramachandran
Greg Ratta
Robby Robson
Anne-Marie Sahazizian
Virginia C. Sulzberger*
Malcolm V. Thaden
Richard L. Townsend
Howard L. Wolfman

*Member Emeritus

Also included are the following nonvoting IEEE-SA Standards Board liaisons:

Satish K. Aggarwal, *NRC Representative*
Alan H. Cookson, *NIST Representative*
Virginia C. Sulzberger, *Member/TAB Representative*

Michelle D. Turner
IEEE Standards Program Manager, Document Development

Michael D. Kipness
IEEE Standards Program Manager, Technical Program Development

Contents

1. Overview 1

1.1 Scope 1
1.2 Purpose 1

2. Normative references 3

3. Definitions 5

4. Abbreviations and acronyms 17

5. General description 23

5.1 General description of the architecture 23
5.1.1 How WLAN systems are different 23
5.1.1.1 Destination address does not equal destination location 23
5.1.1.2 Media impact on design and performance 23
5.1.1.3 The impact of handling mobile STAs 23
5.1.1.4 Interaction with other IEEE 802® layers 24
5.1.1.5 Interaction with non-IEEE-802 protocols 24
5.2 Components of the IEEE 802.11 architecture 24
5.2.1 The independent BSS (IBSS) as an ad hoc network 25
5.2.2 STA membership in a BSS is dynamic 25
5.2.3 Distribution system (DS) concepts 25
5.2.3.1 Extended service set (ESS): The large coverage network 26
5.2.3.2 RSNA 27
5.2.4 Area concepts 27
5.2.5 Integration with wired LANs 29
5.2.6 QoS BSS: The QoS network 30
5.3 Logical service interfaces 31
5.3.1 SS 31
5.3.2 DSS 32
5.4 Overview of the services 32
5.4.1 Distribution of messages within a DS 33
5.4.1.1 Distribution 33
5.4.1.2 Integration 34
5.4.1.3 QoS traffic scheduling 34
5.4.2 Services that support the distribution service 34
5.4.2.1 Mobility types 34
5.4.2.2 Association 35
5.4.2.3 Reassociation 35
5.4.2.4 Disassociation 36
5.4.3 Access control and data confidentiality services 36
5.4.3.1 Authentication 36
5.4.3.2 Deauthentication 37
5.4.3.3 Data confidentiality 38
5.4.3.4 Key management 38
5.4.3.5 Data origin authenticity 38
5.4.3.6 Replay detection 39
5.4.4 Spectrum management services 39
5.4.4.1 TPC 39

Annex A (normative) Protocol Implementation Conformance Statement (PICS) proforma ... 725

A.1 Introduction ... 725
A.2 Abbreviations and special symbols ... 725
A.2.1 Symbols for Status column ... 725
A.2.2 General abbreviations for Item and Support columns ... 725
A.3 Instructions for completing the PICS proforma ... 726
A.3.1 General structure of the PICS proforma ... 726
A.3.2 Additional information ... 726
A.3.3 Exception information ... 726
A.3.4 Conditional status ... 727
A.4 PICS proforma—IEEE Std 802.11-2007 ... 728
A.4.1 Implementation identification ... 728
A.4.2 Protocol summary ... 728
A.4.4 MAC protocol ... 729
A.4.3 IUT configuration ... 729
A.4.5 Frequency hopping (FH) PHY functions ... 737
A.4.6 Direct sequence PHY functions ... 739
A.4.7 IR baseband PHY functions ... 743
A.4.8 OFDM PHY functions ... 746
A.4.9 High Rate, direct sequence PHY functions ... 755
A.4.10 Regulatory Domain Extensions ... 760
A.4.11 ERP functions ... 761
A.4.12 Spectrum management extensions ... 764
A.4.13 Regulatory classes extensions ... 766
A.4.14 QoS base functionality ... 766
A.4.15 QoS enhanced distributed channel access (EDCA) ... 767
A.4.16 QoS hybrid coordination function (HCF) controlled channel access (HCCA) ... 767

Annex B (informative) Hopping sequences ... 769

Annex C (informative) Formal description of a subset of MAC operation ... 783

C.1 Introduction to the MAC formal description ... 786
C.1.1 Fundamental assumptions ... 786
C.1.2 Notation conventions ... 786
C.1.3 Modeling techniques ... 787
C.2 Data type and operator definitions for the MAC state machines ... 788
C.3 State machines for MAC STAs ... 836
C.4 State machines for MAC AP ... 913

Annex D (normative) ASN.1 encoding of the MAC and PHY MIB ... 985

Annex E (reserved for future use) ... 1075

Annex F (informative) High Rate PHY/FH interoperability ... 1077

F.1 Additional CCA recommendations ... 1077

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001209

Annex G (informative) An example of encoding a frame for OFDM PHY 1079

G.1 Introduction 1079
G.2 The message 1079
G.3 Generation of the preamble 1080
G.3.1 Generation of the short sequences 1080
G.3.2 Generation of the long sequences 1083
G.4 Generation of the SIGNAL field 1086
G.4.1 SIGNAL field bit assignment 1086
G.4.2 Coding the SIGNAL field bits 1086
G.4.3 Interleaving the SIGNAL field bits 1087
G.4.4 SIGNAL field frequency domain 1087
G.4.5 SIGNAL field time domain 1088
G.5 Generating the DATA bits 1090
G.5.1 Delineating, SERVICE field prepending, and zero padding 1090
G.5.2 Scrambling 1091
G.6 Generating the first DATA symbol 1094
G.6.1 Coding the DATA bits 1094
G.6.2 Interleaving the DATA bits 1095
G.6.3 Mapping into symbols 1098
G.7 Generating the additional DATA symbols 1099
G.8 The entire packet 1100

Annex H (informative) RSNA reference implementations and test vectors 1107

H.1 TKIP temporal key mixing function reference implementation and test vector 1107
H.1.1 Test vectors 1117
H.2 Michael reference implementation and test vectors 1119
H.2.1 Michael test vectors 1119
H.2.2 Sample code for Michael 1120
H.3 PRF reference implementation and test vectors 1127
H.3.1 PRF reference code 1127
H.3.2 PRF test vectors 1128
H.4 Suggested pass-phrase-to-PSK mapping 1128
H.4.1 Introduction 1128
H.4.2 Reference implementation 1129
H.4.3 Test vectors 1130
H.5 Suggestions for random number generation 1131
H.5.1 Software sampling 1131
H.5.2 Hardware-assisted solution 1132
H.6 Additional test vectors 1133
H.6.1 Notation 1133
H.6.2 WEP cryptographic encapsulation 1134
H.6.3 TKIP test vector 1135
H.6.4 CCMP test vector 1136
H.6.5 PRF test vectors 1136
H.7 Key hierarchy test vectors 1138
H.7.1 Pairwise key derivation 1138

Annex I (informative) Regulatory classes 1141

I.1 External regulatory references 1141
I.2 Radio performance specifications 1143
I.2.1 Transmit and receive in-band and out-of-band spurious emissions 1143

Exhibit 1014
Page 001210

I.2.2 Transmit power levels ... 1143
I.2.3 Transmit spectrum mask ... 1144

Annex J (normative) Country information element and regulatory classes ... 1147

Annex K (informative) Admission control ... 1151

K.1 Example use of TSPEC for admission control ... 1151
K.2 Recommended practices for contention-based admission control ... 1152
K.2.1 Use of ACM (admission control mandatory) subfield ... 1152
K.2.2 Deriving medium time ... 1152
K.3 Guidelines and reference design for sample scheduler and admission control unit ... 1153
K.3.1 Guidelines for deriving service schedule parameters ... 1153
K.3.2 TSPEC construction ... 1153
K.3.3 Reference design for sample scheduler and admission control unit ... 1155

Annex L (informative) An example of encoding a TIM virtual bit map ... 1159

L.1 Introduction ... 1159
L.2 Examples ... 1159
L.3 Sample C code ... 1160

Annex M (informative) Integration function ... 1165

M.1 Introduction ... 1165
M.2 Ethernet V2.0/IEEE 802.3 LAN integration function ... 1165
M.3 Example ... 1165
M.4 Integration service versus bridging ... 1167

Annex N (informative) AP functional description ... 1169

N.1 Introduction ... 1169
N.2 Terminology ... 1169
N.3 Primary ACM_STA functions ... 1173
N.4 Primary AP functions ... 1173
N.5 Primary DS functions ... 1175
N.6 Primary portal function ... 1175
N.7 AU example ... 1175

Annex O (informative) DS SAP specification ... 1177

O.1 Introduction ... 1177
O.2 SAP primitives ... 1178
O.2.1 MSDU transfer ... 1178
O.2.2 Mapping updates ... 1180

Annex P (informative) Bibliography ... 1181

P.1 General ... 1181
P.2 Specification and description language (SDL) documentation ... 1183

IEEE Standard for Information Technology—Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements

Part 11: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) Specifications

1. Overview

1.1 Scope

The scope of this standard is to define one medium access control (MAC) and several physical layer (PHY) specifications for wireless connectivity for fixed, portable, and moving stations (STAs) within a local area.

1.2 Purpose

The purpose of this standard is to provide wireless connectivity to automatic machinery, equipment, or STAs that require rapid deployment, which may be portable or hand-held, or which may be mounted on moving vehicles within a local area. This standard also offers regulatory bodies a means of standardizing access to one or more frequency bands for the purpose of local area communication.

Specifically, this standard

— Describes the functions and services required by an IEEE 802.11™-compliant device to operate within ad hoc and infrastructure networks as well as the aspects of STA mobility (transition) within those networks.

— Defines the MAC procedures to support the asynchronous MAC service data unit (MSDU) delivery services.

— Defines several PHY signaling techniques and interface functions that are controlled by the IEEE 802.11 MAC.

— Permits the operation of an IEEE 802.11-conformant device within a wireless local area network (WLAN) that may coexist with multiple overlapping IEEE 802.11 WLANs.

— Describes the requirements and procedures to provide data confidentiality of user information being transferred over the wireless medium (WM) and authentication of IEEE 802.11-conformant devices.

— Defines mechanisms for dynamic frequency selection (DFS) and transmit power control (TPC) that may be used to satisfy regulatory requirements for operation in the 5 GHz band. The regulations and conformance tests are listed in Clause 2.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001224

— Defines the MAC procedures to support local area network (LAN) applications with quality of service (QoS) requirements, including the transport of voice, audio, and video.

3. Definitions

For the purposes of this standard, the following terms and definitions apply. *The Authoritative Dictionary of IEEE Standards Terms* [B11] should be referenced for terms not defined in this clause.

3.1 access category (AC): A label for the common set of enhanced distributed channel access (EDCA) parameters that are used by a quality of service (QoS) station (STA) to contend for the channel in order to transmit medium access control (MAC) service data units (MSDUs) with certain priorities.

3.2 access control: The prevention of unauthorized usage of resources.

3.3 access point (AP): Any entity that has station (STA) functionality and provides access to the distribution services, via the wireless medium (WM) for associated STAs.

3.4 additional authentication data (AAD): Data that are not encrypted, but are cryptographically protected.

3.5 ad hoc network: Often used as a venacular term for an independent basic service set (IBSS).

3.6 admission control: An algorithm to ensure that admittance of a new flow into a resource constrained network does not violate parameterized service commitments made by the network to admitted flows.

3.7 aggregated schedule: The aggregation of delivery and/or poll schedules by the quality of service (QoS) access point (AP) for a particular non-access point (non-AP) QoS station (STA) into a single service period (SP).

3.8 association: The service used to establish access point/station (AP/STA) mapping and enable STA invocation of the distribution system services (DSSs).

3.9 authentication: The service used to establish the identity of one station (STA) as a member of the set of STAs authorized to associate with another STA.

3.10 authentication and key management (AKM) suite: A set of one or more algorithms designed to provide authentication and key management, either individually or in combination with higher layer authentication and key management algorithms outside the scope of this standard.

3.11 Authentication Server (AS): An entity that provides an authentication service to an Authenticator. This service determines, from the credentials provided by the Supplicant, whether the Supplicant is authorized to access the services provided by the Authenticator. (IEEE Std 802.1X-2004[10])

3.12 Authenticator: An entity at one end of a point-to-point LAN segment that facilitates authentication of the entity attached to the other end of that link. (IEEE Std 802.1X-2004)

3.13 Authenticator address (AA): The medium access control (MAC) address of the IEEE 802.1X Authenticator.

3.14 authorized: To be explicitly allowed.

3.15 basic service area (BSA): The area containing the members of a basic service set (BSS). It may contain members of other BSSs.

[10]Information on references can be found in Clause 2.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001228

3.16 basic service set (BSS): A set of stations (STAs) that have successfully synchronized using the JOIN service primitives[11] and one STA that has used the START primitive. Membership in a BSS does not imply that wireless communication with all other members of the BSS is possible.

3.17 big endian: The concept that, for a given multi-octet numeric representation, the most significant octet has the lowest address.

3.18 broadcast address: A unique multicast address that specifies all stations (STAs).

3.19 channel: An instance of communications medium use for the purpose of passing protocol data units (PDUs) between two or more stations (STAs).

3.20 channel spacing: The difference between the center frequencies of two nonoverlapping and adjacent channels of the radio transmitter.

3.21 cipher suite: A set of one or more algorithms, designed to provide data confidentiality, data authenticity or integrity, and/or replay protection.

3.22 clear channel assessment (CCA) function: That logical function in the physical layer (PHY) that determines the current state of use of the wireless medium (WM).

3.23 contention-free period (CFP): The time period during operation of a point coordination function (PCF) when the right to transmit is assigned to stations (STAs) solely by a point coordinator (PC), allowing frame exchanges to occur between members of the basic service set (BSS) without contention for the wireless medium (WM).

3.24 contention period (CP): The time period outside of the contention-free period (CFP) in a point-coordinated basic service set (BSS). In a BSS where there is no point coordinator (PC), this corresponds to the entire time of operation of the BSS.

3.25 controlled access phase (CAP): A time period when the hybrid coordinator (HC) maintains control of the medium, after gaining medium access by sensing the channel to be idle for a point coordination function (PCF) interframe space (PIFS) duration. It may span multiple consecutive transmission opportunities (TXOPs) and can contain polled TXOPs.

3.26 coordination function: The logical function that determines when a station (STA) operating within a basic service set (BSS) is permitted to transmit protocol data units (PDUs) via the wireless medium (WM). The coordination function within a BSS may have one hybrid coordination function (HCF), or it may have one HCF and one point coordination function (PCF) and will have one distributed coordination function (DCF). A quality of service (QoS) BSS will have one DCF and one HCF.

3.27 contention-free (CF) pollable: A station (STA) that is able to respond to a CF poll with a data frame if such a frame is queued and able to be generated.

3.28 Counter mode with Cipher-block chaining Message authentication code (CCM): A symmetric key block cipher mode providing confidentiality using counter mode (CTR) and data origin authenticity using cipher-block chaining message authentication code (CBC-MAC).

NOTE—See IETF RFC 3610.[12]

[11]Description of these primitives can be found in 10.3.3.

[12]Notes in text, tables, and figures are given for information only and do not contain requirements needed to implement this standard.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001229

3.29 cryptographic encapsulation: The process of generating the cryptographic payload from the plaintext data. This comprises the cipher text as well as any associated cryptographic state required by the receiver of the data, e.g., initialization vectors (IVs), sequence numbers, message integrity codes (MICs), key identifiers.

3.30 data confidentiality: A property of information that prevents disclosure to unauthorized individuals, entities, or processes.

3.31 deauthentication service: The service that voids an existing authentication relationship.

3.32 decapsulate: To recover an unprotected frame from a protected one.

3.33 decapsulation: The process of generating plaintext data by decapsulating an encapsulated frame.

3.34 delivery-enabled access category (AC): A quality of service (QoS) access point (AP) AC where the AP is allowed to use enhanced distributed channel access (EDCA) to deliver traffic from the AC to a non-access point (non-AP) QoS station (STA) in an unscheduled service period (SP) triggered by the STA.

3.35 directed frame: *See:* **unicast frame**.

3.36 direct link: A bidirectional link from one non-access point (non-AP) quality of service (QoS) station (STA) to another non-AP QoS STA operating in the same infrastructure QoS basic service set (BSS) that does not pass through a QoS access point (AP). Once a direct link has been set up, all frames between the two non-AP QoS STAs are exchanged directly.

3.37 disassociation service: The service that removes an existing association.

3.38 distributed coordination function (DCF): A class of coordination function where the same coordination function logic is active in every station (STA) in the basic service set (BSS) whenever the network is in operation.

3.39 distribution service: The service that, by using association information, delivers medium access control (MAC) service data units (MSDUs) within the distribution system (DS).

3.40 distribution system (DS): A system used to interconnect a set of basic service sets (BSSs) and integrated local area networks (LANs) to create an extended service set (ESS).

3.41 distribution system medium (DSM): The medium or set of media used by a distribution system (DS) for communications between access points (APs) and portals of an extended service set (ESS).

3.42 distribution system service (DSS): The set of services provided by the distribution system (DS) that enable the medium access control (MAC) to transport MAC service data units (MSDUs) between stations (STAs) that are not in direct communication with each other over a single instance of the wireless medium (WM). These services include transport of MSDUs between the access points (APs) of basic service sets (BSSs) within an extended service set (ESS), transport of MSDUs between portals and BSSs within an ESS, and transport of MSDUs between STAs in the same BSS in cases where the MSDU has a multicast or broadcast destination address or where the destination is an individual address and the STA is associated with an AP. DSSs are provided between pairs of IEEE 802.11 MACs.

3.43 downlink: A unidirectional link from an access point (AP) to one or more non-AP stations (STAs).

3.44 dynamic frequency selection (DFS): Facilities mandated to satisfy requirements in some regulatory domains for radar detection and uniform channel spreading in the 5 GHz band. These facilities may also be used for other purposes, such as automatic frequency planning.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001230

3.45 dynamic frequency selection (DFS) owner: A station (STA) in an independent basic service set (IBSS) that takes responsibility for selecting the next channel after radar is detected operating in a channel. Due to the nature of IBSSs, it cannot be guaranteed that there will be a single DFS owner at any particular time and the protocol is robust to this situation.

3.46 EAPOL-Key confirmation key (KCK): A key used to integrity-check an EAPOL-Key frame.

3.47 EAPOL-Key encryption key (KEK): A key used to encrypt the Key Data field in an EAPOL-Key frame.

3.48 effective isotropic radiated power (EIRP): The equivalent power of a transmitted signal in terms of an isotropic (omnidirectional) radiator. The EIRP equals the product of the transmitter power and the antenna gain (reduced by any coupling losses between the transmitter and antenna).

3.49 encapsulate: To construct a protected frame from an unprotected frame.

3.50 encapsulation: The process of generating an protected frame by encapsulating plaintext data.

3.51 enhanced distributed channel access (EDCA): The prioritized carrier sense multiple access with collision avoidance (CSMA/CA) access mechanism used by quality of service (QoS) stations (STAs) in a QoS basic service set (BSS). This access mechanism is also used by the QoS access point (AP) and operates concurrently with hybrid coordination function (HCF) controlled channel access (HCCA).

3.52 enhanced distributed channel access function (EDCAF): A logical function in a quality of service (QoS) station (STA) that determines, using enhanced distributed channel access (EDCA), when a frame in the transmit queue with the associated access category (AC) is permitted to be transmitted via the wireless medium (WM). There is one EDCAF per AC.

3.53 extended service area (ESA): The area within which members of an extended service set (ESS) may communicate. An ESA is larger than or equal to a basic service area (BSA) and may involve several basic service sets (BSSs) in overlapping, disjointed, or both configurations.

3.54 extended service set (ESS): A set of one or more interconnected basic service sets (BSSs) that appears as a single BSS to the logical link control (LLC) layer at any station (STA) associated with one of those BSSs.

3.55 4-Way Handshake: A pairwise key management protocol defined by this standard. This handshake confirms mutual possession of a pairwise master key (PMK) by two parties and distributes a group temporal key (GTK).

3.56 4-Way station-to-station link (STSL) transient key (STK) Handshake: A key management protocol between two parties that confirms mutual possession of an STSL master key (SMK) and distributes an STK.

3.57 fragmentation: The process of segmenting a medium access control (MAC) service data unit (MSDU) or MAC management protocol data unit (MMPDU) into a sequence of smaller MAC protocol data units (MPDUs) prior to transmission. The process of recombining a set of fragment MPDUs into an MSDU or MMPDU is known as defragmentation. These processes are described in 5.8.1.9 of ISO/IEC 7498-1:1994.

3.58 Gaussian frequency shift keying (GFSK): A modulation scheme in which the data are first filtered by a Gaussian filter in the baseband and then modulated with a simple frequency modulation.

3.59 group: The entities in a wireless network, e.g., an access point (AP) and its associated stations (STAs), or all the STAs in an independent basic service set (IBSS) network.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001231

3.60 Group Key Handshake: A group key management protocol defined by this standard. It is used only to issue a new group temporal key (GTK) to peers with whom the local station (STA) has already formed security associations.

3.61 group master key (GMK): An auxiliary key that may be used to derive a group temporal key (GTK).

3.62 group temporal key (GTK): A random value, assigned by the broadcast/multicast source, which is used to protect broadcast/multicast medium access control (MAC) protocol data units (MPDUs) from that source. The GTK may be derived from a group master key (GMK).

3.63 group temporal key security association (GTKSA): The context resulting from a successful group temporal key (GTK) distribution exchange via either a Group Key Handshake or a 4-Way Handshake.

3.64 hidden station (STA): A STA whose transmissions cannot be detected using carrier sense (CS) by a second STA, but whose transmissions interfere with transmissions from the second STA to a third STA

3.65 hybrid coordination function (HCF): A coordination function that combines and enhances aspects of the contention-based and contention-free access methods to provide quality of service (QoS) stations (STAs) with prioritized and parameterized QoS access to the wireless medium (WM), while continuing to support non-QoS STAs for best-effort transfer. The HCF includes the functionality provided by both enhanced distributed channel access (EDCA) and HCF controlled channel access (HCCA). The HCF is compatible with the distributed coordination function (DCF) and the point coordination function (PCF). It supports a uniform set of frame formats and exchange sequences that STAs may use during both the contention period (CP) and the contention-free period (CFP).

3.66 hybrid coordinator (HC): A type of coordinator, defined as part of the quality of service (QoS) facility, that implements the frame exchange sequences and medium access control (MAC) service data unit (MSDU) handling rules defined by the hybrid coordination function (HCF). The HC operates during both the contention period (CP) and contention-free period (CFP). The HC performs bandwidth management including the allocation of transmission opportunities (TXOPs) to QoS stations (STAs). The HC is collocated with a QoS access point (AP).

3.67 hybrid coordination function (HCF) controlled channel access (HCCA): The channel access mechanism utilized by the hybrid coordinator (HC) to coordinate contention-free media use by quality of service (QoS) stations (STAs) for downlink unicast, uplink, and direct-link transmissions.

3.68 IEEE 802.1X authentication: Extensible Authentication Protocol (EAP) authentication transported by the IEEE 802.1X protocol.

3.69 independent basic service set (IBSS): A basis service set (BSS) that forms a self-contained network, and in which no access to a distribution system (DS) is available.

3.70 individual address: *See:* **unicast address**.

3.71 infrastructure: The infrastructure includes the distribution system medium (DSM), access point (AP), and portal entities. It is also the logical location of distribution and integration service functions of an extended service set (ESS). An infrastructure contains one or more APs and zero or more portals in addition to the distribution system (DS).

3.72 integration service: The service that enables delivery of medium access control (MAC) service data units (MSDUs) between the distribution system (DS) and a non-IEEE-802.11 local area network (LAN) (via a portal).

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001232

3.73 key counter: A 256-bit (32-octet) counter that is used in the pseudo-random function (PRF) to generate initialization vectors (IVs). There is a single key counter per station (STA) that is global to that STA.

3.74 key data encapsulation (KDE): Format for data other than information elements in the EAPOL-Key Data field.

3.75 key management service: A service to distribute and manage cryptographic keys within a robust security network (RSN).

3.76 link: In the context of an IEEE 802.11 medium access control (MAC) entity, a physical path consisting of exactly one traversal of the wireless medium (WM) that is used to transfer an MAC service data unit (MSDU) between two stations (STAs).

3.77 link margin: Ratio of the received signal power to the minimum desired by the station (STA). The STA may incorporate rate information and channel conditions, including interference, into its computation of link margin. The specific algorithm for computing the link margin is implementation dependent.

3.78 little endian: The concept that, for a given multi-octet numeric representation, the least significant octet has the lowest address.

3.79 liveness: A demonstration that the peer is actually participating in this instance of communication.

3.80 master session key (MSK): Keying material that is derived between the Extensible Authentication Protocol (EAP) peer and exported by the EAP method to the Authentication Server (AS). This key is at least 64 octets in length.

3.81 medium access control (MAC) management protocol data unit (MMPDU): The unit of data exchanged between two peer MAC entities, using services of the physical layer (PHY), to implement the MAC management protocol.

3.82 medium access control (MAC) protocol data unit (MPDU): The unit of data exchanged between two peer MAC entities using the services of the physical layer (PHY).

3.83 medium access control (MAC) service data unit (MSDU): Information that is delivered as a unit between MAC service access points (SAPs).

3.84 message integrity code (MIC): A value generated by a cryptographic function. If the input data are changed, a new value cannot be correctly computed without knowledge of the cryptographic key(s) used by the cryptographic function. This is traditionally called a *message authentication code* (MAC), but the acronym MAC is already reserved for another meaning in this standard.

3.85 Michael: The message integrity code (MIC) for the Temporal Key Integrity Protocol (TKIP).

3.86 mobile station (STA): A type of STA that uses network communications while in motion.

3.87 multicast: When applied to a medium access control (MAC) service data unit (MSDU), it is an MSDU with a multicast address as the destination address (DA). When applied to a MAC protocol data unit (MPDU) or control frame, it is an MPDU or control frame with a multicast address as the receiver address (RA).

3.88 multicast address: A medium access control (MAC) address that has the group bit set.

3.89 multicast-group address: A medium access control (MAC) address associated by higher level convention with a group of logically related stations (STAs).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001233

3.90 network allocation vector (NAV): An indicator, maintained by each station (STA), of time periods when transmission onto the wireless medium (WM) will not be initiated by the STA whether or not the STA's clear channel assessment (CCA) function senses that the WM is busy.

3.91 non-access point (non-AP) quality of service (QoS) station (STA): A STA that supports the QoS facility, but is not an access point (AP). A non-AP STA does not have an hybrid coordinator (HC) and uses the QoS AP for the distribution system services (DSSs).

3.92 nonce: A numerical value, used in cryptographic operations associated with a given cryptographic key, that is not to be reused with that key, including over all reinitializations of the system through all time.

3.93 non-quality of service (non-QoS) access point (AP): An AP that does not support the quality of service (QoS) facility.

3.94 non-quality of service (non-QoS) basic service set (BSS): A BSS that does not support the quality of service (QoS) facility.

3.95 non-quality of service (non-QoS) station (STA): A STA that does not support the quality of service (QoS) facility.

3.96 pairwise: Referring to, or an attribute of, two entities that are associated with each other, e.g., an access point (AP) and an associated station (STA), or two STAs in an independent basic service set (IBSS) network. This term is used to refer to a type of encryption key hierarchy pertaining to keys shared by only two entities.

3.97 pairwise master key (PMK): The highest order key used within this standard. The PMK may be derived from a key generated by an Extensible Authentication Protocol (EAP) method or may be obtained directly from a preshared key (PSK).

3.98 pairwise master key security association (PMKSA): The context resulting from a successful IEEE 802.1X authentication exchange between the peer and Authentication Server (AS) or from a preshared key (PSK).

3.99 pairwise transient key (PTK): A value that is derived from the pairwise master key (PMK), Authenticator address (AA), Supplicant address (SPA), Authenticator nonce (ANonce), and Supplicant nonce (SNonce) using the pseudo-random function (PRF) and that is split up into as many as five keys, i.e., temporal encryption key, two temporal message integrity code (MIC) keys, EAPOL-Key encryption key (KEK), EAPOL-Key confirmation key (KCK).

3.100 pairwise transient key security association (PTKSA): The context resulting from a successful 4-Way Handshake exchange between the peer and Authenticator.

3.101 parameterized quality of service (QoS): The treatment of the medium access control (MAC) protocol data units (MPDUs) depends on the parameters associated with the MPDU. Parameterized QoS is primarily provided through the hybrid coordination function (HCF) controlled channel access (HCCA) mechanism, but may also be provided by the enhanced distributed channel access (EDCA) mechanism when used with a traffic specification (TSPEC) for admission control.

3.102 pass-phrase: A secret text string employed to corroborate the user's identity.

3.103 PeerKey Handshake: A key management protocol composed of the station-to-station link (STSL) master key (SMK) Handshake and the 4-Way STSL transient key (STK) Handshake. This is used to create new SMK security associations (SMKSAs) and STK security associations (STKSAs) to secure the STSLs.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001234

3.104 per-frame encryption key: A unique encryption key constructed for each medium access control (MAC) protocol data unit (MPDU), employed by some IEEE 802.11 security protocols.

3.105 per-frame sequence counter: For Temporal Key Integrity Protocol (TKIP), the counter that is used as the nonce in the derivation of the per-frame encryption key. For Counter mode with Cipher-block chaining Message authentication code Protocol (CCMP), the per-frame initialization vector (IV).

3.106 piggyback: The overloading of a data frame with an acknowledgment of a previously received medium access control (MAC) protocol data unit (MPDU) and/or a poll to the station (STA) to which the frame is directed.

3.107 point coordinator (PC): The entity within the STA in an AP that performs the point coordination function.

3.108 point coordination function (PCF): A class of possible coordination functions in which the coordination function logic is active in only one station (STA) in a basic service set (BSS) at any given time that the network is in operation.

3.109 portable station (STA): A type of station (STA) that may be moved from location to location, but that only uses network communications while at a fixed location.

3.110 portal: The logical point at which the integration service is provided.

3.111 pre-robust security network association (pre-RSNA): The type of association used by a pair of stations (STAs) if the procedure for establishing authentication or association between them did not include the 4-Way Handshake.

3.112 pre-robust security network association (pre-RSNA) equipment: A device that is not able to create robust security network associations (RSNAs).

3.113 preshared key (PSK): A static key that is distributed to the units in the system by a method outside the scope of this standard, always by some out-of-band means.

3.114 prioritized quality of service (QoS): The provisioning of service in which the medium access control (MAC) protocol data units (MPDUs) with higher priority are given a preferential treatment over MPDUs with a lower priority. Prioritized QoS is provided through the enhanced distributed channel access (EDCA) mechanism.

3.115 protection mechanism: Any procedure that attempts to update the network allocation vector (NAV) of all receiving stations (STAs) prior to the transmission of a frame that may or may not be detected as valid network activity by the PHY entities at those receiving STAs.

3.116 protection mechanism frame: Any frame that is sent as part of a protection mechanism procedure.

3.117 pseudo-random function (PRF): A function that hashes various inputs to derive a pseudo-random value. In order to ensure liveness of a communication in which a pseudorandom value is used, a nonce is used as one of the inputs to the function.

3.118 quality of service (QoS) access point (AP): An AP that supports the QoS facility. The functions of a QoS AP are a superset of the functions of a non-QoS AP, and thus a QoS AP is able to function as a non-QoS AP to non-QoS stations (STAs).

3.119 quality of service (QoS) basic service set (BSS): A BSS that provides the QoS facility. An infrastructure QoS BSS contains a QoS access point (AP).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001235

3.120 quality of service (QoS) facility: The set of enhanced functions, channel access rules, frame formats, frame exchange sequences and managed objects used to provide parameterized and prioritized QoS.

3.121 quality of service (QoS) independent basic service set (IBSS): An IBSS in which one or more of its stations (STAs) support the QoS facility.

3.122 quality of service (QoS) station (STA): A STA that implements the QoS facility. A QoS STA acts as a non-QoS STA when associated in a non-QoS basic service set (BSS).

3.123 reassociation service: The service that enables an established association [between access point (AP) and station (STA)] to be transferred from one AP to another (or the same) AP.

3.124 receive power: Mean power measured at the antenna connector.

3.125 received power indicator (RPI): A quantized measure of the received power level as seen at the antenna connector.

3.126 robust security network (RSN): A security network that allows only the creation of robust security network associations (RSNAs). An RSN can be identified by the indication in the RSN information element (IE) of Beacon frames that the group cipher suite specified is not wired equivalent privacy (WEP).

3.127 robust security network association (RSNA): The type of association used by a pair of stations (STAs) if the procedure to establish authentication or association between them includes the 4-Way Handshake. Note that the existence of an RSNA by a pair of devices does not of itself provide robust security. Robust security is provided when all devices in the network use RSNAs.

3.128 robust-security-network-association- (RSNA-) capable equipment: A station (STA) that is able to create RSNAs. Such a device can use pre-RSNAs because of configuration. Notice that RSNA-capable does not imply full compliance with the RSNA Protocol Implementation Conformance Statement (PICS). A legacy device that has been upgraded to support Temporal Key Integrity Protocol (TKIP) can be RSNA-capable, but will not be compliant with the PICS if it does not also support Counter mode with Cipher-block chaining Message authentication code Protocol (CCMP).

3.129 robust-security-network-association- (RSNA-) enabled equipment: A station (STA) when it is RSNA-capable and dot11RSNAEnabled is set to TRUE.

3.130 robust security network association (RSNA) key management: Key management that includes the 4-Way Handshake, the Group Key Handshake, and the PeerKey Handshake.

3.131 scheduled service period (SP): The SP that is scheduled by the quality of service (QoS) access point (AP). Scheduled SPs start at fixed intervals of time.

3.132 security network: A basic service set (BSS) where the station (STA) starting the BSS provides information about the security capabilities and configuration of the BSS by including the robust security network (RSN) information element in Beacon frames.

3.133 selector: An item specifying a list constituent in an IEEE 802.11 Management Message information element.

3.134 service interval (SI): The interval between the start of two successive scheduled service periods (SPs).

3.135 service period (SP): A contiguous time during which one or more downlink unicast frames are transmitted to a quality of service (QoS) station (STA) and/or one or more transmission opportunities

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001236

(TXOPs) are granted to the same STA. SPs can be scheduled or unscheduled. For a non-access point (non-AP) STA, there can be at most one SP active at any time.

3.136 station (STA): Any device that contains an IEEE 802.11-conformant medium access control (MAC) and physical layer (PHY) interface to the wireless medium (WM).

3.137 station service (SS): The set of services that support transport of medium access control (MAC) service data units (MSDUs) between stations (STAs) within a basic service set (BSS).

3.138 station-to-station link (STSL): A direct link established between two stations (STAs) while associated to a common access point (AP). This term refers to a generic mechanism that may be implemented to allow direct station-to-station communication while remaining in the infrastructure mode. Establishment of this type of link includes an initialization step. The STSL is terminated by specific teardown procedures under the conditions prescribed in this standard. The only example of this procedure currently specified is direct link established by the direct-link setup (DLS).

3.139 station-to-station link (STSL) master key (SMK): A random value generated by an access point (AP) during an SMK Handshake. It is used for deriving an STSL transient key (STK).

3.140 station-to-station link (STSL) master key (SMK) Handshake: A key management protocol between two parties that creates a new SMK.

3.141 station-to-station link (STSL) master key security association (SMKSA): The context resulting from a successful STSL master key (SMK) Handshake.

3.142 station-to-station link (STSL) transient key (STK): A value that is derived from the STSL master key (SMK), initiator MAC address (MAC_I), peer MAC address (MAC_P), initiator nonce (INonce), and peer nonce (PNonce), using the pseudo-random function (PRF). The value is split into as many as five keys, i.e., temporal encryption key, two temporal message integrity code (MIC) keys, EAPOL-Key encryption key (KEK), and EAPOL-Key confirmation key (KCK).

3.143 station-to-station link (STSL) transient key security association (STKSA): The context resulting from a successful 4-Way STSL transient key (STK) exchange.

3.144 Supplicant: An entity at one end of a point-to-point LAN segment that is being authenticated by an Authenticator attached to the other end of that link. (IEEE Std 802.1X-2004)

3.145 Supplicant address (SPA): The medium access control (MAC) address of the IEEE 802.1X Supplicant.

3.146 temporal encryption key: The portion of a pairwise transient key (PTK) or group temporal key (GTK) used directly or indirectly to encrypt data in medium access control (MAC) protocol data units (MPDUs).

3.147 temporal key: The combination of temporal encryption key and temporal message integrity code (MIC) key.

3.148 temporal message integrity code (MIC) key: The portion of a transient key used to ensure the integrity of medium access control (MAC) service data units (MSDUs) or MAC protocol data units (MPDUs).

3.149 time unit (TU): A measurement of time equal to 1024 μs.

Exhibit 1014
Page 001237

3.150 traffic category (TC): A label for medium access control (MAC) service data units (MSDUs) that have a distinct user priority (UP), as viewed by higher layer entities, relative to other MSDUs provided for delivery over the same link. Traffic categories are meaningful only to MAC entities that support quality of service (QoS) within the MAC data service. These MAC entities determine the UP for MSDUs belonging to a particular traffic category using the priority value provided with those MSDUs at the MAC service access point (MAC_SAP).

3.151 traffic classification (TCLAS): The specification of certain parameter values to identify the medium access control (MAC) service data units (MSDUs) belonging to a particular traffic stream (TS). The classification process, performed above the MAC service access point (MAC_SAP) at a quality of service (QoS) access point (AP), uses the parameter values for a given TS to examine each incoming MSDU and determine whether this MSDU belongs to that TS. TCLAS may also occur at non-access point (non-AP) QoS station (STA) with multiple streams. However, such classification is beyond the scope of this standard.

3.152 traffic identifier (TID): Any of the identifiers usable by higher layer entities to distinguish medium access control (MAC) service data units (MSDUs) to MAC entities that support quality of service (QoS) within the MAC data service. There are 16 possible TID values; eight identify TCs, and the other eight identify parameterized TSs. The TID is assigned to an MSDU in the layers above the MAC.

3.153 traffic specification (TSPEC): The quality of service (QoS) characteristics of a data flow to and from a non-access point (non-AP) QoS station (STA).

3.154 traffic stream (TS): A set of medium access control (MAC) service data units (MSDUs) to be delivered subject to the quality of service (QoS) parameter values provided to the MAC in a particular traffic specification (TSPEC). TSs are meaningful only to MAC entities that support QoS within the MAC data service. These MAC entities determine the TSPEC applicable for delivery of MSDUs belonging to a particular TS using the TS identifier (TSID) value provided with those MSDUs at the MAC service access point (MAC_SAP).

3.155 traffic stream identifier (TSID): Any of the identifiers usable by higher layer entities to distinguish medium access control (MAC) service data units (MSDUs) to MAC entities for parameterized quality of service (QoS) [i.e., the traffic stream (TS) with a particular traffic specification (TSPEC)] within the MAC data service. The TSID is assigned to an MSDU in the layers above the MAC.

3.156 transition security network (TSN): A security network that allows the creation of pre-robust security network associations (pre-RSNAs) as well as RSNAs. A TSN can be identified by the indication in the robust security network (RSN) information element of Beacon frames that the group cipher suite in use is wired equivalent privacy (WEP).

3.157 transmission opportunity (TXOP): An interval of time when a particular quality of service (QoS) station (STA) has the right to initiate frame exchange sequences onto the wireless medium (WM). A TXOP is defined by a starting time and a maximum duration. The TXOP is either obtained by the STA by successfully contending for the channel or assigned by the hybrid coordinator (HC).

3.158 transmission opportunity (TXOP) holder: A quality of service (QoS) station (STA) that has either been granted a TXOP by the hybrid coordinator (HC) or successfully contended for a TXOP.

3.159 transmit power: The effective isotropic radiated power (EIRP) when referring to the operation of a 5 GHz IEEE 802.11 orthogonal frequency division multiplexing (OFDM) physical layer (PHY) in a country where so regulated.

3.160 trigger-enabled access category (AC): A non-access point (non-AP) quality of service (QoS) station (STA) AC where frames of subtype QoS Data and QoS Null from the non-AP STA that map to the AC trigger an unscheduled service period (SP) if one is not in progress.

Exhibit 1014
Page 001238

3.161 unauthorized disclosure: The process of making information available to unauthorized individuals, entities, or processes.

3.162 unauthorized resource use: Use of a resource not consistent with the defined security policy.

3.163 unicast: When applied to a medium access control (MAC) service data unit (MSDU), it is an MSDU with a single recipient address as the destination address (DA). When applied to a MAC protocol data unit (MPDU) or control frame, it is an MPDU or control frame with a single recipient address as the receiver address (RA).

3.164 unicast address: A medium access control (MAC) address that does not have the group bit set. *Syn:* **directed address**, **individual address**.

3.165 uniform spreading: A regulatory requirement for a channel selection mechanism that provides uniform usage across a minimum set of channels in the regulatory domain.

3.166 unscheduled service period (SP): The period that is started when a non-access point (non-AP) quality of service (QoS) station (STA) transmits a trigger frame to the QoS access point (AP).

3.167 uplink: A unidirectional link from a non-access point (non-AP) station (STA) to an access point (AP).

3.168 user priority (UP): A value associated with an medium access control (MAC) service data unit (MSDU) that indicates how the MSDU is to be handled. The UP is assigned to an MSDU in the layers above the MAC.

3.169 wired equivalent privacy (WEP): A deprecated cryptographic data confidentiality algorithm specified by IEEE Std 802.11 that may be used to provide data confidentiality that is subjectively equivalent to the data confidentiality of a wired local area network (LAN) medium that does not employ cryptographic techniques to enhance data confidentiality.

3.170 wireless distribution system (WDS): A mechanism for wireless communication using a four address frame format specified in this standard. This standard describes such a frame format, but does not describe how such a mechanism or frame format would be used.

3.171 wireless local area network (WLAN) system: A system that includes the distribution system (DS), access points (APs), and portal entities. It is also the logical location of distribution and integration service functions of an extended service set (ESS). A WLAN system contains one or more APs and zero or more portals in addition to the DS.

3.172 wireless medium (WM): The medium used to implement the transfer of protocol data units (PDUs) between peer physical layer (PHY) entities of a wireless local area network (LAN).

5. General description

5.1 General description of the architecture

This clause presents the concepts and terminology used within this standard. Specific terms are defined in Clause 3. Illustrations convey key IEEE 802.11 concepts and the interrelationships of the architectural components. IEEE Std 802.11 uses an architecture to describe functional components of an IEEE 802.11 LAN. The architectural descriptions are not intended to represent any specific physical implementation of IEEE Std 802.11.

5.1.1 How WLAN systems are different

Wireless networks have fundamental characteristics that make them significantly different from traditional wired LANs. Some countries impose specific requirements for radio equipment in addition to those specified in this standard. This standard does not provide information to meet these country-specific radio regulations.

5.1.1.1 Destination address does not equal destination location

In wired LANs, an address is equivalent to a physical location. This is implicitly assumed in the design of wired LANs. In IEEE Std 802.11, the addressable unit is a station (STA). The STA is a message destination, but not (in general) a fixed location.

5.1.1.2 Media impact on design and performance

The PHYs used in IEEE Std 802.11 are fundamentally different from wired media. Thus IEEE 802.11 PHYs

a) Use a medium that has neither absolute nor readily observable boundaries outside of which STAs with conformant PHY transceivers are known to be unable to receive network frames

b) Are unprotected from other signals that may be sharing the medium

c) Communicate over a medium significantly less reliable than wired PHYs

d) Have dynamic topologies

e) Lack full connectivity, and therefore the assumption normally made that every STA can hear every other STA is invalid (i.e., STAs may be “hidden” from each other)

f) Have time-varying and asymmetric propagation properties

g) May experience interference from logically disjoint IEEE 802.11 networks operating in overlapping areas

Because of limitations on wireless PHY ranges, WLANs intended to cover reasonable geographic distances may be built from basic coverage building blocks. When providing QoS services it should be understood that the MAC endeavors to provide QoS “service guarantees” within the limitations of the medium properties identified above. In other words, particularly in unlicensed spectrum, true guarantees are often not possible. However, gradations of service are always possible; and in sufficiently controlled environments, QoS guarantees can truly be made.

5.1.1.3 The impact of handling mobile STAs

One of the requirements of IEEE Std 802.11 is to handle *mobile* as well as *portable* STAs. A *portable* STA is one that is moved from location to location, but that is only used while at a fixed location. *Mobile* STAs actually access the LAN while in motion.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001246

For technical reasons, it is not sufficient to handle only portable STAs. Propagation effects blur the distinction between portable and mobile STAs; stationary STAs often appear to be mobile due to propagation effects.

Another aspect of mobile STAs is that they may often be battery powered. Hence power management is an important consideration. For example, it cannot be presumed that a STA's receiver will always be powered on.

5.1.1.4 Interaction with other IEEE 802® layers

IEEE Std 802.11 is required to appear to higher layers [logical link control (LLC)] as a wired IEEE 802 LAN. This requires that the IEEE 802.11 network handle STA mobility within the MAC sublayer. To meet reliability assumptions (that LLC makes about lower layers), it is necessary for IEEE Std 802.11 to incorporate functionality that is untraditional for MAC sublayers.

In a robust security network association (RSNA), IEEE Std 802.11 provides functions to protect data frames, IEEE Std 802.1X-2004 provides authentication and a Controlled Port, and IEEE Std 802.11 and IEEE Std 802.1X-2004 collaborate to provide key management. All STAs in an RSNA have a corresponding IEEE 802.1X entity that handles these services. This standard defines how an RSNA utilizes IEEE Std 802.1X-2004 to access these services.

When used to support applications with QoS requirements, each IEEE 802.11 LAN provides a link within an end-to-end QoS environment that may be established between, and managed by, higher layer entities. To handle QoS traffic in a manner comparable to other IEEE 802 LANs, the IEEE 802.11 QoS facility requires the IEEE 802.11 MAC sublayers to incorporate functionality that is not traditional for MAC sublayers. In addition, it may be necessary for certain higher layer management entities to be "WLAN aware" at least to the extent of understanding that the available bandwidth and other QoS characteristics of a WLAN are subject to frequent, and sometimes substantial, dynamic changes due to causes other than traffic load and are outside the direct control of network management entities.

5.1.1.5 Interaction with non-IEEE-802 protocols

An RSNA utilizes non-IEEE-802 protocols for its authentication and key management (AKM) services. Some of these protocols are defined by other standards organizations, such as the Internet Engineering Task Force (IETF).

5.2 Components of the IEEE 802.11 architecture

The IEEE 802.11 architecture consists of several components that interact to provide a WLAN that supports STA mobility transparently to upper layers.

The basic service set (BSS) is the basic building block of an IEEE 802.11 LAN. Figure 5-1 shows two BSSs, each of which has two STAs that are members of the BSS.

It is useful to think of the ovals used to depict a BSS as the coverage area within which the member STAs of the BSS may remain in communication. (The concept of area, while not precise, is often good enough.) This area is called the Basic Service Area (BSA). If a STA moves out of its BSA, it can no longer directly communicate with other STAs present in the BSA.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001247

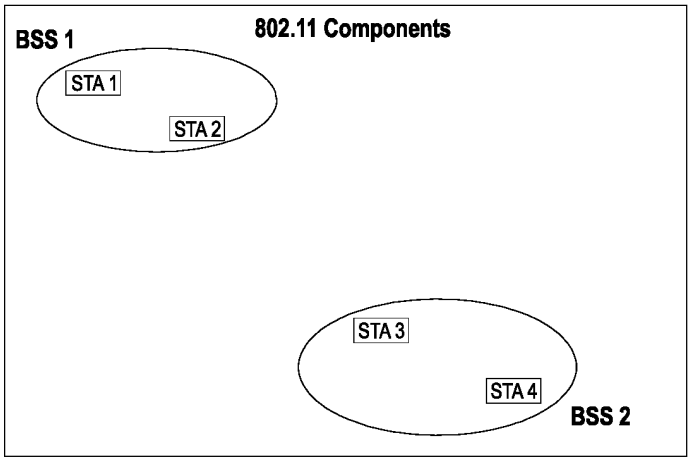

Figure 5-1—BSSs

5.2.1 The independent BSS (IBSS) as an ad hoc network

The IBSS is the most basic type of IEEE 802.11 LAN. A minimum IEEE 802.11 LAN may consist of only two STAs. Since the BSSs shown in Figure 5-1 are simple and lack other components (contrast this with Figure 5-2), the two can be taken to be represenative of two IBSSs.

This mode of operation is possible when IEEE 802.11 STAs are able to communicate directly. Because this type of IEEE 802.11 LAN is often formed without pre-planning, for only as long as the LAN is needed, this type of operation is often referred to as an *ad hoc network*.

5.2.2 STA membership in a BSS is dynamic

A STA's membership in a BSS is dynamic (STAs turn on, turn off, come within range, and go out of range). To become a member of a BSS, a STA joins the BSS using the synchronization procedure described in 11.1.3.4. To access all the services of an infrastructure BSS, a STA shall become "associated." These associations are dynamic and involve the use of the distribution system service (DSS), which is described in 5.3.2.

5.2.3 Distribution system (DS) concepts

PHY limitations determine the direct station-to-station distance that may be supported. For some networks this distance is sufficient; for other networks, increased coverage is required.

Instead of existing independently, a BSS may also form a component of an extended form of network that is built with multiple BSSs. The architectural component used to interconnect BSSs is the DS.

IEEE Std 802.11 logically separates the WM from the distribution system medium (DSM). Each logical medium is used for different purposes, by a different component of the architecture. The IEEE 802.11 definitions neither preclude, nor demand, that the multiple media be either the same or different.

Recognizing that the multiple media are *logically* different is key to understanding the flexibility of the architecture. The IEEE 802.11 LAN architecture is specified independently of the physical characteristics of any specific implementation.

The DS enables mobile device support by providing the logical services necessary to handle address to destination mapping and seamless integration of multiple BSSs.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001248

An access point (AP) is any entity that has STA functionality and enables access to the DS, via the WM for associated STAs.

Figure 5-2 adds the DS, DSM and AP components to the IEEE 802.11 architecture picture.

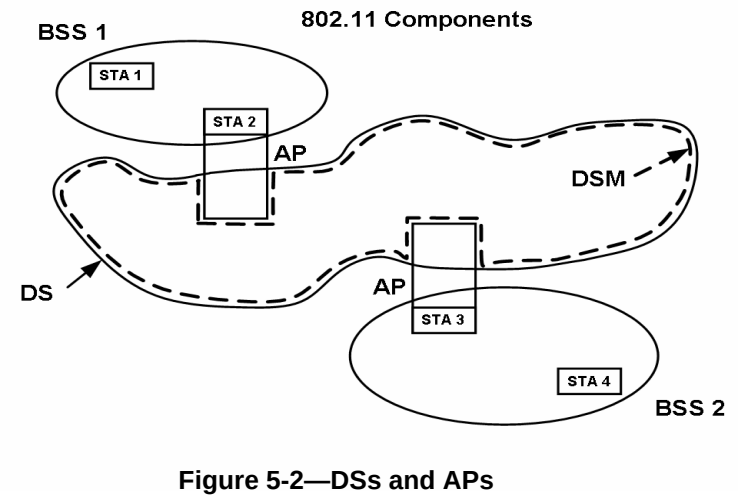

Figure 5-2—DSs and APs

Data move between a BSS and the DS via an AP. Note that all APs are also STAs; thus they are addressable entities. The addresses used by an AP for communication on the WM and on the DSM are not necessarily the same.

Data sent to the AP's STA address by one of the STAs associated with it are always received at the uncontrolled port for processing by the IEEE 802.1X port access entity. In addition, if the controlled port is authorized, these frames conceptually transit the DS.

5.2.3.1 Extended service set (ESS): The large coverage network

The DS and BSSs allow IEEE Std 802.11 to create a wireless network of arbitrary size and complexity. IEEE Std 802.11 refers to this type of network as the ESS network. An ESS is the union of the BSSs connected by a DS. The ESS does not include the DS.

The key concept is that the ESS network appears the same to an LLC layer as an IBSS network. STAs within an ESS may communicate and mobile STAs may move from one BSS to another (within the same ESS) transparently to LLC.

Nothing is assumed by IEEE Std 802.11 about the relative physical locations of the BSSs in Figure 5-3.

All of the following are possible:

a) The BSSs may partially overlap. This is commonly used to arrange contiguous coverage within a physical volume.

b) The BSSs could be physically disjoint. Logically there is no limit to the distance between BSSs.

c) The BSSs may be physically collocated. This may be done to provide redundancy.

d) One (or more) IBSS or ESS networks may be physically present in the same space as one (or more) ESS networks. This may arise for a number of reasons. Some examples are when an ad hoc network is operating in a location that also has an ESS network, when physically overlapping IEEE 802.11 networks have been set up by different organizations, and when two or more different access and security policies are needed in the same location.

Exhibit 1014
Page 001249

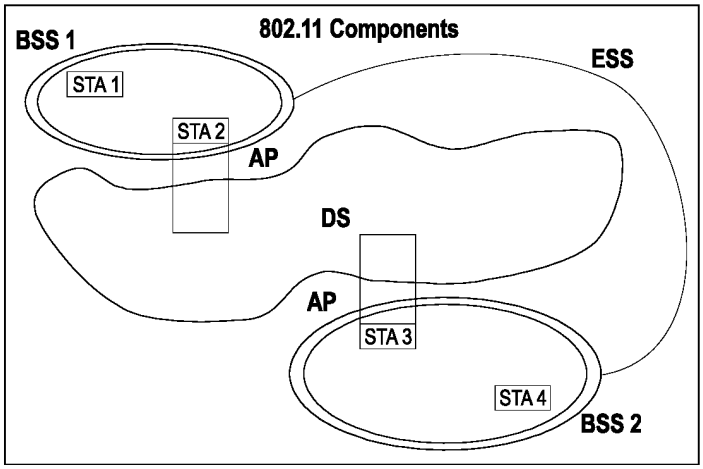

Figure 5-3—ESS

5.2.3.2 RSNA

An RSNA defines a number of security features in addition to wired equivalent privacy (WEP) and IEEE 802.11 authentication. These features include the following:

— Enhanced authentication mechanisms for STAs

— Key management algorithms

— Cryptographic key establishment

— An enhanced data cryptographic encapsulation mechanism, called Counter mode with Cipher-block chaining Message authentication code Protocol (CCMP), and, optionally, Temporal Key Integrity Protocol (TKIP).

An RSNA relies on several components external to the IEEE 802.11 architecture.

The first component is an IEEE 802.1X port access entity (PAE). PAEs are present on all STAs in an RSNA and control the forwarding of data to and from the medium access control (MAC). An AP always implements the Authenticator PAE and Extensible Authentication Protocol (EAP) Authenticator roles, and a non-AP STA always implements the Supplicant PAE and EAP peer roles. In an IBSS, each STA implements both the Authenticator PAE and Supplicant PAE roles and both EAP Authenticator and EAP peer roles.

A second component is the Authentication Server (AS). The AS may authenticate the elements of the RSNA itself, i.e., the non-AP STAs; and APs may provide material that the RSNA elements can use to authenticate each other. The AS communicates through the IEEE 802.1X Authenticator with the IEEE 802.1X Supplicant on each STA, enabling the STA to be authenticated to the AS and vice versa. An RSNA depends upon the use of an EAP method that supports mutual authentication of the AS and the STA, such as those that meet the requirements in IETF RFC 4017. In certain applications, the AS may be integrated into the same physical device as the AP, or into a STA in an IBSS.

5.2.4 Area concepts

For wireless PHYs, well-defined coverage areas simply do not exist. Propagation characteristics are dynamic and unpredictable. Small changes in position or direction may result in dramatic differences in signal strength. Similar effects occur whether a STA is stationary or mobile (as moving objects may impact station-to-station propagation).

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001250

Figure 5-4 shows a signal strength map for a simple square room with a standard metal desk and an open doorway. Figure 5-4 is a static snapshot; the propagation patterns change dynamically as STAs and objects in the environment move. In Figure 5-4 the dark (solid) blocks in the lower left are a metal desk and there is a doorway at the top right of the figure. The figure indicates relative differences in field strength with different intensities and indicates the variability of field strength even in a static environment. The difference between the greatest signal strength and the least signal strength in Figure 5-4 is 50 dB.

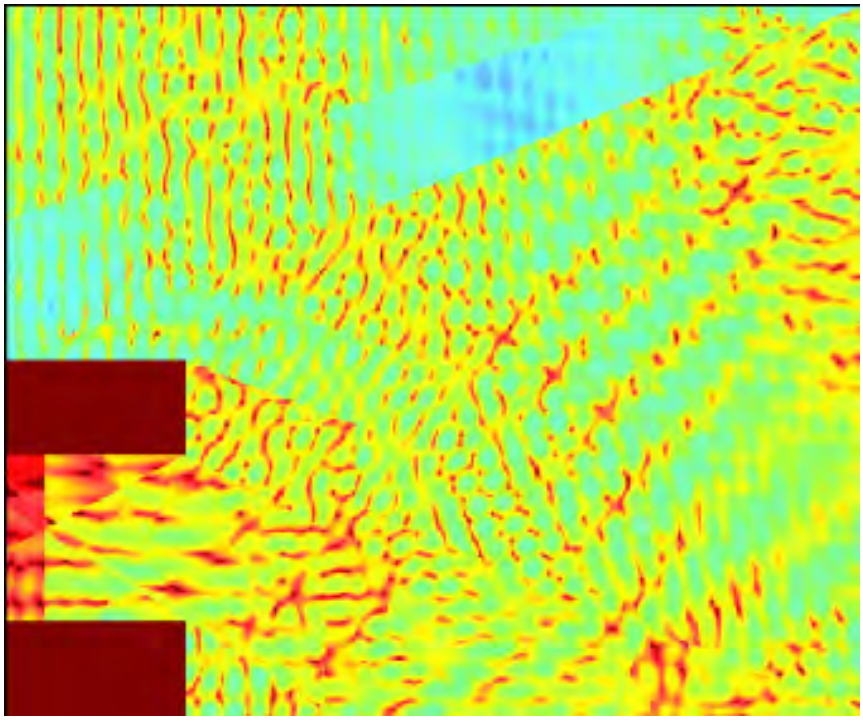

Figure 5-4—A representative signal intensity map

While the architecture diagrams show sharp boundaries for BSSs, this is an artifact of the pictorial representation, not a physical reality. Because dynamic three-dimensional field strength pictures are difficult to draw, well-defined shapes are used by IEEE 802.11 architectural diagrams to represent the coverage of a BSS.

Further description difficulties arise when attempting to describe collocated coverage areas. Consider Figure 5-5, in which STA 6 could belong to BSS 2 or BSS 3.

While the concept of sets of STAs is correct, it is often convenient to talk about areas. For many topics the concept of area is sufficient. *Volume* is a more precise term than area, though still not technically correct. For historical reasons and convenience, this standard uses the common term *area*.

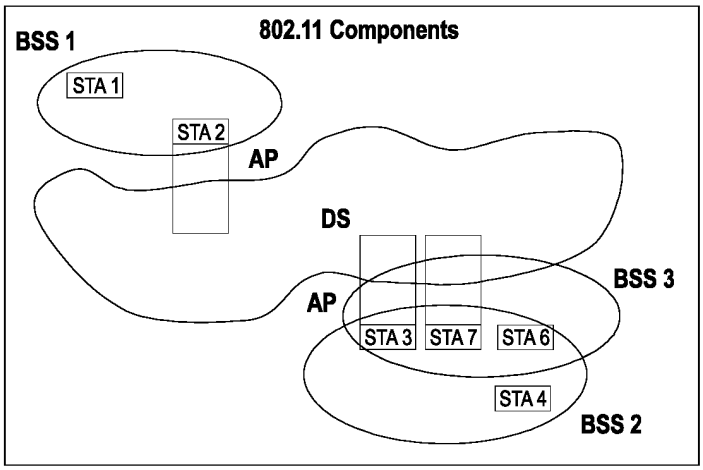

Figure 5-5—Collocated coverage areas

5.2.5 Integration with wired LANs

To integrate the IEEE 802.11 architecture with a traditional wired LAN, a final *logical* architectural component is introduced—a *portal*.

A portal is the logical point at which MSDUs from an integrated non-IEEE-802.11 LAN enter the IEEE 802.11 DS. For example, a portal is shown in Figure 5-6 connecting to a wired IEEE 802 LAN.

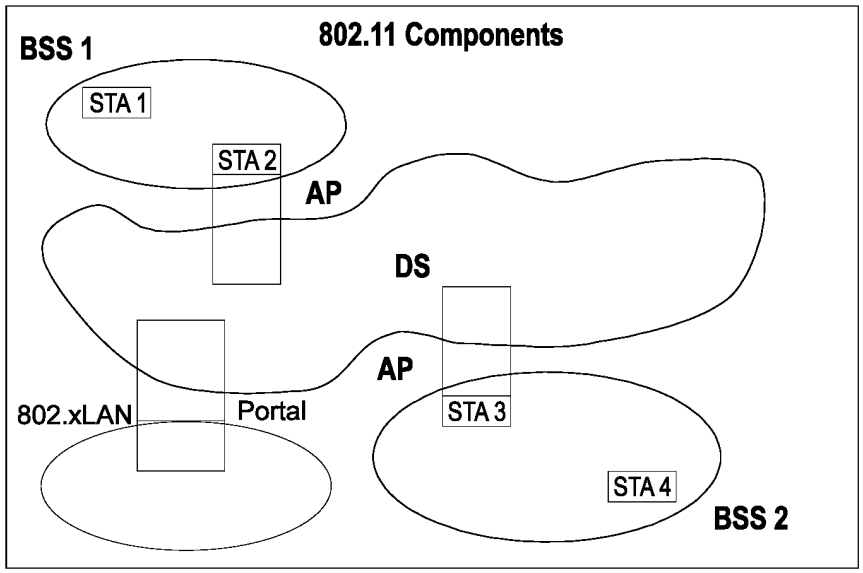

Figure 5-6—Connecting to other IEEE 802 LANs

All data from non-IEEE-802.11 LANs enter the IEEE 802.11 architecture via a portal. The portal is the logical point at which the integration service is provided. The integration service is responsible for any addressing or frame format changes that might be required when frames pass between the DS and the integrated LAN. It is possible for one device to offer both the functions of an AP and a portal.

Page 001252

5.2.6 QoS BSS: The QoS network

The IEEE 802.11 QoS facility provides MAC enhancements to support LAN applications with QoS requirements. The QoS enhancements are available to QoS STAs associated with a QoS access point in a QoS BSS. A subset of the QoS enhancements is available for use between STAs that are members of the same QoS IBSS. Because a QoS STA implements a superset of STA functionality, as defined in this standard, the STA may associate with a non-QoS access point in a non-QoS BSS, to provide non-QoS MAC data service when there is no QoS BSS with which to associate.

The enhancements that distinguish QoS STAs from non-QoS STAs and QoS APs from non-QoS APs are collectively termed the *QoS facility*. The quantity of certain, QoS-specific, mechanisms may vary among QoS implementations, as well as between QoS STAs and QoS APs, over ranges specified in subsequent clauses. All service primitives, frame formats, coordination function and frame exchange rules, and management interface functions except for the Block Acknowledgment (Block Ack) function, direct-link setup (DLS), and automatic power-save delivery (APSD) are part of the core QoS facilities. A QoS STA or QoS AP must implement those core QoS facilities necessary for its QoS functions to interoperate with other STAs in the BSS. Functions such as the Block Ack, DLS, and APSD are separate from the core QoS facilities; and the presence of these functions is indicated by STAs separately from the core QoS facilities. A comprehensive statement on mandatory and optional functionalities is available in Annex A.

This standard provides two mechanisms for the support of applications with QoS requirements.

The first mechanism, designated the *enhanced distributed channel access* (EDCA), delivers traffic based on differentiating user priorities (UPs). This differentiation is achieved by varying the following for different UP values:

— Amount of time a STA senses the channel to be idle before backoff or transmission, or

— The length of the contention window to be used for the backoff, or

— The duration a STA may transmit after it acquires the channel.

These transmissions may also be subject to certain channel access restrictions in the form of admission control. Details of this mechanism are provided in 9.9.1.

The second mechanism, designated the *hybrid coordination function* (HCF) *controlled channel access* (HCCA), allows for the reservation of transmission opportunities (TXOPs) with the hybrid coordinator (HC). A non-access point (non-AP) STA based on its requirements requests the HC for TXOPs, both for its own transmissions as well as for transmissions from the AP to itself.[13] The request is initiated by the station management entity (SME) of the non-AP STA. The HC, which is collocated at the AP, either accepts or rejects the request based on an admission control policy. If the request is accepted, the HC schedules TXOPs for both the AP and the non-AP STA. For transmissions from the non-AP STA, the HC polls the non-AP STA based on the parameters supplied by the non-AP STA at the time of its request. For transmissions to the non-AP STA, the AP directly obtains TXOPs from the collocated HC and delivers the queued frames to the non-AP STA, again based on the parameters supplied by the non-AP STA. Details of the mechanism are provided in 9.9.2 and 11.4. This mechanism may be used for applications such as voice and video, which may need periodic service from the HC. If the application constraints dictate the use of this mechanism, the application initiates this mechanism by using the management service primitives.

Non-QoS STAs may associate in a QoS BSS, if allowed to associate by the AP. All directed frames that are sent to non-QoS STAs by an AP shall not use the frame formats associated with the QoS facility.

A QoS STA associated in a non-QoS BSS shall act as a non-QoS STA.

[13] In the case of downlink traffic streams (TSs).

5.3 Logical service interfaces

A DS may be created from many different technologies including current IEEE 802 wired LANs. IEEE Std 802.11 does not constrain the DS to be either data link or network layer based. Nor does IEEE Std 802.11 constrain a DS to be either centralized or distributed in nature.

IEEE Std 802.11 explicitly does not specify the details of DS implementations. Instead, IEEE Std 802.11 specifies *services*. The services are associated with different components of the architecture. There are two categories of IEEE 802.11 service—the station service (SS) and the distribution system service (DSS). Both categories of service are used by the IEEE 802.11 MAC sublayer.

The complete set of IEEE 802.11 architectural services are as follows:

a) Authentication
b) Association
c) Deauthentication
d) Disassociation
e) Distribution
f) Integration
g) Data confidentiality
h) Reassociation
i) MSDU delivery
j) DFS
k) TPC
l) Higher layer timer synchronization (QoS facility only)
m) QoS traffic scheduling (QoS facility only)

This set of services is divided into two groups: the SS and the DSS. The SS are part of every STA. The DSS are provided by the DS.

5.3.1 SS

The service provided by STAs is known as the SS.

The SS is present in every IEEE 802.11 STA (including APs, as APs include STA functionality). The SS is specified for use by MAC sublayer entities. All conformant STAs provide SS.

The SS is as follows:

a) Authentication
b) Deauthentication
c) Data confidentiality
d) MSDU delivery
e) DFS
f) TPC
g) Higher layer timer synchronization (QoS facility only)
h) QoS traffic scheduling (QoS facility only)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001254

5.3.2 DSS

The service provided by the DS is known as the DSS.

This service is represented in the IEEE 802.11 architecture by arrows within the APs, indicating that the service is used to cross media and possibly address space logical boundaries. An AP is a logical entity, and the functions described may be shared by one or more physical entities.

The services that comprise the DSS are as follows:

a) Association
b) Disassociation
c) Distribution
d) Integration
e) Reassociation
f) QoS traffic scheduling (QoS facility only)

DSSs are specified for use by MAC sublayer entities.

Figure 5-7 combines the components from previous figures with both types of services to show the complete IEEE 802.11 architecture.

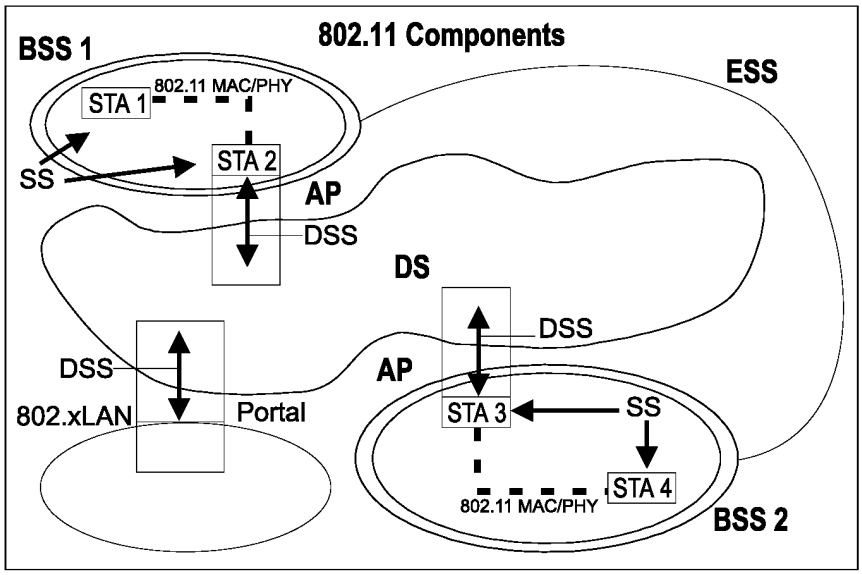

Figure 5-7—Complete IEEE 802.11 architecture

5.4 Overview of the services

There are many services specified by IEEE Std 802.11. Six of the services are used to support medium access control (MAC) service data unit (MSDU) delivery between STAs. Three of the services are used to control IEEE 802.11 LAN access and confidentiality. Two of the services are used to provide spectrum management. One of the services provides support for LAN applications with QoS requirements. Another of the services provides support for higher layer timer synchronization.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001255

This subclause presents the services, an overview of how each service is used, and a description of how each service relates to other services and the IEEE 802.11 architecture. The services are presented in an order designed to help build an understanding of the operation of an IEEE 802.11 ESS network. As a result, the services that comprise the SS and DSS are intermixed in order (rather than being grouped by category).

Each of the services is supported by one or more MAC frame types. Some of the services are supported by MAC management messages and some by MAC data messages. All of the messages gain access to the WM via the IEEE 802.11 MAC sublayer medium access method specified in Clause 9.

The IEEE 802.11 MAC sublayer uses three types of messages—*data*, *management*, and *control* (see Clause 7). The data messages are handled via the MAC data service path.

MAC management messages are used to support the IEEE 802.11 services and are handled via the MAC management service path.

MAC control messages are used to support the delivery of IEEE 802.11 data and management messages.

The examples here assume an ESS network environment. The differences between the ESS and the IBSS network environments are discussed separately in 5.6.

5.4.1 Distribution of messages within a DS

5.4.1.1 Distribution

This is the primary service used by IEEE 802.11 STAs. It is conceptually invoked by every data message to or from an IEEE 802.11 STA operating in an ESS (when the frame is sent via the DS). Distribution is via the DSS.

Refer to the ESS network in Figure 5-7 and consider a data message being sent from STA 1 to STA 4. The message is sent from STA 1 and received by STA 2 (the “input” AP). The AP gives the message to the distribution service of the DS. It is the job of the distribution service to deliver the message within the DS in such a way that it arrives at the appropriate DS destination for the intended recipient. In this example, the message is distributed to STA 3 (the “output” AP) and STA 3 accesses the WM to send the message to STA 4 (the intended destination).

How the message is distributed within the DS is not specified by IEEE Std 802.11. All IEEE Std 802.11 is required to do is to provide the DS with enough information for the DS to be able to determine the “output” point that corresponds to the desired recipient. The necessary information is provided to the DS by the three association related services (association, reassociation, and disassociation).

The previous example was a case in which the AP that invoked the distribution service was different from the AP that received the distributed message. If the message had been intended for a STA that was a member of the same BSS as the sending STA, then the “input” and “output” APs for the message would have been the same.

In either example, the distribution service was logically invoked. Whether the message actually had to traverse the physical DSM or not is a DS implementation matter and is not specified by this standard.

While IEEE Std 802.11 does not specify DS implementations, it does recognize and support the use of the WM as the DSM. This is specifically supported by the IEEE 802.11 frame formats. (Refer to Clause 7 for details.)

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001256

5.4.1.2 Integration

If the distribution service determines that the intended recipient of a message is a member of an integrated LAN, the "output" point of the DS would be a portal instead of an AP.

Messages that are distributed to a portal cause the DS to invoke the Integration function (conceptually after the distribution service). The Integration function is responsible for accomplishing whatever is needed to deliver a message from the DSM to the integrated LAN media (including any required media or address space translations). Integration is one of the services in the DSS.

Messages received from an integrated LAN (via a portal) by the DS for an IEEE 802.11 STA shall invoke the Integration function before the message is distributed by the distribution service.

The details of an Integration function are dependent on a specific DS implementation and are outside the scope of this standard.

5.4.1.3 QoS traffic scheduling

QoS traffic scheduling provides intra-BSS QoS frame transfers under the HCF, using either contention-based or controlled channel access. At each TXOP, a traffic scheduling entity at the STA selects a frame for transmission, from the set of frames at the heads of a plurality of traffic queues, based on requested UP and/or parameter values in the traffic specification (TSPEC) for the requested MSDU. Additional information is available in 9.9.

5.4.2 Services that support the distribution service

The primary purpose of a MAC sublayer is to transfer MSDUs between MAC sublayer entities. The information required for the distribution service to operate is provided by the association services. Before a data message can be handled by the distribution service, a STA shall be "associated."

To understand the concept of association, it is necessary first to understand the concept of mobility.

5.4.2.1 Mobility types

The three transition types of significance to this standard that describe the mobility of STAs within a network are as follows:

a) ***No-transition:*** In this type, two subclasses that are usually indistinguishable are identified:

   1) Static—no motion.

   2) Local movement—movement within the PHY range of the communicating STAs [i.e., movement within a basic service area (BSA)].

b) ***BSS-transition:*** This type is defined as a STA movement from one BSS in one ESS to another BSS within the same ESS.

c) ***ESS-transition:*** This type is defined as STA movement from a BSS in one ESS to a BSS in a different ESS. This case is supported only in the sense that the STA may move. Maintenance of upper-layer connections cannot be guaranteed by IEEE Std 802.11; in fact, disruption of service is likely to occur.

The different association services support the different categories of mobility.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001257

5.4.2.2 Association

To deliver a message within a DS, the distribution service needs to know which AP to access for the given IEEE 802.11 STA. This information is provided to the DS by the concept of association. Association is necessary, but not sufficient, to support BSS-transition mobility. Association is sufficient to support no-transition mobility. Association is one of the services in the DSS.

Before a STA is allowed to send a data message via an AP, it shall first become associated with the AP. The act of becoming associated invokes the association service, which provides the STA to AP mapping to the DS. The DS uses this information to accomplish its message distribution service. How the information provided by the association service is stored and managed within the DS is not specified by this standard.

Within a robust security network (RSN), association is handled differently. In an RSNA, the IEEE 802.1X Port determines when to allow data traffic across an IEEE 802.11 link. A single IEEE 802.1X Port maps to one association, and each association maps to an IEEE 802.1X Port. An IEEE 802.1X Port consists of an IEEE 802.1X Controlled Port and an IEEE 802.1X Uncontrolled Port. The IEEE 802.1X Controlled Port is blocked from passing general data traffic between two STAs until an IEEE 802.1X authentication procedure completes successfully over the IEEE 802.1X Uncontrolled Port. Once the AKM completes successfully, data protection is enabled to prevent unauthorized access, and the IEEE 802.1X Controlled Port unblocks to allow protected data traffic. IEEE 802.1X Supplicants and Authenticators exchange protocol information via the IEEE 802.1X Uncontrolled Port. It is expected that most other protocol exchanges will make use of the IEEE 802.1X Controlled Ports. However, a given protocol may need to bypass the authorization function and make use of the IEEE 802.1X Uncontrolled Port.

NOTE—See IEEE Std 802.1X-2004 for a discussion of Controlled Port and Uncontrolled Port.

At any given instant, a STA may be associated with no more than one AP. This ensures that the DS may determine a unique answer to the question, “Which AP is serving STA X?” Once an association is completed, a STA may make full use of a DS (via the AP) to communicate. Association is always initiated by the mobile STA, not the AP.

An AP may be associated with many STAs at one time.

A STA learns what APs are present and what operational capabilities are available from each of those APs and then invokes the association service to establish an association. For details of how a STA learns about what APs are present, see 11.1.3.

5.4.2.3 Reassociation

Association is sufficient for no-transition message delivery between IEEE 802.11 STAs. Additional functionality is needed to support BSS-transition mobility. The additional required functionality is provided by the reassociation service. Reassociation is one of the services in the DSS.

The reassociation service is invoked to “move” a current association from one AP to another. This keeps the DS informed of the current mapping between AP and STA as the STA moves from BSS to BSS within an ESS. Reassociation also enables changing association attributes of an established association while the STA remains associated with the same AP. Reassociation is always initiated by the mobile STA.

No facilities are provided to move an RSNA during reassociation. Therefore, the old RSNA will be deleted, and a new RSNA will need to be constructed.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001258

5.4.2.4 Disassociation

The disassociation service is invoked when an existing association is to be terminated. Disassociation is one of the services in the DSS.

In an ESS, this tells the DS to void existing association information. Attempts to send messages via the DS to a disassociated STA will be unsuccessful.

The disassociation service may be invoked by either party to an association (non-AP STA or AP). Disassociation is a notification, not a request. Disassociation cannot be refused by either party to the association.

APs may need to disassociate STAs to enable the AP to be removed from a network for service or for other reasons.

STAs shall attempt to disassociate when they leave a network. However, the MAC protocol does not depend on STAs invoking the disassociation service. (MAC management is designed to accommodate loss of communication with an associated STA.)

5.4.3 Access control and data confidentiality services

Two services are required for IEEE Std 802.11 to provide functionality equivalent to that which is inherent to wired LANs. The design of wired LANs assumes the physical attributes of wire. In particular, wired LAN design assumes the physically closed and controlled nature of wired media. The physically open medium nature of an IEEE 802.11 LAN violates those assumptions.

Two services are provided to bring the IEEE 802.11 functionality in line with wired LAN assumptions: authentication and data confidentiality. Authentication is used instead of the wired media physical connection. Data confidentiality is used to provide the confidential aspects of closed wired media.

In a WLAN that does not support RSNA, two services, authentication and data confidentiality, are defined. IEEE 802.11 authentication is used instead of the wired media physical connection. WEP encryption was defined to provide the data confidentiality aspects of closed wired media.

An RSNA uses the IEEE 802.1X authentication service along with TKIP and CCMP to provide access control. The IEEE 802.11 station management entity (SME) provides key management via an exchange of IEEE 802.1X EAPOL-Key frames. Data confidentiality and data integrity are provided by RSN key management together with the TKIP and CCMP.

5.4.3.1 Authentication

IEEE 802.11 authentication operates at the link level between IEEE 802.11 STAs. IEEE Std 802.11 does not provide either end-to-end (message origin to message destination) or user-to-user authentication.

IEEE Std 802.11 attempts to control LAN access via the authentication service. IEEE 802.11 authentication is an SS. This service may be used by all STAs to establish their identity to STAs with which they communicate, in both ESS and IBSS networks. If a mutually acceptable level of authentication has not been established between two STAs, an association shall not be established.

IEEE Std 802.11 defines two authentication methods: Open System authentication and Shared Key authentication. Open System authentication admits any STA to the DS. Shared Key authentication relies on WEP to demonstrate knowledge of a WEP encryption key. The IEEE 802.11 authentication mechanism also allows definition of new authentication methods.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001259

An RSNA also supports authentication based on IEEE Std 802.1X-2004, or preshared keys (PSKs). IEEE 802.1X authentication utilizes the EAP to authenticate STAs and the AS with one another. This standard does not specify an EAP method that is mandatory to implement. See 8.4.4 for a description of the IEEE 802.1X authentication and PSK usage within an IEEE 802.11 IBSS.

In an RSNA, IEEE 802.1X Supplicants and Authenticators exchange protocol information via the IEEE 802.1X Uncontrolled Port. The IEEE 802.1X Controlled Port is blocked from passing general data traffic between two STAs until an IEEE 802.1X authentication procedure completes successfully over the IEEE 802.1X Uncontrolled Port.

The Open System authentication algorithm is used in RSNs based on infrastructure BSS and IBSS, although Open System authentication is optional in an RSN based on an IBSS. RSNA disallows the use of Shared Key authentication.

Management information base (MIB) functions are provided in Annex D to support the standardized authentication schemes.

A STA may be authenticated with many other STAs at any given instant.

5.4.3.1.1 Preauthentication

Because the authentication process could be time-consuming (depending on the authentication protocol in use), the authentication service can be invoked independently of the association service.

Preauthentication is typically done by a STA while it is already associated with an AP (with which it previously authenticated). IEEE Std 802.11 does not require that STAs preauthenticate with APs. However, authentication is required before an association can be established.

If the authentication is left until reassociation time, this may impact the speed with which a STA can reassociate between APs, limiting BSS-transition mobility performance. The use of preauthentication takes the authentication service overhead out of the time-critical reassociation process.

5.4.3.2 Deauthentication

The deauthentication service is invoked when an existing Open System or Shared Key authentication is to be terminated. Deauthentication is an SS.

In an ESS, because authentication is a prerequisite for association, the act of deauthentication shall cause the STA to be disassociated. The deauthentication service may be invoked by either authenticated party (non-AP STA or AP). Deauthentication is not a request; it is a notification. Deauthentication shall not be refused by either party. When an AP sends a deauthentication notice to an associated STA, the association shall also be terminated.

In an RSN ESS, Open System authentication is required. In an RSN ESS, deauthentication results in termination of any association for the deauthenticated STA. It also results in the IEEE 802.1X Controlled Port for that STA being disabled and deletes the pairwise transient key security association (PTKSA). The deauthentication notification is provided to IEEE Std 802.1X-2004 via the MAC layer.

In an RSNA, deauthentication also destroys any related PTKSA, group temporal key security association (GTKSA), station-to-station link (STSL) master key security association (SMKSA), and STSL transient key security association (STKSA) that exist in the STA and closes the associated IEEE 802.1X Controlled Port. If pairwise master key (PMK) caching is not enabled, deauthentication also destroys the pairwise master key security association (PMKSA) from which the deleted PTKSA was derived.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001260

In an RSN IBSS, Open System authentication is optional, but a STA is required to recognize Deauthentication frames. Deauthentication results in the IEEE 802.1X Controlled Port for that STA being disabled and deletes the PTKSA.

5.4.3.3 Data confidentiality

In a wired LAN, only those STAs physically connected to the wire can send or receive LAN traffic. With a wireless shared medium, there is no physical connection, and all STAs and certain other RF devices in or near the LAN may be able to send, receive, and/or interfere with the LAN traffic. Any IEEE 802.11-compliant STA can receive all like-PHY IEEE 802.11 traffic that is within range and can transmit to any other IEEE 802.11 STA within range. Thus, the connection of a single wireless link (without data confidentiality) to an existing wired LAN may seriously degrade the security level of the wired LAN.

To bring the security of the WLAN up to the level implicit in wired LAN design, IEEE Std 802.11 provides the ability to protect the contents of messages. This functionality is provided by the data confidentiality service. Data confidentiality is an SS.

IEEE Std 802.11 provides three cryptographic algorithms to protect data traffic: WEP, TKIP, and CCMP. WEP and TKIP are based on the ARC4[14] algorithm, and CCMP is based on the advanced encryption standard (AES). A means is provided for STAs to select the algorithm(s) to be used for a given association.

The default data confidentiality state for all IEEE 802.11 STAs is “in the clear.” If the data confidentiality service is not invoked, all messages shall be sent unprotected. If this policy is unacceptable to the sender, it shall not send data frames; and if the policy is unacceptable to the receiver, it shall discard any received data frames. Unprotected data frames received at a STA configured for mandatory data confidentiality, as well as protected data frames using a key not available at the receiving STA, are discarded without an indication to LLC (or without indication to distribution services in the case of “To DS” frames received at an AP). These frames are acknowledged on the WM [if received without frame check sequence (FCS) error] to avoid wasting WM bandwidth on retries of frames that are being discarded.

5.4.3.4 Key management

The enhanced data confidentiality, data authentication, and replay protection mechanisms require fresh cryptographic keys. The procedures defined in this standard provide fresh keys by means of protocols called the 4-Way Handshake and Group Key Handshake.

5.4.3.5 Data origin authenticity

The data origin authenticity mechanism defines a means by which a STA that receives a data frame can determine which STA transmitted the MAC protocol data unit (MPDU). This feature is required in an RSNA to prevent one STA from masquerading as a different STA. This mechanism is provided for STAs that use CCMP or TKIP.

Data origin authenticity is only applicable to unicast data frames. The protocols do not guarantee data origin authenticity for broadcast/multicast data frames, as this cannot be accomplished using symmetric keys and public key methods are too computationally expensive.

[14]Details of the ARC4 algorithm are available from RSA Security, Inc. Contact RSA RSA Security, 174 Middlesex Turnpike, Bedford, MA 01730 (http://www.rsasecurity.com/), for algorithm details and the uniform ARC4 license terms that RSA offers to anyone wishing to use ARC4 for the purpose of implementing the IEEE 802.11 WEP option. If necessary, contact the IEEE Standards Department Intellectual Property Rights Administrator for details on how to communicate with RSA.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001261

5.4.3.6 Replay detection

The replay detection mechanism defines a means by which a STA that receives a data frame from another STA can detect whether the data frame is an unauthorized retransmission. This mechanism is provided for STAs that use CCMP or TKIP.

5.4.4 Spectrum management services

Two services are required to satisfy requirements in some regulatory domains for operation in the 5 GHz band. These services are called transmit power control (TPC) and dynamic frequency selection (DFS).

5.4.4.1 TPC

Radio regulations may require radio local area networks (RLANs) operating in the 5 GHz band to use transmitter power control, involving specification of a regulatory maximum transmit power and a mitigation requirement for each allowed channel, to reduce interference with satellite services. The TPC service is used to satisfy this regulatory requirement.

The TPC service provides for the following:

— Association of STAs with an AP in a BSS based on the STAs' power capability.

— Specification of regulatory and local maximum transmit power levels for the current channel.

— Selection of a transmit power for each transmission in a channel within constraints imposed by regulatory requirements.

— Adaptation of transmit power based on a range of information, including path loss and link margin estimates.

5.4.4.2 DFS

Radio regulations may require RLANs operating in the 5 GHz band to implement a mechanism to avoid co-channel operation with radar systems and to ensure uniform utilization of available channels. The DFS service is used to satisfy these regulatory requirements.

The DFS service provides for the following:

— Association of STAs with an AP in a BSS based on the STAs' supported channels.

— Quieting the current channel so it can be tested for the presence of radar with less interference from other STAs.

— Testing channels for radar before using a channel and while operating in a channel.

— Discontinuing operations after detecting radar in the current channel to avoid interference with radar.

— Detecting radar in the current and other channels based on regulatory requirements.

— Requesting and reporting of measurements in the current and other channels.

— Selecting and advertising a new channel to assist the migration of a BSS or IBSS after radar is detected.

5.4.5 Traffic differentiation and QoS support

IEEE Std 802.11 uses a shared medium and provides differentiated control of access to the medium to handle data transfers with QoS requirements. The QoS facility (per MSDU traffic class and TSPEC negotiation) allows an IEEE 802.11 LAN to become part of a larger network providing end-to-end QoS delivery or to function as an independent network providing transport on a per-link basis with specified QoS commitments. The specifications regarding the integration and operability of the QoS facility in

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001262

IEEE 802.11 specification with any other end-to-end QoS delivery mechanism like Resource Reservation Protocol (RSVP) are beyond the scope of this standard.

5.4.6 Support for higher layer timer synchronization

Some applications, e.g., the transport and rendering of audio or video streams, require synchronized timers shared among different STAs. Greater accuracy (in terms of jitter bounds) or finer timer granularity than that provided by a BSS timing synchronization function (TSF) may be an additional requirement. In support of such applications, this standard defines a MAC service that enables layers above the MAC to accurately synchronize application-dependent timers shared among STAs. The service is usable by more than one application at a time.

Although the timer synchronization methods and accuracy requirements are application-dependent and are beyond the scope of this standard, they rely on an indication from each STA's MAC that is provided essentially simultaneously, via multicast, to the STAs. The MAC accomplishes this by indicating the occurrence of the end of the last symbol of particular data frames; the data frames of interest are identified by their MAC header Address 1 field when it contains a group address previously registered with the MAC. The last symbol is observed[15] on the air by STAs within a BSS while the delay between the observation and the delivery of the indication is known within a MAC by design (and communicated to the application by implementation-dependent means). The common reference point in time provided by the end of last symbol indication is the essential building block upon which a variety of application-dependent timer synchronization methods may be based.

5.5 Multiple logical address spaces

Just as the IEEE 802.11 architecture allows for the possibility that the WM, DSM, and an integrated wired LAN may all be different physical media, it also allows for the possibility that each of these components may be operating within different address spaces. IEEE Std 802.11 only uses and specifies the use of the WM address space.

Each IEEE 802.11 PHY operates in a single medium—the WM. The IEEE 802.11 MAC operates in a single address space. MAC addresses are used on the WM in the IEEE 802.11 architecture. Therefore, it is unnecessary for the standard to explicitly specify that its addresses are "WM addresses." This is assumed throughout this standard.

IEEE Std 802.11 has chosen to use the IEEE 802 48-bit address space (see 7.1.3.3.1). Thus IEEE 802.11 addresses are compatible with the address space used by the IEEE 802 LAN family.

The IEEE 802.11 choice of address space implies that for many instantiations of the IEEE 802.11 architecture, the wired LAN MAC address space and the IEEE 802.11 MAC address space may be the same. In those situations where a DS that uses MAC level IEEE 802 addressing is appropriate, all three of the logical address spaces used within a system could be identical. While this is a common case, it is not the only combination allowed by the architecture. The IEEE 802.11 architecture allows for all three logical address spaces to be distinct.

A multiple address space example is one in which the DS implementation uses network layer addressing. In this case, the WM address space and the DS address space would be different.

Note that IEEE 802.11 STAs within a single ESS share the same address space, fulfilling the transparency requirement from the definition of the DS. The DSS uses this same address space, even in the case where the DSM uses a different address space.

[15]The synchronization indication (observed time) within the BSS will vary slightly due to propagation.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001263

The ability of the architecture to handle multiple logical media and address spaces is key to the ability of IEEE Std 802.11 to be independent of the DS implementation and to interface cleanly with network layer mobility approaches. The implementation of the DS is unspecified and is beyond the scope of this standard.

5.6 Differences between ESS and IBSS LANs

In 5.2.1 the concept of the IBSS LAN was introduced. It was noted that an IBSS is often used to support an ad hoc network. In an IBSS network, a STA communicates directly with one or more other STAs.

Consider the full IEEE 802.11 architecture as shown in Figure 5-8.

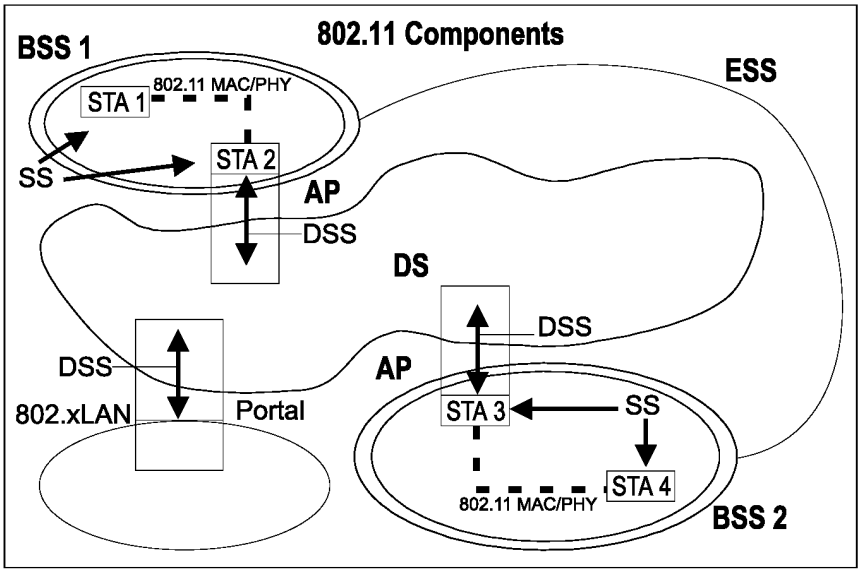

Figure 5-8—IEEE 802.11 architecture (again)

An IBSS consists of STAs that are directly connected. Thus there is (by definition) only one BSS. Further, because there is no physical DS, there cannot be a portal, an integrated wired LAN, or the DSS. The logical picture reduces to Figure 5-9.

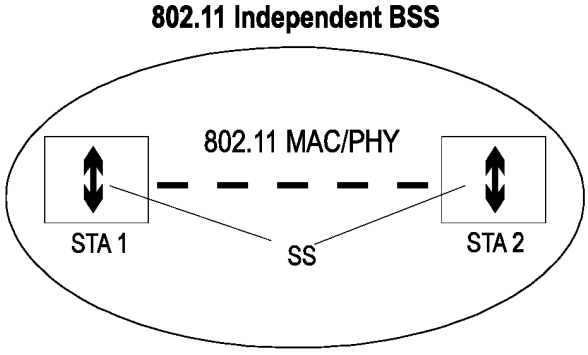

Figure 5-9—Logical architecture of an IBSS

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001264

Only the minimum two STAs are shown in Figure 5-9. An IBSS may have an arbitrary number of members. In an IBSS, only Class 1 and Class 2 frames are allowed because there is no DS in an IBSS.

The services that apply to an IBSS are the SSs. A QoS IBSS supports operation under the HCF using TXOPs gained through the EDCA mechanism. The parameters that control differentiation of traffic classes using EDCA are fixed. A QoS IBSS has no HC and does not support polled TXOP operation and setting up of TSPEC.

In an IBSS, each STA must enforce its own security policy. In an ESS, an AP can enforce a uniform security policy across all STAs.

5.7 Reference model

This standard presents the architectural view, emphasizing the separation of the system into two major parts: the MAC of the data link layer (DLL) and the PHY. These layers are intended to correspond closely to the lowest layers of the ISO/IEC basic reference model of Open Systems Interconnection (OSI) (ISO/IEC 7498-1: 1994). The layers and sublayers described in this standard are shown in Figure 5-10.

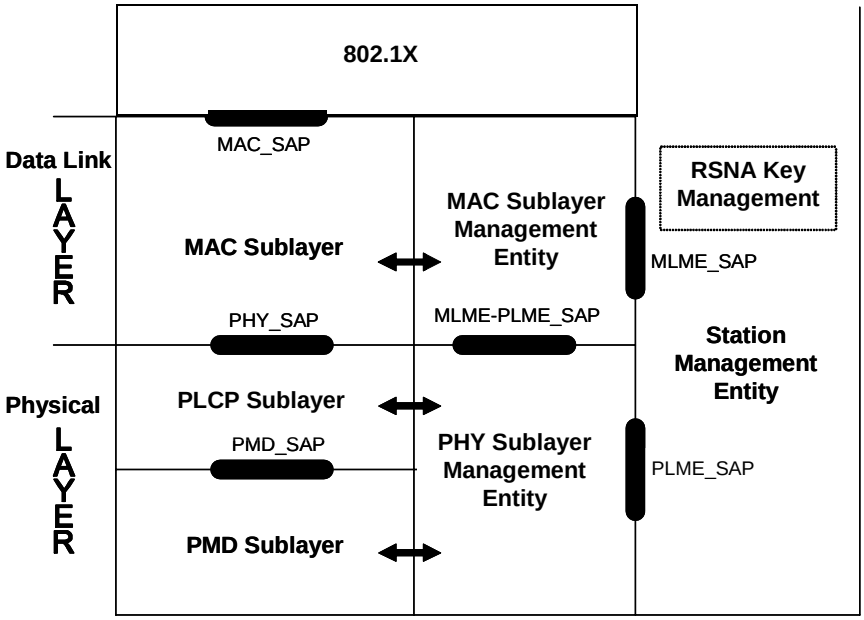

Figure 5-10—Portion of the ISO/IEC basic reference model covered in this standard

There is an interface between the IEEE 802.1X Supplicant/Authenticator and the SME not shown in Figure 5-10. This interface is described in IEEE Std 802.1X-2004.

5.8 IEEE Std 802.11 and IEEE Std 802.1X-2004

An RSNA relies on IEEE Std 802.1X-2004 to provide authentication services and uses the IEEE 802.11 key management scheme defined in 8.5. The IEEE 802.1X access control mechanisms apply to the association between a STA and an AP and to the relationship between the IBSS STA and STA peer. The AP's SME performs the Authenticator and, optionally, the Supplicant and AS roles. In an ESS, a non-AP STA's SME

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001265

performs the Supplicant role. In an IBSS, a STA's SME takes on both the Supplicant and Authenticator roles and may take on the AS role.

5.8.1 IEEE 802.11 usage of IEEE Std 802.1X-2004

IEEE Std 802.11 depends upon IEEE Std 802.1X-2004 to control the flow of MAC service data units (MSDUs) between the DS and STAs by use of the IEEE 802.1X Controlled/Uncontrolled Port model. IEEE 802.1X authentication frames are transmitted in IEEE 802.11 data frames and passed via the IEEE 802.1X Uncontrolled Port. The IEEE 802.1X Controlled Port is blocked from passing general data traffic between two STAs until an IEEE 802.1X authentication procedure completes successfully over the IEEE 802.1X Uncontrolled Port. It is the responsibility of both the Supplicant and the Authenticator to implement port blocking. Each association between a pair of STAs creates a unique pair of IEEE 802.1X Ports, and authentication takes place relative to those ports alone.

IEEE Std 802.11 depends upon IEEE Std 802.1X-2004 and the 4-Way Handshake and Group Key Handshake, described in Clause 8, to establish and change cryptographic keys. Keys are established after authentication has completed. Keys may change for a variety of reasons, including expiration of an IEEE 802.1X authentication timer, key compromise, danger of compromise, or policy.

5.8.2 Infrastructure functional model overview

This subclause summarizes the system setup and operation of an RSN, in two cases: when an IEEE 802.1X AS is used and when a PSK is used. For an ESS, the AP includes an Authenticator, and each associated STA includes a Supplicant.

5.8.2.1 AKM operations with AS

The following AKM operations are carried out when an IEEE 802.1X AS is used:

a) Prior to any use of IEEE Std 802.1X-2004, IEEE Std 802.11 assumes that the Authenticator and AS have established a secure channel. The security of the channel between the Authenticator and the AS is outside the scope of this standard.

   Authentication credentials must be distributed to the Supplicant and AS prior to association.

b) A STA discovers the AP's security policy through passively monitoring Beacon frames or through active probing (shown in Figure 5-11). If IEEE 802.1X authentication is used, the EAP authentication process starts when the AP's Authenticator sends the EAP-Request (shown in Figure 5-12) or the STA's Supplicant sends the EAPOL-Start message. EAP authentication frames pass between the Supplicant and AS via the Authenticator and Supplicant's Uncontrolled Ports. This is shown in Figure 5-12.

c) The Supplicant and AS authenticate each other and generate a PMK. The PMK is sent from the AS to the Authenticator over the secure channel. See Figure 5-12.

A 4-Way Handshake utilizing EAPOL-Key frames is initiated by the Authenticator to do the following:

— Confirm that a live peer holds the PMK.

— Confirm that the PMK is current.

— Derive a fresh pairwise transient key (PTK) from the PMK.

— Install the pairwise encryption and integrity keys into IEEE Std 802.11.

— Transport the group temporal key (GTK) and GTK sequence number from Authenticator to Supplicant and install the GTK and GTK sequence number in the STA and, if not already installed, in the AP.

— Confirm the cipher suite selection.

Exhibit 1014
Page 001266

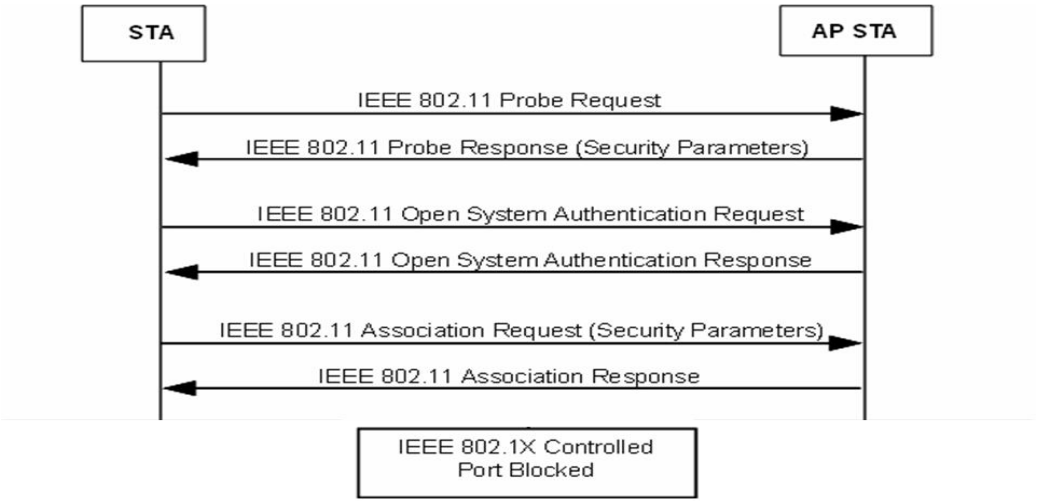

Figure 5-11—Establishing the IEEE 802.11 association

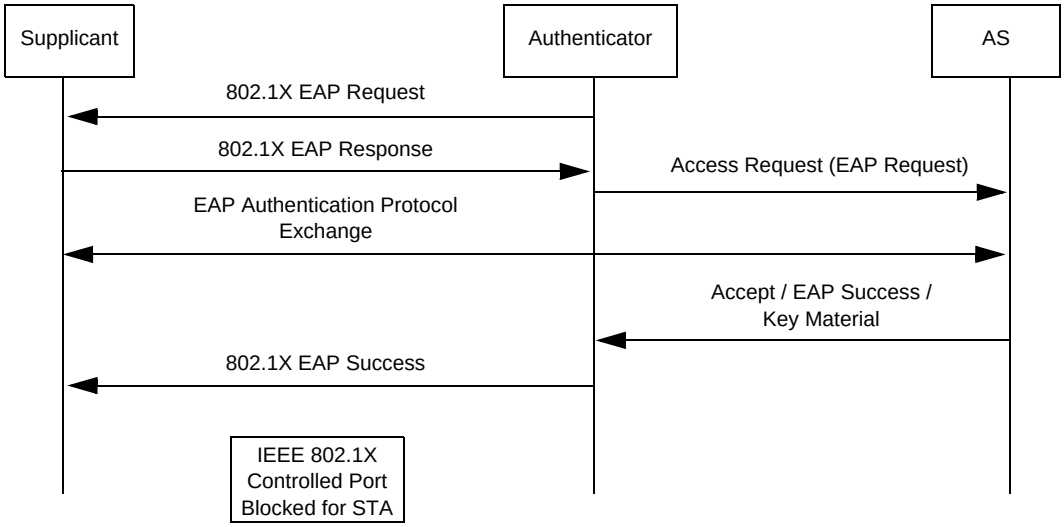

Figure 5-12—IEEE 802.1X EAP authentication

Installing the PTK, and where applicable the GTK keys, causes the MAC to encrypt and decrypt all subsequent MSDUs irrespective of their path through the controlled or uncontrolled ports.

Upon successful completion of the 4-Way Handshake, the Authenticator and Supplicant have authenticated each other; and the IEEE 802.1X Controlled Ports are unblocked to permit general data traffic. See Figure 5-13.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001267

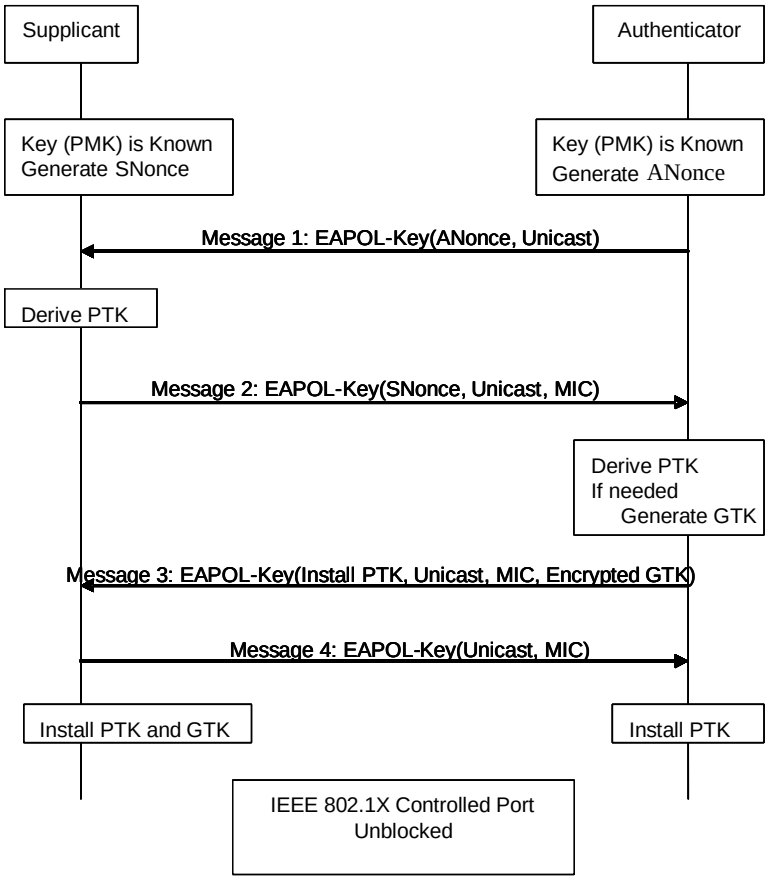

Figure 5-13—Establishing pairwise and group keys

If the Authenticator later changes the GTK, it sends the new GTK and GTK sequence number to the Supplicant using the Group Key Handshake to allow the Supplicant to continue to receive broadcast/ multicast messages and, optionally, to transmit and receive unicast frames. EAPOL-Key frames are used to carry out this exchange. See Figure 5-14.

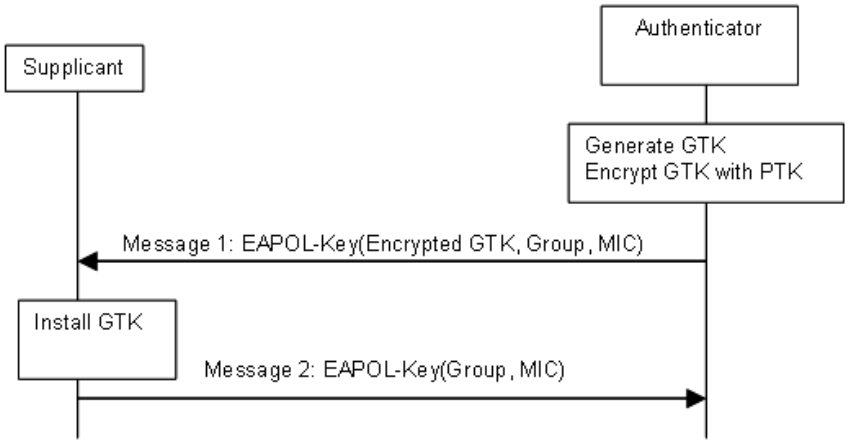

Figure 5-14—Delivery of subsequent group keys

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001268

5.8.2.2 Operations with PSK

The following AKM operations are carried out when the PMK is a PSK:

— A STA discovers the AP's security policy through passively monitoring Beacon frames or through active probing (shown in Figure 5-11). A STA associates with an AP and negotiates a security policy. The PMK is the PSK.

— The 4-Way Handshake using EAPOL-Key frames is used, just as with IEEE 802.1X authentication, when an AS is present. See Figure 5-13.

— The GTK and GTK sequence number are sent from the Authenticator to the Supplicant just as in the AS case. See Figure 5-13 and Figure 5-14.

5.8.2.3 Disassociation

Disassociation initiated by either STA in an RSNA causes the deletion of the PTKSA at both ends and the deletion of the GTKSA in a non-AP STA. The controlled and uncontrolled ports created for this association will also be deleted.

5.8.3 IBSS functional model description

This subclause summarizes the system setup and operation of an RSNA in an IBSS. An IBSS RSNA is specified in 8.4.7.

5.8.3.1 Key usage

In an IBSS, the unicast data frames between two STAs are protected with a pairwise key. The key is part of the PTK, which is derived during a 4-Way Handshake. In an IBSS, the 4-Way Handshak may follow IEEE 802.11 authentication of one STA to another. Such authentication may be used by the peer to cause deletion of the PTKSA and Block the Controlled Port thus reseting any previous handshake.

In an IBSS, the broadcast/multicast data frames are protected by a key, e.g., named B1, that is generated by the STA transmitting the broadcast/multicast frame. To allow other STAs to decrypt broadcast/multicast frames, B1 must be sent to all the other STAs in the IBSS. B1 is sent in an EAPOL-Key frame, encrypted under the EAPOL-Key encryption key (KEK) portion of the PTK, and protected from modification by the EAPOL-Key confirmation key (KCK) portion of the PTK.

In an IBSS, a STA's SME responds to Deauthentication frames from a STA by deleting the PTKSA associated with that STA.

5.8.3.2 Sample IBSS 4-Way Handshakes

In this example (see Figure 5-15), there are three STAs: S1, S2, S3. The broadcast/multicast frames sent by S1 are protected by B1; similarly B2 for S2, and B3 for S3.

For STAs S2 and S3 to decrypt broadcast/multicast frames from S1, B1 must be sent to S2 and S3. This is done using the 4-Way Handshake initially and using the Group Key Handshake for GTK updates.

The 4-Way Handshake from S1 to S2 allows S1 to send broadcast/multicast frames to S2, but does not allow S2 to send broadcast/multicast frames to S1 because S2 has a different transmit GTK. Therefore, S2 needs to initiate a 4-Way Handshake to S1 to allow S1 to decrypt S2's broadcast/multicast frames. Similarly, S2 also needs to initiate a 4-Way Handshake to S3 to enable S3 to receive broadcast/multicast messages from S2.

In a similar manner S3 needs to complete the 4-Way Handshake with S1 and S2 to deliver B3 to S1 and S2.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001269

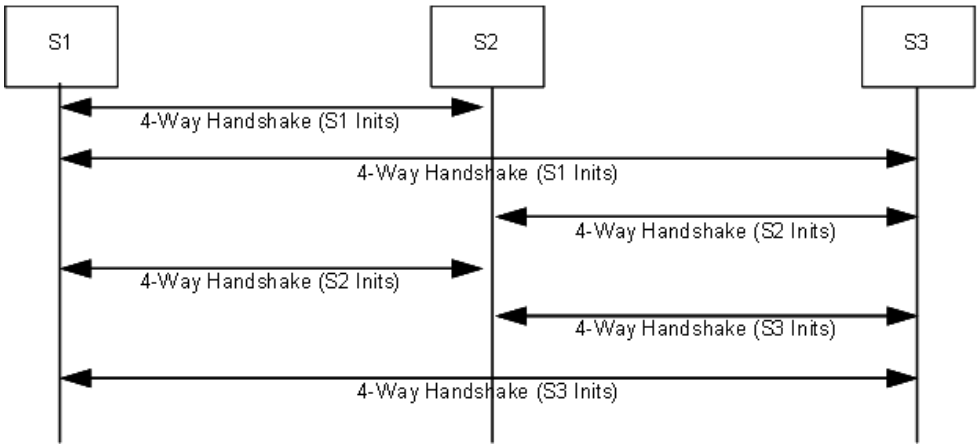

Figure 5-15—Sample 4-Way Handshakes in an IBSS

In this example, there are six 4-Way Handshakes. In general, *N* STA Supplicants require $N(N–1)$ 4-Way Handshakes.

NOTE—In principle the KCK and KEK from a single 4-Way Handshake can be used for the Group Key Handshake in both directions, but using two 4-Way Handshakes means the Authenticator key state machine does not need to be different between IBSS and ESS.

The Group Key Handshake can be used to send the GTKs to the correct STAs. The 4-Way Handshake is used to derive the pairwise key and to send the initial GTK. Because in an IBSS there are two 4-Way Handshakes between any two STA Supplicants and Authenticators, the pairwise key used between any two STAs is from the 4-Way Handshake initiated by the STA Authenticator with the higher MAC address (see 8.5.1 for the notion of address comparison). The KCK and KEK used for a Group Key Handshake are the KCK and KEK derived by the 4-Way Handshake initiated by the same Authenticator that is initiating the Group Key Handshake.

In an IBSS, a secure link exists between two STAs when both 4-Way Handshakes have completed successfully. The Supplicant and Authenticator 4-Way Handshake state machines interact so the IEEE 802.1X variable portValid is not set until both 4-Way Handshakes complete.

If a fourth STA comes within range and its SME decides to initiate a security association with the three peers, its Authenticator initiates 4-Way Handshakes with each of the other three STA Supplicants. Similarly, the original three STA Authenticators in the IBSS need to initiate 4-Way Handshakes to the fourth STA Supplicant. A STA learns that a peer STA is RSNA-enabled and the peer's security policy (e.g., whether the Authentication and Key Management Protocol (AKMP) is PSK or IEEE 802.1X authentication) from the Beacon or Probe Response frame. The initiation may start for a number of reasons:

a) The fourth STA receives a Beacon or Probe Response frame from a MAC address with which it has not completed a 4-Way Handshake.

b) A STA's SME receives a MLME-PROTECTEDFRAMEDROPPED.indication primitive from a MAC address with which it has not completed a 4-Way Handshake. This could be a multicast/ broadcast data frame transmitted by any of the STAs. If the SME wants to set up a security association to the peer STA, but does not know the security policy of the peer, it should send a Probe Request frame to the peer STA to find its security policy before setting up a security association to the peer STA.

c) A STA's SME receives Message 1 of the 4-Way Handshake sent to a STA because the initiator received a broadcast data frame, Beacon frame, or Probe Response frame from that STA. If a STA received a 4-Way Handshake, wants to set up a security association to the peer STA, but does not

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001270

know the security policy of the peer, it should send a Probe Request frame to the peer STA to find its security policy before setting up a security association to the peer STA.

5.8.3.3 IBSS IEEE 802.1X example

When IEEE 802.1X authentication is used, each STA will need to include an IEEE 802.1X Authenticator and AS. A STA learns that a peer STA is RSNA-enabled and the peer's security policy (e.g., whether the AKMP is PSK or IEEE 802.1X authentication) from the Beacon or Probe Response frame.

Each STA's Supplicant will send an EAPOL-Start message to every other STA to which it wants to authenticate, and each STA's Authenticator will respond with the identity of the credential it wants to use.

The EAPOL-Start and EAP-Request/Identity messages are initiated when a protected data frame (indicated via a MLME-PROTECTEDFRAMEDROPPED.indication primitive), an IEEE 802.1X message, Beacon frame, or Probe Response frame is received from a MAC address with which the STA has not completed IEEE 802.1X authentication. If the SME wants to set up a security association to the peer STA, but does not know the security policy of the peer, it should send a Probe Request frame to the peer STA to find its security policy before setting up a security association to the peer STA.

Although Figure 5-16 shows the two IEEE 802.1X exchanges serialized, they may occur interleaved.

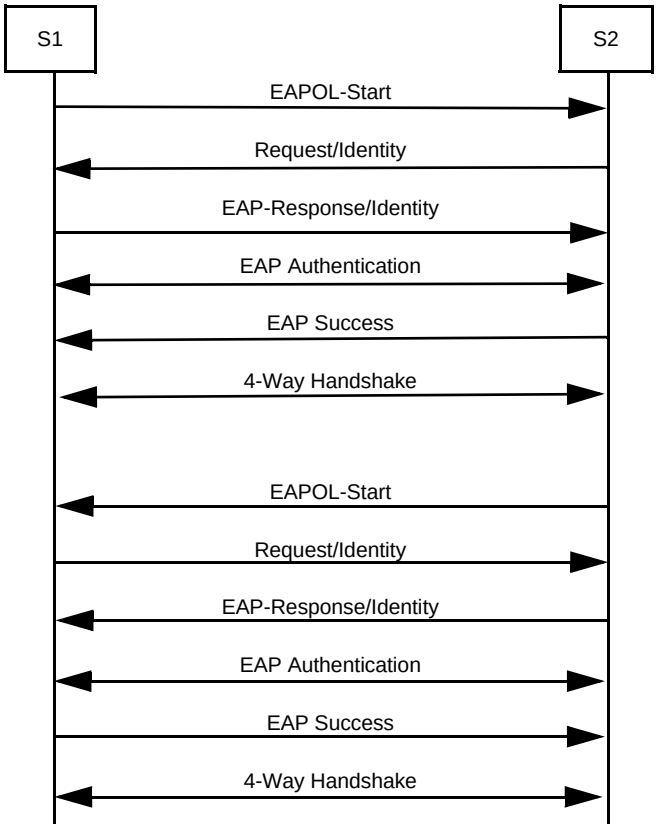

Figure 5-16—Example using IEEE 802.1X authentication

Exhibit 1014
Page 001271

5.8.4 Authenticator-to-AS protocol

The Authenticator-to-AS authentication definition is out of the scope of this standard, but, to provide security assurances, the protocol must support the following functions:

a) Mutual authentication between the Authenticator and AS

b) A channel for the Supplicant/AS authentication

c) The ability to pass the generated key from the AS to the Authenticator in a manner that provides authentication of the key source, ensures integrity of the key transfer, and preserves data confidentiality of the key from all other parties

Suitable protocols include, but are not limited to, remote authentication dial-in user service (RADIUS) (IETF RFC 2865-2000 [B23]) and Diameter (IETF RFC 3588-2003 [B25]).

5.8.5 PMKSA caching

The Authenticator and Supplicant may cache PMKSAs, which include the IEEE 802.1X state. A PMKSA can be deleted from the cache for any reason and at any time.

The STA may supply a list of PMK or PSK key identifiers in the (Re)Association Request frame. Each key identifier names a PMKSA; the PMKSA may contain a single PMK. The Authenticator specifies the selected PMK or PSK key identifier in Message 1 of the 4-Way Handshake. The selection of the key identifiers to be included within the (Re)Association Request frame and Message 1 of the 4-Way Handshake is out of the scope of this standard.

6. MAC service definition

6.1 Overview of MAC services

6.1.1 Data service

This service provides peer LLC entities with the ability to exchange MSDUs. To support this service, the local MAC uses the underlying PHY-level services to transport an MSDU to a peer MAC entity, where it will be delivered to the peer LLC. Such asynchronous MSDU transport is performed on a connectionless basis. By default, MSDU transport is on a best-effort basis. However, the QoS facility uses a traffic identifier (TID) to specify differentiated services on a per-MSDU basis. The QoS facility also permits more synchronous behavior to be supported on a connection-oriented basis using TSPECs. There are no guarantees that the submitted MSDU will be delivered successfully. Broadcast and multicast transport is part of the data service provided by the MAC. Due to the characteristics of the WM, broadcast and multicast MSDUs may experience a lower QoS, compared to that of unicast MSDUs. All STAs will support the data service, but only QoS STAs in a QoS BSS differentiate their MSDU delivery according to the designated traffic category or traffic stream (TS) of individual MSDUs.

Because operation of certain functions of the MAC may cause reordering of some MSDUs, as discussed in more detail below, in non-QoS STAs, there are two service classes within the data service. By selecting the desired service class, each LLC entity initiating the transfer of MSDUs is able to control whether MAC entities are or are not allowed to reorder those MSDUs.

There are two service classes available in a QoS STA: QoSAck and QoSNoAck. The service classes are used to signal if the MSDU is to be transmitted with or without using the MAC-level acknowledgment.

In QoS STAs either associated in a BSS or having membership in an IBSS, the MAC uses a set of rules that tends to cause higher UP MSDUs in a BSS to be sent before lower UP MSDUs in the BSS. The MAC sublayer entities determine the UPs for MSDUs based on the TID values provided with those MSDUs. If a TSPEC has been provided for a TS, via the MAC sublayer management entity, the MAC attempts to deliver MSDUs belonging to that TS in accordance with the QoS parameter values contained in the TSPEC. In a BSS with some STAs supporting the QoS facility and others not supporting the QoS facility, in delivering an MSDU to a non-QoS STA, the QoS STA uses the access category (AC) corresponding to the UP of the MSDU.

6.1.1.1 Determination of UP

The QoS facility supports eight priority values, referred to as *UPs*. The values a UP may take are the integer values from 0 to 7 and are identical to the IEEE 802.1D priority tags. An MSDU with a particular UP is said to belong to a traffic category (TC) with that UP. The UP is provided with each MSDU at the medium access control service access point (MAC_SAP) either directly, in the UP parameter, or indirectly, in a TSPEC designated by the UP parameter.

6.1.1.1.1 Determination of UP of received frames at the AP sent by other STAs in the BSS

The received unicast frames at the AP may be as follows:

a) Non-QoS subtypes, in which case the AP shall assign to them a priority of Contention, if they are received during the contention period (CP), or ContentionFree, if they are received during the contention-free period (CFP).
b) QoS subtypes, in which case the AP shall infer the UP value from the TID in the QoS Control field directly for TID values between 0 and 7. For TID values between 8 and 15, the AP shall extract the UP value in the UP subfield of the TS Info field in the associated TSPEC or from the UP field in the associated TCLAS (traffic classification) element, as applicable.

QoS APs deliver the UP with the received MSDUs to the DS.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001274

6.1.1.2 Interpretation of priority parameter in MAC service primitives

The value of the priority parameter in the MAC service primitives (see 6.2) may be a non-integer value of either Contention or ContentionFree or may be any integer value in the range 0 through 15.

When the priority parameter has an integer value, it is used in the TID subfields that appear in certain frames that are used to deliver and to control the delivery of QoS data across the WM.

Priority parameter and TID subfield values 0 through 7 are interpreted as UPs for the MSDUs. Outgoing MSDUs with UP values 0 through 7 are handled by MAC entities at STAs in accordance with the UP.

Priority parameter and TID subfield values 8 through 15 specify TIDs that are also TS identifiers (TSIDs) and select the TSPEC for the TS designated by the TID. Outgoing MSDUs with priority parameter values 8 through 15 are handled by MAC entities at STAs in accordance with the UP value determined from the UP subfield as well as other parameter values in the selected TSPEC. When an MSDU arrives with a priority value between 8 and 15 and for which there is no TSPEC defined, then the MSDU shall be sent with priority parameter set to 0.

The non-integer values of the priority parameter are allowed at all non-QoS STAs. The use of priority value of ContentionFree is deprecated at QoS STAs. The integer values of the priority parameter (i.e., TID) are supported only at QoS STAs that are either associated in a QoS BSS or members of a QoS IBSS. A range of 0 through 15 is supported by QoS STAs associated in a QoS BSS; whereas a range of 0 through 7 is supported by QoS STAs that are members of a QoS IBSS. If a QoS STA is associated in a non-QoS BSS, the STA is functioning as a non-QoS STA, so the priority value is always Contention or ContentionFree.

At QoS STAs associated in a QoS BSS, MSDUs with a priority of Contention are considered equivalent to MSDUs with TID 0, and those with a priority of ContentionFree are delivered using the contention-free delivery if a point coordinator (PC) is present in the AP. If a PC is not present, MSDUs with a priority of ContentionFree shall be delivered using an UP of 0. At STAs associated in a non-QoS BSS, all MSDUs with an integer priority are considered equivalent to MSDUs with a priority of Contention.

If a STA is associated in a QoS BSS, the MSDUs it receives in QoS data frames are reported with the TID value contained in the MAC header of that frame. The MSDUs such a STA receives in non-QoS data frames are reported to LLC with a priority of Contention, if they are received during the CP, or ContentionFree, if they are received during the CFP.

6.1.1.3 Interpretation of service class parameter in MAC service primitives in a STA

In QoS STAs, the value of the service class parameter in the MAC service primitive (see 6.2) may be a non-integer value of QoSAck or QoSNoAck.

When an MSDU is received from the MAC_SAP and the recipient STA is a QoS STA with the service class set to

— QoSAck, the MSDU is transmitted using a QoS data frame with the Ack Policy subfield in the QoS Control field set to either Normal Acknowledgment (Normal Ack) or Block Ack.

— QoSNoAck, the MSDU is transmitted using a QoS data frame with the Ack Policy subfield in the QoS Control field set to No Acknowledgment (No Ack). If the sender STA is an AP and the frame has a multicast/broadcast DA, then the MSDU is buffered for transmission and is also sent to the DS.

When an MSDU is received from the MAC_SAP and the recipient STA is not a QoS STA, the MSDU is transmitted using a non-QoS data frame.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001275

When a QoS data frame is received from another STA, the service class parameter in MA-UNITDATA.indication primitive is set to

— QoSAck, if the frame is a QoS data frame with the Ack Policy subfield in the QoS Control field set to either Normal Ack or Block Ack.

— QoSNoAck, if the frame is a QoS data frame with the Ack Policy subfield in the QoS Control field set to No Ack. This service class is also used where the DA parameter is a broadcast/multicast address.

When a non-QoS data frame is received from a STA, the service class parameter in MA-UNITDATA.indication primitive is set to

— QoSAck, if the frame is a unicast frame and is acknowledged by the STA.

— QoSNoAck, if the frame is a broadcast/multicast frame and is not acknowledged by the STA.

Note that the broadcast/multicast frames sent by a non-QoS STA are not acknowledged regardless of the service class parameter in MA-UNITDATA.indication primitive.

6.1.2 Security services

Security services in IEEE Std 802.11 are provided by the authentication service and the TKIP and CCMP mechanisms. The scope of the security services provided is limited to station-to-station data exchange. The data confidentiality service offered by an IEEE 802.11 TKIP and CCMP implementation is the protection of the MSDU. For the purposes of this standard, TKIP and CCMP are viewed as logical services located within the MAC sublayer as shown in the reference model, Figure 5-10 (in 5.7). Actual implementations of the TKIP and CCMP services are transparent to the LLC and other layers above the MAC sublayer.

The security services provided by TKIP and CCMP in IEEE Std 802.11 are as follows:

a) Data Confidentiality;

b) Authentication; and

c) Access control in conjunction with layer management.

During the authentication exchange, both parties exchange authentication information as described in Clause 8.

The MAC sublayer security services provided by TKIP and CCMP rely on information from nonlayer-2 management or system entities. Management entities communicate information to TKIP and CCMP through a set of MAC sublayer management entity (MLME) interfaces and MIB attributes; in particular, the decision tree for TKIP and CCMP defined in 8.7 is driven by MIB attributes.

The use of WEP for confidentiality, authentication, or access control is deprecated. The WEP algorithm is unsuitable for the purposes of this standard.

6.1.3 MSDU ordering

The services provided by the MAC sublayer permit, and may in certain cases require, the reordering of MSDUs.

In a non-QoS STA, the MAC does not intentionally reorder MSDUs except as may be necessary to improve the likelihood of successful delivery based on the current operational (“power management”) mode of the designated recipient STA(s). The sole effect of this reordering (if any), for the set of MSDUs received at the MAC service interface of any single STA, is a change in the delivery order of broadcast and multicast MSDUs, relative to directed MSDUs, originating from a single source STA address. If a higher layer protocol using the data service cannot tolerate this possible reordering, the optional StrictlyOrdered service

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001276

class should be used. MSDUs transferred between any pair of STAs using the StrictlyOrdered service class are not subject to the relative reordering that is possible when the ReorderableMulticast service class is used. However, the desire to receive MSDUs sent using the StrictlyOrdered service class at a STA precludes simultaneous use of the MAC power management facilities at that STA.

In QoS STAs operating in a BSS, there are two service classes, designated as QoSAck and QoSNoAck (see 6.1.1.3 for more information). The MSDUs are reordered, not only to improve the likelihood of successful delivery based on the current operational mode of the designated recipient STA(s), but also to honor the priority parameters, specified in the MA-UNITDATA.request primitive, of the individual MSDUs. The effects of this reordering (if any), for the set of MSDUs received at the MAC service interface of any single STA, are

a) A change in the delivery order of broadcast and multicast MSDUs, relative to unicast MSDUs,

b) The reordering of MSDUs with different TID values, originating from a single source STA address, and

c) The reordering of broadcast and multicast MSDUs with the same TID but different service classes.

There shall be no reordering of unicast MSDUs with the same TID value and addressed to the same destination.

STAs operating in a non-QoS BSS shall follow the reordering rules as defined for a non-QoS STA.

In order for the MAC to operate properly, the DS must meet the requirements of ISO/IEC 15802-1:1995.

Operational restrictions that ensure the appropriate ordering of MSDUs are specified in 9.8.

6.1.4 MSDU format

This standard is part of the IEEE 802 family of LAN standards, and as such all MSDUs are LLC PDUs as defined in ISO/IEC 8802-2: 1998. In order to achieve interoperability, implementers are recommended to apply the procedures described in ISO/IEC Technical Report 11802-5:1997(E) (previously known as IEEE Std 802.1H-1997 [B13]), along with a selective translation table (STT) that handles a few specific network protocols, with specific attention to the operations required when passing MSDUs to or from LANs or operating system components that use the Ethernet frame format. Note that such translations may be required in a non-AP STA.

6.1.5 MAC data service architecture

The MAC data plane architecture (i.e., processes that involve transport of all or part of an MSDU) is shown in Figure 6-1. During transmission, an MSDU goes through some or all of the following processes: frame delivery deferral during power save mode, sequence number assignment, fragmentation, encryption, integrity protection, and frame formatting. IEEE Std 802.1X-2004 may block the MSDU at the Controlled Port. At some point, the data frames that contain all or part of the MSDU are queued per AC/TS. This queuing may be at any of the three points indicated in Figure 6-1.

During reception, a received data frame goes through processes of MPDU header and cyclic redundancy code (CRC) validation, duplicate removal, possible reordering if the Block Ack mechanism is used, decryption, defragmentation, integrity checking, and replay detection. After replay detection (or defragmentation if security is used), the MSDU is delivered to the MAC_SAP or to the DS. The IEEE 802.1X Controlled/Uncontrolled Ports discard the MSDU if the Controlled Port is not enabled and if the MSDU does not represent an IEEE 802.1X frame. TKIP and CCMP MPDU frame order enforcement occurs after decryption, but prior to MSDU defragmentation; therefore, defragmentation will fail if MPDUs arrive out of order.

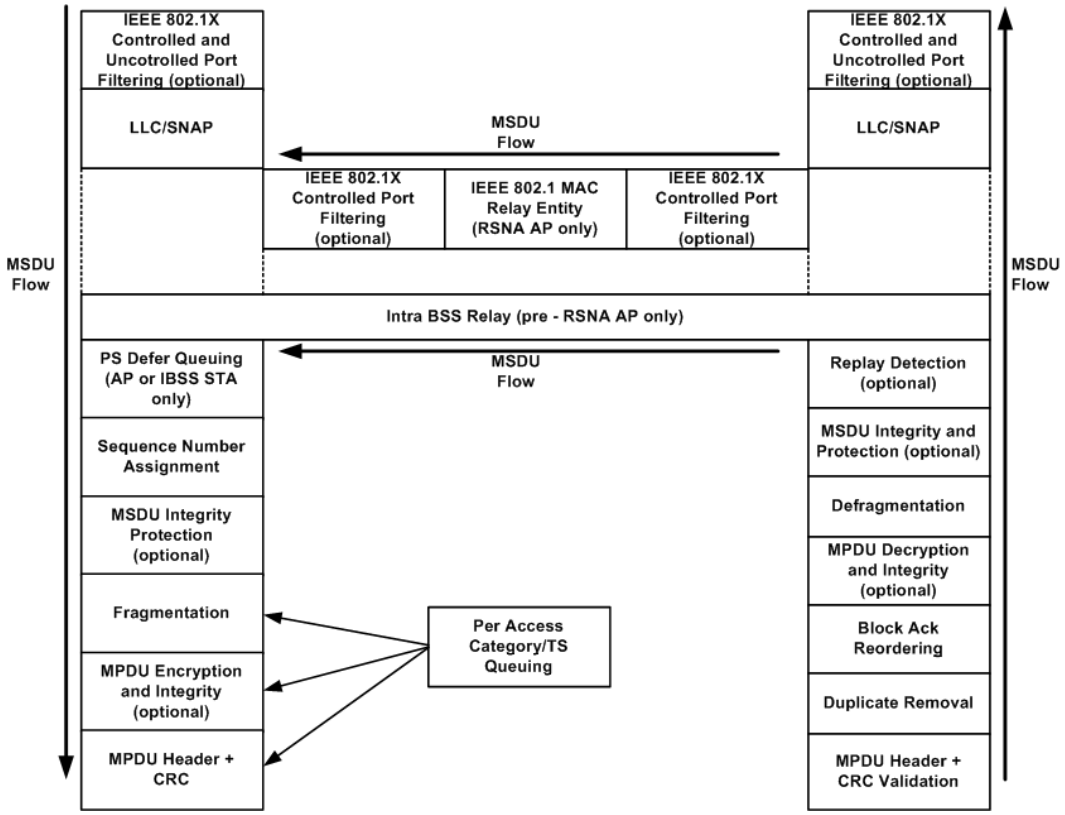

Figure 6-1—MAC data plane architecture

6.2 Detailed service specification

6.2.1 MAC data services

The IEEE 802.11 MAC supports the following service primitives as defined in ISO/IEC 8802-2: 1998:

— MA-UNITDATA.request

— MA-UNITDATA.indication

— MA-UNITDATA.confirm

The LLC definitions of the primitives and specific parameter value restrictions imposed by IEEE Std 802.11 are given in 6.2.1.1 through 6.2.1.3.

6.2.1.1 MA-UNITDATA.request

6.2.1.1.1 Function

This primitive requests a transfer of an MSDU from a local LLC sublayer entity to a single peer LLC sublayer entity, or multiple peer LLC sublayer entities in the case of group addresses.

6.2.1.1.2 Semantics of the service primitive

The parameters of the primitive are as follows:

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001278

MA-UNITDATA.request (
source address,
destination address,
routing information,
data,
priority,
service class
)

The source address (SA) parameter specifies an individual MAC sublayer address of the sublayer entity from which the MSDU is being transferred.

The destination address (DA) parameter specifies either an individual or a group MAC sublayer entity address.

The routing information parameter specifies the route desired for the data transfer (a null value indicates source routing is not to be used). For IEEE Std 802.11, the routing information parameter must be null.

The data parameter specifies the MSDU to be transmitted by the MAC sublayer entity. For IEEE Std 802.11, the length of the MSDU must be less than or equal to 2304 octets.

The priority parameter specifies the priority desired for the data unit transfer. The allowed values of priority are described in 6.1.1.2.

The service class parameter specifies the service class desired for the data unit transfer. The allowed values of service class are described in 6.1.1.3 and 6.1.3.

6.2.1.1.3 When generated

This primitive is generated by the LLC sublayer entity when an MSDU is to be transferred to a peer LLC sublayer entity or entities.

6.2.1.1.4 Effect of receipt

On receipt of this primitive, the MAC sublayer entity determines whether the request can be fulfilled according to the requested parameters. A request that cannot be fulfilled according to the requested parameters is discarded, and this action is indicated to the LLC sublayer entity using an MA-UNITDATA.confirm primitive that describes why the MAC was unable to fulfill the request. If the request can be fulfilled according to the requested parameters, the MAC sublayer entity appends all MAC specified fields (including DA, SA, FCS, and all fields that are unique to IEEE Std 802.11), passes the properly formatted frame to the lower layers for transfer to a peer MAC sublayer entity or entities (see 6.1.4), and indicates this action to the LLC sublayer entity using an MA-UNITDATA.confirm primitive with transmission status set to Successful.

6.2.1.2 MA-UNITDATA.indication

6.2.1.2.1 Function

This primitive defines the transfer of an MSDU from the MAC sublayer entity to the LLC sublayer entity, or entities in the case of group addresses. In the absence of error, the contents of the data parameter are logically complete and unchanged relative to the data parameter in the associated MA-UNITDATA.request primitive.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001279

6.2.1.2.2 Semantics of the service primitive

The parameters of the primitive are as follows:

```
MA-UNITDATA.indication(
                        source address,
                        destination address,
                        routing information,
                        data,
                        reception status,
                        priority,
                        service class
                        )
```

The SA parameter is an individual address as specified by the SA field of the incoming frame.

The DA parameter is either an individual or a group address as specified by the DA field of the incoming frame.

The routing information parameter specifies the route that was used for the data transfer. IEEE Std 802.11 shall always set this field to null.

The data parameter specifies the MSDU as received by the local MAC entity.

The reception status parameter indicates the success or failure of the received frame for those frames that IEEE Std 802.11 reports via a MA-UNITDATA.indication primitive. This MAC always reports "success" because all failures of reception are discarded without generating MA-UNITDATA.indication primitive.

The priority parameter specifies the receive processing priority that was used for the data unit transfer. The allowed values of priority are described in 6.1.1.2.

The service class parameter specifies the receive service class that was used for the data unit transfer. The allowed values of service class are described in 6.1.1.3 and 6.1.3.

6.2.1.2.3 When generated

The MA-UNITDATA.indication primitive is passed from the MAC sublayer entity to the LLC sublayer entity or entities to indicate the arrival of a frame at the local MAC sublayer entity. Frames are reported only if they are validly formatted at the MAC sublayer, received without error, received with valid (or null) security and integrity information, and their destination address designates the local MAC sublayer entity.

6.2.1.2.4 Effect of receipt

The effect of receipt of this primitive by the LLC sublayer is dependent on the content of the MSDU.

6.2.1.3 MA-UNITDATA.confirm

6.2.1.3.1 Function

This primitive has local significance and provides the LLC sublayer with status information for the corresponding preceding MA-UNITDATA.request primitive.

6.2.1.3.2 Semantics of the service primitive

The parameters of the primitive are as follows:

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001280

MA-UNITDATA.confirm(
source address,
destination address,
transmission status,
provided priority,
provided service class
)

The SA parameter is an individual MAC sublayer entity address as specified in the associated MA-UNITDATA.request primitive.

The DA parameter is either an individual or group MAC sublayer entity address as specified in the associated MA-UNITDATA.request primitive.

The transmission status parameter is used to pass status information back to the local requesting LLC sublayer entity. IEEE Std 802.11 specifies the following values for transmission status:

a) Successful.
b) Undeliverable (excessive data length).
c) Undeliverable (non-null source routing).
d) Undeliverable: unsupported priority (for priorities other than Contention or ContentionFree at a non-QoS STA; or for priorities other than Contention, ContentionFree, or an integer between and including 0 and 15 at a QoS STA).
e) Undeliverable: unsupported service class (for service classes other than ReorderableMulticast or StrictlyOrdered for non-QoS STAs and service classes other than QoSAck or QoSNoAck for QoS STAs).
f) Unavailable priority (for ContentionFree when no PC or HC is available, or an integer between and including 1 and 15 at a STA that is associated in a non-QoS BSS, or an integer between and including 8 and 15 at a STA that is a member of an IBSS, in which case the MSDU is transmitted with a provided priority of Contention).
g) Undeliverable: unavailable service class (for StrictlyOrdered service when the STA's power management mode is other than "active" for non-QoS STAs; QoS STAs do not return this value as they do not provide the StrictlyOrdered service).
h) Undeliverable (no BSS available).
i) Undeliverable (cannot encrypt with a null key).

The provided priority parameter specifies the priority that was used for the associated data unit transfer (Contention, ContentionFree, or an integer between and including 0 and 15).

The provided service class parameter specifies the class of service used for the associated data unit transfer. In non-QoS STAs, the value of this parameter is ReorderableMulticast or StrictlyOrdered. In QoS STAs, it is QoSAck or QoSNoAck.

6.2.1.3.3 When generated

The MA-UNITDATA.confirm primitive is passed from the MAC sublayer entity to the LLC sublayer entity to indicate the status of the service provided for the corresponding MA-UNITDATA.request primitive.

6.2.1.3.4 Effect of receipt

The effect of receipt of this primitive by the LLC sublayer is dependent upon the type of operation employed by the LLC sublayer entity.

Exhibit 1014
Page 001281

7. Frame formats

The format of the MAC frames is specified in this clause. A STA shall be able properly to construct a subset of the frames specified in this clause for transmission and to decode a (potentially different) subset of the frames specified in this clause upon validation following reception. The particular subset of these frames that a STA constructs and decodes is determined by the functions supported by that particular STA, as specified in 7.5. All STAs shall be able to validate every received frame using the frame check sequence (FCS) and to interpret certain fields from the MAC headers of all frames.

7.1 MAC frame formats

Each frame consists of the following basic components:

a) A *MAC header*, which comprises frame control, duration, address, and sequence control information, and, for QoS data frames, QoS control information;

b) A variable length *frame body*, which contains information specific to the frame *type* and *subtype*;

c) A *FCS*, which contains an IEEE 32-bit CRC.

7.1.1 Conventions

The MPDUs or frames in the MAC sublayer are described as a sequence of fields in specific order. Each figure in Clause 7 depicts the fields/subfields as they appear in the MAC frame and in the order in which they are passed to the physical layer convergence procedure (PLCP), from left to right.

In figures, all bits within fields are numbered, from 0 to *k*, where the length of the field is $k + 1$ bits. The octet boundaries within a field can be obtained by taking the bit numbers of the field modulo 8. Octets within numeric fields that are longer than a single octet are depicted in increasing order of significance, from lowest numbered bit to highest numbered bit. The octets in fields longer than a single octet are sent to the PLCP in order from the octet containing the lowest numbered bits to the octet containing the highest numbered bits.

Any field containing a CRC is an exception to this convention and is transmitted commencing with the coefficient of the highest-order term.

MAC addresses are assigned as ordered sequences of bits. The Individual/Group bit is always transferred first and is bit 0 of the first octet.

Values specified in decimal are coded in natural binary unless otherwise stated. The values in Table 7-1 are in binary, with the bit assignments shown in the table. Values in other tables are shown in decimal notation.

Reception, in references to frames or fields within frames (e.g., received Beacon frames or a received Duration/ID field), applies to MPDUs or MAC management protocol data units (MMPDUs) indicated from the PHY layer without error and validated by FCS within the MAC sublayer. Without further qualification, *reception* by the MAC sublayer implies that the frame contents are valid, and that the protocol version is supported (see 7.1.3.1.1), with no implication regarding frame addressing or regarding whether the frame type or other fields in the MAC header are meaningful to the MAC entity that has received the frame.

Parentheses enclosing portions of names or acronyms are used to designate a set of related names that vary based on the inclusion of the parenthesized portion. For example,

— *QoS +CF-Poll frame* refers to the three QoS data subtypes that include "+CF-Poll": the QoS Data+CF-Poll frame, subtype 1010; QoS Data+CF-Ack+CF-Poll frame, subtype 1011; and QoS CF-Ack+CF-Poll frame, subtype 1111.

— *QoS CF-Poll frame* refers specifically to the QoS CF-Poll frame, subtype 1110.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001282

— *QoS (+)CF-Poll frame* refers to all four QoS data subtypes with CF-Poll: the QoS CF-Poll frame, subtype 1110; the QoS CF-Ack+CF-Poll frame, subtype 1111; the QoS Data+CF-Poll frame, subtype 1010; and the QoS Data+CF-Ack+CF-Poll frame, subtype 1011.

— *QoS (+)Null frame* refers to all three QoS data subtypes with "no data": the QoS Null (no data) frame, subtype 1100; the QoS CF-Poll (no data) frame, subtype 1110; and the QoS CF-Ack+CF-Poll frame, subtype 1111.

— *QoS +CF-Ack frame* refers to the three QoS data subtypes that include "+CF-Ack": the QoS Data+CF-Ack frame, subtype 1001; QoS Data+CF-Ack+CF-Poll frame, subtype 1011; and QoS CF-Ack+CF-Poll frame, subtype 1111.

— Whereas *(QoS) CF-Poll frame* refers to the QoS CF-Poll frame, subtype 1110, and the CF-Poll frame, subtype 0110.

Reserved fields and subfields are set to 0 upon transmission and are ignored upon reception.

7.1.2 General frame format

The MAC frame format comprises a set of fields that occur in a fixed order in all frames. Figure 7-1 depicts the general MAC frame format. The first three fields (Frame Control, Duration/ID, and Address 1) and the last field (FCS) in Figure 7-1 constitute the minimal frame format and are present in all frames, including reserved types and subtypes. The fields Address 2, Address 3, Sequence Control, Address 4, QoS Control, and Frame Body are present only in certain frame types and subtypes. Each field is defined in 7.1.3. The format of each of the individual subtypes of each frame type is defined in 7.2. The components of management frame bodies are defined in 7.3. The formats of management frames of subtype Action are defined in 7.4

The Frame Body field is of variable size. The maximum frame body size is determined by the maximum MSDU size (2304 octets) plus any overhead from security encapsulation.

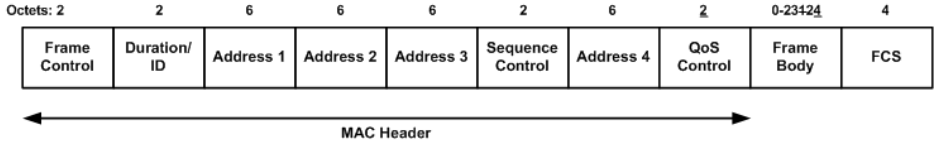

Figure 7-1—MAC frame format

7.1.3 Frame fields

7.1.3.1 Frame Control field

The Frame Control field consists of the following subfields: Protocol Version, Type, Subtype, To DS, From DS, More Fragments, Retry, Power Management, More Data, Protected Frame, and Order. The format of the Frame Control field is illustrated in Figure 7-2.

B0 B1	B2 B3	B4 B7	B8	B9	B10	B11	B12	B13	B14	B15
Protocol Version	Type	Subtype	To DS	From DS	More Frag	Retry	Pwr Mgt	More Data	Protected Frame	Order
Bits : 2	2	4	1	1	1	1	1	1	1	1

Figure 7-2—Frame Control field

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001283

7.1.3.1.1 Protocol Version field

The Protocol Version field is 2 bits in length and is invariant in size and placement across all revisions of this standard. For this standard, the value of the protocol version is 0. All other values are reserved. The revision level will be incremented only when a fundamental incompatibility exists between a new revision and the prior edition of the standard. A MAC entity that receives a frame with a higher revision level than it supports shall discard the frame without indication to the sending STA or to LLC.

7.1.3.1.2 Type and Subtype fields

The Type field is 2 bits in length, and the Subtype field is 4 bits in length. The Type and Subtype fields together identify the function of the frame. There are three frame types: control, data, and management. Each of the frame types has several defined subtypes. In data frames, the most significant bit (MSB) of the Subtype field, b7, is defined as the QoS subfield. Table 7-1 defines the valid combinations of type and subtype. (The numeric values in Table 7-1 are shown in binary.)

Table 7-1—Valid type and subtype combinations

Type value b3 b2	Type description	Subtype value b7 b6 b5 b4	Subtype description
00	Management	0000	Association request
00	Management	0001	Association response
00	Management	0010	Reassociation request
00	Management	0011	Reassociation response
00	Management	0100	Probe request
00	Management	0101	Probe response
00	Management	0110–0111	Reserved
00	Management	1000	Beacon
00	Management	1001	ATIM
00	Management	1010	Disassociation
00	Management	1011	Authentication
00	Management	1100	Deauthentication
00	Management	1101	Action
00	Management	1110–1111	Reserved
01	Control	0000–0111	Reserved
01	Control	1000	Block Ack Request (BlockAckReq)
01	Control	1001	Block Ack (BlockAck)
01	Control	1010	PS-Poll
01	Control	1011	RTS
01	Control	1100	CTS
01	Control	1101	ACK
01	Control	1110	CF-End
01	Control	1111	CF-End + CF-Ack

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001284

Table 7-1—Valid type and subtype combinations *(continued)*

Type value b3 b2	Type description	Subtype value b7 b6 b5 b4	Subtype description
10	Data	0000	Data
10	Data	0001	Data + CF-Ack
10	Data	0010	Data + CF-Poll
10	Data	0011	Data + CF-Ack + CF-Poll
10	Data	0100	Null (no data)
10	Data	0101	CF-Ack (no data)
10	Data	0110	CF-Poll (no data)
10	Data	0111	CF-Ack + CF-Poll (no data)
10	Data	1000	QoS Data
10	Data	1001	QoS Data + CF-Ack
10	Data	1010	QoS Data + CF-Poll
10	Data	1011	QoS Data + CF-Ack + CF-Poll
10	Data	1100	QoS Null (no data)
10	Data	1101	Reserved
10	Data	1110	QoS CF-Poll (no data)
10	Data	1111	QoS CF-Ack + CF-Poll (no data)
11	Reserved	0000–1111	Reserved

Each Subtype field bit position is used to indicate a specific modification of the basic data frame (subtype 0). Frame Control bit 4 is set to 1 in data subtypes that include +CF-Ack, bit 5 is set to 1 in data subtypes that include +CF-Poll, bit 6 is set to 1 in data subtypes that contain no Frame Body field, and bit 7 is set to 1 in the QoS data subtypes, which have QoS Control fields in their MAC headers.

7.1.3.1.3 To DS and From DS fields

The meaning of the combinations of values for the To DS and From DS fields are shown in Table 7-2.

Table 7-2—To/From DS combinations in data frames

To DS and From DS values	Meaning
To DS = 0 From DS = 0	A data frame direct from one STA to another STA within the same IBSS, or a data frame direct from one non-AP STA to another non-AP STA within the same BSS, as well as all management and control frames.
To DS = 1 From DS = 0	A data frame destined for the DS or being sent by a STA associated with an AP to the Port Access Entity in that AP.
To DS = 0 From DS = 1	A data frame exiting the DS or being sent by the Port Access Entity in an AP.
To DS = 1 From DS = 1	A data frame using the four-address format. This standard does not define procedures for using this combination of field values.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001285

7.1.3.1.4 More Fragments field

The More Fragments field is 1 bit in length and is set to 1 in all data or management type frames that have another fragment of the current MSDU or current MMPDU to follow. It is set to 0 in all other frames.

7.1.3.1.5 Retry field

The Retry field is 1 bit in length and is set to 1 in any data or management type frame that is a retransmission of an earlier frame. It is set to 0 in all other frames. A receiving STA uses this indication to aid in the process of eliminating duplicate frames.

7.1.3.1.6 Power Management field

The Power Management field is 1 bit in length and is used to indicate the power management mode of a STA. The value of this field remains constant in each frame from a particular STA within a frame exchange sequence defined in 9.12. The value indicates the mode in which the STA will be after the successful completion of the frame exchange sequence.

A value of 1 indicates that the STA will be in PS mode. A value of 0 indicates that the STA will be in active mode. This field is always set to 0 in frames transmitted by an AP.

7.1.3.1.7 More Data field

The More Data field is 1 bit in length and is used to indicate to a STA in PS mode that more MSDUs or MMPDUs are buffered for that STA at the AP. The More Data field is valid in directed data or management type frames transmitted by an AP to a STA in PS mode. A value of 1 indicates that at least one additional buffered MSDU or MMPDU is present for the same STA.

The More Data field may be set to 1 in directed data type frames transmitted by a CF-Pollable STA to the PC in response to a CF-Poll to indicate that the STA has at least one additional buffered MSDU available for transmission in response to a subsequent CF-Poll.

The More Data field is set to 0 in all other directed frames.

The More Data field is set to 1 in broadcast/multicast frames transmitted by the AP when additional broadcast/multicast MSDUs or MMPDUs remain to be transmitted by the AP during this beacon interval. The More Data field is set to 0 in broadcast/multicast frames transmitted by the AP when no more broadcast/ multicast MSDUs or MMPDUs remain to be transmitted by the AP during this beacon interval and in all broadcast/multicast frames transmitted by non-AP STAs.

For a non-AP STA that has the More Data Ack subfield set in its QoS Capability information element and also has APSD enabled, an AP may set the More Data field to 1 in ACK frames to this non-AP STA to indicate that the AP has a pending transmission for the non-AP STA.

7.1.3.1.8 Protected Frame field

The Protected Frame field is 1 bit in length. The Protected Frame field is set to 1 if the Frame Body field contains information that has been processed by a cryptographic encapsulation algorithm. The Protected Frame field is set to 1 only within data frames and within management frames of subtype Authentication. The Protected Frame field is set to 0 in all other frames. When the Protected Frame field is set to 1, the Frame Body field is protected utilizing the cryptographic encapsulation algorithm and expanded as defined in Clause 8. The Protected Frame field is set to 0 in Data frames of subtype Null Function, CF-ACK (no data), CF-Poll (no data), and CF-ACK+CF-Poll (no data) (see 8.3.2.2 and 8.3.3.1, which show that the frame body must be 1 octet or longer to apply the encapsulation).

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001286

7.1.3.1.9 Order field

The Order field is 1 bit in length and is set to 1 in any non-QoS data frame that contains an MSDU, or fragment thereof, which is being transferred using the StrictlyOrdered service class. This field is set to 0 in all other frames. All QoS STAs set this subfield to 0.

7.1.3.2 Duration/ID field

The Duration/ID field is 16 bits in length. The contents of this field vary with frame type and subtype, with whether the frame is transmitted during the CFP, and with the QoS capabilities of the sending STA. The contents of the field are defined as follows:

a) In control frames of subtype PS-Poll, the Duration/ID field carries the association identifier (AID) of the STA that transmitted the frame in the 14 least significant bits (LSB), and the 2 most significant bits (MSB) both set to 1. The value of the AID is in the range 1–2007.

b) In frames transmitted by the PC and non-QoS STAs, during the CFP, the Duration/ID field is set to a fixed value of 32 768.

c) In all other frames sent by non-QoS STAs and control frames sent by QoS STAs, the Duration/ID field contains a duration value as defined for each frame type in 7.2.

d) In data and management frames sent by QoS STAs, the Duration/ID field contains a duration value as defined for each frame type in 7.1.4.

When the contents of a received Duration/ID field, treated as an unsigned integer and without regard for address values, type, and subtype (even when type or subtype contain reserved values), are less than 32 768, the duration value is used to update the network allocation vector (NAV) according to the procedures defined in 9.2.5.4 or 9.9.2.2.1, as appropriate.

When the contents of a received Duration/ID field, treated as an unsigned integer, are greater than 32 768, the contents are interpreted as appropriate for the frame type and subtype or ignored if the receiving MAC entity does not have a defined interpretation for that type and subtype.

The encoding of the Duration/ID field is given in Table 7-3.

Table 7-3—Duration/ID field encoding

Bits 0–13	Bit 14	Bit 15	Usage
0–32 767		0	Duration value (in microseconds) within all frames other than PS-Poll frames transmitted during the CP, and under HCF for frames transmitted during the CFP
0	0	1	Fixed value under point coordination function (PCF) within frames transmitted during the CFP
1–16 383	0	1	Reserved
0	1	1	Reserved
1–2007	1	1	AID in PS-Poll frames
2008–16 383	1	1	Reserved

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001287

7.1.3.3 Address fields

There are four address fields in the MAC frame format. These fields are used to indicate the basic service set identification (BSSID), source address (SA), destination address (DA), transmitting STA address (TA), and receiving STA address (RA). Certain frames may not contain some of the address fields.

Certain address field usage is specified by the relative position of the address field (1–4) within the MAC header, independent of the type of address present in that field. For example, receiver address matching is always performed on the contents of the Address 1 field in received frames, and the receiver address of CTS and ACK frames is always obtained from the Address 2 field in the corresponding RTS frame, or from the frame being acknowledged.

7.1.3.3.1 Address representation

Each Address field contains a 48-bit address as defined in 5.2 of IEEE Std 802-1990.

7.1.3.3.2 Address designation

A MAC sublayer address is one of the following two types:

a) *Individual address.* The address assigned to a particular STA on the network.

b) *Group address.* A multidestination address, which may be in use by one or more STAs on a given network. The two kinds of group addresses are as follows:

   1) *Multicast-group address.* An address associated by higher level convention with a group of logically related STAs.

   2) *Broadcast address.* A distinguished, predefined multicast address that always denotes the set of all STAs on a given LAN. All ones are interpreted to be the broadcast address. This group is predefined for each communication medium to consist of all STAs actively connected to that medium; it is used to broadcast to all the active STAs on that medium.

The address space is also partitioned into locally administered and universal (globally administered) addresses. The nature of a body and the procedures by which it administers these universal (globally administered) addresses is beyond the scope of this standard. See IEEE Std 802-1990 for more information.

7.1.3.3.3 BSSID field

The BSSID field is a 48-bit field of the same format as an IEEE 802 MAC address. This field uniquely identifies each BSS. The value of this field, in an infrastructure BSS, is the MAC address currently in use by the STA in the AP of the BSS.

The value of this field in an IBSS is a locally administered IEEE MAC address formed from a 46-bit random number generated according to the procedure defined in 11.1.3. The individual/group bit of the address is set to 0. The universal/local bit of the address is set to 1. This mechanism is used to provide a high probability of selecting a unique BSSID.

The value of all 1s is used to indicate the wildcard BSSID. A wildcard BSSID shall not be used in the BSSID field except for management frames of subtype probe request.

7.1.3.3.4 DA field

The DA field contains an IEEE MAC individual or group address that identifies the MAC entity or entities intended as the final recipient(s) of the MSDU (or fragment thereof) contained in the frame body field.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001288

7.1.3.3.5 SA field

The SA field contains an IEEE MAC individual address that identifies the MAC entity from which the transfer of the MSDU (or fragment thereof) contained in the frame body field was initiated. The individual/group bit is always transmitted as a zero in the source address.

7.1.3.3.6 RA field

The RA field contains an IEEE MAC individual or group address that identifies the intended immediate recipient STA(s), on the WM, for the information contained in the frame body field.

7.1.3.3.7 TA field

The TA field contains an IEEE MAC individual address that identifies the STA that has transmitted, onto the WM, the MPDU contained in the frame body field. The Individual/Group bit is always transmitted as a zero in the transmitter address.

7.1.3.4 Sequence Control field

The Sequence Control field is 16 bits in length and consists of two subfields, the Sequence Number and the Fragment Number. The format of the Sequence Control field is illustrated in Figure 7-3. Sequence Control field is not present in control frames.

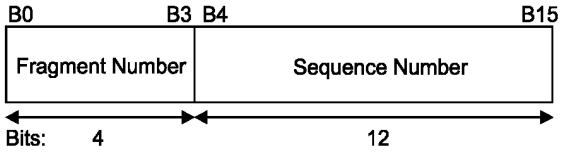

Figure 7-3—Sequence Control field

7.1.3.4.1 Sequence Number field

The Sequence Number field is a 12-bit field indicating the sequence number of an MSDU or MMPDU. Each MSDU or MMPDU transmitted by a STA is assigned a sequence number. Sequence numbers are not assigned to control frames, as the Sequence Control field is not present.

Non-QoS STAs, as well as QoS STAs operating as non-QoS STAs because they are in a non-QoS BSS or non-QoS IBSS, assign sequence numbers, to management frames and data frames (QoS subfield of the Subtype field is set to 0), from a single modulo-4096 counter, starting at 0 and incrementing by 1 for each MSDU or MMPDU.

QoS STAs associated in a QoS BSS maintain one modulo-4096 counter, per TID, per unique receiver (specified by the Address 1 field of the MAC header). Sequence numbers for QoS data frames are assigned using the counter identified by the TID subfield of the QoS Control field of the frame, and that counter is incremented by 1 for each MSDU belonging to that TID. Sequence numbers for management frames, QoS data frames with a broadcast/multicast address in the Address 1 field, and all non-QoS data frames sent by QoS STAs are assigned using an additional single modulo-4096 counter, starting at 0 and incrementing by 1 for each MSDU or MMPDU. Sequence numbers for QoS (+)Null frames may be set to any value.

Each fragment of an MSDU or MMPDU contains a copy of the sequence number assigned to that MSDU or MMPDU. The sequence number remains constant in all retransmissions of an MSDU, MMPDU, or fragment thereof.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001289

7.1.3.4.2 Fragment Number field

The Fragment Number field is a 4-bit field indicating the number of each fragment of an MSDU or MMPDU. The fragment number is set to 0 in the first or only fragment of an MSDU or MMPDU and is incremented by one for each successive fragment of that MSDU or MMPDU. The fragment number remains constant in all retransmissions of the fragment.

7.1.3.5 QoS Control field

The QoS Control field is a 16-bit field that identifies the TC or TS to which the frame belongs and various other QoS-related information about the frame that varies by frame type and subtype. The QoS Control field is present in all data frames in which the QoS subfield of the Subtype field is set to 1 (see 7.1.3.1.2). Each QoS Control field comprises five subfields, as defined for the particular sender (HC or non-AP STA) and frame type and subtype. The usage of these subfields and the various possible layouts of the QoS Control field are described 7.1.3.5.1 through 7.1.3.5.7 and illustrated in Table 7-4.

Table 7-4—QoS Control field

Applicable frame (sub) types	Bits 0–3	Bit 4	Bits 5-6	Bit 7	Bits 8–15
QoS (+)CF-Poll frames sent by HC	TID	EOSP	Ack Policy	Reserved	TXOP Limit
QoS Data, QoS Null, and QoS Data+CF-Ack frames sent by HC	TID	EOSP	Ack Policy	Reserved	AP PS Buffer State
QoS data frames sent by non-AP STAs	TID	0	Ack Policy	Reserved	TXOP Duration Requested
	TID	1	Ack Policy	Reserved	Queue Size

7.1.3.5.1 TID subfield

The TID subfield identifies the TC or TS to which the corresponding MSDU, or fragment thereof, in the Frame Body field belongs. The TID subfield also identifies the TC or TS of traffic for which a TXOP is being requested, through the setting of TXOP duration requested or queue size. The encoding of the TID subfield depends on the access policy (see 7.3.2.30) and is shown in Table 7-5. Additional information on the interpretation of the contents of this field appears in 6.1.1.2 .

Table 7-5—TID subfield

Access policy	Usage	Allowed values in bits 0–3 (TID subfield)
EDCA	UP for either TC or TS, regardless of whether admission control is required	0–7
HCCA	TSID	8–15
HEMM	TSID, regardless of the access mechanism used	8–15

For QoS Data+CF-Poll, the TID subfield in the QoS Control field indicates the TID of the data. For all QoS (+)CF-Poll frames of subtype Null, the TID subfield in the QoS Control field indicates the TID for which the

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001290

poll is intended. The requirement to respond to that TID is nonbinding, and a STA may respond with any frame.

7.1.3.5.2 EOSP (end of service period) subfield

The EOSP subfield is 1 bit in length and is used by the HC to indicate the end of the current service period (SP). The HC sets the EOSP subfield to 1 in its transmission and retransmissions of the SP's final frame to end a scheduled/unscheduled SP and sets it to 0 otherwise.

7.1.3.5.3 Ack Policy subfield

The Ack Policy subfield is 2 bits in length and identifies the acknowledgment policy that is followed upon the delivery of the MPDU. The interpretation of these 2 bits is given in Table 7-6.

Table 7-6—Ack Policy subfield in QoS Control field of QoS data frames

Bits in QoS Control field		Meaning
Bit 5	Bit 6	
0	0	Normal Ack. The addressed recipient returns an ACK or QoS +CF-Ack frame after a short interframe space (SIFS) period, according to the procedures defined in 9.2.8, 9.3.3, and 9.9.2.3. The Ack Policy subfield is set to this value in all directed frames in which the sender requires acknowledgment. For QoS Null (no data) frames, this is the only permissible value for the Ack Policy subfield.
1	0	No Ack The addressed recipient takes no action upon receipt of the frame. More details are provided in 9.11. The Ack Policy subfield is set to this value in all directed frames in which the sender does not require acknowledgment. This combination is also used for broadcast and multicast frames that use the QoS frame format.
0	1	No explicit acknowledgment. There may be a response frame to the frame that is received, but it is neither the ACK nor any data frame of subtype +CF-Ack. For QoS CF-Poll and QoS CF-Ack+CF-Poll data frames, this is the only permissible value for the Ack Policy subfield.
1	1	Block Ack The addressed recipient takes no action upon the receipt of the frame except for recording the state. The recipient can expect a BlockAckReq frame in the future to which it responds using the procedure described in 9.10.

An MSDU is sent using an acknowledgment policy of Normal Ack or Block Ack if the service class parameter in MA-UNITDATA.request primitive is set to QoSAck and of No Ack if the service class parameter in MA-UNITDATA.request primitive is set to QoSNoAck.

7.1.3.5.4 TXOP Limit subfield

The TXOP Limit subfield is an 8-bit field that is present in QoS data frames of subtypes that include CF-Poll and specifies the time limit on a TXOP granted by a QoS (+)CF-Poll frame from an HC in a BSS. In QoS data frames with subtypes that include CF-Poll, the addressed STA is granted a TXOP that begins a SIFS

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001291

period after this frame and lasts no longer than the number of 32 μs periods specified by the TXOP limit value. The range of time values is 32 μs to 8160 μs. A TXOP limit value of 0 implies that one MPDU or one QoS Null frame is to be transmitted immediately following the QoS (+)CF-Poll frame. The TXOP limit is inclusive of the PHY and IFS overhead, and an AP should account for the overhead when granting TXOPs.

7.1.3.5.5 Queue Size subfield

The Queue Size subfield is an 8-bit field that indicates the amount of buffered traffic for a given TC or TS at the non-AP STA sending this frame. The Queue Size subfield is present in QoS data frames sent by STAs associated in a BSS with bit 4 of the QoS Control field set to 1. The AP may use information contained in the Queue Size subfield to determine the TXOP duration assigned to non-AP STA.

The queue size value is the total size, rounded up to the nearest multiple of 256 octets and expressed in units of 256 octets, of all MSDUs buffered at the STA (excluding the MSDU of the present QoS data frame) in the delivery queue used for MSDUs with TID values equal to the value in the TID subfield of this QoS Control field. A queue size value of 0 is used solely to indicate the absence of any buffered traffic in the queue used for the specified TID. A queue size value of 254 is used for all sizes greater than 64 768 octets. A queue size value of 255 is used to indicate an unspecified or unknown size. If a QoS data frame is fragmented, the queue size value may remain constant in all fragments even if the amount of queued traffic changes as successive fragments are transmitted.

7.1.3.5.6 TXOP Duration Requested subfield

The TXOP Duration Requested subfield is an 8-bit field that indicates the duration, in units of 32 μs, that the sending STA desires for its next TXOP for the specified TID. The range of time values is 32 μs to 8160 μs. If the calculated TXOP duration requested is not a factor of 32 μs, that value is rounded up to the next higher integer that is a factor of 32 μs. The TXOP Duration Requested subfield is present in QoS data frames sent by non-AP STAs associated in a BSS with bit 4 of the QoS Control field set to 0. The AP may choose to assign a TXOP duration shorter than that requested in the TXOP Duration Requested subfield. A value of 0 in the TXOP Duration Requested subfield indicates that no TXOP is requested for the MSDUs for the specified TID in the current SP.

TXOP Duration Requested subfield values are not cumulative. A TXOP duration requested for a particular TID supersedes any prior TXOP duration requested for that TID. A value of 0 in the TXOP Duration Requested subfield may be used to cancel a pending unsatisfied TXOP request when its MSDU is no longer queued for transmission. The TXOP duration requested is inclusive of the PHY and IFS overhead, and a STA should account for this when attempting to determine whether a given transmission fits within a specified TXOP duration.

7.1.3.5.7 AP PS Buffer State subfield

The AP PS Buffer State subfield, defined in Figure 7-4, is an 8-bit field that indicates the PS buffer state at the AP for a non-AP STA. The AP PS Buffer State subfield is further subdivided into three subfields: Buffer State Indicated, Highest-Priority Buffered AC, and AP Buffered Load.

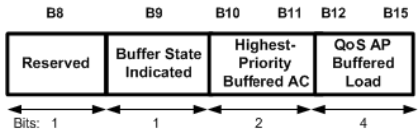

Figure 7-4—QoS AP PS Buffer State subfield

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001292

The Buffered State Indicated subfield is 1 bit in length and is used to indicate whether the AP PS buffer state is specified. A value of 1 indicates that the AP PS buffer state is specified.

The Highest-Priority Buffered AC subfield is 2 bits in length and is used to indicate the AC of the highest priority traffic remaining that is buffered at the AP, excluding the MSDU of the present frame.

The AP Buffered Load subfield is 4 bits in length and is used to indicate the total buffer size, rounded up to the nearest multiple of 4096 octets and expressed in units of 4096 octets, of all MSDUs buffered at the QoS AP (excluding the MSDU of the present QoS data frame). An AP Buffered Load field value of 15 indicates that the buffer size is greater than 57 344 octets. An AP Buffered Load subfield value of 0 is used solely to indicate the absence of any buffered traffic for the indicated highest priority buffered AC when the Buffer State Indicated bit is 1.

When the Buffered State Indicated subfield is set to 0, the Highest-Priority Buffered AC subfield and the AP Buffered Load subfield are reserved; and the values of these subfields are either unspecified or unknown.

7.1.3.6 Frame Body field

The Frame Body is a variable length field that contains information specific to individual frame types and subtypes. The minimum frame body is 0 octets. The maximum length frame body is defined by the maximum length (MSDU + ICV + IV), where integrity check value (ICV) and initialization vector (IV) are the WEP fields defined in 8.2.1.

7.1.3.7 FCS field

The FCS field is a 32-bit field containing a 32-bit CRC. The FCS is calculated over all the fields of the MAC header and the Frame Body field. These are referred to as the *calculation fields.*

The FCS is calculated using the following standard generator polynomial of degree 32:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The FCS is the ones complement of the sum (modulo 2) of the following:

a) The remainder of $x^k \times (x^{31} + x^{30} + x^{29} + \ldots + x^2 + x + 1)$ divided (modulo 2) by $G(x)$, where k is the number of bits in the calculation fields, and

b) The remainder after multiplication of the contents (treated as a polynomial) of the calculation fields by x^{32} and then division by $G(x)$.

The FCS field is transmitted commencing with the coefficient of the highest-order term.

As a typical implementation, at the transmitter, the initial remainder of the division is preset to all ones and is then modified by division of the calculation fields by the generator polynomial $G(x)$. The ones complement of this remainder is transmitted, with the highest-order bit first, as the FCS field.

At the receiver, the initial remainder is preset to all ones and the serial incoming bits of the calculation fields and FCS, when divided by $G(x)$, results in the absence of transmission errors, in a unique nonzero remainder value. The unique remainder value is the polynomial:

$$x^{31} + x^{30} + x^{26} + x^{25} + x^{24} + x^{18} + x^{15} + x^{14} + x^{12} + x^{11} + x^{10} + x^8 + x^6 + x^5 + x^4 + x^3 + x + 1$$

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001293

7.1.4 Duration/ID field in data and management frames

Within all data frames containing QoS CF-Poll, the Duration/ID field value is set to one of the following:

— One SIFS duration plus the TXOP limit, if the TXOP limit is nonzero, or

— The time required for the transmission of one MPDU of nominal MSDU size and the associated ACK frame plus two SIFS intervals, if the TXOP limit is zero.

Within all data or management frames sent in a CP by the QoS STAs outside of a controlled access phase (CAP), following a contention access of the channel, the Duration/ID field is set to one of the following values:

a) For management frames, frames with QoS Data subfield set to 0, and unicast data frames with Ack Policy subfield set to Normal Ack,

   1) The time required for the transmission of one ACK frame (including appropriate IFS values), if the frame is the final fragment of the TXOP, or

   2) The time required for the transmission of one ACK frame plus the time required for the transmission of the following MPDU and its response if required (including appropriate IFS values).

b) For unicast data frames with the Ack Policy subfield set to No Ack or Block Ack and for multicast/ broadcast frames,

   1) Zero, if the frame is the final fragment of the TXOP, or

   2) The time required for the transmission of the following MPDU and its response frame, if required (including appropriate IFS values).

c) The minimum of

   1) The time required for the transmission the pending MPDUs of the AC and the associated ACKs, if any, and applicable SIFS durations, and

   2) The time limit imposed by the MIB attribute dot11EDCATableTXOPLimit (dot11EDCAQAP-TableTXOPLimit for the AP) for that AC minus the already used time within the TXOP.

Within all data or management frames sent under HCCA, to ensure NAV protection for the entire CAP, the Duration/ID field is set to one of the following values:

— The remaining duration of the TXOP, if the frame is a nonfinal frame in a TXOP with multiple frame exchanges.

— The actual remaining time needed for this frame exchange sequence, if the frame is the sole or final frame in the TXOP.

7.2 Format of individual frame types

7.2.1 Control frames

In the following descriptions, “immediately previous” frame means a frame whose reception concluded within the SIFS interval preceding the start of the current frame.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001294

The subfields within the Frame Control field of control frames are set as illustrated in Figure 7-5.

B0										B15
Protocol Version	Type	Subtype	To DS	From DS	More Frag	Retry	Pwr Mgt	More Data	Protected Frame	Order
Protocol Version	Control	Subtype	0	0	0	0	Pwr Mgt	0	0	0
Bits : 2	2	4	1	1	1	1	1	1	1	1

Figure 7-5—Frame Control field subfield values within control frames

7.2.1.1 RTS frame format

The frame format for the RTS frame is as defined in Figure 7-6.

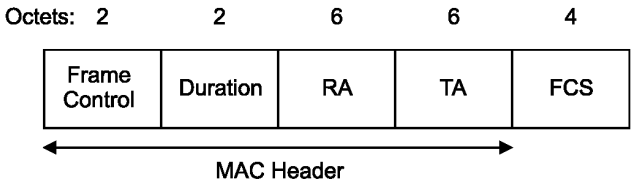

Figure 7-6—RTS frame

The RA field of the RTS frame is the address of the STA, on the WM, that is the intended immediate recipient of the pending directed data or management frame.

The TA field is the address of the STA transmitting the RTS frame.

For all RTS frames sent by non-QoS STAs, the duration value is the time, in microseconds, required to transmit the pending data or management frame, plus one CTS frame, plus one ACK frame, plus three SIFS intervals. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer. For all RTS frames sent by STAs under EDCA, following a contention access of the channel, the duration value is set in the following manner:

— If the NAV protection is desired for only the first or sole frame in the TXOP, the duration value is set to the time, in microseconds, required to transmit the pending frame, plus one CTS frame, plus one ACK frame if required, plus three SIFS intervals.

— Otherwise, the duration value is set to the remaining duration of the TXOP.

For all RTS frames sent under HCCA, the duration value is set to one of the following values:

— If the pending frame is the final frame, the duration value is set to the time, in microseconds, required to transmit the pending frame, plus one CTS frame, plus one ACK frame if required, plus three SIFS intervals.

— If the pending frame is not the final frame in the TXOP, the duration value is set to the remaining duration of the TXOP.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001295

7.2.1.2 CTS frame format

The frame format for the CTS frame is as defined in Figure 7-7.

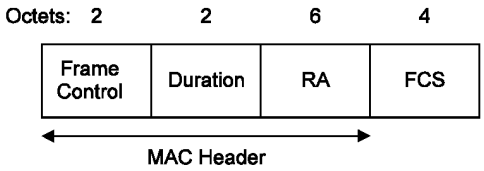

Figure 7-7—CTS frame

When the CTS frame follows an RTS frame, the RA field of the CTS frame is copied from the TA field of the immediately previous RTS frame to which the CTS is a response. When the CTS is the first frame in a frame exchange, the RA field is set to the MAC address of the transmitter.

For all CTS frames sent in response to RTS frames, the duration value is the value obtained from the Duration field of the immediately previous RTS frame, minus the time, in microseconds, required to transmit the CTS frame and its SIFS interval. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer.

At a non-QoS STA, if the CTS is the first frame in the exchange and the pending data or management frame requires acknowledgment, the duration value is the time, in microseconds, required to transmit the pending data or management frame, plus two SIFS intervals plus one ACK frame. At a non-QoS STA, if the CTS is the first frame in the exchange and the pending data or management frame does not require acknowledgment, the duration value is the time, in microseconds, required to transmit the pending data or management frame, plus one SIFS interval. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer.

For all CTS frames sent by STAs as the first frame in the exchange under EDCA, the duration value is set in the following manner:

- If the NAV protection is desired for only the first or sole frame in the TXOP the duration value is set to
  - The time, in microseconds, required to transmit the pending frame, plus one SIFS interval, plus the response frame (ACK or Block Ack), plus an additional SIFS interval, if there is a response frame, or
  - The time, in microseconds, required to transmit the pending frame, plus one SIFS interval, if there is no response frame.
- Otherwise, the duration value is set to the remaining duration of the TXOP.

For CTS frames sent under HCCA, the duration value is set to one of the following values:

- If the pending frame is the sole frame in the TXOP, the duration value is set to
  - The time, in microseconds, required to transmit the pending frame, plus one SIFS interval, plus the response frame (ACK or Block Ack), plus an additional SIFS interval, if there is a response frame, or
  - The time, in microseconds, required to transmit the pending frame, plus one SIFS interval, if there is no response frame.
- If the pending frame is not the final frame in the TXOP, the duration value is set to the remaining duration of the TXOP.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001296

7.2.1.3 ACK frame format

The frame format for the ACK frame is as defined in Figure 7-8.

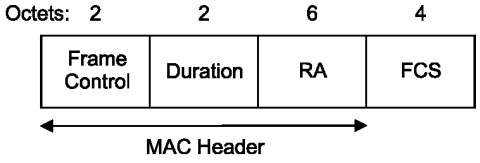

Figure 7-8—ACK frame

The RA field of the ACK frame is copied from the Address 2 field of the immediately previous directed data, management, BlockAckReq control, BlockAck control, or PS-Poll control frame.

For ACK frames sent by non-QoS STAs, if the More Fragments bit was set to 0 in the Frame Control field of the immediately previous directed data or management frame, the duration value is set to 0. In all other ACK frames, the duration value is the value obtained from the Duration/ID field of the immediately previous data, management, PS-Poll, BlockAckReq, or BlockAck frame minus the time, in microseconds, required to transmit the ACK frame and its SIFS interval. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer.

7.2.1.4 PS-Poll frame format

The frame format for the PS-Poll frame is as defined in Figure 7-9.

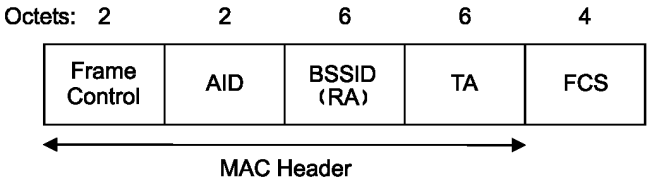

Figure 7-9—PS-Poll frame

The BSSID is the address of the STA contained in the AP. The TA field is the address of the STA transmitting the frame. The AID is the value assigned to the STA transmitting the frame by the AP in the association response frame that established that STA's current association.

The AID value always has its two MSBs each set to 1.

7.2.1.5 CF-End frame format

The frame format for the CF-End frame is as defined in Figure 7-10.

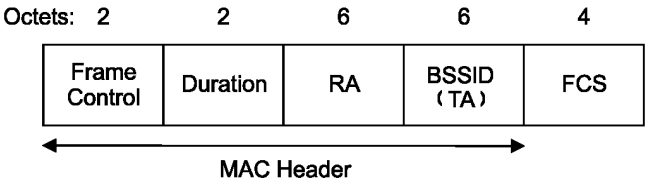

Figure 7-10—CF-End frame

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001297

The BSSID field is the address of the STA contained in the AP. The RA field is the broadcast group address.

The Duration field is set to 0.

7.2.1.6 CF-End+CF-Ack frame format

The frame format for the CF-End+CF-Ack frame is as defined in Figure 7-11.

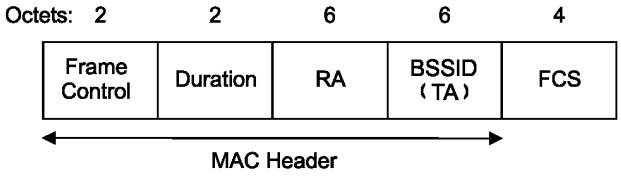

Figure 7-11—CF-End+CF-Ack frame

The BSSID field is the address of the STA contained in the AP. The RA field is the broadcast group address.

The Duration field is set to 0.

7.2.1.7 Block Ack Request (BlockAckReq) frame format

The frame format of the BlockAckReq frame is defined in Figure 7-12.

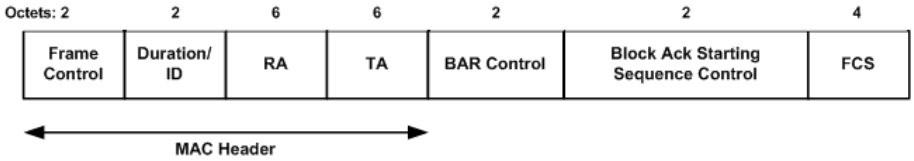

Figure 7-12—BlockAckReq frame

The Duration/ID field value is greater than or equal to the time[16], in microseconds, required to transmit one ACK or BlockAck frame, as applicable, plus one SIFS interval. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer.

The RA field of the BlockAckReq frame is the address of the recipient STA.

The TA field is the address of the STA transmitting the BlockAckReq frame.

The BAR Control field is shown in Figure 7-13.

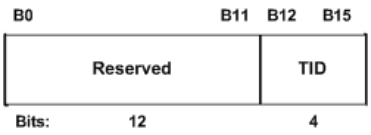

Figure 7-13—BAR Control field

[16]To allow the possibility of time remaining in the TXOP, which the sender may use to schedule other transmissions.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001298

The TID subfield of the BAR Control field contains the TID for which a BlockAck frame is requested.

The Block Ack Starting Sequence Control field is shown in Figure 7-14. The Starting Sequence number subfield is the sequence number of the first MSDU for which this BlockAckReq is sent. The Fragment Number subfield is always set to 0.

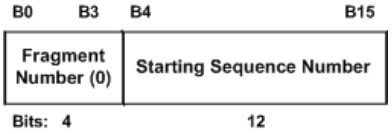

Figure 7-14—Block Ack Starting Sequence Control field

7.2.1.8 Block Ack (BlockAck) frame format

The frame format of the BlockAck frame is defined in Figure 7-15.

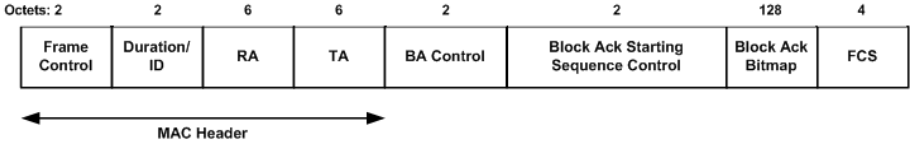

Figure 7-15—BlockAck frame

If the BlockAck frame is sent in response to the BlockAckReq frame, the Duration/ID field value is the value obtained from the Duration/ID field of the immediate BlockAckReq frame, minus the time, in microseconds, required to transmit the BlockAck frame and its SIFS interval. If the BlockAck frame is not sent in response to the BlockAckReq, the Duration/ID field value is greater than (subject to the TXOP limit) or equal to the time[17] for transmission of an ACK frame plus a SIFS interval. If the calculated duration includes a fractional microsecond, that value is rounded to the next higher integer.

The RA field of the BlockAck frame is the address of the recipient STA that requested the Block Ack.

The TA field is the address of the STA transmitting the BlockAck frame.

The BA Control field defined in Figure 7-16 consists of the TID subfield.

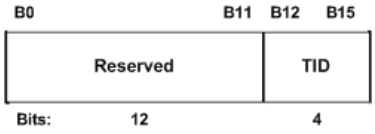

Figure 7-16—BA Control field

The Block Ack Starting Sequence Control field is defined in 7.2.1.7 and is set to the same value as in the immediately previously received BlockAckReq frame.

The Block Ack Bitmap field is 128 octets in length and is used to indicate the receiving status of up to 64 MSDUs. Bit position *n* of the Block Ack bitmap, if set to 1, acknowledges receipt of an MPDU with an

[17]The default values for TXOP limit are expressed in milliseconds and are multiples of 32 μs.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001299

MPDU sequence control value equal to (Block Ack Starting Sequence Control + *n*). Bit position n of the Block Ack bitmap, if set to 0, indicates that an MPDU with MPDU sequence control value equal to (Block Ack Starting Sequence Control + n) has not been received. For unused fragment numbers of an MSDU, the corresponding bits in the bitmap are set to 0.

7.2.2 Data frames

The frame format for a data frame is dependent on the QoS subfield of the Subtype field and is as defined in Figure 7-17.

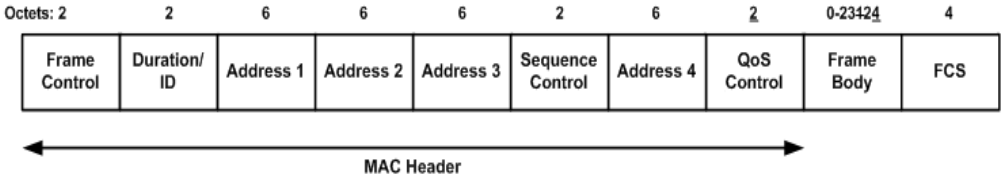

Figure 7-17—Data frame

Data frames with a value of 1 in the QoS subfield of the Subtype field are collectively referred to as *QoS data frames*. Each of these data subtypes contains QoS in their names, and this frame format is distinguished by the presence of a QoS Control field in the MAC header. Data frames with a value of 0 in the QoS subfield of the Subtype field do not have the QoS Control field.

A QoS STA always uses QoS data frames for data transmissions to other QoS STAs. A QoS STA uses frames with the QoS subfield of the Subtype field set to 0 for data transmissions to non-QoS STAs. A non-QoS STA always uses frames with the QoS subfield of the Subtype field set to 0 for data transmissions to other STAs. All STAs use frames with the QoS subfield of the Subtype field set to 0 for broadcast data frames unless a transmitting STA knows that all STAs in a BSS have QoS capability, in which case the transmitting STAs use QoS data frames. All STAs use frames with the QoS subfield of the Subtype field set to 0 for multicast data frames unless it is known to the transmitter that all STAs in the BSS that are members of the multicast group have QoS capability, in which case STAs use QoS data frames.

The content of the address fields of data frames are dependent upon the values of the To DS and From DS fields in the Frame Control field and are defined in Table 7-7. Where the content of a field is shown as not applicable (N/A), the field is omitted. Note that Address 1 always holds the receiver address of the intended receiver (or, in the case of multicast frames, receivers), and that Address 2 always holds the address of the STA that is transmitting the frame.

Table 7-7—Address field contents

To DS	From DS	Address 1	Address 2	Address 3	Address 4
0	0	RA = DA	TA = SA	BSSID	N/A
0	1	RA = DA	TA = BSSID	SA	N/A
1	0	RA = BSSID	TA = SA	DA	N/A
1	1	RA	TA	DA	SA

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001300

A STA uses the contents of the Address 1 field to perform address matching for receive decisions. In cases where the Address 1 field contains a group address, the BSSID also is validated to ensure that the broadcast or multicast originated from a STA in the BSS of which the receiving STA is a member.

A STA uses the contents of the Address 2 field to direct the acknowledgment if an acknowledgment is necessary.

The DA field is the destination of the MSDU (or fragment thereof) in the Frame Body field.

The SA field is the address of the MAC entity that initiated the MSDU (or fragment thereof) in the Frame Body field.

The RA field is the unicast address of the STA that is the immediate intended receiver of the frame or the multicast or broadcast address of the STAs that are the immediate intended receivers of the frame.

The TA field is the address of the STA that is transmitting the frame.

The BSSID of the Data frame is determined as follows:

a) If the STA is an AP or is associated with an AP, the BSSID is the address currently in use by the STA contained in the AP.

b) If the STA is a member of an IBSS, the BSSID is the BSSID of the IBSS.

The Sequence Control field is defined in 7.1.3.4. The Sequence Control field for QoS (+)Null frames is ignored by the receiver upon reception.

The QoS Control field is defined in 7.1.3.5.

The frame body consists of the MSDU, or a fragment thereof, and a security header and trailer (if and only if the Protected Frame subfield in the Frame Control field is set to 1). The frame body is null (0 octets in length) in data frames of subtype Null (no data), CF-Ack (no data), CF-Poll (no data), and CF-Ack+CF-Poll (no data), regardless of the encoding of the QoS subfield in the Frame Control field.

For data frames of subtype Null (no data), CF-Ack (no data), CF-Poll (no data), and CF-Ack+CF-Poll (no data) and for the corresponding QoS data frame subtypes, the Frame Body field is omitted; these subtypes are used for MAC control purposes. For data frames of subtypes Data, Data+CF-Ack, Data+CF-Poll, and Data+CF-Ack+CF+Poll and for the corresponding four QoS data frame subtypes, the Frame Body field contains all of, or a fragment of, an MSDU after any encapsulation for security.

The maximum length of the Frame Body field can be determined from the maximum MSDU length plus any overhead from encapsulation for encryption (i.e., it is always possible to send a maximum length MSDU, with any encapsulations provided by the MAC layer within a single data MPDU).

Within all data frames sent by STAs during the CFP under PCF, the Duration/ID field is set to 32 768. Within all data frames sent by the QoS STA, the Duration/ID field contains a duration value as defined in 7.1.4. Within all data frames sent during the CP by non-QoS STAs, the Duration/ID field is set according to the following rules:

— If the Address 1 field contains a group address, the duration value is set to 0.

— If the More Fragments bit is set to 0 in the Frame Control field of a frame and the Address 1 field contains an individual address, the duration value is set to the time, in microseconds, required to transmit one ACK frame, plus one SIFS interval.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001301

— If the More Fragments bit is set to 1 in the Frame Control field of a frame and the Address 1 field contains an individual address, the duration value is set to the time, in microseconds, required to transmit the next fragment of this data frame, plus two ACK frames, plus three SIFS intervals.

The duration value calculation for the data frame is based on the rules in 9.6 that determine the data rate at which the control frames in the frame exchange sequence are transmitted. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer. All STAs process Duration/ID field values less than or equal to 32 767 from valid data frames (without regard for the RA, DA, and/or BSSID address values that may be present in these frames) to update their NAV settings as appropriate under the coordination function rules.

7.2.3 Management frames

The frame format for a management frame is independent of frame subtype and is as defined in Figure 7-18.

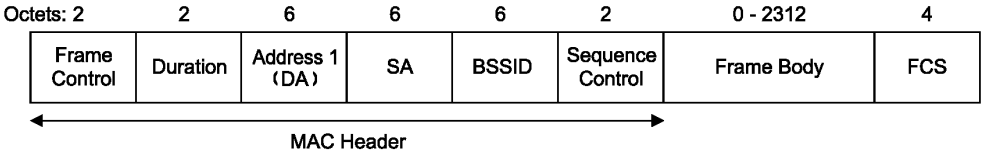

Figure 7-18—Management frame format

A STA uses the contents of the Address 1 (DA) field to perform the address matching for receive decisions. In the case where the Address 1 (DA) field contains a group address and the frame type is other than Beacon, the BSSID also is validated to ensure that the broadcast or multicast originated from a STA in the BSS of which the receiving STA is a member. If the frame type is Beacon, other address matching rules apply, as specified in 11.1.2.3. Frames of type Probe Request with a group address in the Address 1 field are processed as described in 11.1.3.2.1.

The address fields for management frames do not vary by frame subtype.

The BSSID of the management frame is determined as follows:

a) If the STA is an AP or is associated with an AP, the BSSID is the address currently in use by the STA contained in the AP.

b) If the STA is a member of an IBSS, the BSSID is the BSSID of the IBSS.

c) In management frames of subtype Probe Request, the BSSID is either a specific BSSID, or the wildcard BSSID as defined in the procedures specified in 11.1.3.

The DA field is the destination of the frame.

The SA field is the address of the STA transmitting the frame.

Within all management frames sent by STAs during the CFP under PCF, the Duration field is set to the value 32 768. Within all management frames sent by the QoS STA, the Duration field contains a duration value as defined in 7.1.4. Within all management frames sent during the CP by non-QoS STAs, the Duration field is set according to the following rules:

— If the DA field contains a group address, the duration value is set to 0.

— If the More Fragments bit is set to 0 in the Frame Control field of a frame and the DA field contains an individual address, the duration value is set to the time, in microseconds, required to transmit one ACK frame, plus one SIFS interval.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001302

— If the More Fragments bit is set to 1 in the Frame Control field of a frame, and the DA field contains an individual address, the duration value is set to the time, in microseconds, required to transmit the next fragment of this management frame, plus two ACK frames, plus three SIFS intervals.

The duration value calculation for the management frame is based on the rules in 9.6 that determine the data rate at which the control frames in the frame exchange sequence are transmitted. If the calculated duration includes a fractional microsecond, that value is rounded up to the next higher integer. All STAs process Duration field values less than or equal to 32 767 from valid management frames to update their NAV settings as appropriate under the coordination function rules.

The frame body consists of the fields followed by the information elements defined for each management frame subtype. All fields and information elements are mandatory unless stated otherwise and appear in the specified, relative order. STAs that encounter an element ID they do not recognize in the frame body of a received management frame ignore that element and continue to parse the remainder of the management frame body (if any) for additional information elements with recognizable element IDs. A STA receiving a vendor-specific IE that it does not support shall ignore the vendor-specific IE. Unused element ID codes are reserved.

Gaps may exist in the ordering of fields and elements within frames. The order that remains shall be ascending.

7.2.3.1 Beacon frame format

The frame body of a management frame of subtype Beacon contains the information shown in Table 7-8. If the dot11MultiDomainCapabilityEnabled attribute is true, a STA shall include a Country information element in the transmission of Beacon frames. Optionally, the Beacon frame format may also include the information described in either or both of FH Parameters and FH Pattern Table elements. If both FH Parameters and FH Pattern Table elements are sent, they shall describe the same hopping pattern. Note that the information described in FH Parameters and FH Pattern Table elements also may be contained in the Probe Response frame.

Table 7-8—Beacon frame body

Order	Information	Notes

Table 7-8—Beacon frame body *(continued)*

Order	Information	Notes
10	Traffic indication map (TIM)	The TIM information element is present only within Beacon frames generated by APs.
11	Country	The Country information element shall be present when dot11MultiDomainCapabilityEnabled is true or dot11SpectrumManagementRequired is true.
12	FH Parameters	FH Parameters as specified in 7.3.2.10 may be included if dot11MultiDomainCapabilityEnabled is true.
13	FH Pattern Table	FH Pattern Table information as specified in 7.3.2.11 may be included if dot11MultiDomainCapabilityEnabled is true.
14	Power Constraint	Power Constraint element shall be present if dot11SpectrumManagementRequired is true.
15	Channel Switch Announcement	Channel Switch Announcement element may be present if dot11SpectrumManagementRequired is true.
16	Quiet	Quiet element may be present if dot11SpectrumManagementRequired is true.
17	IBSS DFS	IBSS DFS element shall be present if dot11SpectrumManagementRequired is true in an IBSS.
18	TPC Report	TPC Report element shall be present if dot11SpectrumManagementRequired is true.
19	ERP Information	The ERP Information element is present within Beacon frames generated by STAs using extended rate PHYs (ERPs) defined in Clause 19 and is optionally present in other cases.
20	Extended Supported Rates	The Extended Supported Rates element is present whenever there are more than eight supported rates, and it is optional otherwise.
21	RSN	The RSN information element shall be present within Beacon frames generated by STAs that have dot11RSNAEnabled set to TRUE.
22	BSS Load	The BSS Load element is present when dot11QosOption-Implemented and dot11QBSSLoadImplemented are both true.
23	EDCA Parameter Set	The EDCA Parameter Set element is present when dot11QosOptionImplemented is true and the QoS Capability element is not present.
24	QoS Capability	The QoS Capability element is present when dot11QosOption-Implemented is true and EDCA Parameter Set element is not present.
Last	Vendor Specific	One or more vendor-specific information elements may appear in this frame. This information element follows all other information elements.

7.2.3.2 IBSS ATIM frame format

The frame body of a management frame of subtype ATIM is null.

7.2.3.3 Disassociation frame format

The frame body of a management frame of subtype Disassociation contains the information shown in Table 7-9.

Last	Vendor Specific	One or more vendor-specific information elements may appear in this frame. This information element follows all other information elements.

7.2.3.8 Probe Request frame format

The frame body of a management frame of subtype Probe Request contains the information shown in Table 7-14. If the dot11MultiDomainCapabilityEnabled attribute is true, a STA may include a Request information element in the Probe Request frame. The format of the Request information element is specified in 7.3.2.12.

Table 7-14—Probe Request frame body

Order	Information	Notes
1	SSID	
2	Supported rates	
3	Request information	May be included if dot11MultiDomainCapabilityEnabled is true.
4	Extended Supported Rates	The Extended Supported Rates element is present whenever there are more than eight supported rates, and it is optional otherwise.
Last	Vendor Specific	One or more vendor-specific information elements may appear in this frame. This information element follows all other information elements.

7.2.3.9 Probe Response frame format

The frame body of a management frame of subtype Probe Response contains the information shown in Table 7-15. If the dot11MultiDomainCapabilityEnabled attribute is true, the Probe Response frame contains a Country information element and all information elements identified by the Requested Element IDs of a Request information element. Note that the information returned as a result of a Probe Request frame with a Request information element may include the FH parameters and/or the FH Pattern Table possibly replicating optional elements identified by orders 12 and 13.

A STA shall return only the information elements that it supports. In an improperly formed Request information element, a STA may ignore the first information element requested that is not ordered properly and all subsequent information elements requested. In the probe response frame, the STA shall return the requested information elements in the same order as requested in the Request information element.

7.2.3.12 Action frame format

The frame body of a management frame of subtype Action contains the information shown in Table 7-19.

Table 7-19—Action frame body

Order	Information
1	Action
Last	One or more vendor-specific information elements may appear in this frame. This information element follows all other information elements.

7.3 Management frame body components

7.3.1 Fields that are not information elements

7.3.1.1 Authentication Algorithm Number field

The Authentication Algorithm Number field indicates a single authentication algorithm. The length of the Authentication Algorithm Number field is 2 octets. The Authentication Algorithm Number field is illustrated in Figure 7-19. The following values are defined for authentication algorithm number:

Authentication algorithm number = 0: Open System

Authentication algorithm number = 1: Shared Key

All other values of authentication number are reserved.

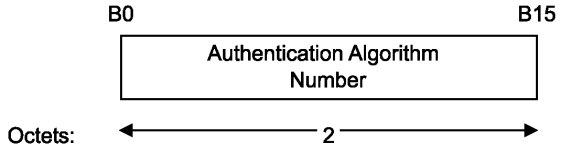

Figure 7-19—Authentication Algorithm Number field

7.3.1.2 Authentication Transaction Sequence Number field

The Authentication Transaction Sequence Number field indicates the current state of progress through a multistep transaction. The length of the Authentication Transaction Sequence Number field is 2 octets. The Authentication Transaction Sequence Number field is illustrated in Figure 7-20.

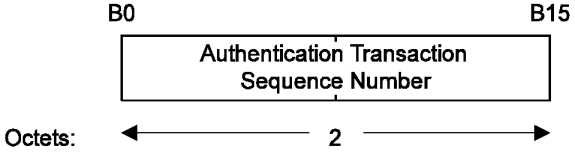

Figure 7-20—Authentication Transaction Sequence Number field

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001310

7.3.1.3 Beacon Interval field

The Beacon Interval field represents the number of time units (TUs) between target beacon transmission times (TBTTs). The length of the Beacon Interval field is 2 octets. The Beacon Interval field is illustrated in Figure 7-21.

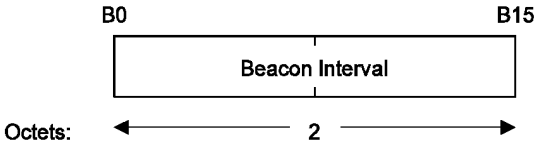

Figure 7-21—Beacon Interval field

7.3.1.4 Capability Information field

The Capability Information field contains a number of subfields that are used to indicate requested or advertised optional capabilities.

The length of the Capability Information field is 2 octets. The format of the Capability Information field is defined in Figure 7-22. No subfield is supplied for ERP as a STA supports ERP operation if it includes all of the Clause 19 mandatory rates in its supported rate set.

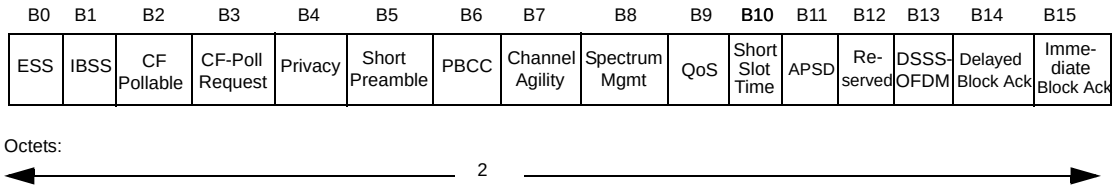

Figure 7-22—Capability Information field

Each Capability Information subfield is interpreted according to the management frame subtype, as defined in this subclause.

APs set the ESS subfield to 1 and the IBSS subfield to 0 within transmitted Beacon or Probe Response management frames. STAs within an IBSS set the ESS subfield to 0 and the IBSS subfield to 1 in transmitted Beacon or Probe Response management frames.

STAs set the QoS, CF-Pollable, and CF-Poll Request subfields in Association and Reassociation Request management frames according to Table 7-20.

Table 7-20—STA usage of QoS, CF-Pollable, and CF-Poll Request

QoS	CF-Pollable	CF-Poll request	Meaning
0	0	0	STA is not CF-Pollable
0	0	1	STA is CF-Pollable, not requesting to be placed on the CF-Polling list
0	1	0	STA is CF-Pollable, requesting to be placed on the CF-Polling list
0	1	1	STA is CF-Pollable, requesting never to be polled

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001311

Table 7-20—STA usage of QoS, CF-Pollable, and CF-Poll Request *(continued)*

QoS	CF-Pollable	CF-Poll request	Meaning
1	0	0	QoS STA requesting association in a QoS BSS
1	0	1	Reserved
1	1	0	Reserved
1	1	1	Reserved

APs set the CF-Pollable and CF-Poll Request subfields in Beacon and Probe Response management frames according to Table 7-21. A non-QoS AP sets the CF-Pollable and CF-Poll Request subfield values in Association Response and Reassociation Response management frames equal to the values in the last Beacon or Probe Response frame that it transmitted.

Table 7-21—AP usage of QoS, CF-Pollable, and CF-Poll Request

QoS	CF-Pollable	CF-Poll Request	Meaning
0	0	0	No PC at non-QoS AP
0	0	1	PC at non-QoS AP for delivery only (no polling)
0	1	0	PC at non-QoS AP for delivery and polling
0	1	1	Reserved
1	0	0	QoS AP (HC) does not use CFP for delivery of unicast data frames
1	0	1	QoS AP (HC) uses CFP for delivery, but does not send CF-Polls to non-QoS STAs
1	1	0	QoS AP (HC) uses CFP for delivery, and sends CF-Polls to non-QoS STAs
1	1	1	Reserved

APs set the Privacy subfield to 1 within transmitted Beacon, Probe Response, Association Response, and Reassociation Response management frames if data confidentiality is required for all data frames exchanged within the BSS. If data confidentiality is not required, the Privacy subfield is set to 0.

In an RSNA, non-AP STAs in an ESS set the Privacy subfield to 0 within transmitted Association and Reassociation Request management frames. APs ignore the Privacy subfield within received Association and Reassociation Request management frames.

STAs within an ESS set the Privacy subfield to 1 in DLS Request and DLS Response frames if encryption is required for all data frames exchanged. If encryption is not required, the Privacy subfield is set to 0.

STAs within an IBSS set the Privacy subfield to 1 in transmitted Beacon or Probe Response management frames if data confidentiality is required for all data frames exchanged within the IBSS. If data confidentiality is not required, STAs in an IBSS set the Privacy subfield to 0 within these management frames.

STAs that include the RSN information element in Beacon and Probe Response frames shall set the Privacy subfield to 1 in any frame that includes the RSN information element.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001312

APs (as well as STAs in IBSSs) shall set the Short Preamble subfield to 1 in transmitted Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs to indicate that the use of the short preamble, as described in 18.2.2.2, is allowed within this BSS. To indicate that the use of the short preamble is not allowed, the Short Preamble subfield shall be set to 0 in Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs transmitted within the BSS.

ERP STAs shall set the MIB variable dot11ShortPreambleOptionImplemented to true as all ERP devices support both long and short preamble formats.

STAs shall set the Short Preamble subfield to 1 in transmitted Association Request and Reassociation Request management frames and in DLS Request and DLS Response frames when the MIB attribute dot11ShortPreambleOptionImplemented is true. Otherwise, STAs shall set the Short Preamble subfield to 0.

APs (as well as STAs in IBSSs) shall set the PBCC subfield to 1 in transmitted Beacon, Probe Response, Association Response, and Reassociation Response management frames to indicate that the packet binary convolutional code (PBCC) modulation option, as described in 18.4.6.6 and 19.6, is allowed within this BSS. To indicate that the PBCC modulation option is not allowed, the PBCC subfield shall be set to 0.

STAs shall set the PBCC subfield to 1 in transmitted Association Request, Reassociation Request, DLS Request, and DLS Response frames when the MIB attribute dot11PBCCOption-Implemented is true. Otherwise, STAs shall set the PBCC subfield to 0.

Bit 7 of the Capabilities Information field shall be used to indicate Channel Agility capability by the High Rate direct sequence spread spectrum (HR/DSSS) PHY or ERP. STAs shall set the Channel Agility bit to 1 when Channel Agility is in use and shall set it to 0 otherwise.

A STA shall set the Spectrum Management subfield in the Capability Information field to 1 if the STA's dot11SpectrumManagementRequired is true; otherwise, it shall be set to 0.

STAs set the QoS subfield to 1 within the Capability Information field when the MIB attribute dot11Qos-OptionImplemented is true and set it to 0 otherwise.

STAs shall set the Short Slot Time subfield to 1 in transmitted Association Request, Reassociation Request, DLS Request, and DLS Response MMPDUs when the MIB attribute dot11ShortSlotTime-OptionImplemented and dot11ShortSlotTimeOptionEnabled are true. Otherwise, the STA shall set the Short Slot Time subfield to 0 in transmitted Association Request and Reassociation Request MMPDUs.

If a STA that does not support Short Slot Time associates, the AP shall use long slot time beginning at the first Beacon subsequent to the association of the long slot time STA. APs shall set the Short Slot Time subfield in transmitted Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs to indicate the currently used slot time value within this BSS.

STAs shall set the MAC variable aSlotTime to the short slot value upon transmission or reception of Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs from the BSS that the STA has joined or started and that have the short slot subfield set to 1 when the MIB attribute dot11ShortSlotTimeOptionImplemented is true. STAs shall set the MAC variable aSlotTime to the long slot value upon transmission or reception of Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs from the BSS that the STA has joined or started and that have the short slot subfield set to 0 when the MIB attribute dot11ShortSlotTimeOptionImplemented is true. STAs shall set the MAC variable aSlotTime to the long slot value at all times when the MIB attribute dot11ShortSlotTime-OptionImplemented is false. When the dot11ShortSlotTimeOptionImplemented MIB attribute is not present, or when the PHY supports only a single slot time value, then the STA shall set the MAC variable aSlotTime to the slot value appropriate for the attached PHY.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001313

For IBSS, the Short Slot Time subfield shall be set to 0.

APs set the APSD subfield to 1 within the Capability Information field when the MIB attribute dot11APSDOptionImplemented is true and set it to 0 otherwise. STAs always set this subfield to 0.

APs as well as STAs in IBSSs shall set the DSSS-OFDM subfield to 1 in transmitted Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs to indicate that the use of direct sequence spread spectrum with orthogonal frequency division multiplexing (DSSS-OFDM), as described in 19.7, is allowed within this BSS or by STAs that want to use DSSS-OFDM within an IBSS. To indicate that the use of DSSS-OFDM is not allowed, the DSSS-OFDM subfield shall be set to 0 in Beacon, Probe Response, Association Response, and Reassociation Response MMPDUs transmitted within the BSS.

STAs shall set the DSSS-OFDM subfield to 1 in transmitted Association Request, Reassociation Request, DLS Request, and DLS Response MMPDUs when the MIB attribute dot11DSSS-OFDMOptionImplemented and dot11DSSS-OFDMOptionEnabled are true. Otherwise, STAs shall set the DSSS-OFDM subfield to 0 in transmitted Association Request and Reassociation Request MMPDUs.

STAs set the Delayed Block Ack subfield to 1 within the Capability Information field when the MIB attribute dot11DelayedBlockAckOptionImplemented is true and set it to 0 otherwise.

STAs set the Immediate Block Ack subfield to 1 within the Capability Information field when the MIB attribute dot11ImmediateBlockAckOptionImplemented is true and set it to 0 otherwise.

Unused bits of the Capability Information field are reserved.

7.3.1.5 Current AP Address field

The Current AP Address field is the MAC address of the AP with which the STA is currently associated. The length of the Current AP Address field is 6 octets. The Current AP Address field is illustrated in Figure 7-23.

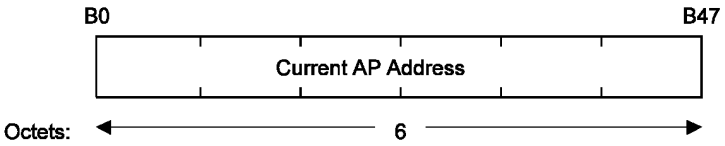

Figure 7-23—Current AP Address field

7.3.1.6 Listen Interval field

The Listen Interval field is used to indicate to the AP how often a STA in power save mode wakes to listen to Beacon management frames. The value of this parameter is the STA's Listen Interval parameter of the MLME-ASSOCIATE.request primitive and is expressed in units of Beacon Interval. The length of the Listen Interval field is 2 octets. The Listen Interval field is illustrated in Figure 7-24.

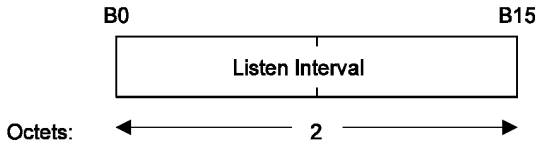

Figure 7-24—Listen Interval field

An AP may use the Listen Interval information in determining the lifetime of frames that it buffers for a STA.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001314

7.3.1.7 Reason Code field

This Reason Code field is used to indicate the reason that an unsolicited notification management frame of type Disassociation, Deauthentication, DELTS, DELBA, or DLS Teardown was generated. The length of the Reason Code field is 2 octets. The Reason Code field is illustrated in Figure 7-25.

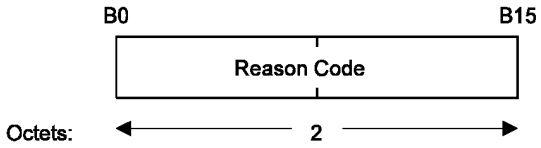

Figure 7-25—Reason Code field

The reason codes are defined in Table 7-22.

Table 7-22—Reason codes

Reason code	Meaning
0	Reserved
1	Unspecified reason
2	Previous authentication no longer valid
3	Deauthenticated because sending STA is leaving (or has left) IBSS or ESS
4	Disassociated due to inactivity
5	Disassociated because AP is unable to handle all currently associated STAs
6	Class 2 frame received from nonauthenticated STA
7	Class 3 frame received from nonassociated STA
8	Disassociated because sending STA is leaving (or has left) BSS
9	STA requesting (re)association is not authenticated with responding STA
10	Disassociated because the information in the Power Capability element is unacceptable
11	Disassociated because the information in the Supported Channels element is unacceptable
12	Reserved
13	Invalid information element, i.e., an information element defined in this standard for which the content does not meet the specifications in Clause 7
14	Message integrity code (MIC) failure
15	4-Way Handshake timeout
16	Group Key Handshake timeout
17	Information element in 4-Way Handshake different from (Re)Association Request/Probe Response/Beacon frame
18	Invalid group cipher
19	Invalid pairwise cipher
20	Invalid AKMP
21	Unsupported RSN information element version
22	Invalid RSN information element capabilities
23	IEEE 802.1X authentication failed
24	Cipher suite rejected because of the security policy

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001315

Table 7-22—Reason codes *(continued)*

Reason code	Meaning
25–31	Reserved
32	Disassociated for unspecified, QoS-related reason
33	Disassociated because QoS AP lacks sufficient bandwidth for this QoS STA
34	Disassociated because excessive number of frames need to be acknowledged, but are not acknowledged due to AP transmissions and/or poor channel conditions
35	Disassociated because STA is transmitting outside the limits of its TXOPs
36	Requested from peer STA as the STA is leaving the BSS (or resetting)
37	Requested from peer STA as it does not want to use the mechanism
38	Requested from peer STA as the STA received frames using the mechanism for which a setup is required
39	Requested from peer STA due to timeout
45	Peer STA does not support the requested cipher suite
46–65 535	Reserved

7.3.1.8 AID field

The AID field is a value assigned by an AP during association that represents the 16-bit ID of a STA. The length of the AID field is 2 octets. The AID field is illustrated in Figure 7-26.

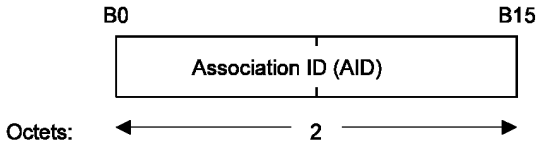

Figure 7-26—AID field

The value assigned as the AID is in the range 1–2007 and is placed in the 14 LSBs of the AID field, with the two MSBs of the AID field each set to 1 (see 7.1.3.2).

7.3.1.9 Status Code field

The Status Code field is used in a response management frame to indicate the success or failure of a requested operation. The length of the Status Code field is 2 octets. The Status Code field is illustrated in Figure 7-27.

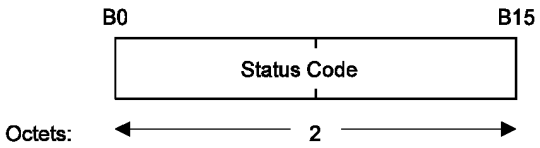

Figure 7-27—Status Code field

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001316

If an operation is successful, then the status code is set to 0. If an operation results in failure, the status code indicates a failure cause. The failure cause codes are defined in Table 7-23.

Table 7-23—Status codes

Status code	Meaning
0	Successful
1	Unspecified failure
2–9	Reserved
10	Cannot support all requested capabilities in the Capability Information field
11	Reassociation denied due to inability to confirm that association exists
12	Association denied due to reason outside the scope of this standard
13	Responding STA does not support the specified authentication algorithm
14	Received an Authentication frame with authentication transaction sequence number out of expected sequence
15	Authentication rejected because of challenge failure
16	Authentication rejected due to timeout waiting for next frame in sequence
17	Association denied because AP is unable to handle additional associated STAs
18	Association denied due to requesting STA not supporting all of the data rates in the BSSBasicRateSet parameter
19	Association denied due to requesting STA not supporting the short preamble option
20	Association denied due to requesting STA not supporting the PBCC modulation option
21	Association denied due to requesting STA not supporting the Channel Agility option
22	Association request rejected because Spectrum Management capability is required
23	Association request rejected because the information in the Power Capability element is unacceptable
24	Association request rejected because the information in the Supported Channels element is unacceptable
25	Association denied due to requesting STA not supporting the Short Slot Time option
26	Association denied due to requesting STA not supporting the DSSS-OFDM option
27–31	Reserved
32	Unspecified, QoS-related failure
33	Association denied because QoS AP has insufficient bandwidth to handle another QoS STA
34	Association denied due to excessive frame loss rates and/or poor conditions on current operating channel
35	Association (with QoS BSS) denied because the requesting STA does not support the QoS facility
36	Reserved
37	The request has been declined
38	The request has not been successful as one or more parameters have invalid values
39	The TS has not been created because the request cannot be honored; however, a suggested TSPEC is provided so that the initiating STA may attempt to set another TS with the suggested changes to the TSPEC
40	Invalid information element, i.e., an information element defined in this standard for which the content does not meet the specifications in Clause 7
41	Invalid group cipher
42	Invalid pairwise cipher
43	Invalid AKMP
44	Unsupported RSN information element version

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001317

Table 7-23—Status codes *(continued)*

Status code	Meaning
45	Invalid RSN information element capabilities
46	Cipher suite rejected because of security policy
47	The TS has not been created; however, the HC may be capable of creating a TS, in response to a request, after the time indicated in the TS Delay element
48	Direct link is not allowed in the BSS by policy
49	The Destination STA is not present within this BSS
50	The Destination STA is not a QoS STA
51	Association denied because the ListenInterval is too large
52–65 535	Reserved

7.3.1.10 Timestamp field

This field represents the value of the timing synchronization function (TSF) timer (see 11.1) of a frame's source. The length of the Timestamp field is 8 octets. The Timestamp field is illustrated in Figure 7-28.

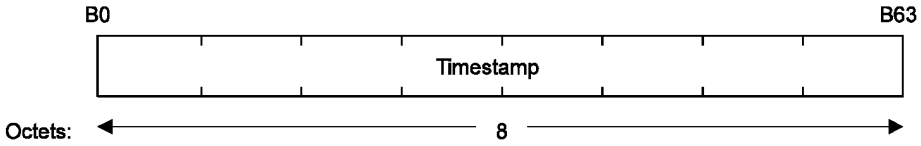

Figure 7-28—Timestamp field

7.3.1.11 Action field

The Action field provides a mechanism for specifying extended management actions. The format of the Action field is shown in Figure 7-29.

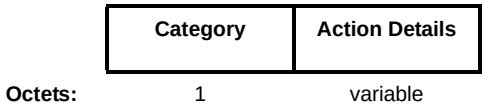

Figure 7-29—Action field

The Category field is set to one of the nonreserved values shown in Table 7-24. Action frames of a given category are referred to as <*category name*> *Action frames*. For example, frames in the QoS category are called *QoS Action frames*.

If a STA receives a unicast Action frame with an unrecognized Category field or some other syntactic error and the MSB of the Category field set to 0, then the STA shall return the Action frame to the source without change except that the MSB of the Category field is set to 1.

The Action Details field contains the details of the action. The details of the actions allowed in each category are described in the appropriate subclause referenced in Table 7-24.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001318

Table 7-24—Category values

Code	Meaning	See subclause
0	Spectrum management	7.4.1
1	QoS	7.4.2
2	DLS	7.4.3
3	Block Ack	7.4.4
4–126	Reserved	—
127	Vendor-specific	7.4.5
128–255	Error	—

Details on the additional fixed fields used within the Action field are given in 7.3.2.12 through 7.2.1.17.

7.3.1.12 Dialog Token field

The Dialog Token field is used for matching action responses with action requests when there are multiple, concurrent action requests. The length of the Dialog Token field is 1 octet. The Dialog Token field is illustrated in Figure 7-30. The value of the Dialog Token field in a request Action frame is arbitrary. The value of the Dialog Token field in a response frame is copied from each request Action frame.

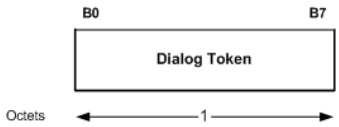

Figure 7-30—Dialog Token fixed field

7.3.1.13 DLS Timeout Value field

The DLS Timeout Value field is used in the DLS Request frame to indicate the timeout value for the direct link. The length of the DLS Timeout Value field is 2 octets. The DLS Timeout Value field is illustrated in Figure 7-31.

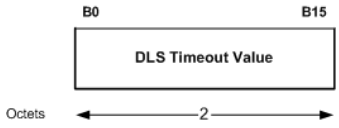

Figure 7-31—DLS Timeout Value fixed field

The DLS Timeout Value field contains the duration, in seconds, after which the direct link is terminated, if there are no frame exchanges within this duration with the peer. A value of 0 implies that the direct link is never to be terminated based on a timeout.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001319

7.3.1.14 Block Ack Parameter Set field

The Block Ack Parameter Set field is used in ADDBA frames to signal the parameters for setting up a Block Ack. The length of the Block Ack Parameter Set field is 2 octets. The Block Ack Parameter Set field is illustrated in Figure 7-32.

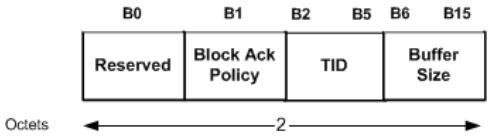

Figure 7-32—Block Ack Parameter Set fixed field

The Block Ack Policy subfield is set to 1 for immediate Block Ack and 0 for delayed Block Ack. The Block Ack Policy subfield value assigned by the originator of the QoS data frames is advisory.

The TID subfield contains the value of the TC or TS for which the Block Ack is being requested.

The Buffer Size subfield indicates the number of buffers of size 2304 octets available for this particular TID.[18]

In an ADDBA Request frame, the Buffer Size subfield is intended to provide guidance for the frame receiver to decide its reordering buffer size and is advisory only. If the Buffer Size subfield is set to 0, it implies that the originator of the Block Ack has no information to specify its value.

In an ADDBA Response frame, when the Status Code field is set to 0, the Buffer Size subfield is set to a value of at least 1.

7.3.1.15 Block Ack Timeout Value field

The Block Ack Timeout Value field is used in the ADDBA Request frame to indicate the timeout value for Block Ack. The length of the Block Ack Timeout Value field is 2 octets. The Block Ack Timeout Value field is illustrated in Figure 7-33.

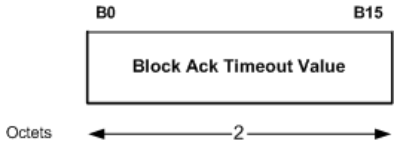

Figure 7-33—Block Ack Timeout Value fixed field

The Block Ack Timeout Value field contains the duration, in TUs, after which the Block Ack setup is terminated, if there are no frame exchanges (see 11.5.3) within this duration using this Block Ack agreement. A value of 0 disables the timeout.

[18]For buffer size, the recipient of data advertises a single scalar number that is the number of maximum-size fragment buffers available. Every buffered MPDU will consume one of these buffers regardless of whether the frame contains a whole MSDU or a fragment of an MSDU. In other words, ten maximum-size unfragmented MSDUs will consume the same amount of buffer space at the recipient as 10 small fragments.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001320

7.3.1.16 DELBA Parameter Set field

The DELBA Parameter Set field is used in a DELBA frame to terminate an already setup Block Ack. The length of the DELBA Parameters field is 2 octets. The DELBA Parameters field is illustrated in Figure 7-34.

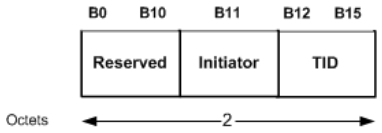

Figure 7-34—DELBA Parameters fixed field

The Initiator subfield indicates if the originator or the recipient of the data is sending this frame. It is set to 1 to indicate the originator and is set to 0 to indicate the recipient. The TID subfield indicates the TSID or the UP for which the Block Ack has been originally set up.

7.3.1.17 QoS Info field

The QoS Info field is 1 octet in length and contains capability information bits. The contents of the field are dependent on whether the STA is an AP or a non-AP STA.

The format of the QoS Info field, when sent by the AP, is defined in Figure 7-35.

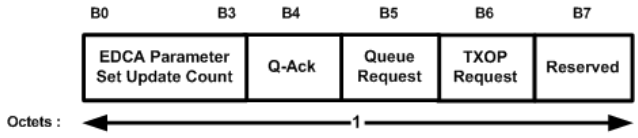

Figure 7-35—QoS Info field when sent by an AP

In the Beacon frame, the EDCA Parameter Set Update Count subfield is initially set by the AP to 0 and is incremented every time any of the AC parameters changes.

APs set the Q-Ack subfield to 1 when the MIB attribute dot11QAckOptionImplemented is true and set it to 0 otherwise.

APs set the Queue Request subfield to 1 if they can process a nonzero Queue Size subfield in the QoS Control field in QoS data frames and set it to 0 otherwise.

APs set the TXOP Request subfield to 1 if they can process a nonzero TXOP Duration Requested subfield in the QoS Control field in QoS data frames and set it to 0 otherwise.

The format of the QoS Info field, when sent by the non-AP STA, is defined in Figure 7-36.

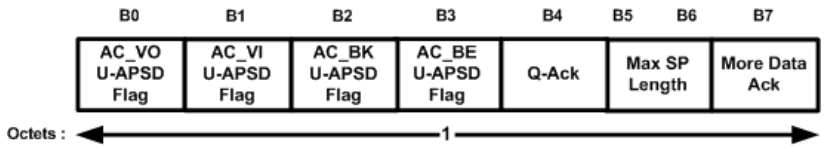

Figure 7-36—QoS Info field when set by a non-AP STA

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001321

Each of the ACs U-APSD Flag subfields is 1 bit in length and set to 1 in (Re)Association Request frames to indicate that the corresponding AC (AC_BE, AC_BK, AC_VI, or AC_VO) is both trigger-enabled and delivery-enabled. It is set to 0 in (Re)Association Request frames to indicate that the corresponding AC is neither trigger-enabled nor delivery-enabled. A TSPEC as described in 11.2.1.4 is to be used to make a particular AC exclusively either trigger-enabled or delivery-enabled. These subfields are always set to 0 when the APSD subfield in the Capability Information field is set to 0.

Non-AP STAs set the Q-Ack subfield to 1 when the MIB attribute dot11QAckOptionImplemented is true and set it to 0 otherwise.

The Max SP Length subfield is 2 bits in length and indicates the maximum number of total buffered MSDUs and MMPDUs the AP may deliver to a non-AP STA during any SP triggered by the non-AP STA. This subfield is reserved when the APSD subfield in the Capability Information field is set to 0. This subfield is also reserved when all four U-APSD flags are set to 0. If the APSD subfield in the Capability Information field is set to 1 and at least one of the four U-APSD flags is set to 1, the settings of the values in the Max SP Length subfield are defined in Table 7-25.

Table 7-25—Settings of the Max SP Length subfield

Bit 5	Bit 6	Usage
0	0	AP may deliver all buffered MSDUs and MMPDUs.
1	0	AP may deliver a maximum of two MSDUs and MMPDUs per SP.
0	1	AP may deliver a maximum of four MSDUs and MMPDUs per SP.
1	1	AP may deliver a maximum of six MSDUs and MMPDUs per SP.

Non-AP STAs set the More Data Ack subfield to 1 to indicate that they can process ACK frames with the More Data bit in the Frame Control field set to 1 and will remain in the Awake state. Non-AP STAs set the More Data Ack subfield to 0 otherwise. For APs, the More Data Ack subfield is reserved.

7.3.2 Information elements

Elements are defined to have a common general format consisting of a 1 octet Element ID field, a 1 octet length field, and a variable-length element-specific information field. Each element is assigned a unique Element ID as defined in this standard. The Length field specifies the number of octets in the Information field. See Figure 7-37.

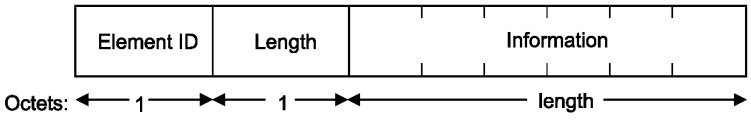

Figure 7-37—Element format

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001322

The set of valid elements is defined in Table 7-26.

Table 7-26—Element IDs

Information element	Element ID	Length (in octets)
SSID (see 7.3.2.1)	0	2 to 34
Supported rates (see 7.3.2.2)	1	3 to 10
FH Parameter Set (see 7.3.2.3)	2	7
DS Parameter Set (see 7.3.2.4)	3	3
CF Parameter Set (see 7.3.2.5)	4	8
TIM (see 7.3.2.6)	5	6 to 256
IBSS Parameter Set (see 7.3.2.7)	6	4
Country (see 7.3.2.9)	7	8 to 256
Hopping Pattern Parameters (see 7.3.2.10)	8	4
Hopping Pattern Table (see 7.3.2.11)	9	6 to 256
Request (see 7.3.2.12)	10	2 to 256
BSS Load (see 7.3.2.28)	11	7
EDCA Parameter Set (see 7.3.2.29)	12	20
TSPEC (see 7.3.2.30)	13	57
TCLAS (see 7.3.2.31)	14	2 to 257
Schedule (see 7.3.2.34)	15	16
Challenge text (see 7.3.2.8)	16	3 to 255
Reserved	17–31	
Power Constraint (see 7.3.2.15)	32	3
Power Capability (see 7.3.2.16)	33	4
TPC Request (see 7.3.2.17)	34	2
TPC Report (see 7.3.2.18)	35	4
Supported Channels (see 7.3.2.19)	36	4 to 256
Channel Switch Announcement (see 7.3.2.20)	37	5
Measurement Request (see 7.3.2.21)	38	5 to 16
Measurement Report (see 7.3.2.22)	39	5 to 24
Quiet (see 7.3.2.23)	40	8
IBSS DFS (see 7.3.2.24)	41	10 to 255

QoS Capability (see 7.3.2.35)	46	3
Reserved	47	
RSN (see 7.3.2.25)	48	36 to 256
Reserved	49	
Extended Supported Rates (see 7.3.2.14)	50	3 to 257
Reserved	51–126	

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001323

Table 7-26—Element IDs *(continued)*

Information element	Element ID	Length (in octets)
Extended Capabilities	127	2 to 257
Reserved	128–220	
Vendor Specific (see 7.3.2.26)	221	3 to 257
Reserved	222–255	

A STA that encounters an unknown or reserved element ID value in a management frame received without error shall ignore that element and shall parse any remaining management frame body for additional information elements with recognizable element ID values. The frame body components specified for many management subtypes result in elements ordered by ascending element ID.

7.3.2.1 SSID element

The SSID element indicates the identity of an ESS or IBSS. See Figure 7-38.

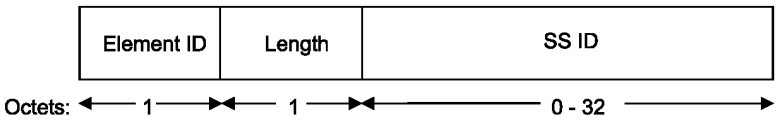

Figure 7-38—SSID element format

The length of the SSID information field is between 0 and 32 octets. A 0 length information field is used within Probe Request management frames to indicate the wildcard SSID.

7.3.2.2 Supported Rates element

The Supported Rates element specifies up to eight rates in the Operational-Rate-Set parameter, as described in the MLME-JOIN.request and MLME-START.request primitives. The information field is encoded as 1 to 8 octets, where each octet describes a single Supported Rate. If the number of rates in the Operational Rate Set exceeds eight, then an Extended Supported Rate element shall be generated to specify the remaining supported rates. The use of the Extended Supported Rates element is optional otherwise.

Within Beacon, Probe Response, Association Response, and Reassociation Response management frames, each Supported Rate contained in the BSSBasicRateSet parameter is encoded as an octet with the MSB (bit 7) set to 1, and bits 6 through 0 are set to the data rate, if necessary rounded up to the next 500kb/s, in units of 500 kb/s. For example, a 2.25 Mb/s rate contained in the BSSBasicRateSet parameter is encoded as X'85'. Rates not contained in the BSSBasicRateSet parameter are encoded with the MSB set to 0, and bits 6 through 0 are set to the appropriate value from the valid range column of the DATA_RATE row of the table in 10.4.4.2 (e.g., a 2 Mb/s rate not contained in the BSSBasicRateSet parameter is encoded as X'04'). The MSB of each Supported Rate octet in other management frame types is ignored by receiving STAs.

The Supported Rate information in Beacon and Probe Response management frames is delivered to the management entity in a STA via the BSSBasicRateSet parameter in the MLME-SCAN.confirm primitive. It is used by the management entity in a STA to avoid associating with a BSS if the STA cannot receive and transmit all the data rates in the BSSBasicRateSet parameter (see Figure 7-39).

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001324

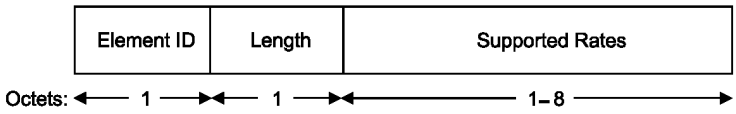

Figure 7-39—Supported rates element format

If the DSSS-OFDM bit is set to 1 in the transmitted Capability Information field of an MMPDU, then any supported rates transmitted in that frame that include rates that are common to both DSSS-OFDM and ERP-OFDM shall be interpreted by receiving and transmitting STA to indicate support for both DSSS-OFDM and ERP-OFDM at the indicated rate. However, if any of those rates are indicated as basic (a rate in the BSSBasicRateSet parameter), then the basic rate designation shall be interpreted by receiving and transmitting STA to apply only for the ERP-OFDM modulation and rate. If the PBCC bit is set to 1 in the transmitted capability field of an MMPDU, then any supported rates transmitted in that frame that include rates that are common to both PBCC and CCK shall be interpreted by receiving and transmitting STA to indicate support for both PBCC and CCK at the indicated rate. However, if any of those rates are indicated as basic, then the basic rate designation shall be interpreted by receiving and transmitting STA to apply only for the CCK modulation and rate. That is, if the rate is indicated as basic, the basic designation does not apply to DSSS-OFDM, PBCC, or ERP-PBCC.

7.3.2.3 FH Parameter Set element

The FH Parameter Set element contains the set of parameters necessary to allow synchronization for STAs using an FH PHY. The information field contains Dwell Time, Hop Set, Hop Pattern, and Hop Index parameters. The total length of the information field is 5 octets. See Figure 7-40.

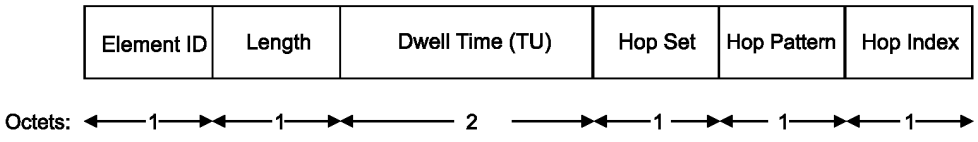

Figure 7-40—FH Parameter Set element format

The Dwell Time field is 2 octets in length and contains the dwell time in TU.

The Hop Set field identifies the current set (dot11CurrentSet) of hop patterns and is a single octet.

The Hop Pattern field identifies the current pattern (dot11CurrentPattern) within a set of hop patterns and is a single octet.

The Hop Index field selects the current index (dot11CurrentIndex) within a pattern and is a single octet.

The description of the attributes used in this subclause can be found in 14.8.2.

7.3.2.4 DS Parameter Set element

The DS Parameter Set element contains information to allow channel number identification for STAs using a DSSS PHY. The information field contains a single parameter containing the dot11CurrentChannel-Number (see 15.4.6.2 for values). The length of the dot11CurrentChannelNumber parameter is 1 octet. See Figure 7-41.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001325

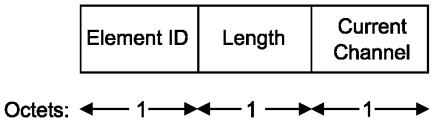

Figure 7-41—DS Parameter Set element format

7.3.2.5 CF Parameter Set element

The CF Parameter Set element contains the set of parameters necessary to support the PCF. The information field contains the CFPCount, CFPPeriod, CFPMaxDuration, and CFPDurRemaining fields. The total length of the information field is 6 octets. See Figure 7-42.

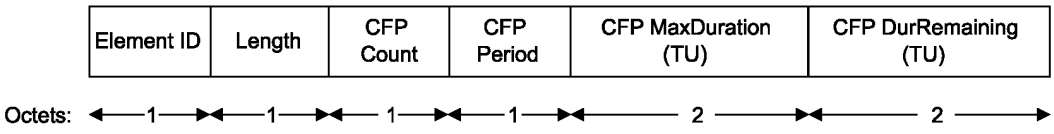

Figure 7-42—CF Parameter Set element format

CFPCount indicates how many delivery traffic indication messages (DTIMs) (including the current frame) appear before the next CFP start. A CFPCount of 0 indicates that the current DTIM marks the start of the CFP.

CFPPeriod indicates the number of DTIM intervals between the start of CFPs. The value is an integral number of DTIM intervals.

CFPMaxDuration indicates the maximum duration, in TU, of the CFP that may be generated by this PCF. This value is used by STAs to set their NAV at the TBTT of Beacon frames that begin CFPs.

CFPDurRemaining indicates the maximum time, in TU, remaining in the present CFP, and is set to 0 in CFP Parameter elements of Beacon frames transmitted during the CP. The value of CFPDurRemaining is referenced to the immediately previous TBTT. This value is used by all STAs to update their NAVs during CFPs.

7.3.2.6 TIM

The TIM element contains four fields: DTIM Count, DTIM Period, Bitmap Control, and Partial Virtual Bitmap. See Figure 7-43.

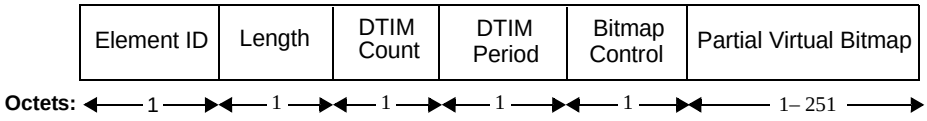

Figure 7-43—TIM element format

The Length field for this element indicates the length of the information field, which is constrained as described below.

The DTIM Count field indicates how many Beacon frames (including the current frame) appear before the next DTIM. A DTIM Count of 0 indicates that the current TIM is a DTIM. The DTIM count field is a single octet.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001326

The DTIM Period field indicates the number of beacon intervals between successive DTIMs. If all TIMs are DTIMs, the DTIM Period field has the value 1. The DTIM Period value 0 is reserved. The DTIM period field is a single octet.

The Bitmap Control field is a single octet. Bit 0 of the field contains the Traffic Indicator bit associated with Association ID 0. This bit is set to 1 in TIM elements with a value of 0 in the DTIM Count field when one or more broadcast or multicast frames are buffered at the AP. The remaining 7 bits of the field form the Bitmap Offset.

The traffic-indication virtual bitmap, maintained by the AP that generates a TIM, consists of 2008 bits, and is organized into 251 octets such that bit number N ($0 \le N \le 2007$) in the bitmap corresponds to bit number (N mod 8) in octet number $\lfloor N / 8 \rfloor$ where the low-order bit of each octet is bit number 0, and the high order bit is bit number 7. Each bit in the traffic-indication virtual bitmap corresponds to traffic buffered for a specific STA within the BSS that the AP is prepared to deliver at the time the Beacon frame is transmitted. Bit number N is 0 if there are no directed frames buffered for the STA whose Association ID is N. If any directed frames for that STA are buffered and the AP is prepared to deliver them, bit number N in the traffic-indication virtual bitmap is 1. A PC may decline to set bits in the TIM for CF-Pollable STAs it does not intend to poll (see 11.2.1.6).

The Partial Virtual Bitmap field consists of octets numbered $N1$ through $N2$ of the traffic indication virtual bitmap, where $N1$ is the largest even number such that bits numbered 1 through $(N1 \times 8) - 1$ in the bitmap are all 0 and $N2$ is the smallest number such that bits numbered $(N2 + 1) \times 8$ through 2007 in the bitmap are all 0. In this case, the Bitmap Offset subfield value contains the number $\lfloor N1/2 \rfloor$, and the Length field is set to $(N2 - N1) + 4$.

In the event that all bits other than bit 0 in the virtual bitmap are 0, the Partial Virtual Bitmap field is encoded as a single octet equal to 0, the Bitmap Offset subfield is 0, and the Length field is 4.

7.3.2.7 IBSS Parameter Set element

The IBSS Parameter Set element contains the set of parameters necessary to support an IBSS. The information field contains the ATIM Window parameter. See Figure 7-44.

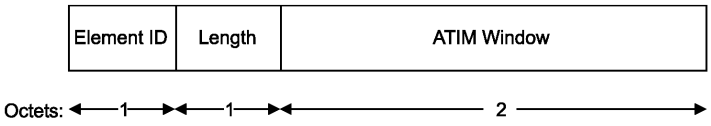

Figure 7-44—IBSS Parameter Set element format

The ATIM Window field is 2 octets in length and contains the ATIM Window length in TU.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001327

7.3.2.8 Challenge Text element

The Challenge Text element contains the challenge text within Authentication exchanges. The element information field length is dependent upon the authentication algorithm and the transaction sequence number as specified in 8.2.2.2. See Figure 7-45.

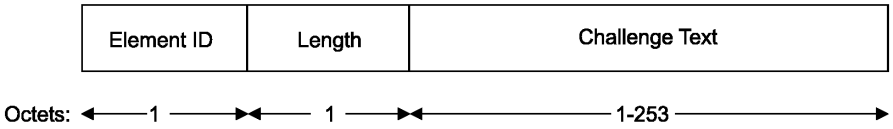

Figure 7-45—Challenge Text element format

7.3.2.9 Country information element

The Country information element contains the information required to allow a STA to identify the regulatory domain in which the STA is located and to configure its PHY for operation in that regulatory domain. The format of this information element shall be as shown in Figure 7-46.

	Element ID	Length
Country String (Octet 1)	Country String (Octet 2)	Country String (Octet 3)
First Channel Number/ Regulatory Extension Identifier	Number of Channels/ Regulatory Class	Maximum Transmit Power Level/ Coverage Class
. . .	. . .	. . .
Pad (if needed)		

Figure 7-46—Country information element format

The element ID for this information element shall be 7. The length of the information element is variable, as the element may contain more than one triplet comprising the First Channel Number, Number of Channels, and Maximum Transmit Power Level fields and referred to as subband triplets. Alternatively, where dot11RegulatoryClassesRequired is true and the First Channel Number/Regulatory Extension Identifier octet has a positive integer value of 201 or greater, then that triplet comprises the Regulatory Extension Identifier, Regulatory Class, and Coverage Class fields. Together they are referred to as a regulatory triplet. The minimum length of the information element is 8 octets.

The Country String field of the element shall be 3 octets in length. The AP shall set this field to the value contained in the dot11CountryString attribute before transmission in a Beacon or Probe Response frame. Upon reception of this element, a STA shall set the value of the dot11CountryString to the value contained in this field.

The First Channel Number/Regulatory Extension Identifier field shall be 1 octet in length. If the field has a positive integer value less than 201, then it shall contain a positive integer value that indicates the lowest channel number in the subband described in this information element. The group of channels described by each pair of the First Channel Number and the Number of Channels fields shall not have overlapping channel identifiers. [For example, the pairs (2,4) and (5,2) overlap and shall not be used together.] The First Channel Numbers shall be monotonically increasing where dot11RegulatoryClassesRequired is not true.

Where dot11RegulatoryClassesRequired is true, consecutive subband triplets following a regulatory triplet shall have monotonically increasing First Channel Number fields.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001328

The Number of Channels field of the subelement shall be 1 octet in length.

The Maximum Transmit Power Level field is a signed number and shall be 1 octet in length. It shall indicate the maximum power, in dBm, allowed to be transmitted. As the method of measurement for maximum transmit power level differs by regulatory domain, the value in this field shall be interpreted according to the regulations applicable for the domain identified by the Country String.

A regulatory class is an index into a set of values for radio equipment sets of rules. The Regulatory Class field shall be 1 octet in length.

A coverage class is an index into a set of values for aAirPropagationTime. The Coverage Class field shall be 1 octet in length.

The Coverage Class field of the regulatory triplet specifies the aAirPropagationTime characteristic used in BSS operation, as shown in Table 7-27. The characteristic aAirPropagationTime describes variations in actual propagation time that are accounted for in a BSS and, together with maximum transmit power level, allow control of BSS diameter.

The Pad field is 0 or 1 octet in length. The length of the Country information element shall be evenly divisible by 2. The Pad shall be used to add a single octet to the element if the length is not evenly divisible by 2. The value of the Pad field shall be 0.

7.3.2.10 Hopping Pattern Parameters information element

The Hopping Pattern Parameters information element contains the information necessary to allow a STA to calculate the code family using the hyperbolic congruence code (HCC) and extended HCC (EHCC) algorithms. See 9.8.2.1 for a description of the HCC and EHCC algorithms. The format of this information element shall be as shown in Figure 7-47.

Figure 7-47—Hopping Pattern Parameters information element

The Element ID of this information element shall be 8. The length of this element is 4 octets.

The Prime Radix field of this element shall indicate the value to be used as the prime radix (*N*) in the HCC and EHCC algorithms. The value of this field shall be a positive integer. The size of this field is 1 octet.

The Number of Channels field of this element shall indicate the value to be used as the maximum for the family index (*a*) in the HCC and EHCC algorithms. The value of this field shall be a positive integer and shall not be less than the prime radix minus 3 (*N*–3). The size of this field is 1 octet.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001330

7.3.2.11 Hopping Pattern Table information element

The Hopping Pattern Table information element contains the information necessary for an FH implementation to be able to create the hopping sequences necessary to operate in the regulatory domain in which the information element was received. The format of the information element shall be as shown in Figure 7-48.

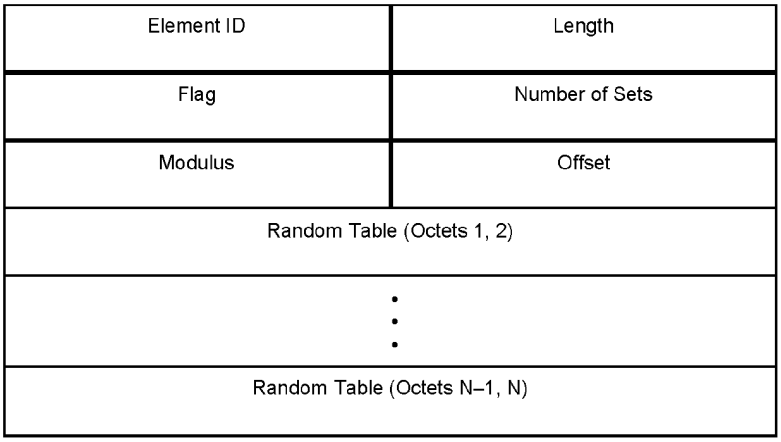

Figure 7-48—Hopping Pattern Table information element

The Element ID of this information element shall be 9. The information element is variable in length. The length of the information element is indicated by the Length field.

The Flag field indicates that a Random Table is present when the value is 1. When the flag value is 0, it indicates that a Random Table is not present and that the hop index method is to be used to determine the hopping sequence. The size of this field is 1 octet.

The Number of Sets field indicates the total number of sets within the hopping patterns. The size of this field is 1 octet.

The Modulus and Offset fields indicate the values to be used in the equations to create a hopping sequence from the Random Table information. The size of these fields are each 1 octet.

The Random Table field is a variable length field. It is a vector of single octet values that indicate the random sequence to be followed during a hopping sequence. The size of the Random Table field is found by subtracting 4 from the value of the Length field of this element.

Two equations are used to create a hopping sequence from the information in the Frequency Hopping information element and the Hopping Pattern Table information element. Equation (7-1), the Random Table Method, shall be used when the value of the Flag field of the Hopping Pattern Table information element is 1. Equation (7-2), the Hop Index Method, shall be used when the value of the Flag field of the Hopping Pattern Table information element is 0.

$$f_x(i) = [b(i) + x] \bmod (m) + q \quad (7\text{-}1)$$

$$f_x(i) = [(i-1) \times x] \bmod (m) + q \quad (7\text{-}2)$$

$$x = n \times p + s - 1 \quad (7\text{-}3)$$

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001331

where

i is the index.
m is the modulus.
q is the offset.
n is the number of sets.
p is the current pattern.
s is the current set number.

The values of *i*, *p*, and *s* are found in the Frequency Hopping information element. The values of *m*, *n*, and *q* are found in the Hopping Pattern Table information element.

7.3.2.12 Request information element

This element is placed in a Probe Request frame to request that the responding STA include the requested information in the Probe Response frame. The format of the information element shall be as shown in Figure 7-49.

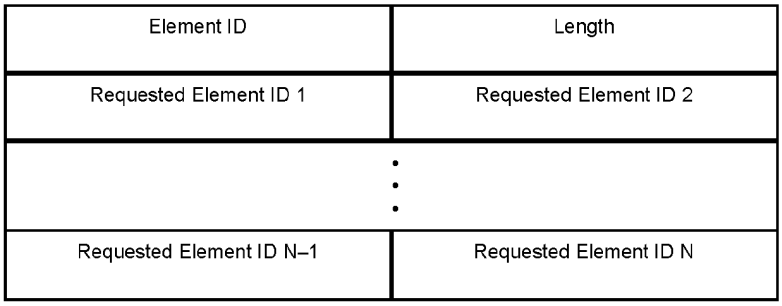

Figure 7-49—Request information element

The Element ID of this information element shall be 10. The information element is variable in length. The length of the information element is indicated in the Length field.

The Requested Element IDs are the list of elements that are to be included in the responding STA's Probe Response frame. The Requested Element IDs shall be listed in order of increasing element ID.

A STA shall return only those information elements that it supports. In an improperly formed Request information element, a STA may ignore the first information element requested that is not ordered properly and all subsequent information elements requested. In the probe response frame, the STA shall return the requested information elements in the same order requested in the Request information element of the probe request frame.

7.3.2.13 ERP Information element

The ERP Information element contains information on the presence of Clause 15 or Clause 18 STAs in the BSS that are not capable of Clause 19 (ERP-OFDM) data rates. It also contains the requirement of the ERP Information element sender (AP in a BSS or STA in an IBSS) as to the use of protection mechanisms to optimize BSS performance and as to the use of long or short Barker preambles. See Figure 7-50 for a definition of the frame element.

If one or more NonERP STAs are associated in the BSS, the Use_Protection bit shall be set to 1 in transmitted ERP Information elements.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001332

In an IBSS, the setting of the Use_Protection bit is left to the STA. In an IBSS, there is no uniform concept of association; therefore, a typical algorithm for setting the Use_Protection bit will take into account the traffic pattern and history on the network. If a member of an IBSS detects one or more NonERP STAs that are members of the same IBSS or receives a Beacon from a member of the same IBSS with the Use_Protection bit set to 1, then the Use_Protection bit should be set to 1 in the ERP Information Element of transmitted Beacon and Probe Response frames.

The NonERP_Present bit shall be set to 1 when a NonERP STA is associated with the BSS. Examples of when the NonERP present bit may additionally be set to 1 include, but are not limited to, when

a) A NonERP infrastructure or independent BSS is overlapping (a NonERP BSS may be detected by the reception of a Beacon where the supported rates contain only Clause 15 or Clause 18 rates).

b) In an IBSS, if a Beacon frame is received from one of the IBSS participants where the supported rate set contains only Clause 15 or Clause 18 rates.

c) A management frame (excluding a Probe Request) is received where the supported rate set includes only Clause 15 or Clause 18 rates.

ERP APs and ERP STAs shall invoke the use of a protection mechanism after transmission or reception of the Use_Protection bit with a value of 1 in an MMPDU to or from the BSS that the ERP AP or ERP STA has joined or started. ERP APs and ERP STAs may additionally invoke protection mechanism use at other times. ERP APs and ERP STAs may disable protection mechanism use after transmission or reception of the Use_Protection bit with a value of 0 in an MMPDU to or from the BSS that the ERP AP or ERP STA has joined or started.

When there are no NonERP STAs associated with the BSS and the ERP Information Element sender's dot11ShortPreambleOptionImplemented MIB variable is set to true, then the Barker_Preamble_Mode bit may be set to 0. The Barker_Preamble_Mode bit shall be set to 1 by the ERP Information Element sender if one or more associated NonERP STAs are not short preamble capable as indicated in their Capability Information field, or if the ERP Information Element senders dot11ShortPreambleOptionImplemented MIB variable is set to false.

If a member of an IBSS detects one or more nonshort-preamble-capable STAs that are members of the same IBSS, then the Barker_Preamble_Mode bit should be set to 1 in the transmitted ERP Information Element.

ERP APs and ERP STAs shall use long preambles when transmitting Clause 15, Clause 18, and Clause 19 frames after transmission or reception of an ERP Information Element with a Barker_Preamble_Mode value of 1 in an MMPDU to or from the BSS that the ERP AP or ERP STA has joined or started, regardless of the value of the short preamble capability bit from the same received or transmitted MMPDU that contained the ERP Information Element. ERP APs and ERP STAs may additionally use long preambles when transmitting Clause 15, Clause 18, and Clause 19 frames at other times. ERP APs and ERP STAs may use short preambles when transmitting Clause 15, Clause 18, and Clause 19 frames after transmission or reception of an ERP Information Element with a Barker_Preamble_Mode value of 0 in an MMPDU to or from the BSS that the ERP AP or ERP STA has joined or started, regardless of the value of the short preamble capability bit from the same received or transmitted MMPDU. NonERP STAs and NonERP APs may also follow the rules given in this paragraph.

Recommended behavior for setting the Use_Protection bit is contained in 9.13.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001333

The ERP Information element shall have the form shown in Figure 7-50.

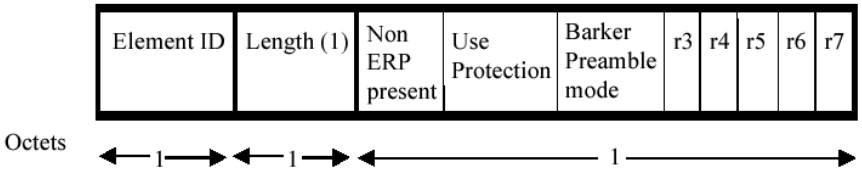

Figure 7-50—ERP Information element

Bits r3 through r7 are reserved, set to 0, and ignored on reception. Note that the length of this element is flexible and may be expanded in the future.

7.3.2.14 Extended Supported Rates element

The Extended Supported Rates element specifies the rates in the OperationalRateSet as described in the MLME_JOIN.request and MLME_START.request primitives that are not carried in the Supported Rates element. The information field is encoded as 1 to 255 octets where each octet describes a single supported rate.

Within Beacon, Probe Response, Association Response, and Reassociation Response management frames, each supported rate contained in the BSSBasicRateSet parameter, as defined in 10.3.10.1, is encoded as an octet with the MSB (bit 7) set to 1 and bits 6 through 0 are set to the appropriate value from the valid range column of the DATA_RATE row of the table in 10.4.4.2 (e.g., a 1 Mb/s rate contained in the BSSBasicRateSet parameter is encoded as X'82'). Rates not contained in the BSSBasicRateSet parameter are encoded with the MSB set to 0, and bits 6 through 0 are set to the appropriate value from the valid range column of the DATA_RATE row of the table in 10.4.4.2 (e.g., a 2 Mb/s rate not contained in the BSSBasicRateSet parameter is encoded as X'04'). The MSB of each octet in the Extended Supported Rate element in other management frame types is ignored by receiving STAs.

Extended Supported Rate information in Beacon and Probe Response management frames is used by STAs in order to avoid associating with a BSS if they do not support all the data rates in the BSSBasicRateSet parameter.

For STAs supporting eight or fewer data rates, this element is optional for inclusion in all of the frame types that include the supported rates element. For STAs supporting more than eight data rates, this element shall be included in all of the frame types that include the supported rates element.

The Extended Supported Rates element has the format shown in Figure 7-51.

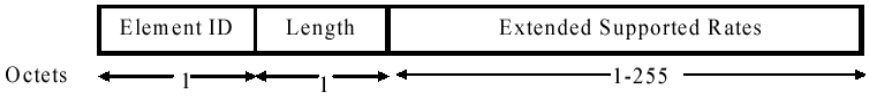

Figure 7-51—Extended Supported Rates element format

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001334

7.3.2.15 Power Constraint element

The Power Constraint element contains the information necessary to allow a STA to determine the local maximum transmit power in the current channel. The format of the Power Constraint element is shown in Figure 7-52.

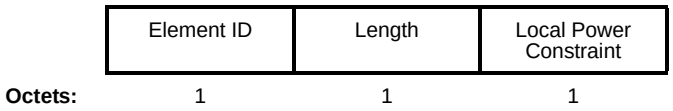

Figure 7-52—Power Constraint element format

The Length field shall be set to 1.

The Local Power Constraint field shall be set to a value that allows the mitigation requirements to be satisfied in the current channel. The field is coded as an unsigned integer in units of decibels relative to 1mW. The local maximum transmit power for a channel is thus defined as the maximum transmit power level specified for the channel in the Country element minus the local power constraint specified for the channel (from the MIB) in the Power Constraint element.

The Power Constraint element is included in Beacon frames, as described in 7.2.3.1, and Probe Response frames, as described in 7.2.3.9. The use of Power Constraint elements is described in 11.8.2.

7.3.2.16 Power Capability element

The Power Capability element specifies the minimum and maximum transmit powers with which a STA is capable of transmitting in the current channel. The format of the Power Capability element is shown in Figure 7-53.

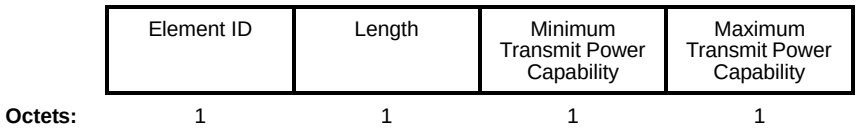

Figure 7-53—Power Capability element format

The Length field shall be set to 2.

The Minimum Transmit Power Capability field shall be set to the nominal minimum transmit power with which the STA is capable of transmitting in the current channel, with a tolerance ± 5 dB. The field is coded as a signed integer in units of decibels relative to 1 mW.

The Maximum Transmit Power Capability field shall be set to the nominal maximum transmit power with which the STA is capable of transmitting in the current channel, with a tolerance ± 5 dB. The field is coded as a signed integer in units of decibels relative to 1 mW.

The Power Capability element is included in Association Request frames, as described in 7.2.3.4, and Reassociation Request frames, as described in 7.2.3.6. The use of Power Capability elements is described in 11.8.1.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001335

7.3.2.17 TPC Request element

The TPC Request element contains a request for a STA to report transmit power and link margin information using a TPC Report element. The format of the TPC Request element is shown in Figure 7-54.

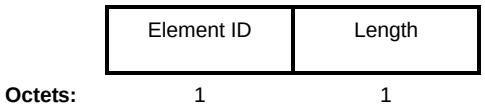

Figure 7-54—TPC Request element format

The Length field shall be set to 0.

The TPC Request element is included in TPC Request frames, as described in 7.4.1.3. The use of TPC Request elements and frames is described in 11.8.4.

7.3.2.18 TPC Report element

The TPC Report element contains transmit power and link margin information sent in response to a TPC Request element. A TPC Report element is included in a Beacon frame or Probe Response frame without a corresponding request. The format of the TPC Report element is shown in Figure 7-55.

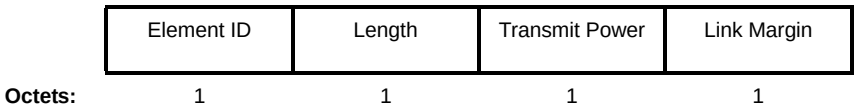

Figure 7-55—TPC Report element format

The Length field shall be set to 2.

The Transmit Power field shall be set to the transmit power used to transmit the frame containing the TPC Report element. The field is coded as a signed integer in units of decibels relative to 1 mW. The maximum tolerance for the transmit power value reported in the TPC Response element shall be ± 5 dB. This tolerance is defined as the difference, in decibels, between the reported power value and the actual EIRP of the STA (measured when transmitting 1500 octet frames).

The Link Margin field contains the link margin at the time and for the rate at which the frame containing the TPC Request element was received. The field is coded as a signed integer in units of decibels. The Link Margin field shall be set to 0 and shall be ignored when a TPC Report element is included in a Beacon frame or Probe Response frame. The measurement method of Link Margin is beyond the scope of this standard.

The TPC Report element is included in TPC Report frames, as described in 7.4.1.4; Beacon frames, as described in 7.2.3.1; and Probe Response frames, as described in 7.2.3.9. The use of TPC Report elements and frames is described in 11.8.4.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001336

7.3.2.19 Supported Channels element

The Supported Channels element contains a list of channel subbands (from those channels defined in 17.3.8.3.3) in which a STA is capable of operating. The format of the Supported Channels element is shown in Figure 7-56.

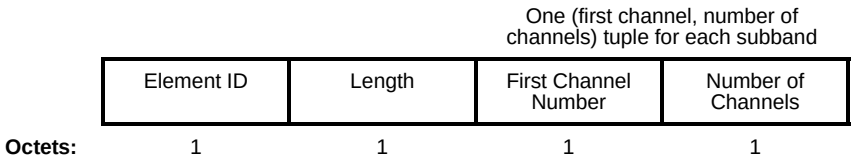

Figure 7-56—Supported Channels element format

The Length field is variable and depends on the number of subbands, defined by a First Channel Number–Number of Channels pair, that are included in the element.

The First Channel Number field shall be set to the first channel (as defined in 17.3.8.3.3) in a subband of supported channels.

The Number of Channels field shall be set to the number of channels in a subband of supported channels.

The Supported Channels element is included in Association Request frames, as described in 7.2.3.4, and Reassociation Request frames, as described in 7.2.3.6. The use of the Supported Channels element is described in 11.9.1 and 11.9.7.

7.3.2.20 Channel Switch Announcement element

The Channel Switch Announcement element is used by an AP in a BSS or a STA in an IBSS to advertise when it is changing to a new channel and the channel number of the new channel. The format of the Channel Switch Announcement element is shown in Figure 7-57.

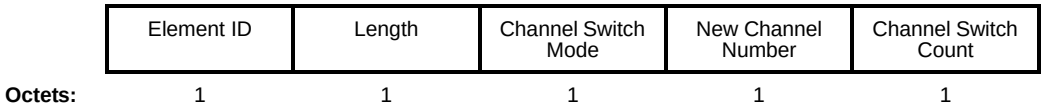

Figure 7-57—Channel Switch Announcement element format

The Length field shall be set to 3.

The Channel Switch Mode field indicates any restrictions on transmission until a channel switch. An AP in a BSS or a STA in an IBSS shall set the Channel Switch Mode field to either 0 or 1 on transmission. A Channel Switch Mode set to 1 means that the STA in a BSS to which the frame containing the element is addressed shall transmit no further frames within the BSS until the scheduled channel switch. A STA in an IBSS may treat a Channel Switch Mode field set to 1 as advisory. A Channel Switch Mode set to 0 does not impose any requirement on the receiving STA.

The New Channel Number field shall be set to the number of the channel to which the STA is moving (as defined in 17.3.8.3.3).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001337

The Channel Switch Count field either shall be set to the number of TBTTs until the STA sending the Channel Switch Announcement element switches to the new channel or shall be set to 0. A value of 1 indicates that the switch shall occur immediately before the next TBTT. A value of 0 indicates that the switch shall occur at any time after the frame containing the element is transmitted.

The Channel Switch Announcement element is included in Channel Switch Announcement frames, as described in 7.4.1.5, and may be included in Beacon frames, as described in 7.2.3.1, and Probe Response frames, as described in 7.2.3.9. The use of Channel Switch Announcement elements and frames is described in 11.9.7.

7.3.2.21 Measurement Request element

The Measurement Request element contains a request that the receiving STA undertake the specified measurement action. The format of the Measurement Request element is shown in Figure 7-58.

	Element ID	Length	Measurement Token	Measurement Request Mode (see Figure 7-59)	Measurement Type	Measurement Request
Octets:	1	1	1	1	1	variable

Figure 7-58—Measurement Request element format

	Reserved (0)	Enable	Request	Report	Reserved (0)
Bit:	0	1	2	3	4–7

Figure 7-59—Measurement Request Mode field

The Length field is variable and depends on the length of the Measurement Request field. The minimum value of the Length field is 3 (based on a minimum length for the Measurement Request field of 0 octets).

The Measurement Token shall be set to a nonzero number that is unique among the Measurement Request elements in a particular Measurement Request frame.

The Measurement Request Mode field (shown in Figure 7-59) is a bit field with the following bits defined:

— Enable bit (bit 1) indicates whether this element is used to request the destination STA to enable or disable the sending of measurement requests and autonomous measurement reports of a specified type to this STA. The Enable bit shall be set to 1 when the Request bit and Report bit are valid. The Enable bit shall be set to 0 when the Request bit and Report bit are invalid.

— Request bit (bit 2) indicates whether the STA receiving the request shall enable or disable measurement requests of the type specified in the Measurement Type field. The Request bit shall be set to 1 when enabling a measurement request. The Request bit shall be set to 0 when disabling a measurement request or when the Request bit is invalid (i.e., when the Enable bit is set to 0 or when the Measurement Type field contains a reserved measurement request type value).

— Report bit (bit 3) indicates whether the STA receiving the request shall enable or disable autonomous measurement reports of the type corresponding to the measurement report specified in the Measurement Type field. The Report bit shall be set to 1 when enabling an autonomous measurement report. The Report bit shall be set to 0 when disabling an autonomous measurement

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001338

report or when the Report bit is invalid (i.e., when the Enable bit is set to 0 or when the Measurement Type field contains a reserved measurement report type value).

— All other bits are reserved and shall be set to 0.

The use of the Enable, Request, and Report bits is also summarized in Table 7-28. See 11.9.6 for the description of how a STA shall handle requests to enable or disable measurement requests and autonomous reports.

Table 7-28—Summary of use of Enable, Request, and Report bits

Bits			Meaning of bits
Enable	Request	Report	
0	0	0	When Enable bit is set to 0, Request and Report bits are invalid and shall be set to 0.
0	0	1	Not allowed.
0	1	0	Not allowed.
0	1	1	Not allowed.
1	0	0	The transmitting STA is requesting that it be sent neither measurement requests nor autonomous measurement reports of the types indicated in the Measurement Type field.
1	1	0	The transmitting STA is indicating it will accept measurement requests and requesting it not be sent autonomous measurement reports of the types indicated in the Measurement Type field.
1	0	1	The transmitting STA is requesting it not be sent measurement requests and indicating it will accept autonomous measurement reports of the types indicated in the Measurement Type field.
1	1	1	The transmitting STA is indicating it will accept measurement requests and autonomous measurement reports of the type indicated in the Measurement Type field.

The Measurement Type field shall be set to a number that identifies a measurement request or a measurement report. The Measurement Types that have been allocated for measurement requests are shown in Table 7-29 and measurement reports are shown in Table 7-30 (in 7.3.2.22).

Table 7-29—Measurement Type definitions for measurement requests

Name	Measurement Type
Basic request	0
Clear channel assessment (CCA) request	1
Receive power indication (RPI) histogram request	2

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001339

The Measurement Request field shall be null when the Enable bit is set to 1 and shall contain the specification of the measurement request, as described in 7.3.2.21.1 through 7.3.2.21.3, when the Enable bit is set to 0.

The Measurement Request element is included in a Measurement Request frame as described in 7.4.1.1. The use of Measurement Request elements and frames is described in 11.9.6.

7.3.2.21.1 Basic request

A Measurement Type in the Measurement Request element may indicate a basic request. The response to a basic request is a basic report. It is mandatory for a STA in a BSS to generate a basic report in response to a basic request if the request is received from the AP with which it is associated, except as specified in 11.9.6. The Measurement Request field corresponding to a basic request is shown in Figure 7-60.

	Channel Number	Measurement Start Time	Measurement Duration
Octets:	1	8	2

Figure 7-60—Measurement Request field format for a basic request

The Channel Number field shall be set to the channel number for which the measurement request applies (as defined in 17.3.8.3.3).

The Measurement Start Time field shall be set to the TSF timer at the time (± 32 μs) at which the requested basic request measurement shall start. A value of 0 shall indicate it shall start immediately.

The Measurement Duration field shall be set to the duration of the requested measurement, expressed in TUs.

7.3.2.21.2 CCA request

A Measurement Type in the Measurement Request element may indicate a CCA request. A response to a CCA request is a CCA report. It is optional for a STA to generate a CCA report in response to a CCA Request. The Measurement Request field corresponding to a CCA request is shown in Figure 7-61.

	Channel Number	Measurement Start Time	Measurement Duration
Octets:	1	8	2

Figure 7-61—Measurement Request field format for a CCA request

The Channel Number field shall be set to the channel number for which the measurement request applies (as defined in 17.3.8.3.3).

The Measurement Start Time field shall be set to the TSF at the time (± 32 μs) at which the requested CCA request measurement shall start. A value of 0 shall indicate it shall start immediately.

The Measurement Duration field shall be set to the duration of the requested measurement, expressed in TUs.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001340

7.3.2.21.3 RPI histogram request

A Measurement Type in the Measurement Request element may indicate an RPI histogram request. A response to an RPI histogram request is an RPI histogram report. It is optional for a STA to generate a RPI histogram report in response to a RPI histogram request. The Measurement Request field corresponding to an RPI histogram request is shown in Figure 7-62.

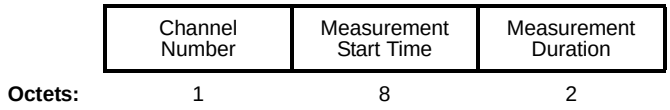

Figure 7-62—Measurement Request field format for a RPI histogram request

The Channel Number field shall be set to the channel number for which the measurement request applies (as defined in 17.3.8.3.3).

The Measurement Start Time field shall be set to the TSF at the time (± 32 μs) at which the requested RPI histogram request measurement shall start. A value of 0 shall indicate it shall start immediately.

The Measurement Duration field shall be set to the duration of the requested measurement, expressed in TUs.

7.3.2.22 Measurement Report element

The Measurement Report element contains a measurement report. The format of the Measurement Report element is shown in Figure 7-63.

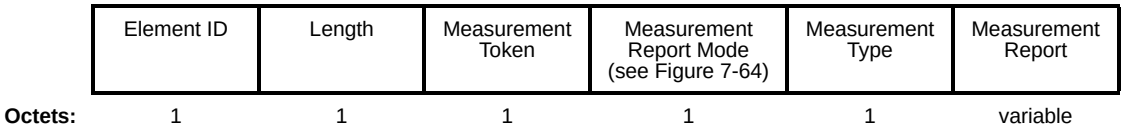

Figure 7-63—Measurement Report element format

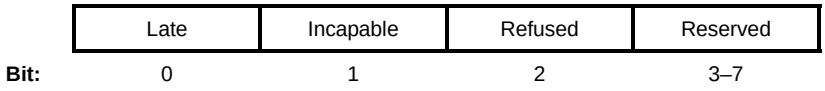

Figure 7-64—Measurement Report Mode field

The Length field is variable and depends on the length of the Measurement Report field. The minimum value of the Length field is 3.

The Measurement Token field shall be set to the Measurement Token in the corresponding Measurement Request element. If the Measurement Report element is being sent autonomously, then the Measurement Token shall be set to 0.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001341

The Measurement Report Mode field (shown in Figure 7-64) is a bit field with the following bits defined:

— Late bit (bit 0) indicates whether this STA is unable to carry out a measurement request because it received the request after the requested measurement time. The Late bit shall be set to 1 to indicate the request was too late. The Late bit shall be set to 0 to indicate the request was received in time for the measurement to be executed.

— Incapable bit (bit 1) indicates whether this STA is incapable of generating a report of the type specified in the Measurement Type field that was previously requested by the destination STA of this Measurement Report element. The Incapable bit shall be set to 1 to indicate the STA is incapable. The Incapable bit shall be set to 0 to indicate the STA is capable or the report is autonomous.

— Refused bit (bit 2) indicates whether this STA is refusing to generate a report of the type specified in the Measurement Type field that was previously requested by the destination STA of this Measurement Report element. The Refused bit shall be set to 1 to indicate the STA is refusing. The Refused bit shall be set to 0 to indicate the STA is not refusing or the report is autonomous.

— All other bits are reserved and shall be set to 0.

The Measurement Type field shall be set to a number that identifies the measurement report. The Measurement Types that have been allocated are shown in Table 7-30.

Table 7-30—Measurement Type definitions for measurement reports

Name	Measurement Type
Basic report	0
CCA report	1
RPI histogram report	2
Reserved	3–255

The Measurement Report field shall be null when the Late bit is set to 1, the Incapable bit is set to 1, or the Refused bit is set to 1. Otherwise, it shall contain the specification of the measurement report, as described in 7.3.2.22.1 through 7.3.2.22.3.

The Measurement Report element is included in a Measurement Report frame as described in 7.4.1.2. The use of Measurement Report elements and frames is described in 11.9.6.

7.3.2.22.1 Basic report

A Measurement Type in the Measurement Report element may indicate a basic report. The format of the Measurement Report field corresponding to a basic report is shown in Figure 7-65. It is mandatory for a STA to support the generation of this report.

	Channel Number	Measurement Start Time	Measurement Duration	Map (see Figure 7-66)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001342

	BSS	Orthogonal frequency division multiplexing (OFDM) Preamble	Unidentified Signal	Radar	Unmeasured	Reserved (0)
Bit:	0	1	2	3	4	5-7

Figure 7-66—Map field format

The Channel Number field shall be set to the channel number to which the basic report applies (as defined in 17.3.8.3.3).

The Measurement Start Time field shall be set to the TSF at the time (± 32 μs) at which the basic report measurement started.

The Measurement Duration field shall be set to the duration over which the basic report was measured, expressed in TUs.

The Map field is coded as a bit field, as shown in Figure 7-66, and shall contain the following bits:

— BSS bit, which shall be set to 1 when at least one valid MPDU was received in the channel during the measurement period from another BSS or IBSS. Otherwise, the BSS bit shall be set to 0.

— OFDM preamble bit, which shall be set to 1 when at least one sequence of short training symbols, as defined in 17.3.3, was detected in the channel during the measurement period without a subsequent valid Signal field (see 17.3.4). This may indicate the presence of an OFDM preamble, such as high-performance RLAN/2 (HIPERLAN/2). Otherwise, the OFDM preamble bit shall be set to 0.

— Unidentified Signal bit, which may be set to 1 when significant power is detected in the channel during the measurement period that cannot be characterized as radar, an OFDM preamble, or a valid MPDU. Otherwise, the Unidentified Signal bit shall be set to 0. The definition of significant power is implementation dependent.

— Radar bit, which shall be set to 1 when radar was detected operating in the channel during the measurement period. The algorithm to detect radar shall satisfy regulatory requirements and is outside the scope of this standard. Otherwise, the Radar bit shall be set to 0.

— Unmeasured bit, which shall be set to 1 when this channel has not been measured. Otherwise, the Unmeasured bit shall be set to 0. When the Unmeasured field is set to 1, all the other bit fields shall be set to 0.

7.3.2.22.2 CCA report

A Measurement Type in the Measurement Report element may indicate a CCA report. It is optional for a STA to support the generation of this report. The format of the Measurement Report field corresponding to a CCA report is shown in Figure 7-67.

	Channel Number	Measurement Start Time	Measurement Duration	CCA Busy Fraction
Octets:	1	8	2	1

Figure 7-67—Measurement Report field format for a CCA report

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001343

The Channel Number field shall contain the channel number to which the CCA report applies (as defined in 17.3.8.3.3).

The Measurement Start Time field shall be set to the TSF at the time (± 32 μs) at which the CCA report measurement started.

The Measurement Duration field shall be set to the duration over which the CCA report was measured, expressed in TUs.

The CCA Busy Fraction field shall contain the fractional duration over which CCA indicated the channel was busy during the measurement duration. The resolution of the CCA busy measurement is in microseconds. The CCA Busy Fraction value is defined as Ceiling (255 * [Duration CCA indicated channel was busy (microseconds)] / (1024 * [Measurement duration (TUs)])).

7.3.2.22.3 RPI histogram report

A Measurement Type in the Measurement Report element may indicate an RPI histogram report. It is optional for a STA to support the generation of this report. The format of the Measurement Report field corresponding to an RPI histogram report is shown in Figure 7-68.

	Channel Number	Measurement Start Time	Measurement Duration
Octets:	1	8	2

	RPI 0 density	RPI 1 density	RPI 2 density	RPI 3 density	RPI 4 density	RPI 5 density	RPI 6 density	RPI 7 density
Octets:	1	1	1	1	1	1	1	1

Figure 7-68—Measurement Report field format for an RPI histogram report

The Channel Number field shall be set to the channel number to which the RPI histogram report applies (as defined in 17.3.8.3.3).

The Measurement Start Time field shall be set to the TSF at the time (± 32 μs) at which the RPI histogram report measurement started.

The Measurement Duration field shall be set to the duration over which the RPI histogram report was measured, expressed in TUs.

The RPI histogram report shall contain the RPI densities observed in the channel for the eight RPI levels defined in Table 7-31. To compute the RPI densities, the STA shall measure the received power level on the specified channel, as detected at the antenna connector, as a function of time over the measurement duration. The maximum tolerance of the received power measurements shall be ± 5 dB. Furthermore, the received signal power measurement should be a monotonic function of the actual power at the antenna. The time resolution of the received power measurements is in microseconds. The received power measurements are converted to a sequence of RPI values by quantizing the measurements according to Table 7-31. The RPI densities are then computed for each of the eight possible RPI values using Ceiling (255 * [Duration receiving at RPI value (microseconds) / (1024 * Measurement duration)]). The sum of the RPI densities will be approximately 255, but could be up to 262 because of rounding effects.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001344

Table 7-31—RPI definitions for an RPI histogram report

RPI	Power observed at the antenna (dBm)
0	Power ≤ –87
1	–87 < Power ≤ –82
2	–82 < Power ≤ –77
3	–77 < Power ≤ –72
4	–72 < Power ≤ –67
5	–67 < Power ≤ –62
6	–62 < Power ≤ –57
7	–57 < Power

The RPI histogram report provides an additional mechanism for a STA to gather information on the state of a channel from other STAs. The STA may use this information to assist in the choice of new channel, to help avoid false radar detections, and to assess the general level of interference present on a channel.

7.3.2.23 Quiet element

The Quiet element defines an interval during which no transmission shall occur in the current channel. This interval may be used to assist in making channel measurements without interference from other STAs in the BSS or IBSS. The format of the Quiet element is shown in Figure 7-69.

	Element ID	Length	Quiet Count	Quiet Period	Quiet Duration	Quiet Offset
Octets:	1	1	1	1	2	2

Figure 7-69—Quiet element format

The Length field shall be set to 6.

The Quiet Count field shall be set to the number of TBTTs until the beacon interval during which the next quiet interval shall start. A value of 1 indicates the quiet interval shall start during the beacon interval starting at the next TBTT. A value of 0 is reserved.

The Quiet Period field shall be set to the number of beacon intervals between the start of regularly scheduled quiet intervals defined by this Quiet element. A value of 0 indicates that no periodic quiet interval is defined.

The Quiet Duration field shall be set to the duration of the quiet interval, expressed in TUs.

The Quiet Offset field shall be set to the offset of the start of the quiet interval from the TBTT specified by the Quiet Count field, expressed in TUs. The value of the Quiet Offset field shall be less than one beacon interval.

The Quiet element may be included in Beacon frames, as described in 7.2.3.1, and Probe Response frames, as described in 7.2.3.9. The use of Quiet elements is described in 11.9.2.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001345

7.3.2.24 IBSS DFS element

The IBSS DFS element contains information for DFS operation in an IBSS. The format of the IBSS DFS element is shown in Figure 7-70.

	Element ID	Length	DFS Owner	DFS Recovery Interval	Channel Map (see Figure 7-71)
Octets:	1	1	6	1	2*n*

Figure 7-70—IBSS DFS element format

	Channel Number	Map	*n* tuples, one for each supported channel
Octets:	1	1	

Figure 7-71—Channel Map field format

The Length field is variable.

The DFS Owner field shall be set to the individual IEEE MAC address of the STA that is the currently known DFS Owner in the IBSS.

The DFS Recovery Interval field indicates the time interval that shall be used for DFS owner recovery, expressed as an integral number of beacon intervals. The DFS Recovery Interval value is static throughout the lifetime of the IBSS and is determined by the STA that starts the IBSS.

The Channel Map field shown in Figure 7-71 shall contain a Channel Number field and a Map field (see 7.3.2.22.1) for each channel supported by the STA transmitting the IBSS DFS element. Note that *n* in Figure 7-70 is the number of channels supported by the STA.

The IBSS DFS element may be included in Beacon frames, as described in 7.2.3.1, and Probe Response frames, as described in 7.2.3.9. The use of IBSS DFS elements is described in 11.9.7.2.

7.3.2.25 RSN information element

The RSN information element contains authentication and pairwise cipher suite selectors, a single group cipher suite selector, an RSN Capabilities field, the PMK identifier (PMKID) count, and PMKID list. See Figure 7-72. All STAs implementing RSNA shall support this element. The size of the RSN information element is limited by the size of an information element, which is 255 octets. Therefore, the number of pairwise cipher suites, AKM suites, and PMKIDs is limited.

	Element ID	Length	Version	Group Cipher Suite	Pairwise Cipher Suite Count	Pairwise Cipher Suite List	AKM Suite Count	AKM Suite List	RSN Capabili-ties	PMKID Count	PMKI DList
Octets:	1	1	2	4	2	4-*m*	2	4-*n*	2	2	16-*s*

Figure 7-72—RSN information element format

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001346

In Figure 7-72, *m* denotes the pairwise cipher suite count, *n* the AKM suite count, and *s* is the PMKID count.

All fields use the bit convention from 7.1.1. The RSN information element shall contain up to and including the Version field. All fields after the Version field are optional. If any optional field is absent, then none of the subsequent fields shall be included.

Element ID shall be 48 decimal (30 hex).

Length gives the number of octets in the information field (field(s) following the Element ID and Length fields) of the information element.

The Version field indicates the version number of the RSNA protocol. The range of Version field values a STA supports shall be contiguous. Values 0 and 2 or higher of the Version field are reserved. RSN Version 1 is defined in this standard.

NOTE—The following represent sample information elements:

802.1X authentication, CCMP pairwise and group cipher suites (WEP-40, WEP-104, and TKIP not allowed):

30, // information element id, 48 expressed as Hex value
14, // length in octets, 20 expressed as Hex value
01 00, // Version 1
00 0F AC 04, // CCMP as group cipher suite
01 00, // pairwise cipher suite count
00 0F AC 04, // CCMP as pairwise cipher suite
01 00, // authentication count
00 0F AC 01 // 802.1X authentication
00 00 // No capabilities

802.1X authentication, CCMP pairwise and group cipher suites (WEP-40, WEP-104 and TKIP not allowed), preauthentication supported:

30, // information element id, 48 expressed as Hex value
14, // length in octets, 20 expressed as Hex value
01 00, // Version 1
00 0F AC 04, // CCMP as group cipher suite
01 00, // pairwise cipher suite count
00 0F AC 04, // CCMP as pairwise cipher suite
01 00, // authentication count
00 0F AC 01 // 802.1X authentication
01 00 // Preauthentication capabilities

802.1X authentication, Use GTK for pairwise cipher suite, WEP-40 group cipher suites, optional RSN Capabilities field omitted:

30, // information element id, 48 expressed as Hex value
12, // length in octets, 18 expressed as Hex value
01 00, // Version 1
00 0F AC 01, // WEP-40 as group cipher suite
01 00, // pairwise cipher suite count
00 0F AC 00, // Use group key as pairwise cipher suite
01 00, // authentication count
00 0F AC 01 // 802.1X authentication

802.1X authentication, Use CCMP for pairwise cipher suite, CCMP group cipher suites, preauthentication and a PMKID:

30, // information element id, 48 expressed as Hex value
26 // length in octets, 38 expressed as Hex value
01 00, // Version 1
00 0F AC 04, // CCMP as group cipher suite
01 00, // pairwise cipher suite count
00 0F AC 04, // CCMP as pairwise cipher suite
01 00, // authentication count
00 0F AC 01 // 802.1X authentication
01 00 // Preauthentication capabilities
01 00 // PMKID Count
01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 // PMKID

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001347

7.3.2.25.1 Cipher suites

The Group Cipher Suite field contains the cipher suite selector used by the BSS to protect broadcast/ multicast traffic.

The Pairwise Cipher Suite Count field indicates the number of pairwise cipher suite selectors that are contained in the Pairwise Cipher Suite List field.

The Pairwise Cipher Suite List field contains a series of cipher suite selectors that indicate the pairwise cipher suites contained in the RSN information element.

A suite selector has the format shown in Figure 7-73.

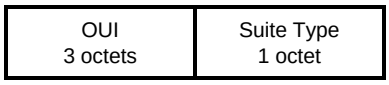

Figure 7-73—Suite selector format

The order of the organizationally unique indentifier (OUI) field shall follow the ordering convention for MAC addresses from 7.1.1.

Table 7-32 provides the cipher suite selectors defined by this standard.

Table 7-32—Cipher suite selectors

OUI	Suite type	Meaning
00-0F-AC	0	Use group cipher suite
00-0F-AC	1	WEP-40
00-0F-AC	2	TKIP
00-0F-AC	3	Reserved
00-0F-AC	4	CCMP – default in an RSNA
00-0F-AC	5	WEP-104
00-0F-AC	6–255	Reserved
Vendor OUI	Other	Vendor-specific
Other	Any	Reserved

The cipher suite selector 00-0F-AC:4 (CCMP) shall be the default cipher suite value.

The cipher suite selectors 00-0F-AC:1 (WEP-40) and 00-0F-AC:5 (WEP-104) are only valid as a group cipher suite in a transition security network (TSN) to allow pre-RSNA devices to join the BSS.

Use of CCMP as the group cipher suite with TKIP as the pairwise cipher suite shall not be supported.

NOTE—If the STAs can support CCMP, then there is no need for a weaker data confidentiality protocol.

The cipher suite selector 00-0F-AC:0 (Use group cipher suite) is only valid as the pairwise cipher suite. An AP may specify the selector 00-0F-AC:0 (Use group cipher suite) for a pairwise cipher suite if it does not

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001348

support any pairwise cipher suites. If an AP specifies 00-0F-AC:0 (Use group cipher suite) as the pairwise cipher selection, this shall be the only pairwise cipher selection the AP advertises.

If CCMP is enabled, then the AP supports pairwise keys, and thus the suite selector 00-0F-AC:0 (Use group cipher suite) shall not be a valid option.

Table 7-33 indicates the circumstances under which each cipher suite shall be used.

Table 7-33—Cipher suite usage

Cipher suite selector	GTK	PTK
Use group key	No	Yes
WEP-40	Yes	No
WEP-104	Yes	No
TKIP	Yes	Yes
CCMP	Yes	Yes

7.3.2.25.2 AKM suites

The AKM Suite Count field indicates the number of AKM suite selectors that are contained in the AKM Suite List field.

The AKM Suite List field contains a series of AKM suite selectors contained in the RSN information element. In an IBSS, only a single AKM suite selector may be specified because STAs in an IBSS must use the same AKM suite and because there is no mechanism to negotiate the AKMP in an IBSS (see 8.4.4).

Each AKM suite selector specifies an AKMP. Table 7-34 gives the AKM suite selectors defined by this standard.

Table 7-34—AKM suite selectors

OUI	Suite type	Meaning	
		Authentication type	Key management type
00-0F-AC	0	Reserved	Reserved
00-0F-AC	1	Authentication negotiated over IEEE 802.1X or using PMKSA caching as defined in 8.4.6.2 – RSNA default	RSNA key management as defined in 8.5 or using PMKSA caching as defined in 8.4.6.2 – RSNA default
00-0F-AC	2	PSK	RSNA key management as defined in 8.5, using PSK
00-0F-AC	3–255	Reserved	Reserved
Vendor OUI	Any	Vendor-specific	Vendor-specific
Other	Any	Reserved	Reserved

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001349

The AKM suite selector value 00-0F-AC:1 (Authentication negotiated over IEEE 802.1X) with (RSNA key management as defined in 8.5 or using PMKSA caching as defined in 8.4.6.2) shall be the assumed default when the AKM suite selector field is not supplied.

NOTE—The selector value 00-0F-AC:1 specifies only that IEEE Std 802.1X-2004 is used as the authentication transport. IEEE Std 802.1X-2004 selects the authentication mechanism.

The AKM suite selector value 00-0F-AC:2 (PSK) is used when a PSK is used with RSNA key management.

NOTE—Selector values 00-0F-AC:1 and 00-0F-AC:2 can simultaneously be enabled by an Authenticator.

7.3.2.25.3 RSN capabilities

The RSN Capabilities field indicates requested or advertised capabilities. The value of each of the RSN Capabilities fields shall be taken to be 0 if the RSN Capabilities field is not available in the RSN information element.

The length of the RSN Capabilities field is 2 octets. The format of the RSN Capabilities field is as illustrated in Figure 7-74 and described after the figure.

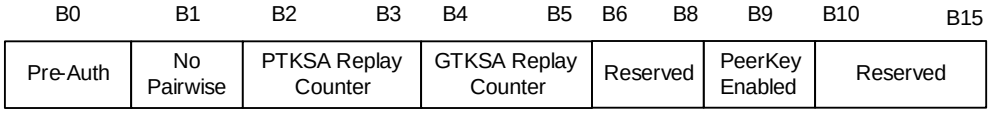

Figure 7-74—RSN Capabilities field format

— Bit 0: Pre-Authentication. An AP sets the Pre-Authentication subfield of the RSN Capabilities field to 1 to signal it supports preauthentication (see 8.4.6.1) and sets the subfield to 0 when it does not support preauthentication. A non-AP STA sets the Pre-Authentication subfield to 0.

— Bit 1: No Pairwise. If a STA can support WEP default key 0 simultaneously with a pairwise key (see 8.5.1), then the STA sets the No Pairwise subfield of the RSN Capabilities field to 0.

  If a STA cannot support WEP default key 0 simultaneously with a pairwise key (see 8.5.1), then the STA sets the No Pairwise subfield of the RSN Capabilities field to 1.

  The No Pairwise subfield describes a capability of a non-AP STA. STAs in an IBSS and APs set the No Pairwise subfield to 0.

  The No Pairwise subfield shall be set only in a TSN and when the pairwise cipher suite selected by the STA is TKIP.

— Bits 2–3: PTKSA Replay Counter. A STA sets the PTKSA Replay Counter subfield of the RSN Capabilities field to the value contained in dot11RSNAConfigNumberofPTKSAReplayCounters. The least significant bit (LSB) of dot11RSNAConfigNumberofPTKSAReplayCounters is put in bit 2. See 8.3.2.6 and 8.3.3.4.3. The meaning of the value in the PTKSA/GTKSA/STKSA Replay Counter subfield is defined in Table 7-35. The number of replay counters per STKSA is the same as the number of replay counters per PTKSA.

— Bits 4–5: GTKSA Replay Counter. A STA sets the GTKSA Replay Counter subfield of the RSN Capabilities field to the value contained in dot11RSNAConfigNumberofPTKSAReplayCounters. The LSB of dot11RSNAConfigNumberofGTKSAReplayCounters is put in bit 4. See 8.3.2.6 and 8.3.3.4.3. The meaning of the value in the GTKSA Replay Counter subfield is defined in Table 7-35.

— Bits 9: PeerKey Enabled. An AP STA sets the PeerKey Enabled subfield of the RSN Capabilities field to 1 to signal it supports PeerKey Handshake (see 8.5.8). This field is used by AP STA to describe its ability to support PeerKey Handshake.

— Bits 6–8 and 10–15: Reserved. The remaining subfields of the RSN Capabilities field are reserved and shall be set to 0 on transmission and ignored on reception.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001350

Table 7-35—PTKSA/GTKSA/STKSA replay counters usage

Replay counter value	Meaning
0	1 replay counter per PTKSA/GTKSA/STKSA
1	2 replay counters per PTKSA/GTKSA/STKSA
2	4 replay counters per PTKSA/GTKSA/STKSA
3	16 replay counters per PTKSA/GTKSA/STKSA

7.3.2.25.4 PMKID

The PMKID Count and List fields shall be used only in the RSN information element in the (Re)Association Request frame to an AP. The PMKID Count specifies the number of PMKIDs in the PMKID List field. The PMKID list contains 0 or more PMKIDs that the STA believes to be valid for the destination AP. The PMKID can refer to

a) A cached PMKSA that has been obtained through preauthentication with the target AP

b) A cached PMKSA from an EAP authentication

c) A PMKSA derived from a PSK for the target AP

See 8.5.1.2 for the construction of the PMKID.

NOTE—A STA can choose not to insert a PMKID in the PMKID List field if the STA does not want to use that PMKSA.

7.3.2.26 Vendor Specific information element

The Vendor Specific information element is used to carry information not defined in this standard within a single defined format, so that reserved information element IDs are not usurped for nonstandard purposes and so that interoperability is more easily achieved in the presence of nonstandard information. The information element is in the format shown in Figure 7-75 and requires that the first 3 octets of the information field contain the OUI of the entity that has defined the content of the particular Vendor Specific information element. The length of the information field (n) is $3 \le n \le 255$. The OUI field shall be a public OUI assigned by the IEEE. It is 3 octets in length. The length of the vendor-specific content is n–3 octets.

	Element ID	Length	OUI	Vendor-specific content
Octets:	1	1	3	n-3

Figure 7-75—Vendor Specific information element format

Multiple Vendor Specific information elements may appear in a single frame. Each Vendor Specific information element can have a different OUI value. The number of Vendor Specific information elements that may appear in a frame is limited only by the maximum frame size.

7.3.2.27 Extended Capabilities information element

The Extended Capabilities information element carries information about the capabilities of an IEEE 802.11 STA, intended to augment the Capability Information field (CIF) when these bits are fully allocated. The format of this information element is shown in Figure 7-76.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001351

	Element ID	Length	Capabilities
Octets:	1	1	n

Figure 7-76—Extended Capabilities element format

The element ID of this information element is 127.

The value of the Length field is equal to the number of octets in the Capabilities field.

The Capabilities field is a bit field indicating the capabilities being advertised by the STA transmitting the information element. There are no capabilities defined for this field in this revision of the standard.

7.3.2.28 BSS Load element

The BSS Load element contains information on the current STA population and traffic levels in the BSS. The element information format is defined in Figure 7-77. This element may be used by the non-AP STA for vendor-specific AP selection algorithm when roaming.

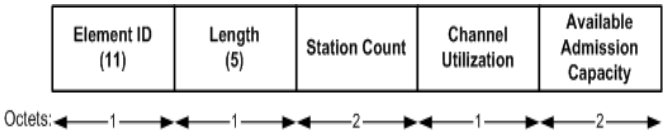

Figure 7-77—BSS Load element format

The STA Count field is interpreted as an unsigned integer that indicates the total number of STAs currently associated with this BSS.

The Channel Utilization field is defined as the percentage of time, normalized to 255, the AP sensed the medium was busy, as indicated by either the physical or virtual carrier sense (CS) mechanism. This percentage is computed using the formula,

((channel busy time/(dot11ChannelUtilizationBeaconIntervals * dot11BeaconPeriod * 1024)) * 255),

where *channel busy time* is defined to be the number of microseconds during which the CS mechanism, as defined in 9.2.1, has indicated a channel busy indication, and the MIB attribute dot11ChannelUtilization-BeaconIntervals represents the number of consecutive beacon intervals during which the channel busy time is measured. The default value of dot11ChannelUtilizationBeaconIntervals is defined in Annex D.

The Available Admission Capacity field is 2 octets long and contains an unsigned integer that specifies the remaining amount of medium time available via explicit admission control, in units of 32 μs/s. The field is helpful for roaming non-AP STAs to select an AP that is likely to accept future admission control requests, but it does not represent a guarantee that the HC will admit these requests.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001352

7.3.2.29 EDCA Parameter Set element

The EDCA Parameter Set element provides information needed by non-AP STAs for proper operation of the QoS facility during the CP. The format of the EDCA Parameter Set element is defined in Figure 7-78.

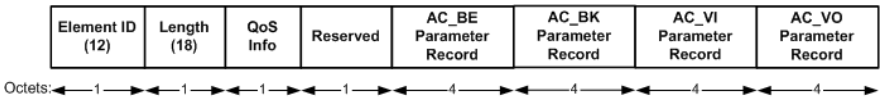

Figure 7-78—EDCA Parameter Set element

The EDCA Parameter Set element is used by the AP to establish policy (by changing default MIB attribute values), to change policies when accepting new STAs or new traffic, or to adapt to changes in offered load. The most recent EDCA parameter set element received by a non-AP STA is used to update the appropriate MIB values.

The format of the QoS Info field is defined in 7.3.1.17. The QoS Info field contains the EDCA Parameter Set Update Count subfield, which is initially set to 0 and is incremented each time any of the AC parameters changes. This subfield is used by non-AP STAs to determine whether the EDCA parameter set has changed and requires updating the appropriate MIB attributes.

The formats of AC_BE, AC_BK, AC_VI, and AC_VO Parameter Record fields are identical and are illustrated in Figure 7-79.

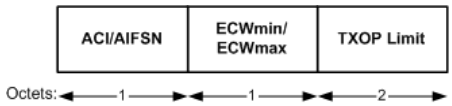

Figure 7-79—AC_BE, AC_BK, AC_VI, and AC_VO Parameter Record field format

The format of the ACI/AIFSN field is illustrated in Figure 7-80.

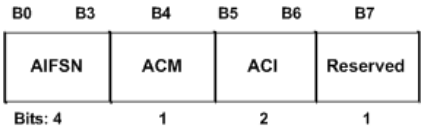

Figure 7-80—ACI/AIFSN field

The value of the AC index (ACI) references the AC to which all parameters in this record correspond. The mapping between ACI and AC is defined in Table 7-36. The ACM (admission control mandatory) subfield indicates that admission control is required for the AC. If the ACM subfield is set to 0, then there is no admission control for the corresponding AC. If the ACM subfield is set to 1, admission control has to be used prior to transmission using the access parameters specified for this AC. The AIFSN subfield indicates the number of slots after a SIFS duration a non-AP STA should defer before either invoking a backoff or starting a transmission. The minimum value for the AIFSN subfield is 2.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001353

Table 7-36—ACI-to-AC coding

ACI	AC	Description
00	AC_BE	Best effort
01	AC_BK	Background
10	AC_VI	Video
11	AC_VO	Voice

The ECWmin and ECWmax fields are illustrated in Figure 7-81.

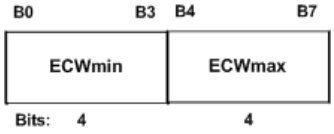

Figure 7-81—ECWmin and ECWmax fields

The ECWmin and ECWmax fields encode the values of CWmin and CWmax, respectively, in an exponent form. The ECWmin and ECWmax values are defined so that

$$CWmin = 2^{ECWmin} - 1$$

$$CWmax = 2^{ECWmax} - 1$$

Hence the minimum encoded value of CWmin and CWmax is 0, and the maximum value is 32 767.

The value of the TXOP Limit field is specified as an unsigned integer, with the least significant octet transmitted first, in units of 32 μs. A TXOP Limit field value of 0 indicates that a single MSDU or MMPDU, in addition to a possible RTS/CTS exchange or CTS to itself, may be transmitted at any rate for each TXOP.

The default values used by non-AP STAs for the parameters in the EDCA Parameter Set element are defined in Table 7-37.[19]

Table 7-37—Default EDCA Parameter Set element parameter values

AC	CWmin	CWmax	AIFSN	TXOP limit		
				For PHYs defined in Clause 15 and Clause 18	For PHYs defined in Clause 17 and Clause 19	Other PHYs
AC_BK	aCWmin	aCWmax	7	0	0	0
AC_BE	aCWmin	aCWmax	3	0	0	0
AC_VI	(aCWmin+1)/2 – 1	aCWmin	2	6.016 ms	3.008 ms	0
AC_VO	(aCWmin+1)/4 – 1	(aCWmin+1)/2 – 1	2	3.264 ms	1.504 ms	0

[19]The default values for TXOP limit are expressed in milliseconds and are multiples of 32 μs.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001354

7.3.2.30 TSPEC element

The TSPEC element contains the set of parameters that define the characteristics and QoS expectations of a traffic flow, in the context of a particular non-AP STA, for use by the HC and non-AP STA(s) in support of QoS traffic transfer using the procedures defined in 11.4. The element information format comprises the items as defined in this subclause, and the structure is defined in Figure 7-82.

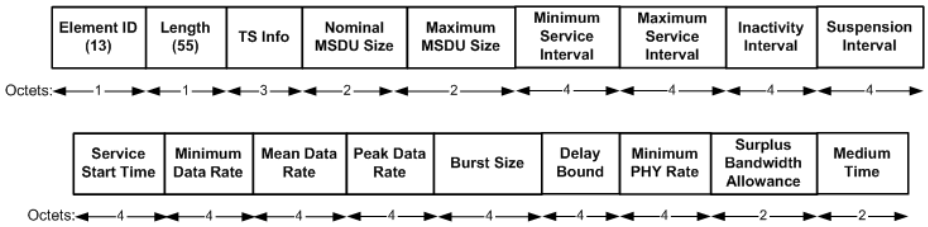

Figure 7-82—TSPEC element format

The TSPEC allows a set of parameters more extensive than may be needed, or may be available, for any particular instance of parameterized QoS traffic. Unless indicated otherwise, fields that follow the TS Info field are set to 0 for any unspecified parameter values. Non-AP STAs set the value of any parameters to unspecified if they have no information for setting that parameter. The HC may change the value of parameters that have been set unspecified by the STA to any value that it deems appropriate, including leaving them unspecified.

The structure of the TS Info field is defined in Figure 7-83.

Figure 7-83—TS Info field

— The Traffic Type subfield is a single bit and is set to 1 for a periodic traffic pattern (e.g., isochronous TS of MSDUs, with constant or variable sizes, that are originated at fixed rate) or set to 0 for an aperiodic, or unspecified, traffic pattern (e.g., asynchronous TS of low-duty cycles).

— The TSID subfield is 4 bits in length and contains a value that is a TSID. Note that the MSB (bit 4 in TS Info field) of the TSID subfield is always set to 1. The combination of the TSID and Direction subfields identify the TS, in the context of the non-AP STA, to which the TSPEC applies. The same TSID may be used for multiple TSs at different non-AP STAs. A non-AP STA may use the TSID subfield value for a downlink TSPEC and either an uplink or a direct-link TSPEC at the same time. A non-AP STA shall not use the same TSID for both uplink and direct-link TS. A bidirectional link request is equivalent to a downlink TS and an uplink TS, each with the same TSID and parameters.

— The Direction subfield specifies the direction of data carried by the TS as defined in Table 7-38.

Table 7-38—Direction subfield encoding

Bit 5	Bit 6	Usage
0	0	Uplink (MSDUs are sent from the non-AP STA to HC)
1	0	Downlink (MSDUs are sent from the HC to the non-AP STA)

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001355

Table 7-38—Direction subfield encoding *(continued)*

Bit 5	Bit 6	Usage
0	1	Direct link (MSDUs are sent from the non-AP STA to another non-AP STA)
1	1	Bidirectional link (equivalent to a downlink request plus an uplink request, each direction having the same parameters). The fields in the TSPEC element specify resources for a single direction. Double the specified resources are required to support both streams.

— The Access Policy subfield is 2 bits in length, specifies the access that would be used for the TS, and is defined in Table 7-39.

Table 7-39—Access Policy subfield

Bit 7	Bit 8	Usage
0	0	Reserved
1	0	Contention-based channel access (EDCA)
0	1	Controlled channel access (HCCA)
1	1	HCCA, EDCA mixed mode (HEMM)

— The Aggregation subfield is 1 bit in length. The Aggregation subfield is valid only when access method is HCCA or when the access method is EDCA and the Schedule subfield is set to 1. It is set to 1 by a non-AP STA to indicate that an aggregate schedule is required. It is set to 1 by the AP if an aggregate schedule is being provided to the non-AP STA. It is set to 0 otherwise. In all other cases, the Aggregation subfield is reserved.

— The APSD subfield is a single bit and is set to 1 to indicate that automatic PS delivery is to be used for the traffic associated with the TSPEC and set to 0 otherwise.

— The UP subfield is 3 bits and indicates the actual value of the UP to be used for the transport of MSDUs belonging to this TS in cases where relative prioritization is required. When the TCLAS element is present in the request, the UP subfield in TS Info field of the TSPEC element is reserved.

— The TS Info Ack Policy subfield is 2 bits in length and indicates whether MAC acknowledgments are required for MPDUs belonging to this TID and the desired form of those acknowledgments. The encoding of the TS Info Ack Policy subfield is shown in Table 7-40. If the TS Info Ack Policy subfield is set to Block Ack and the type of Block Ack policy is unknown to the HC, the HC shall assume, for TXOP scheduling, that the immediate Block Ack policy is being used (see 9.10).

Table 7-40—TS Info Ack Policy subfield encoding

Bit 14	Bit 15	Usage
0	0	Normal IEEE 802.11 acknowledgment The addressed recipient returns an ACK or QoS +CF-Ack frame after a SIFS period, according to the procedures defined in 9.2.8, 9.3.3, and 9.9.2.3.
1	0	No Ack: The recipient(s) do not acknowledge the transmission.
0	1	Reserved
1	1	Block Ack: A separate Block Ack setup mechanism described in 9.10 is used.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001356

— The Schedule subfield is 1 bit in length and specifies the requested type of schedule. The setting of the subfield when the access policy is EDCA is shown in Table 7-41. When the Access Policy subfield is set to any value other than EDCA, the Schedule subfield is reserved. When the Schedule and APSD subfields are set to 1, the AP shall set the aggregation bit to 1, indicating that an aggregate schedule is being provided to the non-AP STA.

Table 7-41—Setting of Schedule subfield

APSD	Schedule	Usage
0	0	No Schedule
1	0	Unscheduled APSD
0	1	Reserved
1	1	Scheduled APSD

The configuration of APSD=0, Schedule=1 is reserved.

The Nominal MSDU Size field is 2 octets long, contains an unsigned integer that specifies the nominal size, in octets, of MSDUs belonging to the TS under this TSPEC, and is defined in Figure 7-84. If the Fixed subfield is set to 1, then the size of the MSDU is fixed and is indicated by the Size subfield. If the Fixed subfield is set to 0, then the size of the MSDU might not be fixed and the Size subfield indicates the nominal MSDU size. If both the Fixed and Size subfields are set to 0, then the nominal MSDU size is unspecified.

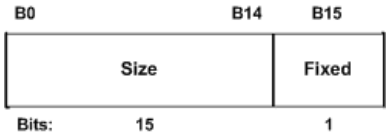

Figure 7-84—Nominal MSDU Size field

The Maximum MSDU Size field is 2 octets long and contains an unsigned integer that specifies the maximum size, in octets, of MSDUs belonging to the TS under this TSPEC.

The Minimum Service Interval field is 4 octets long and contains an unsigned integer that specifies the minimum interval, in microseconds, between the start of two successive SPs.

The Maximum Service Interval field is 4 octets long and contains an unsigned integer that specifies the maximum interval, in microseconds, between the start of two successive SPs.

The Inactivity Interval field is 4 octets long and contains an unsigned integer that specifies the minimum amount of time, in microseconds, that may elapse without arrival or transfer of an MPDU belonging to the TS before this TS is deleted by the MAC entity at the HC.

The Suspension Interval field is 4 octets long and contains an unsigned integer that specifies the minimum amount of time, in microseconds, that may elapse without arrival or transfer of an MSDU belonging to the TS before the generation of successive QoS(+)CF-Poll is stopped for this TS. A value of 4 294 967 295 (= $2^{32} - 1$) disables the suspension interval, indicating that polling for the TS is not to be interrupted based on inactivity. The value of the suspension interval is always less than or equal to the inactivity interval.

The Service Start Time field is 4 octets and contains an unsigned integer that specifies the time, expressed in microseconds, when the first scheduled SP starts. The service start time indicates to AP the time when a

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001357

non-AP STA first expects to be ready to send frames and a power-saving non-AP STA will be awake to receive frames. This may help the AP to schedule service so that the MSDUs encounter small delays in the MAC and help the power-saving non-AP STAs to reduce power consumption. The field represents the four lower order octets of the TSF timer at the start of the SP. If APSD subfield is set to 0, this field is also set to 0 (unspecified).

The Minimum Data Rate field is 4 octets long and contains an unsigned integer that specifies the lowest data rate specified at the MAC_SAP, in bits per second, for transport of MSDUs belonging to this TS within the bounds of this TSPEC. The minimum data rate does not include the MAC and PHY overheads incurred in transferring the MSDUs.

The Mean Data Rate[20] field is 4 octets long and contains an unsigned integer that specifies the average data rate specified at the MAC_SAP, in bits per second, for transport of MSDUs belonging to this TS within the bounds of this TSPEC. The mean data rate does not include the MAC and PHY overheads incurred in transferring the MSDUs.

The Peak Data Rate field is 4 octets long and contains an unsigned integer that specifies the maximum allowable data rate, in bits per second, for transfer of MSDUs belonging to this TS within the bounds of this TSPEC. If p is the peak rate in bits per second, then the maximum amount of data, belonging to this TS, arriving in any time interval $[t1,t2]$, where $t1 < t2$ and $t2 - t1 > 1$ TU, does not exceed $p * (t2 - t1)$ bits.

The Burst Size field is 4 octets long and contains an unsigned integer that specifies the maximum burst, in octets, of the MSDUs belonging to this TS that arrive at the MAC_SAP at the peak data rate. A value of 0 indicates that there are no bursts.

The Delay Bound field is 4 octets long and contains an unsigned integer that specifies the maximum amount of time, in microseconds, allowed to transport an MSDU belonging to the TS in this TSPEC, measured between the time marking the arrival of the MSDU at the local MAC sublayer from the local MAC_SAP and the time of completion of the successful transmission or retransmission of the MSDU to the destination. The completion of the MSDU transmission includes the relevant acknowledgment frame transmission time, if present.

The Minimum PHY Rate field is 4 octets long and contains an unsigned integer that specifies the desired minimum PHY rate to use for this TS, in bits per second, that is required for transport of the MSDUs belonging to the TS in this TSPEC.[21]

The Surplus Bandwidth Allowance field is 2 octets long and specifies the excess allocation of time (and bandwidth) over and above the stated application rates required to transport an MSDU belonging to the TS in this TSPEC. This field is represented as an unsigned binary number and, when specified, is greater than 0. The 13 least significant bits (LSBs) indicate the decimal part while the three MSBs indicate the integer part of the number. This field takes into account the retransmissions, as the rate information does not include retransmissions. It represents the ratio of over-the-air bandwidth (i.e., time that the scheduler allocates for the transmission of MSDUs at the required rates) to bandwidth of the transported MSDUs required for successful transmission (i.e., time that would be necessary at the minimum PHY rate if there were no errors on the channel) to meet throughput and delay bounds under this TSPEC, when specified. As such, it should be greater than unity. A value of 1 indicates that no additional allocation of time is requested.

[20]The mean data rate, the peak data rate, and the burst size are the parameters of the token bucket model, which provides standard terminology for describing the behavior of a traffic source. The token bucket model is described in IETF RFC 2212-1997 [B19], IETF RFC 2215-1997 [B20], and IETF RFC 3290-2002 [B24].

[21]This rate information is intended to ensure that the TSPEC parameter values resulting from an admission control negotiation are sufficient to provide the required throughput for the TS. In a typical implementation, a TS is admitted only if the defined traffic volume can be accommodated at the specified rate within an amount of WM occupancy time that the admissions control entity is willing to allocate to this TS.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001358

The Medium Time field is a 16-bit unsigned integer and contains the amount of time admitted to access the medium, in units of 32 μs/s. This field is reserved in the ADDTS Request frame and is set by the HC in the ADDTS Response frame. The derivation of this field is described in K.2.2. This field is not used for controlled channel access.

The UP, Minimum Data Rate, Mean Data Rate, Peak Data Rate, Burst Size, Minimum PHY Rate, and Delay Bound fields in a TSPEC element express the QoS expectations requested by a non-AP STA, if this TSPEC was issued by that non-AP STA, or provided by the HC, if this TSPEC was issued by the HC, when these fields are specified with nonzero values. Unspecified parameters in these fields as indicated by a zero value indicate that the non-AP STA does not have specific requirements for these parameters if the TSPEC was issued by that non-AP STA or that the HC does not provide any specific values for these parameters if the TSPEC was issued by the HC.

7.3.2.31 TCLAS element

The TCLAS element specifies an information element that contains a set of parameters necessary to identify incoming MSDUs (from a higher layer in all STAs or from the DS in an AP) with a particular TS to which they belong. If required, the TCLAS element is provided in ADDTS Request and ADDTS Response frames only for the downlink or bidirectional links. TCLAS element need not be provided for the uplink or direct-link transmissions. The structure of this element is shown in Figure 7-85.

Figure 7-85—TCLAS element format

The UP field contains the value of the UP of the associated MSDUs.

The Frame Classifier field is 3–255 octets in length and is defined in Figure 7-86.

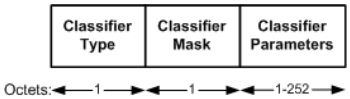

Figure 7-86—Frame Classifier field

The Frame Classifier field comprises the following subfields: Classifier Type, Classifier Mask, and Classifier Parameters. The Classifier Type subfield is 1 octet in length and specifies the type of classifier parameters in this TCLAS as defined in Table 7-42. Three classifier types are defined later in this subclause.

Table 7-42—Frame classifier type

Classifier type	Classifier parameters
0	Ethernet parameters
1	TCP/UDP IP parameters
2	IEEE 802.1D/Q parameters
3–255	Reserved

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001359

The Classifier Mask subfield specifies a bitmap where bits that are set to 1 identify a subset of the classifier parameters whose values must match those of the corresponding parameters in a given MSDU for that MSDU to be classified to the TS of the affiliated TSPEC. The bitmap is ordered from the LSB to the MSB, with each bit pointing to one of the classifier parameters of the same relative position as shown in this subclause based on classifier type. An incoming MSDU that failed to be classified to a particular TS may be classified to another active TS based on the frame classifier for that TS. If, however, all the frame classifiers for the active TS have been exhausted, the MSDU does not belong to any active TS and is classified to be a best-effort MSDU. In cases where there are more bits in the bitmap than classifier parameters that follow, the MSBs that do not point to any classifier parameters are reserved.

For Classifier Type 0, the classifier parameters are the following parameters contained in an Ethernet packet header: Source Address, Destination Address, and Type ("Ethernet" [B5]). The Frame Classifier field for Classifier Type 0 is defined in Figure 7-87. It has a length of 16 octets.

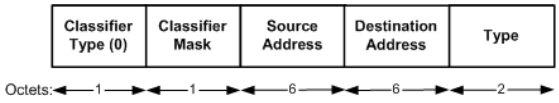

Figure 7-87—Frame Classifier field of Classifier Type 0

For Classifier Type 1, frame classifier is defined for both IPv4 and IPv6, shown in Figure 7-88 and Figure 7-89, and distinguished by the Version field. The subfields in the classifier parameters are represented and transmitted in the big-endian format. The classifier parameters are the following parameters:

— In a TCP or UDP header: Source Address, Destination Address, Source Port, Destination Port, and Version, plus

— One of the following:

  — In an IPv4 header: Differentiated Services Code Point (DSCP) (IETF RFC 2474-1998 [B21]) and Protocol, or

  — In an IPv6 header: Flow Label.

The DSCP field shall contain the value in the 6 LSBs, and the 2 MSBs are set to 0. The 2 MSBs of the DSCP field are ignored for frame classification.

Figure 7-88—Frame Classifier field of Classifier Type 1 for traffic over IPv4

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001360

For Classifier Type 2, the Classifier Parameters are the following parameters in an IEEE 802.1Q tag header: IEEE 802.1D user priority and IEEE 802.1Q VLAN ID (see IEEE Std 802.1Q, 2003 Edition, [B14]). The Frame Classifier field for Classifier Type 2 is defined in Figure 7-90.

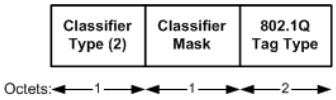

Figure 7-90—Frame Classifier field of Classifier Type 2

7.3.2.32 TS Delay element

The TS Delay element is used in the ADDTS Response frame transmitted by the HC to a non-AP STA and indicates the time after which the ADDTS may be retried. The TS Delay element is defined in Figure 7-91.

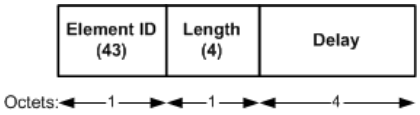

Figure 7-91—TS Delay element

The Delay field is 4 octets long and specifies the amount of time, in TUs, a non-AP STA should wait before it reinitiates setup of a TS.

The TS Delay element is set to 0 when an AP does not want to serve any TSPECs for an indeterminate time and it does not know this time a priori.

7.3.2.33 TCLAS Processing element

The TCLAS Processing element is present in the ADDTS Request and Response frames if there are multiple TCLASs associated with the request. It indicates how an MSDU received from higher layers should be processed by the classifier. The TCLAS Processing element is defined in Figure 7-92.

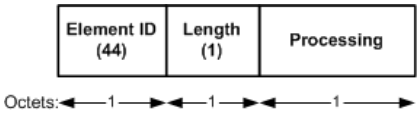

Figure 7-92—TCLAS Processing element

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001361

The Processing subfield is 1 octet long. The encoding of the Processing subfield is shown in Table 7-43.

Table 7-43—Encoding of Processing subfield

Processing subfield value	Meaning
0	Incoming MSDU's higher layer parameters have to match to the parameters in all the associated TCLAS elements.
1	Incoming MSDU's higher layer parameters have to match to at least one of the associated TCLAS elements.
2	Incoming MSDUs that do not belong to any other TS are classified to the TS for which this TCLAS Processing element is used. In this case, there shall not be any associated TCLAS elements.
3–255	Reserved

7.3.2.34 Schedule element

The Schedule element is transmitted by the HC to a non-AP STA to announce the schedule that the HC/AP follows for admitted streams originating from or destined to that non-AP STA in the future. The information in this element may be used by the non-AP STA for power management, internal scheduling, or any other purpose. The element information format is shown in Figure 7-93.

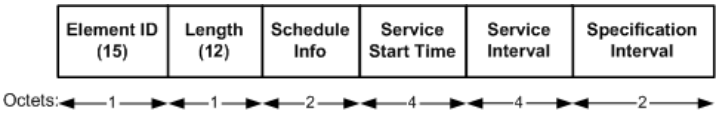

Figure 7-93—Schedule element

The Schedule Info field is shown in Figure 7-94.

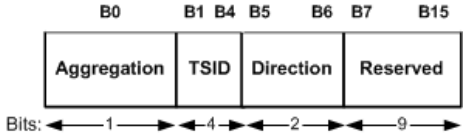

Figure 7-94—Schedule Info field

The Aggregation subfield is set to 1 if the schedule is an aggregate schedule for all TSIDs associated with the non-AP STA to which the frame is directed. It is set to 0 otherwise. The TSID subfield is as defined in 7.1.3.5.1 and indicates the TSID for which this schedule applies. The Direction subfield is as defined in 7.3.2.30 and defines the direction of the TSPEC associated with the schedule. The TSID and Direction subfields are valid only when the Aggregation subfield is set to 0. If the Aggregation subfield is set to 1, the TSID and Direction subfields are reserved.

The Service Start Time field is 4 octets and indicates the anticipated time, expressed in microseconds, when service starts and represents the lower order 4 octets of the TSF timer value at the start of the first SP. The AP uses this field to confirm or modify the service start time indicated in the TSPEC request.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001362

The Service Interval field is 4 octets and indicates the time, expressed in microseconds, between two successive SPs and represents the measured time from the start of one SP to the start of the next SP.

The Specification Interval field is 2 octets long and contains an unsigned integer that specifies the time interval, in TUs, to verify schedule conformance.

The HC may set the Service Start Time field and the Service Interval field to 0 (unspecified) for nonpower-saving STAs.

7.3.2.35 QoS Capability element

The QoS Capability element contains a number of subfields that are used to advertise optional QoS capabilities at a QoS STA. The QoS Capability element is present in Beacon frames that do not contain the EDCA Parameter Set element and in (Re)Association Request frames. The QoS Capability element is defined in Figure 7-95.

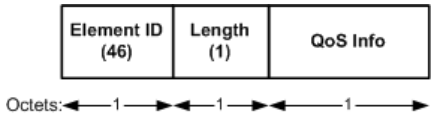

Figure 7-95—QoS Capability element format

The QoS Info field is 1 octet in length and is defined in 7.3.1.17.

7.4 Action frame format details

This subclause describes the Action frame formats, including the Action Details field, allowed in each of the action categories defined in Table 7-24 in 7.3.1.11.

7.4.1 Spectrum management action details

Five Action frame formats are defined for spectrum management. An Action Value field, in the octet field immediately after the Category field, differentiates the five formats. The Action Value field values associated with each frame format are defined in Table 7-44.

Table 7-44—Spectrum management Action Value field values

Action Value field value	Description
0	Measurement Request
1	Measurement Report
2	TPC Request
3	TPC Report
4	Channel Switch Announcement
5–255	Reserved

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001363

7.4.1.1 Measurement Request frame format

The Measurement Request frame uses the Action frame body format and is transmitted by a STA requesting another STA to measure one or more channels. The format of the Measurement Request frame body is shown in Figure 7-96.

	Category	Action Value	Dialog Token	Measurement Request Elements
Octets:	1	1	1	variable

Figure 7-96—Measurement Request frame body format

The Category field shall be set to 0 (representing spectrum management).

The Action Value field shall be set to 0 (representing a Measurement Request frame).

The Dialog Token field shall be set to a nonzero value chosen by the STA sending the measurement request to identify the request/report transaction.

The Measurement Request Elements field shall contain one or more of the Measurement Request elements described in 7.3.2.21. The number and length of the Measurement Request elements in a Measurement Request frame is limited by the maximum allowed MMPDU size.

7.4.1.2 Measurement Report frame format

The Measurement Report frame uses the Action frame body format and is transmitted by a STA in response to a Measurement Request frame or by a STA autonomously providing measurement information. The format of the Measurement Report frame body is shown in Figure 7-97.

	Category	Action Value	Dialog Token	Measurement Report Elements
Octets:	1	1	1	variable

Figure 7-97—Measurement Report frame body format

The Category field shall be set to 0 (representing spectrum management).

The Action Value field shall be set to 1 (representing a Measurement Report frame).

The Dialog Token field shall be set to the value in any corresponding Measurement Request frame. If the Measurement Report frame is not being transmitted in response to a Measurement Request frame, then the Dialog token shall be set to 0.

The Measurement Report Elements field shall contain one or more of the Measurement Report elements described in 7.3.2.22. The number and length of the Measurement Report elements in a Measurement Report frame is limited by the maximum allowed MMPDU size.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001364

7.4.1.3 TPC Request frame format

The TPC Request frame uses the Action frame body format and is transmitted by a STA requesting another STA for transmit power and link margin information. The format of the TPC Request frame body is shown in Figure 7-98.

	Category	Action Value	Dialog Token	TPC Request element
Octets:	1	1	1	2

Figure 7-98—TPC Request frame body format

The Category field shall be set to 0 (representing spectrum management).

The Action Value field shall be set to 2 (representing a TPC Request frame).

The Dialog Token field shall be set to a nonzero value chosen by the STA sending the request to identify the transaction.

The TPC Request element shall be set as described in 7.3.2.17.

7.4.1.4 TPC Report frame format

The TPC Report frame uses the Action frame body format and is transmitted by a STA in response to a TPC Request frame. The format of the TPC Report frame body is shown in Figure 7-99.

	Category	Action Value	Dialog Token	TPC Report element
Octets:	1	1	1	4

Figure 7-99—TPC Report frame body format

The Category field shall be set to 0 (representing spectrum management).

The Action Value field shall be set to 3 (representing a TPC Report frame).

The Dialog Token field shall be set to the Dialog Token value in the corresponding TPC Request frame.

The TPC Report element shall be set as described 7.3.2.18.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001365

7.4.1.5 Channel Switch Announcement frame format

The Channel Switch Announcement frame uses the Action frame body format and is transmitted by an AP in a BSS or a STA in an IBSS to advertise a channel switch. The format of the Channel Switch Announcement frame body is shown in Figure 7-100.

	Category	Action Value	Channel Switch Announcement element
Octets:	1	1	5

Figure 7-100—Channel Switch Announcement frame body format

The Category field shall be set to 0 (representing spectrum management).

The Action Value field shall be set to 4 (representing a Channel Switch Announcement frame).

The Channel Switch Announcement element shall be set as described 7.3.2.20.

7.4.2 QoS Action frame details

Several Action frame formats are defined for QoS purposes. The Action field values associated with each frame format within the QoS category are defined in Table 7-45.

Table 7-45—QoS Action field values

Action field value	Meaning
0	ADDTS Request
1	ADDTS Response
2	DELTS
3	Schedule
4–255	Reserved

7.4.2.1 ADDTS Request frame format

The ADDTS frames are used to carry TSPEC and optionally TCLAS elements to set up and maintain TSs using the procedures defined in 11.4.

The frame body of the ADDTS Request frame contains the information shown in Table 7-46.

Table 7-46—ADDTS Request frame body

Order	Information
1	Category
2	Action

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001366

Table 7-46—ADDTS Request frame body *(continued)*

Order	Information
3	Dialog Token
4	TSPEC
5–n	TCLAS (optional)
n + 1	TCLAS Processing (optional)

The Category field is set to 1 (representing QoS).

The Action field is set to 0 (representing ADDTS request).

The Dialog Token, TCLAS, and TCLAS Processing fields of this frame are contained in an MLME-ADDTS.request primitive that causes the frame to be sent. Some of the TSPEC parameters are contained in the MLME-ADDTS.request primitive while the other parameters (i.e., Surplus Bandwidth Allowance, Minimum Service Interval, Maximum Service Interval, and Minimum PHY Rate) are generated within the MAC.

The TSPEC element, defined in 7.3.2.30, and the optional TCLAS element, defined in 7.3.2.31, contain the QoS parameters that define the TS. The TS is identified by the TSID and Direction fields within the TSPEC element. The TCLAS element is optional at the discretion of the non-AP STA that sends the ADDTS Request frame, regardless of the setting of the access policy (EDCA or HCCA). There may be one or more TCLAS elements in the ADDTS frame. The TCLAS Processing element is present when there are more than one TCLAS element and is defined in 7.3.2.33.

7.4.2.2 ADDTS Response frame format

The ADDTS Response frame is transmitted in response to an ADDTS request frame. The frame body of the ADDTS Response frame contains the information shown in Table 7-47.

Table 7-47—ADDTS Response frame body

Order	Information
1	Category
2	Action
3	Dialog Token
4	Status Code
5	TS Delay
6	TSPEC
7–n	TCLAS (optional)
n + 1	TCLAS Processing (optional)
n + 2	Schedule

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001367

The Category field is set to 1(representing QoS).

The Action field is set to 1 (representing ADDTS response).

The Status Code field is defined in 7.3.1.9.

The Dialog Token, TS Delay, TSPEC, TCLAS, and TCLAS Processing fields in this frame are contained in an MLME-ADDTS.response primitive that causes the frame to be sent. The TS Delay information element is present in an ADDTS Response frame only if the status code is set to 47.

The Schedule element, defined in 7.3.2.34, is present in an ADDTS Response frame only if the status code is set to 0 (i.e., when the TS is admitted).

7.4.2.3 DELTS frame format

The DELTS frame is used to delete a TS using the procedures defined in 11.4.7.

The frame body of a DELTS frame contains the information shown in Table 7-48.

Table 7-48—DELTS frame body

Order	Information
1	Category
2	Action
3	TS Info
4	Reason Code

The Category field is set to 1 (representing QoS).

The Action field is set to 2 (representing DELTS).

The TS Info field is defined in 7.3.2.30.

The Reason Code field is defined in 7.3.1.7.

A DELTS frame is used to delete a TS characterized by the TS Info field in the frame. A DELTS frame may be sent from the HC to the source STA of that TS, or vice versa, to indicate an imperative request, to which no response is required from the recipient STA.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001368

7.4.2.4 Schedule frame format

The Schedule frame is transmitted by the HC to a non-AP STA to announce the schedule of delivery of data and polls. The frame body of the Schedule frame contains the information shown in Table 7-49.

Table 7-49—Schedule frame body

Order	Information
1	Category
2	Action
3	Schedule

The Category field is set to 1 (representing QoS).

The Action field is set to 3 (representing Schedule).

The Schedule element is defined in 7.3.2.34.

7.4.3 DLS Action frame details

Several Action frame formats are defined for DLS management purposes. An Action field, in the octet field immediately after the Category field, differentiates the formats. The Action field values associated with each frame format are defined in Table 7-50.

Table 7-50—DLS Action field values

Action field value	Meaning
0	DLS Request
1	DLS Response
2	DLS Teardown
3–255	Reserved

7.4.3.1 DLS Request frame format

The DLS Request frame is used to set up a direct link with a peer MAC. The frame body of the DLS Request frame contains the information shown in Table 7-51.

Table 7-51—DLS Request frame body

Order	Information
1	Category
2	Action

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001369

Table 7-51—DLS Request frame body *(continued)*

Order	Information
3	Destination MACAddress
4	Source MACAddress
5	Capability Information
6	DLS Timeout Value
7	Supported rates
8	Extended Supported Rates

The Category field is set to 2 (representing DLS).

The Action field is set to 0 (representing DLS request).

The Destination MAC Address field value is the MAC address of the target destination.

The Source MAC Address field value is the MAC address of the initiating STA.

The Capability Information field value is the capability information of the originator of the request.

The DLS Timeout Value field is defined in 7.3.1.13.

The Supported Rates and Extended Supported Rates fields contain the supported rates information of the originator.

7.4.3.2 DLS Response frame format

The DLS Response frame is sent in response to a DLS Request frame. The frame body of a DLS Response frame contains the information shown in Table 7-52.

Table 7-52—DLS Response frame body

Order	Information
1	Category
2	Action
3	Status Code

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001370

The Category field is set to 2 (representing DLS).

The Action field is set to 1 (representing DLS response).

The Status Code field is defined in 7.3.1.9.

The Destination MAC Address field value and the Source MAC Address field value are copied from the corresponding fields in the DLS Request frame.

The Capability Information field is the capability information of the target destination. This information is included only if the DLS result code corresponds to SUCCESS (DLS status code 0).

The Supported Rates and Extended Supported Rates fields contain the supported rates information of the target destination. This information is included only if the DLS result code corresponds to SUCCESS (DLS status code 0).

7.4.3.3 DLS Teardown frame format

The DLS Teardown frame is sent to terminate a direct link with a peer MAC. The frame body of the DLS Teardown frame contains the information shown in Table 7-53.

Table 7-53—DLS Teardown frame body

Order	Information
1	Category
2	Action
3	Destination MACAddress
4	Source MACAddress
5	Reason Code

The Category field is set to 2 (representing DLS).

The Action field is set to 2 (representing DLS teardown).

The Destination MAC Address field value is the MAC address of the target destination.

The Source MAC Address field value is the MAC address of the initiating STA.

The Reason Code field is defined in 7.3.1.7.

7.4.4 Block Ack Action frame details

The ADDBA frames are used to set up Block Ack for a specific TC or TS. The Action field values associated with each frame format within the Block Ack category are defined in Table 7-54.

Table 7-54—Block Ack Action field values

Action field values	Meaning
0	ADDBA Request
1	ADDBA Response
2	DELBA
3–255	Reserved

7.4.4.1 ADDBA Request frame format

An ADDBA Request frame is sent by an originator of Block Ack to another STA. The frame body of an ADDBA Request frame contains the information shown in Table 7-55.

Table 7-55—ADDBA Request frame body

Order	Information
1	Category
2	Action
3	Dialog Token
4	Block Ack Parameter Set
5	Block Ack Timeout Value
6	Block Ack Starting Sequence Control

The Category field is set to 3 (representing Block Ack).

The Action field is set to 0 (representing ADDBA request).

The Dialog Token field is set to a nonzero value chosen by the STA.

The Block Ack Parameter Set field is defined in 7.3.1.14.

The Block Ack Timeout Value field is defined in 7.3.1.15.

The Block Ack Starting Sequence Control field is defined in 7.2.1.7.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001372

7.4.4.2 ADDBA Response frame format

The ADDBA Response frame is sent in response to an ADDBA Request frame. The frame body of an ADDBA Response frame contains the information shown in Table 7-56.

Table 7-56—ADDBA Response frame body

Order	Information
1	Category
2	Action
3	Dialog Token
4	Status Code
5	Block Ack Parameter Set
6	Block Ack Timeout Value

The Category field is set to 3 (representing Block Ack).

The Action field is set to 1 (representing ADDBA response).

The Dialog Token field value is copied from the corresponding received ADDBA Request frame.

The Status Code field is defined in 7.3.1.9.

The Block Ack Parameter Set field is defined in 7.3.1.14.

The Block Ack Timeout Value field is defined in 7.3.1.15.

7.4.4.3 DELBA frame format

The DELBA frame is sent by either the originator of the traffic or the recipient to terminate the Block Ack participation. The frame body of a DELBA frame format contains the information shown in Table 7-57.

Table 7-57—DELBA frame body

Order	Information
1	Category
2	Action
3	DELBA Parameter Set
4	Reason Code

The Category field is set to 3 (representing DELBA).

The Action field is set to 2 (representing DELBA).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001373

The DELBA Parameters field is defined in 7.3.1.16.

The Reason Code field is defined in 7.3.1.7.

7.4.5 Vendor-specific action details

The Vendor Specific Action frame is defined for vendor-specific signaling. The format of the Vendor Specific Action frame is shown in Figure 7-101. An OUI, in the octet field immediately after the Category field, differentiates the vendors.

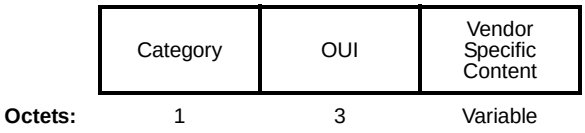

Figure 7-101—Vendor Specific Action frame format

The Category field is set to the value indicating the vendor-specific category, as specified in Table 7-24.

The OUI field is a public OUI assigned by the IEEE. It is 3 octets in length. It contains the OUI of the entity that has defined the content of the particular vendor-specific action.

The Vendor Specific Content contains vendor-specific field(s). The length of the Vendor Specific Content in a Vendor Specific Action frame is limited by the maximum allowed MMPDU size.

7.5 Frame usage

Table 7-58 shows which frame subtypes are transmitted and received by different kinds of MAC entities operating in the different types of BSS and under the available coordination functions.

Table 7-58—Frame subtype usage by BSS type, MAC entity type, and coordination function

Frame subtype	IBSS		Infrastructure BSS							
	non-QoS	QoS	non-QoS				QoS

Table 7-58—Frame subtype usage by BSS type, MAC entity type, and coordination function *(continued)*

Frame subtype	IBSS		Infrastructure BSS							
	non-QoS	QoS	non-QoS				QoS			
	CP	CP	CP		CFP		CP		CFP	
	STA	STA	STA	AP	STA	AP	STA	AP	STA	AP
QoS Data+CF-Ack	- - -	- - -	- - -	- - -	- - -	- - -	T, Rq, Rda	Tda, Tq, R	T, Rq, Rda	Tda, Tq, R

Symbols:

T frame subtype is transmitted by MAC entity for column.

R frame subtype is received by MAC entity for column.

(R) frame subtype is received, but only from other BSSs, by MAC entity for column.

Tb frame subtype is transmitted by STA that most recently won beacon arbitration.

Tbe frame subtype is transmitted by a QoS STA in an IBSS pursuant to receiving directed request.

Tda frame subtype is transmitted only if recipient of +CF-Ack function is addressee.

Rda frame subtype is received if QoS STA is addressee.

Tq frame subtype is transmitted only if recipient of +CF-Ack function has set the Q-Ack subfield in QoS Capability element to 1.

Rq frame subtype is received if QoS STA is not the addressee, but has set the Q-Ack subfield in QoS Capability element to 1.

- - - frame subtype is neither received nor transmitted by MAC entity for column.

8. Security

8.1 Framework

This standard defines two classes of security algorithms for IEEE 802.11 networks:

— Algorithms for creating and using an RSNA, called *RSNA algorithms*

— Pre-RSNA algorithms

NOTE—This standard does not prohibit STAs from simultaneously operating pre-RSNA and RSNA algorithms.

8.1.1 Security methods

Pre-RSNA security comprises the following algorithms:

— WEP, described in 8.2.1

— IEEE 802.11 entity authentication, described in 8.2.2

RSNA security comprises the following algorithms:

— TKIP, described in 8.3.2

— CCMP, described in 8.3.3

— RSNA establishment and termination procedures, including use of IEEE 802.1X authentication, described in 8.4

— Key management procedures, described in 8.5

8.1.2 RSNA equipment and RSNA capabilities

RSNA-capable equipment can create RSNAs. When dot11RSNAEnabled is true, RSNA-capable equipment shall include the RSN information element in Beacon, Probe Response, and (Re)Association Request frames and in Message 2 and Message 3 of the 4-Way Handshake. Pre-RSNA equipment is not capable of creating RSNAs.

8.1.3 RSNA establishment

A STA's SME establishes an RSNA in one of four ways:

a) When using IEEE 802.1X AKM in an ESS, an RSNA-capable STA's SME establishes an RSNA as follows:
   1) It identifies the AP as RSNA-capable from the AP's Beacon or Probe Response frames.
   2) It shall invoke Open System authentication.
   3) It negotiates cipher suites during the association process, as described in 8.4.2 and 8.4.3.
   4) It uses IEEE Std 802.1X-2004 to authenticate, as described in 8.4.6 and 8.4.7.
   5) It establishes temporal keys by executing a key management algorithm, using the protocol defined by 8.5.
   6) It programs the agreed-upon temporal keys and cipher suites into the MAC and invokes protection. See 8.3.2 and 8.3.3 for a description of the RSNA data protection mechanisms.

b) If an RSNA is based on a PSK in an ESS, the STA's SME establishes an RSNA as follows:
   1) It identifies the AP as RSNA-capable from the AP's Beacon or Probe Response frames.
   2) It shall invoke Open System authentication.
   3) It negotiates cipher suites during the association process, as described in 8.4.2 and 8.4.3.
   4) It establishes temporal keys by executing a key management algorithm, using the protocol defined by 8.5. It uses the PSK as the PMK.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001378

5) It protects the data link by programming the negotiated cipher suites and the established temporal key into the MAC and then invoking protection.

c) If an RSNA is based on a PSK in an IBSS, the STA's SME executes the following sequence of procedures:

1) It identifies the peer as RSNA-capable from the peer's Beacon or Probe Response frames.

NOTE—STAs may respond to a data MPDU from an unrecognized STA by sending a Probe Request frame to find out whether the unrecognized STA is RSNA-capable.

2) It may optionally invoke Open System authentication.

3) Each STA uses the procedures in 8.5, to establish temporal keys and to negotiate cipher suites. It uses a PSK as the PMK. Note that two peer STAs may follow this procedure simultaneously. See 8.4.9.

4) It protects the data link by programming the negotiated cipher suites and the established temporal key and then invoking protection.

d) An RSNA-capable STA's SME using IEEE 802.1X AKM in an IBSS establishes an RSNA as follows:

1) It identifies the peer as RSNA-capable from the peer's Beacon or Probe Response frames.

NOTE—STAs may respond to a data MPDU from an unrecognized STA by sending a Probe Request frame to find out whether the unrecognized STA is RSNA-capable.

2) It may optionally invoke Open System authentication.

3) Each STA uses IEEE Std 802.1X-2004 to authenticate with the AS associated with the other STA's Authenticator, as described in 8.4.6 and 8.4.7. Hence two authentications are happening at the same time.

4) Each STA's SME establishes temporal keys by executing a key management algorithm, using the protocol defined in 8.5. Hence two such key management algorithms are happening in parallel between any two STA's Supplicants and Authenticators.

5) Both STAs use the agreed-upon temporal key portion of the PTK and pairwise cipher suite from one of the exchanges to protect the link. Each STA uses the GTK established by the exchange it initiated to protect the multicast and broadcast frames it transmits.

The time a security association takes to set up shall be less than the MIB variable dot11RSNAConfigSA-Timeout. The security association setup starts when initiated by the SME and completes when the MLME-SETPROTECTION.request primitive is invoked. The action the STA takes on the timeout is a policy decision. Some options include retrying the security association setup or trying another STA. This timeout allows recovery when one of the STAs setting up a security association fails to respond correctly to setting up the security association. It also allows recovery in IBSS when one of the two security associations fails because of a security association timeout.

8.1.4 RSNA PeerKey Support

The PeerKey protocol provides mutual authentication, session identification, and data confidentiality for a station-to-station connection. A PeerKey association, composed of an SMKSA and an STKSA, shall be allowed only within the context of an existing RSNA by both peers with a common AP. Both the initiator STA and the peer STA shall ensure that dot11RSNAEnabled is true before initiating the STSL master key (SMK) Handshake and STSL transient key (STK) Handshake and establishing their respective security associations.

A STSL session may chose to allow unprotected communication between STAs. In this case, the PeerKey protocol is not used.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001379

8.1.5 RSNA assumptions and constraints

An RSNA assumes the following:

a) Each STA can generate cryptographic-quality random numbers. This assumption is fundamental, as cryptographic methods require a source of randomness. See H.6 for suggested hardware and software methods to achieve randomness suitable for this purpose.

b) When IEEE 802.1X authentication is used, the specific EAP method used performs mutual authentication. This assumption is intrinsic to the design of RSN in IEEE 802.11 LANs and cannot be removed without exposing both the STAs to man-in-the-middle attacks. EAP-MD5 is an example of an EAP method that does not meet this constraint (see IETF RFC 3748 [B26]). Furthermore, the use of EAP authentication methods where server and client credentials cannot be differentiated reduces the security of the method to that of a PSK due to the fact that malicious insiders can masquerade as servers and establish a man-in-the-middle attack.

   In particular, the mutual authentication requirement implies an unspecified prior enrollment process (e.g., a long-lived authentication key or establishment of trust through a third party such as a certification authority), as the STA must be able to identify the ESS or IBSS as a trustworthy entity and vice versa. The STA shares authentication credentials with the AS utilized by the selected AP or, in the case of PSK, the selected AP. The SSID provides an unprotected indication that the selected AP's authentication entity shares credentials with the STA. Only the successful completion of the IEEE 802.1X EAP or PSK authentication, after association, can validate any such indication that the AP is connected to an authorized network or service provider.

c) The mutual authentication method must be strong, meaning impersonation attacks are computationally infeasible when based on the information exposed by the authentication. This assumption is intrinsic to the design of RSN.

d) The AP and AS have a trustworthy channel between them that can be used to exchange cryptographic keys without exposure to any intermediate parties.

e) An IEEE 802.1X AS never exposes the common symmetric key to any party except the AP with which the STA is currently communicating. This is a very strong constraint. It implies that the AS itself is never compromised. It also implies that the IEEE 802.1X AS is embedded in the AP or that the AP is physically secure and the AS and the AP lie entirely within the same administrative domain. This assumption follows from the fact that if the AP and the AS are not co-located or do not share pairwise key encryption keys directly, then it is impossible to assure the mobile STA that its key, which is distributed by the AS to the AP, has not been compromised prior to use.

f) Similarly, a STA never shares with a third party a common symmetric key that it shares with a peer. Doing so destroys the utility of the key for detecting MPDU replay and forgery.

g) The STA's Supplicant and the Authenticator generate a different, fresh PTK for each session between the pair. This assumption is fundamental, as reuse of any PTK would enable compromise of all the data protected by that key.

h) The destination STA chosen by the transmitter is the correct destination. For example, Address Resolution Protocol (ARP) and Internet Control Message Protocol (ICMP) are methods of determining the destination STA MAC address that are not secure from attacks by other members of the ESS. One of the possible solutions to this problem might be for the STA to send or receive only frames whose final DA or SA are the AP and for the AP to provide a network layer routing function. However, such solutions are outside the scope of this standard.

8.2 Pre-RSNA security methods

Except for Open System authentication, all pre-RSNA security mechanisms have been deprecated, as they fail to meet their security goals. New implementations should support pre-RSNA methods only to aid migration to RSNA methods.

8.2.1 Wired equivalent privacy (WEP)

8.2.1.1 WEP overview

WEP-40 was defined as a means of protecting (using a 40-bit key) the confidentiality of data exchanged among authorized users of a WLAN from casual eavesdropping. Implementation of WEP is optional. The same algorithms have been widely used with a 104-bit key instead of a 40-bit key in fielded implementations; this is called WEP-104. The WEP cryptographic encapsulation and decapsulation mechanics are the same whether a 40-bit or a 104-bit key is used. Therefore, subsequently, WEP can refer to either WEP-40 or WEP-104.

8.2.1.2 WEP MPDU format

Figure 8-1 depicts the encrypted frame body as constructed by the WEP algorithm.

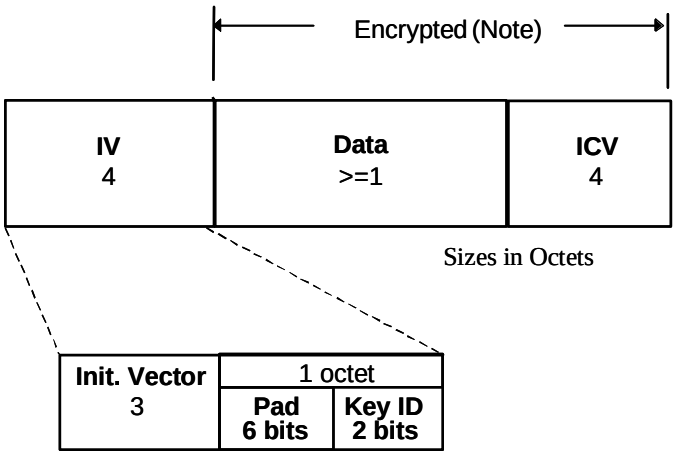

Figure 8-1—Construction of expanded WEP MPDU

The WEP ICV field shall be 32 bits in length. The expanded frame body shall start with a 32-bit IV field. This field shall contain three subfields: a 3-octet subfield that contains the IV, a 2-bit Key ID subfield, and a 6-bit Pad subfield. The ordering conventions defined in 7.1.1 apply to the IV field and its subfields and to the ICV field. The Key ID subfield contents select one of four possible secret key values for use in decrypting this frame body. When key-mapping keys are used, the Key ID field value is ignored.

Interpretation of these bits is discussed further in 8.2.1.3. The contents of the Pad subfield shall be 0. The Key ID subfield occupies the 2 MSBs of the last octet of the IV field, while the Pad subfield occupies the 6 LSBs of this octet.

8.2.1.3 WEP state

WEP uses encryption keys only; it performs no data authentication. Therefore, it does not have data integrity keys. WEP uses two types of encryption keys: key-mapping keys and default keys.

A key-mapping key is an unnamed key corresponding to a distinct transmitter address-receiver address <TA,RA> pair. Implementations shall use the key-mapping key if it is configured for a <TA,RA> pair. In other words, the key-mapping key shall be used to WEP-encapsulate or -decapsulate MPDUs transmitted by TA to RA, regardless of the presence of other key types. When a key-mapping key for an address pair is present, the WEP Key ID subfield in the MPDU shall be set to 0 on transmit and ignored on receive.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001381

A default key is an item in a four-element MIB array called dot11WEPDefaultKeys, named by the value of a related array index called dot11WEPDefaultKeyID. If a key-mapping key is not configured for a WEP MPDU's <TA,RA> pair, WEP shall use a default key to encapsulate or decapsulate the MPDU. On transmit, the key selected is the element of the dot11DefaultKeys array given by the index dot11WEPDefault-KeyID—a value of 0, 1, 2, or 3—corresponding to the first, second, third, or fourth element, respectively, of dot11WEPDefaultKeys. The value the transmitter encodes in the WEP Key ID subfield of the transmitted MPDU shall be the dot11WEPDefaultKeyID value. The receiver shall use the Key ID subfield of the MPDU to index into dot11WEPDefaultKeys to obtain the correct default key. All WEP implementations shall support default keys.

NOTE—Many implementations also support 104-bit WEP keys. These are used exactly like 40-bit WEP keys: a 24-bit WEP IV is prepended to the 104-bit key to construct a 128-bit WEP seed, as explained in 8.2.1.4.3. The resulting 128-bit WEP seed is then consumed by the ARC4 stream cipher.

This construction based on 104-bit keys affords no more assurance than the 40-bit construction, and its implementation and use are in no way condoned by this standard. Rather, the 104-bit construction is noted only to document de facto practice.

The default value for all WEP keys shall be null. WEP implementations shall discard the MSDU and generate an MA-UNITDATA.confirm with transmission status indicating that a frame may not be encapsulated with a null key in response to any request to encapsulate an MPDU with a null key.

8.2.1.4 WEP procedures

8.2.1.4.1 WEP ICV algorithm

The WEP ICV shall be computed using the CRC-32, as defined in 7.1.3.6, calculated over the plaintext MPDU Data (PDU) field.

8.2.1.4.2 WEP encryption algorithm

A WEP implementation shall use the ARC4 stream cipher from RSA Security, Inc., as its encryption and decryption algorithm. ARC4 uses a pseudo-random number generator (PRNG) to generate a key stream that it exclusive-ORs (XORs) with a plaintext data stream to produce cipher text or to recover plaintext from a cipher text.

8.2.1.4.3 WEP seed construction

A WEP implementation shall construct a per-MPDU key, called a *seed*, by concatenating an encryption key to an IV.

For WEP-40, bits 0–39 of the WEP key correspond to bits 24–63 of the seed, and bits 0–23 of the IV correspond to bits 0–23 of the seed, respectively. The bit numbering conventions in 7.1.1 apply to the seed. The seed shall be the input to ARC4, in order to encrypt or decrypt the WEP Data and ICV fields.

NOTE—For WEP-104, bits 0–103 of the WEP key correspond to bits 24–127 of the seed, and bit 0–23 of the IV correspond to bits 0–23 of the seed, respectively.

The WEP implementation encapsulating an MPDU's plaintext data should select a new IV for every MPDU it WEP-protects. The IV selection algorithm is unspecified. The algorithm used to select the encryption key used to construct the seed is also unspecified.

The WEP implementation decapsulating an MPDU shall use the IV from the received MPDU's Init Vector subfield. See 8.2.1.4.5 for the specification of how the decapsulator selects the key to use to construct the per-MPDU key.

Exhibit 1014
Page 001382

8.2.1.4.4 WEP MPDU cryptographic encapsulation

WEP shall apply three transformations to the plaintext MPDU to effect the WEP cryptographic encapsulation. WEP computes the ICV over the plaintext data and appends this after the MPDU data. WEP encrypts the MPDU plaintext data and ICV using ARC4 with a seed constructed as specified in 8.2.1.4.3. WEP encodes the IV and key identifier into the IV field, prepended to the encrypted Data field.

Figure 8-2 depicts the WEP cryptographic encapsulation process. The ICV shall be computed and appended to the plaintext data prior to encryption, but the IV encoding step may occur in any order convenient for the implementation.

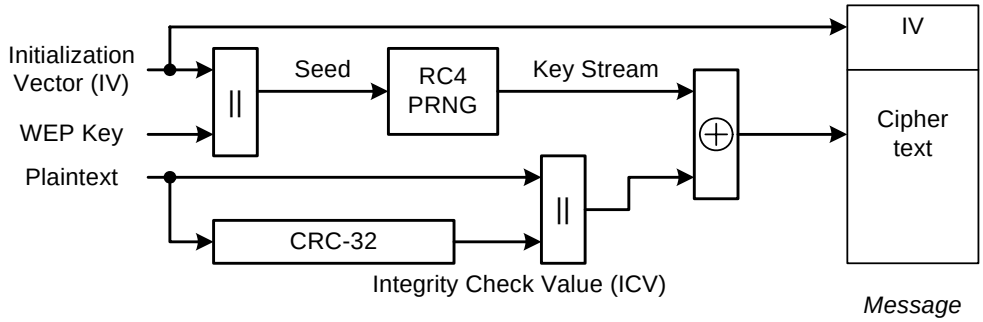

Figure 8-2—WEP encapsulation block diagram

8.2.1.4.5 WEP MPDU decapsulation

WEP shall apply three transformations to the WEP MPDU to decapsulate its payload. WEP extracts the IV and key identifier from the received MPDU. If a key-mapping key is present for the <TA,RA> pair, then this shall be used as the WEP key. Otherwise, the key identifier is extracted from the Key ID subfield of the WEP IV field in the received MPDU, identifying the default key to use.

WEP uses the constructed seed to decrypt the Data field of the WEP MPDU; this produces plaintext data and an ICV. Finally WEP recomputes the ICV and bit-wise compares it with the decrypted ICV from the MPDU. If the two are bit-wise identical, then WEP removes the IV and ICV from the MPDU, which is accepted as valid. If they differ in any bit position, WEP generates an error indication to MAC management. MSDUs with erroneous MPDUs (due to inability to decrypt) shall not be passed to LLC.

Figure 8-3 depicts a block diagram for WEP decapsulation. Unlike cryptographic encapsulation, the decapsulation steps shall be in the indicated order.

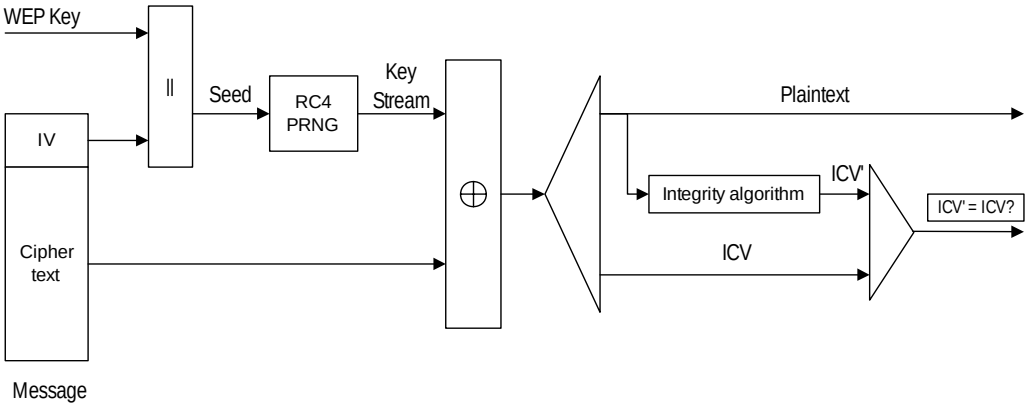

Figure 8-3—WEP decapsulation block diagram

8.2.2 Pre-RSNA authentication

8.2.2.1 Overview

In an ESS, a non-AP STA and an AP must both complete an IEEE 802.11 authentication exchange prior to association. Such an exchange is optional in an independent BSS network.

All management frames of subtype Authentication shall be unicast, as IEEE 802.11 authentication is performed between pairs of STAs, i.e., broadcast/multicast authentication is not allowed. Management frames of subtype Deauthentication are advisory and may be sent as group addressed frames.

Shared Key authentication is deprecated and should not be implemented except for backward compatibility with pre-RSNA devices.

8.2.2.2 Open System authentication

Open System authentication is a null authentication algorithm. Any STA requesting Open System authentication may be authenticated if dot11AuthenticationAlgorithm at the recipient STA is set to Open System authentication. A STA may decline to authenticate with another requesting STA. Open System authentication is the default authentication algorithm for pre-RSNA equipment.

Open System authentication utilizes a two-message authentication transaction sequence. The first message asserts identity and requests authentication. The second message returns the authentication result. If the result is "successful," the STAs shall be declared mutually authenticated.

In the description in 8.2.2.2.1 and 8.2.2.2.2, the STA initiating the authentication exchange is referred to as the *requester*, and the STA to which the initial frame in the exchange is addressed is referred to as the *responder*. The specific items in each of the messages described in the following subclauses are defined in 7.2.3.10, Table 7-16, and Table 7-17.

8.2.2.2.1 Open System authentication (first frame)

— Message type: Management
— Message subtype: Authentication
— Information items:
  • Authentication Algorithm Identification = "Open System"
  • STA Identity Assertion (in SA field of header)
  • Authentication transaction sequence number = 1
  • Authentication algorithm dependent information (none)
— Direction of message: From requester to responder

8.2.2.2.2 Open System authentication (final frame)

— Message type: Management
— Message subtype: Authentication
— Information items:
  • Authentication Algorithm Identification = "Open System"
  • Authentication transaction sequence number = 2
  • Authentication algorithm dependent information (none)
  • The result of the requested authentication as defined in 7.3.1.9
— Direction of message: From responder to requester

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001384

If dot11AuthenticationAlgorithm does not include the value “Open System,” the result code shall not take the value “successful.”

8.2.2.3 Shared Key authentication

Shared Key authentication seeks to authenticate STAs as either a member of those who know a shared secret key or a member of those who do not.

Shared Key authentication can be used if and only if WEP has been selected.

This mechanism uses a shared key delivered to participating STAs via a secure channel that is independent of IEEE Std 802.11. This shared key is set in a write-only MIB attribute with the intent to keep the key value internal to the STA.

A STA shall not initiate a Shared Key authentication exchange unless its dot11PrivacyOptionImplemented attribute is true.

In the description in 8.2.2.3.1 through 8.2.2.3.5, the STA initiating the authentication exchange is referred to as the *requester*, and the STA to which the initial frame in the exchange is addressed is referred to as the *responder*. The specific items in each of the messages described in the following subclauses are defined in 7.2.3.10, Table 7-16, and Table 7-17.

8.2.2.3.1 Shared Key authentication (first frame)

— Message type: Management

— Message subtype: Authentication

— Information items:

- STA Identity Assertion (in SA field of header)
- Authentication Algorithm Identification = “Shared Key”
- Authentication transaction sequence number = 1
- Authentication algorithm dependent information (none)

— Direction of message: From requester to responder

8.2.2.3.2 Shared Key authentication (second frame)

Before sending the second frame in the Shared Key authentication sequence, the responder shall use WEP to generate a string of octets to be used as the authentication challenge text.

— Message type: Management

— Message subtype: Authentication

— Information items:

- Authentication Algorithm Identification = “Shared Key”
- Authentication transaction sequence number = 2
- Authentication algorithm dependent information = The authentication result
- The status code of the requested authentication as defined in 7.3.1.9.

  If the status code is not “successful,” this shall be the last frame of the transaction sequence; and the content of the challenge text field is unspecified.

  If the status code is “successful,” the following additional information items shall have valid contents:

  Authentication algorithm dependent information = The challenge text

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001385

This authentication result shall be of fixed length of 128 octets. The field shall be filled with octets generated by the WEP PRNG. The actual value of the challenge field is unimportant, but the value shall not be a static value.

— Direction of message: From responder to requester

8.2.2.3.3 Shared Key authentication (third frame)

The requester shall copy the challenge text from the second frame into the third frame. The third frame shall be transmitted after cryptographic encapsulation by WEP, as defined in 8.2.1, using the shared key.

— Message type: Management

— Message subtype: Authentication

— Information items:

- Authentication Algorithm Identification = “Shared Key”
- Authentication transaction sequence number = 3
- Authentication algorithm dependent information = The challenge text from the second frame

— Direction of message: From requester to responder

8.2.2.3.4 Shared Key authentication (final frame)

The responder shall WEP-decapsulate the third frame as described in 8.2.1. If the WEP ICV check is successful, the responder shall compare the decrypted contents of the Challenge Text field with the challenge text sent in second frame. If they are the same, then the responder shall respond with a successful status code in the final frame of the sequence. If the WEP ICV check fails or challenge text comparison fails, the responder shall respond with an unsuccessful status code in final frame.

— Message type: Management

— Message subtype: Authentication

— Information items:

- Authentication Algorithm Identification = “Shared Key”
- Authentication transaction sequence number = 4
- Authentication algorithm dependent information = The authentication result
- The status code of the requested authentication as defined in 7.3.1.9.

  This is a fixed length item with values “successful” and “unsuccessful.”

— Direction of message: From responder to requester

8.2.2.3.5 Shared key MIB attributes

To transmit a management frame of subtype Authentication, with an Authentication Transaction Sequence Number field value of 2, the MAC shall operate according to the following decision tree:

if dot11PrivacyOptionImplemented is “false” **then**

the MMPDU is transmitted with a sequence of 0 octets in the Challenge Text field and a status code value of 13

else

the MMPDU is transmitted with a sequence of 128 octets generated using the WEP PRNG and a key whose value is unspecified and beyond the scope of this standard and a randomly chosen IV value (note that this will typically be selected by the same mechanism for choosing IV values for transmitted data MPDUs) in the Challenge Text field and a status code value of 0 (the IV used is immaterial and is not transmitted). Note that there are cryptographic issues involved in the choice of key/IV for this process as the challenge text is sent unencrypted and, therefore, provides a known output sequence from the PRNG.

endif

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001386

To receive a management frame of subtype Authentication, with an Authentication Transaction Sequence Number field value of 2, the MAC shall operate according to the following decision tree:

if the Protected Frame subfield of the Frame Control field is 1 **then**
respond with a status code value of 15
else
if dot11PrivacyOptionImplemented is "true" **then**
if there is a mapping in dot11WEPKeyMappings matching the MSDU's TA **then**
if that key is null **then**
respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of 15, and no Challenge Text field, without encrypting the contents of the frame
else
respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of 0, and the identical Challenge Text field, encrypted using that key, and setting the Key ID subfield in the IV field to 0
endif
else
if dot11WEPDefaultKeys[dot11WEPDefaultKeyID] is null **then**
respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of 15, and no Challenge Text field, without encrypting the contents of the frame
else
respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of 0, and the identical Challenge Text field, WEP-encapsulating the frame under the key dot11WEPDefaultKeys[dot11WEPDefaultKeyID], and setting the Key ID subfield in the IV field to dot11WEPDefaultKeyID
endif
endif
else
respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of 13, and no Challenge Text field, without encrypting the contents of the frame
endif
endif

When receiving a management frame of subtype Authentication, with an Authentication Transaction Sequence Number field value of 3, the MAC shall operate according to the following decision tree:

if the Protected Frame subfield of the Frame Control field is 0 **then**
respond with a status code value of 15
else
if dot11PrivacyOptionImplemented is "true" **then**
if there is a mapping in dot11WEPKeyMappings matching the MSDU's TA **then**
if that key is null **then**
respond with a frame whose Authentication Transaction Sequence Number field is 4 that contains the appropriate authentication algorithm number and a status code value of 15 without encrypting the contents of the frame
else
WEP-decapsulate with that key, incrementing dot11WEPICVErrorCount and responding with a status code value of 15 if the ICV check fails

Page 001387

endif
else
if dot11WEPDefaultKeys[dot11WEPDefaultKeyID] is null **then**
respond with a frame whose Authentication Transaction Sequence Number field is 4 that contains the appropriate authentication algorithm number and a status code value of 15 without encrypting the contents of the frame
else
WEP-decapsulate with dot11WEPDefaultKeys[dot11WEPDefault-KeyID], incrementing dot11WEPICVErrorCount and responding with a status code value of 15 if the ICV check fails
endif
endif
else
respond with a frame whose Authentication Transaction Sequence Number field is 4 that contains the appropriate authentication algorithm number and a status code value of 15
endif
endif

The attribute dot11PrivacyInvoked shall not take the value of true if the attribute dot11PrivacyOption-Implemented is false. Setting dot11WEPKeyMappings to a value that includes more than dot11WEPKey-MappingLength entries is illegal and shall have an implementation-specific effect on the operation of the data confidentiality service. Note that dot11WEPKeyMappings may contain from zero to dot11WEPKey-MappingLength entries, inclusive.

The values of the attributes in the aPrivacygrp should not be changed during the authentication sequence, as unintended operation may result.

8.3 RSNA data confidentiality protocols

8.3.1 Overview

This standard defines two RSNA data confidentiality and integrity protocols: TKIP and CCMP. Implementation of CCMP shall be mandatory in all IEEE 802.11 devices claiming RSNA compliance. Implementation of TKIP is optional for an RSNA. A design aim for TKIP was that the algorithm should be implementable within the capabilities of most devices supporting only WEP, so that many such devices would be field-upgradeable by the supplier to support TKIP.

NOTE—Use of any of the data confidentiality algorithms depends on local policies. The data confidentiality and integrity mechanisms of TKIP are not as robust as those of CCMP. TKIP is designed to operate within the hardware limitations of a broad class of pre-RSNA devices. TKIP is suitable for firmware-only, hardware-compatible upgrade of fielded equipment. RSNA devices should only use TKIP when communicating with devices that are unable or not configured to communicate using CCMP.

8.3.2 Temporal Key Integrity Protocol (TKIP)

8.3.2.1 TKIP overview

The TKIP is a cipher suite enhancing the WEP protocol on pre-RSNA hardware. TKIP modifies WEP as follows:

a) A transmitter calculates a keyed cryptographic message integrity code (MIC) over the MSDU SA and DA, the MSDU priority (see 8.3.2.3), and the MSDU plaintext data. TKIP appends the computed MIC to the MSDU data prior to fragmentation into MPDUs. The receiver verifies the MIC after decryption, ICV checking, and defragmentation of the MPDUs into an MSDU and

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001388

discards any received MSDUs with invalid MICs. TKIP's MIC provides a defense against forgery attacks.

b) Because of the design constraints of the TKIP MIC, it is still possible for an adversary to compromise message integrity; therefore, TKIP also implements countermeasures. The countermeasures bound the probability of a successful forgery and the amount of information an attacker can learn about a key.

c) TKIP uses a per-MPDU TKIP sequence counter (TSC) to sequence the MPDUs it sends. The receiver drops MPDUs received out of order, i.e., not received with increasing sequence numbers. This provides replay protection. TKIP encodes the TSC value from the sender to the receiver as a WEP IV and extended IV.

d) TKIP uses a cryptographic mixing function to combine a temporal key, the TA, and the TSC into the WEP seed. The receiver recovers the TSC from a received MPDU and utilizes the mixing function to compute the same WEP seed needed to correctly decrypt the MPDU. The key mixing function is designed to defeat weak-key attacks against the WEP key.

TKIP defines additional MIB variables; see Annex D.

8.3.2.1.1 TKIP cryptographic encapsulation

TKIP enhances the WEP cryptographic encapsulation with several additional functions, as depicted in Figure 8-4.

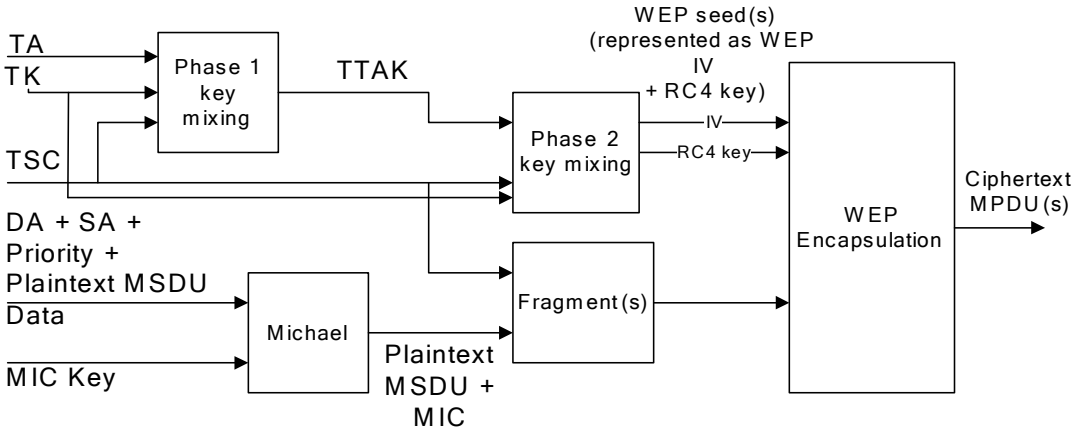

Figure 8-4—TKIP encapsulation block diagram

a) TKIP MIC computation protects the MSDU Data field and corresponding SA, DA, and Priority fields. The computation of the MIC is performed on the ordered concatenation of the SA, DA, Priority, and MSDU Data fields. The MIC is appended to the MSDU Data field. TKIP discards any MIC padding prior to appending the MIC.

b) If needed, IEEE Std 802.11 fragments the MSDU with MIC into one or more MPDUs. TKIP assigns a monotonically increasing TSC value to each MPDU, taking care that all the MPDUs generated from the same MSDU have the same value of extended IV (see 8.3.2.2).

c) For each MPDU, TKIP uses the key mixing function to compute the WEP seed.

d) TKIP represents the WEP seed as a WEP IV and ARC4 key and passes these with each MPDU to WEP for generation of the ICV (see 7.1.3.6), and for encryption of the plaintext MPDU, including all or part of the MIC, if present. WEP uses the WEP seed as a WEP default key, identified by a key identifier associated with the temporal key.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001389

NOTE—When the TSC space is exhausted, the choices available to an implementation are to replace the temporal key with a new one or to end communications. Reuse of any TSC value compromises already sent traffic. Note that retransmitted MPDUs reuse the TSC without any compromise of security. The TSC is large enough, however, that TSC space exhaustion should not be an issue.

In Figure 8-4, the TKIP-mixed transmit address and key (TTAK) denotes the intermediate key produced by Phase 1 of the TKIP mixing function (see 8.3.2.5).

8.3.2.1.2 TKIP decapsulation

TKIP enhances the WEP decapsulation process with the following additional steps:

a) Before WEP decapsulates a received MPDU, TKIP extracts the TSC sequence number and key identifier from the WEP IV and the extended IV. TKIP discards a received MPDU that violates the sequencing rules (see 8.3.2.6) and otherwise uses the mixing function to construct the WEP seed.

b) TKIP represents the WEP seed as a WEP IV and ARC4 key and passes these with the MPDU to WEP for decapsulation.

c) If WEP indicates the ICV check succeeded, the implementation reassembles the MPDU into an MSDU. If the MSDU defragmentation succeeds, the receiver verifies the TKIP MIC. If MSDU defragmentation fails, then the MSDU is discarded.

d) The MIC verification step recomputes the MIC over the MSDU SA, DA, Priority, and MSDU Data fields (but not the TKIP MIC field). The calculated TKIP MIC result is then compared bit-wise against the received MIC.

e) If the received and the locally computed MIC values are identical, the verification succeeds, and TKIP shall deliver the MSDU to the upper layer. If the two differ, then the verification fails; the receiver shall discard the MSDU and shall engage in appropriate countermeasures.

Figure 8-5 depicts this process.

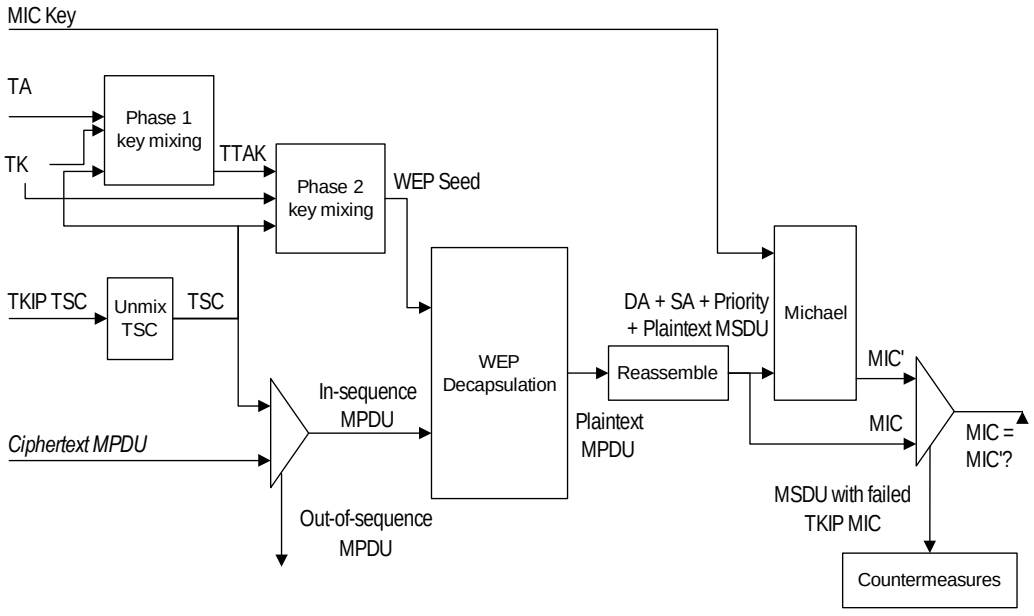

Figure 8-5—TKIP decapsulation block diagram

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001390

8.3.2.2 TKIP MPDU formats

TKIP reuses the pre-RSNA WEP MPDU format. It extends the MPDU by 4 octets to accommodate an extension to the WEP IV, denoted by the Extended IV field, and extends the MSDU format by 8 octets to accommodate the new MIC field. TKIP inserts the Extended IV field immediately after the WEP IV field and before the encrypted data. TKIP appends the MIC to the MSDU Data field; the MIC becomes part of the encrypted data.

Once the MIC is appended to the MSDU data, the added MIC octets are considered part of the MSDU for subsequent fragmentation.

Figure 8-6 depicts the layout of the encrypted MPDU when using TKIP. Note the figure only depicts the case when the MSDU can be encapsulated in a single MPDU.

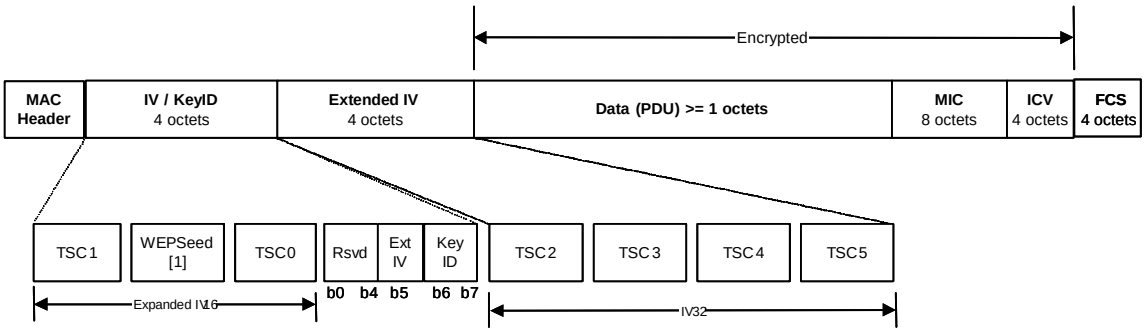

Figure 8-6—Construction of expanded TKIP MPDU

The ExtIV bit in the Key ID octet indicates the presence or absence of an extended IV. If the ExtIV bit is 0, only the nonextended IV is transferred. If the ExtIV bit is 1, an extended IV of 4 octets follows the original IV. For TKIP the ExtIV bit shall be set, and the Extended IV field shall be supplied. The ExtIV bit shall be 0 for WEP frames. The Key ID field shall be set to the key index supplied by the MLME-SETKEYS.request primitive for the key used in cryptographic encapsulation of the frame.

TSC5 is the most significant octet of the TSC, and TSC0 is the least significant. Octets TSC0 and TSC1 form the IV sequence number and are used with the TKIP Phase 2 key mixing. Octets TSC2–TSC5 are used in the TKIP Phase 1 key hashing and are in the Extended IV field. When the lower 16-bit sequence number rolls over (0xFFFF → 0x0000), the extended IV value, i.e., the upper 32 bits of the entire 48-bit TSC, shall be incremented by 1.

NOTE—The rationale for this construction is as follows:

— Aligning on word boundaries eases implementation on legacy devices.

— Adding 4 octets of extended IV eliminates TSC exhaustion as a reason to rekey.

— Key ID octet changes. Bit 5 indicates that an extended IV is present. The receiver/transmitter interprets the 4 octets following the Key ID as the extended IV. The receiving/transmitting STA also uses the value of octets TSC0 and TSC1 to detect that the cached TTAK must be updated.

The Extended IV field shall not be encrypted.

WEPSeed[1] is not used to construct the TSC, but is set to (TSC1 | 0x20) & 0x7f.

TKIP shall encrypt all the MPDUs generated from one MSDU under the same temporal key.

8.3.2.3 TKIP MIC

Flaws in the IEEE 802.11 WEP design cause it to fail to meet its goal of protecting data traffic content from casual eavesdroppers. Among the most significant WEP flaws is the lack of a mechanism to defeat message forgeries and other active attacks. To defend against active attacks, TKIP includes a MIC, named Michael. This MIC offers only weak defenses against message forgeries, but it constitutes the best that can be achieved with the majority of legacy hardware. TKIP uses different MIC keys depending on the direction of the transfer as described in 8.6.1 and 8.6.2.

Annex H contains an implementation of the TKIP MIC. It also provides test vectors for the MIC.

8.3.2.3.1 Motivation for the TKIP MIC

Before defining the details of the MIC, it is useful to review the context in which this mechanism operates. Active attacks enabled by the original WEP design include the following:

— Bit-flipping attacks

— Data (payload) truncation, concatenation, and splicing

— Fragmentation attacks

— Iterative guessing attacks against the key

— Redirection by modifying the MPDU DA or RA field

— Impersonation attacks by modifying the MPDU SA or TA field

The MIC makes it more difficult for any of these attacks to succeed.

All of these attacks remain at the MPDU level with the TKIP MIC. The MIC, however, applies to the MSDU, so it blocks successful MPDU-level attacks. TKIP applies the MIC to the MSDU at the transmitter and verifies it at the MSDU level at the receiver. If a MIC check fails at the MSDU level, the implementation shall discard the MSDU and invoke countermeasures (see 8.3.2.4).

Informative Figure 8-7 depicts different peer layers communicating.

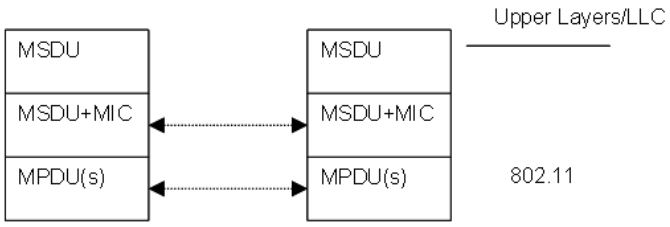

Figure 8-7—TKIP MIC relation to IEEE 802.11 processing (informative)

This figure depicts an architecture where the MIC is logically appended to the raw MSDU in response to the MA-UNITDATA.request primitive. The TKIP MIC is computed over

— The MSDU DA

— The MSDU SA

— The MSDU Priority

— The entire unencrypted MSDU data (payload)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001392

The DA field, SA field, three reserved octets, and a 1-octet Priority field are used only for calculating the MIC. The Priority field refers to the priority parameter of the MA-UNITDATA.request service primitive. The fields in Figure 8-8 are treated as an octet stream using the conventions described in 7.1.1.

6	6	1	3	M	1	1	1	1	1	1	1	1	octets
DA	SA	Priority	0	Data	M 0	M 1	M 2	M 3	M 4	M 5	M 6	M 7	

Figure 8-8—TKIP MIC processing format

TKIP appends the MIC at the end of the MSDU payload. The MIC is 8 octets in size for Michael. The IEEE 802.11 MAC then applies its normal processing to transmit this MSDU-with-MIC as a sequence of one or more MPDUs. In other words, the MSDU-with-MIC can be partitioned into one or more MPDUs, the WEP ICV is calculated over each MPDU, and the MIC can even be partitioned to lie in two MPDUs after fragmentation. The TKIP MIC augments, but does not replace, the WEP ICV. Because the TKIP MIC is a weak construction, TKIP protects the MIC with encryption, which makes TKIP MIC forgeries more difficult. The WEP ICV helps to prevent false detection of MIC failures that would cause countermeasures to be invoked.

The receiver reverses this procedure to reassemble the MSDU; and, after the MSDU has been logically reassembled, the IEEE 802.11 MAC verifies the MIC prior to delivery of the MSDU to upper layers. If the MIC validation succeeds, the MAC delivers the MSDU. If the MIC validation fails, the MAC shall discard the MSDU and invoke countermeasures (see 8.3.2.4).

NOTE—TKIP calculates the MIC over the MSDU rather than the MPDU, because doing so increases the implementation flexibility with pre-existing WEP hardware.

It should be noted that a MIC alone cannot provide complete forgery protection, as it cannot defend against replay attacks. Therefore, TKIP provides replay detection by TSC sequencing and ICV validation. Furthermore, if TKIP is utilized with a GTK, an insider STA can masquerade as any other STA belonging to the group.

8.3.2.3.2 Definition of the TKIP MIC

Michael generates a 64-bit MIC. The Michael key consists of 64 bits, represented as an 8-octet sequence, $k_0...k_7$. This is converted to two 32-bit words, K_0 and K_1. Throughout this subclause, all conversions between octets and 32-bit words shall use the little endian conventions, given in 7.1.1.

Michael operates on each MSDU including the Priority field, 3 reserved octets, SA field, and DA field. An MSDU consists of octets $m_0...m_{n-1}$ where n is the number of MSDU octets, including SA, DA, Priority, and Data fields. The message is padded at the end with a single octet with value 0x5a, followed by between 4 and 7 zero octets. The number of zero octets is chosen so that the overall length of the padded MSDU is a multiple of four. The padding is not transmitted with the MSDU; it is used to simplify the computation over the final block. The MSDU is then converted to a sequence of 32-bit words $M_0 ...M_{N-1}$, where $N = \lceil (n+5)/4 \rceil$, and where $\lceil a \rceil$ means to round a up to the nearest integer. By construction, $M_{N-1} = 0$ and $M_{N-2} \neq 0$.

The MIC value is computed iteratively starting with the key value (K_0 and K_1) and applying a block function b for every message word, as shown in Figure 8-9. The algorithm loop runs a total of N times (i takes on the values 0 to N–1 inclusive), where N is as above, the number of 32-bit words composing the padded MSDU. The algorithm results in two words (l and r), which are converted to a sequence of 8 octets using the least-significant-octet-first convention:

— M0 = l & 0xff

— M1 = (l/0x100) & 0xff

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001393

— M2 = (*l*/0x10000) & 0xff
— M3 = (*l*/0x1000000) & 0xff
— M4 = *r* & 0xff
— M5 = (*r*/0x100) & 0xff
— M6 = (*r*/0x10000) & 0xff
— M7 = (*r*/0x1000000) & 0xff

This is the MIC value. The MIC value is appended to the MSDU as data to be sent.

```
Input: Key (K0, K1) and padded MSDU (represented as 32-bit words) M0...MN-1
Output: MIC value (V0, V1)
        MICHAEL((K0, K1) , (M0,...,MN))
        (l,r) ← (K0, K1)
        for i = 0 to N–1 do
                l ← l ⊕ M-i
                (l, r) ← b(l, r)
        return (l,r)
```

Figure 8-9—Michael message processing

Figure 8-10 defines the Michael block function *b*. It is a Feistel-type construction with alternating additions and XOR operations. It uses <<< to denote the rotate-left operator on 32-bit values, >>> for the rotate-right operator, and XSWAP for a function that swaps the position of the 2 least significant octets. It also uses the position of the two most significant octets in a word.

```
Input: (l,r)
Output: (l,r)
b(L,R)
        r ← r ⊕ (l <<< 17)
        l ← (l + r) mod 232
        r ← r ⊕ XSWAP(l)
        l ← (l + r) mod 232
        r ← r ⊕ (l <<< 3)
        l ← (l + r) mod 232
        r ← r ⊕ (l >>> 2)
        l ← (l + r) mod 232
        return (l, r)
```

Figure 8-10—Michael block function

8.3.2.4 TKIP countermeasures procedures

The TKIP MIC trades off security in favor of implementability on pre-RSNA devices. Michael provides only weak protection against active attacks. A failure of the MIC in a received MSDU indicates a probable active attack. A successful attack against the MIC would mean an attacker could inject forged data frames and perform further effective attacks against the encryption key itself. If TKIP implementation detects a probable active attack, TKIP shall take countermeasures as specified in this subclause. These countermeasures accomplish the following goals:

— MIC failure events *should* be logged as a security-relevant matter. A MIC failure is an almost certain indication of an active attack and warrants a follow-up by the system administrator.
— The rate of MIC failures *must* be kept below two per minute. This implies that STAs and APs detecting two MIC failure events within 60 s must disable all receptions using TKIP for a period of 60 s. The slowdown makes it difficult for an attacker to make a large number of forgery attempts in a short time.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001394

— As an additional security feature, the PTK and, in the case of the Authenticator, the GTK should be changed.

Before verifying the MIC, the receiver shall check the FCS, ICV, and TSC for all related MPDUs. Any MPDU that has an invalid FCS, an incorrect ICV, or a TSC value that is less than or equal to the TSC replay counter shall be discarded before checking the MIC. This avoids unnecessary MIC failure events. Checking the TSC before the MIC makes countermeasure-based denial-of-service attacks harder to perform. While the FCS and ICV mechanisms are sufficient to detect noise, they are insufficient to detect active attacks. The FCS and ICV provide error detection, but not integrity protection.

A single counter or timer shall be used to log MIC failure events. These failure events are defined as follows:

— For an Authenticator:
  — Detection of a MIC failure on a received unicast frame.
  — Receipt of Michael MIC Failure Report frame.
— For a Supplicant:
  — Detection of a MIC failure on a received unicast or broadcast/multicast frame.
  — Attempt to transmit a Michael MIC Failure Report frame.

The number of MIC failures is accrued independent of the particular key context. Any single MIC failure, whether detected by the Supplicant or the Authenticator and whether resulting from a group MIC key failure or a pairwise MIC key failure, shall be treated as cause for a MIC failure event.

The Supplicant uses a single Michael MIC Failure Report frame to report a MIC failure event to the Authenticator. A Michael MIC Failure Report is an EAPOL-Key frame with the following Key Information field bits set to 1: MIC bit, Error bit, Request bit, Secure bit. The Supplicant protects this message with the current PTK; the Supplicant uses the KCK portion of the PTK to compute the IEEE 802.1X EAPOL MIC.

MLME-MICHEALMICFAILURE.indication primitive is used by the IEEE 802.11 MAC to attempt to indicate a MIC failure to the local IEEE 802.1X Supplicant or Authenticator. MLME-EAPOL.request primitive is used by the Supplicant to send the EAPOL-Key frame containing the Michael MIC Failure Report. MLME-EAPOL.confirm primitive indicates to the Supplicant when an IEEE 802.11 MAC ACK has been received for this EAPOL-Key frame.

The first MIC failure shall be logged, and a timer initiated to enable enforcement of the countermeasures. If the MIC failure event is detected by the Supplicant, it shall also report the event to the AP by sending a Michael MIC Failure Report frame.

If a subsequent MIC failure occurs within 60 s of the most recent previous failure, then a STA whose IEEE 802.1X entity has acted as a Supplicant shall deauthenticate (as defined in 11.3.1.3) itself or deauthenticate all the STAs with a security association if its IEEE 802.1X entity acted as an Authenticator. For an IBSS STA, both Supplicant and Authenticator actions shall be taken. Furthermore, the device shall not receive or transmit any TKIP-encrypted data frames, and shall not receive or transmit any unencrypted data frames other than IEEE 802.1X messages, to or from any peer for a period of at least 60 s after it detects the second failure. If the device is an AP, it shall disallow new associations using TKIP during this 60 s period; at the end of the 60 s period, the AP shall resume normal operations and allow STAs to (re)associate. If the device is an IBSS STA, it shall disallow any new security associations using TKIP during this 60 s period. If the device is a Supplicant, it shall first send a Michael MIC Failure Report frame prior to revoking its PTKSA and deauthenticating itself.

The `aMICFailTime` attribute shall contain the `sysUpTime` value at the time the MIC failure was logged.

Exhibit 1014
Page 001395

8.3.2.4.1 TKIP countermeasures for an Authenticator

The countermeasures used by an Authenticator are depicted in Figure 8-11 and described as follows:

a) For an Authenticator's STA that receives a frame with a MIC error,
   1) Discard the frame.
   2) Increment the MIC failure counter, dot11RSNAStatsTKIPLocalMICFailures.
   3) Generate a MLME-MICHAELMICFAILURE.indication primitive.

b) For an Authenticator that receives a MLME-MICHAELMICFAILURE.indication primitive or a Michael MIC Failure Report frame,
   1) If it is a Michael MIC Failure Report frame, then increment dot11RSNAStatsTKIP-RemoteMICFailures.
   2) If this is the first MIC failure within the past 60 s, initialize the countermeasures timer.
   3) If less than 60 s have passed since the most recent previous MIC failure, the Authenticator shall deauthenticate and delete all PTKSAs for all STAs using TKIP. If the current GTKSA uses TKIP, that GTKSA shall be discarded, and a new GTKSA constructed, but not used for 60 s. The Authenticator shall refuse the construction of new PTKSAs using TKIP as one or more of the ciphers for 60 s. At the end of this period, the MIC failure counter and timer shall be reset, and creation of PTKSAs accepted as usual.
   4) If the Authenticator is using IEEE 802.1X authentication, the Authenticator shall transition the state of the IEEE 802.1X Authenticator state machine to the INITIALIZE state. This will restart the IEEE 802.1X state machine. If the Authenticator is instead using PSKs, this step is omitted.

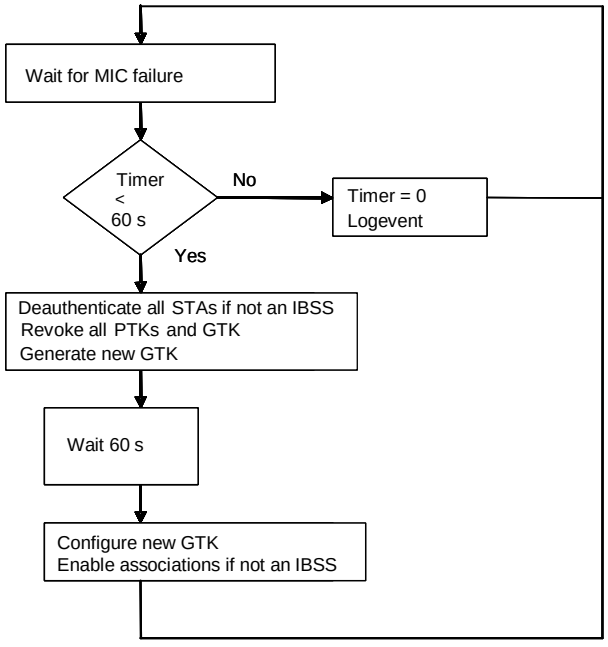

Figure 8-11—Authenticator MIC countermeasures

Note that a Supplicant's STA may deauthenticate with a reason code of MIC failure if it is an ESS STA. The Authenticator shall not log the deauthenticate as a MIC failure event to prevent denial-of-service attacks through deauthentications. The Supplicant's STA must report the MIC failure event through the Michael MIC Failure Report frame in order for the AP to log the event.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001396

The requirement to deauthenticate all STAs using TKIP will include those using CCMP as a pairwise cipher if they are also using TKIP as the group cipher.

8.3.2.4.2 TKIP countermeasures for a Supplicant

The countermeasures used by a Supplicant are depicted in Figure 8-12 and described as follows:

a) For a Supplicant's STA that receives a frame with a MIC error,
   1) Increment the MIC failure counter, dot11RSNAStatsTKIPLocalMICFailures.
   2) Discard the offending frame.
   3) Generate a MLME-MICHAELMICFAILURE.indication primitive.

b) For a Supplicant that receives an MLME-MICHAELMICFAILURE.indication primitive from its STA,
   1) Send a Michael MIC Failure Report frame to the AP.
   2) If this is the first MIC failure within the past 60 s, initialize the countermeasures timer.
   3) If less than 60 s have passed since the most recent previous MIC failure, delete the PTKSA and GTKSA. Deauthenticate from the AP and wait for 60 s before (re)establishing a TKIP association with the same AP. A TKIP association is any IEEE 802.11 association that uses TKIP for its pairwise or group cipher suite.

c) If a non-AP STA receives a deauthenticate frame with the reason code "MIC failure," it cannot be certain that the frame has not been forged, as it does not contain a MIC. The STA may attempt association with this, or another, AP. If the frame was genuine, then it is probable that attempts to associate with the same AP requesting the use of TKIP will fail because the AP will be conducting countermeasures.

8.3.2.5 TKIP mixing function

Annex H defines a C-language reference implementation of the TKIP mixing function. It also provides test vectors for the mixing function.

The mixing function has two phases. Phase 1 mixes the appropriate temporal key (pairwise or group) with the TA and TSC. A STA may cache the output of this phase to reuse with subsequent MPDUs associated with the same temporal key and TA. Phase 2 mixes the output of Phase 1 with the TSC and temporal key (TK) to produce the WEP seed, also called the *per-frame key*. The WEP seed may be precomputed before it is used. The two-phase process may be summarized as follows:

```
TTAK := Phase1 (TK, TA, TSC)
WEP seed := Phase2 (TTAK, TK, TSC)
```

8.3.2.5.1 S-Box

Both Phase 1 and Phase 2 rely on an S-box, defined in this subclause. The S-box substitutes one 16-bit value with another 16-bit value. This function may be implemented as a table look up.

NOTE—The S-box is a nonlinear substitution. The table look-up can be organized as either a single table with 65 536 entries and a 16-bit index (128K octets of table) or two tables with 256 entries and an 8-bit index (1024 octets for both tables). When the two smaller tables are used, the high-order octet is used to obtain a 16-bit value from one table, the low-order octet is used to obtain a 16-bit value from the other table, and the S-box output is the XOR (⊕) of the two 16-bit values. The second S-box table is an octet-swapped replica of the first.

```
#define _S_(v16)     (Sbox[0][Lo8(v16)] ^ Sbox[1][Hi8(v16)])

/* 2-byte by 2-byte subset of the full AES S-box table */
const u16b Sbox[2][256]=       /* Sbox for hash (can be in ROM)     */

8.3.2.5.2 Phase 1 Definition

The inputs to Phase 1 of the temporal key mixing function shall be a temporal key (*TK*), the TA, and the TSC. The temporal key shall be 128 bits in length. Only the 32 MSBs of the TSC and all of the temporal key are used in Phase 1. The output, *TTAK*, shall be 80 bits in length and is represented by an array of 16-bit values: $TTAK_0$ $TTAK_1$ $TTAK_2$ $TTAK_3$ $TTAK_4$.

The description of the Phase 1 algorithm treats all of the following values as arrays of 8-bit values: $TA_0..TA_5$, $TK_0..TK_{15}$. The *TA* octet order is represented according to the conventions from 7.1.1, and the first 3 octets represent the OUI.

The XOR (⊕) operation, the bit-wise-and (&) operation, and the addition (+) operation are used in the Phase 1 specification. A loop counter, *i*, and an array index temporary variable, *j*, are also employed.

One function, *Mk*16, is used in the definition of Phase 1. The function *Mk*16 constructs a 16-bit value from two 8-bit inputs as $Mk16(X,Y) = (256 \cdot X)+Y$.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001399

Two steps make up the Phase 1 algorithm. The first step initializes *TTAK* from *TSC* and *TA*. The second step uses an S-box to iteratively mix the keying material into the 80-bit *TTAK*. The second step sets the PHASE1_LOOP_COUNT to 8.

```
Input: transmit address TA0...TA5, Temporal Key TK0..TK15, and TSC0..TSC5
Output: intermediate key TTAK0..TTAK4
PHASE1-KEY-MIXING(TA0...TA5, TK0..TK15, TSC0..TSC5)
    PHASE1_STEP1:
    TTAK0 ← MK16(TSC3, TSC2)
    TTAK1 ← MK16(TSC5, TSC4)
    TTAK2 ← Mk16(TA1,TA0)
    TTAK3 ← Mk16(TA3,TA2)
    TTAK4 ← Mk16(TA5,TA4)
    PHASE1_STEP2:
    for i = 0 to PHASE1_LOOP_COUNT-1
        j ← 2·(i & 1)
        TTAK0 ← TTAK0 + S[TTAK4 ⊕ Mk16(TK1+j,TK0+j)]
        TTAK1 ← TTAK1 + S[TTAK0 ⊕ Mk16(TK5+j,TK4+j)]
        TTAK2 ← TTAK2 + S[TTAK1 ⊕ Mk16(TK9+j,TK8+j)]
        TTAK3 ← TTAK3 + S[TTAK2 ⊕ Mk16(TK13+j,TK12+j)]
        TTAK4 ← TTAK4 + S[TTAK3 ⊕ Mk16(TK1+j,TK0+j)] + i
```

Figure 8-13—Phase 1 key mixing

NOTE 1—The TA is mixed into the temporal key in Phase 1 of the hash function. Implementations can achieve a significant performance improvement by caching the output of Phase 1. The Phase 1 output is the same for 2^{16} = 65 536 consecutive frames from the same temporal key and TA. Consider the simple case where a STA communicates only with an AP. The STA will perform Phase 1 using its own address, and the *TTAK* will be used to protect traffic sent to the AP. The STA will perform Phase 1 using the AP address, and it will be used to unwrap traffic received from the AP.

NOTE 2—The cached *TTAK* from Phase 1 will need to be updated when the lower 16 bits of the TSC wrap and the upper 32 bits need to be updated.

8.3.2.5.3 Phase 2 definition

The inputs to Phase 2 of the temporal key mixing function shall be the output of Phase 1 (*TTAK*) together with the temporal key and the TSC. The *TTAK* is 80-bits in length. Only the 16 LSBs of the TSC are used in Phase 2. The temporal key is 128 bits. The output is the WEP seed, which is a per-frame key, and is 128 bits in length. The constructed WEP seed has an internal structure conforming to the WEP specification. In other words, the first 24 bits of the WEP seed shall be transmitted in plaintext as the WEP IV. As such, these 24 bits are used to convey lower 16 bits of the TSC from the sender (encryptor) to the receiver (decryptor). The rest of the TSC shall be conveyed in the Extended IV field. The temporal key and *TTAK* values are represented as in Phase 1. The WEP seed is treated as an array of 8-bit values: $WEPSeed_0 \ldots WEPSeed_{15}$. The TSC shall be treated as an array of 8-bit values: $TSC_0\ TSC_1\ TSC_2\ TSC_3\ TSC_4\ TSC_5$.

The pseudo-code specifying the Phase 2 mixing function employs one variable: *PPK*, which is 96 bits long. The *PPK* is represented as an array of 16-bit values: $PPK_0..PPK_5$. The pseudo-code also employs a loop counter, *i*. As detailed in this subclause, the mapping from the 16-bit *PPK* values to the 8-bit *WEPseed* values is explicitly little endian to match the endian architecture of the most common processors used for this application.

The XOR (⊕) operation, the addition (+) operation, the AND (&) operation, the OR (|) operation, and the right bit shift (>>) operation are used in the specification of Phase 2.

        *PPK*0 ← *PPK*0 + *RotR*1(*PPK*5 ⊕ *Mk*16(*TK*13,*TK*12))
        *PPK*1 ← *PPK*1 + *RotR*1(*PPK*0 ⊕ *Mk*16(*TK*15,*TK*14))
        *PPK*2 ← *PPK*2 + *RotR*1(*PPK*1)
        *PPK*3 ← *PPK*3 + *RotR*1(*PPK*2)
        *PPK*4 ← *PPK*4 + *RotR*1(*PPK*3)
        *PPK*5 ← *PPK*5 + *RotR*1(*PPK*4)
    PHASE2_STEP3:
        *WEPSeed*0 ← *TSC*1
        *WEPSeed*1 ← (TSC1 | 0x20) & 0x7F
        *WEPSeed*2 ← TSC0
        *WEPSeed*3 ← *Lo*8((*PPK*5 ⊕ *Mk*16(*TK*1,*TK*0)) >> 1)
        for *i* = 0 to 5
            *WEPSeed*4+(2·*i*) ← *Lo*8(*PPKi*)
            *WEPSeed*5+(2·*i*) ← *Hi*8(*PPKi*)
        end
    return *WEPSeed*0…*WEPSeed*15

Figure 8-14—Phase 2 key mixing

The algorithm specification relies on four functions:

— The first function, *Lo*8, references the 8 LSBs of the 16-bit input value.

— The second function, *Hi*8, references the 8 MSBs of the 16-bit value.

— The third function, *RotR*1, rotates its 16-bit argument 1 bit to the right.

— The fourth function, *Mk*16, is already used in Phase 1, defined by $Mk16(X,Y) = (256 \cdot X)+Y$, and constructs a 16-bit output from two 8-bit inputs.

NOTE—The rotate and addition operations in STEP2 make Phase 2 particularly sensitive to the endian architecture of the processor, although the performance degradation due to running this algorithm on a big endian processor should be minor.

Phase 2 comprises three steps:

— STEP1 makes a copy of *TTAK* and brings in the TSC.

— STEP2 is a 96-bit bijective mixing, employing an S-box.

— STEP3 brings in the last of the temporal key *TK* bits and assigns the 24-bit WEP IV value.

The WEP IV format carries 3 octets. STEP3 of Phase 2 determines the value of each of these three octets. The construction was selected to preclude the use of known ARC4 weak keys. The recipient can reconstruct the 16 LSBs of the TSC used by the originator by concatenating the third and first octets, ignoring the second octet. The remaining 32 bits of the TSC are obtained from the Extended IV field.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001401

8.3.2.6 TKIP replay protection procedures

TKIP implementations shall use the TSC field to defend against replay attacks by implementing the following rules:

a) Each MPDU shall have a unique TKIP TSC value.

b) Each transmitter shall maintain a single TSC (48-bit counter) for each PTKSA, GTKSA, and STKSA.

c) The TSC shall be implemented as a 48-bit monotonically incrementing counter, initialized to 1 when the corresponding TKIP temporal key is initialized or refreshed.

d) The WEP IV format carries the 16 LSBs of the 48-bit TSC, as defined by the TKIP mixing function (Phase 2, STEP3). The remainder of the TSC is carried in the Extended IV field.

e) A receiver shall maintain a separate set of TKIP TSC replay counters for each PTKSA, GTKSA, and STKSA.

f) TKIP replay detection takes place after the MIC verification and any reordering required by ACK processing. Thus, a receiver shall delay advancing a TKIP TSC replay counter until an MSDU passes the MIC check, to prevent attackers from injecting MPDUs with valid ICVs and TSCs, but invalid MICs.

   NOTE—This works because if an attacker modifies the TSC, then the encryption key is modified and hence both the ICV and MIC will ordinarily decrypt incorrectly, causing the received MPDU to be dropped.

g) For each PTKSA, GTKSA, and STKSA, the receiver shall maintain a separate replay counter for each frame priority and shall use the TSC recovered from a received frame to detect replayed frames, subject to the limitations on the number of supported replay counters indicated in the RSN Capabilities field, as described in 7.3.2.25. A replayed frame occurs when the TSC extracted from a received frame is less than or equal to the current replay counter value for the frame's priority. A transmitter shall not reorder frames with different priorities without ensuring that the receiver supports the required number of replay counters. The transmitter shall not reorder frames within a replay counter, but may reorder frames across replay counters. One possible reason for reordering frames is the IEEE 802.11 MSDU priority.

h) A receiver shall discard any MPDU that is received out of order and shall increment the value of dot11RSNAStatsTKIPReplays for this key.

i) For MSDUs sent using the Block Ack feature, reordering of received MSDUs according to the Block Ack receiver operation (described in 9.10.4) is performed prior to replay detection.

8.3.3 CTR with CBC-MAC Protocol (CCMP)

This subclause specifies the CCMP, which provides data confidentiality, authentication, integrity, and replay protection. CCMP is mandatory for RSN compliance.

8.3.3.1 CCMP overview

CCMP is based on the CCM of the AES encryption algorithm. CCM combines CTR for data confidentiality and CBC-MAC for authentication and integrity. CCM protects the integrity of both the MPDU Data field and selected portions of the IEEE 802.11 MPDU header.

The AES algorithm is defined in FIPS PUB 197-2001. All AES processing used within CCMP uses AES with a 128-bit key and a 128-bit block size.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001402

CCM is defined in IETF RFC 3610. CCM is a generic mode that can be used with any block-oriented encryption algorithm. CCM has two parameters (*M* and *L*), and CCMP uses the following values for the CCM parameters:

— *M* = 8; indicating that the MIC is 8 octets.

— *L* = 2; indicating that the Length field is 2 octets, which is sufficient to hold the length of the largest possible IEEE 802.11 MPDU, expressed in octets.

CCM requires a fresh temporal key for every session. CCM also requires a unique nonce value for each frame protected by a given temporal key, and CCMP uses a 48-bit packet number (PN) for this purpose. Reuse of a PN with the same temporal key voids all security guarantees.

Annex H provides a test vector for CCM.

8.3.3.2 CCMP MPDU format

Figure 8-15 depicts the MPDU when using CCMP.

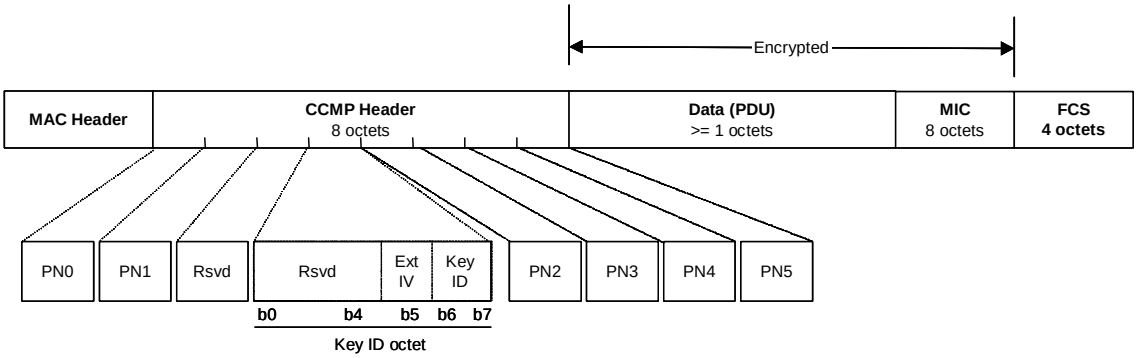

Figure 8-15—Expanded CCMP MPDU

CCMP processing expands the original MPDU size by 16 octets, 8 octets for the CCMP Header field and 8 octets for the MIC field. The CCMP Header field is constructed from the PN, ExtIV, and Key ID subfields. PN is a 48-bit PN represented as an array of 6 octets. PN5 is the most significant octet of the PN, and PN0 is the least significant. Note that CCMP does not use the WEP ICV.

The ExtIV subfield (bit 5) of the Key ID octet signals that the CCMP Header field extends the MPDU header by a total of 8 octets, compared to the 4 octets added to the MPDU header when WEP is used. The ExtIV bit (bit 5) is always set to 1 for CCMP.

Bits 6–7 of the Key ID octet are for the Key ID subfield.

The reserved bits shall be set to 0 and shall be ignored on reception.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001403

8.3.3.3 CCMP cryptographic encapsulation

The CCMP cryptographic encapsulation process is depicted in Figure 8-16.

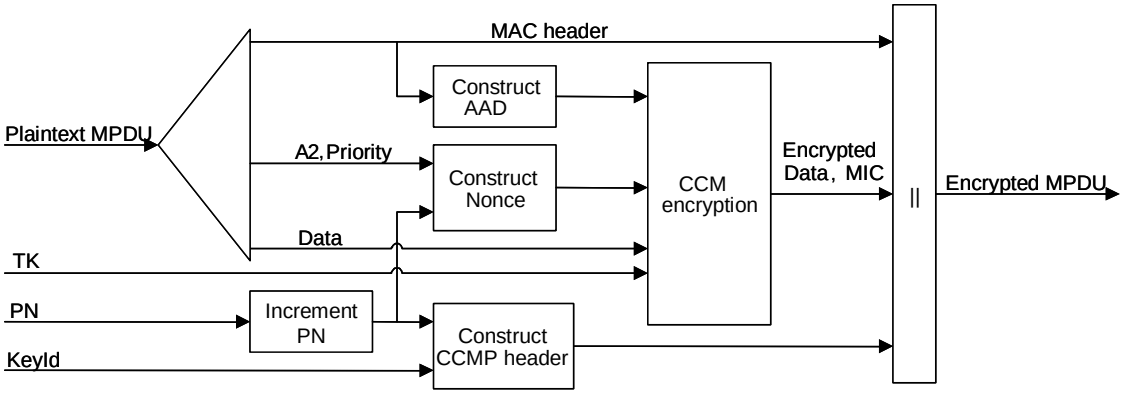

Figure 8-16—CCMP encapsulation block diagram

CCMP encrypts the payload of a plaintext MPDU and encapsulates the resulting cipher text using the following steps:

a) Increment the PN, to obtain a fresh PN for each MPDU, so that the PN never repeats for the same temporal key. Note that retransmitted MPDUs are not modified on retransmission.

b) Use the fields in the MPDU header to construct the additional authentication data (AAD) for CCM. The CCM algorithm provides integrity protection for the fields included in the AAD. MPDU header fields that may change when retransmitted are muted by being masked to 0 when calculating the AAD.

c) Construct the CCM Nonce block from the PN, A2, and the Priority field of the MPDU where A2 is MPDU Address 2.

d) Place the new PN and the key identifier into the 8-octet CCMP header.

e) Use the temporal key, AAD, nonce, and MPDU data to form the cipher text and MIC. This step is known as CCM originator processing.

f) Form the encrypted MPDU by combining the original MPDU header, the CCMP header, the encrypted data and MIC, as described in 8.3.3.2.

The CCM reference describes the processing of the key, nonce, AAD, and data to produce the encrypted output. See 8.3.3.3.1 through 8.3.3.3.5 for details of the creation of the AAD and nonce from the MPDU and the associated MPDU-specific processing.

8.3.3.3.1 PN processing

The PN is incremented by a positive number for each MPDU. The PN shall never repeat for a series of encrypted MPDUs using the same temporal key.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001404

8.3.3.3.2 Construct AAD

The format of the AAD is shown in Figure 8-17.

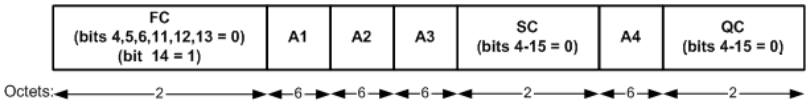

Figure 8-17—AAD construction

The length of the AAD varies depending on the presence or absence of the QC and A4 fields and is shown in Table 8-1:

Table 8-1—AAD length

QC field	A4 field	AAD length (octets)
Absent	Absent	22
Present	Absent	24
Absent	Present	28
Present	Present	30

The AAD is constructed from the MPDU header. The AAD does not include the header Duration field, because the Duration field value can change due to normal IEEE 802.11 operation (e.g., a rate change during retransmission). For similar reasons, several subfields in the Frame Control field are masked to 0. AAD construction is performed as follows:

a) FC – MPDU Frame Control field, with
   1) Subtype bits (bits 4 5 6) masked to 0
   2) Retry bit (bit 11) masked to 0
   3) PwrMgt bit (bit 12) masked to 0
   4) MoreData bit (bit 13) masked to 0
   5) Protected Frame bit (bit 14) always set to 1

b) A1 – MPDU Address 1 field.

c) A2 – MPDU Address 2 field.

d) A3 – MPDU Address 3 field.

e) SC – MPDU Sequence Control field, with the Sequence Number subfield (bits 4–15 of the Sequence Control field) masked to 0. The Fragment Number subfield is not modified.

f) A4 – MPDU Address field, if present in the MPDU.

g) QC – QoS Control field, if present, a 2-octet field that includes the MSDU priority. The QC TID is used in the construction of the AAD, and the remaining QC fields are set to 0 for the AAD calculation (bits 4 to 15 are set to 0).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001405

8.3.3.3.3 Construct CCM nonce

The Nonce field occupies 13 octets, and its structure is shown in Figure 8-18.

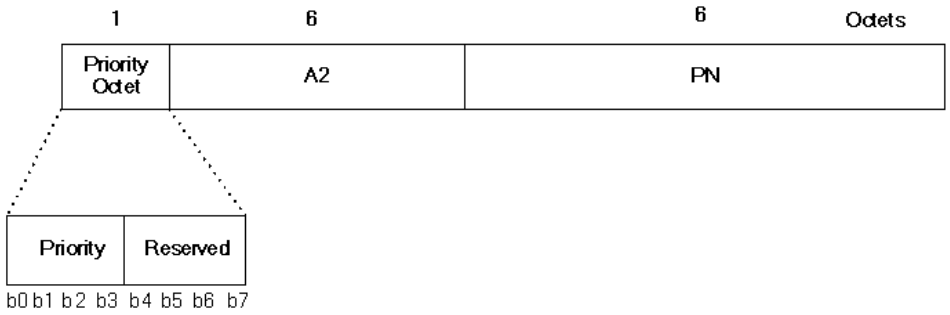

Figure 8-18—Nonce construction

The Nonce field has an internal structure of Priority Octet || A2 || PN ("||" is concatenation), where

— The Priority Octet field shall be set to the fixed value 0 (0x00) when there is no QC field present in the MPDU header. When the QC field is present, bits 0 to 3 of the Priority Octet field shall be set to the value of the QC TID (bits 0 to 3 of the QC field). Bits 4 to 7 of the Proirity Octet field are reserved and shall be set to 0.

— MPDU address A2 field occupies octets 1–6. This shall be encoded with the octets ordered with A2 octet 0 at octet index 1 and A2 octet 5 at octet index 6.

— The PN field occupies octets 7–12. The octets of PN shall be ordered so that PN0 is at octet index 12 and PN5 is at octet index 7.

8.3.3.3.4 Construct CCMP header

The format of the 8-octet CCMP header is given in 8.3.3.2. The header encodes the PN, Key ID, and ExtIV field values used to encrypt the MPDU.

8.3.3.3.5 CCM originator processing

CCM is a generic authenticate-and-encrypt block cipher mode, and in this standard, CCM is used with the AES block cipher.

There are four inputs to CCM originator processing:

a) *Key:* the temporal key (16 octets).

b) *Nonce:* the nonce (13 octets) constructed as described in 8.3.3.3.3.

c) *Frame body:* the frame body of the MPDU (1–2296 octets; 2296 = 2312 – 8 MIC octets – 8 CCMP header octets).

d) *AAD:* the AAD (22–30 octets) constructed from the MPDU header as described in 8.3.3.3.2.

The CCM originator processing provides authentication and integrity of the frame body and the AAD as well as data confidentiality of the frame body. The output from the CCM originator processing consists of the encrypted data and 8 additional octets of encrypted MIC (see Figure 8-15).

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001406

8.3.3.4 CCMP decapsulation

Figure 8-19 depicts the CCMP decapsulation process.

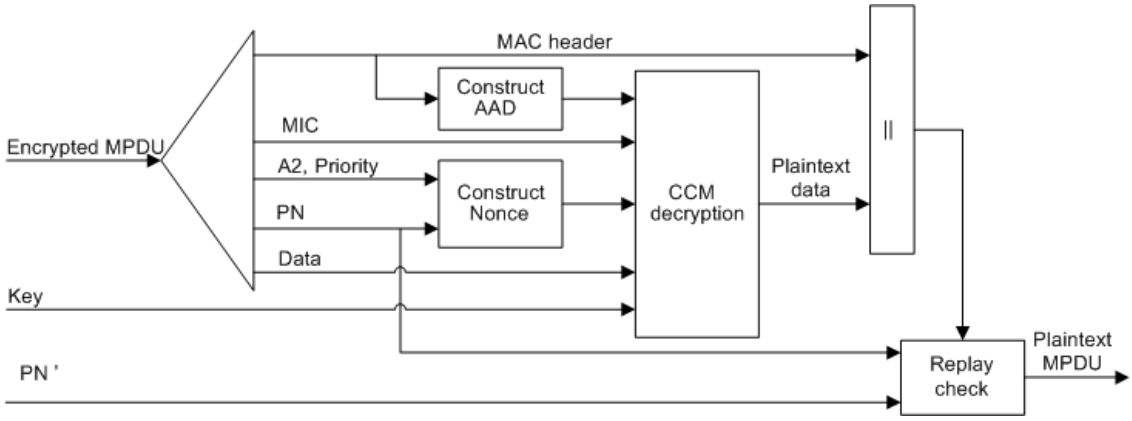

Figure 8-19—CCMP decapsulation block diagram

CCMP decrypts the payload of a cipher text MPDU and decapsulates a plaintext MPDU using the following steps:

a) The encrypted MPDU is parsed to construct the AAD and nonce values.

b) The AAD is formed from the MPDU header of the encrypted MPDU.

c) The Nonce value is constructed from the A2, PN, and Priority Octet fields.

d) The MIC is extracted for use in the CCM integrity checking.

e) The CCM recipient processing uses the temporal key, AAD, nonce, MIC, and MPDU cipher text data to recover the MPDU plaintext data as well as to check the integrity of the AAD and MPDU plaintext data.

f) The received MPDU header and the MPDU plaintext data from the CCM recipient processing may be concatenated to form a plaintext MPDU.

g) The decryption processing prevents replay of MPDUs by validating that the PN in the MPDU is greater than the replay counter maintained for the session.

See 8.3.3.4.1 through 8.3.3.4.3 for details of this processing.

8.3.3.4.1 CCM recipient processing

CCM recipient processing must use the same parameters as CCM originator processing.

There are four inputs to CCM recipient processing:

— *Key:* the temporal key (16 octets).

— *Nonce:* the nonce (13 octets) constructed as described in 8.3.3.3.3.

— *Encrypted frame body:* the encrypted frame body from the received MPDU. The encrypted frame body includes an 8-octet MIC (9–2304 octets).

— *AAD:* the AAD (22–30 octets) that is the canonical MPDU header as described in 8.3.3.3.2.

The CCM recipient processing checks the authentication and integrity of the frame body and the AAD as well as decrypting the frame body. The plaintext is returned only if the MIC check is successful.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001407

There is one output from error-free CCM recipient processing:

— *Frame body:* the plaintext frame body, which is 8 octets smaller than the encrypted frame body.

8.3.3.4.2 Decrypted CCMP MPDU

The decapsulation process succeeds when the calculated MIC matches the MIC value obtained from decrypting the received encrypted MPDU. The original MPDU header is concatenated with the plaintext data resulting from the successful CCM recipient processing to create the plaintext MPDU.

8.3.3.4.3 PN and replay detection

To effect replay detection, the receiver extracts the PN from the CCMP header. See 8.3.3.2 for a description of how the PN is encoded in the CCMP header. The following processing rules are used to detect replay:

a) The PN values sequentially number each MPDU.

b) Each transmitter shall maintain a single PN (48-bit counter) for each PTKSA, GTKSA, and STKSA.

c) The PN shall be implemented as a 48-bit monotonically incrementing non-negative integer, initialized to 1 when the corresponding temporal key is initialized or refreshed.

d) A receiver shall maintain a separate set of PN replay counters for each PTKSA, GTKSA, and STKSA. The receiver initializes these replay counters to 0 when it resets the temporal key for a peer. The replay counter is set to the PN value of accepted CCMP MPDUs.

e) For each PTKSA, GTKSA, and STKSA, the recipient shall maintain a separate replay counter for each IEEE 802.11 MSDU priority and shall use the PN recovered from a received frame to detect replayed frames, subject to the limitation of the number of supported replay counters indicated in the RSN Capabilities field (see 7.3.2.25). A replayed frame occurs when the PN extracted from a received frame is less that or equal to the current replay counter value for the frame's MSDU priority. A transmitter shall not use IEEE 802.11 MSDU priorities without ensuring that the receiver supports the required number of replay counters. The transmitter shall not reorder frames within a replay counter, but may reorder frames across replay counters. One possible reason for reordering frames is the IEEE 802.11 MSDU priority.

f) The receiver shall discard MSDUs whose constituent MPDU PN values are not sequential. A receiver shall discard any MPDU that is received with its PN less than or equal to the replay counter and shall increment the value of dot11RSNAStatsCCMPReplays for this key.

g) For MSDUs sent using the Block Ack feature, reordering of received MSDUs according to the Block Ack receiver operation (described in 9.10.4) is performed prior to replay detection.

8.4 RSNA security association management

8.4.1 Security associations

8.4.1.1 Security association definitions

IEEE Std 802.11 uses the notion of a security association to describe secure operation. Secure communications are possible only within the context of a security association, as this is the context providing the state—cryptographic keys, counters, sequence spaces, etc.—needed for correct operation of the IEEE 802.11 cipher suites.

A security association is a set of policy(ies) and key(s) used to protect information. The information in the security association is stored by each party of the security association, must be consistent among all parties, and must have an identity. The identity is a compact name of the key and other bits of security association information to fit into a table index or an MPDU. There are four types of security associations supported by an RSN STA:

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001408

— PMKSA: A result of a successful IEEE 802.lX exchange, preshared PMK information, or PMK cached via some other mechanism.
— PTKSA: A result of a successful 4-Way Handshake.
— GTKSA: A result of a successful Group Key Handshake or successful 4-Way Handshake.
— SMKSA: A result of a successful initial SMK Handshake.
— STKSA: A result of a successful 4-Way STK Handshake following the initial SMK Handshake or subsequent rekeying.

8.4.1.1.1 PMKSA

When the PMKSA is the result of a successful IEEE 802.1X authentication, it is derived from the EAP authentication and authorization parameters provided by the AS. This security association is bidirectional. In other words, both parties use the information in the security association for both sending and receiving. The PMKSA is created by the Supplicant's SME when the EAP authentication completes successfully or the PSK is configured. The PMKSA is created by the Authenticator's SME when the PMK is created from the keying information transferred from the AS or the PSK is configured. The PMKSA is used to create the PTKSA. PMKSAs are cached for up to their lifetimes. The PMKSA consists of the following elements:

— PMKID, as defined in 8.5.1.2. The PMKID identifies the security association.
— Authenticator MAC address.
— PMK.
— Lifetime, as defined in 8.5.1.2.
— AKMP.
— All authorization parameters specified by the AS or local configuration. This can include parameters such as the STA's authorized SSID.

8.4.1.1.2 PTKSA

The PTKSA is a result of the 4-Way Handshake. This security association is also bidirectional. The PTKSA is used to create the key hierarchy. PTKSAs are cached for the life of the PMKSA. Because the PTKSA is tied to the PMKSA, it only has the additional information from the 4-Way Handshake. There shall be only one PTKSA with the same Supplicant and Authenticator MAC addresses. There is state created between Message 1 and Message 3 of a 4-Way Handshake. This does not create a PTKSA until Message 3 is validated on the Supplicant and Message 4 is validated by the Authenticator. The PTKSA consists of the following elements:

— PTK
— Pairwise cipher suite selector
— Supplicant MAC address
— Authenticator MAC address

8.4.1.1.3 GTKSA

The GTKSA results from a successful 4-Way Handshake or the Group Key Handshake and is unidirectional. In an ESS, there is one GTKSA, used exclusively for encrypting broadcast/multicast MPDUs that are transmitted by the AP and for decrypting broadcast/multicast transmissions that are received by the STAs. In an IBSS, each STA defines its own GTKSA, which is used to encrypt its broadcast/multicast transmissions, and stores a separate GTKSA for each peer STA so that encrypted broadcast/multicast traffic received from other STAs may be decrypted. A GTKSA is created by the Supplicant's SME when Message 3 of the 4-Way Handshake is received or when Message 1 of the Group Key Handshake is received. The GTKSA is created by the Authenticator's SME when the SME changes the GTK and has sent the GTK to all STAs with which it has a PTKSA. A GTKSA consists of the following elements:

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001409

— Direction vector (whether the GTK is used for transmit or receive).
— Group cipher suite selector.
— GTK.
— Authenticator MAC address.
— All authorization parameters specified by local configuration. This can include parameters such as the STA's authorized SSID.

When the GTK is used to encrypt unicast traffic (the selectable cipher suite is "Use group key"), the GTKSA is bidirectional.

8.4.1.1.4 SMKSA

An SMKSA is the result of a successful SMK Handshake by the initiator STA (described in 8.5.8). It is derived from parameters provided by the STAs and AP. This security association is bidirectional between the initiator and the peer STA. In other words, both parties use the information in the security association for both sending and receiving. The SMKSA is created as a result of a successful SMK Handshake (see 8.5.8). The SMKSA is used to create the STKSA. The SMKSA consists of the following elements:

— SMKID, as defined in 8.5.8. The SMKID identifies the security association.
— BSSID
— Initiator MAC address
— Peer MAC address
— SMK
— Lifetime, as defined in 8.5.8.
— Pairwise cipher suite selector list, as proposed by initiator STA
— Pairwise cipher suite selector, as selected by peer STA

8.4.1.1.5 STKSA

The STKSA is a result of successful completion of the 4-Way STK Handshake. This security association is bidirectional between the initiator and the peer STAs. The STKSA is used to create session keys to protect this STSL. STKSAs are cached for the life of the SMKSA or until the STSL ends, whichever comes first. There shall be only one STKSA with the same initiator STA and peer MAC addresses at any one time. STKSA is created as a result of PeerKey Handshake (see 8.5.8). The STKSA consists of the following elements:

— STK
— Pairwise cipher suite selector
— Initiator MAC address
— Peer MAC address

8.4.1.2 Security association life cycle

A STA can operate in either an ESS or in an IBSS, and a security association has a distinct life cycle for each.

8.4.1.2.1 Security association in an ESS

In an ESS there are two cases:

— Initial contact between the STA and the ESS
— Roaming by the STA within the ESS

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001410

A STA and AP establish an initial security association via the following steps:

a) The STA selects an authorized ESS by selecting among APs that advertise an appropriate SSID.

b) The STA then uses IEEE 802.11 Open System authentication followed by association to the chosen AP. Negotiation of security parameters takes place during association.

NOTE 1—It is possible for more than one PMKSA to exist. As an example, a second PMKSA may come into existence through PMKSA caching. A STA might leave the ESS and flush its cache. Before its PMKSA expires in the AP's cache, the STA returns to the ESS and establishes a second PMKSA from the AP's perspective.

NOTE 2—An attack altering the security parameters will be detected by the key derivation procedure.

NOTE 3—IEEE 802.11 Open System authentication provides no security, but is included to maintain backward compatibility with the IEEE 802.11 state machine (see 11.3).

c) The AP's Authenticator or the STA's Supplicant initiates IEEE 802.1X authentication. The EAP method used by IEEE Std 802.1X-2004 will support mutual authentication, as the STA needs assurance that the AP is a legitimate AP.

NOTE 1—Prior to the completion of IEEE 802.1X authentication and the installation of keys, the IEEE 802.1X Controlled Port in the AP will block all data frames. The IEEE 802.1X Controlled Port returns to the unauthorized state and blocks all data frames before invocation of an MLME-DELETEKEYS.request primitive. The IEEE 802.1X Uncontrolled Port allows IEEE 802.1X frames to pass between the Supplicant and Authenticator. Although IEEE Std 802.1X-2004 does not require a Supplicant Controlled Port, this standard assumes that the Supplicant has a Controlled Port in order to provide the needed level of security. Supplicants without a Controlled Port compromise RSN security and should not be used.

NOTE 2—Any secure network cannot support promiscuous association, e.g., an unsecured operation of IEEE Std 802.11. A trust relationship must exist between the STA and the AS of the targeted SSID prior to association and secure operation, in order for the association to be trustworthy. The reason is that an attacker can deploy a rogue AP just as easily as a legitimate network provider can deploy a legitimate AP, so some sort of prior relationship is necessary to establish credentials between the ESS and the STA.

d) The last step is key management. The authentication process creates cryptographic keys shared between the IEEE 802.1X AS and the STA. The AS transfers these keys to the AP, and the AP and STA use one key confirmation handshake, called the 4-Way Handshake, to complete security association establishment. The key confirmation handshake indicates when the link has been secured by the keys and is ready to allow normal data traffic.

A STA roaming within an ESS establishes a new PMKSA by one of three schemes:

— In the case of (re)association followed by IEEE 802.1X or PSK authentication, the STA repeats the same actions as for an initial contact association, but its Supplicant also deletes the PTKSA when it roams from the old AP. The STA's Supplicant also deletes the PTKSA when it disassociates/deauthenticates from all BSSIDs in the ESS.

— A STA (AP) can retain PMKs for APs (STAs) in the ESS to which it has previously performed a full IEEE 802.1X authentication. If a STA wishes to roam to an AP for which it has cached one or more PMKSAs, it can include one or more PMKIDs in the RSN information element of its (Re)Association Request frame. An AP whose Authenticator has retained the PMK for one or more of the PMKIDs can skip the IEEE 802.1X authentication and proceed with the 4-Way Handshake. The AP shall include the PMKID of the selected PMK in Message 1 of the 4-Way Handshake. If none of the PMKIDs of the cached PMKSAs matches any of the supplied PMKIDs, then the Authenticator shall perform another IEEE 802.1X authentication. Similarly, if the STA fails to send a PMKID, the STA and AP must perform a full IEEE 802.1X authentication.

— A STA already associated with the ESS can request its IEEE 802.1X Supplicant to authenticate with a new AP before associating to that new AP. The normal operation of the DS via the old AP provides the communication between the STA and the new AP. The STA's IEEE 802.11 management entity delays reassociation with the new AP until IEEE 802.1X authentication completes via the DS. If IEEE 802.1X authentication completes successfully, then PMKSAs shared between the new AP and the STA will be cached, thereby enabling the possible usage of reassociation without requiring a subsequent full IEEE 802.1X authentication procedure.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001411

The MLME-DELETEKEYS.request primitive destroys the temporal keys established for the security association so that they cannot be used to protect subsequent IEEE 802.11 traffic. A STA's SME uses this primitive when it deletes a PTKSA or GTKSA.

8.4.1.2.2 Security association in an IBSS

In an IBSS, when a STA's SME establishes a security association with a peer STA, it creates both an IEEE 802.1X Supplicant and Authenticator for the peer.

A STA can receive IEEE 802.1X messages from a previously unknown MAC address.

Any STA within an IBSS may decline to form a security association with a STA joining the IBSS. An attempt to form a security association may also fail because, for example, the peer uses a different PSK from what the STA expects.

In an IBSS each STA defines its own group key, i.e., GTK, to secure its broadcast/multicast transmissions. Each STA shall use either the 4-Way Handshake or the Group Key Handshake to distribute its transmit GTK to its new peer STA. When the STA generates a new GTK, it also uses the Group Key Handshake to distribute the new GTK to each established peer.

8.4.2 RSNA selection

A STA prepared to establish RSNAs shall advertise its capabilities by including the RSN information element in Beacon and Probe Response messages. The included RSN information element shall specify all the authentication and cipher suites enabled by the STA's policy. A STA shall not advertise any authentication or cipher suite that is not enabled.

The STA's IEEE 802.11 management entity shall utilize the MLME-SCAN.request primitive to identify neighboring STAs that assert robust security and advertise an SSID identifying an authorized ESS or IBSS. A STA may decline to communicate with STAs that fail to advertise an RSN information element in their Beacon and Probe Response frames or that do not advertise an authorized SSID. A STA may also decline to communicate with other STAs that do not advertise authorized authentication and cipher suites within their RSN information elements.

A STA shall advertise the same RSN information element in both its Beacon and Probe Response frames.

NOTE 1—Whether a STA with robust security enabled may attempt to communicate with a STA that does not include the RSN information element is a matter of policy.

NOTE 2—As a practical matter, if maximal interoperability is a goal, an AP will support TKIP as well as CCMP.

A STA shall observe the following rules when processing an RSN information element:

— A STA shall advertise the highest version it supports.
— A STA shall request the highest Version field value it supports that is less than or equal to the version advertised by the peer STA.
— Two peer STAs without overlapping supported Version field values shall not use RSNA methods to secure their communication.
— A STA shall ignore suite selectors that it does not recognize.

8.4.3 RSNA policy selection in an ESS

RSNA policy selection in an ESS utilizes the normal IEEE 802.11 association procedure. RSNA policy selection is performed by the associating STA. The STA does this by including an RSN information element in its (Re)Association Requests.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001412

In an RSN, an AP shall not associate with pre-RSNA STAs, i.e., with STAs that fail to include the RSN information element in the Association or Reassociation Request frame.

The STA's SME initiating an association shall insert an RSN information element into its (Re)Association Request; via the MLME-ASSOCIATE.request primitive, when the targeted AP indicates RSNA support. The initiating STA's RSN information element shall include one authentication and pairwise cipher suite from among those advertised by the targeted AP in its Beacon and Probe Response frames. It shall also specify the group cipher suite specified by the targeted AP. If at least one RSN information element field from the AP's RSN information element fails to overlap with any value the STA supports, the STA shall decline to associate with that AP.

If an RSNA-capable AP receives a (Re)Association Request including an RSN information element and if it chooses to accept the association as a secure association, then it shall use the authentication and pairwise cipher suites in the (Re)Association Request, unless the AP includes an optional second RSN information element in Message 3 of the 4-Way Handshake. If the second RSN information element is supplied in Message 3, then the pairwise cipher suite used by the security association, if established, shall be the pairwise cipher from the second RSN information element.

In order to accommodate local security policy, a STA may choose not to associate with an AP that does not support any pairwise cipher suites. An AP indicates that it does not support any pairwise keys by advertising "Use group key" as the pairwise cipher suite selector.

NOTE—When an ESS uses PSKs, STAs negotiate a pairwise cipher. However, any STA in the ESS can derive the pairwise keys of any other that uses the same PSK by capturing the first two messages of the 4-Way Handshake. This provides malicious insiders with the ability to eavesdrop as well as the ability to establish a man-in-the-middle attack.

8.4.3.1 TSN policy selection in an ESS

In a TSN, an RSN STA shall include the RSN information element in its (Re)Association Requests.

An RSNA-capable AP configured to operate in a TSN shall include the RSN information element and may associate with both RSNA and pre-RSNA STAs. In other words, an RSNA-capable AP shall respond to an associating STA that includes the RSN information element just as in an RSN.

If an AP operating within a TSN receives a (Re)Association Request without an RSN information element, its IEEE 802.1X Controlled Port shall initially be blocked. The SME shall unblock the IEEE 802.1X Controlled Port when WEP has been enabled.

8.4.4 RSNA policy selection in an IBSS

In an IBSS, all STAs must use a single group cipher suite, and all STAs must support a common subset of pairwise cipher suites. However, the SMEs of any pair of STAs may negotiate to use any common pairwise cipher suite they both support. Each STA shall include the group cipher suite and its list of pairwise cipher suites in its Beacon and Probe Response messages. Two STAs shall not establish a PMKSA unless they have advertised the same group cipher suite. Similarly, the two STAs shall not establish a PMKSA if the STAs have advertised disjoint sets of pairwise cipher suites.

When an IBSS STA's SME wants to set up a security association with a peer STA, but does not know the peer's policy, it must first obtain the peer's security policy using a Probe Request frame. The SME entities of the two STAs select the pairwise cipher suites using one of the 4-Way Handshakes. The SMEs of each pair of STAs within an IBSS may use the EAPOL-Key 4-Way Handshake to select a pairwise cipher suite. As specified in 8.5.2, Message 2 and Message 3 of the 4-Way Handshake convey an RSN information element. The Message 2 RSN information element includes the selected pairwise cipher suite, and Message 3 includes the RSN information element that the STA would send in a Probe Response frame.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001413

The pair of STAs shall use the pairwise cipher suite specified in Message 3 of the 4-Way Handshake sent by the Authenticator STA with the higher MAC address (see 8.5.1).

The SME shall check that the group cipher suite and AKMP match those in the Beacon and Probe Response frames for the IBSS.

NOTE 1—The RSN information elements in Message 2 and Message 3 are not the same as in the Beacon frame. The group cipher and AKMP are the same, but the pairwise ciphers may differ because Beacon frames from different STAs may advertise different pairwise ciphers. Thus, STAs in an IBSS use the same AKM suite and group cipher, while different pairwise ciphers can be used between STA pairs.

NOTE 2—When an IBSS network uses PSKs, STAs can negotiate a pairwise cipher. However, any STA in the IBSS can derive the PTKs of any other that uses the same PSK by capturing the first two messages of the 4-Way Handshake. This provides malicious insiders with the ability to eavesdrop as well as the ability to establish a man-in-the-middle attack.

8.4.4.1 TSN policy selection in an IBSS

Pre-RSNA STAs generate Beacon and Probe Response frames without an RSN information element and will ignore the RSN information element because it is unknown to them. This allows an RSNA STA to identify the pre-RSNA STAs from which it has received Beacon and Probe Response frames.

If an RSNA STA's SME instead identifies a possible IBSS member on the basis of a received broadcast/multicast message, via MLME-PROTECTEDFRAMEDROPPED.indication primitive, it cannot identify the peer's security policy directly. The SME can attempt to obtain the peer STA's security policy via a Probe Request frame.

8.4.5 RSN management of the IEEE 802.1X Controlled Port

When the policy selection process chooses IEEE 802.1X authentication, this standard assumes that IEEE 802.1X Supplicants and Authenticators exchange protocol information via the IEEE 802.1X Uncontrolled port. The IEEE 802.1X Controlled Port is blocked from passing general data traffic between the STAs until an IEEE 802.1X authentication procedure completes successfully over the IEEE 802.1X Uncontrolled Port. The security of an RSNA depends on this assumption being true.

In an ESS, the STA indicates the IEEE 802.11 link is available by invoking the MLME-ASSOCIATE.confirm or MLME-REASSOCIATE.confirm primitive. This signals the Supplicant that the MAC has transitioned from the disabled to enabled state. At this point, the Supplicant's Controlled Port is blocked, and communication of all non-IEEE-802.1X MSDUs sent or received via the port is not authorized.

In an ESS, the AP indicates that the IEEE 802.11 link is available by invoking the MLME-ASSOCIATE.indication or MLME-REASSOCIATE.indication primitive. At this point the Authenticator's Controlled Port corresponding to the STA's association is blocked, and communication of all non-IEEE-802.1X MSDUs sent or received via the Controlled Port is not authorized.

In an IBSS, the STA shall block all IEEE 802.1X ports at initialization. Communication of all non-IEEE-802.1X MSDUs sent or received via the Controlled Port is not authorized.

This standard assumes each Controlled Port remains blocked until the IEEE 802.1X state variables portValid and keyDone both become true. This assumption means that the IEEE 802.1X Controlled Port discards MSDUs sent across the IEEE 802.11 channel prior to the installation of cryptographic keys into the MAC. This protects the STA's host from forged MSDUs written to the channel while it is still being initialized.

The MAC does not distinguish between MSDUs for the Controlled Port, and MSDUs for the Uncontrolled Port. In other words, IEEE 802.1X EAPOL frames will only be encrypted after invocation of the MLME-SETPROTECTION.request primitive.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001414

This standard assumes that IEEE Std 802.1X-2004 does not block the Controlled Port when authentication is triggered through reauthentication. During IEEE 802.1X reauthentication, an existing RSNA can protect all MSDUs exchanged between the STAs. Blocking MSDUs is not required during reauthentication over an RSNA.

8.4.6 RSNA authentication in an ESS

When establishing an RSNA, a STA shall use IEEE 802.11 Open System authentication prior to (re)association.

IEEE 802.1X authentication is initiated by any one of the following mechanisms:

— If a STA negotiates to use IEEE 802.1X authentication during (re)association, the STA's management entity can respond to the MLME-ASSOCIATE.confirm (or indication) primitive by requesting the STA's Supplicant (or AP's Authenticator) to initiate IEEE 802.1X authentication. Thus, in this case, authentication is driven by the STA's decision to associate and the AP's decision to accept the association.

— If a STA's MLME-SCAN.confirm primitive finds another AP within the current ESS, a STA may signal its Supplicant to use IEEE Std 802.1X-2004 to preauthenticate with that AP.

NOTE—A roaming STA's IEEE 802.1X Supplicant may initiate preauthentication by sending an EAPOL-Start message via its old AP, through the DS, to a new AP.

— If a STA receives an IEEE 802.1X message, it delivers this to its Supplicant or Authenticator, which may initiate a new IEEE 802.1X authentication.

8.4.6.1 Preauthentication and RSNA key management

A STA shall not use preauthentication except when pairwise keys are employed. Preauthentication shall not be used unless the new AP advertises the preauthentication capability in the RSN information element.

When preauthentication is used, then

a) Authentication is independent of roaming.

b) The STA's Supplicant may authenticate with multiple APs at a time.

NOTE—Preauthentication can be useful as a performance enhancement, as reassociation will not include the protocol overhead of a full reauthentication when it is used.

Preauthentication uses the IEEE 802.1X protocol and state machines with EtherType 88-C7, rather than the EtherType 88-8E. Only IEEE 802.1X frame types EAP-Packet and EAPOL-Start are valid for preauthentication.

NOTE—Some IEEE 802.1X Authenticators may not bridge IEEE 802.1X frames, as suggested in C.1.1 of IEEE Std 802.1X-2004. Preauthentication uses a distinct EtherType to enable such devices to bridge preauthentication frames.

A STA's Supplicant can initiate preauthentication when it has completed the 4-Way Handshake and configured the required temporal keys. To effect preauthentication, the STA's Supplicant sends an IEEE 802.1X EAPOL-Start message with the DA being the BSSID of a targeted AP and the RA being the BSSID of the AP with which it is associated. The target AP shall use a BSSID equal to the MAC address of its Authenticator. As preauthentication frames do not use the IEEE 802.1X EAPOL EtherType field, the AP with which the STA is currently associated need not apply any special handling. The AP and the MAC in the STA shall handle these frames in the same way as other frames with arbitrary EtherType field values that require distribution via the DS.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001415

An AP's Authenticator that receives an EAPOL-Start message via the DS may initiate IEEE 802.1X authentication to the STA via the DS. The DS will forward this message to the AP with which the STA is associated.

The result of preauthentication may be a PMKSA, if the IEEE 802.1X authentication completes successfully. If preauthentication produces a PMKSA, then, when the Supplicant's STA associates with the preauthenticated AP, the Supplicant can use the PMKSA with the 4-Way Handshake.

Successful completion of EAP authentication over IEEE 802.1X establishes a PMKSA at the Supplicant. The Authenticator has the PMKSA when the AS completes the authentication, passes the keying information (the master session key (MSK), a portion of which is the PMK) to the Authenticator, and the Authenticator creates a PMKSA using the PMK. The PMKSA is inserted into the PMKSA cache. Therefore, if the Supplicant and Authenticator lose synchronization with respect to the PMKSA, the 4-Way Handshake will fail. In such circumstances, the MIB variable dot11RSNAStats-4WayHandshakeFailures shall be incremented.

A STA's Supplicant may initiate preauthentication with any AP within its present ESS with preauthentication enabled regardless of whether the targeted AP is within radio range.

Even if a STA has preauthenticated, it is still possible that it may have to undergo a full IEEE 802.1X authentication, as the AP's Authenticator may have purged its PMKSA due to, for example, unavailability of resources, delay in the STA associating, etc.

8.4.6.2 Cached PMKSAs and RSNA key management

A STA can retain PMKSAs it establishes as a result of previous authentication. The PMKSA cannot be changed while cached. The PMK in the PMKSA is used with the 4-Way Handshake to establish fresh PTKs.

If a non-AP STA in an ESS has determined it has a valid PMKSA with an AP to which it is about to (re)associate, it includes the PMKID for the PMKSA in the RSN information element in the (Re)Association Request. Upon receipt of a (Re)Association Request with one or more PMKIDs, an AP checks whether its Authenticator has retained a PMK for the PMKIDs and whether the PMK is still valid. If so, it asserts possession of that PMK by beginning the 4-Way Handshake after association has completed; otherwise it begins a full IEEE 802.1X authentication after association has completed.

If both sides assert possession of a cached PMKSA, but the 4-Way Handshake fails, both sides may delete the cached PMKSA for the selected PMKID.

If a STA roams to an AP with which it is preauthenticating and the STA does not have a PMKSA for that AP, the STA must initiate a full IEEE 802.1X EAP authentication.

8.4.7 RSNA authentication in an IBSS

When authentication is used in an IBSS, it is driven by each STA wishing to establish communications. The management entity of this STA chooses a set of STAs with which it may want to authenticate and then may cause the MAC to send an IEEE 802.11 Open System authentication message to each targeted STA. Candidate STAs can be identified from Beacon frames, Probe Response frames, and data frames from the same BSSID. Before communicating with STAs identified from data frames, the security policy of the STAs may be obtained, e.g., by sending a Probe Request frame to the STA and obtaining a Probe Response frame. Targeted STAs that wish to respond may return an IEEE 802.11 Open System authentication message to the initiating STA.

When IEEE 802.1X authentication is used, the STA management entity will then request its local IEEE 802.1X entity to create a Supplicant PAE for the peer STA. The Supplicant PAE will initiate the

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001416

authentication to the peer STA by sending an EAPOL-Start message to the peer. The STA management entity will also request its local IEEE 802.1X entity to create an Authenticator PAE for the peer STA on receipt of the EAPOL-Start message. The Authenticator will initiate authentication to the peer STA by sending an EAP-Request message or, if PSK mode is in effect, Message 1 of the 4-Way Handshake.

Upon initial authentication between any pair of STAs, data frames, other than IEEE 802.1X messages, are not allowed to flow between the pair of STAs until both STAs in each pair of STAs have successfully completed AKM and have provided the supplied encryption keys.

Upon the initiation of an IEEE 802.1X reauthentication by any STA of a pair of STAs, data frames will continue to flow between the STAs while authentication completes. Upon a timeout or failure in the authentication process, the Authenticator of the STA initiating the reauthentication shall cause a Deauthentication message to be sent to the Supplicant of the STA targeted for reauthentication. The Deauthentication message will cause both STAs in the pair of STAs to follow the deauthentication procedure defined in 11.3.1.3 and 11.3.1.4.

The IEEE 802.1X reauthentication timers in each STA are independent. If the reauthentication timer of the STA with the higher MAC address (see 8.5.1 for MAC comparison) triggers the reauthentication via its Authenticator, its Supplicant must send an EAPOL-Start message to the authenticator of the STA with the lower MAC address to trigger reauthentication on the other STA. This process keeps the pair of STAs in a consistent state with respect to derivation of fresh temporal keys upon an IEEE 802.1X reauthentication.

When it receives an MLME-AUTHENTICATE.indicate primitive due to an Open System authentication request, the IEEE 802.11 management entity on a targeted STA shall, if it wants to set up a security association with the peer STA, request its Authenticator to begin IEEE 802.1X authentication, i.e., to send an EAP-Request/Identity message or Message 1 of the 4-Way Handshake to the Supplicant.

The EAPOL-Key frame is used to exchange information between the Supplicant and the Authenticator to negotiate a fresh PTK. The 4-Way Handshake produces a single PTK from the PMK. The 4-Way Handshake and Group Key Handshake use the PTK to protect the GTK as it is transferred to the receiving STA.

PSK authentication may also be used in an IBSS. When a single PSK is shared among the IBSS STAs, the STA wishing to establish communication sends 4-Way Handshake Message 1 to the target STA(s). The targeted STA responds to Message 1 with Message 2 of the 4-Way Handshake and begins its 4-Way Handshake by sending Message 1 to the initiating STA. The two 4-Way Handshakes establish PTKSAs and GTKSAs to be used between the initiating STA and the targeted STA. PSK PMKIDs may also be used, enabling support for pairwise PSKs.

The model for security in an IBSS is not general. In particular, it assumes the following:

a) The sets of use cases for which the authentication procedures described in this subclause are valid are as follows:
    1) PSK-based authentication, typically managed by the pass-phrase hash method as described in H.4
    2) EAP-based authentication, using credentials that have been issued and preinstalled on the STAs within a common administrative domain, such as a single organization
b) All of the STAs are in direct radio communication. In particular, there is no routing, bridging, or forwarding of traffic by a third STA to effect communication. This assumption is made, because the model makes no provision to protect IBSS topology information from tampering by one of the members.

8.4.8 RSNA key management in an ESS

When the IEEE 802.1X authentication completes successfully, this standard assumes that the STA's IEEE 802.1X Supplicant and the IEEE 802.1X AS will share a secret, called a PMK. The AS transfers the PMK, within the MSK, to the AP, using a technique that is outside the scope of this standard; the derivation of the PMK from the MSK is EAP-method-specific. With the PMK in place, the AP initiates a key confirmation handshake with the STA. The key confirmation handshake sets the IEEE 802.1X state variable portValid (as described in IEEE Std 802.1X-2004) to TRUE.

The key confirmation handshake is implemented by the 4-Way Handshake. The purposes of the 4-Way Handshake are as follows:

a) Confirm the existence of the PMK at the peer.
b) Ensure that the security association keys are fresh.
c) Synchronize the installation of temporal keys into the MAC.
d) Transfer the GTK from the Authenticator to the Supplicant.
e) Confirm the selection of cipher suites.

NOTE 1—Message 1 of the 4-Way Handshake can be forged. However, the forgery attempt will be detected in the failure of the 4-Way Handshake.

NOTE 2—Neither the AP nor the STA can use the PMK for any purpose but the one specified herein without compromising the key. If the AP uses it for another purpose, then the STA can masquerade as the AP; similarly if the STA reuses the PMK in another context, then the AP can masquerade as the STA.

The Supplicant and Authenticator signal the completion of key management by utilizing the MLME-SETKEYS.request primitive to configure the agreed-upon temporal pairwise key into the IEEE 802.11 MAC and by calling the MLME-SETPROTECTION.request primitive to enable its use.

A second key exchange, the Group Key Handshake, is also defined. It distributes a subsequent GTK. The AP's Authenticator can use the Group Key Handshake to update the GTK at the STA's Supplicant. The Group Key Handshake uses the EAPOL-Key frames for this exchange. When it completes, the STA's Supplicant can use the MLME-SETKEYS.request primitive to configure the GTK into the IEEE 802.11 MAC.

8.4.9 RSNA key management in an IBSS

To establish a security association between two STAs in an IBSS, each STA's SME must have an accompanying IEEE 802.1X Authenticator and Supplicant. Each STA's SME initiates the 4-Way Handshake from the Authenticator to the peer STA's Supplicant (see 8.4.7). Two separate 4-Way Handshakes are conducted.

The 4-Way Handshake is used to negotiate the pairwise cipher suites, as described in 8.4.4. The IEEE 802.11 SME configures the temporal key portion of the PTK into the IEEE 802.11 MAC. Each Authenticator uses the KCK and KEK portions of the PTK negotiated by the exchange it initiates to distribute its own GTK. Each Authenticator generates its own GTK and uses either the 4-Way Handshake or the Group Key Handshake to transfer the GTK to other STAs with whom it has completed a 4-Way Handshake. The pairwise key used between any two STAs shall be the pairwise key from the 4-Way Handshake initiated by the STA with the highest MAC address.

A STA joining an IBSS is required to adopt the security configuration of the IBSS, which includes the group cipher suite, pairwise cipher suite, and AKMP (see 8.4.4). The STA shall not set up a security association with any STA having a different security configuration. The Beacon and Probe Response frames of the various STAs within an IBSS must reflect a consistent security policy, as the beacon initiation rotates among the STAs.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001418

A STA joining an IBSS shall support and advertise in the Beacon frame the security configuration of the IBSS, which includes the group cipher suite, advertised pairwise cipher suite, and AKMP (see 8.4.4). The STA may use the Probe Request frame to discover the security policy of a STA, including additional unicast cipher suites the STA supports. A STA shall ignore Beacon frames that advertise a different security policy.

8.4.10 RSNA security association termination

When a non-AP STA SME receives a successful MLME Association or Reassociation confirm primitive or receives or invokes an MLME Disassociation or Deauthentication primitive, it will delete some security associations. Similarly, when an AP SME receives an MLME Association or Reassociation indication primitive, or receives or invokes an MLME Disassociation or Deauthentication primitive it will delete some security associations. In the case of an ESS, the non-AP STA's SME shall delete the PTKSA, GTKSA, SMKSA, and any STKSA, and the AP's SME shall delete the PTKSA and invoke an STSL application teardown procedure for any of its STKSAs. An example of an STSL application teardown procedure is described in 11.7.3. In the case of an IBSS, the STA's SME shall delete the PTKSA and the receive GTKSA. Once the security associations have been deleted, the SME then invokes MLME-DELETEKEYS.request primitive to delete all temporal keys associated with the deleted security associations. The IEEE 802.1X Controlled Port returns to being blocked. As a result, all data frames are unauthorized before invocation of an MLME-DELETEKEYS.request primitive.

If a STA loses key state synchronization, it can apply the following rules to recover:

a) Any protected frame(s) received shall be discarded, and MLME-PROTECTEDFRAMEDROPPED.indication primitive is invoked.

b) If the STA is RSNA-enabled and has joined an IBSS, the SME shall execute the authentication procedure as described in 11.3.1.1.

c) If the STA is RSNA-enabled and has joined an ESS, the SME shall execute the deauthentication procedures as described in 11.3.1.3. However, if the STA has initiated the RSN security association, but has not yet invoked the MLME-SETPROTECTION.request primitive, then no additional action is required.

NOTE 1—There is a race condition between when MLME-SETPROTECTION.request primitive is invoked on the Supplicant and when it is invoked on the Authenticator. During this time, an encrypted MPDU may be received that cannot be decrypted; and the MPDU will be discarded without a deauthentication occurring.

NOTE 2—Because the IEEE 802.11 null data MPDU does not derive from an MA-UNITDATA.request, it is not protected.

If the selected AKMP fails between a STA and an AP that are associated, then both the STA and the AP shall invoke the MAC deauthentication procedure described in 11.3.1.3.

If the SMK Handshake fails between a pair of associated STAs and AP, then the STAs and the AP shall invoke an STSL application teardown procedure.

8.5 Keys and key distribution

8.5.1 Key hierarchy

RSNA defines two key hierarchies:

a) Pairwise key hierarchy, to protect unicast traffic

b) GTK, a hierarchy consisting of a single key to protect multicast and broadcast traffic

NOTE—Pairwise key support with TKIP or CCMP allows a receiving STA to detect MAC address spoofing and data forgery. The RSNA architecture binds the transmit and receive addresses to the pairwise key. If an attacker creates an MPDU with the spoofed TA, then the decapsulation procedure at the receiver will generate an error. GTKs do not have this property.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001419

The description of the key hierarchies uses the following two functions:

— L(*Str*, *F*, *L*)From *Str* starting from the left, extract bits *F* through *F*+*L*–1, using the IEEE 802.11 bit conventions from 7.1.1.

— PRF-*n* Pseudo-random function producing *n* bits of output, defined in 8.5.1.1.

In an ESS, the IEEE 802.1X Authenticator MAC address (AA) and the AP's BSSID are the same, and the Supplicant's MAC address (SPA) and the STA's MAC address are equal. For the purposes of comparison, the MAC address is encoded as 6 octets, taken to represent an unsigned binary number. The first octet of the MAC address shall be used as the most significant octet. The bit numbering conventions in 7.1.1 shall be used within each octet.

An RSNA STA using CCMP shall support at least one pairwise key for any <TA,RA> pair. The <TA,RA> identifies the pairwise key, which does not correspond to any WEP key identifer.

In a a mixed environment, an AP may simultaneously communicate with some STAs using WEP with shared WEP keys and to STAs using CCMP or TKIP with pairwise keys. The STAs running WEP use default keys 0–3 for shared WEP keys; the important point here is that WEP can still use WEP default key 0. The AP can be configured to use the WEP key in WEP default key 0 for WEP; if the AP is configured in this way, STAs that cannot support WEP default key 0 simultaneously with a TKIP pairwise key shall specify the No Pairwise subfield in the RSN Capabilities field. If an AP is configured to use WEP default key 0 as a WEP key and a "No Pairwise" STA associates, the AP shall not set the Install bit in the 4-Way Handshake. In other words, the STA will not install a pairwise temporal key and instead will use WEP default key 0 for all traffic.

NOTE—The behavior of "No Pairwise" STAs is only intended to support the migration of WEP to RSNA.

TKIP STAs in a mixed environment are expected to support a single pairwise key either by using a key mapping key or by mapping to default key 0. The AP will use a pairwise key for unicast traffic between the AP and the STA. If a key mapping key is available, the <RA,TA> pair identifies the key; if there is no key mapping key, then the default key 0 is used because the key index in the message will be 0.

A STA that cannot support TKIP keys and WEP default key 0 simultaneously advertises this deficiency by setting the No Pairwise subfield in the RSN information element it sends in the (Re)Association Request to the AP. In response, the AP will, in Message 3 of the 4-Way Handshake, clear the Install bit to notify the STA not to install the pairwise key. The AP will instead send the WEP shared key to the STA to be plumbed as the WEP default key 0; this key will then be used with WEP to send and receive unicast traffic between the AP and the STA.

The TKIP STA that has this limitation may not know that it will be forced to use WEP for all transmissions until it has associated with the AP and been given the keys to use. (The STA cannot know that the AP has been configured to use WEP default key 0 for WEP communication.) If this does not satisfy the security policy configured at the STA, the STA's only recourse is to disassociate and try a different AP.

CCMP STAs in a TSN shall support pairwise keys and WEP default key 0 simultaneously. It is invalid for the STA to negotiate the No Pairwise subfield when CCMP is one of the configured ciphers.

8.5.1.1 PRF

A PRF is used in a number of places in this standard. Depending on its use, it may need to output 128 bits, 192 bits, 256 bits, 384 bits, or 512 bits. This subclause defines five functions:

— PRF-128, which outputs 128 bits

— PRF-192, which outputs 192 bits

— PRF-256, which outputs 256 bits

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001420

— PRF-384, which outputs 384 bits
— PRF-512, which outputs 512 bits

In the following, *A* is a unique label for each different purpose of the PRF; *Y* is a single octet containing 0; *X* is a single octet containing the parameter; and || denotes concatenation:

H-SHA-1(*K*, *A*, *B*, *X*) ← HMAC-SHA-1(*K*, *A* || *Y* || *B* || *X*)

PRF(*K*, *A*, *B*, *Len*)
for *i* ← 0 **to** (*Len*+159)/160 **do**
R ← *R* || H-SHA-1(*K*, *A*, *B*, *i)*
return L(*R*, 0, Len)

PRF-128(*K*, *A*, *B*) = PRF(*K*, *A*, *B*, 128)
PRF-192(*K*, *A*, *B*) = PRF(*K*, *A*, *B*, 192)
PRF-256(*K*, *A*, *B*) = PRF(*K*, *A*, *B*, 256)
PRF-384(*K*, *A*, *B*) = PRF(*K*, *A*, *B*, 384)
PRF-512(*K*, *A*, *B*) = PRF(*K*, *A*, *B*, 512)

8.5.1.2 Pairwise key hierarchy

The pairwise key hierarchy utilizes PRF-384 or PRF-512 to derive session-specific keys from a PMK, as depicted in Figure 8-20. The PMK shall be 256 bits. The pairwise key hierarchy takes a PMK and generates a PTK. The PTK is partitioned into KCK, KEK, and temporal keys, which are used by the MAC to protect unicast communication between the Authenticator's and Supplicant's respective STAs. PTKs are used between a single Supplicant and a single Authenticator.

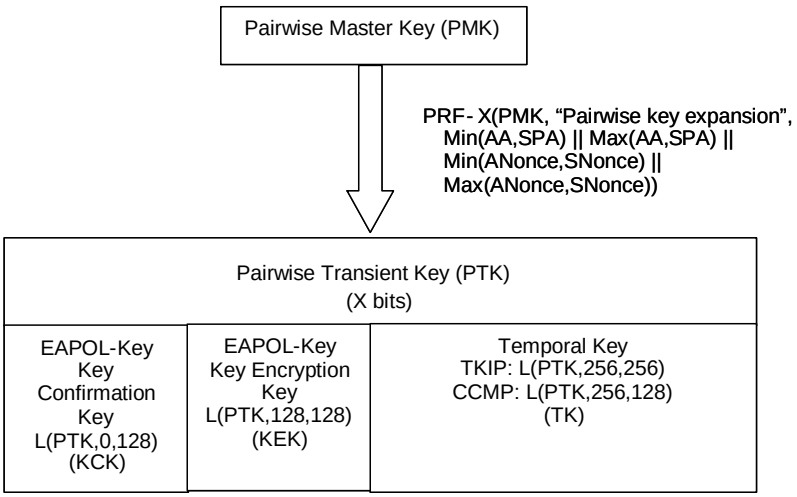

Figure 8-20—Pairwise key hierarchy

When not using a PSK, the PMK is derived from the MSK. The PMK shall be computed as the first 256 bits (bits 0–255) of the MSK: PMK ← L(MSK, 0, 256). When this derivation is used, the MSK must consist of at least 256 bits.

The PTK shall not be used longer than the PMK lifetime as determined by the minimum of the PMK lifetime indicated by the AS, e.g., Session-Timeout + dot1xAuthTxPeriod or from the dot11RSNAConfigPMK-Lifetime MIB variable. When RADIUS is used and the Session-Timeout attribute is not in the RADIUS Accept message, and if the key lifetime is not otherwise specified, then the PMK lifetime is infinite.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001421

NOTE 1—If the protocol between the Authenticator (or AP) and AS is RADIUS, then the MS-MPPE-Recv-Key attribute (vendor-id = 17; see Section 2.4.3 in IETF RFC 2548-1999 [B22]) may be used to transport the PMK to the AP.

NOTE 2—When reauthenticating and changing the pairwise key, a race condition may occur. If a frame is received while MLME-SETKEYS.request primitive is being processed, the received frame may be decrypted with one key and the MIC checked with a different key. Two possible options to avoid this race condition are as follows: the frame can be checked against the old MIC key, and the received frames may be queued while the keys are changed.

NOTE 3—If the AKMP is RSNA-PSK, then a 256-bit PSK may be configured into the STA and AP or a pass-phrase may be configured into the Supplicant or Authenticator. The method used to configure the PSK is outside this standard, but one method is via user interaction. If a pass-phrase is configured, then a 256-bit key is derived and used as the PSK. In any RSNA-PSK method, the PSK is used directly as the PMK. Implementations may support different PSKs for each pair of communicating STAs.

Here, the following assumptions apply:

— SNonce is a random or pseudo-random value contributed by the Supplicant; its value is taken when a PTK is instantiated and is sent to the PTK Authenticator.

— ANonce is a random or pseudo-random value contributed by the Authenticator.

— The PTK shall be derived from the PMK by

PTK ← PRF-X(PMK, “Pairwise key expansion”, Min(AA,SPA) || Max(AA,SPA) || Min(ANonce,SNonce) || Max(ANonce,SNonce))

TKIP uses X = 512 and CCMP uses X = 384. The Min and Max operations for IEEE 802 addresses are with the address converted to a positive integer treating the first transmitted octet as the most significant octet of the integer. The Min and Max operations for nonces are with the nonces treated as positive integers converted as specified in 7.1.1.

NOTE—The Authenticator and Supplicant normally derive a PTK only once per association. A Supplicant or an Authenticator may use the 4-Way Handshake to derive a new PTK. Both the Authenticator and Supplicant create a new nonce value for each 4-Way Handshake instance.

— The KCK shall be computed as the first 128 bits (bits 0–127) of the PTK:

KCK ← L(PTK, 0, 128)

The KCK is used by IEEE Std 802.1X-2004 to provided data origin authenticity in the 4-Way Handshake and Group Key Handshake messages.

— The KEK shall be computed as bits 128–255 of the PTK:

KEK ← L(PTK, 128, 128)

The KEK is used by the EAPOL-Key frames to provide data confidentiality in the 4-Way Handshake and Group Key Handshake messages.

— The temporal key (TK) shall be computed as bits 256–383 (for CCMP) or bits 256–511 (for TKIP) of the PTK:

TK ← L(PTK, 256, 128) or

TK ← L(PTK, 256, 256)

The EAPOL-Key state machines (see 8.5.5 and 8.5.6) use the MLME-SETKEYS.request primitive to configure the temporal key into the STA. The STA uses the temporal key with the pairwise cipher suite; interpretation of this value is cipher-suite-specific.

A PMK identifier is defined as

PMKID = HMAC-SHA1-128(PMK, "PMK Name" || AA || SPA)

Here, HMAC-SHA1-128 is the first 128 bits of the HMAC-SHA1 of its argument list.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001422

8.5.1.3 Group key hierarchy

The GTK shall be a random number.

Any group master key (GMK) may be reinitialized at a time interval configured into the AP to reduce the exposure of data if the GMK is ever compromised.

The Authenticator can update the GTK for a number of reasons:

a) The Authenticator may change the GTK on disassociation or deauthentication of a STA.

b) An event within the STA's SME can trigger a Group Key Handshake.

Figure 8-21 depicts an example of a relationship among the keys of the group key hierarchy. In this model, the group key hierarchy takes a GMK and generates a GTK. The GTK is partitioned into temporal keys used by the MAC to protect broadcast/multicast communication. GTKs are used between a single Authenticator and all Supplicants authenticated to that Authenticator. The Authenticator derives new GTKs when it wants to update the GTKs.

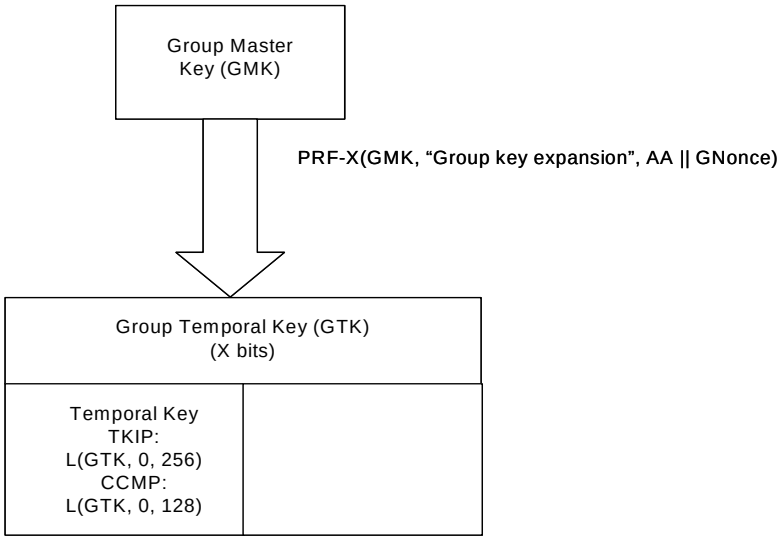

Figure 8-21—Group key hierarchy (informative)

In this example, the following assumptions apply:

a) Group nonce (GNonce) is a random or pseudo-random value contributed by the IEEE 802.1X Authenticator.

b) The GTK is derived from the GMK by

c) GTK ← PRF-X(GMK, "Group key expansion" || AA || GNonce)

d) TKIP uses X = 256, CCMP uses X = 128 and WEP use X = 40 or X = 104. AA is represented as an IEEE 802 address and GNonce as a bit string as defined in 7.1.1.

e) The temporal key (TK) is bit 0–39, bits 0–103, bits 0–127, or bits 0–255 of the GTK:
TK ← L(GTK, 0, 40) or
TK ← L(GTK, 0, 104) or

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001423

TK ← L(GTK, 0, 128) or
TK ← L(GTK, 0, 256)

f) The EAPOL-Key state machines (see 8.5.5 and 8.5.6) configure the temporal key into IEEE Std 802.11 via the MLME-SETKEYS.request primitive, and IEEE Std 802.11 uses this key. Its interpretation is cipher-suite-specific.

8.5.1.4 PeerKey key hierarchy

The station-to-station key hierarchy utilizes PRF-384 or PRF-512 to derive session-specific keys from an SMK, as depicted in Figure 8-22. The SMK shall be 256 bits. The pairwise key hierarchy takes an SMK and generates an STK. The STK is partitioned into SKCK, SKEK, and temporal keys, which are used by the MAC to protect unicast communication between the initiator and peer STAs. STKs are used between a single initiator STA and a single peer STA.

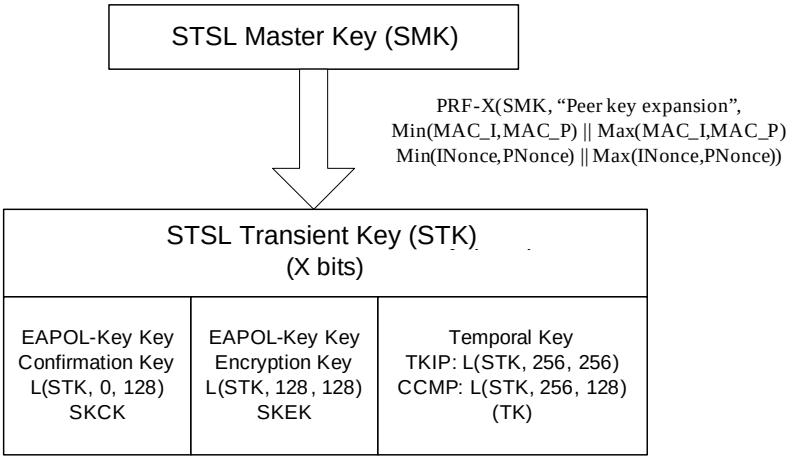

Figure 8-22—PeerKey hierarchy

The following apply and are depicted in Figure 8-22:

a) INonce is a random or pseudo-random value contributed by the initiator STA.

b) PNonce is a random or pseudo-random value contributed by the peer STA.

c) The STK shall be derived from the SMK by

STK ← PRF-X(SMK, "Peer key expansion", Min(MAC_I,MAC_P) || Max(MAC_I,MAC_P) || Min(INonce,PNonce) || Max(INonce,PNonce))

TKIP uses X = 512 and CCMP uses X = 384. The Min and Max operations for IEEE 802 addresses are with the address converted to a positive integer treating the first transmitted octet as the most significant octet of the integer. The Min and Max operations for nonces are with the nonces treated as positive integers converted as specified in 7.1.1.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001424

d) The SKCK shall be computed as the first 128 bits (bits 0–127) of the STK:

SKCK ← L(STK, 0, 128)

The SKCK is used to provide data origin authenticity in the 4-Way STK Handshake.

e) The SKEK shall be computed as bits 128–255 of the STK:

SKEK ← L(STK, 128, 128)

The SKEK is used by the EAPOL-Key frames to provide confidentiality in the 4-Way STK Handshake.

f) The temporal key (TK) shall be computed as bits 256–383 (for CCMP) or bits 256–511 (for TKIP) of the STK:

TK ← L(STK, 256, 128) or TK ← L(STK, 256, 256)

The EAPOL-Key state machines (see 8.5.5 and 8.5.6) use the MLME-SETKEYS.request primitive to configure the temporal key into the STA. The STA uses the temporal key with the pairwise cipher suite; interpretation of this value is cipher-suite-specific.

A SMK identifier is defined as

SMKID = HMAC-SHA1-128(SMK, "SMK Name" || PNonce || MAC_P || INonce || MAC_I)

Here, HMAC-SHA1-128 is the first 128 bits of the HMAC-SHA1 of its argument list.

8.5.2 EAPOL-Key frames

IEEE Std 802.11 uses EAPOL-Key frames to exchange information between STAs' Supplicants and Authenticators. These exchanges result in cryptographic keys and synchronization of security association state. EAPOL-Key frames are used to implement three different exchanges:

— 4-Way Handshake, to confirm that the PMK between associated STAs is the same and live and to transfer the GTK to the STA.

— Group Key Handshake, to update the GTK at the STA.

— PeerKey initial SMK Handshake to deliver the SMK and final 4-Way STK Handshake to deliver the STK to the initiating and peer STAs.

When priority processing of data frames is supported, a STA's SME should send EAPOL-Key frames at the highest priority.

The RSNA key descriptor used by IEEE Std 802.11 does not use the IEEE 802.1X key descriptor. Instead, it uses the key descriptor described in this subclause.

The bit and octet convention for fields in the EAPOL-Key frame are defined in 7.1 of IEEE Std 802.1X-2004. EAPOL-Key frames containing invalid field values shall be silently discarded. Figure 8-23 depicts the format of an EAPOL-Key frame.

Key Descriptor Version	Key Type		Reserved		Install	Key Ack	Key MIC	Se-cure	Error	Request	Encrypted Key Data	SMK Message	Reserved	

Figure 8-24—Key Information bit layout

The bit convention used is as in 7.1 of IEEE Std 802.1X-2004. The subfields of the Key Information field are as follows:

1) Key Descriptor Version (bits 0–2) specifies the key descriptor version type.
   i) The value 1 shall be used for all EAPOL-Key frames to and from a STA when neither the group nor pairwise ciphers are CCMP for Key Descriptor 1. This value indicates the following:
      — HMAC-MD5 is the EAPOL-Key MIC.
      — ARC4 is the EAPOL-Key encryption algorithm used to protect the Key Data field.
   ii) The value 2 shall be used for all EAPOL-Key frames to and from a STA when either the pairwise or the group cipher is AES-CCMP for Key Descriptor 2. This value indicates the following:
      — HMAC-SHA1-128 is the EAPOL-Key MIC. HMAC is defined in IETF RFC 2104; and SHA1, by FIPS PUB 180-1-1995. The output of the HMAC-SHA1 shall be truncated to its 128 MSBs (octets 0–15 of the digest output by HMAC-SHA1), i.e., the last four octets generated shall be discarded.
      — The NIST AES key wrap is the EAPOL-Key encryption algorithm used to protect the Key Data field. IETF RFC 3394 defines the NIST AES key wrap algorithm.
2) Key Type (bit 3) specifies whether this EAPOL-Key frame is part of a 4-Way Handshake deriving a PTK.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001426

i) The value 0 (Group/SMK) indicates the message is not part of a PTK derivation.

ii) The value 1 (Pairwise) indicates the message is part of a PTK derivation.

3) Reserved (bits 4–5). The sender shall set them to 0, and the receiver shall ignore the value of these bits.

4) Install (bit 6).

i) If the value of Key Type (bit 3) is 1, then for the Install bit,

— The value 1 means the IEEE 802.1X component shall configure the temporal key derived from this message into its IEEE 802.11 STA.

— The value 0 means the IEEE 802.1X component shall not configure the temporal key into the IEEE 802.11 STA.

ii) If the value of Key Type (bit 3) is 0, then this bit shall be 0 on transmit and ignored on receive.

5) Key Ack (bit 7) is set in messages from the Authenticator if an EAPOL-Key frame is required in response to this message and is clear otherwise. The Supplicant's response to this message shall use the same replay counter as this message.

6) Key MIC (bit 8) is set if a MIC is in this EAPOL-Key frame and is clear if this message contains no MIC.

7) Secure (bit 9) is set once the initial key exchange is complete.

The Authenticator shall set the Secure bit to 0 in all EAPOL-Key frames sent before the Supplicant has the PTK and the GTK. The Authenticator shall set the Secure bit to 1 in all EAPOL-Key frames it sends to the Supplicant containing the last key needed to complete the Supplicant's initialization.

The Supplicant shall set the Secure bit to 0 in all EAPOL-Key frames it sends before it has the PTK and the GTK and before it has received an EAPOL-Key frame from the Authenticator with the Secure bit set to 1 (this should be before receiving Message 3 of the 4-Way Handshake). The Supplicant shall set the Secure bit to 1 in all EAPOL-Key Frames sent after this until it loses the security association it shares with the Authenticator.

8) Error (bit 10) is set by a Supplicant to report that a MIC failure occurred in a TKIP MSDU or SMK Handshake failure. In case of a MIC failure, a Supplicant shall set this bit only when the Request (bit 11) is set. In the case that the SMK Message bit is set, Error shall be set to indicate the key data field contains an Error KDE.

9) Request (bit 11) is set by a Supplicant to request that the Authenticator initiate either a 4-Way Handshake or Group Key Handshake, is set by a Supplicant in a Michael MIC Failure Report, and is set by the STSL peer STA to request initiator STA rekeying of the STK. The Supplicant shall not set this bit in on-going 4-Way Handshakes, i.e., the Key Ack bit (bit 7) shall not be set in any message with the Request bit set. The Authenticator shall never set this bit.

In a Michael MIC Failure Report, setting the bit is not a request to initiate a new handshake. However the recipient may initiate a new handshake on receiving such a message.

If the EAPOL-Key frame with Request bit set has a key type of Pairwise, the Authenticator shall initiate a 4-Way Handshake. If the EAPOL-Key frame with Request bit set has a key type of Group/SMK, the Authenticator shall change the GTK, initiate a 4-Way Handshake with the Supplicant, and then execute the Group Key Handshake to all Supplicants.

If the EAPOL-Key frame with Request bit set has the SMK Message bit set, the initiator STA shall take appropriate action to create a new STK (based on 8.5.8).

10) Encrypted Key Data (bit 12) is set if the Key Data field is encrypted and is clear if the Key Data field is not encrypted. This subfield shall be set, and the Key Data field shall be encrypted, if any key material (e.g., GTK or SMK) is included in the frame.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001427

11) SMK Message (bit 13) specifies whether this EAPOL-Key frame is part of an SMK Handshake. If the SMK Handshake is not supported, the STA shall set the SMK message bit to 0 and shall ignore the value of this bit upon receipt.

12) Reserved (bits 14–15). The sender shall set them to 0, and the receiver shall ignore the value of these bits.

c) **Key Length**. This field is 2 octets in length, represented as an unsigned binary number. The value defines the length in octets of the pairwise temporal key to configure into IEEE Std 802.11. See Table 8-2.

Table 8-2—Cipher suite key lengths

Cipher suite	CCMP	TKIP	WEP-40	WEP-104
Key length (octets)	16	32	5	13

d) **Key Replay Counter**. This field is 8 octets, represented as an unsigned binary number, and is initialized to 0 when the PMK is established. The Supplicant shall use the key replay counter in the received EAPOL-Key frame when responding to an EAPOL-Key frame. It carries a sequence number that the protocol uses to detect replayed EAPOL-Key frames.

The Supplicant and Authenticator shall track the key replay counter per security association. The key replay counter shall be initialized to 0 on (re)association. The Authenticator shall increment the key replay counter on each successive EAPOL-Key frame.

When replying to a message from the Authenticator, the Supplicant shall use the Key Replay Counter field value from the last valid EAPOL-Key frames received from the Authenticator. The Authenticator should use the key replay counter to identify invalid messages to silently discard. The Supplicant should also use the key replay counter and ignore EAPOL-Key frames with a Key Replay Counter field value smaller than or equal to any received in a valid message. The local Key Replay Counter field should not be updated until the after EAPOL-Key MIC is checked and is valid. In other words, the Supplicant never updates the Key Replay Counter field for Message 1 in the 4-Way Handshake, as it includes no MIC. This implies the Supplicant must allow for retransmission of Message 1 when checking for the key replay counter of Message 3.

The Supplicant shall maintain a separate key replay counter for sending EAPOL-Key request frames to the Authenticator; the Authenticator also shall enforce monotonicity of a separate replay counter to filter received EAPOL-Key Request frames.

NOTE—The key replay counter does not play any role beyond a performance optimization in the 4-Way Handshake. In particular, replay protection is provided by selecting a never-before-used nonce value to incorporate into the PTK. It does, however, play a useful role in the Group Key Handshake.

e) **Key Nonce**. This field is 32 octets. It conveys the ANonce from the Authenticator and the SNonce from the Supplicant. It may contain 0 if a nonce is not required to be sent.

f) **EAPOL-Key IV**. This field is 16 octets. It contains the IV used with the KEK. It shall contain 0 when an IV is not required. It should be initialized by taking the current value of the global key counter (see 8.5.6) and then incrementing the counter. Note that only the lower 16 octets of the counter value will be used.

g) **Key RSC**. This field is 8 octets in length. It contains the receive sequence counter (RSC) for the GTK being installed in IEEE Std 802.11. It is used in Message 3 of the 4-Way Handshake and Message 1 of the Group Key Handshake, where it is used to synchronize the IEEE 802.11 replay state. It may also be used in the Michael MIC Failure Report frame, to report the TSC field value of the frame experiencing a MIC failure. It shall contain 0 in other messages. The Key RSC field gives the current message number for the GTK, to allow a STA to identify replayed MPDUs. If the Key RSC field value is less than 8 octets in length, the remaining octets shall be set to 0. The least significant octet of the TSC or PN should be in the first octet of the Key RSC field.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001428

NOTE—The Key RSC field value for TKIP is the TSC in the first 6 octets and for CCMP is the PN in the first 6 octets. See Table 8-3.

Table 8-3—Key RSC field

KeyRSC 0	KeyRSC 1	KeyRSC 2	KeyRSC 3	KeyRSC 4	KeyRSC 5	KeyRSC 6	KeyRSC 7
TSC0	TSC1	TSC2	TSC3	TSC4	TSC5	0	0
PN0	PN1	PN2	PN3	PN4	PN5	0	0

For WEP, the Key RSC value shall be set to 0 on transmit and shall not be used at the receiver.

h) **Key MIC**. This field is 16 octets in length when the Key Descriptor Version subfield is 1 or 2. The EAPOL-Key MIC is a MIC of the EAPOL-Key frames, from and including the EAPOL protocol version field to and including the Key Data field, calculated with the Key MIC field set to 0. If the Encrypted Key Data subfield (of the Key Information field) is set, the Key Data field is encrypted prior to computing the MIC.

1) **Key Descriptor Version 1**: HMAC-MD5; IETF RFC 2104 and IETF RFC 1321 together define this function.

2) **Key Descriptor Version 2**: HMAC-SHA1-128.

i) **Key Data Length**. This field is 2 octets in length, taken to represent an unsigned binary number. This represents the length of the Key Data field in octets. If the Encrypted Key Data subfield (of the Key Information field) is set, the length is the length of the Key Data field after encryption, including any padding.

j) **Key Data**. This field is a variable-length field that is used to include any additional data required for the key exchange that is not included in the fields of the EAPOL-Key frame. The additional data may be zero or more information element(s) (such as the RSN information element) and zero or more key data cryptographic encapsulation(s) (KDEs) (such as GTK(s) or PMKID(s)). Information elements sent in the Key Data field include the Element ID and Length subfields. KDEs shall be encapsulated using the format in Figure 8-25.

Type (0xdd)	Length	OUI	Data Type	Data
1 octet	1 octet	3 octets	1 octet	(Length – 4) octets

Figure 8-25—KDE format

The Type field shall be set to 0xdd. The Length field specifies the number of octets in the OUI, Data Type, and Data fields. The order of the OUI field shall follow the ordering convention for MAC addresses from 7.1.1.

Table 8-4 lists the KDE selectors defined by this standard.

Table 8-4—KDE

OUI	Data type	Meaning
00-0F-AC	0	Reserved
00-0F-AC	1	GTK KDE
00-0F-AC	2	Reserved
00-0F-AC	3	MAC address KDE
00-0F-AC	4	PMKID KDE

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001429

Table 8-4—KDE *(continued)*

OUI	Data type	Meaning
00-0F-AC	5	SMK KDE
00-0F-AC	6	Nonce KDE
00-0F-AC	7	Lifetime KDE
00-0F-AC	8	Error KDE
00-0F-AC	9–255	Reserved
Vendor OUI	Any	Vendor specific
Other	Any	Reserved

STAs shall ignore any information elements and KDEs they do not understand.

If the Encrypted Key Data subfield (of the Key Information field) is set, the entire Key Data field shall be encrypted. If the Key Data field uses the NIST AES key wrap, then the Key Data field shall be padded before encrypting if the key data length is less than 16 octets or if it is not a multiple of 8. The padding consists of appending a single octet 0xdd followed by zero or more 0x00 octets. When processing a received EAPOL-Key message, the receiver shall ignore this trailing padding. Key Data fields that are encrypted, but do not contain the GroupKey or SMK KDE, shall be accepted.

If the GroupKey or SMK KDE is included in the Key Data field, but the Key Data field is not encrypted, the EAPOL-Key frames shall be ignored.

The format of the GTK KDE is shown in Figure 8-26.

KeyID (0,1,2, or 3)	Tx	Reserved (0)	Reserved (0)	GTK
bits 0–1	bit 2	bit 3–7	1 octet	(Length – 6) octets

Figure 8-26—GTK KDE format

If the value of the Tx field is 1, then the IEEE 802.1X component shall configure the temporal key derived from this KDE into its IEEE 802.11 STA for both transmission and reception.

If the value of the Tx field is 0, then the IEEE 802.1X component shall configure the temporal key derived from this KDE into its IEEE 802.11 STA for reception only.

The format of the MAC address KDE is shown in Figure 8-27.

Exhibit 1014
Page 001431

Table 8-6—SMK error types

Error name	Error type	Error meaning
ERR_STA_NR	1	STA is not reachable from AP. See 8.5.9.5.1
ERR_STA_NRSN	2	STA to AP secure network not present. See 8.5.9.5.2
ERR_CPHR_NS	3	Cipher suites not supported. See 8.5.8.4.3.
ERR_NO_STSL	4	No STSL session present. See 8.5.8.4.4.

The following EAPOL-Key frames are used to implement the three different exchanges:

— **4-Way Handshake Message 1** is an EAPOL-Key frame with the Key Type subfield set to 1. The Key Data field shall contain an encapsulated PMKID for the PMK that is being used in this key derivation and need not be encrypted.

— **4-Way Handshake Message 2** is an EAPOL-Key frame with the Key Type subfield set to 1. The Key Data field shall contain an RSN information element and need not be encrypted.

An ESS Supplicant's SME shall insert the RSN information element it sent in its (Re)Association Request frame. The RSN information element is included as transmitted in the management frame. On receipt of Message 2, the Authenticator's SME shall validate the selected security configuration against the RSN information element received in the IEEE 802.11 (Re)Association Request.

An IBSS Supplicant's SME shall insert an RSN information element containing the pairwise cipher suite select it wants to negotiate. The Authenticator's SME shall validate that the pairwise cipher suite selected is one of its configured cipher suites and that the group cipher suite and AKM are consistent.

— **4-Way Handshake Message 3** is an EAPOL-Key frame with the Key Type subfield set to 1. The Key Data field shall contain one or two RSN information elements. If a group cipher has been negotiated, this field shall also include an encapsulated GTK. This field shall be encrypted if a GTK is included.

An Authenticator's SME shall insert the RSN information element it sent in its Beacon or Probe Response frame. The Supplicant's SME shall validate the selected security configuration against the RSN information element received in Message 3. If the second optional RSN information element is present, the STA shall either use that cipher suite with its pairwise key or deauthenticate. In either case, if the values do not match, then the receiver shall consider the RSN information element modified and shall use the MLME-DEAUTHENTICATE.request primitive to break the association. A security error should be logged at this time.

It may happen, for example, that a STA's Supplicant selects a pairwise cipher suite which is advertised by an AP, but which policy disallows for this particular STA. An Authenticator may, therefore, insert a second RSN information element to overrule the STA's selection. An Authenticator's SME shall insert the second RSN information element, after the first RSN information element, only for this purpose. The pairwise cipher suite in the second RSN information element included shall be one of the ciphers advertised by the Authenticator. All other fields in the second RSN information element shall be identical to the first RSN information element.

An encapsulated GTK shall be included and the unencrypted length of the GTK is six less than the length of the GTK KDE in octets. The entire Key Data field shall be encrypted as specified by the key descriptor version.

— **4-Way Handshake Message 4** is an EAPOL-Key frame with the Key Type subfield set to 1. The Key Data field can be empty.

— **Group Key Handshake Message 1** is an EAPOL-Key frame with the Key Type subfield set to 0. The Key Data field shall contain a GTK KDE and shall be encrypted.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001432

— **Group Key Handshake Message 2** is an EAPOL-Key frame with the Key Type subfield set to 0. The Key Data field can be empty.

PeerKey Handshake Messages use EAPOL-Key frames as defined in 8.5.8.

The key wrap algorithm selected depends on the key descriptor version:

— **Key Descriptor Version 1**: ARC4 is used to encrypt the Key Data field using the KEK field from the derived PTK. No padding shall be used. The encryption key is generated by concatenating the EAPOL-Key IV field and the KEK. The first 256 octets of the ARC4 key stream shall be discarded following ARC4 stream cipher initialization with the KEK, and encryption begins using the 257th key stream octet.

— **Key Descriptor Version 2**: AES key wrap, defined in IETF RFC 3394, shall be used to encrypt the Key Data field using the KEK field from the derived PTK. The key wrap default initial value shall be used.

NOTE—The cipher text output of the AES key wrap algorithm is 8 octets longer than the plaintext input.

8.5.2.1 EAPOL-Key frame notation

The following notation is used throughout the remainder of 8.5 to represent EAPOL-Key frames:

EAPOL-Key(S, M, A, I, K, SM, KeyRSC, ANonce/SNonce, MIC, DataKDs)

where

S	means the initial key exchange is complete. This is the Secure bit of the Key Information field.
M	means the MIC is available in message. This should be set in all messages except Message 1 of a 4-Way Handshake. This is the Key MIC bit of the Key Information field.
A	means a response is required to this message. This is used when the receiver should respond to this message. This is the Key Ack bit of the Key Information field.
I	is the Install bit: Install/Not install for the pairwise key. This is the Install bit of the Key Information field.
K	is the key type: P (Pairwise), G (Group/SMK). This is the Key Type bit of the Key Information field.
SM	is the SMK Message bit: indicates that this message is part of SMK Handshake.
KeyRSC	is the key RSC. This is the Key RSC field.
ANonce/SNonce	is the Authenticator/Supplicant nonce. This is the Key Nonce field.
MIC	is the integrity check, which is generated using the KCK. This is the Key MIC field.
DataKDs	is a sequence of zero or more information elements and KDEs, contained in the Key Data field, which may contain the following:
RSNIE	is the RSN information element, described in 7.3.2.25.
GTK[N]	is the GTK, with the key identifier field set to N. The key identifier specifies which index is used for this GTK. Index 0 shall not be used for GTKs, except in mixed environments, as described in 8.5.1.
PMKID	is of type PMKID KDE and is the key identifier used during 4-Way PTK Handshake for PMK key identification and during 4-Way STK Handshake for SMK key identification.
Lifetime	is the key lifetime KDE used for sending the expiry timeout value for SMK used during PeerKey Handshake for SMK identification.
Initiator MAC	is the Initiator MAC KDE used during PeerKey Handshake
Peer MAC	is the Peer MAC KDE used during PeerKey Handshake
Initiator Nonce	is the Initiator Nonce KDE used during PeerKey Handshake. This is used when multiple nonces need to be sent.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001433

Peer Nonce	is the Peer Nonce KDE used during PeerKey Handshake. This is used when multiple nonces need to be sent.
SMK KDE	is the encapsulated SMK during SMK Handshake.
Error KDE	is an error KDE used when error bit E is set during PeerKey Handshake.

8.5.3 4-Way Handshake

RSNA defines a protocol using IEEE 802.1X EAPOL-Key frames called the 4-Way Handshake. The handshake completes the IEEE 802.1X authentication process. The information flow of the 4-Way Handshake is as follows:

Message 1: Authenticator → Supplicant: EAPOL-Key(0,0,1,0,P,0,0,ANonce,0,DataKD_M1)
where DataKD_M1 = 0 or PMKID for PTK generation, or PMKID KDE (for sending SMKID) for STK generation

Message 2: Supplicant → Authenticator: EAPOL-Key(0,1,0,0,P,0,0,SNonce,MIC,DataKD_M2)
where DataKD_M2 = RSNIE for creating PTK generation or peer RSNIE, Lifetime KDE, SMKID KDE (for sending SMKID) for STK generation

Message 3: Authenticator → Supplicant:
EAPOL-Key(1,1,1,1,P,0,KeyRSC,ANonce,MIC,DataKD_M3)
where DataKD_M3 = RSNIE,GTK[N] for creating PTK generation or initiator RSNIE, Lifetime KDE for STK generation

Message 4: Supplicant → Authenticator: EAPOL-Key(1,1,0,0,P,0,0,0,MIC,DataKD_M4)
where DataKD_M4 = 0.

Here, the following assumptions apply:

— EAPOL-Key(·) denotes an EAPOL-Key frame conveying the specified argument list, using the notation introduced in 8.5.2.1.

— ANonce is a nonce that the Authenticator contributes for PTK generation or that the initiator STA contributes for STK generation. ANonce has the same value in Message 1 and Message 3.

— SNonce is a nonce from the Supplicant for PTK generation or from the peer STA for STK generation.

— P means the pairwise bit is set.

— The MIC is computed over the body of the EAPOL-Key frame (with the Key MIC field first zeroed before the computation) using the KCK defined in 8.5.1.2 for PTK generation or SKCK defined in 8.5.1.4.

— RSNIE represents the appropriate RSN information elements.

— GTK[N] represents the encapsulated GTK with its key identifier.

— SMKID represents the SMKID key identifier used during STK generation.

— Lifetime represents the expiry timeout used for exchanging SMK expiry value.

NOTE—While the MIC calculation is the same in each direction, the Key Ack bit is different in each direction. It is set in EAPOL-Key frames from the Authenticator and clear in EAPOL-Key frames from the Supplicant. 4-Way Handshake requests from the Supplicant have the Request bit set. The Authenticator and Supplicant must check these bits to stop reflection attacks. Message 1 contents must not update state, in particular the keys in use, until the data are validated with Message 3.

8.5.3.1 4-Way Handshake Message 1

Message 1 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001434

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 1 (Pairwise)

SMK Message = 0

Install = 0

Key Ack = 1

Key MIC = 0

Secure = 0

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0 – unused by this protocol version

Key Length = Cipher-suite-specific; see Table 8-2

Key Replay Counter = *n* – to allow Authenticator or initiator STA to match the right Message 2 from Supplicant or peer STA

Key Nonce = ANonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = 0

Key Data Length = length of Key Data field in octets

Key Data = PMKID for the PMK being used during PTK generation or SMKID for SMK being used during STK generation

Processing for PTK generation is as follows:

The Authenticator sends Message 1 to the Supplicant at the end of a successful IEEE 802.1X authentication, after PSK authentication is negotiated, when a cached PMKSA is used, or after a STA requests a new key. On reception of Message 1, the Supplicant determines whether the Key Replay Counter field value has been used before with the current PMKSA. If the Key Replay Counter field value is less than or equal to the current local value, the Supplicant discards the message. Otherwise, the Supplicant

a) Generates a new nonce SNonce.

b) Derives PTK.

c) Constructs Message 2.

Processing for STK generation is as follows:

The initiator STA (STA_I) sends Message 1 to the peer STA (STA_P) at the end of a successful SMK Handshake, when SMKSA is created. On reception of Message 1, the STA_P determines whether the Key Replay Counter field value has been used before with the current SMKSA. If the Key Replay Counter field value is less than or equal to the current local value, the STA_P discards the message. Otherwise, the STA_P

a) Generates 256-bit random number that is sent as a peer Nonce as part Key Nonce field. This Nonce is different from the peer Nonce generated as part SMK Handshake Message 3.

b) Derives STK.

c) Constructs Message 2.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001435

8.5.3.2 4-Way Handshake Message 2

Message 2 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128) – same as Message 1

Key Type = 1 (Pairwise) – same as Message 1

SMK Message = 0 – same as Message 1

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 0 – same as Message 1

Error = 0 – same as Message 1

Request = 0 – same as Message 1

Encrypted Key Data = 0

Reserved = 0 – unused by this protocol version

Key Length = 0

Key Replay Counter = *n* – to let the Authenticator or initiator STA know to which Message 1 this corresponds

Key Nonce = SNonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC(KCK, EAPOL) – MIC computed over the body of this EAPOL-Key frame with the Key MIC field first initialized to 0

Key Data Length = length of Key Data field in octets

Key Data = included RSNIE – the sending STA's RSNIE for PTK generation or peer RSNIE, Lifetime of SMK and SMKID for STK generation

Processing for PTK generation is as follows:

The Supplicant sends Message 2 to the Authenticator.

On reception of Message 2, the Authenticator checks that the key replay counter corresponds to the outstanding Message 1. If not, it silently discards the message. Otherwise, the Authenticator

a) Derives PTK.
b) Verifies the Message 2 MIC.
    1) If the calculated MIC does not match the MIC that the Supplicant included in the EAPOL-Key frame, the Authenticator silently discards Message 2.
    2) If the MIC is valid, the Authenticator checks that the RSN information element bit-wise matches that from the (Re)Association Request message.
        i) If these are not exactly the same, the Authenticator uses MLME-DEAUTHENTICATE.request primitive to terminate the association.
        ii) If they do match bit-wise, the Authenticator constructs Message 3.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001436

Processing for STK generation is as follows:

The STA_P sends Message 2 to the STA_I. On reception of Message 2, the STA_I checks that the key replay counter corresponds to Message 1. If not, it silently discards the message. Otherwise, the STA_I

a) Derives the STK.

b) Verifies the Message 2 MIC using SKCK key. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the STA_I silently discards Message 2.

c) If the MIC is valid, the STA_I checks that the RSNIE bit-wise matches that from the SMK Handshake Message 5. If these are not exactly the same, STA_I silently discards the message and restarts the 4-Way Handshake after deleting the existing 4-Way Handshake states.

d) If they do match bit-wise, the STA_I checks SMKID with the value of SMKID in SMKSA. If these are not exactly the same, STA_I silently discards the message and restarts the 4-Way Handshake after deleting the existing 4-Way Handshake states.

e) If they do match, the STA_I constructs Message 3. It also compares the Key Lifetime value from the KDE with value in its SMKSA. If value in its SMKSA is less, it discards the value received in Message 2. Otherwise, it updates the value in SMKSA with value in Message 2.

8.5.3.3 4-Way Handshake Message 3

Message 3 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128) – same as Message 1

Key Type = 1 (Pairwise) – same as Message 1

SMK Message = 0 - same as Message 1

Install = 0/1 – For PTK generation, 0 only if the AP does not support key mapping keys, or if the STA has the No Pairwise bit (in the RSN Capabilities field) set and only the group key will be used. For STK generation, this bit is set to 1.

Key Ack = 1

Key MIC = 1

Secure = 1 (keys installed)

Error = 0 – same as Message 1

Request = 0 – same as Message 1

Encrypted Key Data = 1

Reserved = 0 – unused by this protocol version

Key Length = Cipher-suite-specific; see Table 8-2

Key Replay Counter = *n+1*

Key Nonce = ANonce – same as Message 1

EAPOL-Key IV = 0 (Version 2) or random (Version 1)

Key RSC = For PTK generation, starting sequence number that the Authenticator's STA will use in MPDUs protected by GTK. For STK generation, this is set to 0.

Key MIC = MIC(KCK, EAPOL) or MIC(SKCK, EAPOL) – MIC computed over the body of this EAPOL-Key frame with the Key MIC field first initialized to 0

Key Data Length = length of Key Data field in octets of included RSN information elements and GTK

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001437

Key Data = For PTK generation, the AP's Beacon/Probe Response frame's RSN information element, and, optionally, a second RSN information element that is the Authenticator's pairwise cipher suite assignment, and, if a group cipher has been negotiated, the encapsulated GTK and the GTK's key identifier (see 8.5.2). For STK generation Initiator RSNIE, Lifetime of SMK is used.

Processing for PTK generation is as follows:

The Authenticator sends Message 3 to the Supplicant.

On reception of Message 3, the Supplicant silently discards the message if the Key Replay Counter field value has already been used or if the ANonce value in Message 3 differs from the ANonce value in Message 1. The Supplicant also

a) Verifies the RSNIE. If it is not identical to that the STA received in the Beacon or Probe Response frame, the STA shall disassociate. If a second RSN information element is provided in the message, the Supplicant uses the pairwise cipher suite specified in the second RSNIE or deauthenticates.
b) Verifies the Message 3 MIC. If the calculated MIC does not match the MIC that the Authenticator included in the EAPOL-Key frame, the Supplicant silently discards Message 3.
c) Updates the last-seen value of the Key Replay Counter field.
d) Constructs Message 4.
e) Sends Message 4 to the Authenticator.
f) Uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to send and receive Class 3 unicast MPDUs protected by the PTK. The GTK is also configured by MLME-SETKEYS primitive.

Processing for STK generation is as follows:

The STA_I sends Message 3 to the STA_P. On reception of Message 3, the STA_P silently discards the message if the Key Replay Counter field value has already been used or if the INonce value in Message 3 differs form the INonce value in Message 1. Otherwise,

a) The STA_P verifies the Message 3 MIC using SKCK key in SMKSA. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the STA_I silently discards Message 3.
b) If the MIC is valid, the STA_P checks that the RSNIE bit-wise matches that from the 4-Way Handshake Message 2. If these are not exactly the same, STA_P silently discards the message and deletes existing 4-Way Handshake states.
c) If they do match, the STA_P constructs Message 4. It also compares the Key Lifetime value from KDE with value in its SMKSA. If value in SMKSA is less, it discards the value received in Message 3. Otherwise, it updates the value in SMKSA with value in Message 3.

8.5.3.4 4-Way Handshake Message 4

Message 4 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128) – same as Message 1

Key Type = 1 (Pairwise) – same as Message 1

SMK Message = 0 - same as Message 1

Install = 0

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001438

Key Ack = 0 – this is the last message

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0 – unused by this protocol version

Key Length = 0

Key Replay Counter = *n+1*

Key Nonce = 0

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC(KCK, EAPOL) or MIC(SKCK, EAPOL) – MIC computed over the body of this EAPOL-Key frame with the Key MIC field first initialized to 0

Key Data Length = length of Key Data field in octets

Key Data = none required

Processing for PTK generation is as follows:

The Supplicant sends Message 4 to the Authenticator. Note that when the 4-Way Handshake is first used, Message 4 is sent in the clear.

On reception of Message 4, the Authenticator verifies that the Key Replay Counter field value is one that it used on this 4-Way Handshake; if it is not, it silently discards the message. Otherwise:

a) The Authenticator checks the MIC. If the calculated MIC does not match the MIC that the Supplicant included in the EAPOL-Key frame, the Authenticator silently discards Message 4.
b) If the MIC is valid, the Authenticator uses the MLME-SETKEYS.request primitive to configure the PTK into the IEEE 802.11 MAC.
c) The Authenticator updates the Key Replay Counter field so that it will use a fresh value if a rekey becomes necessary.

Processing for STK generation is as follows:

The STA_P sends Message 4 to the STA_I. On reception of Message 4, the STA_I verifies that the Key Replay Counter field value is one that it used on this 4-Way Handshake; if it is not, it silently discards the message. Otherwise,

a) The STA_I checks the MIC. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the STA_I silently discards Message 4.
b) If the MIC is valid, the STA_I configures the STK into the IEEE 802.11 MAC.
c) The STA_I updates the Key Replay Counter field so that it will use a fresh value if a rekey becomes necessary.

8.5.3.5 4-Way Handshake implementation considerations

When the 4-Way Handshake is used as part of the STK Handshake, the initiator STA acts as Authenticator and peer STA acts as Supplicant.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001439

If the Authenticator does not receive a reply to its messages, it shall attempt dot11RSNAConfigPairwise-UpdateCount transmits of the message, plus a final timeout. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval, then 100 ms shall be used for all timeout values. If it still has not received a response after these retries, then for PTK generation the Authenticator should deauthenticate the STA, and for STK generation the STAs should delete the SMKSA and initiate an STSL application teardown procedure.

For PTK generation, if the STA does not receive Message 1 within the expected time interval (prior to IEEE 802.1X timeout), it should disassociate, deauthenticate, and try another AP/STA. For STK generation, if the peer STA does not receive Message 1 or Message 3 within the expected time interval (prior to dot11RSNAConfigSATimeout as specified in 8.5.8), it deletes the SMKSA and invokes an STSL application teardown procedure.

The Authenticator should ignore EAPOL-Key frames it is not expecting in reply to messages it has sent or EAPOL-Key frames with the Ack bit set. This stops an attacker from sending the first message to the Supplicant who responds to the Authenticator.

An implementation should save the KCK and KEK beyond the 4-Way Handshake, as they are needed for Group Key Handshakes, STK Rekeying, and recovery from TKIP MIC failures.

The Supplicant uses the MLME-SETKEYS.request primitive to configure the temporal key from 8.5.1 into its STA after sending Message 4 to the Authenticator.

NOTE 1—If the RSN information element check for Message 2 or Message 3 fails, IEEE Std 802.1X-2004 should log an error and deauthenticate the peer.

NOTE 2—The Supplicant should check that if the RSN information element specified a pairwise cipher suite, then the 4-Way Handshake did specify to configure the temporal key portion of the PTK into the IEEE 802.11 STA.

8.5.3.6 Sample 4-Way Handshake

The following is an informative sample of a 4-Way Handshake for illustration.

After IEEE 802.1X authentication completes by the AP sending an EAP-Success, the AP initiates the 4-Way Handshake. See Figure 8-33.

The 4-Way Handshake consists of the following steps:

a) The Authenticator sends an EAPOL-Key frame containing an ANonce.
b) The Supplicant derives a PTK from ANonce and SNonce.
c) The Supplicant sends an EAPOL-Key frame containing SNonce, the RSN information element from the (Re)Association Request frame, and a MIC.
d) The Authenticator derives PTK from ANonce and SNonce and validates the MIC in the EAPOL-Key frame.
e) The Authenticator sends an EAPOL-Key frame containing ANonce, the RSN information element from its Beacon or Probe Response messages, MIC, whether to install the temporal keys, and the encapsulated GTK.
f) The Supplicant sends an EAPOL-Key frame to confirm that the temporal keys are installed.

Exhibit 1014
Page 001440

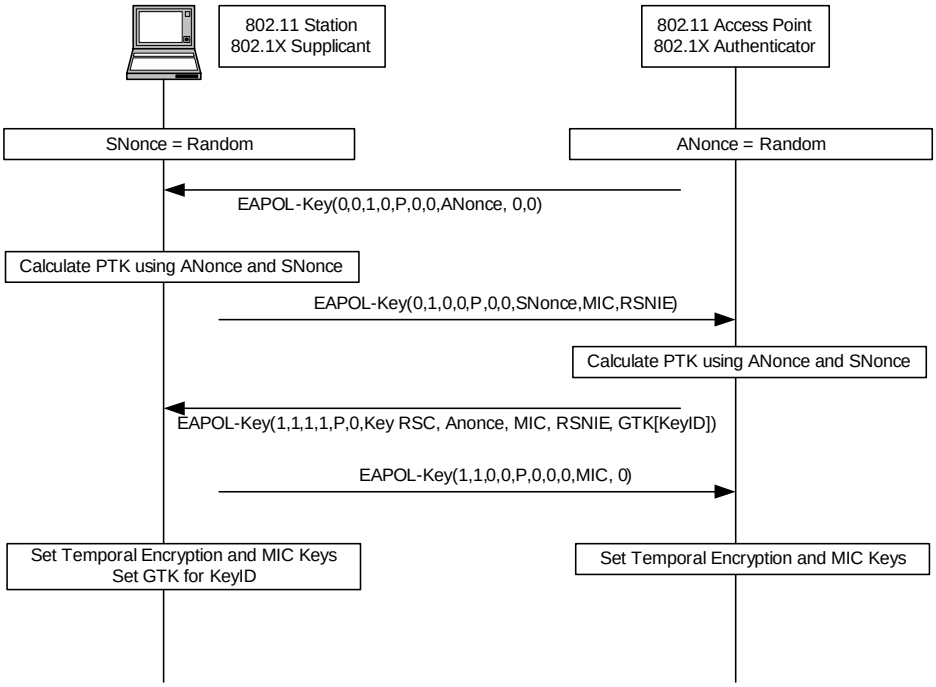

Figure 8-33—Sample 4-Way Handshake

8.5.3.7 4-Way Handshake analysis

The following is an informative analysis of the the 4-Way Handshake.

This subclause makes the trust assumptions used in this protocol explicit. The protocol assumes the following:

— The PMK is known only by the Supplicant's STA and the Authenticator's STA.

— The Supplicant's STA uses IEEE 802 address SPA.

— The Authenticator's STA uses IEEE 802 address AA.

In many instantiations the RSNA architecture immediately breaks the first assumption because the IEEE 802.1X AS also knows the PMK. Therefore, additional assumptions are required:

— The AS does not expose the PMK to other parties.

— The AS does not masquerade as the Supplicant to the Authenticator.

— The AS does not masquerade as the Authenticator to the Supplicant.

— The AS does not masquerade as the Supplicant's STA.

— The AS does not masquerade as the Authenticator's STA.

The protocol also assumes this particular Supplicant-Authenticator pair is authorized to know this PMK and to use it in the 4-Way Handshake. If any of these assumptions are broken, then the protocol fails to provide any security guarantees.

The protocol also assumes that the AS delivers the correct PMK to the AP with IEEE 802 address AA and that the non-AP STA with IEEE 802 address SPA hosts the Supplicant that negotiated the PMK with the AS. None of the protocols defined by this standard and IEEE Std 802.1X-2004 permit the AS, the Authenticator, the Supplicant, or either STA to verify these assumptions.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001441

The PTK derivation step

PTK ← PRF-X(PMK, "Pairwise key expansion" || Min(AA,SPA) || Max(AA,SPA) || Min(ANonce,SNonce) || Max(ANonce,SNonce))

performs a number of functions:

- Including the AA and SPA in the computation
  - Binds the PTK to the communicating STAs and
  - Prevents undetected man-in-the-middle attacks against 4-Way Handshake messages between the STAs with these two IEEE 802 addresses.
- If ANonce is randomly selected, including ANonce
  - Guarantees the STA at IEEE 802 address AA that PTK is fresh,
  - Guarantees that Message 2 and Message 4 are live, and
  - Uniquely identifies PTK as <AA, ANonce>.
- If SNonce is randomly selected, including SNonce
  - Guarantees the STA at IEEE 802 address SPA that PTK is fresh,
  - Guarantees that Message 3 is live, and
  - Uniquely identifies PTK as <SPA, SNonce>.

Choosing the nonces randomly helps prevent precomputation attacks. With unpredictable nonces, a man-in-the-middle attack that uses the Supplicant to precompute messages to attack the Authenticator cannot progress beyond Message 2, and a similar attack against the Supplicant cannot progress beyond Message 3. The protocol can be executed further before an error if predictable nonces are used.

Message 1 delivers ANonce to the Supplicant and initiates negotiation for a new PTK. It identifies AA as the peer STA to the Supplicant's STA. If an adversary modifies either of the addresses or ANonce, the Authenticator will detect the result when validating the MIC in Message 2. Message 1 does not carry a MIC, as it is impossible for the Supplicant to distinguish this message from a replay without maintaining state of all security associations through all time (PMK might be a static key).

Message 2 delivers SNonce to the Authenticator so it can derive the PTK. If the Authenticator selected ANonce randomly, Message 2 also demonstrates to the Authenticator that the Supplicant is live, that the PTK is fresh, and that there is no man-in-the-middle attack, as the PTK includes the IEEE 802 MAC addresses of both. Inclusion of ANonce in the PTK derivation also protects against replay. The MIC prevents undetected modification of Message 2 contents.

Message 3 confirms to the Supplicant that there is no man-in-the-middle attack. If the Supplicant selected SNonce randomly, it also demonstrates that the PTK is fresh and that the Authenticator is live. The MIC again prevents undetected modification of Message 3.

While Message 4 serves no cryptographic purpose, it serves as an acknowledgment to Message 3. It is required to ensure reliability and to inform the Authenticator that the Supplicant has installed the PTK and GTK and hence can receive encrypted frames.

The PTK and GTK are installed by using MLME-SETKEYS.request primitive after Message 4 is sent. The PTK is installed before the GTK.

Then the 4-Way Handshake uses a correct, but unusual, mechanism to guard against replay. As noted earlier in this subclause, ANonce provides replay protection to the Authenticator, and SNonce to the Supplicant. In most session initiation protocols, replay protection is accomplished explicitly by selecting a nonce randomly and requiring the peer to reflect the received nonce in a response message. The 4-Way Handshake instead mixes ANonce and SNonce into the PTK, and replays are detected implicitly by MIC failures. In particular,

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001442

the Key Replay Counter field serves no cryptographic purpose in the 4-Way Handshake. Its presence is not detrimental, however, and it plays a useful role as a minor performance optimization for processing stale instances of Message 2. This replay mechanism is correct, but its implicit nature makes the protocol harder to understand than an explicit approach.

It is critical to the correctness of the 4-Way Handshake that at least one bit differs in each message. Within the 4-Way Handshake, Message 1 can be recognized as the only one with the Key MIC bit clear, meaning Message 1 does not include the MIC, while Message 2 through Message 4 do. Message 3 differs from Message 2 by not asserting the Ack bit and from Message 4 by asserting the Ack Bit. Message 2 differs from Message 4 by including the RSN information element.

Request messages cannot be confused with 4-Way Handshake messages because the former asserts the Request bit and 4-Way Handshake messages do not. Group Key Handshake messages cannot be mistaken for 4-Way Handshake messages because they assert a different key type.

8.5.4 Group Key Handshake

The Authenticator uses the Group Key Handshake to send a new GTK to the Supplicant.

The Authenticator may initiate the exchange when a Supplicant is disassociated or deauthenticated.

Message 1: Authenticator → Supplicant: EAPOL-Key(1,1,1,0,G,0,Key RSC,0, MIC,GTK[N])

Message 2: Supplicant → Authenticator: EAPOL-Key(1,1,0,0,G,0,0,0,MIC,0)

Here, the following assumptions apply:

— Key RSC denotes the last frame sequence number sent using the GTK.

— GTK[N] denotes the GTK encapsulated with its key identifier as defined in 8.5.2 using the KEK defined in 8.5.1.2 and associated IV.

— The MIC is computed over the body of the EAPOL-Key frame (with the MIC field zeroed for the computation) using the KCK defined in 8.5.1.2.

The Supplicant may trigger a Group Key Handshake by sending an EAPOL-Key frame with the Request bit set to 1 and the type of the Group Key bit.

An Authenticator shall do a 4-Way Handshake before a Group Key Handshake if both are required to be done.

NOTE—The Authenticator cannot initiate the Group Key Handshake until the 4-Way Handshake completes successfully.

8.5.4.1 Group Key Handshake Message 1

Message 1 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 0

Install = 0

Key Ack = 1

Key MIC = 1

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001443

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 1

Reserved = 0

Key Length = 0

Key Replay Counter = *n*+2

Key Nonce = 0

EAPOL-Key IV = 0 (Version 2) or random (Version 1)

Key RSC = last transmit sequence number for the GTK

Key MIC = MIC(KCK, EAPOL)

Key Data Length = Cipher-suite-specific; see Table 8-2

Key Data = encrypted, encapsulated GTK and the GTK's key identifier (see 8.5.2)

The Authenticator sends Message 1 to the Supplicant.

On reception of Message 1, the Supplicant

a) Verifies that the Key Replay Counter field value has not yet been seen before, i.e., its value is strictly larger than that in any other EAPOL-Key frame received thus far during this session.
b) Verifies that the MIC is valid, i.e., it uses the KCK that is part of the PTK to verify that there is no data integrity error.
c) Uses the MLME-SETKEYS.request primitive to configure the temporal GTK into its IEEE 802.11 MAC.
d) Responds by creating and sending Message 2 of the Group Key Handshake to the Authenticator and incrementing the replay counter.

NOTE—The Authenticator must increment and use a new Key Replay Counter field value on every Message 1 instance, even retries, because the Message 2 responding to an earlier Message 1 may have been lost. If the Authenticator did not increment the replay counter, the Supplicant will discard the retry, and no responding Message 2 will ever arrive.

8.5.4.2 Group Key Handshake Message 2

Message 2 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128) – same as Message 1

Key Type = 0 (Group/SMK) – same as Message 1

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001444

Key Replay Counter = *n*+2 – same as Message 1

Key Nonce = 0

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC(KCK, EAPOL)

Key Data Length = 0

Key Data = none required

On reception of Message 2, the Authenticator

a) Verifies that the Key Replay Counter field value matches one it has used in the Group Key Handshake.

b) Verifies that the MIC is valid, i.e., it uses the KCK that is part of the PTK to verify that there is no data integrity error.

8.5.4.3 Group Key Handshake implementation considerations

If the Authenticator does not receive a reply to its messages, its shall attempt dot11RSNAConfigGroupUpdateCount transmits of the message, plus a final timeout. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval, then 100 ms shall be used for all timeout values. If it still has not received a response after this, then the Authenticator's STA should use the MLME-DEAUTHENTICATE.request primitive to deauthenticate the STA.

8.5.4.4 Sample Group Key Handshake

The following is an informative sample of a Group Key Handshake for illustration.

The state machines in 8.5.5 and 8.5.6 change the GTK in use by the network. See Figure 8-34.

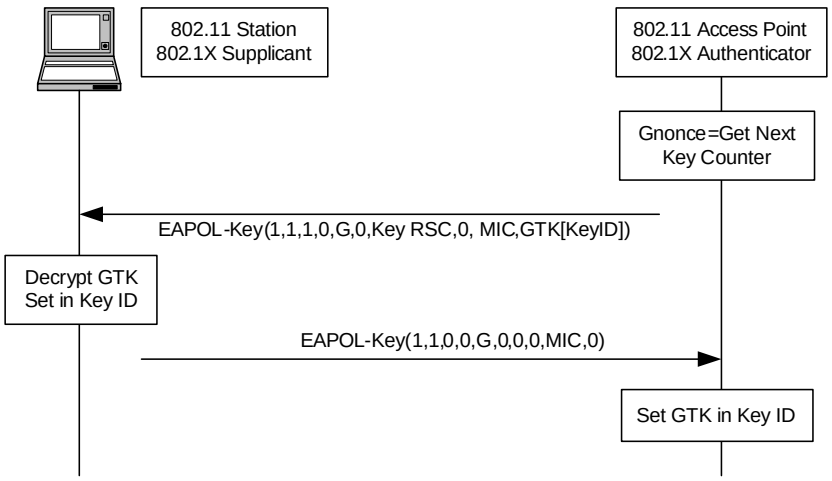

Figure 8-34—Sample Group Key Handshake

The following steps occur:

a) The Authenticator generates a new GTK. It encapsulates the GTK and sends an EAPOL-Key frame containing the GTK (Message 1), along with the last sequence number used with the GTK (RSC).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001445

b) On receiving the EAPOL-Key frame, the Supplicant validates the MIC, decapsulates the GTK, and uses the MLME-SETKEYS.request primitive to configure the GTK and the RSC in its STA.

c) The Supplicant then constructs and sends an EAPOL-Key frame in acknowledgment to the Authenticator.

d) On receiving the EAPOL-Key frame, the Authenticator validates the MIC. If the GTK is not already configured into IEEE 802.11 MAC, after the Authenticator has delivered the GTK to all associated STAs, it uses the MLME-SETKEYS.request primitive to configure the GTK into the IEEE 802.11 STA.

8.5.5 RSNA Supplicant key management state machine

The Supplicant shall reinitialize the Supplicant state machine whenever its system initializes. A Supplicant enters the AUTHENTICATION state on an event from the MAC that requests another STA to be authenticated. A Supplicant enters the STAKEYSTART state on receiving an EAPOL-Key frame from the Authenticator. If the MIC or any of the EAPOL-Key frames fails, the Supplicant silently discards the frame. Figure 8-35 depicts the RSNA Supplicant state machine.

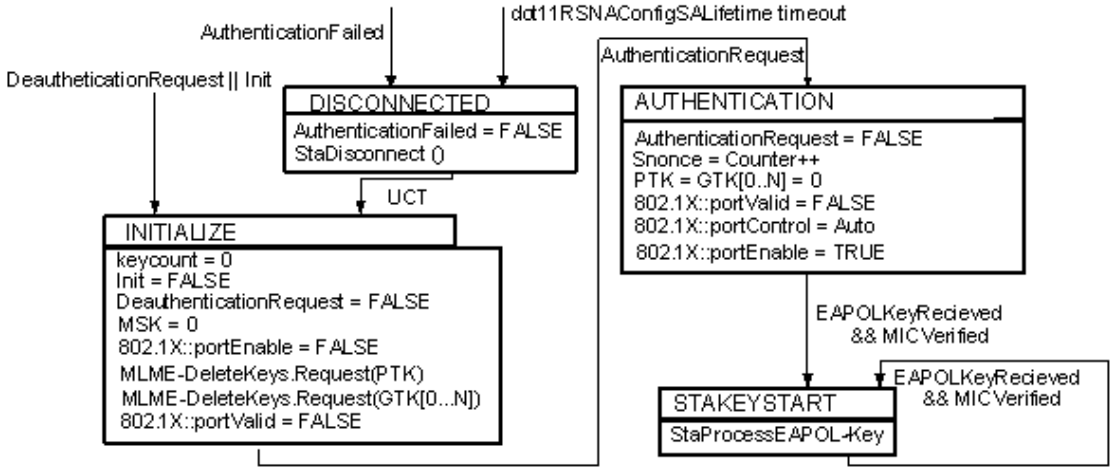

Figure 8-35—RSNA Supplicant key management state machine

Unconditional transfer (UCT) means the event triggers an immediate transition.

This state machine does not use timeouts or retries. The IEEE 802.1X state machine has timeouts that recover from authentication failures, etc.

The management entity will send an authentication request event when it wants an Authenticator authenticated. This can be before or after the STA associates to the AP. In an IBSS environment, the event will be generated when a Probe Response frame is received.

8.5.5.1 Supplicant state machine states

The following list summarizes the states of the Supplicant state machine:

— **AUTHENTICATION**: A STA's Supplicant enters this state when it sends an IEEE 802.1X AuthenticationRequest to authenticate to an SSID.

— **DISCONNECTED**: A STA's Supplicant enters this state when IEEE 802.1X authentication fails. The Supplicant executes StaDisconnect and enters the INITIALIZE state.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001446

— **INITIALIZE**: A STA's Supplicant enters this state from the DISCONNECTED state, when it receives Disassociation or Deauthentication messages or when the STA initializes, causing the STA's Supplicant to initialize the key state variables.

— **STAKEYSTART:** A STA's Supplicant enters this state when it receives an EAPOL-Key frame. All the information to process the EAPOL-Key frame is in the message and is described in the StaProcessEAPOL-Key procedure.

8.5.5.2 Supplicant state machine variables

The following list summarizes the variables used by the Supplicant state machine:

— *DeauthenticationRequest* – The Supplicant sets this variable to TRUE if the Supplicant's STA reports it has received Disassociation or Deauthentication messages.

— *AuthenticationRequest* – The Supplicant sets this variable to TRUE if its STA's IEEE 802.11 management entity reports it wants an SSID authenticated. This can be on association or at other times.

— *AuthenticationFailed* – The Supplicant sets this variable to TRUE if the IEEE 802.1X authentication failed. The Supplicant uses the MLME-DISASSOCIATE.request primitive to cause its STA to disassociate from the Authenticator's STA.

— *EAPOLKeyReceived* – The Supplicant sets this variable to TRUE when it receives an EAPOL-Key frame.

— *IntegrityFailed* **–** The Supplicant sets this variable to TRUE when its STA reports that a fatal data integrity error (e.g., Michael failure) has occurred.

NOTE—A Michael failure is not the same as MICVerified because IntegrityFailed is generated if the Michael integrity check fails; MICVerified is generated from validating the EAPOL-Key integrity check. Note also the STA does not generate this event for CCMP because countermeasures are not required.

— *MICVerified* **–** The Supplicant sets this variable to TRUE if the MIC on the received EAPOL-Key frame verifies as correct. The Supplicant silently discards any EAPOL-Key frame received with an invalid MIC.

— *Counter* **–** The Supplicant uses this variable as a global counter used for generating nonces.

— *SNonce* **–** This variable represents the Supplicant's nonce.

— *PTK* **–** This variable represents the current PTK.

— *TPTK* **–** This variable represents the current PTK until Message 3 of the 4-Way Handshake arrives and is verified.

— *GTK[]* **–** This variable represents the current GTKs for each group key index.

— *PMK* **–** This variable represents the current PMK.

— *keycount* – This variable is used in IBSS mode to decide when all the keys have been delivered and an IBSS link is secure.

— *802.1X::XXX* **–** This variable denotes another IEEE 802.1X state variable *XXX* not specified in this standard.

8.5.5.3 Supplicant state machine procedures

The following list summarizes the procedures used by the Supplicant state machine:

— **STADisconnect** – The Supplicant invokes this procedure to disassociate and deauthenticate its STA from the AP.

— **MIC**(*x*) – The Supplicant invokes this procedure to compute a MIC of the data *x*.

— **CheckMIC**() – The Supplicant invokes this procedure to verify a MIC computed by the MIC() function.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001447

— **StaProcessEAPOL-Key –** The Supplicant invokes this procedure to process a received EAPOL-Key frame. The pseudo-code for this procedure is as follows:

StaProcessEAPOL-Key (*S*, *M*, *A*, *I*, *K*, *RSC*, *ANonce*, RSC, *MIC*, RSNIE, *GTK[N]*)

```
TPTK ← PTK
TSNonce ← 0
PRSC ← 0
UpdatePTK ← 0

                    if (GTK[N] ← Decrypt GTK) succeeds then
                        if MLME-SETKEYS.request(N, T, RSC, GTK[N]) fails then
                            invoke MLME-
                            DEAUTHENTICATE.request
                        endif
                    else
                        State ← FAILED
                    endif
                else
                    State ← FAILED
                endif
            endif
            if A = 1 && State ≠ Failed then
                Send EAPOL-Key(0,1,0,0,K,0,0,TSNonce,MIC(TPTK),RSNIE)
            endif
            if UpdatePTK = 1 then
                MLME-SETPROTECTION.request(TA, Tx_Rx)
            endif
            if State = MICOK && S = 1 then
                MLME-SETPROTECTION.request(TA, Tx_Rx)
                if IBSS then
                    keycount++
                    if keycount = 2 then
                        802.1X::portValid← TRUE
                    endif
                else
                    802.1X::portValid← TRUE
                endif
            endif
```

Here UNKNOWN, MICOK, and FAILED are values of the variable State used in the Supplicant pseudo-code. State is used to decide how to do the key processing. MICOK is set when the MIC of the EAPOL-Key has been checked and is valid. FAILED is used when a failure has occurred in processing the EAPOL-Key frame. UNKNOWN is the initial value of the variable State.

When processing 4-Way Handshake Message 3, the GTK is decrypted from the EAPOL-Key frame and installed. The PTK shall be installed before the GTK.

The Key Replay Counter field used by the Supplicant for EAPOL-Key frames that are sent in response to a received EAPOL-Key frame shall be the received Key Replay Counter field. Invalid EAPOL-Key frames such as invalid MIC, GTK without a MIC, etc., shall be ignored.

NOTE 1—TPTK is used to stop attackers changing the PTK on the Supplicant by sending the first message of the 4-Way Handshake. An attacker can still affect the 4-Way Handshake while the 4-Way Handshake is being carried out.

NOTE 2—The PMK will be supplied by the authentication method used with IEEE Std 802.1X-2004 if preshared mode is not used.

NOTE 3—A PTK is configured into the encryption/integrity engine depending on the Tx/Rx bit, but if configured, is always a transmit key. A GTK is configured into the encryption/integrity engine independent of the state of the Tx/Rx bit, but whether the GTK is used as a transmit key is dependent on the state of the Tx/Rx bit.

— **CalcGTK**(x) – Generates the GTK.

— **DecryptGTK(x)** – Decrypt the GTK from the EAPOL-Key frame.

8.5.5.4 Supplicant PeerKey state machine states

Figure 8-36 depicts the PeerKey Handshake Supplicant key management state machine. The following list summarizes the states the Supplicant state machine uses to support the PeerKey Handshake:

— **STKINIT:** This state is the idle state and is entered when the IEEE 802.1X Supplicant completes successful Authentication.

— **SMKNEGOTIATING1:** This state is entered when the MLME-STKSTART.Request message is received for the SMK Handshake by the initiator STA.

— **SMKNEGOTIATING2:** This state is entered when the first EAPOL-Key frame of the SMK Handshake is received by the peer STA.

— **SMKNEGOTIATING3:** This state is entered when the fifth EAPOL-Key frame of the SMK Handshake is received by the initiator STA.

— **SMKNEGOTIATING4:** This state is entered when the fourth EAPOL-Key frame of the SMK Handshake is received by the peer STA.

— **STKSTART:** Once the SMKSA is created, the initiator STA enters this state. This is the start of 4-Way STK Handshake.

— **STKCALCNEGOTIATING:** This state is entered when the second EAPOL-Key frame of the 4-Way STK Handshake is received by the initiator STA and the MIC is verified.

— **STKCALCNEGOTIATING1:** This state is entered when the first EAPOL-Key frame of the 4-Way STK Handshake is received by the peer STA and the MIC is verified.

— **STKCALCNEGOTIATING2:** This state is entered unconditionally by the initiator STA.

— **STKCALCNEGOTIATING3:** This state is entered unconditionally by the peer STA.

— **STKCALCNEGOTIATING4:** This state is entered when the third EAPOL-Key frame of the 4-Way STK Handshake is received by the peer STA and the MIC is verified.

— **STKINITDONE:** This state is entered by the initiator STA when the fourth EAPOL-Key frame of the 4-Way STK Handshake is received. This state is entered by the peer STA when the fourth EAPOL-Key frame of the 4-Way STK Handshake is sent.

8.5.5.5 Supplicant PeerKey state machine variables

The following list summarizes the variables used by the Supplicant state machine:

— *PeerKeyInit* – This variable is used to initialize the PeerKey state machine.

— *TimeoutEvt* – This variable is set to TRUE if the EAPOL-Key frame sent fails to obtain a response from the Supplicant. The variable may be set by management action or set by the operation of a timeout while in the different states.

— *TimeoutCtr* – This variable maintains the count of EAPOL-Key receive timeouts. It is incremented each time a timeout occurs on EAPOL-Key receive event and is initialized to 0. Annex D contains details of the timeout values. The Key Replay Counter field value for the EAPOL-Key frame shall be incremented on each transmission of the EAPOL-Key frame.

— *MICVerified* – This variable is set to TRUE if the MIC on the received EAPOL-Key frame is verified and is correct. Any EAPOL-Key frames with an invalid MIC are dropped and ignored.

— *SMKMesgNo* – This variable indicates SMK Handshake EAPOL-Key frame types. Details for each message type (1-5) are provided in 8.5.8.

— *STKMesgNo* – This variable indicates 4-Way STK Handshake EAPOL-Key frame types. Details for each message type (1-4) are provided in 8.5.3.

— *STA_P* – This variable indicates the MAC address of the peer STA participating in the PeerKey Handshake.

— *STA_I* – This variable indicates the MAC address of the initiator STA participating in the PeerKey Handshake.

Exhibit 1014
Page 001450

— *STKKey* – The STK Key generated as a result of the 4-Way STK Handshake.

— *EAPOLKeyReceived* – The Supplicant sets this variable to TRUE when it receives an EAPOL-Key frame.

8.5.6 RSNA Authenticator key management state machine

There is one state diagram for the Authenticator. In an ESS, the Authenticator will always be on the AP; and in an IBSS environment, the Authenticator will be on every STA.

The state diagram shown in parts in Figure 8-37 through Figure 8-40 consists of the following states:

a) The AUTHENTICATION, AUTHENTICATION2, INITPMK, INITPSK, PTKSTART, PTKCALCNEGOTIATING, PTKCALCNEGOTIATING2, PTKINITNEGOTIATING, PTKINIT-DONE, DISCONNECT, DISCONNECTED, and INITIALIZE states. These states handle the initialization, 4-Way Handshake, tear-down, and general clean-up. These states are per associated STA.

b) The IDLE, REKEYNEGOTIATING, KEYERROR, and REKEYESTABLISHED states. These states handle the transfer of the GTK to the associated client. These states are per associated STA.

c) The GTK_INIT, SETKEYS, and SETKEYSDONE states. These states change the GTK when required, trigger all the PTK group key state machines, and update the IEEE 802.11 MAC in the Authenticator's AP when all STAs have the updated GTK. These states are global to the Authenticator.

Because there are two GTKs, responsibility for updating these keys is given to the group key state machine (see Figure 8-39). In other words, this state machine determines which GTK is in use at any time.

When a second STA associates, the group key state machine is already initialized, and a GTK is already available and in use.

When the GTK is to be updated the variable GTKReKey is set. The SETKEYS state updates the GTK and triggers all the PTK group key state machines that currently exist—one per associated STA. Each PTK group key state machine sends the GTK to its STA. When all the STAs have received the GTK (or failed to receive the key), the SETKEYSDONE state is executed which updates the APs encryption/integrity engine with the new key.

Both the PTK state machine and the PTK group key state machine use received EAPOL-Key frames as an event to change states. The PTK state machine only uses EAPOL-Key frames with the Key Type field set to

Pairwise, and the PTK group key state machine only uses EAPOL-Key frames with the Key Type field set to Group.

8.5.6.1 Authenticator state machine states

8.5.6.1.1 Authenticator state machine: 4-Way Handshake (per STA)

The following list summarizes the states the Authenticator state machine uses to support the 4-Way Handshake:

— **AUTHENTICATION**: This state is entered when an AuthenticationRequest is sent from the management entity to authenticate a BSSID.

— **AUTHENTICATION2**: This state is entered from the AUTHENTICATION state or from the PTKINITDONE state.

— **DISCONNECT**: This state is entered if an EAPOL-Key frame is received and fails its MIC check. It sends a Deauthentication message to the STA and enters the INITIALIZE state.

— **DISCONNECTED**: This state is entered when Disassociation or Deauthentication messages are received.

— **INITIALIZE**: This state is entered from the DISCONNECTED state, when a deauthentication request event occurs, or when the STA initializes. The state initializes the key state variables.

Exhibit 1014
Page 001454

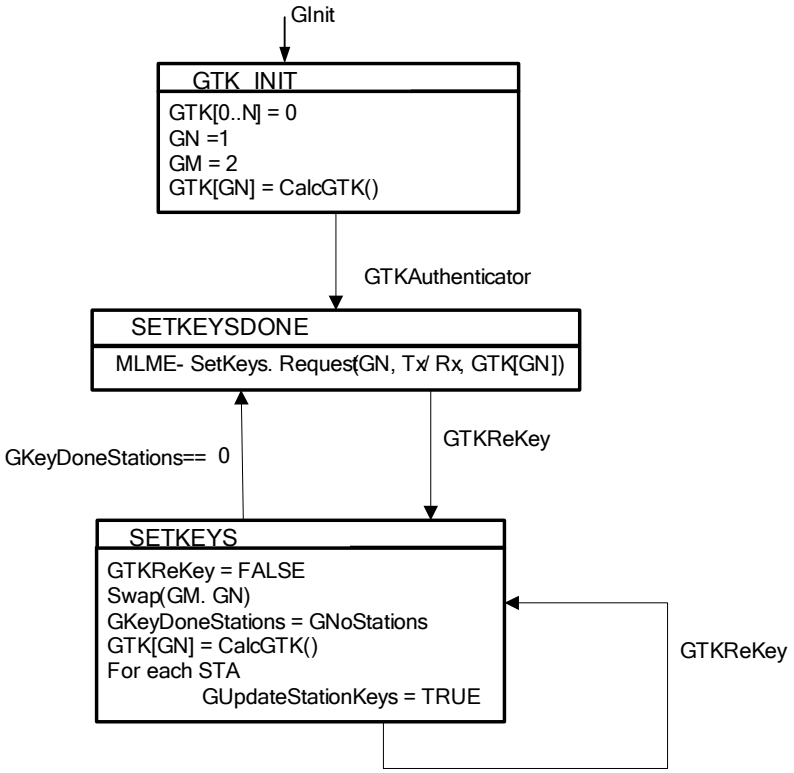

Figure 8-40—Authenticator state machines, part 4

— **INITPMK**: This state is entered when the IEEE 802.1X backend AS completes successfully. If a PMK is supplied, it goes to the PTKSTART state; otherwise, it goes to the DISCONNECTED state.

— **INITPSK:** This state is entered when a PSK is configured.

— **PTKCALCNEGOTIATING:** This state is entered when the second EAPOL-Key frame for the 4-Way Handshake is received with the key type of Pairwise.

— **PTKCALNEGOTIATING2:** This state is entered when the MIC for the second EAPOL-Key frame of the 4-Way Handshake is verified.

— **PTKINITNEGOTIATING:** This state is entered when the MIC for the second EAPOL-Key frame for the 4-Way Handshake is verified. When Message 3 of the 4-Way Handshake is sent in state PTKINITNEGOTIATING, the encrypted GTK shall be sent at the end of the data field, and the GTK length is put in the GTK Length field.

— **PTKINITDONE:** This state is entered when the last EAPOL-Key frame for the 4-Way Handshake is received with the key type of Pairwise. This state may call SetPTK; if this call fails, the AP should detect and recover from the situation, for example, by doing a disconnect event for this association.

— **PTKSTART:** This state is entered from INITPMK or INITPSK to start the 4-Way Handshake or if no response to the 4-Way Handshake occurs.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001455

8.5.6.1.2 Authenticator state machine: Group Key Handshake (per STA)

The following list summarizes the states the Authenticator state machine uses to support the Group Key Handshake:

— **IDLE:** This state is entered when no Group Key Handshake is occurring.

— **KEYERROR:** This state is entered if the EAPOL-Key acknowledgment for the Group Key Handshake is not received.

— **REKEYESTABLISHED:** This state is entered when an EAPOL-Key frame is received from the Supplicant with the Key Type subfield set to Group.

— **REKEYNEGOTIATING:** This state is entered when the GTK is to be sent to the Supplicant.

NOTE—The TxRx flag for sending a GTK is always the opposite of whether the pairwise key is used for data encryption/integrity or not. If a pairwise key is used for encryption/integrity, then the STA never transmits with the GTK; otherwise, the STA uses the GTK for transmit.

8.5.6.1.3 Authenticator state machine: Group Key Handshake (global)

The following list summarizes the states the Authenticator state machine uses to coordinate a group key update of all STAs:

— **GTK_INIT:** This state is entered on system initialization.

— **SETKEYS:** This state is entered if the GTK is to be updated on all Supplicants.

— **SETKEYSDONE:** This state is entered if the GTK has been updated on all Supplicants.

NOTE—SETKEYSDONE calls SetGTK to set the GTK for all associated STA. If this fails, all communication via this key will fail, and the AP needs to detect and recover from this situation.

8.5.6.2 Authenticator state machine variables

The following list summarizes the variables used by the Authenticator state machine:

— *AuthenticationRequest* – This variable is set to TRUE if the STA's IEEE 802.11 management entity wants an association to be authenticated. This can be set when the STA associates or at other times.

— *ReAuthenticationRequest* – This variable is set to TRUE if the IEEE 802.1X Authenticator received an eapStart or 802.1X::reAuthenticate is set.

— *DeauthenticationRequest* – This variable is set to TRUE if a Disassociation or Deauthentication message is received.

— *Disconnect* – This variable is set to TRUE when the STA should initiate a deauthentication.

— *EAPOLKeyReceived* – This variable is set to TRUE when an EAPOL-Key frame is received. EAPOL-Key frames that are received in response to an EAPOL-Key frame sent by the Authenticator must contain the same Key Replay Counter field value as the Key Replay Counter field in the transmitted message. EAPOL-Key frames that contain different Key Replay Counter field values should be discarded. An EAPOL-Key frame that is sent by the Supplicant in response to an EAPOL-Key frame from the Authenticator must not have the Ack bit set. EAPOL-Key frames sent by the Supplicant not in response to an EAPOL-Key frame from the Authenticator must have the Request bit set.

NOTE 1—EAPOL-Key frames with a key type of Pairwise and a nonzero key index should be ignored.

NOTE 2—EAPOL-Key frames with a key type of Group and an invalid key index should be ignored.

NOTE 3—When an EAPOL-Key frame with the Ack bit cleared is received, then it is expected as a reply to a message that the Authenticator sent, and the replay counter is checked against the replay counter used in the sent EAPOL-Key frame. When an EAPOL-Key frame with the Request bit set is received, then a replay counter for these messages is used that is a different replay counter than the replay counter used for sending messages to the Supplicant.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001456

— *GTimeoutCtr* – This variable maintains the count of EAPOL-Key receive timeouts for the Group Key Handshake. It is incremented each time a timeout occurs on EAPOL-Key receive event and is initialized to 0. Annex D details the timeout values. The Key Replay Counter field value for the EAPOL-Key frame shall be incremented on each transmission of the EAPOL-Key frame.

— *GInit* – This variable is used to initialize the group key state machine. This is a group variable.

— *Init* – This variable is used to initialize per-STA state machine

— *TimeoutEvt* – This variable is set to TRUE if the EAPOL-Key frame sent out fails to obtain a response from the Supplicant. The variable may be set by management action or set by the operation of a timeout while in the PTKSTART and REKEYNEGOTIATING states.

— *TimeoutCtr* **–** This variable maintains the count of EAPOL-Key receive timeouts. It is incremented each time a timeout occurs on EAPOL-Key receive event and is initialized to 0. Annex D contains details of the timeout values. The Key Replay Counter field value for the EAPOL-Key frame shall be incremented on each transmission of the EAPOL-Key frame.

— *MICVerified* – This variable is set to TRUE if the MIC on the received EAPOL-Key frame is verified and is correct. Any EAPOL-Key frames with an invalid MIC are dropped and ignored.

— *GTKAuthenticator* – This variable is set to TRUE if the Authenticator is on an AP or it is the designated Authenticator for an IBSS.

— *GKeyDoneStations* – Count of number of STAs left to have their GTK updated. This is a global variable.

— *GTKRekey* – This variable is set to TRUE when a Group Key Handshake is required. This is a global variable.

— *GUpdateStationKeys* – This variable is set to TRUE when a new GTK is available to be sent to Supplicants.

— *GNoStations* – This variable counts the number of Authenticators so it is known how many Supplicants need to be sent the GTK. This is a global variable.

— *Counter* – This variable is the global STA key counter.

— *ANonce* – This variable holds the current nonce to be used if the STA is an Authenticator.

— *GN***,** *GM* – These are the current key indices for GTKs. Swap(GM, GN) means that the global key index in GN is swapped with the global key index in GM, so now GM and GN are reversed.

— *PTK* – This variable is the current PTK.

— *GTK[]* – This variable is the current GTKs for each GTK index.

— *PMK* – This variable is the buffer holding the current PMK.

— *802.1X::XXX* – This variable is the IEEE 802.1X state variable *XXX*.

— *keycount* – This variable is used in IBSS mode to decide when all the keys have been delivered and an IBSS link is secure.

8.5.6.3 Authenticator state machine procedures

The following list summarizes the procedures used by the Authenticator state machine:

— **STADisconnect**() – Execution of this procedure deauthenticates the STA.

— **CalcGTK**(x) – Generates the GTK.

— **MIC**(x) – Computes a MIC over the plaintext data.

8.5.7 Nonce generation

The following is an informative description of Nonce generation.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001457

All STAs contain a global key counter, which is 256 bits in size. It should be initialized at system boot-up time to a fresh cryptographic-quality random number. Refer to H.6 on random number generation. It is recommended that the counter value is initialized to the following:

PRF-256(Random number, "Init Counter", Local MAC Address || Time)

The local MAC address should be AA on the Authenticator and SPA on the Supplicant.

The random number is 256 bits in size. Time should be the current time [from Network Time Protocol (NTP) or another time in NTP format] whenever possible. This initialization is to ensure that different initial key counter values occur across system restarts regardless of whether a real-time clock is available. The key counter must be incremented (all 256 bits) each time a value is used as an IV. The key counter must not be allowed to wrap to the initialization value.

8.5.8 PeerKey Handshake

The PeerKey Handshake occurs after any other STSL setup procedures and is used to create an STKSA providing data confidentiality between the two STAs. The AP must establish an RSNA with each STA prior to PeerKey setup. The initiator STA starts the PeerKey Handshake, at the conclusion of which a key is established to secure the connection.

STSL security PeerKey Handshake is used to establish security for data frames passed directly between two STAs associated with the same AP. The AP must establish an RSNA with each STA prior to the PeerKey Handshake. After the STAs establish the STSL, the initiator STA starts the PeerKey Handshake, at the conclusion of which a key is established to secure the connection. The PeerKey Handshake is used to create an STKSA between the two STAs.

The PeerKey EAPOL-Key exchange provides a mechanism for obtaining the keys to be used for direct station-to-station communication. The initiator STA shall start a timer when it sends the first EAPOL-Key message, and the peer STA shall do the same on receipt of the first EAPOL-Key message. On expiration of this timer, the STA shall transition to the STKINIT state.

A STA should use the PeerKey Handshake prior to transferring any direct station-to-station data frames. The STKSA should be deleted when the station-to-station connection is terminated.

Here, the following assumptions apply:

— EAPOL-Key() denotes an EAPOL-Key frame conveying the specified argument list, using the notation introduced in 8.5.2.1.

— STA_I is the initiator STA.

— STA_P is the peer STA.

— AP is the access point with which both the STA_I and the STA_P are associated.

— MAC_I is the MAC address of the STA_I.

— MAC_P is the MAC address of the STA_I.

— INonce is the nonce generated by the STA_I.

— PNonce is the nonce generated by the STA_P.

The PeerKey Handshake has two components:

a) **SMK Handshake:** This handshake is initiated by the initiator STA, and as a result of this handshake, the SMKSA is installed in both the STAs. This message exchange goes through the AP and is protected using the PTK.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001458

b) **4-Way STK Handshake:** Using the installed SMKSA, the initiator STA initiates the 4-Way Handshake (per 8.5.3.4), and as a result of this, the STKSA gets installed in both the STAs. The STKSA is used for securing data exchange between the initiator STA and the peer STA.

8.5.8.1 SMK Handshake

The initiator STA initiates the SMK Handshake by sending the first message to the AP to establish an SMKSA between itself and another STA associated with the same AP. Unlike the 4-Way Handshake and the Group Key Handshake, the SMK Handshake is initiated by the initiator STA.

Message 1: Initiator STA → AP: EAPOL-Key(1,1,0,0,0,1,0, INonce, MIC, RSNIE_I, MAC_P KDE)

Message 2: AP → Peer STA: EAPOL-Key(1,1,1,0,0,1,0, INonce, MIC, RSNIE_I, MAC_I KDE)

Message 3: Peer STA → AP: EAPOL-Key(1,1,0,0,0,1,0, PNonce, MIC, RSNIE_P, MAC_I KDE, INonce KDE)

Message 4: AP → Peer STA: EAPOL-Key(1,1,0,1,0,1,0, PNonce, MIC, MAC_I KDE, INonce KDE, SMK KDE, Lifetime KDE)

Message 5: AP → Initiator STA: EAPOL-Key(1,1,0,0,0,1,0, INonce, MIC, RSNIE_P, MAC_P KDE, PNonce KDE, SMK KDE, Lifetime KDE)

8.5.8.1.1 SMK Handshake Message 1

The initiator STA creates the RSN information element (see 7.3.2.25) by including the element ID, length, version, and pairwise cipher suite list fields. Since the group cipher suit field is before the pairwise cipher suite list field (so the STA needs to include it), the STA includes any value in this field, and the receiving STA ignores it. The initiator STA also generates a 256-bit random number that is sent in the Key Nonce field.

Message 1 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 1

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter of initiating STA

Key Nonce = INonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (initiating STA’s KCK, EAPOL)

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001459

Key Data Length = Length of Key Data field in octets

Key Data = Initiator RSNIE, peer MAC address KDE

The STA_I sends Message 1 to the AP.

On receipt of Message 1, the AP checks that the key replay counter corresponds to Message 1. If not, it silently discards the message. Otherwise,

a) The AP verifies the Message 1 MIC using the STA_I PTKSA. If the calculated MIC does not match the MIC that the STA_I included in the EAPOL-Key frame, the AP silently discards Message 1.

b) If the MIC is correct, the AP checks if the STA_P is reachable. If it is not reachable, the AP shall send an error EAPOL-Key message to STA_I per 8.5.8.4.1. After sending the message, AP silently discards Message 1.

c) The AP checks if the AP has a secure connection with STA_P. If not, the AP shall send an error EAPOL-Key message to STA_I per 8.5.8.4.2. After sending the message, AP silently discards Message 1.

d) If all checks succeed, the AP creates Message 2 using the STA_P PTKSA. The AP copies the contents of Message 1 to create Message 2.

8.5.8.1.2 SMK Handshake Message 2

Message 2 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 1

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter of AP and STA_P

Key Nonce = INonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of the STA_P, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Initiator RSNIE, initiator MAC address KDE

The AP sends Message 2 to the STA_P. On receipt of Message 2, the STA_P checks that the key replay counter corresponds to Message 2. If not, it silently discards the message. Otherwise,

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001460

a) The STA_P verifies the Message 2 MIC using the STA_P PTKSA. If the calculated MIC does not match the MIC that the AP included in the EAPOL-Key frame, the STA_P silently discards Message 2.

b) If the MIC is correct, the STA_P checks if it supports at least one cipher suites proposed by the STA_I. If it does not, the STA_P shall send an error EAPOL-Key message to STA_I through the AP per 8.5.8.4.3. After sending the errror message, the STA_P silently discards Message 2.

c) STA_O checks if it has already created an STSL with STA_I. If it has not, STA_P shall send an error EAPOL-Key message to STA_I through the AP per 8.5.8.4.4. After sending the error message, the STA_P silently discards Message 2.

d) If all checks succeed, the STA_P creates the state of PeerKey Handshake and stores the initiator Nonce and the RSNIE received in Message 2.

e) STA_P selects a support cipher suite from the cipher suite list proposed by the STA_I and creates the peer RSNIE, which is sent with Message 3.

f) STA_P generates a 256-bit random number that is sent as the peer Nonce KDE with Message 3.

g) Using all the information, STA_P creates Message 3.

8.5.8.1.3 SMK Handshake Message 3

Message 3 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter of peer STA

Key Nonce = PNonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of STA_I, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Peer RSNIE, initiator MAC address KDE, initiator Nonce KDE

The STA_P sends Message 3 to the AP. On receipt of Message 3, the AP checks that the key replay counter corresponds to Message 3. If not, it silently discards the message. Otherwise,

a) The AP verifies the Message 1 MIC using the STA_I PTKSA. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the AP silently discards Message 1.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001461

b) If MIC is correct, the AP checks if the STA_I is reachable. If it is not reachable, the AP shall send an error EAPOL-Key message to the STA_P per 8.5.8.4.1. After sending the message, the AP silently discards Message 3.

c) The AP checks if the AP has secure connection with STA_I. If it does not, the AP shall send an error EAPOL-Key message to STA_P per 8.5.8.4.2. After sending the message, the AP silently discards Message 3.

d) If all checks succeed, the AP generates a 256-bit random number that is used as the SMK, which is sent with Message 4 and Message 5 as SMK KDEs.

e) Depending on the strength of random number generator, the AP sets the lifetime of the SMK, which is sent with Message 4 and Message 5 as Lifetime KDEs.

f) Using all the information, the AP creates Message 4 and Message 5.

8.5.8.1.4 SMK Handshake Message 4

Message 4 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 1

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 1

Reserved = 0

Key Length = Cipher-suite-specific; see Table 8-2

Key Replay Counter = request EAPOL replay counter of AP

Key Nonce = PNonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of the STA_I, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Encrypted initiator MAC address KDE, INonce KDE, SMK KDE (contains SMK and PNonce), Lifetime KDE

The AP sends Message 4 to the STA_P. On receipt of Message 4, the STA_P checks that the key replay counter corresponds to Message 4. If it does not, STA_P silently discards the message. Otherwise,

a) The STA_P verifies the Message 4 MIC using STA_P PTKSA. If the calculated MIC does not match the MIC that the AP included in the EAPOL-Key frame, the STA_P silently discards Message 4.

b) If the MIC is correct, STA_P identifies the PeerKey session using peer Nonce sent as part of the Key Nonce field of Message 4. If STA_P has an existing PeerKey state for this session, i.e., STA_P has

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001462

received Message 2 and this message is a follow-up to that. If STA_P has an existing PeerKey state for this session, STA_P silently discards Message 4.

c) If all checks succeed, STA_P decrypts the Key Data field of Message 4 and extracts the MAC_I, the INonce, the PNonce, the SMK, and the lifetime from Message 4. The STA_P verifies the extracted INonce against the INonce originally received as part of Message 2.

d) The STA_P calculates the SMKID per 8.5.1.4.

e) The STA_P checks the value of the lifetime with the maximum value it can support. If the lifetime suggested by the AP is too long, the STA_P selects a lower value that it can support.

f) Using all the information, the STA_P creates the SMKSA for this PeerKey session.

8.5.8.1.5 SMK Handshake Message 5

Message 5 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 1

Reserved = 0

Key Length = Cipher-suite-specific; see Table 8-2

Key Replay Counter = request EAPOL replay counter of AP

Key Nonce = INonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of the STA_I, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Encrypted peer RSNIE, peer MAC address KDE, peer Nonce KDE, SMK KDE (contains SMK and INonce), Lifetime KDE

The AP sends Message 5 to the STA_I. On receipt of Message 5, the STA_I checks that the key replay counter corresponds to Message 5. If it does not, the STA_I silently discards the message. Otherwise,

a) STA_I verifies the Message 4 MIC using STA P PTKSA. If the calculated MIC does not match the MIC that the AP included in the EAPOL-Key frame, the STA_I silently discards Message 5.

b) If the MIC is correct, the STA_I identifies the PeerKey session using the initiator Nonce sent as part of the Key Nonce field of Message 5. If STA_I has an existing PeerKey state for this session, i.e., STA_I has initiated this message exchange using Message 1 and this message is a follow-up to that. If STA_I has an exisiing PeerKey state for this session, STA_I shall silently discard Message 5.

c) If all checks succeed, STA_I decrypts the Key Data field of Message 5 and extracts the peer RSNIE, the MAC_P, the INonce, the PNonce, the SMK, and the lifetime from Message 5.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001463

d) The STA_I verifies that the peer RSNIE includes a valid cipher (i.e., one that was included in an initiator RSNIE). If not, STA_I discards the message and sends an Error KDE ERR_CPHR_NS.

e) The STA_I calculates SMKID per 8.5.1.4.

f) The STA_I checks the value of the lifetime with the maximum value it can support. If the lifetime suggested by the AP is too long, STA_I selects a lower value that can support.

g) Using all the information, the STA_I creates the SMKSA for this PeerKey session.

8.5.8.2 PeerKey setup and handshake error conditions

If the STA_P does not receive a valid SMK Message 2 or a 4-Way STK Message 1 after sending the EAPOL request message to initiate the PeerKey rekey within a 200 ms timeout, the STA_P shall invoke an STSL application teardown procedure.

If the STA_I does not receive an SMK Message 5 from the AP, the STA_I shall attempt dot11RSNAConfigSMKUpdateCount transmits of the SMK Handshake Message 1 plus a final timeout. If the STA_I still has not received a response after these retries, it shall invoke an STSL application teardown procedure. The retransmit timeout value shall be 200 ms for the first timeout, the listen interval for the second timeout, and twice the listen interval for subsequent timeouts. If there is no listen interval, then 200 ms shall be used for all timeout values.

There is no specific recovery mechanism at the AP if the SMK Message 3 is dropped. This will result in a timeout by the STA_I after nonreceipt of SMK Message 5, as described in the preceding paragraph.

If the SMK Message 4 is not received by the STA_P, a failure will be detected during the 4-Way STK Handshake. In this case, the STA_P will discard the EAPOL-Key messages without the proper key. This failure is covered by behavior described in 8.5.3.5 and will result in teardown of the STSL.

Upon receipt of the SMK Message 5, the STA_I will transmit Message 1 of the 4-Way STK Handshake to the STA_P. If the STA_I does not receive Message 2 of the 4-Way STK Handshake from the STA_P, it shall attempt dot11RSNAConfigSMKUpdateCount transmits of 4-Way STK Handshake Message 1, plus a final timeout. If STA_I still has not received a response after these retries, it shall invoke an STSL application teardown procedure. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval, then 100 ms shall be used for all timeout values.

There is no specific recovery mechanism at the STA_P if the SMK Message 3 is lost. This will result in a timeout on the STA_I, as described in the preceding paragraph, and a subsequent reinitiation of the SMK Handshake. The STA_P shall allow reinitiation of the SMK Handshake at any point prior to receipt of SMK Message 4.

8.5.8.3 STKSA rekeying

Rekeying is always initiated by the STA_I. When needed, the STA_P sends an EAPOL request message to the STA_I to request rekeying. The STA_P shall wait a minimum of one half the IEEE 802.1X timeout after the STSL setup before initiating a PeerKey rekey procedure. To perform rekeying, there are two cases:

a) If SMK timer has not expired, the STAs will initiate a 4-Way Handshake to create a new STK. The 4-Way Handshake is always initiated by the STA_I. In this case, the STA_P should not delete any existing STKSA prior to verifying Message 3 of the 4-Way Handshake with STA_I for this session.

b) If the SMK has expired, the STA_I shall not use an existing STKSA and shall start the SMK Handshake followed by a 4-Way Handshake to create new keys.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001464

The format of the EAPOL-Key request message in case a) from STA_P to STA_I is as follows:

Request Message: STA_P → STA_I: EAPOL-Key(1,1,0,0,1,0,0,0, MIC, PMKID KDE)

The request message uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 1 (PTK)

SMK Message = 0

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 1

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request replay counter of peer STA

Key Nonce = 0

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC computed over the body of this EAPOL-Key frame

Key Data Length = Length of Key Data field in octets

Key Data = SMKID in SMKID KDE

8.5.8.4 Error Reporting

Error reporting messages are defined in this subclause and used to report errors whenever STAs or an AP detect an error during the SMK Handshake.

The AP, upon receiving the error messages defined in this subclause or upon generating the error messages defined in this subclause, should log the error. The STA, upon receipt of the error messages defined in this subclause, shall tear down the STSL with the other STA and clear all the PeerKey states.

The format of EAPOL-Key request message for reporting an error message is as follows:

Error Message: EAPOL-Key(1,1,0,0,0,1,0, 0, MIC, Error KDE, MAC Address KDE).

The request message uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 8.5.2

Key Information:

Key Descriptor Version = 1 (RC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA1-128)

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Exhibit 1014
Page 001465

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 1

Request = 1 when the message is going from the STA to an AP or 0 when the message is going from an AP to the STA

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter

Key Nonce = 0

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC computed over the body of this EAPOL-Key frame

Key Data Length = Length of Key Data field in octets

Key Data = Error KDE (different types defined in Table 8-6), MAC Address KDE

8.5.8.4.1 Error ERR_STA_NR

This error message is sent whenever an AP finds that the STA to which it needs to send a message is not reachable. In response to this error, the AP creates an Error KDE with error type ERR_STA_NR and sends the message back to the other STA involved in the handshake. The MAC address KDE contains the MAC address of the unreachable STA.

8.5.8.4.2 Error ERR_STA_NRSN

This error message is sent whenever the AP finds that the STA to which it needs to send the message does not have a secure RSNA connection. In response of this error, the AP creates an Error KDE with error type ERR_STA_NRSN and sends the message back to the STA from which it received the last message. The MAC address KDE contains the MAC address of the STA with which the AP does not have a secure RSNA connection.

8.5.8.4.3 Error ERR_CPHR_NS

This error message is sent whenever a STA finds that it does not support any of the cipher suites proposed by the other STA. In response to this error, the STA creates an Error KDE with error type ERR_CPHR_NS and sends the message back to the other STA. The MAC address KDE contains the MAC address of the other STA.

8.5.8.4.4 Error ERR_NO_STSL

This error message is sent whenever a STA finds that it does not have an existing STSL with the other STA. In response of this error, the STA creates an Error KDE with error type ERR_NO_STSL and sends the message back to the other STA. The MAC address KDE contains the MAC address of the other STA.

8.6 Mapping EAPOL keys to IEEE 802.11 keys

8.6.1 Mapping PTK to TKIP keys

See 8.5.1.2 for the definition of the EAPOL temporal key derived from PTK.

A STA shall use bits 0–127 of the temporal key as its input to the TKIP Phase 1 and Phase 2 mixing functions.

A STA shall use bits 128–191 of the temporal key as the Michael key for MSDUs from the Authenticator's STA to the Supplicant's STA.

A STA shall use bits 192–255 of the temporal key as the Michael key for MSDUs from the Supplicant's STA to the Authenticator's STA.

8.6.2 Mapping GTK to TKIP keys

See 8.5.1.3 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use bits 0–127 of the temporal key as the input to the TKIP Phase 1 and Phase 2 mixing functions.

A STA shall use bits 128–191 of the temporal key as the Michael key for MSDUs from the Authenticator's STA to the Supplicant's STA.

A STA shall use bits 192–255 of the temporal key as the Michael key for MSDUs from the Supplicant's STA to the Authenticator's STA.

8.6.3 Mapping PTK to CCMP keys

See 8.5.1.2 for the definition of the EAPOL temporal key derived from PTK.

A STA shall use the temporal key as the CCMP key for MSDUs between the two communicating STAs.

8.6.4 Mapping GTK to CCMP keys

See 8.5.1.3 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use the temporal key as the CCMP key.

8.6.5 Mapping GTK to WEP-40 keys

See 8.5.1.3 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use bits 0–39 of the temporal key as the WEP-40 key.

8.6.6 Mapping GTK to WEP-104 keys

See 8.5.1.3 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use bits 0–103 of the temporal key as the WEP-104 key.

Exhibit 1014
Page 001467

8.7 Per-frame pseudo-code

8.7.1 WEP frame pseudo-code

An MPDU of type Data with the Protected Frame subfield of the Frame Control field equal to 1 is called a WEP MPDU. Other MPDUs of type Data are called non-WEP MPDUs.

A STA shall not transmit WEP-encapsulated MPDUs when value of the MIB variable dot11PrivacyInvoked is set to FALSE. This MIB variable does not affect MPDU or MMPDU reception.

if dot11PrivacyInvoked is “false” **then**
the MPDU is transmitted without WEP cryptographic encapsulation
else
if (the MPDU has an individual RA and there is an entry in dot11WEPKeyMappings for that RA) **then**
if that entry has WEPOn set to “false” **then**
the MPDU is transmitted without WEP cryptographic encapsulation
else
if that entry contains a key that is null **then**
discard the MPDU’s entire MSDU and generate an MA-UNITDATA.confirm primitive to notify LLC that the MSDU was undeliverable due to a null WEP key
else
encrypt the MPDU using that entry’s key, setting the Key ID subfield of the IV field to zero
endif
endif
else
if (the MPDU has a group RA and the Privacy subfield of the Capability Information field in this BSS is set to 0) **then**
the MPDU is transmitted without WEP cryptographic encapsulation
else
if dot11WEPDefaultKeys[dot11WEPDefaultKeyID] is null **then**
discard the MPDU’s entire MSDU and generate an MA-UNITDATA.confirm primitive to notify LLC that the MSDU was undeliverable due to a null WEP key
else
WEP-encapsulate the MPDU using the key dot11WEPDefaultKeys-[dot11WEPDefaultKeyID], setting the Key ID subfield of the IV field to dot11WEPDefaultKeyID
endif
endif
endif
endif

When the boolean attribute aExcludeUnencrypted is set to TRUE, non-WEP MPDUs shall not be indicated at the MAC service interface, and only MSDUs successfully reassembled from successfully decrypted MPDUs shall be indicated at the MAC service interface. When receiving a frame of type Data, the values of dot11PrivacyOptionImplemented, dot11WEPKeyMappings, dot11WEPDefaultKeys, dot11WEPDefault-KeyID, and aExcludeUnencrypted in effect at the time the PHY-RXSTART.indication primitive is received by the MAC shall be used according to the following decision tree:

if the Protected Frame subfield of the Frame Control field is zero **then**
if `aExcludeUnencrypted` is “true” **then**

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001468

```
            discard the frame body without indication to LLC and increment
              dot11WEPExcludedCount
        else
            receive the frame without WEP decapsulation
        endif
    else
        if dot11PrivacyOptionImplemented is "true" then
            if (the MPDU has individual RA and there is an entry in dot11WEPKeyMappings match-
              ing the MPDU's TA) then
                if that entry has WEPOn set to "false" then
                    discard the frame body and increment dot11WEPUndecryptableCount
                else
                    if that entry contains a key that is null then
                        discard the frame body and increment dot11WEPUndecryptableCount
                    else
                        WEP-decapsulate with that key, incrementing dot11WEPICVErrorCount if
                          the ICV check fails
                    endif
                endif
            else
                if dot11WEPDefaultKeys[Key ID] is null then
                    discard the frame body and increment dot11WEPUndecryptableCount
                else
                    WEP-decapsulate with dot11WEPDefaultKeys[Key ID], incrementing
                      dot11WEPICVErrorCount if the ICV check fails
                endif
            endif
        else
            discard the frame body and increment dot11WEPUndecryptableCount
        endif
    endif
```

8.7.2 RSNA frame pseudo-code

STAs transmit protected MSDUs to a RA when temporal keys are configured and an MLME-SETPROTECTION.request primitive has been invoked for transmit to that RA. STAs expect to receive protected MSDUs from a TA when temporal keys are configured and an MLME-SET-PROTECTION.request primitive has been invoked for receive from that TA. MSDUs that do not match these conditions are sent in the clear and are received in the clear.

8.7.2.1 Per-MSDU Tx pseudo-code

```
    if dot11RSNAEnabled = true then
        if MSDU has an individual RA and Protection for RA is off for Tx then
            transmit the MSDU without protections
        else if (MPDU has individual RA and Pairwise key exists for the MPDU's RA) or (MPDU has
          a multicast or broadcast RA and network type is IBSS and IBSS GTK exists for MPDU's
          TA) then
            // If we find a suitable Pairwise or GTK for the mode we are in…
            if key is a null key then
                discard the entire MSDU and generate an MA-UNITDATA.confirm primitive to
                  notify LLC that the MSDU was undeliverable due to a null key
            else
                // Note that it is assumed that no entry will be in the key
```

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001469

```
                    // mapping table of a cipher type that is unsupported.
                    Set the Key ID subfield of the IV field to zero.
                    if cipher type of entry is AES-CCM then
                        Transmit the MSDU, to be protected after fragmentation using AES-CCM
                    else if cipher type of entry is TKIP then
                        Compute MIC using Michael algorithm and entry's Tx MIC key.
                        Append MIC to MSDU
                        Transmit the MSDU, to be protected with TKIP
                    else if cipher type of entry is WEP then
                        Transmit the MSDU, to be protected with WEP
                    endif
                endif
            else // Else we did not find a key but we are protected, so handle the default key case or discard
                if GTK entry for Key ID contains null then
                    discard the MSDU and generate an MA-UNITDATA.confirm primitive to notify
                      LLC that the entire MSDU was undeliverable due to a null GTK
                else if GTK entry for Key ID is not null then
                    Set the Key ID subfield of the IV field to the Key ID.
                    if MPDU has an individual RA and cipher type of entry is not TKIP then
                        discard the entire MSDU and generate an MA-UNITDATA.confirm primitive
                          to notify LLC that the MSDU was undeliverable due to a null key
                    else if cipher type of entry is AES-CCM then
                        Transmit the MSDU, to be protected after fragmentation using AES-CCM
                    else if cipher type of entry is TKIP then
                        Compute MIC using Michael algorithm and entry's Tx MIC key.
                        Append MIC to MSDU
                        Transmit the MSDU, to be protected with TKIP
                    else if cipher type of entry is WEP then
                        Transmit the MSDU, to be protected with WEP
                    endif
                endif
            endif
        endif
```

8.7.2.2 Per-MPDU Tx pseudo-code

```
if dot11RSNAEnabled = TRUE then
    if MPDU is member of an MSDU that is to be transmitted without protections
        transmit the MPDU without protections
    else if MSDU that MPDU is a member of is to be protected using AES-CCM
        Protect the MPDU using entry's key and AES-CCM
        Transmit the MPDU
    else if MSDU that MPDU is a member of is to be protected using TKIP
        Protect the MPDU using TKIP encryption
        Transmit the MPDU
    else if MSDU that MPDU is a member of is to be protected using WEP
        Encrypt the MPDU using entry's key and WEP
        Transmit the MPDU
    else
        // should not arrive here
    endif
endif
```

9. MAC sublayer functional description

The MAC functional description is presented in this clause. The architecture of the MAC sublayer, including the distributed coordination function (DCF), the point coordination function (PCF), the hybrid coordination function (HCF), and their coexistence in an IEEE 802.11 LAN are introduced in 9.1. These functions are expanded on in 9.2 (DCF), 9.3 (PCF), and 9.9 (HCF). Fragmentation and defragmentation are defined in 9.4 and 9.5. Multirate support is addressed in 9.6. A number of additional restrictions to limit the cases in which MSDUs are reordered or discarded are described in 9.7. Operation across regulatory domains is defined in 9.8. The Block Ack mechanism is described in 9.10. The No Ack mechanism is described in 9.11. The allowable frame exchange sequences are defined in 9.12. The protection mechanism is described in 9.13.

9.1 MAC architecture

The MAC architecture can be described as shown in Figure 9-1 as providing the PCF and HCF through the services of the DCF. Note that in a non-QoS STA, HCF is not present. In a QoS STA implementation, both DCF and HCF are present. PCF is optional in all STAs.

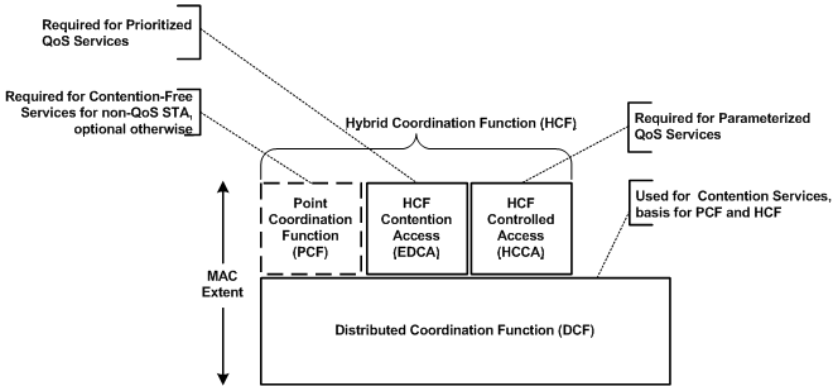

Figure 9-1—MAC architecture

9.1.1 DCF

The fundamental access method of the IEEE 802.11 MAC is a DCF known as *carrier sense multiple access with collision avoidance* (CSMA/CA). The DCF shall be implemented in all STAs, for use within both IBSS and infrastructure network configurations.

For a STA to transmit, it shall sense the medium to determine if another STA is transmitting. If the medium is not determined to be busy (see 9.2.1), the transmission may proceed. The CSMA/CA distributed algorithm mandates that a gap of a minimum specified duration exist between contiguous frame sequences. A transmitting STA shall ensure that the medium is idle for this required duration before attempting to transmit. If the medium is determined to be busy, the STA shall defer until the end of the current transmission. After deferral, or prior to attempting to transmit again immediately after a successful transmission, the STA shall select a random backoff interval and shall decrement the backoff interval counter while the medium is idle. A transmission is successful either when an ACK frame is received from the STA addressed by the RA field of the transmitted frame or when a frame with a group address in the RA field is transmitted completely. A refinement of the method may be used under various circumstances to further minimize collisions—here the transmitting and receiving STA exchange short control frames (RTS and CTS frames) after determining that the medium is idle and after any deferrals or backoffs, prior to data transmission. The details of CSMA/CA, deferrals, and backoffs are described in 9.2. RTS/CTS exchanges are also presented in 9.2.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001474

9.1.2 PCF

The IEEE 802.11 MAC may also incorporate an optional access method called a PCF, which is only usable on infrastructure network configurations. This access method uses a PC, which shall operate at the AP of the BSS, to determine which STA currently has the right to transmit. The operation is essentially that of polling, with the PC performing the role of the polling master. The operation of the PCF may require additional coordination, not specified in this standard, to permit efficient operation in cases where multiple point-coordinated BSSs are operating on the same channel, in overlapping physical space.

The PCF uses a virtual carrier sense (CS) mechanism aided by an access priority mechanism. The PCF shall distribute information within Beacon management frames to gain control of the medium by setting the NAV in STAs. In addition, all frame transmissions under the PCF may use an interframe space (IFS) that is smaller than the IFS for frames transmitted via the DCF. The use of a smaller IFS implies that point-coordinated traffic shall have priority access to the medium over STAs in overlapping BSSs operating under the DCF access method.

The access priority provided by a PCF may be utilized to create a CF access method. The PC controls the frame transmissions of the STAs so as to eliminate contention for a limited period of time.

9.1.3 Hybrid coordination function (HCF)

The QoS facility includes an additional coordination function called *HCF* that is only usable in QoS network configurations. The HCF shall be implemented in all QoS STAs. The HCF combines functions from the DCF and PCF with some enhanced, QoS-specific mechanisms and frame subtypes to allow a uniform set of frame exchange sequences to be used for QoS data transfers during both the CP and CFP. The HCF uses both a contention-based channel access method, called the *enhanced distributed channel access* (EDCA) mechanism for contention-based transfer and a controlled channel access, referred to as the *HCF controlled channel access* (HCCA) mechanism, for contention-free transfer.

STAs may obtain TXOPs using one or both of the channel access mechanisms specified in 9.9. If a TXOP is obtained using the contention-based channel access, it is defined as *EDCA TXOP*. If a TXOP is obtained using the controlled channel access, it is defined as *HCCA TXOP*. If an HCCA TXOP is obtained due to a QoS (+)CF-Poll frame from the HC, the TXOP is defined as a *polled TXOP*.

9.1.3.1 HCF contention-based channel access (EDCA)

The EDCA mechanism provides differentiated, distributed access to the WM for STAs using eight different UPs. The EDCA mechanism defines four access categories (ACs) that provide support for the delivery of traffic with UPs at the STAs. The AC is derived from the UPs as shown in Table 9-1.

For each AC, an enhanced variant of the DCF, called an *enhanced distributed channel access function* (EDCAF), contends for TXOPs using a set of EDCA parameters from the EDCA Parameter Set element or from the default values for the parameters when no EDCA Parameter Set element is received from the AP of the BSS with which the STA is associated, where

a) The parameters used by the EDCAF to control its operation are defined by MIB attribute table dot11QAPEDCATable at the AP and by MIB attribute table dot11EDCATable at the non-AP STA.

b) The minimum specified idle duration time is not the constant value (DIFS) as defined for DCF, but is a distinct value (contained in the MIB attribute table dot11QAPEDCATableAIFSN for an AP and in the MIB table dot11EDCATableAIFSN for a non-AP STA; see 9.9.1) assigned either by a management entity or by an AP.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001475

Table 9-1—UP-to-AC mappings

Priority	UP (Same as 802.1D user priority)	802.1D designation	AC	Designation (informative)
Lowest ↓ Highest	1	BK	AC_BK	Background
	2	—	AC_BK	Background
	0	BE	AC_BE	Best Effort
	3	EE	AC_BE	Best Effort
	4	CL	AC_VI	Video
	5	VI	AC_VI	Video
	6	VO	AC_VO	Voice
	7	NC	AC_VO	Voice

c) The contention window limits aCWmin and aCWmax, from which the random backoff is computed, are not fixed per PHY, as with DCF, but are variable (contained in the MIB attribute tables dot11QAPEDCACWmin and dot11QAPEDCACWmax for an AP and in the MIB attribute tables dot11EDCATableCWmin and dot11EDCATableCWmax for a non-AP STA) and assigned by a management entity or by an AP.

d) Collisions between contending EDCAFs within a STA are resolved within the STA so that the data frames from the higher priority AC receives the TXOP and the data frames from the lower priority colliding AC(s) behave as if there were an external collision on the WM. Note, however, that this collision behavior does not include setting retry bits in the MAC headers of MPDUs at the head of the lower priority ACs, as would be done after a transmission attempt that was unsuccessful due to an actual external collision on the WM.

e) During an EDCA TXOP won by an EDCAF, a STA may initiate multiple frame exchange sequences to transmit MMPDUs and/or MSDUs within the same AC. The duration of this EDCA TXOP is bounded, for an AC, by the value in dot11QAPEDCATXOPLimit MIB variable for an AP and in dot11EDCATableTXOPLimit MIB table for a non-AP STA. A value of 0 for this duration means that the EDCA TXOP is limited to a single MSDU or MMPDU at any rate in the operational set of the BSS.

The QoS AP announces the EDCA parameters in selected Beacon frames and in all Probe Response and (Re)Association Response frames by the inclusion of the EDCA Parameter Set information element. If no such element is received, the STAs shall use the default values for the parameters. The fields following the QoS Info field in the EDCA Parameter Set information element shall be included in all Beacon frames occurring within two or more delivery traffic indication message (DTIM) periods following a change in AC parameters to assure that all STAs are able to receive the updated EDCA parameters. A QoS STA shall update its MIB values of the EDCA parameters within an interval of time equal to one beacon interval after receiving an updated EDCA parameter set. QoS STAs update the MIB attributes and store the EDCA Parameter Set update count value in the QoS Info field. An AP may change the EDCA access parameters by changing the EDCA Parameter Set element in the Beacon and Probe Response frames. However, the AP should change them only rarely. A QoS STA shall use the EDCA Parameter Set Update Count Value subfield in the QoS Capability element of all Beacon frames to determine whether the STA is using the current EDCA Parameter Values. If the EDCA Parameter Set update count value in the QoS Capability element is different from the value that has been stored, the QoS STA shall query the updated EDCA parameter values by sending a Probe Request frame to the AP.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001476

The AP may use a different set of EDCA parameters than it advertises to the STAs in its BSS.

The management frames shall be sent using the access category AC_VO without being restricted by admission control procedures. A QoS STA shall also send management frames using the access category AC_VO before associating with any BSS, even if there is no QoS facility available in that BSS. BlockAckReq and BlockAck control frames shall be sent using the same QoS parameters as the corresponding QoS data frames. PS-Poll control frames shall be sent using the access category AC_BE to reduce the likelihood of collision following a Beacon frame. For the purpose of determining the proper AC for an RTS frame, the RTS frame shall inherit the UP of the data or management frame(s) that are included in the frame exchange sequence where the RTS is the first frame.

The operation rules of HCF contention-based channel access are defined in 9.9.1.

9.1.3.2 HCF controlled channel access (HCCA)

The HCCA mechanism uses a QoS-aware centralized coordinator, called a *hybrid coordinator* (HC), and operates under rules that are different from the PC of the PCF. The HC is collocated with the AP of the BSS and uses the HC's higher priority of access to the WM to initiate frame exchange sequences and to allocate TXOPs to itself and other STAs in order to provide limited-duration controlled access phase (CAP) for contention-free transfer of QoS data.

The HC traffic delivery and TXOP allocation may be scheduled during the CP and any locally generated CFP (generated optionally by the HC) to meet the QoS requirements of a particular TC or TS. TXOP allocations and contention-free transfers of QoS traffic can be based on the HC's BSS-wide knowledge of the amounts of pending traffic belonging to different TS and/or TCs and are subject to BSS-specific QoS policies.

An AP may indicate availability of CF-Polls to non-QoS STAs, thereby providing non-QoS contention-free transfers during the CFP. This provisioning of contention-free transfers during the CFP to non-QoS STAs, however, is not recommended. Implementers are cautioned that QoS STAs are not required to interpret data subtypes that include QoS +CF-Ack in frames not addressed to themselves unless they set the Q-Ack subfield in the QoS Capability information element to 1. QoS STAs are also not required to interpret data subtypes that are non-QoS (+)CF-Poll frames (i.e., data frames with bits 7, 5, and 4 in the Frame Control field set to 0, 1, and 0, respectively); therefore, QoS STAs cannot be treated as CF-Pollable STAs. This requires an AP that provides non-QoS CF-polling to adhere to frame sequence restrictions considerably more complex than, and less efficient than, those specified for either PCF or HCF. In addition, the achievable service quality is likely to be degraded when non-QoS STAs are associated and being polled.

The HCF protects the transmissions during each CAP using the virtual CS mechanism.

A STA may initiate multiple frame exchange sequences during a polled TXOP of sufficient duration to perform more than one such sequence. The use of virtual CS by the HC provides improved protection of the CFP, in addition to the protection provided by having all STAs in the BSA setting their NAVs to dot11CFPMaxDuration at the target beacon transmission time (TBTT) of DTIM Beacon frames.

The operation rules of the HCCA are defined in 9.9.2.

9.1.4 Combined use of DCF, PCF, and HCF

The DCF and a centralized coordination function (either PCF or HCF) are defined so they may operate within the same BSS. When a PC is operating in a BSS, the PCF and DCF access methods alternate, with a CFP followed by a CP. This is described in greater detail in 9.3. When an HC is operating in a BSS, it may generate an alternation of CFP and CP in the same way as a PC, using the DCF access method only during the CP. The HCF access methods (controlled and contention-based) operate sequentially when the channel is in CP.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001477

Sequential operation allows the polled and contention-based access methods to alternate, within intervals as short as the time to transmit a frame exchange sequence, under rules defined in 9.9.

9.1.5 Fragmentation/defragmentation overview

The process of partitioning an MSDU or an MMPDU into smaller MAC level frames, MPDUs, is called *fragmentation*. Fragmentation creates MPDUs smaller than the original MSDU or MMPDU length to increase reliability, by increasing the probability of successful transmission (as defined in 9.1.1) of the MSDU or MMPDU in cases where channel characteristics limit reception reliability for longer frames. STAs may use fragmentation to use the medium efficiently in consideration of the duration available in granted TXOPs, as long as the rules in 9.4 are followed. Fragmentation is accomplished at each immediate transmitter. The process of recombining MPDUs into a single MSDU or MMPDU is defined as *defragmentation*. Defragmentation is accomplished at each immediate recipient.

Only MPDUs with a unicast receiver address shall be fragmented. Broadcast/multicast frames shall not be fragmented even if their length exceeds dot11FragmentationThreshold.

When an individually addressed MSDU is received from the LLC or an individually addressed MMPDU is received from the MLME that would result in a length greater than dot11FragmentationThreshold when the MAC header and FCS are added, the MSDU or MMPDU shall be fragmented. The MSDU or MMPDU is divided into MPDUs. Each fragment is a frame no larger than dot11FragmentationThreshold. It is possible that any fragment may be a frame smaller than dot11FragmentationThreshold. An illustration of fragmentation is shown in Figure 9-2.

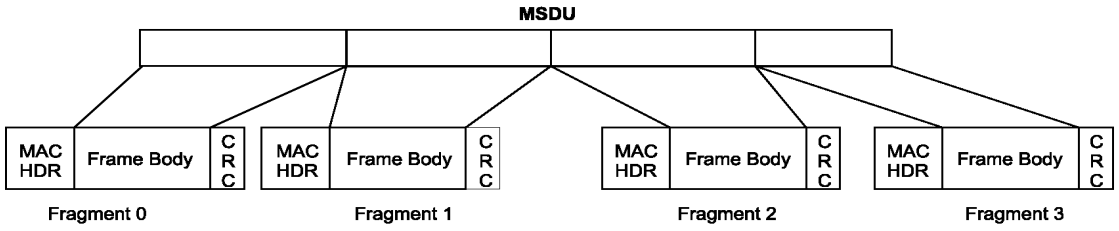

Figure 9-2—Fragmentation

The MPDUs resulting from the fragmentation of an MSDU or MMPDU are sent as independent transmissions, each of which is separately acknowledged. This permits transmission retries to occur per fragment, rather than per MSDU or MMPDU. Unless interrupted due to medium occupancy limitations for a given PHY or TXOP limitations for STA, the fragments of a single MSDU or MMPDU are sent as a burst during the CP, using a single invocation of the DCF or EDCA medium access procedure. The fragments of a single MSDU or MMPDU are either

— Sent during a CFP as individual frames obeying the rules of the PC medium access procedure or

— Sent as a burst in an EDCA or HCCA TXOP.

9.1.6 MAC data service

The MAC data service provides the transport of MSDUs between MAC peer entities as characterized in 6.1.1.

The transmission process is started by receipt of an MA-UNITDATA.request primitive containing an MSDU and the associated parameters. This may cause one or more data MPDUs containing the MSDU to be transmitted following fragmentation and security encapsulation, as appropriate.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001478

The MA-UNITDATA.indication primitive is generated in response to one or more received data MPDUs containing an MSDU following validation, address filtering, decryption, decapsulation, and defragmentation, as appropriate.

In a QoS STA, the TID parameter of the MA-UNITDATA.request results in a TID being specified for the transmitted MSDU. This TID associates the MSDU with the AC or TS queue for the indicated traffic.

9.2 DCF

The basic medium access protocol is a DCF that allows for automatic medium sharing between compatible PHYs through the use of CSMA/CA and a random backoff time following a busy medium condition. In addition, all individually addressed traffic uses immediate positive acknowledgment (ACK frame) where retransmission is scheduled by the sender if no ACK is received.

The CSMA/CA protocol is designed to reduce the collision probability between multiple STAs accessing a medium, at the point where collisions would most likely occur. Just after the medium becomes idle following a busy medium (as indicated by the CS function) is when the highest probability of a collision exists. This is because multiple STAs could have been waiting for the medium to become available again. This is the situation that necessitates a random backoff procedure to resolve medium contention conflicts.

CS shall be performed both through physical and virtual mechanisms.

The virtual CS mechanism is achieved by distributing reservation information announcing the impending use of the medium. The exchange of RTS and CTS frames prior to the actual data frame is one means of distribution of this medium reservation information. The RTS and CTS frames contain a Duration field that defines the period of time that the medium is to be reserved to transmit the actual data frame and the returning ACK frame. All STAs within the reception range of either the originating STA (which transmits the RTS) or the destination STA (which transmits the CTS) shall learn of the medium reservation. Thus, a STA can be unable to receive from the originating STA and yet still know about the impending use of the medium to transmit a data frame.

Another means of distributing the medium reservation information is the Duration/ID field in individually addressed frames. This field gives the time that the medium is reserved, either to the end of the immediately following ACK, or in the case of a fragment sequence, to the end of the ACK following the next fragment.

The RTS/CTS exchange also performs both a type of fast collision inference and a transmission path check. If the return CTS is not detected by the STA originating the RTS, the originating STA may repeat the process (after observing the other medium-use rules) more quickly than if the long data frame had been transmitted and a return ACK frame had not been detected.

Another advantage of the RTS/CTS mechanism occurs where multiple BSSs utilizing the same channel overlap. The medium reservation mechanism works across the BSA boundaries. The RTS/CTS mechanism may also improve operation in a typical situation where all STAs can receive from the AP, but may not be able to receive from all other STAs in the BSA.

The RTS/CTS mechanism cannot be used for MPDUs with broadcast and multicast immediate destination because there are multiple recipients for the RTS, and thus potentially multiple concurrent senders of the CTS in response. The RTS/CTS mechanism need not be used for every data frame transmission. Because the additional RTS and CTS frames add overhead inefficiency, the mechanism is not always justified, especially for short data frames.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001479

The use of the RTS/CTS mechanism is under control of the dot11RTSThreshold attribute. This attribute may be set on a per-STA basis. This mechanism allows STAs to be configured to use RTS/CTS either always, never, or only on frames longer than a specified length.

A STA configured not to initiate the RTS/CTS mechanism shall still update its virtual CS mechanism with the duration information contained in a received RTS or CTS frame, and shall always respond to an RTS addressed to it with a CTS if permitted by medium access rules.

The medium access protocol allows for STAs to support different sets of data rates. All STAs shall be able to receive and transmit at all the data rates in the BSSBasicRateSet parameter of the MLME-START.request or BSSBasicRateSet parameter of the BSSDescription representing the SelectedBSS parameter of the MLME-JOIN.request. To support the proper operation of the RTS/CTS and the virtual CS mechanism, all STAs shall be able to detect the RTS and CTS frames.

Data frames sent under the DCF shall use the frame type Data and subtype Data or Null Function. STAs receiving Data type frames shall not indicate a data frame to LLC when the subtype is Null Function, but shall indicate a data frame to LLC when the subtype is Data, even if the frame body contains zero octets.

9.2.1 CS mechanism

Physical and virtual CS functions are used to determine the state of the medium. When either function indicates a busy medium, the medium shall be considered busy; otherwise, it shall be considered idle.

A physical CS mechanism shall be provided by the PHY. See Clause 12 for how this information is conveyed to the MAC. The details of physical CS are provided in the individual PHY specifications.

A virtual CS mechanism shall be provided by the MAC. This mechanism is referred to as the NAV. The NAV maintains a prediction of future traffic on the medium based on duration information that is announced in RTS/CTS frames prior to the actual exchange of data. The duration information is also available in the MAC headers of all frames sent during the CP other than PS-Poll Control frames. The mechanism for setting the NAV using RTS/CTS in the DCF is described in 9.2.5.4, use of the NAV in PCF is described in 9.3.2.2, and use of the NAV in HCF is described in 9.9.2.2.1. Additional details regarding NAV usage and update appear in 9.2.5.6, 9.2.11, and 9.13.

The CS mechanism combines the NAV state and the STA's transmitter status with physical CS to determine the busy/idle state of the medium. The NAV may be thought of as a counter, which counts down to zero at a uniform rate. When the counter is zero, the virtual CS indication is that the medium is idle; when nonzero, the indication is busy. The medium shall be determined to be busy when the STA is transmitting.

9.2.2 MAC-Level acknowledgments

The reception of some frames, as described in 9.2.8, 9.3.3.4, and 9.12, requires the receiving STA to respond with an acknowledgment, generally an ACK frame, if the FCS of the received frame is correct. This technique is known as positive acknowledgment.

Lack of reception of an expected ACK frame indicates to the STA initiating the frame exchange that an error has occurred. Note, however, that the destination STA may have received the frame correctly, and that the error may have occurred in the transfer or reception of the ACK frame. To the initiator of the frame exchange, this condition is indistinguishable from an error occurring in the initial frame.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001480

9.2.3 IFS

The time interval between frames is called the *IFS*. A STA shall determine that the medium is idle through the use of the CS function for the interval specified. Five different IFSs are defined to provide priority levels for access to the wireless media. Figure 9-3 shows some of these relationships.

a) SIFS short interframe space

b) PIFS PCF interframe space

c) DIFS DCF interframe space

d) AIFS arbitration interframe space (used by the QoS facility)

e) EIFS extended interframe space

The different IFSs shall be independent of the STA bit rate. The IFS timings are defined as time gaps on the medium, and the IFS timings except AIFS are fixed for each PHY (even in multirate-capable PHYs). The IFS values are determined from attributes specified by the PHY.

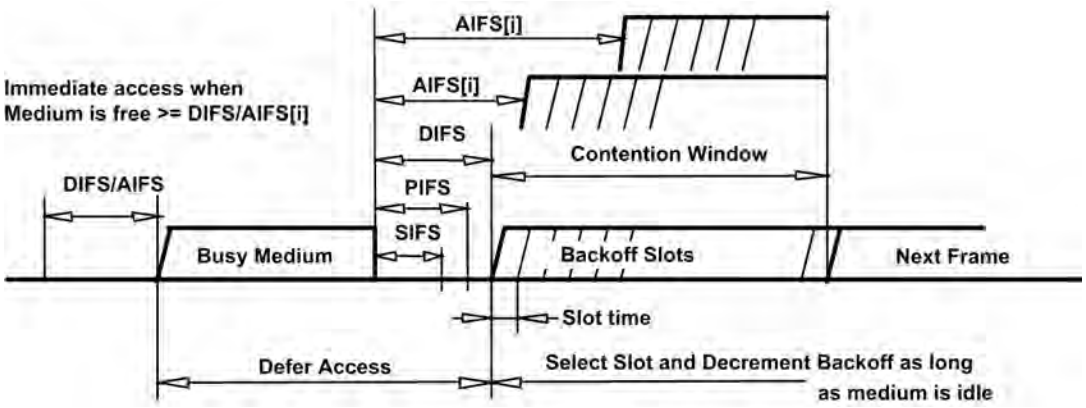

Figure 9-3—Some IFS relationships

9.2.3.1 SIFS

The SIFS shall be used prior to transmission of an ACK frame, a CTS frame, the second or subsequent MPDU of a fragment burst, and by a STA responding to any polling by the PCF. The SIFS may also be used by a PC for any types of frames during the CFP (see 9.3). The SIFS is the time from the end of the last symbol of the previous frame to the beginning of the first symbol of the preamble of the subsequent frame as seen at the air interface. The valid cases where the SIFS may or shall be used are listed in the frame exchange sequences in 9.12.

The SIFS timing shall be achieved when the transmission of the subsequent frame is started at the TxSIFS Slot boundary as specified in 9.2.10. An IEEE 802.11 implementation shall not allow the space between frames that are defined to be separated by a SIFS time, as measured on the medium, to vary from the nominal SIFS value by more than ±10% of aSlotTime for the PHY in use.

SIFS is the shortest of the IFSs. SIFS shall be used when STAs have seized the medium and need to keep it for the duration of the frame exchange sequence to be performed. Using the smallest gap between transmissions within the frame exchange sequence prevents other STAs, which are required to wait for the medium to be idle for a longer gap, from attempting to use the medium, thus giving priority to completion of the frame exchange sequence in progress.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001481

9.2.3.2 PIFS

The PIFS shall be used only by STAs operating under the PCF to gain priority access to the medium at the start of the CFP or by a STA to transmit a Channel Switch Announcement frame. A STA using the PCF shall be allowed to transmit CF traffic after its CS mechanism (see 9.2.1) determines that the medium is idle at the TxPIFS slot boundary as defined in 9.2.10. A STA may also transmit a Channel Switch Announcement frame after its CS mechanism (see 9.2.1) determines that the medium is idle at the TxPIFS slot boundary. The use of the PIFS by STAs operating under the PCF is described in 9.3. The use of PIFS by STAs transmitting a Channel Switch Announcement frame is described in 11.9.

9.2.3.3 DIFS

The DIFS shall be used by STAs operating under the DCF to transmit data frames (MPDUs) and management frames (MMPDUs). A STA using the DCF shall be allowed to transmit if its CS mechanism (see 9.2.1) determines that the medium is idle at the TxDIFS slot boundary as defined in 9.2.10 after a correctly received frame, and its backoff time has expired. A correctly received frame is one where the PHY-RXEND.indication does not indicate an error and the FCS indicates the frame is error free.

9.2.3.4 AIFS

The AIFS shall be used by QoS STAs to transmit all data frames (MPDUs), all management frames (MMPDUs), and the following control frames: PS-Poll, RTS, CTS (when not transmitted as a response to the RTS), BlockAckReq, and BlockAck (when not transmitted as a response to the BlockAckReq). A STA using the EDCA shall obtain a TXOP for an AC if the STA's CS mechanism (see 9.2.1) determines that the medium is idle at the AIFS[AC] slot boundary (see 9.9.1.3), after a correctly received frame, and the backoff time for that AC has expired.

A STA using the EDCA shall not transmit within an EIFS-DIFS+AIFS[AC] plus any backoff time after that STA determines that the medium is idle following reception of a frame for which the PHYRXEND.indication primitive reported an error or a frame for which the MAC FCS value was not correct, unless a subsequent reception of an error-free frame resynchronizes the STA. This resynchronization allows the STA to transmit using the AIFS[AC] following that subsequent frame, provided that the backoff time for that AC has expired.

A non-AP QoS STA computes the time periods for each AIFS[AC] from the dot11EDCATableAIFSN attributes in the MIB. QoS STAs update their dot11EDCATableAIFSN values using information in the most recent EDCA Parameter Set element of Beacon frames received from the AP of the BSS (see 7.3.2.28). A QoS AP computes the time periods for each AIFS[AC] from the dot11QAPEDCATableAIFSN attributes in its MIB.

9.2.3.5 EIFS

A STA's DCF shall use EIFS before transmission, when it determines that the medium is idle following reception of a frame for which the PHY-RXEND.indication primitive contained an error or a frame for which the MAC FCS value was not correct. Similarly, a STA's EDCA mechanism under HCF shall use the EIFS-DIFS+AIFS[AC] interval. The duration of an EIFS is defined in 9.2.10. The EIFS or EIFS-DIFS+AIFS[AC] interval shall begin following indication by the PHY that the medium is idle after detection of the erroneous frame, without regard to the virtual CS mechanism. The STA shall not begin a transmission until the expiration of the later of the NAV and EIFS or EIFS-DIFS+AIFS[AC]. The EIFS and EIFS-DIFS+AIFS[AC] are defined to provide enough time for another STA to acknowledge what was, to this STA, an incorrectly received frame before this STA commences transmission. Reception of an error-free frame during the EIFS or EIFS-DIFS+AIFS[AC] resynchronizes the STA to the actual busy/idle state of the medium, so the EIFS or EIFS-DIFS+AIFS[AC] is terminated and normal medium access (using DIFS or AIFS as appropriate and, if necessary, backoff) continues following reception of that frame. At the expiration or termination of the EIFS or EIFS-DIFS+AIFS[AC], the STA reverts to the NAV and physical CS to control access to the medium.

Exhibit 1014
Page 001482

9.2.4 Random backoff time

A STA desiring to initiate transfer of data MPDUs and/or MMPDUs shall invoke the CS mechanism (see 9.2.1) to determine the busy/idle state of the medium. If the medium is busy, the STA shall defer until the medium is determined to be idle without interruption for a period of time equal to DIFS when the last frame detected on the medium was received correctly, or after the medium is determined to be idle without interruption for a period of time equal to EIFS when the last frame detected on the medium was not received correctly. After this DIFS or EIFS medium idle time, the STA shall then generate a random backoff period for an additional deferral time before transmitting, unless the backoff timer already contains a nonzero value, in which case the selection of a random number is not needed and not performed. This process minimizes collisions during contention between multiple STAs that have been deferring to the same event.

Backoff Time = Random() × aSlotTime

where

Random() = Pseudo-random integer drawn from a uniform distribution over the interval [0,CW], where CW is an integer within the range of values of the PHY characteristics aCWmin and aCWmax, aCWmin ≤ CW ≤ aCWmax. It is important that designers recognize the need for statistical independence among the random number streams among STAs.

aSlotTime = The value of the correspondingly named PHY characteristic.

The contention window (CW) parameter shall take an initial value of aCWmin. Every STA shall maintain a STA short retry count (SSRC) as well as a STA long retry count (SLRC), both of which shall take an initial value of zero. The SSRC shall be incremented when any short retry count (SRC) associated with any MPDU of type Data is incremented. The SLRC shall be incremented when any long retry count (LRC) associated with any MPDU of type Data is incremented. The CW shall take the next value in the series every time an unsuccessful attempt to transmit an MPDU causes either STA retry counter to increment, until the CW reaches the value of aCWmax. A retry is defined as the entire sequence of frames sent, separated by SIFS intervals, in an attempt to deliver an MPDU, as described in 9.12. Once it reaches aCWmax, the CW shall remain at the value of aCWmax until the CW is reset. This improves the stability of the access protocol under high-load conditions. See Figure 9-4.

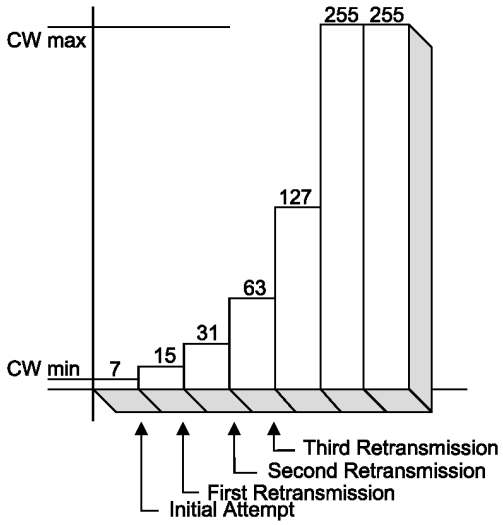

Figure 9-4—Example of exponential increase of CW

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001483

The CW shall be reset to aCWmin after every successful attempt to transmit an MPDU or MMPDU, when SLRC reaches dot11LongRetryLimit, or when SSRC reaches dot11ShortRetryLimit. The SSRC shall be reset to 0 when a CTS frame is received in response to an RTS frame, when an ACK frame is received in response to an MPDU or MMPDU transmission, or when a frame with a group address in the Address1 field is transmitted. The SLRC shall be reset to 0 when an ACK frame is received in response to transmission of an MPDU or MMPDU of length greater than dot11RTSThreshold, or when a frame with a group address in the Address1 field is transmitted.

The set of CW values shall be sequentially ascending integer powers of 2, minus 1, beginning with a PHY-specific aCWmin value, and continuing up to and including a PHY-specific aCWmax value.

9.2.5 DCF access procedure

The CSMA/CA access method is the foundation of the DCF. The operational rules vary slightly between the DCF and the PCF.

9.2.5.1 Basic access

Basic access refers to the core mechanism a STA uses to determine whether it may transmit.

In general, a STA may transmit a pending MPDU when it is operating under the DCF access method, either in the absence of a PC, or in the CP of the PCF access method, when the STA determines that the medium is idle for greater than or equal to a DIFS period, or an EIFS period if the immediately preceding medium-busy event was caused by detection of a frame that was not received at this STA with a correct MAC FCS value. If, under these conditions, the medium is determined by the CS mechanism to be busy when a STA desires to initiate the initial frame of one of the frame exchanges described in 9.12, exclusive of the CF period, the random backoff procedure described in 9.2.5.2 shall be followed. There are conditions, specified in 9.2.5.2 and 9.2.5.5, where the random backoff procedure shall be followed even for the first attempt to initiate a frame exchange sequence.

In a STA having an FH PHY, control of the channel is lost at the dwell time boundary and the STA shall have to contend for the channel after that dwell boundary. It is required that STAs having an FH PHY complete transmission of the entire MPDU and associated acknowledgment (if required) before the dwell time boundary. If, when transmitting or retransmitting an MPDU, there is not enough time remaining in the dwell to allow transmission of the MPDU plus the acknowledgment (if required), the STA shall defer the transmission by selecting a random backoff time, using the present CW (without advancing to the next value in the series). The short retry counter and long retry counter for the MSDU are not affected.

The basic access mechanism is illustrated in Figure 9-5.

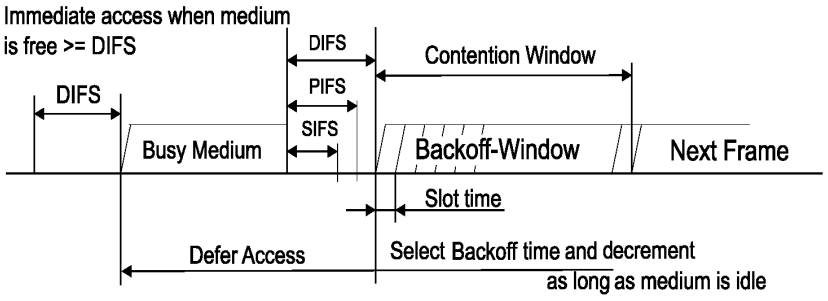

Figure 9-5—Basic access method

Exhibit 1014
Page 001484

9.2.5.2 Backoff procedure for DCF

This subclause describes backoff procedure that is to be invoked when DCF is used. For the backoff procedure when EDCA is used, see 9.9.1.5.

The backoff procedure shall be invoked for a STA to transfer a frame when finding the medium busy as indicated by either the physical or virtual CS mechanism (see Figure 9-6). The backoff procedure shall also be invoked when a transmitting STA infers a failed transmission as defined in 9.2.5.7 or 9.2.8.

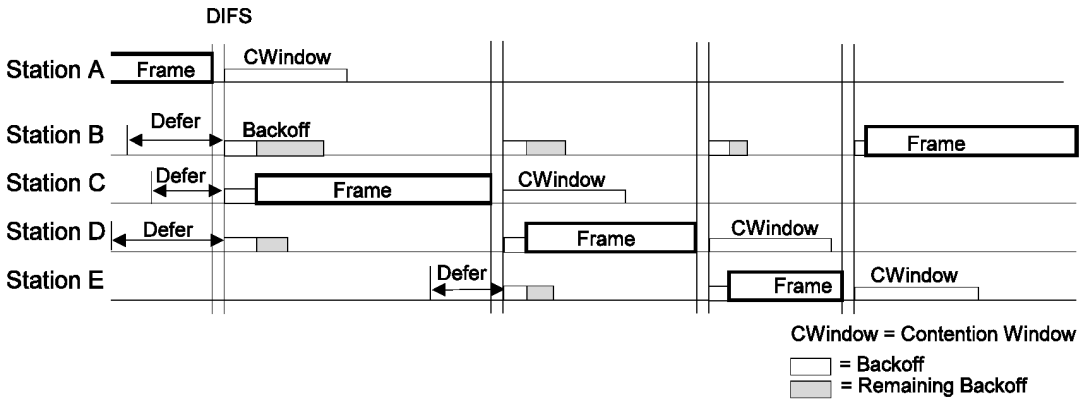

Figure 9-6—Backoff procedure

To begin the backoff procedure, the STA shall set its Backoff Timer to a random backoff time using the equation in 9.2.4. All backoff slots occur following a DIFS period during which the medium is determined to be idle for the duration of the DIFS period, or following an EIFS period during which the medium is determined to be idle for the duration of the EIFS period, as appropriate (see 9.2.3).

A STA performing the backoff procedure shall use the CS mechanism (see 9.2.1) to determine whether there is activity during each backoff slot. If no medium activity is indicated for the duration of a particular backoff slot, then the backoff procedure shall decrement its backoff time by aSlotTime.

If the medium is determined to be busy at any time during a backoff slot, then the backoff procedure is suspended; that is, the backoff timer shall not decrement for that slot. The medium shall be determined to be idle for the duration of a DIFS period or EIFS, as appropriate (see 9.2.3), before the backoff procedure is allowed to resume. Transmission shall commence when the Backoff Timer reaches zero.

A backoff procedure shall be performed immediately after the end of every transmission with the More Fragments bit set to 0 of an MPDU of type Data, Management, or Control with subtype PS-Poll, even if no additional transmissions are currently queued. In the case of successful acknowledged transmissions, this backoff procedure shall begin at the end of the received ACK frame. In the case of unsuccessful transmissions requiring acknowledgment, this backoff procedure shall begin at the end of the ACKTimeout interval (as defined in 9.2.8). An unsuccessful transmission is one where an ACK frame is not received from the STA addressed by the RA field of the transmitted frame and the value of the RA field is an individual address. If the transmission is successful, the CW value reverts to aCWmin before the random backoff interval is chosen, and the SSRC and/or SLRC are updated as described in 9.2.4. This assures that transmitted frames from a STA are always separated by at least one backoff interval.

The effect of this procedure is that when multiple STAs are deferring and go into random backoff, then the STA selecting the smallest backoff time using the random function will win the contention (assuming all of the contending STAs detect the same instances of WM activity at their respective receivers).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001485

In an IBSS, the backoff time for a pending nonbeacon or non-ATIM transmission shall not decrement in the period from the TBTT until the expiration of the ATIM window, and the backoff time for a pending ATIM management frame shall decrement only within the ATIM window. (See Clause 11.) Within an IBSS, a separate backoff interval shall be generated to precede the transmission of a Beacon frame, as described in 11.1.2.2.

9.2.5.3 Recovery procedures and retransmit limits

Error recovery is always the responsibility of the STA that initiates a frame exchange sequence, as defined in 9.12. Many circumstances may cause an error to occur that requires recovery. For example, the CTS frame may not be returned after an RTS frame is transmitted. This may happen due to a collision with another transmission, due to interference in the channel during the RTS or CTS frame, or because the STA receiving the RTS frame has an active virtual CS condition (indicating a busy medium time period).

Error recovery shall be attempted by retrying transmissions for frame exchange sequences that the initiating STA infers have failed. Retries shall continue, for each failing frame exchange sequence, until the transmission is successful, or until the relevant retry limit is reached, whichever occurs first. STAs shall maintain a SRC and a LRC for each MSDU or MMPDU awaiting transmission. These counts are incremented and reset independently of each other.

After an RTS frame is transmitted, the STA shall perform the CTS procedure, as defined in 9.2.5.7. If the RTS transmission fails, the SRC for the MSDU or MMPDU and the SSRC are incremented. This process shall continue until the number of attempts to transmit that MSDU or MMPDU reaches dot11ShortRetryLimit.

After transmitting a frame that requires acknowledgment, the STA shall perform the ACK procedure, as defined in 9.2.8. The SRC for an MPDU of type Data or MMPDU and the SSRC shall be incremented every time transmission of a MAC frame of length less than or equal to dot11RTSThreshold fails for that MPDU of type Data or MMPDU. This SRC and the SSRC shall be reset when a MAC frame of length less than or equal to dot11RTSThreshold succeeds for that MPDU of type Data or MMPDU. The LRC for an MPDU of type Data or MMPDU and the SLRC shall be incremented every time transmission of a MAC frame of length greater than dot11RTSThreshold fails for that MPDU of type Data or MMPDU. This LRC and the SLRC shall be reset when a MAC frame of length greater than dot11RTSThreshold succeeds for that MPDU of type Data or MMPDU. All retransmission attempts for an MPDU of type Data or MMPDU that has failed the ACK procedure one or more times shall be made with the Retry field set to 1 in the Data or Management type frame.

Retries for failed transmission attempts shall continue until the SRC for the MPDU of type Data or MMPDU is equal to dot11ShortRetryLimit or until the LRC for the MPDU of type Data or MMPDU is equal to dot11LongRetryLimit. When either of these limits is reached, retry attempts shall cease, and the MPDU of type Data (and any MSDU of which it is a part) or MMPDU shall be discarded.

A STA in PS mode, in an ESS, initiates a frame exchange sequence by transmitting a PS-Poll frame to request data from an AP. In the event that neither an ACK frame nor a data frame is received from the AP in response to a PS-Poll frame, then the STA shall retry the sequence, by transmitting another PS-Poll frame, at its convenience. If the AP sends a data frame in response to a PS-Poll frame, but fails to receive the ACK frame acknowledging this data frame, the next PS-Poll frame from the same STA may cause a retransmission of the last MSDU. This duplicate MSDU shall be filtered at the receiving STA using the normal duplicate frame filtering mechanism. If the AP responds to a PS-Poll by transmitting an ACK frame, then responsibility for the data frame delivery error recovery shifts to the AP because the data are transferred in a subsequent frame exchange sequence, which is initiated by the AP. The AP shall attempt to deliver one MSDU to the STA that transmitted the PS-Poll, using any frame exchange sequence valid for an individually addressed MSDU. If the PS STA that transmitted the PS-Poll returns to Doze state after transmitting the ACK frame in response to successful receipt of this MSDU, but the AP fails to receive this ACK frame, the AP will retry transmission of this MSDU until the relevant retry limit is reached. See Clause 11 for details on filtering of extra PS-Poll frames.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001486

9.2.5.4 Setting and resetting the NAV

STAs receiving a valid frame shall update their NAV with the information received in the Duration field for all frames where the new NAV value is greater than the current NAV value, except the NAV shall not be updated where the RA is equal to the receiving STA's MAC address. Upon receipt of a PS-Poll frame, a STA shall update its NAV settings as appropriate under the data rate selection rules using a duration value equal to the time, in microseconds, required to transmit one ACK frame plus one SIFS interval, but only when the new NAV value is greater than the current NAV value. If the calculated duration includes a fractional microsecond, that value is rounded up the next higher integer. Various additional conditions may set or reset the NAV, as described in 9.3.2.2. When the NAV is reset, a PHY-CCARESET.request shall be issued.

Figure 9-7 indicates the NAV for STAs that may receive the RTS frame, while other STAs may only receive the CTS frame, resulting in the lower NAV bar as shown (with the exception of the STA to which the RTS was addressed).

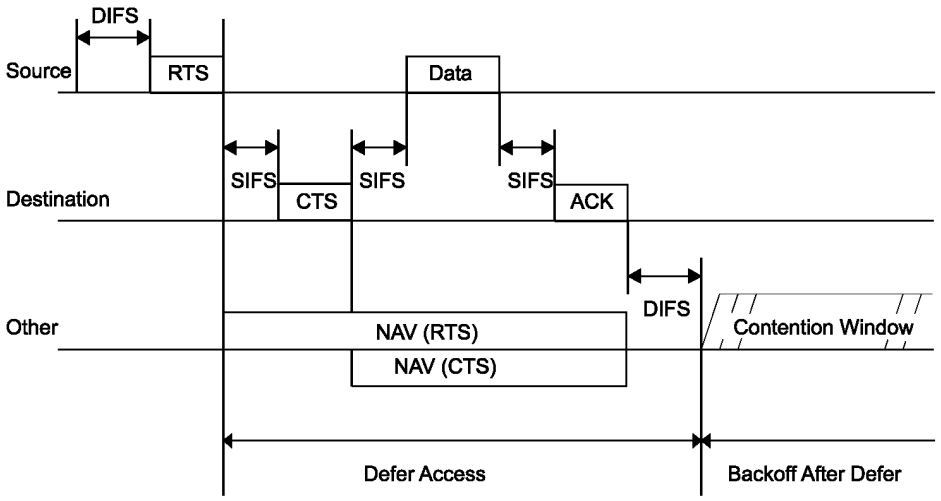

Figure 9-7—RTS/CTS/data/ACK and NAV setting

A STA that used information from an RTS frame as the most recent basis to update its NAV setting is permitted to reset its NAV if no PHY-RXSTART.indication is detected from the PHY during a period with a duration of (2 × aSIFSTime) + (CTS_Time) + aPHY-RX-START-Delay + (2 × aSlotTime) starting at the PHY-RXEND.indication corresponding to the detection of the RTS frame. The "CTS_Time" shall be calculated using the length of the CTS frame and the data rate at which the RTS frame used for the most recent NAV update was received.

9.2.5.5 Control of the channel

The SIFS is used to provide an efficient MSDU delivery mechanism. Once the STA has contended for the channel, that STA shall continue to send fragments until either all fragments of a single MSDU or MMPDU have been sent, an acknowledgment is not received, or the STA is restricted from sending any additional fragments due to a dwell time boundary. Should the sending of the fragments be interrupted due to one of these reasons, when the next opportunity for transmission occurs the STA shall resume transmission. The algorithm by which the STA decides which of the outstanding MSDUs shall next be attempted after an unsuccessful transmission (as defined in 9.2.5.2) attempt is beyond the scope of this standard, but any such algorithm shall comply with the restrictions listed in 9.7.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001487

Figure 9-8 illustrates the transmission of a multiple-fragment MSDU using the SIFS.

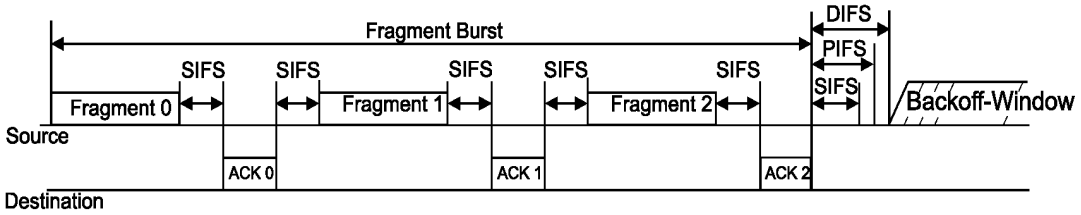

Figure 9-8—Transmission of a multiple-fragment MSDU using SIFS

When the source STA transmits a fragment, it shall release the channel, then immediately monitor the channel for an acknowledgment as described in 9.2.8.

When the destination STA has finished sending the acknowledgment, the SIFS following the acknowledgment shall be reserved for the source STA to continue (if necessary) with another fragment. The STA sending the acknowledgment shall not transmit on the channel immediately following the acknowledgment.

The process of sending multiple fragments after contending for the channel is defined as a fragment burst.

If the source STA receives an acknowledgment but there is not enough time to transmit the next fragment and receive an acknowledgment due to an impending dwell boundary, the source STA shall contend for the channel at the beginning of the next dwell time.

If the source STA does not receive an acknowledgment frame, it shall attempt to retransmit the failed MPDU or another eligible MPDU, as defined in 9.7, after performing the backoff procedure and the contention process.

After a STA contends for the channel to retransmit a fragment of an MSDU, it shall start with the last fragment that was not acknowledged. The destination STA shall receive the fragments in order (because the source sends them in order and they are individually acknowledged). It is possible, however, that the destination STA may receive duplicate fragments. It shall be the responsibility of the receiving STA to detect and discard duplicate fragments.

A STA shall transmit after the SIFS only under the following conditions during a fragment burst:

— The STA has just received a fragment that requires acknowledgment.

— The source STA has received an acknowledgment for a previous fragment, has more fragment(s) for the same MSDU to transmit, and there is enough time before the next dwell boundary to send the next fragment and receive its acknowledgment.

The following rules shall also apply:

— When a STA has transmitted a frame other than an initial or intermediate fragment, that STA shall not transmit on the channel following the acknowledgment for that frame, without performing the backoff procedure.

— When an MSDU has been successfully delivered or all retransmission attempts have been exhausted, and the STA has a subsequent MSDU to transmit, then that STA shall perform a backoff procedure.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001488

9.2.5.6 RTS/CTS usage with fragmentation

The following is a description of using RTS/CTS for a fragmented MSDU or MMPDU. The RTS/CTS frames define the duration of the following frame and acknowledgment. The Duration/ID field in the data and ACK frames specifies the total duration of the next fragment and acknowledgment. This is illustrated in Figure 9-9.

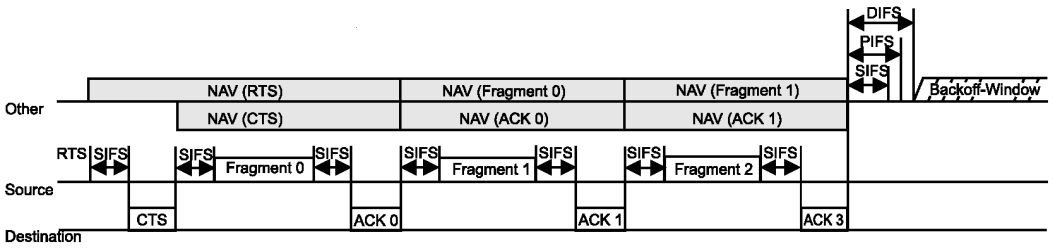

Figure 9-9—RTS/CTS with fragmented MSDU

Each frame contains information that defines the duration of the next transmission. The duration information from RTS frames shall be used to update the NAV to indicate busy until the end of ACK 0. The duration information from the CTS frame shall also be used to update the NAV to indicate busy until the end of ACK 0. Both Fragment 0 and ACK 0 shall contain duration information to update the NAV to indicate busy until the end of ACK 1. This shall be done by using the Duration/ID field in the Data and ACK frames. This shall continue until the last fragment, which shall have a duration of one ACK time plus one SIFS time, and its ACK, which shall have its Duration/ID field set to 0. Each fragment and ACK acts as a virtual RTS and CTS; therefore no further RTS/CTS frames need to be generated after the RTS/CTS that began the frame exchange sequence even though subsequent fragments may be larger than dot11RTSThreshold. At STAs using an FH PHY, when there is insufficient time before the next dwell boundary to transmit the subsequent fragment, the STA initiating the frame exchange sequence may set the Duration/ID field in the last data or management frame to be transmitted before the dwell boundary to the duration of one ACK time plus one SIFS time.

In the case where an acknowledgment is sent but not received by the source STA, STAs that heard the fragment, or ACK, will mark the channel busy for the next frame exchange due to the NAV having been updated from these frames. This is the worst-case situation, and it is shown in Figure 9-10. If an acknowledgment is not sent by the destination STA, STAs that can only hear the destination STA will not update their NAV and may attempt to access the channel when their NAV updated from the previously received frame reaches zero. All STAs that hear the source will be free to access the channel after their NAV updated from the transmitted fragment has expired.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001489

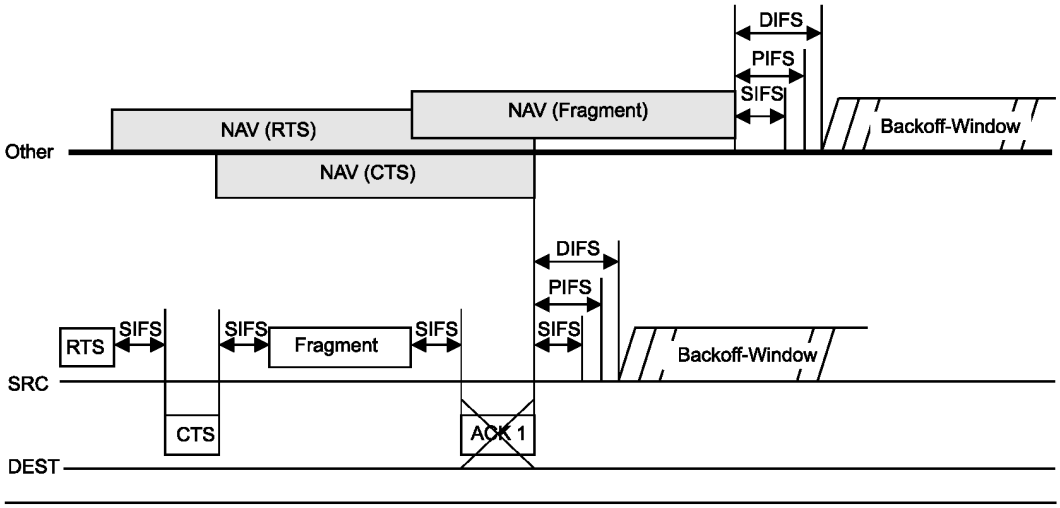

Figure 9-10—RTS/CTS with transmitter priority and missed acknowledgment

9.2.5.7 CTS procedure

A STA that is addressed by an RTS frame shall transmit a CTS frame after a SIFS period if the NAV at the STA receiving the RTS frame indicates that the medium is idle. If the NAV at the STA receiving the RTS indicates the medium is not idle, that STA shall not respond to the RTS frame. The RA field of the CTS frame shall be the value obtained from the TA field of the RTS frame to which this CTS frame is a response. The Duration field in the CTS frame shall be the duration field from the received RTS frame, adjusted by subtraction of aSIFSTime and the number of microseconds required to transmit the CTS frame at a data rate determined by the rules in 9.6.

After transmitting an RTS frame, the STA shall wait for a CTSTimeout interval, with a value of aSIFSTime + aSlotTime + aPHY-RX-START-Delay, starting at the PHY-TXEND.confirm. If a PHY-RXSTART.indication does not occur during the CTSTimeout interval, the STA shall conclude that the transmission of the RTS has failed, and this STA shall invoke its backoff procedure upon expiration of the CTSTimeout interval. If a PHY-RXSTART.indication does occur during the CTSTimeout interval, the STA shall wait for the corresponding PHY-RXEND.indication to determine whether the RTS transmission was successful. The recognition of a valid CTS frame sent by the recipient of the RTS frame, corresponding to this PHY-RXEND.indication, shall be interpreted as successful response, permitting the frame sequence to continue (see 9.12). The recognition of anything else, including any other valid frame, shall be interpreted as failure of the RTS transmission. In this instance, the STA shall invoke its backoff procedure at the PHY-RXEND.indication and may process the received frame.

9.2.6 Individually addressed MPDU transfer procedure

A STA shall use an RTS/CTS exchange for individually addressed frames only when the length of the MPDU is greater than the length threshold indicated by the dot11RTSThreshold attribute.

The dot11RTSThreshold attribute shall be a managed object within the MAC MIB, and its value may be set and retrieved by the MLME. The value 0 shall be used to indicate that all MPDUs shall be delivered with the use of RTS/CTS. Values of dot11RTSThreshold larger than the maximum MSDU length shall indicate that all MPDUs shall be delivered without RTS/CTS exchanges.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001490

When an RTS/CTS exchange is used, the asynchronous data frame shall be transmitted starting one SIFS period after the end of the CTS frame. No regard shall be given to the busy or idle status of the medium when transmitting this data frame.

When an RTS/CTS exchange is not used, the asynchronous data frame shall be transmitted following the success of the basic access procedure. With or without the use of the RTS/CTS exchange procedure, the STA that is the destination of an asynchronous data frame shall follow the ACK procedure.

9.2.7 Broadcast and multicast MPDU transfer procedure

In the absence of a PCF, when broadcast or multicast MPDUs are transferred from a STA with the To DS field clear, only the basic access procedure shall be used. Regardless of the length of the frame, no RTS/CTS exchange shall be used. In addition, no ACK shall be transmitted by any of the recipients of the frame. Any broadcast or multicast MPDUs transferred from a STA with a To DS field set shall, in addition to conforming to the basic access procedure of CSMA/CA, obey the rules for RTS/CTS exchange and the ACK procedure because the MPDU is directed to the AP. The broadcast/multicast message shall be distributed into the BSS. The STA originating the message shall receive the message as a broadcast/multicast message. Therefore, all STAs shall filter out broadcast/multicast messages that contain their address as the source address. Broadcast and multicast MSDUs shall be propagated throughout the ESS.

There is no MAC-level recovery on broadcast or multicast frames, except for those frames sent with the To DS field set. As a result, the reliability of this traffic is reduced, relative to the reliability of individually addressed traffic, due to the increased probability of lost frames from interference, collisions, or time-varying channel properties.

9.2.8 ACK procedure

An ACK frame shall be generated as shown in the frame exchange sequences listed in 9.12.

Upon successful reception of a frame of a type that requires acknowledgment with the To DS field set, an AP shall generate an ACK frame. An ACK frame shall be transmitted by the destination STA that is not an AP, when it successfully receives a unicast frame of a type that requires acknowledgment, but not if it receives a broadcast or multicast frame of such type. After a successful reception of a frame requiring acknowledgment, transmission of the ACK frame shall commence after a SIFS period, without regard to the busy/idle state of the medium. (See Figure 9-11.)

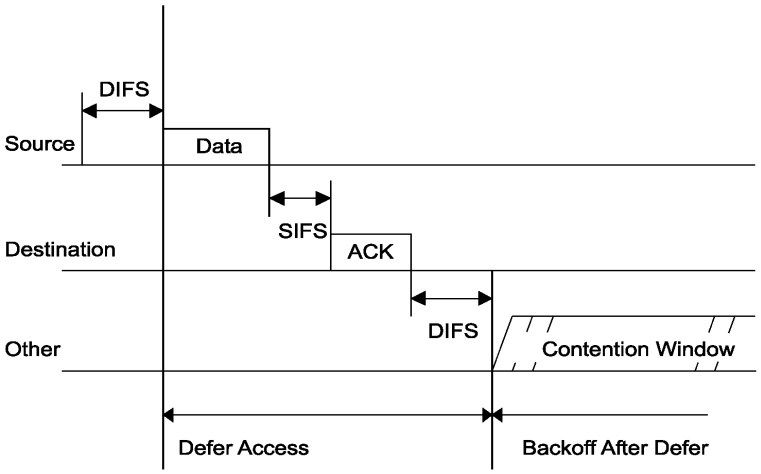

Figure 9-11—Individually addressed data/ACK MPDU

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001491

After transmitting an MPDU that requires an ACK frame as a response (see 9.12), the STA shall wait for an ACKTimeout interval, with a value of aSIFSTime + aSlotTime + aPHY-RX-START-Delay, starting at the PHY-TXEND.confirm. If a PHY-RXSTART.indication does not occur during the ACKTimeout interval, the STA concludes that the transmission of the MPDU has failed, and this STA shall invoke its backoff procedure upon expiration of the ACKTimeout interval. If a PHY-RXSTART.indication does occur during the ACKTimeout interval, the STA shall wait for the corresponding PHY-RXEND.indication to determine whether the MPDU transmission was successful. The recognition of a valid ACK frame sent by the recipient of the MPDU requiring acknowledgment, corresponding to this PHY-RXEND.indication, shall be interpreted as successful acknowledgment, permitting the frame sequence to continue, or to end without retries, as appropriate for the particular frame sequence in progress. The recognition of anything else, including any other valid frame, shall be interpreted as failure of the MPDU transmission. In this instance, the STA shall invoke its backoff procedure at the PHY-RXEND.indication and may process the received frame. The sole exception is that recognition of a valid data frame sent by the recipient of a PS-Poll frame shall also be accepted as successful acknowledgment of the PS-Poll frame.

9.2.9 Duplicate detection and recovery

Because MAC-level acknowledgments and retransmissions are incorporated into the protocol, there is the possibility that a frame may be received more than once. Such duplicate frames shall be filtered out within the receiver MAC.

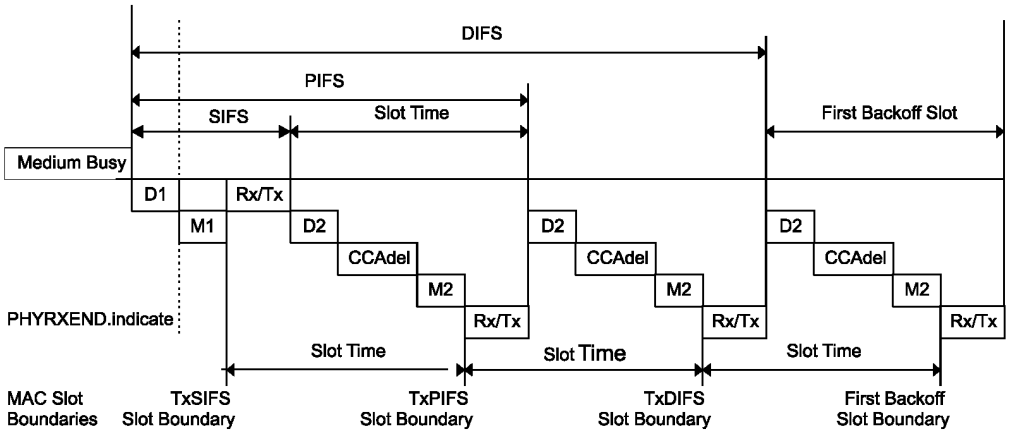
Duplicate frame filtering is facilitated through the inclusion of a Sequence Control field (consisting of a sequence number and fragment number) within data and management frames as well as TID subfield in the QoS Control field within QoS data frames. MPDUs that are part of the same MSDU shall have the same sequence number, and different MSDUs shall (with a high probability) have a different sequence number.

The sequence number, for management frames and for data frames with QoS subfield of the Subtype field set to 0, is generated by the transmitting STA as an incrementing sequence of integers. In a QoS STA, the sequence numbers for QoS (+)Data frames are generated by different counters for each TID and receiver pair and shall be incremented by one for each new MSDU corresponding to the TID/receiver pair.

The receiving STA shall keep a cache of recently received <Address 2, sequence-number, fragment-number> tuples. The receiving QoS STA shall also keep a cache of recently received <Address 2, TID, sequence-number, fragment-number> tuples for all STAs from whom it has received QoS data frames. A receiving STA is required to keep only the most recent cache entry per <Address 2-sequence-number> pair, storing only the most recently received fragment number for that pair. A receiving QoS STA is also required to keep only the most recent cache entry per <Address 2, TID, sequence-number> triple, storing only the most recently received fragment number for that triple. A receiving STA may omit tuples obtained from broadcast/multicast or ATIM frames from the cache.

A non-QoS receiver STA shall reject as a duplicate frame any frame that has the Retry bit set in the Frame Control field and that matches an <Address 2, sequence-number, fragment-number> tuple of an entry in the cache. A receiver QoS STA shall also reject as a duplicate frame any frame that has the Retry bit set in the Frame Control field and that matches an <Address 2, TID, sequence-number, fragment-number> tuple of an entry in the cache.

There is a small possibility that a frame may be improperly rejected due to such a match; however, this occurrence would be rare and simply results in a lost frame (similar to an FCS error in other LAN protocols).



The receiver STA shall perform the ACK procedure on all successfully received frames requiring acknowledgment, even if the frame is discarded due to duplicate filtering.

Exhibit 1014
Page 001492

9.2.10 DCF timing relations

The relationships between the IFS specifications are defined as time gaps on the medium. The associated attributes are provided by the specific PHY. (See Figure 9-12.)

D1 = aRxRFDelay + aRxPLCPDelay (referenced from the end of the last symbol of a frame on the medium)
D2 = D1 + Air Propagation Time
Rx/Tx = aRXTXTurnaroundTime (begins with a PHYTXSTART.request)
M1 = M2 = aMACProcessingDelay
CCAdel = aCCA Time - D1

Figure 9-12—DCF timing relationships

All timings that are referenced from the end of the transmission are referenced from the end of the last symbol of a frame on the medium. The beginning of transmission refers to the first symbol of the preamble of the next frame on the medium.

aSIFSTime and aSlotTime are fixed per PHY.

aSIFSTime is: aRxRFDelay + aRxPLCPDelay + aMACProcessingDelay + aRxTxTurnaroundTime.

aSlotTime is: aCCATime + aRxTxTurnaroundTime + aAirPropagationTime + aMACProcessingDelay.

The PIFS and DIFS are derived by the following equations, as illustrated in Figure 9-12.

PIFS = aSIFSTime + aSlotTime

DIFS = aSIFSTime + 2 × aSlotTime

The EIFS is derived from the SIFS and the DIFS and the length of time it takes to transmit an ACK Control frame at the lowest PHY mandatory rate by the following equation:

EIFS = aSIFSTime + DIFS + ACKTxTime

where

ACKTxTime is the time expressed in microseconds required to transmit an ACK frame, including preamble, PLCP header and any additional PHY dependent information, at the lowest PHY mandatory rate.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001493

Figure 9-12 illustrates the relation between the SIFS, PIFS, and DIFS as they are measured on the medium and the different MAC slot boundaries TxSIFS, TxPIFS, and TxDIFS. These slot boundaries define when the transmitter shall be turned on by the MAC to meet the different IFS timings on the medium, after subsequent detection of the CCA result of the previous slot time.

The following equations define the MAC Slot Boundaries, using attributes provided by the PHY, which are such that they compensate for implementation timing variations. The starting reference of these slot boundaries is again the end of the last symbol of the previous frame on the medium.

TxSIFS = SIFS – aRxTxTurnaroundTime

TxPIFS = TxSIFS + aSlotTime

TxDIFS = TxSIFS + 2 × aSlotTime.

The tolerances are specified in the physical layer management entity (PLME) SAP interface specification (see 10.4) and shall only apply to the SIFS specification so that tolerances shall not accumulate.

9.2.11 NAV distribution

When a node needs to distribute NAV information, for instance, to reserve the medium for a transmission of a nonbasic rate frame (that may not be heard by other nodes in the BSS), the node may first transmit a CTS frame with the RA field equal to its own MAC address (CTS-to-self) and with a duration value that protects the pending transmission, plus possibly an ACK frame.

The CTS-to-self NAV distribution mechanism is lower in network overhead cost than is the RTS/CTS NAV distribution mechanism, but CTS-to-self is less robust against hidden nodes and collisions than RTS/CTS. STAs employing a NAV distribution mechanism should choose a mechanism such as CTS-to-self or RTS/CTS that is appropriate for the given network conditions. If errors occur when employing the CTS-to-self mechanism, STAs should switch to a more robust mechanism.

9.2.12 Determination of PLME aCWmin characteristics

In the case of the Clause 19 ERP, the aCWmin value is dependent on the requestor's characteristic rate set. The characteristic rate set is equal to the IBSS's supported rate set when the STA is operating as a member of an IBSS. It is equal to the AP's supported rate set when the STA is associated with an AP. At all other times, it is equal to the STA's mandatory rate set. The MAC variable aCWmin is set to aCWmin(0) if the characteristic rate set includes only rates in the set 1, 2, 5.5, 11; otherwise, aCWmin is set to aCWmin(1). If the returned value for aCWmin is a scalar, then the MAC always sets the variable aCWmin to the returned scalar value of aCWmin.

9.3 PCF

The PCF provides CF frame transfer. The PC shall reside in the AP. It is an option for an AP to be able to become the PC. All STAs inherently obey the medium access rules of the PCF, because these rules are based on the DCF, and all STAs set their NAV at the beginning of each CFP. The operating characteristics of the PCF are such that all STAs are able to operate properly in the presence of a BSS in which a PC is operating, and, if associated with a point-coordinated BSS, are able to receive all frames sent under PCF control. It is also an option for a STA to be able to respond to a CF-Poll received from a PC. A STA that is able to respond to CF-Polls is referred to as being CF-Pollable, and may request to be polled by an active PC. CF-Pollable STAs and the PC do not use RTS/CTS in the CFP. When polled by the PC, a CF-Pollable STA may transmit only one MPDU, which can be sent to the PC but may have any destination, and may "piggyback" the acknowledgment of a frame received from the PC using particular data frame subtypes for this transmission. If the data frame is

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001494

not in turn acknowledged, the CF-Pollable STA shall not retransmit the frame unless it is polled again by the PC, or it decides to retransmit during the CP. If the addressed recipient of a CF transmission is not CF-Pollable, that STA acknowledges the transmission using the DCF acknowledgment rules, and the PC retains control of the medium. A PC may use CF frame transfer solely for delivery of frames to STAs, and never to poll CF-Pollable STAs.

A PC may perform a backoff on retransmission of an unacknowledged frame during the CFP. A PC that is maintaining a polling list may retry the unacknowledged frame the next time the particular AID is at the top of the polling list.

A PC may retransmit an unacknowledged frame during the CFP after a PIFS time.

When more than one point-coordinated BSS is operating on the same PHY channel in overlapping space, the potential exists for collisions between PCF transfer activities by the independent PCs. The rules under which multiple, overlapping point-coordinated BSSs may coexist are presented in 9.3.3.2. As shown in Figure 9-1 (in 9.1), the PCF is built on top of the CSMA/CA-based DCF, by utilizing the access priority provisions provided by this scheme. An active PC shall be located at an AP, which restricts PCF operation to infrastructure networks. PCF is activated at a PC-capable AP by setting the CFPMaxDuration parameter in the CF Parameter Set of the MLMEStart.request to a nonzero value.

Data frames sent by, or in response to polling by, the PC during the CFP shall use the appropriate data subtypes based upon the following usage rules:

— Data+CF-Poll, Data+CF-Ack+CF-Poll, CF-Poll, and CF-Ack+CF-Poll shall only be sent by a PC.

— Data, Data+CF-Ack, Null Function, and CF-Ack may be sent by a PC or by any CF-Pollable STA.

STAs receiving Data type frames shall only consider the frame body as the basis of a possible indication to LLC, if the frame is of subtype Data, Data+CF-Ack, Data+CF-Poll, or Data+CF-Ack+CF-Poll. CF-Pollable STAs shall interpret all subtype bits of received Data type frames that contain the BSSID of the current BSS for CF purposes, but shall inspect the frame body only if the frame is of subtype Data, Data+CF-Ack, Data+CF-Poll, or Data+CF-Ack+CF-Poll.

9.3.1 CFP structure and timing

The PCF controls frame transfers during a CFP. The CFP shall alternate with a CP, when the DCF controls frame transfers, as shown in Figure 9-13. Each CFP shall begin with a Beacon frame that contains a DTIM element (hereafter referred to as a DTIM). The CFPs shall occur at a defined repetition rate, which shall be synchronized with the beacon interval as specified in the following paragraphs.

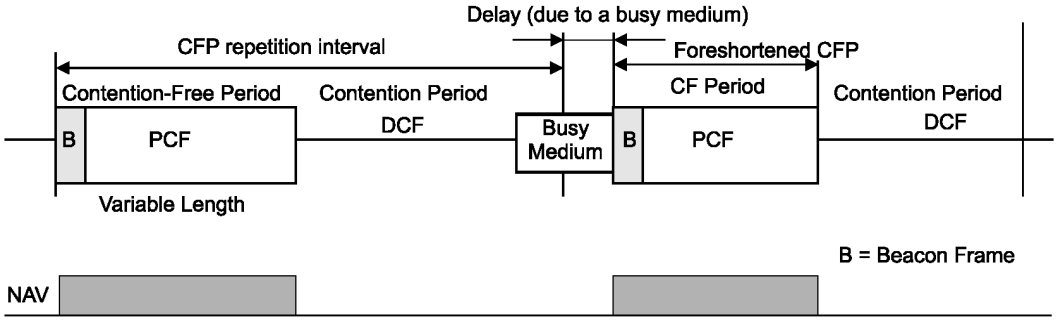

Figure 9-13—CFP/CP alternation

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001495

The PC generates CFPs at the CFP repetition interval (CFPPeriod), which is defined as a number of DTIM intervals. The PC shall determine the CFPPeriod (depicted as a repetition interval in the illustrations in Figure 9-13 and Figure 9-14) to use from the CFPPeriod parameter in the CF Parameter Set. This value, in units of DTIM intervals, shall be communicated to other STAs in the BSS in the CFPPeriod field of the CF Parameter Set element of Beacon frames. The CF Parameter Set element shall only be present in Beacon and Probe Response frames transmitted by STAs containing an active PC.

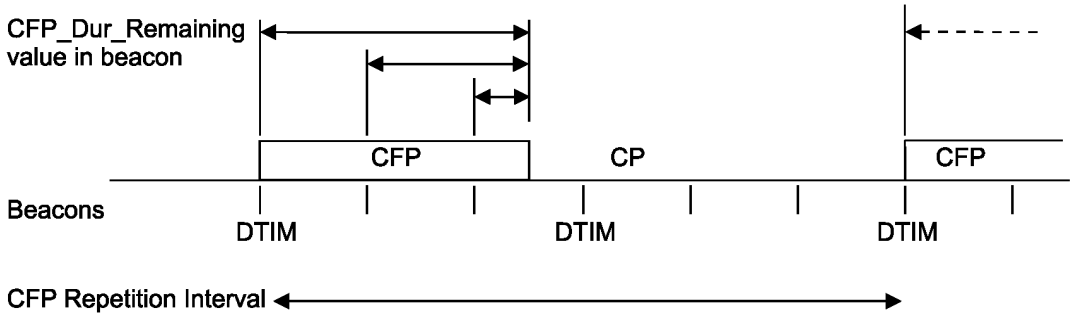

Figure 9-14—Beacon frames and CFPs

The length of the CFP is controlled by the PC, with maximum duration specified by the value of the CFPMaxDuration Parameter in the CF Parameter Set at the PC. Neither the maximum duration nor the actual duration (signaled by transmission of a Control frame of subtype CF-End or CF-End+ACK by the PC) is constrained to be a multiple of the beacon interval. If the CFP duration is greater than the beacon interval, the PC shall transmit Beacon frames at the appropriate times during the CFP (subject to delay due to traffic at the nominal times, as with all Beacon frames). The CF Parameter Set element in all Beacon frames at the start of, or within, a CFP shall contain a nonzero value in the CFPDurRemaining field. This value, in units of TU, shall specify the maximum time from the most recent TBTT to the end of this CFP. The value of the CFPDurRemaining field shall be zero in Beacon frames sent during the CP. An example of these relationships is illustrated in Figure 9-14, which shows a case where the CFPPeriod is two DTIM intervals, the DTIM interval is three beacon intervals, and the aCFPMaxDuration value is approximately 2.5 beacon intervals.

The PC may terminate any CFP at or before the aCFPMaxDuration, based on available traffic and size of the polling list. Because the transmission of any Beacon frame may be delayed due to a medium busy condition at the TBTT, a CFP may be foreshortened by the amount of the delay. In the case of a busy medium due to DCF traffic, the Beacon frame shall be delayed for the time required to complete the current DCF frame exchange. In cases where the Beacon frame transmission is delayed, the CFPDurRemaining value in the Beacon frame at the beginning of the CFP shall specify a time that causes the CFP to end no later than TBTT plus the value of aCFPMaxDuration. This is illustrated in Figure 9-15.

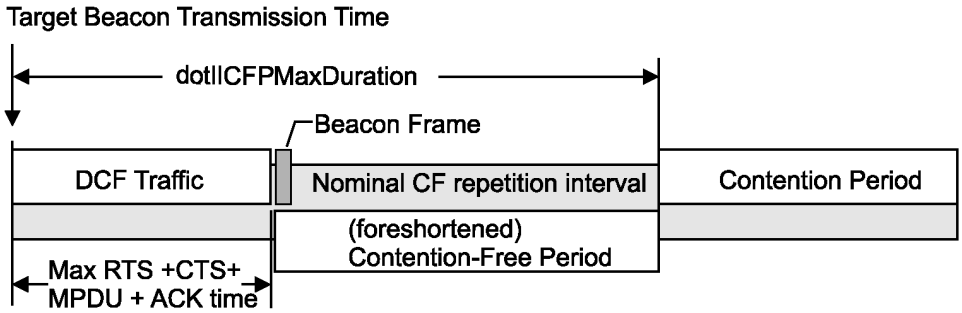

Figure 9-15—Example of delayed beacon and foreshortened CFP

Exhibit 1014
Page 001496

9.3.2 PCF access procedure

The CF transfer protocol is based on a polling scheme controlled by a PC operating at the AP of the BSS. The PC gains control of the medium at the beginning of the CFP and attempts to maintain control for the entire CFP by waiting a shorter time between transmissions than the STAs using the DCF access procedure. All STAs that receive Beacon frames containing a CF Parameter Set information element, including STAs not associated with the BSS, set their NAVs to the CFPMaxDuration value at the nominal start time of each CFP. This prevents most contention by preventing nonpolled transmissions by STAs regardless of whether they are CF-Pollable. Acknowledgment of frames sent during the CFP may be accomplished using Data+CF-ACK, CF-ACK, Data+CF-ACK+CF-Poll (only on frames transmitted by the PC), or CF-ACK+CF-Poll (only on frames transmitted by the PC) frames in cases where a Data (or Null) frame immediately follows the frame being acknowledged, thereby avoiding the overhead of separate ACK Control frames. Non-CF-Pollable or unpolled CF-Pollable STAs acknowledge frames during the CFP using the DCF ACK procedure.

9.3.2.1 Fundamental access

At the nominal beginning of each CFP, the PC shall sense the medium. When the medium is determined to be idle for one PIFS period, the PC shall transmit a Beacon frame containing the CF Parameter Set element and a DTIM element.

After the initial Beacon frame, the PC shall wait for one SIFS period, and then transmit one of the following: a data frame, a CF-Poll frame, a Data+CF-Poll frame, a management frame, or a CF-End frame. If the CFP is null, i.e., no traffic is buffered and no polls exist to send at the PC, a CF-End frame shall be transmitted immediately after the initial Beacon frame. If there are buffered multicast or broadcast frames, the PC shall transmit these prior to any unicast frames.

STAs receiving individually addressed, error-free frames from the PC are expected to respond after a SIFS period, in accordance with the transfer procedures defined in 9.3.3. If the recipient STA is not CF-Pollable, the response to receipt of an error-free data frame shall always be an ACK frame.

9.3.2.2 NAV operation during the CFP

The mechanism for handling the NAV during the CFP is designed to facilitate the operation of overlapping CFP coordinated infrastructure BSSs. The mechanism by which infrastructure BSSs coordinate their CFPs is beyond the scope of this standard.

Each STA, except the STA with the PC, shall preset its NAV to the CFPMaxDuration value (obtained from the CF Parameter Set element in Beacon frames from this PC) at each TBTT (see Clause 11) at which a CFP is scheduled to start (based on the CFPCount field in the CF Parameter Set element of the Beacon frames from this PC). Each non-PC STA shall update its NAV using the CFPDurRemaining value in the CF Parameter Set element of any error-free Beacon frame that the STA receives. This includes CFPDurRemaining values in CF Parameter Set elements from Beacon frames received from other (overlapping) BSSs.

These actions prevent STAs from taking control of the medium during the CFP, which is especially important in cases where the CFP spans multiple medium-occupancy intervals, such as dwell periods of an FH PHY. This setting of the NAV also reduces the risk of hidden STAs determining the medium to be idle for a DIFS period during the CFP and possibly corrupting a transmission in progress.

A STA joining a BSS operating with a PC shall use the information in the CFPDurRemaining element of the CF parameter set of any received Beacon or Probe Response frames to update its NAV prior to initiating any transmissions.

The PC shall transmit a CF-End or CF-End+ACK frame at the end of each CFP. A STA that receives either of these frames, from any BSS, shall reset its NAV.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001497

9.3.3 PCF transfer procedure

Frame transfers under the PCF may consist of frames alternately sent from the AP/PC and sent to the AP/PC. During the CFP, the ordering of these transmissions, and the STA allowed to transmit frames to the PC at any given point in time, shall be controlled by the PC. Figure 9-16 depicts frame transfer during a typical CFP. The rules under which this frame transfer takes place are detailed in 9.3.3.1 through 9.3.3.4.

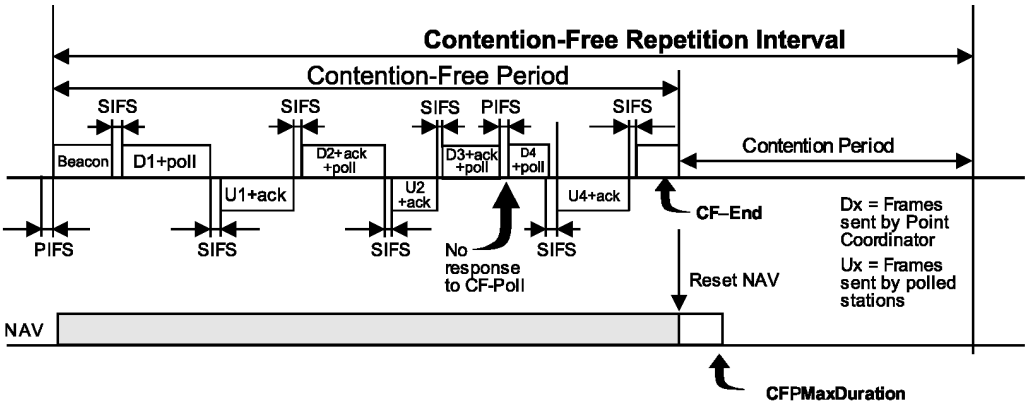

Figure 9-16—Example of PCF frame transfer

In a STA having an FH PHY, control of the channel is lost at a dwell time boundary. It is required that the current MPDU transmission and the accompanying acknowledgment of the MPDU be transmitted before the dwell time boundary. After having been polled by the PC, if there is not enough time remaining in the dwell to allow transmission of the MPDU plus the acknowledgment, the STA shall defer the transmission of the MPDU and shall transmit a Null frame or CF-ACK frame. The short retry counter and long retry counter for the MSDU shall not be affected.

MaxMPDUTime is the time to transmit the maximum-sized MAC frame, expanded by security mechanisms, plus the time to transmit the PHY preamble, header, trailer, and expansion bits, if any. In a STA having an FH PHY, the PC shall not transmit a frame with any data subtype that includes CF-Poll to a STA if there is insufficient time remaining before the dwell boundary for the STA to respond with a Null frame or CF-ACK frame.

9.3.3.1 PCF transfers when the PC STA is transmitter or recipient

The PC shall transmit frames between the Beacon that starts the CFP and the CF-End using the SIFS except in cases where a transmission by another STA is expected by the PC and a SIFS period elapses without the receipt of the expected transmission. In such cases the PC may send its next pending transmission as soon as one PIFS after the end of its last transmission. This permits the PC to retain control of the medium in the presence of an overlapping BSS. The PC may transmit any of the following frame types to CF-Pollable STAs:

— Data, used to send data from the PC when the addressed recipient is not being polled and there is no previous frame to acknowledge;

— Data+CF-ACK, used to send data from the PC when the addressed recipient is not being polled or is not CF-Pollable or the DA is a group address and the PC needs to acknowledge the receipt of a frame received from a CF-Pollable STA a SIFS period before starting this transmission;

— Data+CF-Poll, used to send data from the PC when the addressed recipient is the next STA to be permitted to transmit during this CFP and there is no previous frame to acknowledge;

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001498

— Data+CF-ACK+CF-Poll, used to send data from the PC when the addressed recipient is the next STA to be permitted to transmit during this CFP and the PC needs to acknowledge the receipt of a frame received from a CF-Pollable STA a SIFS period before starting this transmission;

— CF-Poll, used when the PC is not sending data to the addressed recipient but the addressed recipient is the next STA to be permitted to transmit during this CFP and there is no previous frame to acknowledge;

— CF-ACK+CF-Poll, used when the PC is not sending data to the addressed recipient but the addressed recipient is the next STA to be permitted to transmit during this CFP and the PC needs to acknowledge the receipt of a frame from a CF-Pollable STA a SIFS period before starting this transmission;

— CF-ACK, used when the PC is not sending data to, or polling, the addressed recipient, but the PC needs to acknowledge receipt of a frame from a CF-Pollable STA a SIFS period before starting this transmission (useful when the next transmission by the PC is a management frame, such as a Beacon frame); or

— Any management frame that is appropriate for the AP to send under the rules for that frame type.

The PC may transmit data or management frames to non-CF-Pollable, non-PS STAs during the CFP. These STAs shall acknowledge receipt with ACK frames after a SIFS, as with the DCF. The PC may also transmit broadcast or multicast frames during the CFP. Because the Beacon frame that initiates the CFP contains a DTIM element, if there are associated STAs using PS mode, the broadcasts and multicasts buffered shall be sent immediately after any Beacon frame containing a TIM element with a DTIM count field with a value of 0.

A CF-Pollable STA that receives an individually addressed data frame of any subtype that includes CF-Poll may transmit one data frame a SIFS period after receiving the CF-Poll. CF-Pollable STAs shall ignore, but not reset, their NAV when performing transmissions in response to a CF-Poll.

Non-CF-Pollable STAs that receive an individually addressed frame during the CFP shall transmit an ACK, but shall not reset their NAV.

For frames that require MAC-level acknowledgment, CF-Pollable STAs that received a CF-Poll (of any type) may perform this acknowledgment using the Data+CF-ACK subtype in the response to the CF-Poll. For example, the U1 frame in Figure 9-16 contains the acknowledgment to the preceding D1 frame. The D2 frame contains the acknowledgment to the preceding U1 frame. The PC may use the CF-ACK subtypes to acknowledge a received frame even if the data frame sent with the CF-ACK subtype is addressed to a different STA than the one being acknowledged. CF-Pollable STAs that are expecting an acknowledgment shall interpret the subtype of the frame (if any) sent by the PC a SIFS period after that STA's transmission to the PC. If a frame that requires MAC-level acknowledgment is received by a non-CF-Pollable STA, that STA shall not interpret the CF-Poll indication (if any), and shall acknowledge the frame by sending an ACK Control frame after a SIFS period.

The lengths of the frames may be variable, only bounded by the frame and/or fragment length limitations that apply for the BSS. If a CF-Pollable STA does not respond to a CF-Poll (of any type) within the SIFS period following a transmission from the PC, or a non-CF-Pollable STA does not return the ACK frame within a SIFS period following a transmission from the PC that requires acknowledgment, then the PC shall resume control and may transmit its next frame after a PIFS period from the end of the PC's last transmission.

A CF-Pollable STA shall always respond to a frame with any data subtype that includes CF-Poll directed to its MAC address and received without error. If the STA has no frame to send when polled, the response shall be a Null frame. If the STA has no frame to send when polled, but an acknowledgment is required for the frame that conveyed the CF-Poll, the response shall be a CF-ACK (no data) frame. The null response is required to permit a "no-traffic" situation to be distinguished from a collision between overlapping PCs.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001499

The CFP shall end when the CFPDurRemaining time has elapsed since the Beacon frame originating the CFP or when the PC has no further frames to transmit nor STAs to poll. In either case, the end of the CFP shall be signaled by the transmission of a CF-End by the PC. If there is a received frame that requires acknowledgment at the time the CF-End is to be transmitted, the PC shall transmit a CF-End+ACK frame instead. All STAs of the BSS receiving a CF-End or CF-End+ACK shall reset their NAVs so they may attempt to transmit during the CP.

9.3.3.2 Operation with overlapping point-coordinated BSSs

Because the PCF operates without the CSMA/CA CW randomization and backoff of the DCF, there is a risk of repeated collisions if multiple, overlapping, point-coordinated BSSs are operating on the same PHY channel, and their CFP Rates and beacon intervals are approximately equal. To minimize the risk of significant frame loss due to CF collisions, the PC shall use a DIFS plus a random backoff delay (with CW in the range of 1 to aCWmin) to start a CFP when the initial Beacon frame is delayed because of deferral due to a busy medium. The PC may optionally use this backoff during the CFP prior to retransmitting an unacknowledged, individually addressed data or management frame.

To further reduce the susceptibility to inter-PC collisions, the PC shall require that the medium be determined as being idle for a DIFS period plus a random (over a range of 1 to aCWmin) number of slot times once every aMediumOccupancyLimit TU during the CFP. This results in loss of control of the medium to overlapping BSS or hidden STA traffic, because the STAs in this BSS are prevented from transmitting by their NAV setting to CFPMaxDuration or CFPDurRemaining. For operation of the PCF in conjunction with an FH PHY, aMediumOccupancyLimit shall be set equal to the dwell time. For operation in conjunction with other PHY types, aMediumOccupancyLimit may be set equal to CFPMaxDuration, unless extra protection against PCF collisions is desired. The aMediumOccupancyLimit is also useful for compliance in regulatory domains that impose limits on continuous transmission time by a single STA as part of a spectrum etiquette.

9.3.3.3 CFPMaxDuration limit

The value of CFPMaxDuration shall be limited to allow coexistence between contention and CF traffic.

The minimum value for CFPMaxDuration is two times MaxMPDUTime plus the time required to send the initial Beacon frame and the CF-End frame of the CFP. This may allow sufficient time for the AP to send one data frame to a STA, while polling that STA, and for the polled STA to respond with one data frame.

The maximum value for CFPMaxDuration is the duration of (BeaconPeriod × DTIMPeriod × CFPPeriod) minus [MaxMPDUTime plus (2 × aSIFSTime) plus (2 × aSlotTime) plus (8 × ACKSize)], expressed in microseconds. MaxMPDUTime is the time to transmit the maximum-sized MAC frame, expanded by security mechanisms, plus the time to transmit the PHY preamble, header, trailer, and expansion bits, if any. This allows sufficient time to send at least one data frame during the CP.

9.3.3.4 CF usage rules

A PC may send broadcast or multicast frames, and individually addressed data or management frames to any active STA, as well as to CF-Pollable PS STAs. During the CFP, CF-Pollable STAs shall acknowledge after a SIFS period, the receipt of each Data+CF-Poll frame or Data+CF-ACK+CF-Poll frame using Data+CF-Ack or CF-Ack (no data) frames, the receipt of each CF_Poll (no data) using Data or Null (no data), and the receipt of all other data and management frames using ACK Control frames. Non-CF-Pollable STAs shall acknowledge receipt of data and management frames using ACK Control frames sent after a SIFS period. This non-CF-Pollable operation is the same as that already employed by such STAs for DCF operation.

When polled by the PCF (Data+CF-Poll, Data+CF-ACK+CF-Poll, CF-Poll, or CF-ACK+CF-Poll) a CF-Pollable STA may send one data frame to any destination. Such a frame directed to or through the PC STA shall be acknowledged by the PC, using the CF-ACK indication (Data+CF-ACK, Data+CF-ACK+CF-Poll,

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001500

CF-ACK, CF-ACK+CF-Poll, or CF-End+ACK) sent after a SIFS. Such a frame directed to a non-CF-Pollable STA shall be acknowledged using an ACK Control frame sent after a SIFS period. A polled CF-Pollable STA with neither a data frame nor an acknowledgment to send shall respond by transmitting a Null frame after a SIFS period. A polled CF-Pollable STA with insufficient time before the end of the CFP or current medium occupancy limit, to send its queued MPDU and receive an acknowledgment, shall respond by transmitting a Null frame, or a CF-ACK frame if polled using Data+CF-Poll or Data+CF-ACK+CF-Poll, after a SIFS period. The CF-Pollable STA may set the More Data bit in its response to permit the PC to distinguish between an empty STA queue and a response due to insufficient time to transfer an MPDU.

The PC shall not issue frames with a subtype that includes CF-Polls if insufficient time remains in the current CFP to permit the polled STA to transmit a data frame containing a minimum length MPDU.

9.3.4 CF polling list

If the PC supports use of the CFP for inbound frame transfer as well as for frame delivery, the PC shall maintain a "polling list" for use in selecting STAs that are eligible to receive CF-Polls during CFPs. The polling list functional characteristics are defined below. If the PC supports the use of the CFP solely for frame delivery, the PC does not require a polling list, and shall never generate data frames with a subtype that includes CF-Poll. The form of CF support provided by the PC is identified in the Capability Information field of Beacon, Association Response, Reassociation Response, and Probe Response management frames, which are sent from APs. Any such frames sent by STAs, as in noninfrastructure networks, shall always have these bits set to 0.

The polling list is used to force the polling of CF-Pollable STAs, whether or not the PC has pending traffic to transmit to those STAs. The polling list may be used to control the use of Data+CF-Poll and Data+CF-ACK+CF-Poll types for transmission of data frames being sent to CF-Pollable STAs by the PC. The polling list is a *logical* construct, which is not exposed outside of the PC. A minimum set of polling list maintenance techniques are required to ensure interoperability of arbitrary CF-Pollable STAs in BSSs controlled by arbitrary APs with active PCs. APs may also implement additional polling list maintenance techniques that are outside the scope of this standard.

9.3.4.1 Polling list processing

The PC shall send a CF-Poll to at least one STA during each CFP when there are entries in the polling list. During each CFP, the PC shall issue polls to a subset of the STAs on the polling list in order by ascending AID value.

While time remains in the CFP, all CF frames have been delivered, and all STAs on the polling list have been polled, the PC may generate one or more CF-Polls to *any* STAs on the polling list. While time remains in the CFP, all CF frames have been delivered, and all STAs on the polling list have been polled, the PC *may* send data or management frames to *any* STAs.

In order to gain maximum efficiency from the CFP, and the ability to piggyback acknowledgments on successor data frames in the opposite direction, the PC should generally use Data+CF-Poll and Data+CF-ACK+CF-Poll types for each data frame transmitted while sufficient time for the potential response to the CF-Poll remains in the CFP.

9.3.4.2 Polling list update procedure

A STA indicates its CF-Pollability using the CF-Pollable subfield of the Capability Information field of Association Request and Reassociation Request frames. If a STA desires to change the PC's record of CF-Pollability, that STA shall perform a reassociation. During association, a CF-Pollable STA may request to be placed on the polling list, or to never be polled, by appropriate use of bits in the Capability Information field of the Associate Request or Reassociate Request frame, as shown in Table 7-21 (see 7.3.1.4).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001501

CF-Pollable STAs that are not on the polling list, but did not request never to be polled during their most recent association, may be dynamically placed on the polling list by the PC to handle bursts of frame transfer activity by that STA.

9.4 Fragmentation

The MAC may fragment and reassemble individually addressed MSDUs or MMPDUs. The fragmentation and defragmentation mechanisms allow for fragment retransmission.

The length of each fragment shall be an equal number of octets for all fragments except the last, which may be smaller. The length of each fragment shall always be an even number of octets, except for the last fragment of an MSDU or MMPDU, which may be either an even or an odd number of octets. The length of a fragment shall never be larger than dot11FragmentationThreshold unless WEP is invoked for the MPDU. If WEP is active for the MPDU, then the MPDU shall be expanded by IV and ICV (see 8.2.1); this may result in a fragment larger than dot11FragmentationThreshold.

A fragment is an MPDU, the payload of which carries all or a portion of an MSDU or MMPDU. When data are to be transmitted, the number of octets in the fragment (before processing by the security mechanism) shall be determined by dot11FragmentationThreshold and the number of octets in the MPDU that have yet to be assigned to a fragment at the instant the fragment is constructed for the first time. Once a fragment is transmitted for the first time, its frame body content and length shall be fixed until it is successfully delivered to the immediate receiving STA. A STA shall be capable of receiving fragments of arbitrary length.

If a fragment requires retransmission, its frame body content and length shall remain fixed for the lifetime of the MSDU or MMPDU at that STA. After a fragment is transmitted once, contents and length of that fragment are not allowed to fluctuate to accommodate the dwell time boundaries. Each fragment shall contain a Sequence Control field, which is comprised of a sequence number and fragment number. When a STA is transmitting an MSDU or MMPDU, the sequence number shall remain the same for all fragments of that MSDU or MMPDU. The fragments shall be sent in order of lowest fragment number to highest fragment number, where the fragment number value starts at zero, and increases by one for each successive fragment. The Frame Control field also contains a bit, the More Fragments bit, that is equal to zero to indicate the last (or only) fragment of the MSDU or MMPDU.

The source STA shall maintain a transmit MSDU timer for each MSDU being transmitted. The attribute dot11MaxTransmitMSDULifetime specifies the maximum amount of time allowed to transmit an MSDU. The timer starts on the initial attempt to transmit the first fragment of the MSDU. If the timer exceeds dot11MaxTransmitMSDULifetime, then all remaining fragments are discarded by the source STA and no attempt is made to complete transmission of the MSDU.

9.5 Defragmentation

Each fragment contains information to allow the complete MSDU or MMPDU to be reassembled from its constituent fragments. The header of each fragment contains the following information that is used by the destination STA to reassemble the MSDU or MMPDU:

- Frame type
- Address of the sender, obtained from the Address2 field
- Destination address
- *Sequence Control field:* This field allows the destination STA to check that all incoming fragments belong to the same MSDU or MMPDU, and the sequence in which the fragments should be reassembled. The sequence number within the Sequence Control field remains the same for all fragments of an MSDU or MMPDU, while the fragment number within the Sequence Control field increments for each fragment.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001502

— *More Fragments indicator:* Indicates to the destination STA that this is not the last fragment of the MSDU or MMPDU. Only the last or sole fragment of the MSDU or MMPDU shall have this bit set to 0. All other fragments of the MSDU or MMPDU shall have this bit set to 1.

The destination STA shall reconstruct the MSDU or MMPDU by combining the fragments in order of fragment number subfield of the Sequence Control field. If WEP has been applied to the fragment, it shall be decrypted before the fragment is used for defragmentation of the MSDU or MMPDU. If the fragment with the More Fragments bit set to 0 has not yet been received, then the destination STA knows that the MSDU or MMPDU is not yet complete. As soon as the STA receives the fragment with the More Fragments bit set to 0, the STA knows that no more fragments may be received for the MSDU or MMPDU.

All STAs shall support the concurrent reception of fragments of at least three MSDUs or MMPDUs. Note that a STA receiving more than three fragmented MSDUs or MMPDUs concurrently may experience a significant increase in the number of frames discarded.

The destination STA shall maintain a Receive Timer for each MSDU or MMPDU being received, for a minimum of three MSDUs or MMPDUs. The STA may implement additional timers to be able to receive additional concurrent MSDUs or MMPDUs. The receiving STA shall discard all fragments that are part of an MSDU or MMPDU for which a timer is not maintained. There is also an attribute, aMaxReceiveLifetime, that specifies the maximum amount of time allowed to receive an MSDU. The receive MSDU or MMPDU timer starts on the reception of the first fragment of the MSDU or MMPDU. If the receive MSDU timer exceeds aMaxReceiveLifetime, then all received fragments of this MSDU or MMPDU are discarded by the destination STA. If additional fragments of an individually addressed MSDU or MMPDU are received after its aMaxReceiveLifetime is exceeded, those fragments shall be acknowledged and discarded.

To properly reassemble MPDUs into an MSDU or MMPDU, a destination STA shall discard any duplicated fragments received. A STA shall discard duplicate fragments as described in 9.2.9. However, an acknowledgment shall be sent in response to a duplicate fragment of an individually addressed MSDU.

9.6 Multirate support

Some PHYs have multiple data transfer rate capabilities that allow implementations to perform dynamic rate switching with the objective of improving performance. The algorithm for performing rate switching is beyond the scope of this standard, but in order to ensure coexistence and interoperability on multirate-capable PHYs, this standard defines a set of rules to be followed by all STAs.

Control frames that initiate a frame exchange shall be transmitted at one of the rates in the BSS-BasicRateSet parameter except in the following cases:

— When the transmitting STA’s protection mechanism is enabled and the control frame is a protection mechanism frame

— When the control frame is a BlockAckReq or BlockAck frame

In the former case, the control frame shall be transmitted at a rate according to the separate rules for determining the rates of transmission of protection frames in 9.13. In the latter case, the control frame shall be transmitted in accordance with this subclause.

All frames with multicast and broadcast in the Address 1 field that have a UP of zero shall be transmitted at one of the rates included in the BSSBasicRateSet parameter, regardless of their type or subtype.

All data frames of subtype (QoS) (+)CF-Poll sent in the CP shall be transmitted at one of the rates in the BSSBasicRateSet parameter so that they will be understood by all STAs in the BSS, unless an RTS/CTS exchange has already been performed before the transmission of the data frame of subtype CF-Poll and the Duration field in the RTS frame covers the entire TXOP. All other data, BlockAckReq, and BlockAck frames

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001503

and/or management MPDUs with unicast in the Address 1 field shall be sent using any data rate subject to the following constraints. No STA shall transmit a unicast frame at a rate that is not supported by the receiver STA, as reported in any Supported Rates and Extended Supported Rates element in the management frames transmitted by that STA. For frames of type (QoS) Data+CF-Ack, (QoS) Data+CF-Poll+CF-Ack, and (QoS) CF-Poll+CF-Ack, the rate chosen to transmit the frame should be supported by both the addressed recipient STA and the STA to which the ACK frame is intended. The BlockAck control frame shall be sent at the same rate and modulation class as the BlockAckReq frame if it is sent in response to a BlockAckReq frame.

Under no circumstances shall a STA initiate transmission of a data or management frame at a data rate higher than the greatest rate in the OperationalRateSet, a parameter of the MLME-JOIN.request primitive. In the case where the supported rate set of the receiving STA is not known, the transmitting STA shall transmit at a rate contained in the BSSBasicRateSet parameter or a rate at which the transmitting STA has received a frame from the receiving STA.

To allow the transmitting STA to calculate the contents of the Duration/ID field, a STA responding to a received frame shall transmit its Control Response frame (either CTS or ACK), other than the BlockAck control frame, at the highest rate in the BSSBasicRateSet parameter that is less than or equal to the rate of the immediately previous frame in the frame exchange sequence (as defined in 9.12) and that is of the same modulation class (see 9.6.1) as the received frame. If no rate contained in the BSSBasicRateSet parameter meets these conditions, then the control frame sent in response to a received frame shall be transmitted at the highest mandatory rate of the PHY that is less than or equal to the rate of the received frame, and that is of the same modulation class as the received frame. In addition, the Control Response frame shall be sent using the same PHY options as the received frame, unless they conflict with the requirement to use the BSSBasicRateSet parameter.

An alternative rate for the control response frame may be used, provided that the duration of the control response frame at the alternative rate is the same as the duration of the control response frame at the origi-nally chosen rate and the alternative rate is in either the BSSBasicRateSet parameter or the mandatory rate set of the PHY and the modulation of the control response frame at the alternative rate is the same type as that of the received frame.

For the Clause 17, Clause 18, and Clause 19 PHYs, the time required to transmit a frame for use in the Duration/ID field is determined using the PLME-TXTIME.request primitive (see 10.4.6) and the PLME-TXTIME.confirm primitive (see 10.4.7), both defined in 17.4.3, 18.3.4, 19.8.3.1, 19.8.3.2, or 19.8.3.3 depending on the PHY options. In QoS STAs, the Duration/ID field may cover multiple frames and may involve using the PLME-TXTIME.request primitive several times.

9.6.1 Modulation classes

In order to determine the rules for response frames given in 9.6, the following modulation classes are defined in Table 9-2. Each row defines a modulation class. Modulations described within the same row have the same modulation class, while modulations described in different rows have different modulation classes.

Table 9-2—Modulation classes

Modulation class	Description of modulation
1	Infrared (IR) PHY (Clause 16)
2	Frequency-hopping spread spectrum (FHSS) PHY (Clause 14)
3	DSSS PHY (Clause 15) and HR/DSSS PHY (Clause 18)
4	ERP-PBCC PHY (19.6)

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001504

Table 9-2—Modulation classes *(continued)*

Modulation class	Description of modulation
5	DSSS-OFDM PHY (19.7)
6	ERP-OFDM PHY (19.5)
7	OFDM PHY (Clause 17)

9.7 MSDU transmission restrictions

To avoid reordering MSDUs between pairs of LLC entities and/or unnecessarily discarding MSDUs, the following restrictions shall be observed by any STA that is able to concurrently process multiple outstanding MSDUs for transmission. Note that here the term *outstanding* refers to an MSDU or MMPDU that is eligible to be transmitted at a particular time. A STA may have any number (greater than or equal to one) of eligible MSDUs outstanding concurrently, subject to the restrictions below.

A non-QoS STA shall ensure that no more than one MSDU or MMPDU from a particular SA to a particular individual RA is outstanding at a time. Note that a simpler, more restrictive invariant to maintain is that no more than one MSDU with a particular individual RA may be outstanding at a time.

For all transmissions not using the acknowledgment policy of Block Ack, a QoS STA shall ensure that no more than one MSDU or MMPDU with a particular TID from a particular SA to a particular individual RA is outstanding at any time. Note that a simpler, more restrictive invariant to maintain is that no more than one MSDU with any particular TID with a particular individual RA may be outstanding at any time. This restriction is not applicable for MSDUs that are to be transmitted using the Block Ack mechanism.

In a STA where the optional StrictlyOrdered service class has been implemented, that STA shall ensure that there is no group-addressed (multidestination) MSDU of the StrictlyOrdered service class outstanding from the SA of any other outstanding MSDU (either individual or group-addressed). This is because a group-addressed MSDU is implicitly addressed to a collection of peer STAs that could include any individual RA.

It is recommended that the STA select a value of dot11MaxTransmitMSDULifetime that is sufficiently large that the STA does not discard MSDUs due to excessive Transmit MSDU timeouts under normal operating conditions.

For MSDUs belonging to the service class of QoSAck when the receiver is a QoS STA, the QoS data frames that are used to send these MSDUs shall have the Ack Policy subfield in the QoS Control field set to Normal Ack or Block Ack. For MSDUs belonging to the service class of QoSNoAck when the receiver is a QoS STA, the QoS data frames that are used to send these MSDUs shall have the Ack Policy subfield in the QoS Control field set to No Ack.

9.8 Operation across regulatory domains

The PHY of a WLAN is subject to regulations that can vary significantly from one regulatory domain to another. This clause provides the framework for operation across regulatory domains and describes the mechanism that supports cross-domain mobility and operation in multiple regulatory domains. When this mechanisms is active, the dot11MultiDomainCapabilityEnabled attribute shall be true.

NOTE—This clause does not eliminate the need to obtain type acceptance, regulatory approval, equipment authorization, or equipment certification in each of the regulatory domains in which the equipment will operate. The mechanisms described in this clause provide the information to the STA to identify the regulatory domain in which it is

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001505

located and to cease operation while in those domains for which it does not have type approval. It is incumbent upon the implementer to provide proof of compliance to the requirements of individual regulatory agencies.

The method for configuring individual STAs is outside the scope of this standard. A STA must be properly configured for operation in a particular regulatory domain prior to beginning normal operation. Particular care must be taken when operating in an IBSS configuration.

9.8.1 Operation upon entering a regulatory domain

A STA that is enabled for operation across regulatory domains shall default to passive scanning when it has lost connectivity with its ESS. Passive scanning is performed using only the receive capabilities of the STA and is, thus, compatible with regulatory requirements. The timeout for determining the loss of connectivity is system dependent and beyond the scope of this standard.

When a STA enters a regulatory domain, it shall passively scan to learn at least one valid channel, i.e., a channel upon which it detects IEEE 802.11 frames. The Beacon frame contains information on the country code, the maximum allowable transmit power, and the channels to be used for the regulatory domain. Optionally, the Beacon frame may also include, on a periodic basis, the regulatory information that would be returned in a Probe Response frame. Once the STA has acquired the information so that it is able to meet the transmit requirements of the regulatory domain, it shall transmit a Probe Request to an AP to gain the additional regulatory domain information contained in the Probe Response frame, unless the information was previously received in a Beacon frame. The STA then has sufficient information available to configure its PHY for operation in the regulatory domain.

9.8.2 Support for FH PHYs

9.8.2.1 Determination of hopping patterns

When operating in a regulatory domain that does not have a method for determining a hopping pattern described in 14.6.8 or a hopping table in Annex B, hopping patterns shall be determined by an AP using HCCs or EHCCs. The HCC hopping sequences are derived from a simple formula that uses field operations on a group. For full details of the HCC placement operator function, please see the references. The placement operator function shall be as shown in Equation (9-4).

$$y_{HCC}(k;a) = \frac{a}{k} \bmod N \qquad \text{for } k,\ a \in J'_N \tag{9-4}$$

where

N is the prime radix
a is the family index
k is in the group J'_N
J'_N is the group remaining when the element containing the value zero is removed from the field J_N

Therefore, k does not take the value 0. The value $1/k$ is the multiplicative inverse of k on the field J_N. The multiplicative inverse of k on the group J_N is the integer value w, such that $(k \times w) \bmod N = 1$. The values computed for y_{HCC} are the channel numbers, a corresponds to the hopping pattern number, and k corresponds to the index into the hopping pattern. A code family is the set of N–1 hopping patterns generated for the prime radix N. There is no value equivalent to the hopping set of Clause 14. Each hopping pattern comprises N–1 channels.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001506

As an example, consider a code family that supports 10 channels. The prime radix for such a family is 11. The code family generated by the HCC algorithm is shown below in Table 9-3.

Table 9-3—HCC family – *N* = 11; Family indices (SEQ) 1 through 10

INDEX (k) ---->										
	1	2	3	4	5	6	7	8	9	10
SEQ										
1	1	6	4	3	9	2	8	7	5	10
2	2	1	8	6	7	4	5	3	10	9
3	3	7	1	9	5	6	2	10	4	8
4	4	2	5	1	3	8	10	6	9	7
5	5	8	9	4	1	10	7	2	3	6
6	6	3	2	7	10	1	4	9	8	5
7	7	9	6	10	8	3	1	5	2	4
8	8	4	10	2	6	5	9	1	7	3
9	9	10	3	5	4	7	6	8	1	2
10	10	5	7	8	2	9	3	4	6	1

The HCC method to calculate hopping sequences only generates sequences of a length that is one less than the prime radix. The EHCC algorithm extends the original HCC algorithm to support a larger number of possible hopping sequence lengths. The EHCC algorithm works through a process known as “deletion of the diagonals.” This creates hopping patterns with *N*–2 and *N*–3 channels.

Using the same example in Table 9-3, a family of codes cannot be generated for code lengths of 9 or 8 by the HCC algorithm because neither 9 or 8 is equal to a prime number minus one. However, the diagonals of the array in Table 9-3 represent the end points of the group. Thus, code families for code lengths 9 and 8 can be easily generated from the table simply by removing the diagonals. Table 9-4 shows such a code family with a code length of 9 (constructed by removing the diagonal of 10s).

Table 9-4 now contains a near diagonal (upper left to lower right) consisting entirely of ones. This is a necessary mathematical property of the result of removing the initial diagonal of (p–1) in the previous operation, and will be exhibited for any prime p.

Extending the process, Table 9-5 shows a code family with a code length of 8 (constructed from Table 9-4 by removing the entry from each row that has a value of 1, subtracting 1 from each value remaining in the row, and discarding the last row).

Exhibit 1014
Page 001508

To obtain a code family of length *N*–2, the code family of length *N*–1 calculated by the HCC algorithm shall be modified by deleting the diagonal of the code family with the value of *N*–1 and removing the row of the code family with the family coefficient of *N*–1. This results in a code family represented in a square (*N*–2) by (*N*–2) array.

To obtain a code family of length *N*–3, the code family of length *N*–1 calculated by the HCC algorithm shall be modified by deleting the diagonals of the code family with the values of 1 and *N*–1, removing the rows of the code family with the family coefficients of *N*–1 and *N*–2, and subtracting 1 from all remaining values in the code family array. This results in a code family represented in a square (*N*–3) by (*N*–3) array with array values of 1 through *N*–3.

When using hopping patterns calculated using the HCC or EHCC algorithms, the values in the FH parameter set element shall be set as follows:

a) The Hop Set field shall be 0; the value of 0 for the Hop Set field indicates that the HCC/EHCC algorithm is in use and that the Hop Pattern field contains the HCC/EHCC family index and the Hop Index field contains the HCC/EHCC index.

b) The family index of the code being used shall be placed in the Hop Pattern field.

c) The index shall be placed in the Hop Index field.

9.9 HCF

Under HCF, the basic unit of allocation of the right to transmit onto the WM is the TXOP. Each TXOP is defined by a starting time and a defined maximum length. The TXOP may be obtained by a STA winning an instance of EDCA contention (see 9.9.1) during the CP or by a non-AP STA receiving a QoS (+)CF-Poll frame (see 9.9.2) during the CP or CFP. The former is called *EDCA TXOP*, while the latter is called *HCCA TXOP* or *polled TXOP*. An HCCA TXOP shall not extend across a TBTT. A TXOP shall not exceed dot11MaxDwellTime (if using an FH PHY). The occurrence of a TBTT implies the end of the HCCA TXOP, after which the regular channel access procedure (EDCA or HCCA) is resumed. It is possible that no frame was transmitted during the TXOP. The foreshortened termination of the HCCA TXOP does not imply an error condition.

9.9.1 HCF contention-based channel access (EDCA)

9.9.1.1 Reference implementation

The channel access protocol is derived from the DCF procedures described in 9.2.

A model of the reference implementation is shown in Figure 9-17 and illustrates a mapping from frame type or UP to AC: the four transmit queues and the four independent EDCAFs, one for each queue. The mapping of UP to the AC is described in 9.1.3.1 and Table 9-1. The mapping of frame types to ACs is described in 9.1.3.1.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001509

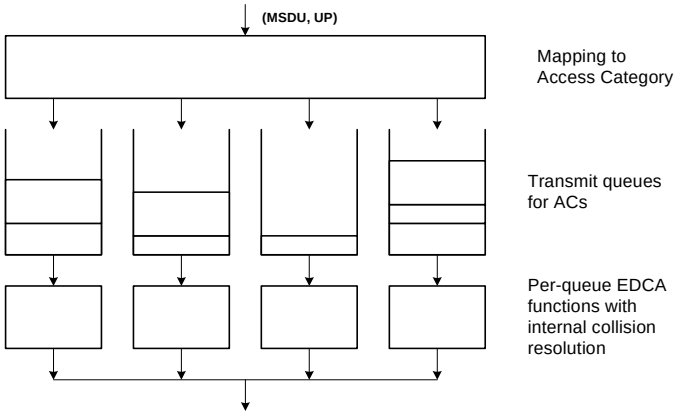

Figure 9-17—Reference implementation model

9.9.1.2 EDCA TXOPs

There are two modes of EDCA TXOP defined, the initiation of the EDCA TXOP and the multiple frame transmission within an EDCA TXOP. An initiation of the TXOP occurs when the EDCA rules permit access to the medium. A multiple frame transmission within the TXOP occurs when an EDCAF retains the right to access the medium following the completion of a frame exchange sequence, such as on receipt of an ACK frame.

The TXOP limit duration values are advertised by the AP in the EDCA Parameter Set information element in Beacon and Probe Response frames transmitted by the AP. A TXOP limit value of 0 indicates that a single MSDU or MMPDU, in addition to a possible RTS/CTS exchange or CTS to itself, may be transmitted at any rate for each TXOP.

Non-AP STAs shall ensure that the duration of TXOPs obtained using the EDCA rules do not exceed the TXOP limit. The duration of a TXOP is the duration during which the TXOP holder maintains uninterrupted control of the medium, and it includes the time required to transmit frames sent as an immediate response to the TXOP holder's transmissions.

A STA shall fragment a unicast MSDU so that the transmission of the first MPDU of the TXOP does not cause the TXOP limit to be exceeded at the PHY rate selected for the initial transmission attempt of that MPDU. The TXOP limit may be exceeded, when using a lower PHY rate than selected for the initial transmission attempt of the first MPDU, for a retransmission of an MPDU, for the initial transmission of an MPDU if any previous MPDU in the current MSDU has been retransmitted, or for broadcast/multicast MSDUs. When the TXOP limit is exceeded due to the retransmission of an MPDU at a reduced PHY rate, the STA shall not transmit more than one MPDU in the TXOP.

It should be noted, that when transmitting multiple frames in a TXOP using acknowledgment mechanisms other than Normal Ack, a protective mechanism should be used (such as RTS/CTS or the protection mechanism described in 9.13). A QoS AP may send broadcast/multicast frames without using any protection mechanism. In a QoS IBSS, broadcast/multicast frames shall be sent one at a time, and backoff shall be performed after the transmission of each of the broadcast/multicast frames.

9.9.1.3 Obtaining an EDCA TXOP

Each channel access timer shall maintain a backoff function (timer), which has a value measured in backoff slots.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001510

The duration AIFS[AC] is a duration derived from the value AIFSN[AC] by the relation

AIFS[AC] = AIFSN[AC] × aSlotTime + aSIFSTime.

The value of AIFSN[AC] shall be greater than or equal to 2 for non-AP STAs and is advertised by the AP in the EDCA Parameter Set information element in Beacon and Probe Response frames transmitted by the AP. The value of AIFSN[AC] shall be greater than or equal to 1 for APs. An EDCA TXOP is granted to an EDCAF when the EDCAF determines that it shall initiate the transmission of a frame exchange sequence. Transmission initiation shall be determined according to the following rules:

On specific slot boundaries, each EDCAF shall make a determination to perform one and only one of the following functions:

— Initiate the transmission of a frame exchange sequence for that access function.

— Decrement the backoff timer for that access function.

— Invoke the backoff procedure due to an internal collision.

— Do nothing for that access function.

The specific slot boundaries at which exactly one of these operations shall be performed are defined as follows, for each EDCAF:

a) Following AIFSN[AC] × aSlotTime – aRxTxTurnaroundTime of idle medium after SIFS (not necessarily idle medium during the SIFS duration) after the last busy medium on the antenna that was the result of a reception of a frame with a correct FCS.

b) Following EIFS – DIFS + AIFSN[AC] × aSlotTime + aSIFSTime – aRxTxTurnaroundTime of idle medium after the last indicated idle medium as determined by the physical CS mechanism that was the result of a frame reception that has resulted in FCS error, or PHY-RXEND.indication (RXERROR) primitive where the value of RXERROR is not NoError.

c) When any other EDCAF at this STA transmitted a frame requiring acknowledgment, the earlier of

   1) The end of the ACK-Timeout interval timed from the PHY_TXEND.confirm primitive, followed by AIFSN[AC] x aSlotTime + aSIFSTime – aRxTxTurnaroundTime of idle medium, and

   2) The end of the first AIFSN[AC] × aSlotTime – aRxTxTurnaroundTime of idle medium after SIFS (not necessarily medium idle during the SIFS duration, the start of the SIFS duration implied by the length in the PLCP header of the previous frame) when a PHY-RXEND.indication primitive occurs as specified in 9.2.8.

d) Following AIFSN[AC] × aSlotTime – aRxTxTurnaroundTime of idle medium after SIFS (not necessarily medium idle during the SIFS duration) after the last busy medium on the antenna that was the result of a transmission of a frame for any EDCAF and which did not require an acknowledgment.

e) Following AIFSN[AC] × aSlotTime + aSIFSTime – aRxTxTurnaroundTime of idle medium after the last indicated idle medium as indicated by the CS mechanism that is not covered by a) through d).

f) Following aSlotTime of idle medium, which occurs immediately after any of these conditions, a) through f), is met for the EDCAF.

At each of the above-described specific slot boundaries, each EDCAF shall initiate a transmission sequence if

— There is a frame available for transmission at that EDCAF, and

— The backoff timer for that EDCAF has a value of zero, and

— Initiation of a transmission sequence is not allowed to commence at this time for an EDCAF of higher UP.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001511

At each of the above-described specific slot boundaries, each EDCAF shall decrement the backoff timer if the backoff timer for that EDCAF has a nonzero value.

At each of the above-described specific slot boundaries, each EDCAF shall invoke the backoff procedure due to an internal collision if

— There is a frame available for transmission at that EDCAF, and
— The backoff timer for that EDCAF has a value of zero, and
— Initiation of a transmission sequence is allowed to commence at this time for an EDCAF of higher UP.

At each of the above-described specific slot boundaries, an EDCAF shall do nothing if none of the above actions is taken.

An example showing the relationship between AIFS, AIFSN, DIFS, and slot times immediately following a medium busy condition (and assuming that medium busy condition was not caused by a frame in error) is shown in Figure 9-18. In this case, with AIFSN = 2, the EDCAF may decrement the backoff counter for the first time at 2 × aSlotTime following the end of the medium busy condition (end of the medium busy condition happens at the end of M1 in Figure 9-18). If, in this example, the backoff counter contained a value of 1 at the time the medium became idle, transmission would start as a result of an EDCA TXOP on-air at a time

aSIFSTime + 3 × aSlotTime

following the end of the medium busy condition.

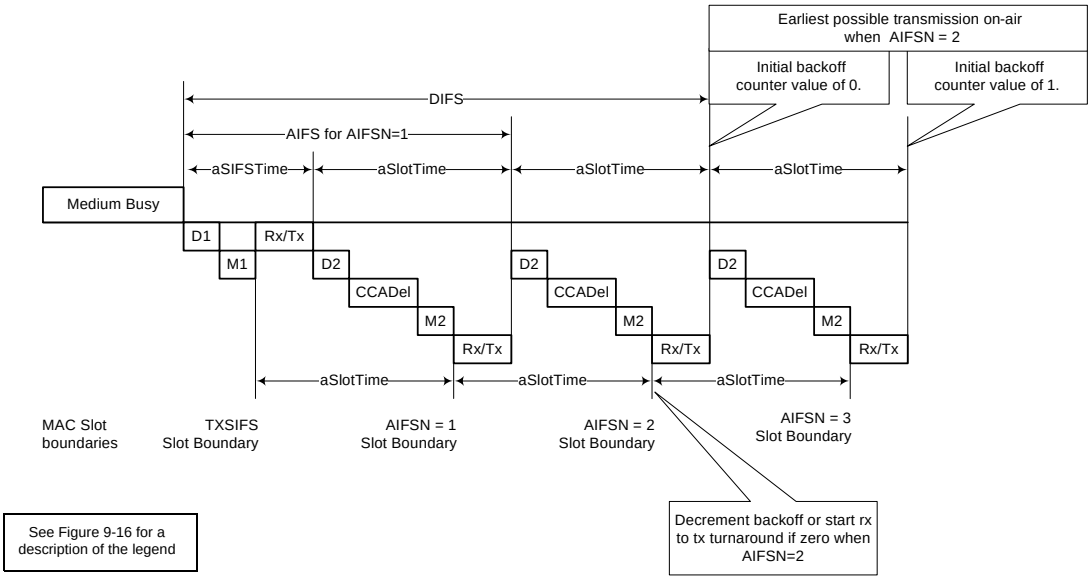

Figure 9-18—EDCA mechanism timing relationships

9.9.1.4 Multiple frame transmission in an EDCA TXOP

Multiple frames may be transmitted in an acquired EDCA TXOP following the rules in 9.9.1.3 if there is more than one frame pending in the AC for which the channel has been acquired. However, those frames that are pending in other ACs shall not be transmitted in this EDCA TXOP. If a STA has in its transmit queue an additional frame of the same AC as the one just transmitted and the duration of transmission of that frame plus any expected acknowledgment for that frame is less than the remaining medium occupancy timer value, then

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001512

the STA may commence transmission of that frame at SIFS after the completion of the immediately preceding frame exchange sequence. The intention of using the multiple frame transmission shall be indicated by the STA through the setting of the duration/ID values in one of the following two ways (see 7.1.4):

a) Long enough to cover the response frame, the next frame, and its response frame.

b) Long enough to cover the transmission of a burst of MPDUs subject to the limit set by dot11EDCATableTXOPLimit.

If the Duration/ID field is set for multiple frame transmission and there is a transmission failure, the corresponding channel access function may recover before the expiry of the NAV setting due to the setting of the Duration/ID field in the frame that resulted in a transmission failure. The backoff procedure is described in 9.9.1.5. However, at the expiry of the NAV set by the frame that resulted in a transmission failure, if the channel access function has not recovered, then the EDCAF shall invoke backoff procedure.

No other AC at the STA shall transmit before the expiry of the NAV set by the frame that resulted in a transmission failure. All other ACs at the STA shall treat the medium as busy until the expiry of the NAV set by the frame that resulted in a transmission failure, just as they would if they had received that transmission from another STA.

A frame exchange may be a multicast frame, a frame transmitted with No Ack policy (for which there is no expected acknowledgment), or a unicast frame followed by a correctly received ACK frame transmitted by either a non-AP STA or an AP.

Note that, as for an EDCA TXOP, a multiple frame transmission is granted to an EDCAF, not to a non-AP STA or AP, so that the multiple frame transmission is permitted only for the transmission of a frame of the same AC as the frame that was granted the EDCA TXOP.

9.9.1.5 EDCA backoff procedure

Each EDCAF shall maintain a state variable CW[AC], which shall be initialized to the value of the parameter CWmin[AC].

If a frame is successfully transmitted by a specific EDCAF, indicated by the successful reception of a CTS in response to an RTS, the successful reception of an ACK frame in response to a unicast MPDU or BlockAck, the successful reception of a BlockAck or ACK frame in response to a BlockAckReq frame, or the transmission of a multicast frame or a frame with No Ack policy, CW[AC] shall be reset to CWmin[AC].

The backoff procedure shall be invoked for an EDCAF when any of the following events occurs:

— A frame with that AC is requested to be transmitted, the medium is busy as indicated by either physical or virtual CS, and the backoff timer has a value of zero for that AC.

— The final transmission by the TXOP holder initiated during the TXOP for that AC was successful.

— The transmission of a frame of that AC fails, indicated by a failure to receive a CTS in response to an RTS, a failure to receive an ACK frame that was expected in response to a unicast MPDU, or a failure to receive a BlockAck or ACK frame in response to a BlockAckReq frame.

— The transmission attempt collides internally with another EDCAF of an AC that has higher priority, that is, two or more EDCAFs in the same STA are granted a TXOP at the same time.

If the backoff procedure is invoked for reason a) above, the value of CW[AC] shall be left unchanged. If the backoff procedure is invoked because of reason b) above, the value of CW[AC] shall be reset to CWmin[AC].

If the backoff procedure is invoked because of a failure event [either reason c) or d) above], the value of CW[AC] shall be updated as follows before invoking the backoff procedure:

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001513

a) If the QSRC[AC] or the QLRC[AC] for the QoS STA has reached dot11ShortRetryLimit or dot11LongRetryLimit respectively, CW[AC] shall be reset to CWmin[AC].

b) Otherwise,

   1) If CW[AC] is less than CWmax[AC], CW[AC] shall be set to the value (CW[AC] + 1)*2 – 1.

   2) If CW[AC] is equal to CWmax[AC], CW[AC] shall remain unchanged for the remainder of any retries.

The backoff timer is set to an integer value chosen randomly with a uniform distribution taking values in the range [0,CW[AC]] inclusive.

All backoff slots occur following an AIFS[AC] period during which the medium is determined to be idle for the duration of the AIFS[AC] period, or following an EIFS – DIFS + AIFS[AC] period during which the medium is determined to be idle for the duration of the EIFS – DIFS + AIFS[AC] period, as appropriate (see 9.2.3).

9.9.1.6 Retransmit procedures

QoS STAs shall maintain a short retry counter and a long retry counter for each MSDU or MMPDU that belongs to a TC requiring acknowledgment. The initial value for the short and long retry counters shall be zero. QoS STAs also maintain a short retry counter and a long retry counter for each AC. They are defined as QSRC[AC] and QLRC[AC], respectively, and each is initialized to a value of zero.

After transmitting a frame that requires acknowledgment, the STA shall perform the acknowledgment procedure, as defined in 9.2.8. The short retry count for an MSDU or MMPDU and the QSRC[AC] shall be incremented every time transmission of a MAC frame of length less than or equal to dot11RTSThreshold fails for that MSDU or MMPDU. This short retry count and the QoS STA QSRC[AC] shall be reset when a MAC frame of length less than or equal to dot11RTSThreshold succeeds for that MSDU or MMPDU. The long retry count for an MSDU or MMPDU and the QLRC[AC] shall be incremented every time transmission of a MAC frame of length greater than dot11RTSThreshold fails for that MSDU or MMPDU. This long retry count and the QLRC[AC] shall be reset when a MAC frame of length greater than dot11RTSThreshold succeeds for that MSDU or MMPDU. All retransmission attempts for an MPDU that has failed the acknowledgment procedure one or more times shall be made with the Retry field set to 1 in the data or management frame.

Retries for failed transmission attempts shall continue until the short retry count for the MSDU or MMPDU is equal to dot11ShortRetryLimit or until the long retry count for the MSDU or MMPDU is equal to dot11LongRetryLimit. When either of these limits is reached, retry attempts shall cease, and the MSDU or MMPDU shall be discarded.

For internal collisions occurring with the EDCA access method, the appropriate retry counters (short retry counter for MSDU or MMPDU and QSRC[AC] or long retry counter for MSDU or MMPDU and QLRC[AC]) are incremented. For transmissions that use Block Ack, the rules in 9.10.3 also apply. STAs shall retry failed transmissions until the transmission is successful or until the relevant retry limit is reached.

With the exception of a frame belonging to a TID for which Block Ack is set up, a QoS STA shall not initiate the transmission of any management or data frame to a specific RA while the transmission of another management or data frame with the same RA and having been assigned its sequence number from the same sequence counter has not yet completed to the point of success, retry fail, or other MAC discard (e.g., lifetime expiry).

QoS STAs shall maintain a transmit MSDU timer for each MSDU passed to the MAC. The MIB attribute dot11EDCATableMSDULifetime specifies the maximum amount of time allowed to transmit an MSDU for a given AC. The transmit MSDU timer shall be started when the MSDU is passed to the MAC. If the value of this timer exceeds the appropriate entry in dot11EDCATableMSDULifetime, then the MSDU, or any

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001514

remaining, undelivered fragments of that MSDU, shall be discarded by the source STA without any further attempt to complete delivery of that MSDU.

9.9.2 HCCA

The HCCA mechanism manages access to the WM, using a HC that has higher medium access priority than non-AP STAs. This allows it to transfer MSDUs to non-AP STAs and to allocate TXOPs to non-AP STAs.

The HC is a type of centralized coordinator, but differs from the PC used in PCF in several significant ways, although it may optionally implement the functionality of a PC. Most important is that HCF frame exchange sequences may be used among STAs associated in a BSS during both the CP and the CFP. Another significant difference is that the HC grants a non-AP STA a polled TXOP with duration specified in a QoS (+)CF-Poll frame. Non-AP STAs may transmit multiple frame exchange sequences within given polled TXOPs, subject to the limit on TXOP duration.

All STAs inherently obey the NAV rules of the HCF because each frame transmitted under HCF by the HC or by a non-AP STA contains a duration value chosen to cause STAs in the BSS to set their NAVs to protect the expected subsequent frames.

All non-AP QoS STAs shall be able to respond to QoS (+)CF-Poll frames received from an HC with the Address 1 field matching their own addresses.

The HC shall perform delivery of buffered broadcast and multicast frames following DTIM Beacon frames. The HC may also operate as a PC, providing (non-QoS) CF-Polls to associated CF-Pollable STAs using the frame formats, frame exchange sequences, and other applicable rules for PCF specified in 9.3.[22]

An HC may perform a backoff following an interruption of a frame exchange sequence due to lack of an expected response under the rules described in 9.9.2.1.3, using the parameters dot11HCCWmin, dot11HCCWmax, and dot11HCCAIFSN and the backoff rules in 9.1 and 9.9.1.5. The decision to perform a backoff by the HC is dependent on conditions such as interference from an overlapping BSS. The mechanism to detect the interference from an overlapping BSS and the decision to perform a backoff, DFS (such as in 11.6), or other techniques (such as inter-BSS scheduling) is beyond the scope of this standard.

9.9.2.1 HCCA procedure

The HC gains control of the WM as needed to send QoS traffic to non-AP STAs and to issue QoS (+)CF-Poll frames to non-AP STAs by waiting a shorter time between transmissions than the STAs using the EDCA procedures. The duration values used in QoS frame exchange sequences reserve the medium to permit completion of the current sequence.

The HC may include a CF Parameter Set element in the Beacon frames it generates. This causes the BSS to appear to be a point-coordinated BSS to STAs. This causes STAs to set their NAVs to the CFPDurRemaining value in the CF Parameter Set element value at TBTT, as specified in 9.3.3.2. This prevents most contention in the CFP by preventing nonpolled transmissions by non-AP STAs whether or not they are CF-Pollable.

[22]Attempting to intersperse HCF frame exchange sequences and PCF frame exchange sequences in a single CFP can be extremely complex.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001515

9.9.2.1.1 CFP generation

The HC may function as a PC that uses the CFP for delivery, generating a CFP as shown in Figure 9-13, with the restriction that the CFP initiated by an HC shall always end with a CF-End frame. The HC may also issue QoS (+)CF-Poll frames to associated non-AP STAs during the CFP. However, because the HC can also grant polled TXOPs, by sending QoS (+)CF-Poll frames, during the CP, it is not mandatory for the HC to use the CFP for QoS data transfers.

Only an AP that also issues non-QoS CF-Poll frames to associated CF-Pollable STAs may end a CFP with a CF-End+CF-Ack frame and only when the CF-End+CF-Ack is acknowledging a reception from a CF-Pollable non-QoS STA. The use of a non-QoS CF-Poll frame by an AP to a non-AP QoS STA is deprecated (for further discussion, see 7.3.1.4).

9.9.2.1.2 CAP generation

When the HC needs access to the WM to start a CFP or a TXOP in CP, the HC shall sense the WM. When the WM is determined to be idle for one PIFS period, the HC shall transmit the first frame of any permitted frame exchange sequence, with the duration value set to cover the CFP or the TXOP. The first permitted frame in a CFP after a TBTT is the Beacon frame. CAPs along with the CFPs and the CPs are illustrated in Figure 9-19.

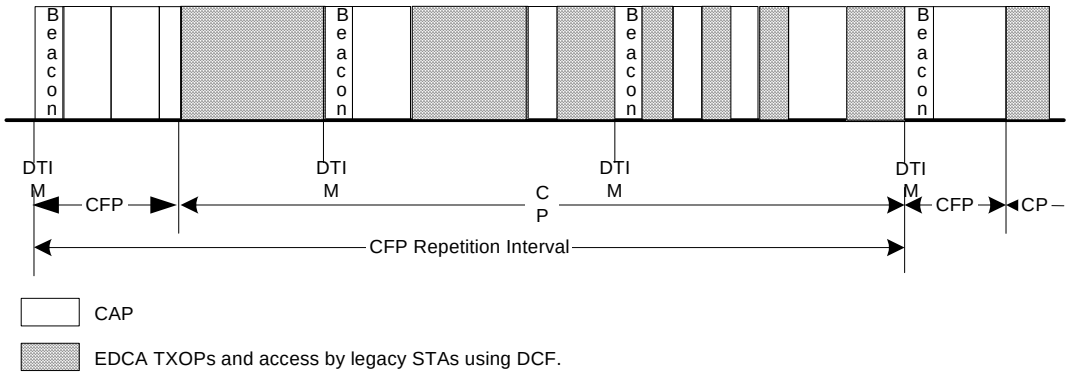

Figure 9-19—CAP/CFP/CP periods

After the last frame of all other nonfinal frame exchange sequences (e.g., sequences that convey unicast QoS data or management frames) during a TXOP, the holder of the current TXOP shall wait for one SIFS period before transmitting the first frame of the next frame exchange sequence. The HC may sense the channel and reclaim the channel after a duration of PIFS after the TXOP, if the channel remains idle. A CAP ends when the HC does not reclaim the channel after a duration of PIFS after the end of a TXOP.

9.9.2.1.3 Recovery from the absence of an expected reception

This subclause describes recovery from the absence of an expected reception in a CAP. It should be noted that the recovery rules from the absence of an expected reception are different from EDCA because in this case the NAVs of all the STAs in the BSS have already been set up by the transmissions by the HC. The recovery rules for the multiple frame transmission are different because a non-AP STA may always be hidden and may have not set its NAV due to the transmission by another non-AP STA. Finally, since an HC is collocated with the AP, the AP may recover using the rules described in this subclause even if the recovery is from the absence of an expected reception.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001516

If the beginning of reception of an expected response, as detected by the occurrence of PHY-CCA.indication(busy) primitive at the STA that is expecting the response, does not occur during the first slot time following SIFS, then[23]

a) If the transmitting STA is the HC, it may initiate recovery by transmitting at a PIFS after the end of the HC's last transmission only if PHY-CCA.indication primitive is clear.

b) If the transmitting STA is a non-AP QoS STA, it shall initiate recovery by transmitting at a PIFS after the end of the last transmission, if the polled TXOP limit is greater than 0 and at least one frame (re)transmissions can be completed within the remaining duration of a nonzero polled TXOP limit.

If the transmitted frame is not of type QoS (+)CF-Poll and the expected response frame is not received correctly, regardless of the occurrence of the PHY-RXSTART.indication primitive, the QoS STA may initiate recovery following the occurrence of PHY-CCA.indication(idle) primitive so that a SIFS time interval occurs between the last energy on the air and the transmission of the recovery frame.

When there is a transmission failure within a polled TXOP, the frame retry counter corresponding to the AC of the failed frame shall be incremented. An MPDU belonging to a TC is subject to the respective retry limit as well as the dot11EDCATableMSDULifetime and is discarded when either of them is exceeded. An MPDU belonging to a TS with a specified delay bound is subject to delay bound and is discarded if the MPDU could not be transmitted successfully since it has been delivered to the MAC. An MPDU belonging to a TS with an unspecified delay is subject to dot11MaxTransmitMSDULifetime and is discarded when it is exceeded.

Non-AP STAs that receive a QoS (+)CF-Poll frame shall respond within a SIFS period, regardless of the NAV setting. If a response is not received but a PHY-CCA.indication(busy) primitive occurs during the slot following SIFS and is followed by a PHY-RXSTART.indication or PHY-RXEND.indication primitive prior to a PHY-CCA.indication(idle) primitive, then the HC shall assume that the transmitted QoS (+)CF-Poll frame was successfully received by the polled non-AP STA. In the cases of QoS Data+CF-Poll, QoS Data+CF-Ack+CF-Poll, or QoS CF-Ack+CF-Poll, the PHY-CCA.indication(busy) primitive is used only to determine whether the transfer of control of the channel has been successful. The PHY-CCA.indication(busy) primitive is not used for determining the success or failure of the transmission. If the CF-Poll is piggybacked onto a QoS data frame, the HC may have to retransmit that QoS data frame subsequently.

If an HC receives a frame from a STA with a duration/ID covering only the response frame, the HC shall assume that the STA is terminating its TXOP, and the HC may initiate other transmissions or allow the channel to go into the CP.

If a polled non-AP QoS STA has no queued traffic to send or if the MPDUs available to send are too long to be transmitted within the specified TXOP limit, the non-AP QoS STA shall send a QoS (+)Null frame. In the case of no queued traffic, this QoS (+)Null frame shall have a QoS Control field that reports a queue size of 0 for any TID with the duration/ID set to the time required for the transmission of one ACK frame, plus one SIFS interval. In the case of insufficient TXOP size, such as when the maximum MSDU size is not specified, this QoS (+)Null frame shall have a QoS Control field that contains the TID and TXOP duration or a nonzero queue size needed to send the MPDU that is ready for transmission. When a queue size is transmitted, the HC shall combine the queue size information with the rate of the received QoS (+)Null frame to determine the required size of the requested TXOP.

Within a polled TXOP, the unused portion of TXOPs shall be returned back to the HC. The recipient of the final frame, with the Ack Policy subfield set to Normal Ack, shall be the HC if there will be time remaining in the TXOP after the transmission of the final frame and its expected ACK response frame. If there are no frames to be sent to the HC, then the non-AP QoS STA shall send to the HC a QoS Null with the Queue Size subfield in the QoS Control field set to 0. If there is not enough time within the unused portion of the TXOP to transmit

[23] This restriction is intended to avoid collisions due to inconsistent CCA reports in different STAs, not to optimize the bandwidth usage efficiency.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001517

either the QoS Null frame or the frame with the Duration/ID field covering only the response frame, then the non-AP STA shall cease control of the channel.[24] If the beginning of the reception of an expected ACK response frame to the final frame does not occur, detected as the nonoccurrence of PHY-CCA.indication(busy) primitive at the non-AP QoS STA that is expecting the response during the first slot time following SIFS, the non-AP QoS STA shall retransmit the frame or transmit a QoS Null frame, with the Ack Policy subfield set to Normal Ack and the Queue Size subfield set to 0, after PIFS from the end of last transmission, until such time that it receives an acknowledgment or when there is not enough time remaining in the TXOP for sending such a frame. This is to avoid the situation where the HC may not receive the frame and may result in an inefficient use of the channel. If a PHY-CCA.indication(busy) primitive occurs at the non-AP STA that is expecting the ACK response frame during the first slot following SIFS after the end of the transmission of the final frame, it shall be interpreted as indicating that the channel control has been successfully transferred and no further frames shall be transmitted by the non-AP STA in the TXOP, even though the ACK frame from HC may be incorrectly received. Note that while PHY-CCA.indication(busy) primitive is used in this instance to determine the control of the channel, it is not used for determining the success or failure of the transmission.

9.9.2.2 TXOP structure and timing

Any QoS data frame of a subtype that includes CF-Poll contains a TXOP limit in its QoS Control field. The ensuing polled TXOP is protected by the NAV set by the Duration field of the frame that contained the QoS (+)CF-Poll function, as shown in Figure 9-20. Within a polled TXOP, a STA may initiate the transmission of one or more frame exchange sequences, with all such sequences nominally separated by a SIFS interval. The STA shall not initiate transmission of a frame unless the transmission and any acknowledgment or other immediate response expected from the peer MAC entity are able to complete prior to the end of the remaining TXOP duration. All transmissions, including the response frames, within the polled TXOP are considered to be the part of the TXOP, and the HC shall account for these when setting the TXOP limit. If the TXOP Limit subfield in the QoS Control field of the QoS data frame that includes CF-Poll is set to 0, then the STA to which the frame is directed to shall respond with either one MPDU or one QoS Null frame.

A TXOP or transmission within a TXOP shall not extend across TBTT, dot11CFPMaxDuration (if during CFP), dot11MaxDwellTime (if using an FH PHY), or dot11CAPLimit. The HC shall ensure that the full duration of any granted TXOP meets these requirements so that non-AP STAs may use the time prior to the TXOP limit of a polled TXOP without checking for these constraints. Subject to these limitations, all decisions regarding what MSDUs and/or MMPDUs are transmitted during any given TXOP are made by the STA that holds the TXOP.[25, 26]

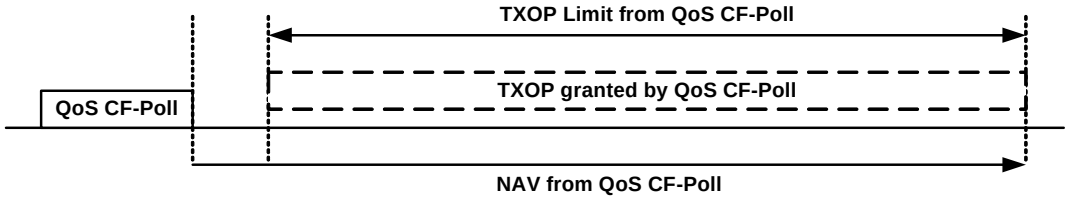

Figure 9-20—Polled TXOP

[24]In this case the channel will not be accessed until the NAVs expire at all the STAs.

[25]In certain regulatory domains, channel sensing must be done at periodic intervals (for example, in Japan, this period is 4 ms). This means that the duration of a TXOP in these regulatory domains might not be more than this periodic interval. If longer durations are desired, then the TXOP holder needs to sense the channel at least once in the limit imposed in the regulatory domain, by waiting for at least for the duration of one PIFS during which it senses the channel. If it does not detect any energy, it may continue by sending the next frame. In other words, the total TXOP size assigned should include an extra time allocated (i.e., $n \times$ aSlotTime, where n is the number of times the STA needs to sense the channel and is given by floor(TXOP limit/limit imposed in the regulatory domain).

[26]The TID value in the QoS Control field of a QoS Data+CF-Poll frame pertains only to the MSDU or fragment thereof in the Frame Body field of that frame. This TID value does not pertain to the TXOP limit value and does not place any constraints on what frame(s) the addressed STA may send in the granted TXOP.

Exhibit 1014
Page 001518

9.9.2.2.1 NAV operation during a TXOP

A HC shall set its own NAV to prevent its transmitting during a TXOP that it has granted to a STA through an HCCA poll. However, the HC may reclaim the TXOP if a STA is not using it or ends the TXOP early (see 9.9.2.1.3).

In a CFP or CP, if the HC has no more STAs to poll and it has no more data, management, BlockAckReq, or BlockAck frames to send, it may reset the NAVs of all STAs in the BSS by sending a QoS CF-Poll frame with the RA matching its own MAC address and with the Duration/ID field set to 0. When the AP contains a PC, during the CFP, it may reset the NAVs of all STAs within the BSS (i.e., corresponding to the same BSSID) by sending a CF-End frame, regardless of how the NAVs have been originally set.

A non-AP STA that receives a CF-End frame containing the BSSID of the BSS, in which the non-AP STA is associated, shall reset the NAV value to 0. A non-AP STA that receives a QoS (+)CF-Poll frame with a MAC address in the Address 1 field that matches the HC's MAC address and the Duration/ID field value equal to zero shall reset the NAV value to 0.

When a STA receives a QoS (+)CF-Poll frame containing the BSSID of the BSS in which the STA is associated, that STA shall update the NAV if necessary and shall save the TXOP holder address for that BSS, which is the MAC address from the Address 1 field of the frame containing the QoS (+)CF-Poll. If an RTS frame is received with the RA address matching the MAC address of the STA and the MAC address in the TA field in the RTS frame matches the saved TXOP holder address, then the STA shall send the CTS frame after SIFS, without regard for, and without resetting, its NAV. The saved TXOP holder address shall be cleared when the NAV is reset or when the NAV counts down to 0.

When a STA receives a frame addressed to it and requires an acknowledgment, it shall respond with an ACK or QoS +CF-Ack frame independent of its NAV. A non-AP STA shall accept a polled TXOP by initiating a frame exchange sequence independent of its NAV.

9.9.2.3 HCCA transfer rules

A TXOP obtained by receiving a QoS (+)CF-Poll frame uses the specified TXOP limit consisting of one or more frame exchange sequences with the sole time-related restriction being that the final sequence shall end not later than the TXOP limit. In QoS CF-Poll and QoS CF-Ack+CF-Poll frames, the TID subfield in the QoS Control field indicates the TS for which the poll is intended. The requirement to respond to that TID is nonbinding, and a STA may respond with any frame. Upon receiving a QoS (+)CF-Poll frame, a non-AP STA may send any frames, i.e., QoS data frames belonging to any TID as well as management frames in the obtained TXOP. MSDUs may be fragmented in order to fit within TXOPs.

The QoS CF-Poll frames shall be sent only by an HC. Non-AP STAs are not allowed to send QoS (+)CF-Poll frames. Non-AP STAs shall not send QoS (+)Data frames in response to any data frame other than the QoS (+)CF-Poll frames.

If a STA has set up at least one TS for which the Aggregation subfield in the associated TSPEC is set to 0, the AP shall use only QoS CF-Poll or QoS CF-Ack+CF-Poll frames to poll the STA and shall never use QoS (+)Data+CF-Poll to poll the STA. It should be noted that although QoS (+)CF-Poll is a data frame, but it should be transmitted at one of the rates in the BSSBasicRateSet parameter in order to set the NAV of all STAs that are not being polled (see 9.6). If a CF-Poll is piggybacked with a QoS data frame, then the MSDU may be transmitted at the rate that is below the negotiated minimum PHY rate.

QoS STAs shall use QoS data frames for all MSDU transfers to another QoS STA. The TID in the QoS Control fields of these frames shall indicate the TC or TS to which the MPDU belongs. Furthermore, either the Queue Size subfield shall indicate the amount of queued traffic present in the output queue that the STA uses for traffic belonging to this TC or TS, or the TXOP Duration Requested subfield shall indicate the duration that the

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001519

STA desires for the next TXOP for traffic belonging to this TC or TS. The queue size value reflects the amount on the appropriate queue not including the present MPDU. A non-AP STA that wishes to inform the HC of queue status may use the QoS Null frame indicating the TID and the queue size or TXOP duration request (also see 9.9.2.3.1).

QoS STAs shall be able to receive QoS +CF-Ack frames. The HC may use QoS Data+CF-Ack frames to send frames to the same non-AP STA a SIFS after receiving the final transmission of the previous TXOP. The HC may also use QoS Data+CF-Ack frames to send frames to any other non-AP STA a SIFS after receiving the final transmission of the previous TXOP, if the non-AP STA that sent the final transmission of the previous TXOP has set the Q-Ack subfield in the QoS Capability information element in the (Re)Association Request frame to 1. In both CFP and CP, STAs shall always respond to QoS data frames having the Ack Policy subfield in the QoS Control field set to Normal Ack with an ACK frame, unless the acknowledgment is piggybacked in which case it shall use a QoS +CF-Ack frame. Piggybacked frames are allowed only in CFP or within TXOPs initiated by the HC. The HC shall not send a QoS data frame containing a +CF-Ack with an Address 1 that does not correspond to the address of the STA for which the +CF-Ack is intended, unless the STA to which the +CF-Ack is intended, sets the Q-Ack subfield in the QoS Capability information element in the (Re)Association Request frame. STAs are not required to be able to transmit QoS data frames with subtypes that include +CF-Ack.

An AP that has dot11QAckOptionImplemented true may allow associations with STAs advertising support for the Q-Ack option. Such associations do not require the AP to employ piggyback acknowledgments directed toward that associated STA in frames that are not directed to that associated STA. QoS STAs shall be able to process received QoS data frames with subtypes that include +CF-Ack when the STA to which the acknowledgment is directed is the same as the STA addressed by the Address 1 field of that data frame. A STA that does not set the Q-Ack subfield to 1 in the QoS Capability information element in the (Re)Association Request frame is not required to handle the received QoS (+)Data+CF-Ack frames that are addressed to other STAs. The net effect of these restrictions on the use of QoS +CF-Ack frames is that the principal QoS +CF-Ack subtype that is useful is the QoS Data+CF-Ack frame, which can be sent by a non-AP STA as the first frame in a polled TXOP when that TXOP was conveyed in a QoS Data+CF-Poll(+CF-Ack) frame and the outgoing frame is directed to the HC's STA address. QoS (Data+)CF-Poll+CF-Ack frames are useful if the HC wants to grant another TXOP to the same non-AP STA a SIFS after receiving the final transmission of that non-AP STA's previous TXOP. QoS (Data+)CF-Poll+CF-Ack frames are also useful if the HC wants to grant another TXOP to a different non-AP STA a SIFS after receiving the final transmission of a non-AP STA's previous TXOP, if the non-AP STA that sent the final transmission of the previous TXOP has set the Q-Ack subfield in the QoS Capability information element in the (Re)Association Request frame to 1.

HCF contention-based channel access shall not be used to transmit MSDUs belonging to an established TS (with the HC's acceptance of the associated TSPEC), unless the granted TSPEC indicates it is permitted to do so when the Access Policy subfield of the TS Info field is set to "HCCA, EDCA mixed mode" (HEMM), the polled STA utilized the full TXOP provided by the HC, and it has to send more MPDUs. When this STA sends frames belonging to a TS using contention-based channel access, it shall encode the TID subfield in the QoS data frame with the TID associated with the TS. When the AP grants a TSPEC with the Access Policy subfield set to HEMM and if the corresponding AC needs admission control, the AP shall include the medium time that specifies the granted time for EDCA access in the ADDTS Response frame.

9.9.2.3.1 TXOP requests

Non-AP STAs may send TXOP requests during polled TXOPs or EDCA TXOPs using the QoS Control field in the QoS data or QoS Null frame directed to the HC, with the TXOP Duration Requested or Queue Size subfield value and TID subfield value indicated to the HC. APs indicate whether they process TXOP request or queue size in the QoS Info field in the Beacon, Probe Response, and (Re)Association Response frames. APs shall process requests in at least one format. The AP may reallocate TXOPs if the request belongs to TS or update the EDCA parameter set if the above request belongs to TC. Non-AP STAs shall use only the request format that the AP indicates it can process.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001520

Even if the value of TXOP Duration Requested subfield or Queue Size subfield in a QoS data frame is zero, the HC shall continue to poll according to the negotiated schedule.

9.9.2.3.2 Use of RTS/CTS

STAs may send an RTS frame as the first frame of any frame exchange sequence for which improved NAV protection is desired, during either the CP or CFP, and without regard for dot11RTSThreshold.[27]

If a QoS STA sends an RTS frame and does not receive an expected CTS frame, then the recovery rules are as specified in 9.9.2.1.3.

If NAV protection is desired for a transmission to the AP in response to a QoS data frame with a subtype that includes CF-Poll, the polled non-AP STA is allowed to send a CTS frame (as a CTS frame is shorter than a QoS data frame and can be sent with a higher probability that it will be received by other STAs) with the RA containing its own MAC address in order to set the NAV in its own vicinity without the extra time to send an RTS frame.[28]

9.9.3 Admission Control at the HC

An IEEE 802.11 network may use admission control to administer policy or regulate the available bandwidth resources. Admission control is also required when a STA desires guarantee on the amount of time that it can access the channel. The HC, which is in the AP, is used to administer admission control in the network. As the QoS facility supports two access mechanisms, there are two distinct admission control mechanisms: one for contention-based access and another for controlled access.

Admission control, in general, depends on vendors' implementation of the scheduler, available channel capacity, link conditions, retransmission limits, and the scheduling requirements of a given stream. All of these criteria affect the admissibility of a given stream. If the HC has admitted no streams that require polling, it may not find it necessary to perform the scheduler or related HC functions.

9.9.3.1 Contention-based admission control procedures

A non-AP STA may support admission control procedures in 9.9.3.1.2 to send frames in the AC where admission control is mandated; but, if it does not support that procedure, it shall use EDCA parameters of a lower priority AC, as indicated in Table 9-1, that does not require admission control. APs shall support admission control procedures, at least to the minimal extent of advertising that admission is not mandatory on its ACs.

The AP uses the ACM (admission control mandatory) subfields advertised in the EDCA Parameter Set element to indicate whether admission control is required for each of the ACs. While the CWmin, CWmax, AIFS, TXOP limit parameters may be adjusted over time by the AP, the ACM bit shall be static for the duration of the lifetime of the BSS. An ADDTS Request frame shall be transmitted by a non-AP STA to the HC in order to request admission of traffic in any direction (i.e., uplink, downlink, direct, or bidirectional) employing an AC that requires admission control. The ADDTS Request frame shall contain the UP associated with the traffic and shall indicate EDCA as the access policy. The AP shall associate the received UP of the ADDTS Request frame with the appropriate AC per the UP-to-AC mappings described in 9.1.3.1. The non-AP STA may

[27]The sending of an RTS frame during the CFP is usually unnecessary, but may be used to ensure that the addressed recipient QoS STA is within range and awake and to elicit a CTS response that sets the NAV at STAs in the vicinity of the addressed recipient. This is useful when there are nearby STAs that are members of other BSSs and are out of range to receive Beacon frames from this BSS. Sending an RTS frame during the CFP is useful only when the recipient is a QoS STA, because a non-QoS STA in the same BSS has its NAV set to protect the CFP, which renders those non-QoS STAs unable to respond. Using the same duration calculation during the CFP as specified for the CP is directly applicable for all cases except when the RTS frame is sent by the HC and the following frame includes a QoS (+)CF-Poll.

[28]This is unnecessary because the NAVs in the vicinity of the QoS AP were set by the QoS (+)CF-Poll frame.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001521

transmit unadmitted traffic for the ACs for which the AP does not require admission control. If a STA desires to send data without admission control using an AC that mandates admission control, the STA shall use EDCA parameters that correspond to a lower priority and do not require admission control. All ACs with priority higher than that of an AC with an ACM flag equal to 1 should have the ACM flag set to 1.

9.9.3.1.1 Procedures at the AP

Regardless of the AC's ACM setting, the AP shall respond to an ADDTS Request frame with an ADDTS Response frame that may be to accept or deny the request. On receipt of an ADDTS Request frame from a non-AP STA, the AP shall make a determination about whether to

a) Accept the request, or

b) Deny the request.

The algorithm used by the AP to make this determination is a local matter. If the AP decides to accept the request, the AP shall also derive the medium time from the information conveyed in the TSPEC element in the ADDTS Request frame. The AP may use any algorithm in deriving the medium time, but K.2.2 provides a procedure that may be used. Having made such a determination, the AP shall transmit a TSPEC element to the requesting non-AP STA contained in an ADDTS Response frame. If the AP is accepting the request, the Medium Time field shall be specified.

9.9.3.1.2 Procedure at non-AP STAs

Each EDCAF shall maintain two variables: admitted_time and used_time.

The admitted_time and used_time shall be set to 0 at the time of (re)association. The non-AP STA may subsequently decide to explicitly request medium time for the AC that is associated with the specified priority.

In order to make such a request, the non-AP STA shall transmit a TSPEC element contained in an ADDTS Request frame with the following fields specified (i.e., nonzero): Nominal MSDU Size, Mean Data Rate, Minimum PHY Rate, Inactivity Interval, and Surplus Bandwidth Allowance. The Medium Time field is not used in the request frame and shall be set to 0.

On receipt of a TSPEC element contained in a ADDTS Response frame indicating that the request has been accepted, the non-AP STA shall recompute the admitted_time for the specified EDCAF as follows:

admitted_time = admitted_time + dot11EDCAAveragingPeriod * (medium time of TSPEC).

The non-AP STA may choose to tear down the explicit request at any time. For the teardown of an explicit admission, the non-AP STA shall transmit a DELTS frame containing the TSID and direction that specify the TSPEC to the AP.

If the non-AP STA sends or receives a DELTS frame, it shall recompute the admitted_time for the specified EDCAF as follows:

admitted_time = admitted_time – dot11EDCAAveragingPeriod * (medium time of TSPEC).

To describe the behavior at the non-AP STA, two parameters are defined. The parameter used_time signifies the amount of time used, in units of 32 μs, by the non-AP STA in dot11EDCAAveragingPeriod. The parameter admitted_time is the medium time allowed by the AP, in units of 32 μs, in dot11EDCA-AveragingPeriod. The non-AP STA shall update the value of used_time:

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001522

a) At dot11EDCAAveragingPeriod second intervals

used_time = max((used_time – admitted_time), 0)

b) After each successful or unsuccessful MPDU (re)transmission attempt,

used_time = used_time + MPDUExchangeTime

The MPDUExchangeTime equals the time required to transmit the MPDU sequence. For the case of an MPDU transmitted with Normal Ack policy and without RTS/CTS protection, this equals the time required to transmit the MPDU plus the time required to transmit the expected response frame plus one SIFS. If the used_time value reaches or exceeds the admitted_time value, the corresponding EDCAF shall no longer transmit using the EDCA parameters for that AC as specified in the QoS Parameter Set element. However, a non-AP STA may choose to temporarily replace the EDCA parameters for that EDCAF with those specified for an AC of lower priority, if no admission control is required for those ACs.

If, for example, a non-AP STA has made and had accepted an explicit admission for a TS and the channel conditions subsequently worsen, possibly including a change in PHY data rate so that it requires more time to send the same data, the non-AP STA may make a request for more admitted_time to the AP and at the same time downgrade the EDCA parameters for that AC for short intervals in order to send some of the traffic at the admitted priority and some at the unadmitted priority, while waiting for a response to the admission request.

9.9.3.2 Controlled-access admission control

This subclause describes the schedule management of the admitted HCCA streams by the HC. When the HC provides controlled channel access to non-AP STAs, it is responsible for granting or denying polling service to a TS based on the parameters in the associated TSPEC. If the TS is admitted, the HC is responsible for scheduling channel access to this TS based on the negotiated TSPEC parameters. The HC should not initiate a modification of TSPEC parameters of an admitted TS unless requested by the STA. The HC should not tear down a TS unless explicitly requested by the STA or at the expiry of the inactivity timer. The polling service based on admitted TS provides a “guaranteed channel access” from the scheduler in order to have its QoS requirements met. This is an achievable goal when the WM operates free of external interference (such as operation within the channel by other technologies and co-channel overlapping BSS interference). The nature of wireless communications may preclude absolute guarantees to satisfy QoS requirements. However, in a controlled environment (e.g., no interference), the behavior of the scheduler can be observed and verified to be compliant to meet the service schedule.

The normative behavior of the scheduler is as follows:

— The scheduler shall be implemented so that, under controlled operating conditions, all STAs with admitted TS are offered TXOPs that satisfy the service schedule.

— Specifically, if a TS is admitted by the HC, then the scheduler shall service the non-AP STA during an SP. An SP is a contiguous time during which a set of one or more downlink unicast frames and/or one or more polled TXOPs are granted to the STA. An SP starts at fixed intervals of time specified in Service Interval field. The first SP starts when the lower order 4 octets of the TSF timer equals the value specified in Service Start Time field.[29] Additionally, the minimum TXOP duration shall be at least the time to transmit one maximum MSDU size successfully at the minimum PHY rate specified in the TSPEC. If maximum MSDU size is not specified in the TSPEC, then the minimum TXOP duration shall be at least the time to transmit one nominal MSDU size successfully at the minimum PHY rate. The vendors are free to implement any optimized algorithms, such as reducing the polling overheads, increasing the TXOP duration, etc., within the parameters of the transmitted schedule.

[29]The lower order 4 octets of the TSF timer cover a span of around 71 min. Due to TSF timer wrapover and due to the possibility of receiving the schedule frame after the indicated start time timer, ambiguity may occur. This ambiguity is resolved by using the nearest absolute TSF timer value in past or future when the lower order 4 octets match the Start Time field in the Schedule element.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001523

When the HC aggregates the admitted TS, it shall set the Aggregation field in the granted TSPEC to 1. An AP shall schedule the transmissions in HCCA TXOPs and communicate the service schedule to the non-AP STA. The HC shall provide an aggregate service schedule if the non-AP STA sets the Aggregation field in its TSPEC request. If the AP establishes an aggregate service schedule for a non-AP STA, it shall aggregate all HCCA streams for the STA. The service schedule is communicated to the non-AP STA in a Schedule element contained in an ADDTS Response frame. In the ADDTS Response frame, the modified service start time shall not exceed the requested service start time, if specified in ADDTS Request frame, by more than one maximum service interval (SI). The HC uses the maximum SI for the initial scheduling only as there may be situations that HC may not be able to service the TS at the scheduled timing, due to an EDCA or DCF transmission or other interferences interrupting the schedule. The Service Interval field value in the Schedule element shall be greater than the minimum SI. The service schedule could be subsequently updated by an AP as long as it meets TSPEC requirements.

The HC may update the service schedule at any time by sending a Schedule element in a Schedule frame. The updated schedule is in effect when the HC receives the ACK frame for the Schedule frame. The service start time in the Schedule element in the Schedule frame shall not exceed the beginning of the immediately previous SP by more than the maximum SI. The service start time shall not precede the beginning of the immediately previous SP by more than the minimum SI.

A non-AP STA may affect the service schedule by modifying or deleting its existing TS as specified in 11.4.

K.3.1 provides guidelines for deriving an aggregate service schedule for a single non-AP STA from the non-AP STA's admitted TS. The schedule shall meet the QoS requirements specified in the TSPEC.

During any time interval [$t1$, $t2$] including the interval that is greater than the specification interval, the cumulative TXOP duration shall be greater than the time required to transmit all MSDUs (of nominal MSDU size) arriving at the mean data rate for the stream, over the period [$t1$, $t2 - D$]. The parameter D is set to the specified maximum SI in the TSPEC. If maximum SI is not specified, then D is set to the delay bound in the TSPEC.

The HC shall use the minimum PHY rate in calculating TXOPs if the minimum PHY rate is present in the TSPEC field in the ADDTS response. Otherwise, the HC may use an observed PHY rate in calculating TXOPs. Non-AP STAs may have an operational rate lower than the minimum PHY rate due to varying conditions on the channel for a short time and still may be able to sustain the TS without changing the minimum PHY rate in the TSPEC.

A minimum set of TSPEC parameters shall be specified during the TSPEC negotiation. The specification of a minimum set of parameters is required so that the scheduler can determine a schedule for the stream that is to be admitted. These parameters are Mean Data Rate, Nominal MSDU Size, Minimum PHY Rate, Surplus Bandwidth Allowance, and at least one of Maximum Service Interval and Delay Bound in the ADDTS Request frame. In the ADDTS Response frame, these parameters are Mean Data Rate, Nominal MSDU Size, Minimum PHY Rate, Surplus Bandwidth Allowance, and Maximum Service Interval and shall be nonzero when a stream is admitted.

If any of the elements in the minimum set of parameters does not have the required nonzero value, as specified above in this subclause, in the ADDTS Request frame, the HC may replace the unspecified parameters with nonzero values and admit the stream, or it may reject the stream. If the HC admits the stream with the alternative set of TSPEC parameters, these parameters are indicated to the non-AP STA through the ADDTS Response frame. If both maximum SI and delay bound are specified, the HC may use only the maximum SI. If any other parameter is specified in the TSPEC element, the scheduler may use it when calculating the schedule for the stream. The HC may also use the UP value in the TS Info field for admission control or scheduling purposes; however, this decision is outside the scope of this standard. The mandatory set of parameters can be set by any higher layer entity or may be generated autonomously by the MAC.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001524

If a STA specifies a nonzero minimum SI and if the TS is admitted, the HC shall generate a schedule that conforms to the specified minimum SI.

A reference design for a sample scheduler and admission control unit is provided in Annex K. A sample use of the TSPEC for admission control is also described in Annex K.

9.10 Block Acknowledgment (Block Ack)

9.10.1 Introduction

The Block Ack mechanism improves channel efficiency by aggregating several acknowledgments into one frame. There are two types of Block Ack mechanisms: immediate and delayed. Immediate Block Ack is suitable for high-bandwidth, low-latency traffic while the delayed Block Ack is suitable for applications that tolerate moderate latency.[30] In this subclause, the STA with data to send using the Block Ack mechanism is referred to as the *originator*, and the receiver of that data as the *recipient*.

The Block Ack mechanism is initialized by an exchange of ADDBA Request/Response frames. After initialization, blocks of QoS data frames can be transmitted from the originator to the recipient. A block may be started within a polled TXOP or by winning EDCA contention. The number of frames in the block is limited, and the amount of state that is to be kept by the recipient is bounded. The MPDUs within the block of frames are acknowledged by a BlockAck control frame, which is requested by a BlockAckReq control frame.

The Block Ack mechanism does not require the setting up of a TS; however, QoS STAs using the TS facility may choose to signal their intention to use Block Ack mechanism for the scheduler's consideration in assigning TXOPs. Acknowledgments of frames belonging to the same TID, but transmitted during multiple TXOPs, may also be combined into a single BlockAck frame. This mechanism allows the originator to have flexibility regarding the transmission of data MPDUs. The originator may split the block of frames across TXOPs, separate the data transfer and the Block Ack exchange, and interleave blocks of MSDUs for different TIDs or RAs.

Figure 9-21 illustrates the message sequence chart for the setup, data and Block Ack transfer, and the teardown of the Block Ack mechanism, which are discussed in detail in 9.10.2 through 9.10.5.

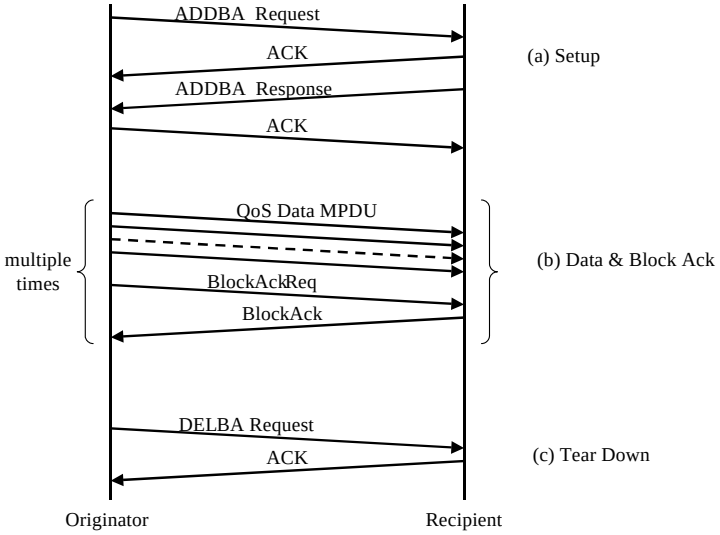

Figure 9-21—Message sequence chart for Block Ack mechanism: (a) setup, (b) data and acknowledgment transfer and (c) tear down

[30] The delayed Block Ack mechanism is primarily intended to allow existing implementations to use this feature with minimal hardware changes and also to allow inexpensive implementations that would use the processing power on the host.

Exhibit 1014
Page 001525

9.10.2 Setup and modification of the Block Ack parameters

A STA that intends to use the Block Ack mechanism for the transmission of QoS data frames to a peer should first check whether the intended peer STA is capable of participating in Block Ack mechanism by discovering and examining its Delayed Block Ack and Immediate Block Ack capability bits. If the intended peer STA is capable of participating, the originator sends an ADDBA Request frame indicating the TID for which the Block Ack is being set up. The Block Ack Policy and Buffer Size fields in the ADDBA Request frame are advisory and may be changed by the recipient. The receiving STA shall respond by an ADDBA Response frame. The receiving STA, which is the intended peer, has the option of accepting or rejecting the request. When the STA accepts, then a Block Ack agreement exists between the originator and recipient. When the STA accepts, it indicates the type of Block Ack and the number of buffers that it shall allocate for the support of this block. If the receiving STA rejects the request, then the originator shall not use the Block Ack mechanism.

If the Block Ack mechanism is being set up for a TS, bandwidth negotiation (using ADDTS Request and Response frames) should precede the setup of the Block Ack mechanism.

Once the Block Ack exchange has been set up, data and ACK frames are transferred using the procedure described in 9.10.3.

9.10.3 Data and acknowledgment transfer

After setting up for the Block exchange following the procedure in 9.10.2, the originator may transmit a block of QoS data frames separated by SIFS period, with the total number of frames not exceeding the Buffer Size subfield value in the associated ADDBA Response frame. Each of the frames shall have the Ack Policy subfield in the QoS Control field set to Block Ack. The RA field of the frames shall be the recipient's *unicast* address. The originator requests acknowledgment of outstanding QoS data frames by sending a BlockAckReq frame. The recipient shall maintain a Block Ack record for the block.

Subject to any constraints in this subclause about permitted use of TXOP according to the channel access mechanism used, the originator may

— Separate the Block and BlockAckReq frames into separate TXOPs

— Split a Block frame across multiple TXOPs

— Split transmission of data MPDUs sent under Block Ack policy across multiple TXOPs

— Interleave MPDUs with different TIDs within the same TXOP

— Sequence or interleave MPDUs for different RAs within a TXOP

A protective mechanism (such as transmitting using HCCA, RTS/CTS, or the mechanism described in 9.13) should be used to reduce the probability of other STAs transmitting during the TXOP. If no protective mechanism is used, then the first frame that is sent as a block shall have a response frame and shall have the Duration field set so that the NAVs are set to appropriate values at all STAs in the BSS.

The originator shall use the Block Ack starting sequence control to signal the first MPDU in the block for which an acknowledgment is expected. MPDUs in the recipient's buffer with a sequence control value that precedes the starting sequence control value are called *preceding MPDUs*. The recipient shall reassemble any complete MSDUs from buffered preceding MPDUs and indicate these to its higher layer. The recipient shall then release any buffers held by preceding MPDUs. The range of the outstanding MPDUs (i.e., the reorder buffer) shall begin on an MSDU boundary. The total number of frames that can be sent depends on the total number of MPDUs in all the outstanding MSDUs. The total number of MPDUs in these MSDUs may not exceed the reorder buffer size in the receiver.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001526

The recipient shall maintain a Block Ack record consisting of originator address, TID, and a record of reordering buffer size indexed by the received MPDU sequence control value. This record holds the acknowledgment state of the data frames received from the originator.

If the immediate Block Ack policy is used, the recipient shall respond to a BlockAckReq frame with a BlockAck frame. If the recipient sends the BlockAck frame, the originator updates its own record and retries any frames that are not acknowledged in the BlockAck frame, either in another block or individually.

If the delayed Block Ack policy is used, the recipient shall respond to a BlockAckReq frame with an ACK frame. The recipient shall then send its Block Ack response in a subsequently obtained TXOP. Once the contents of the BlockAck frame have been prepared, the recipient shall send this frame in the earliest possible TXOP using the highest priority AC. The originator shall respond with an ACK frame upon receipt of the BlockAck frame. If delayed Block Ack policy is used and if the HC is the recipient, then the HC may respond with a +CF-Ack frame if the BlockAckReq frame is the final frame of the polled TXOP's frame exchange. If delayed Block Ack policy is used and if the HC is the originator, then the HC may respond with a +CF-Ack frame if the BlockAck frame is the final frame of the TXOP's frame exchange.

The BlockAck frame contains acknowledgments for the MPDUs of up to 64 previous MSDUs. In the BlockAck frame, the STA acknowledges only the MPDUs starting from the starting sequence control until the MPDU with the highest sequence number (modulo 2^{12}) that has been received, and the STA shall set bits in the Block Ack bitmap corresponding to all other MPDUs to 0. The status of MPDUs that are considered "old" and prior to the sequence number range for which the receiver maintains status shall be reported as successfully received (i.e., the corresponding bit in the bitmap shall be set to 1). The sequence number space is considered divided into two parts, one of which is "old" and one of which is "new" by means of a boundary created by adding half the sequence number range to the current start of receive window (modulo 2^{12}). If the BlockAck frame indicates that an MPDU was not received correctly, the originator shall retry that MPDU subject to that MPDU's appropriate lifetime limit.

A typical BlockAck frame exchange sequence using the immediate Block Ack for a single TID is shown in Figure 9-22.

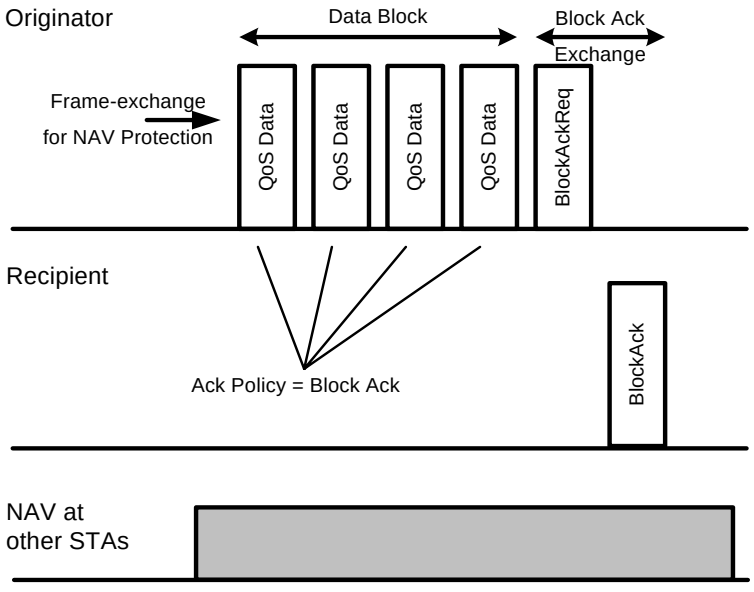

Figure 9-22—A typical Block Ack sequence when immediate policy is used

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001527

A typical Block Ack sequence using the delayed Block Ack is shown in Figure 9-23.

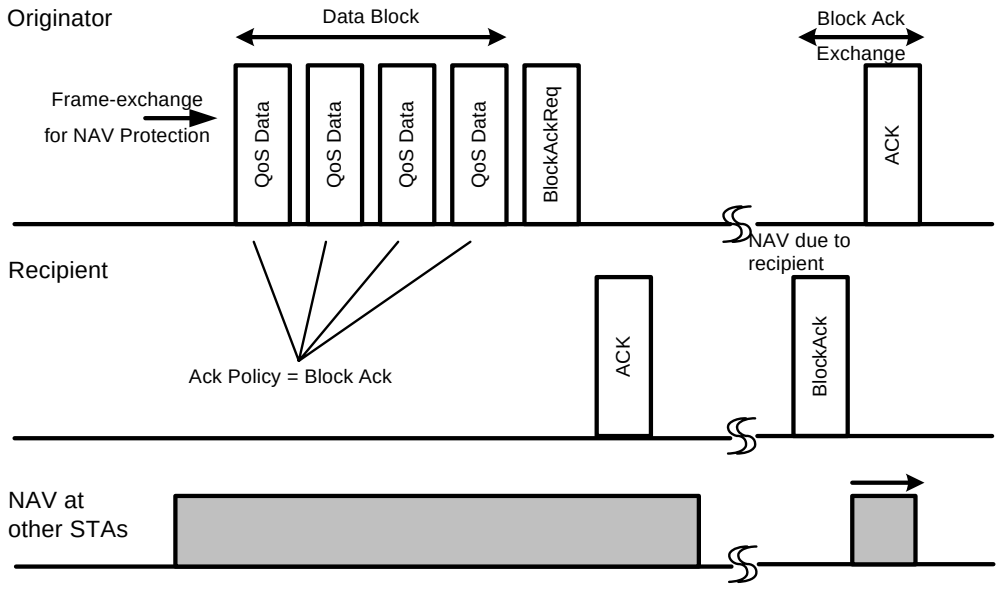

Figure 9-23—A typical BlockAck sequence when delayed policy is used

The subsequent Block Ack request starting sequence number shall be higher than or equal to the starting sequence number (modulo 2^{12}) of the immediately preceding BlockAckReq frame for the same TID.

The originator may continue to transmit MPDUs to the recipient after transmitting the BlockAckReq frame, but before receiving the BlockAck frame (applicable only to delayed Block Ack). The bitmap in the BlockAck frame shall include the status of frames received between the start sequence number and the transmission of the BlockAckReq frame. A recipient sending a delayed BlockAck frame may update the bitmap with information on QoS data frames received between the receipt of the BlockAckReq frame and the transmission of the BlockAck frame.

If there is no response (i.e., neither a BlockAck nor an ACK frame) to the BlockAckReq frame, the originator may retransmit the BlockAckReq frame within the current TXOP (if time permits) or within a subsequent TXOP. MSDUs that are sent using the Block Ack mechanism are not subject to retry limits but only to MSDU lifetime. The originator need not set the retry bit for any possible retransmissions of the MPDUs.

The BlockAckReq frame shall be discarded if all MSDUs referenced by this BlockAckReq frame have been discarded from the transmit buffer due to expiry of their lifetime limit.

In order to improve efficiency, originators using the Block Ack facility may send MPDU frames with the Ack Policy subfield in QoS control frames set to Normal Ack if only a few MPDUs are available for transmission. The Block Ack record shall be updated irrespective of the Ack Policy subfield in the QoS data frame for the TID with an active Block Ack. When there are sufficient number of MPDUs, the originator may switch back to the use of Block Ack. The reception of QoS data frames using Normal Ack policy shall not be used by the recipient to reset the timer to detect Block Ack timeout (see 11.5.3). This allows the recipient to delete the Block Ack if the originator does not switch back to using Block Ack.

The frame exchange sequences are provided in 9.12.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001528

9.10.4 Receive buffer operation

Upon the receipt of a QoS data frame from the originator for which the Block Ack agreement exists, the recipient shall buffer the MSDU regardless of the value of the Ack Policy subfield within the QoS Control field of the QoS data frame.

The recipient flushes received MSDUs from its receive buffer as described in this subclause.

If a BlockAckReq frame is received, all complete MSDUs with lower sequence numbers than the starting sequence number contained in the BlockAckReq frame shall be indicated to the MAC client using the MA-UNIDATA.indication primitive. Upon arrival of a BlockAckReq frame, the recipient shall indicate the MSDUs starting with the starting sequence number sequentially until there is an incomplete MSDU in the buffer.

If, after an MPDU is received, the receive buffer is full, the complete MSDU with the earliest sequence number shall be indicated to the MAC client using the MA-UNIDATA.indication primitive.

All comparisons of sequence numbers are performed circularly modulo 2^{12}.

The recipient shall always indicate the reception of MSDU to its MAC client in order of increasing sequence number.

9.10.5 Teardown of the Block Ack mechanism

When the originator has no data to send and the final Block Ack exchange has completed, it shall signal the end of its use of the Block Ack mechanism by sending the DELBA frame to its recipient. There is no management response frame from the recipient.[31] The recipient of the DELBA frame shall release all resources allocated for the Block Ack transfer.

The Block Ack agreement may be torn down if there are no BlockAck, BlockAckReq, or QoS data frames (sent under Block Ack policy) for the Block Ack's TID received from the peer within a duration of Block Ack timeout value (see 11.5.3).

9.11 No Acknowledgment (No Ack)

The usage of No Ack is determined by the policy at the QoS STA. When No Ack policy is used, there is no MAC-level recovery, and the reliability of this traffic is reduced, relative to the reliability of traffic with other acknowledgment policies, due to the increased probability of lost frames from interference, collisions, or time-varying channel parameters. A protective mechanism (such as transmitting using HCCA, RTS/CTS, or the mechanism described in 9.13) should be used to reduce the probability of other STAs transmitting during the TXOP.

9.12 Frame exchange sequences

The allowable frame exchange sequences are defined using an extension of the EBNF format as defined in ISO/IEC 14977 : 1996(E). The elements of this syntax that are used here are as follows:

— [a] = a is optional.

— {a} = a is repeated zero or more times.

— n{a} = a is repeated n or more times. For example, 3{a} requires 3 or more "a".

[31]Normal Ack rules apply.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001529

— a|b = a or b.

— ( ) = grouping, so "a (b|c)" is equivalent to "a b | a c".

— (* a *) = “a” is a comment. Comments are placed before the text they relate to.

— < > = order of frames not relevant. For example, <a b> is either "a b" or "b a."

— A rule is termined by a semicolon ";"

— Whitespace is not significant, but it is used to highlight the nesting of grouped terms.

Two types of terminals are defined:

— **Frames.** A frame is shown in Bold and identified by its type/subtype (e.g., Beacon, Data). Frames are shown in an initial capital letter.

— *Attributes.* Attributes are shown in italic. An attribute is introduced by the the "+" character. The attribute specifies a condition that applies to the frame that preceeds it. Where there are multiple attributes applied, they are generally ordered in the same order of the fields in the frame to which they refer.

Nonterminals of this syntax are shown in a normal font, i.e., a sequence of words joined by hyphens (e.g., cf-frame-exchange-sequence).

The attributes are defined in Table 9-6.

Table 9-6—Attributes applicable to frame exchange sequence definition

Attribute	Description
block-ack	QoS Data frame has ack policy set to Block Ack
broadcast	Frame RA is the broadcast address
CF	Beacon contains a CFP element
CF-Ack	Data type CF-Ack subtype bit set or CF-End+CF-Ack frame
CF-Poll	Data type CF-Poll subtype bit set
delayed	BlockAck or BlockAckReq under a delayed policy
DTIM	Beacon is a DTIM
frag	Frame has its More Fragments field set to 1
group	Frame RA has i/g bit set to 1
individual	Frame RA has i/g bit set to 0
last	Frame has its More Fragments field set to 0
no-ack	QoS Data frame has ack policy set to No Ack
normal-ack	QoS Data frame has ack policy set to Normal Ack
null	Data type Null Data subtype bit set
pifs	Frame is transmitted using a PIFS
QAP	Frame is transmitted by a QoS AP
QoS	Data type QoS subtype bit set
self	Frame RA = TA

9.13 Protection mechanism for non-ERP receivers

The intent of a protection mechanism is to ensure that a STA does not transmit an MPDU of type Data or an MMPDU with an ERP-OFDM preamble and header unless it has attempted to update the NAV of receiving NonERP STAs. The updated NAV period shall be longer than or equal to the total time required to send the data and any required response frames. ERP STAs shall use protection mechanisms (such as RTS/CTS or CTS-to-self) for ERP-OFDM MPDUs of type Data or an MMPDU when the Use_Protection field of the ERP

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001533

Information element is set to 1 (see the requirements of 9.6). Protection mechanisms frames shall be sent using one of the mandatory Clause 15 or Clause 18 rates and using one of the mandatory Clause 15 or Clause 18 waveforms, so all STAs in the BSA will know the duration of the exchange even if they cannot detect the ERP-OFDM signals using their CCA function.

Note that when using the Clause 19 options, ERP-PBCC or DSSS-OFDM, there is no need to use protection mechanisms, as these frames start with a DSSS header.

In the case of a BSS composed of only ERP STAs, but with knowledge of a neighboring co-channel BSS having NonERP traffic, the AP may require protection mechanisms to protect the BSS's traffic from interference. This will provide propagation of NAV to all attached STAs and all STAs in a neighboring co-channel BSS within range by messages sent using rates contained in the BSSBasicRateSet parameter. The frames that propagate the NAV throughout the BSS include RTS/CTS/ACK frames, all data frames with the "more fragments" field set to 1, all data frames sent in response to PS-Poll that are not proceeded in the frame sequence by a data frame with the "more fragments" field set to 1, Beacon frames with nonzero CFDurRemaining, CF-End frames, and CF-End+ACK frames.

When RTS/CTS is used as the protection mechanism, cases exist such as NAV resetting (discretionary, as indicated in 9.2.5.4), where a hidden STA may reset its NAV and this may cause a collision. The likelihood of occurrence is low, and it is not considered to represent a significant impairment to overall system operation. A mechanism to address this possible situation would be to use alternative protection mechanisms or to revert to alternative modulation methods.

If a protection mechanism is being used, a fragment sequence shall use ERP-OFDM modulation for the final fragment and control response.

The rules for calculating RTS/CTS NAV fields are unchanged when using RTS/CTS as a protection mechanism.

Additionally, if any of the rates in the BSSBasicRateSet parameter of the protection mechanism frame transmitting STA's BSS are Clause 15 or Clause 18 rates, then the protection mechanism frames shall be sent at one of those Clause 15 or Clause 18 basic rates.

10. Layer management

10.1 Overview of management model

Both the MAC sublayer and PHY conceptually include management entities, called MLME and PLME, respectively. These entities provide the layer management service interfaces through which layer management functions can be invoked.

In order to provide correct MAC operation, an SME is present within each STA. The SME is a layer-independent entity that can be viewed as residing in a separate management plane or as residing "off to the side." The exact functions of the SME are not specified in this standard, but in general this entity can be viewed as being responsible for such functions as the gathering of layer-dependent status from the various layer management entities (LMEs), and similarly setting the value of layer-specific parameters. SME would typically perform such functions on behalf of general system management entities and would implement standard management protocols. Figure 5-10 (in 5.7) depicts the relationship among management entities.

The various entities within this model interact in various ways. Certain of these interactions are defined explicitly within this standard, via a SAP across which defined primitives are exchanged. Other interactions are not defined explicitly within this standard, such as the interfaces between MAC and MLME and between PLCP and PLME, represented as double arrows within Figure 10-1. The specific manner in which these MAC and PHY LMEs are integrated into the overall MAC sublayer and PHY is not specified within this standard.

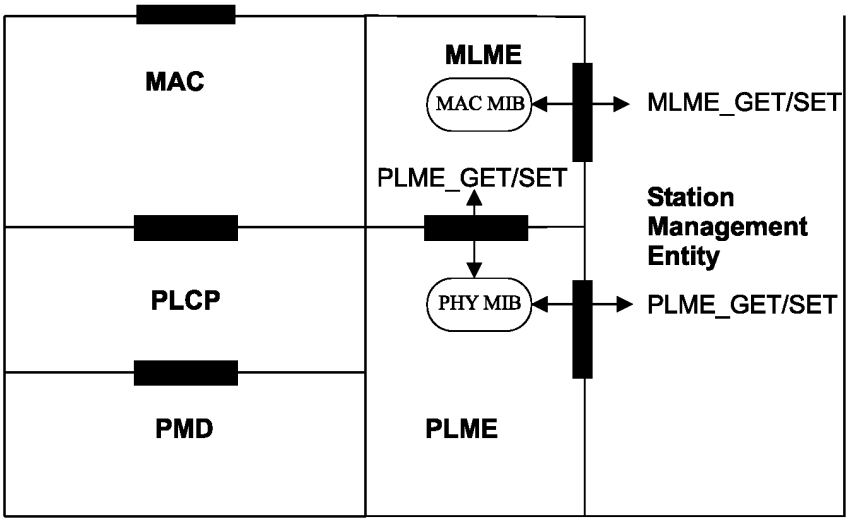

Figure 10-1—GET and SET operations

The management SAPs within this model are the following:

— SME-MLME SAP

— SME-PLME SAP

— MLME-PLME SAP

The latter two SAPs support identical primitives, and in fact can be viewed as a single SAP (called the PLME SAP) that can be used either directly by MLME or by SME. In this fashion, the model reflects what is anticipated to be a common implementation approach in which PLME functions are controlled by the

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001536

MLME (on behalf of SME). In particular, PHY implementations are not required to have separate interfaces defined other than their interfaces with the MAC and MLME.

10.2 Generic management primitives

The management information specific to each layer is represented as a MIB for that layer. The MLME and PLME are viewed as "containing" the MIB for that layer. The generic model of MIB-related management primitives exchanged across the management SAPs is to allow the SAP user-entity to either GET the value of a MIB attribute, or to SET the value of a MIB attribute. The invocation of a SET.request primitive can require that the layer entity perform certain defined actions.

Figure 10-1 depicts these generic primitives.

The GET and SET primitives are represented as REQUESTs with associated CONFIRM primitives. These primitives are prefixed by MLME or PLME depending upon whether the MAC sublayer or PHY management SAP is involved. In the following, XX denotes MLME or PLME:

XX-GET.request(MIBattribute)
: Requests the value of the given MIBattribute.

XX-GET.confirm(status, MIBattribute, MIBattributevalue)
: Returns the appropriate MIB attribute value if status = "success," otherwise returns an error indication in the Status field. Possible error status values include "invalid MIB attribute" and "attempt to get write-only MIB attribute."

XX-SET.request(MIBattribute, MIBattributevalue)
: Requests that the indicated MIB attribute be set to the given value. If this MIBattribute implies a specific action, then this requests that the action be performed.

XX-SET.confirm(status, MIBattribute)
: If status = "success," this confirms that the indicated MIB attribute was set to the requested value, otherwise it returns an error condition in status field. If this MIBattribute implies a specific action, then this confirms that the action was performed. Possible error status values include "invalid MIB attribute" and "attempt to set read-only MIB attribute."

Additionally, there are certain requests (with associated confirms) that can be invoked across a given SAP that do not involve the setting or getting of a specific MIB attribute. One of these is supported by each SAP, as follows:

— XX-RESET.request: where XX is MLME or PLME as appropriate
— XX-RESET.confirm

This service is used to initialize the management entities, the MIBs, and the datapath entities. It can include a list of attributes for items to be initialized to nondefault values. The corresponding .confirm indicates success or failure of the request.

Other SAP-specific primitives are identified in 10.3.

10.3 MLME SAP interface

The services provided by the MLME to the SME are specified in this subclause. These services are described in an abstract way and do not imply any particular implementation or exposed interface. MLME SAP primitives are of the general form ACTION.request followed by ACTION.confirm. The SME uses the services provided by the MLME through the MLME SAP.

10.3.1 Power management

This mechanism supports the process of establishment and maintenance of the power management mode of a STA.

10.3.1.1 MLME-POWERMGT.request

10.3.1.1.1 Function

This primitive requests a change in the power management mode.

10.3.1.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-POWERMGT.request(
                        PowerManagementMode,
                        WakeUp,
                        ReceiveDTIMs
                        )
```

Name	Type	Valid range	Description
PowerManagementMode	Enumeration	ACTIVE, POWER_SAVE	An enumerated type that describes the desired power management mode of the STA.
WakeUp	Boolean	True, false	When true, the MAC is forced immediately into the Awake state. This parameter has no effect if the current power management mode is ACTIVE.
ReceiveDTIMs	Boolean	True, false	When true, this parameter causes the STA to awaken to receive all DTIM frames. When false, the STA is not required to awaken for every DTIM frame.

10.3.1.1.3 When generated

This primitive is generated by the SME to implement the power-saving strategy of an implementation.

10.3.1.1.4 Effect of receipt

This request sets the STA's power management parameters. The MLME subsequently issues a MLME-POWERMGT.confirm that reflects the results of the power management change request.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001538

10.3.1.2 MLME-POWERMGT.confirm

10.3.1.2.1 Function

This primitive confirms the change in power management mode.

10.3.1.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-POWERMGT.confirm(
ResultCode
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, NOT_SUPPORTED	Indicates the result of the MLME-POWERMGT.request.

10.3.1.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-POWERMGT.request to establish a new power management mode. It is not generated until the change has completed as defined in 11.2.1.

10.3.1.2.4 Effect of receipt

The SME is notified of the change of power management mode.

Exhibit 1014
Page 001539

10.3.2 Scan

This mechanism supports the process of determining the characteristics of the available BSSs.

10.3.2.1 MLME-SCAN.request

10.3.2.1.1 Function

This primitive requests a survey of potential BSSs that the STA can later elect to try to join.

10.3.2.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SCAN.request(
BSSType,
BSSID,
SSID,
ScanType,
ProbeDelay,
ChannelList,
MinChannelTime,
MaxChannelTime,
VendorSpecificInfo
)

Name	Type	Valid range	Description
BSSType	Enumeration	INFRASTRUCTURE, INDEPENDENT, ANY_BSS	Determines whether infrastructure BSS, IBSS, or both, are included in the scan.
BSSID	MACAddress	Any valid individual or broadcast MAC address	Identifies a specific or wildcard BSSID.
SSID	Octet string	0–32 octets	Specifies the desired SSID or the wildcard SSID.
ScanType	Enumeration	ACTIVE, PASSIVE	Indicates either active or passive scanning.
ProbeDelay	Integer	N/A	Delay (in microseconds) to be used prior to transmitting a Probe frame during active scanning.
ChannelList	Ordered set of integers	Each channel will be selected from the valid channel range for the appropriate PHY and carrier set.	Specifies a list of channels that are examined when scanning for a BSS.
MinChannelTime	Integer	≥ ProbeDelay	The minimum time (in TU) to spend on each channel when scanning.
MaxChannelTime	Integer	≥ MinChannelTime	The maximum time (in TU) to spend on each channel when scanning.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.2.1.3 When generated

This primitive is generated by the SME for a STA to determine if there are other BSSs that it can join.

10.3.2.1.4 Effect of receipt

This request initiates the scan process when the current frame exchange sequence is completed.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001540

10.3.2.2 MLME-SCAN.confirm

10.3.2.2.1 Function

This primitive returns the descriptions of the set of BSSs detected by the scan process.

10.3.2.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SCAN.confirm(
BSSDescriptionSet,
ResultCode,
VendorSpecificInfo
)

Name	Type	Valid range	Description
BSSDescriptionSet	Set of BSSDescriptions	N/A	The BSSDescriptionSet is returned to indicate the results of the scan request. It is a set containing zero or more instances of a BSSDescription.
ResultCode	Enumeration	SUCCESS, INVALID_ PARAMETERS, NOT_SUPPORTED	Indicates the result of the MLME-SCAN.confirm.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

Each BSSDescription consists of the following elements:

Name	Type	Valid range	Description
BSSID	MACAddress	N/A	The BSSID of the found BSS.
SSID	Octet string	1–32 octets	The SSID of the found BSS.
BSSType	Enumeration	INFRASTRUC-TURE, INDEPENDENT	The type of the found BSS.
Beacon Period	Integer	N/A	The Beacon period of the found BSS (in TU).
DTIM Period	Integer	As defined in frame format	The DTIM period of the BSS (in beacon periods).
Timestamp	Integer	N/A	The timestamp of the received frame (probe response/beacon) from the found BSS.
Local Time	Integer	N/A	The value of the STA's TSF timer at the start of reception of the first octet of the timestamp field of the received frame (probe response or beacon) from the found BSS.
PHY Parameter Set	As defined in frame format or according to the relevant PHY clause.	As defined in frame format or according to the relevant PHY clause.	The parameter sets relevant to the PHY from the received Beacon or Probe Response frame. If no PHY Parameter Set information element is present in the received frame, this parameter contains the channel number on which the frame was received. Valid channel numbers are defined in the relevant PHY clause.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001541

Name	Type	Valid range	Description
CF Parameter Set	As defined in frame format	As defined in frame format	The parameter set for the CF periods, if found BSS supports CF mode.
IBSS Parameter Set	As defined in frame format	As defined in frame format	The parameter set for the IBSS, if found BSS is an IBSS.
CapabilityInformation	As defined in frame format	As defined in frame format	The advertised capabilities of the BSS.
BSSBasicRateSet	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that must be supported by all STAs that desire to join this BSS. The STAs must be able to receive and transmit at each of the data rates listed in the set.
OperationalRateSet	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that the STA desires to use for communication within the BSS. The STA must be able to receive at each of the data rates listed in the set. This set is a superset of the rates contained in the BSSBasicRateSet parameter.
Country	As defined in the Country element	As defined in the Country element	The information required to identify the regulatory domain in which the STA is located and to configure its PHY for operation in that regulatory domain. Present only when TPC functionality is required, as specified in 11.8, or when dot11MultiDomainCapabilityEnabled is true.
IBSS DFS Recovery Interval	Integer	1–255	Only present if BSSType = INDEPENDENT. The time interval that is used for DFS recovery. Present only when DFS functionality is required, as specified in 11.9.
RSN	RSN information element	As defined in frame format	A description of the cipher suites and AKM suites supported in the BSS.
Load	As defined in frame format	As defined in frame format	The values from the BSS Load information element if such an element was present in the probe response or Beacon frame, else null.
EDCAParameterSet	As defined in frame format	As defined in frame format	The values from the EDCA Parameter Set information element if such an element was present in the probe response or Beacon frame, else null.
QoSCapability	As defined in frame format	As defined in frame format	The values from the QoS Capability information element if such an element was present in the probe response or Beacon frame, else null.

10.3.2.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-SCAN.request to ascertain the operating environment of the STA.

10.3.2.2.4 Effect of receipt

The SME is notified of the results of the scan procedure.

10.3.3 Synchronization

This mechanism supports the process of selection of a peer in the authentication process.

10.3.3.1 MLME-JOIN.request

10.3.3.1.1 Function

This primitive requests synchronization with a BSS.

10.3.3.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-JOIN.request(
SelectedBSS,
JoinFailureTimeout,
ProbeDelay,
OperationalRateSet,
VendorSpecificInfo
)

Name	Type	Valid range	Description
SelectedBSS	BSSDescription	N/A	The BSSDescription of the BSS to join. The SelectedBSS is a member of the set of descriptions that was returned as a result of a MLME-SCAN.request.
JoinFailureTimeout	Integer	≥ 1	The time limit, in units of beacon intervals, after which the join procedure will be terminated.
ProbeDelay	Integer	N/A	Delay (in microseconds) to be used prior to transmitting a Probe frame during active scanning.
OperationalRateSet	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that the STA desires to use for communication within the BSS. The STA must be able to receive at each of the data rates listed in the set. This set is a superset of the rates contained in the BSSBasicRateSet parameter.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.3.1.3 When generated

This primitive is generated by the SME for a STA to establish synchronization with a BSS.

10.3.3.1.4 Effect of receipt

This primitive initiates a synchronization procedure once the current frame exchange sequence is complete. The MLME synchronizes its timing with the specified BSS based on the elements provided in the SelectedBSS parameter. The MLME subsequently issues a MLME-JOIN.confirm that reflects the results.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001543

10.3.3.2 MLME-JOIN.confirm

10.3.3.2.1 Function

This primitive confirms synchronization with a BSS.

10.3.3.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-JOIN.confirm(
                        ResultCode,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_ PARAMETERS, TIMEOUT	Indicates the result of the MLME-JOIN.request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.3.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-JOIN.request to establish synchronization with a BSS.

10.3.3.2.4 Effect of receipt

The SME is notified of the results of the synchronization procedure.

10.3.4 Authenticate

This mechanism supports the process of establishing an authentication relationship with a peer MAC entity.

10.3.4.1 MLME-AUTHENTICATE.request

10.3.4.1.1 Function

This primitive requests authentication with a specified peer MAC entity.

10.3.4.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-AUTHENTICATE.request(
                                    PeerSTAAddress,
                                    AuthenticationType,
                                    AuthenticateFailureTimeout,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which to perform the authentication process.
AuthenticationType	Enumeration	OPEN_SYSTEM, SHARED_KEY	Specifies the type of authentication algorithm to use during the authentication process.
AuthenticationFail-ureTimeout	Integer	≥ 1	Specifies a time limit (in TU) after which the authentication procedure will be terminated.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.4.1.3 When generated

This primitive is generated by the SME for a STA to establish authentication with a specified peer MAC entity in order to permit Class 2 frames to be exchanged between the two STAs. During the authentication procedure, the SME can generate additional MLME-AUTHENTICATE.request primitives.

10.3.4.1.4 Effect of receipt

This primitive initiates an authentication procedure. The MLME subsequently issues a MLME-AUTHENTICATE.confirm that reflects the results.

Copyright © 2007 IEEE. All rights reserved.

Exhibit 1014
Page 001545

10.3.4.2 MLME-AUTHENTICATE.confirm

10.3.4.2.1 Function

This primitive reports the results of an authentication attempt with a specified peer MAC entity.

10.3.4.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-AUTHENTICATE.confirm(
                                    PeerSTAAddress,
                                    AuthenticationType,
                                    ResultCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which the authentication process was attempted. This value must match the peerSTAAddress parameter specified in the corresponding MLME-AUTHENTICATE.request.
AuthenticationType	Enumeration	OPEN_SYSTEM, SHARED_KEY	Specifies the type of authentication algorithm that was used during the authentication process. This value must match the authenticationType parameter specified in the corresponding MLME-AUTHENTICATE.request.
ResultCode	Enumeration	SUCCESS, INVALID_ PARAMETERS, TIMEOUT, TOO_MANY_ SIMULTANEOUS_ REQUESTS, REFUSED	Indicates the result of the MLME-AUTHENTICATE.request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.4.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-AUTHENTICATE.request to authenticate with a specified peer MAC entity.

10.3.4.2.4 Effect of receipt

The SME is notified of the results of the authentication procedure.

10.3.4.3 MLME-AUTHENTICATE.indication

10.3.4.3.1 Function

This primitive indicates receipt of a request from a specific peer MAC entity to establish an authentication relationship with the STA processing this primitive.

10.3.4.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-AUTHENTICATE.indication(
PeerSTAAddress,
AuthenticationType,
VendorSpecificInfo
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which the authentication relationship was established.
AuthenticationType	Enumeration	OPEN_SYSTEM, SHARED_KEY	Specifies the type of authentication algorithm that was used during the authentication process.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.4.3.3 When generated

This primitive is generated by the MLME as a result of the receipt of an authentication request from a specific peer MAC entity.

10.3.4.3.4 Effect of receipt

The SME is notified of the receipt of the authentication request.

Page 001547

10.3.4.4 MLME-AUTHENTICATE.response

10.3.4.4.1 Function

This primitive is used to send a response to a specific peer MAC entity that requested authentication with the STA that issued this primitive.

10.3.4.4.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-AUTHENTICATE.response(
                                    PeerSTAAddress,
                                    ResultCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity from which the authentication request was received.
ResultCode	Enumeration	SUCCESS, REFUSED	Indicates the result response to the authentication request from the peer MAC entity.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.4.4.3 When generated

This primitive is generated by the SME of a STA as a response to an MLME-AUTHENTICATE.indication primitive.

10.3.4.4.4 Effect of receipt

This primitive initiates transmission of a response to the specific peer MAC entity that requested authentication.

10.3.5 Deauthenticate

This mechanism supports the process of invalidating an authentication relationship with a peer MAC entity.

10.3.5.1 MLME-DEAUTHENTICATE.request

10.3.5.1.1 Function

This primitive requests that the authentication relationship with a specified peer MAC entity be invalidated.

10.3.5.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DEAUTHENTICATE.request(
                                    PeerSTAAddress,
                                    ReasonCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which to perform the deauthentication process.
ReasonCode	As defined in frame format	As defined in frame format	Specifies the reason for initiating the deauthentication procedure.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.5.1.3 When generated

This primitive is generated by the SME for a STA to invalidate authentication with a specified peer MAC entity in order to prevent the exchange of Class 2 frames between the two STAs. During the deauthentication procedure, the SME can generate additional MLME-DEAUTHENTICATE.request primitives.

10.3.5.1.4 Effect of receipt

This primitive initiates a deauthentication procedure. The MLME subsequently issues a MLME-DEAUTHENTICATE.confirm that reflects the results.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001549

10.3.5.2 MLME-DEAUTHENTICATE.confirm

10.3.5.2.1 Function

This primitive reports the results of a deauthentication attempt with a specified peer MAC entity.

10.3.5.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DEAUTHENTICATE.confirm(
                                    PeerSTAAddress,
                                    ResultCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which the deauthentication process was attempted.
ResultCode	Enumeration	SUCCESS, INVALID_ PARAMETERS, TOO_MANY_ SIMULTANEOUS_ REQUESTS	Indicates the result of the MLME-DEAUTHENTICATE.request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.5.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-DEAUTHENTICATE.request to invalidate the authentication relationship with a specified peer MAC entity.

10.3.5.2.4 Effect of receipt

The SME is notified of the results of the deauthentication procedure.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001550

10.3.5.3 MLME-DEAUTHENTICATE.indication

10.3.5.3.1 Function

This primitive reports the invalidation of an authentication relationship with a specific peer MAC entity.

10.3.5.3.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DEAUTHENTICATE.indication(
                                    PeerSTAAddress,
                                    ReasonCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which the authentication relationship was invalidated.
ReasonCode	As defined in frame format.	As defined in frame format	Specifies the reason the deauthentication procedure was initiated.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.5.3.3 When generated

This primitive is generated by the MLME as a result of the invalidation of an authentication relationship with a specific peer MAC entity.

10.3.5.3.4 Effect of receipt

The SME is notified of the invalidation of the specific authentication relationship.

10.3.6 Associate

The following primitives describe how a STA becomes associated with an AP.

10.3.6.1 MLME-ASSOCIATE.request

10.3.6.1.1 Function

This primitive requests association with a specified peer MAC entity that is within an AP.

10.3.6.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ASSOCIATE.request(
PeerSTAAddress,
AssociateFailureTimeout,
CapabilityInformation,
ListenInterval,
Supported Channels,
RSN,
QoSCapability,
VendorSpecificInfo
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which to perform the association process.
AssociateFailureTime-out	Integer	≥ 1	Specifies a time limit (in TU) after which the associate procedure will be terminated.
CapabilityInformation	As defined in frame format	As defined in frame format	Specifies the requested operational capabilities to the AP.
ListenInterval	Integer	≥ 0	Specifies the number of beacon intervals that can pass before the STA awakens and listens for the next Beacon frame.
Supported Channels	As defined in the Supported Channels element	As defined in the Supported Channels element	The list of channels in which the STA is capable of operating. Present only when DFS functionality is required, as specified in 11.9.
RSN	RSN information element	As defined in frame format	A description of the cipher suites and AKM suites supported in the BSS.
QoSCapability	As defined in frame format	As defined in frame format	Specifies the parameters within the QoS Capability information element that are supported by the MAC entity. The parameter shall be present only if the MIB attribute dot11QosOptionImplemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

Additional parameters needed to perform the association procedure are not included in the primitive parameter list since the MLME already has that data (maintained as internal state).

10.3.6.1.3 When generated

This primitive is generated by the SME when a STA wishes to establish association with an AP.

10.3.6.1.4 Effect of receipt

This primitive initiates an association procedure. The MLME subsequently issues an MLME-ASSOCIATE.confirm that reflects the results.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001552

10.3.6.2 MLME-ASSOCIATE.confirm

10.3.6.2.1 Function

This primitive reports the results of an association attempt with a specified peer MAC entity that is within an AP.

10.3.6.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ASSOCIATE.confirm(
ResultCode,
CapabilityInformation,
AssociationID,
SupportedRates,
EDCAParameterSet,
VendorSpecificInfo
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, TIMEOUT, REFUSED_REASON_UNSPECIFIED, REFUSED_NOT_AUTHENTICATED, REFUSED_CAPABILITIES_MISMATCH, REFUSED_EXTERNAL_REASON, REFUSED_AP_OUT_OF_MEMORY, REFUSED_BASIC_RATES_MISMATCH	Indicates the result of the MLME-ASSOCIATE.request.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capabilities advertised by the AP.
AssociationID	Integer	1–2007 inclusive	If the association request result was SUCCESS, then AssociationID specifies the association ID value assigned by the AP.
SupportedRates	Set of integers	2–127 inclusive (for each integer in the set), bit 7 is set to 1 to indicate that a rate is a member of the BBSBasicRateSet.	The set of data rates (in units of 500 kb/s) that are supported by AP, including indication of which rates are part of the BSSBasicRateSet (according to 7.3.2.2).
EDCA-ParameterSet	As defined in frame format	As defined in frame format	Specifies the EDCA parameter set that the STA should use. The parameter shall be present only if the MIB attribute dot11QosOptionImplemented is true.
Vendor-SpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.6.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-ASSOCIATE.request or receipt of an association response frame from the peer MAC entity to associate with a specified peer MAC entity that is within an AP.

10.3.6.2.4 Effect of receipt

The SME is notified of the results of the association procedure.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001553

10.3.6.3 MLME-ASSOCIATE.indication

10.3.6.3.1 Function

This primitive indicates that a specific peer MAC entity is requesting association with the local MAC entity, which is within an AP.

10.3.6.3.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-ASSOCIATE.indication(
                                    PeerSTAAddress,
                                    CapabilityInformation,
                                    ListenInterval,
                                    SSID,
                                    SupportedRates,
                                    RSN,
                                    QoSCapability,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity from which the association was received.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capability definitions provided by the peer MAC entity as part of the association request.
ListenInterval	Integer	≥ 0	Specifies the listen interval value provided by the peer MAC as part of the association request.
SSID	Octet string	0–32 octets	Specifies the SSID provided by the peer MAC entity as part of the association request.
SupportedRates	Set of integers	2–127 inclusive (for each integer in the set)	The set of data rates (in units of 500 kb/s) that are supported by the STA that is requesting association.
RSN	RSN information element	As defined in frame format	A description of the cipher suites and AKM suites supported in the BSS. Only one pairwise cipher suite and only one authenticated key suite are allowed in the RSN information element.
QoSCapability	As defined in frame format	As defined in frame format	Specifies the parameters within the QoSCapability that are supported by the peer MAC entity. The parameter may be present only if the MIB attribute dot11QosOption-Implemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.6.3.3 When generated

This primitive is generated by the MLME as a result of the receipt of an association request from a specific peer MAC entity.

10.3.6.3.4 Effect of receipt

The SME is notified of the receipt of the association request.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001554

10.3.6.4 MLME-ASSOCIATE.response

10.3.6.4.1 Function

This primitive is used to send a response to a specific peer MAC entity that requested an association with the STA that issued this primitive, which is within an AP.

10.3.6.4.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ASSOCIATE.response(
PeerSTAAddress,
ResultCode,
CapabilityInformation,
AssociationID,
EDCAParameterSet,
VendorSpecificInfo
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity from which the association request was received.
ResultCode	Enumeration	SUCCESS, REFUSED_REASON_UNSPECIFIED, REFUSED_CAPABILITIES_MISMATCH, REFUSED_EXTERNAL_REASON, REFUSED_AP_OUT_OF_MEMORY, REFUSED_BASIC_RATES_MISMATCH	Indicates the result response to the association request from the peer MAC entity.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capabilities advertised by the AP.
AssociationID	Integer	1–2007 inclusive	If the association request result was SUCCESS, then AssociationID specifies the association ID value assigned to the peer MAC entity by the AP.
EDCAParameter-Set	As defined in frame format	As defined in frame format	Specifies the EDCA parameter set that the STA should use. The parameter shall be present only if the MIB attribute dot11Qos-OptionImplemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

Additional parameters needed to perform the association response procedure are not included in the primitive parameter list since the MLME already has that data (maintained as internal state).

10.3.6.4.3 When generated

This primitive is generated by the SME of a STA that is within an AP as a response to an MLME-ASSOCIATE.indication primitive.

10.3.6.4.4 Effect of receipt

This primitive initiates transmission of an AssociationResponse to the specific peer MAC entity that requested association.

Exhibit 1014
Page 001555

10.3.7 Reassociate

The following primitives describe how a STA becomes associated with another AP.

10.3.7.1 MLME-REASSOCIATE.request

10.3.7.1.1 Function

This primitive requests a change in association to a specified new peer MAC entity that is within an AP.

10.3.7.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-REASSOCIATE.request(
NewAPAddress,
ReassociateFailureTimeout,
CapabilityInformation,
ListenInterval,
Supported Channels
RSN,
QoSCapability,
VendorSpecificInfo
)

Name	Type	Valid range	Description
NewAPAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which to perform the reassociation process.
ReassociateFailure-Timeout	Integer	≥ 1	Specifies a time limit (in TU) after which the reassociate procedure will be terminated.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the requested operational capabilities to the AP.
ListenInterval	Integer	≥ 0	Specifies the number of beacon intervals that can pass before the STA awakens and listens for the next Beacon frame.
Supported Channels	As defined in the Supported Channels element	As defined in the Supported Channels element	The list of channels in which the STA is capable of operating. Present only when DFS functionality is required, as specified in 11.9.
RSN	RSN information element	As defined in frame format	A description of the cipher suites and AKM suites supported in the BSS.
QoSCapability	As defined in frame format	As defined in frame format	Specifies the parameters within the QoS Capability information element that are supported by the MAC entity. The parameter shall be present only if the MIB attribute dot11QosOptionImplemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

Additional parameters needed to perform the reassociation procedure are not included in the primitive parameter list since the MLME already has that data (maintained as internal state).

10.3.7.1.3 When generated

This primitive is generated by the SME for a STA to change association to a specified new peer MAC entity that is within an AP.

10.3.7.1.4 Effect of receipt

This primitive initiates a reassociation procedure. The MLME subsequently issues a MLME-REASSOCIATE.confirm that reflects the results.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001556

10.3.7.2 MLME-REASSOCIATE.confirm

10.3.7.2.1 Function

This primitive reports the results of a reassociation attempt with a specified peer MAC entity that is within an AP.

10.3.7.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-REASSOCIATE.confirm(
ResultCode,
CapabilityInformation,
AssociationID,
SupportedRates,
EDCAParameterSet,
VendorSpecificInfo
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, TIMEOUT, REFUSED_REASON_UNSPECIFIED, REFUSED_NOT_AUTHENTICATED, REFUSED_CAPABILITIES_MISMATCH, REFUSED_EXTERNAL_REASON, REFUSED_AP_OUT_OF_MEMORY, REFUSED_BASIC_RATES_MISMATCH	Indicates the result of the MLME-REASSOCIATE.request.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capabilities advertised by the AP.
AssociationID	Integer	1–2007 inclusive	If the association request result was SUCCESS, then AssociationID specifies the association ID value assigned by the AP.
Supported-Rates	Set of integers	2–127 inclusive (for each integer in the set), bit 7 is set to 1 to indicate that a rate is a member of the BBSBasicRateSet.	The set of data rates (in units of 500 kb/s) that are supported by AP, including indication of which rates are part of the BSSBasicRateSet (according to 7.3.2.2).
EDCAParameterSet	As defined in frame format	As defined in frame format	Specifies the EDCA parameter set that the STA should use. The parameter shall be present only if the MIB attribute dot11QosOptionImplemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.7.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-REASSOCIATE.request to reassociate with a specified peer MAC entity that is within an AP.

10.3.7.2.4 Effect of receipt

The SME is notified of the results of the reassociation procedure.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001557

10.3.7.3 MLME-REASSOCIATE.indication

10.3.7.3.1 Function

This primitive indicates that a specific peer MAC entity is requesting reassociation with the local MAC entity, which is within an AP.

10.3.7.3.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-REASSOCIATE.indication(
                                    PeerSTAAddress,
                                    CurrentAPAddress,
                                    CapabilityInformation,
                                    ListenInterval,
                                    SSID,
                                    SupportedRates,
                                    RSN,
                                    QoSCapability,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity from which the reassociation request was received.
CurrentAPAddress	MACAddress	Any valid individual MAC address	Specifies the address of the AP with which the peer STA is currently associated.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capability definitions provided by the peer MAC entity as part of the association request.
ListenInterval	Integer	≥ 0	Specifies the listen interval value provided by the peer MAC as part of the association request.
SSID	Octet string	0–32 octets	Specifies the desired SSID provided by the peer MAC as part of the association request.
SupportedRates	Set of integers	2–127 inclusive (for each integer in the set)	The set of data rates (in units of 500 kb/s) that are supported by the STA that is requesting reassociation.
RSN	RSN information element	As defined in frame format	A description of the cipher suites and AKM suites supported in the BSS.
QoSCapability	As defined in frame format	As defined in frame format	Specifies the parameters within the QoS Capability that are supported by the peer MAC entity. The parameter shall be present only if the MIB attribute dot11QosOption-Implemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.7.3.3 When generated

This primitive is generated by the MLME as a result of the establishment of a reassociation with a specific peer MAC entity that resulted from a reassociation procedure that was initiated by that specific peer MAC entity.

10.3.7.3.4 Effect of receipt

The SME is notified of the establishment of the reassociation.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001558

10.3.7.4 MLME-REASSOCIATE.response

10.3.7.4.1 Function

This primitive is used to send a response to a specific peer MAC entity that requested a reassociation with the STA that issued this primitive, which is within an AP.

10.3.7.4.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-REASSOCIATE.response(
PeerSTAAddress,
ResultCode,
CapabilityInformation,
AssociationID,
EDCAParameterSet,
VendorSpecificInfo
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity from which the reassociation request was received.
ResultCode	Enumeration	SUCCESS, REFUSED_REASON_UNSPECIFIED, REFUSED_CAPABILITIES_MISMATCH, REFUSED_EXTERNAL_REASON, REFUSED_AP_OUT_OF_MEMORY, REFUSED_BASIC_RATES_MISMATCH	Indicates the result response to the reassociation request from the peer MAC entity.
Capability-Information	As defined in Frame Format	As defined in Frame Format	Specifies the operational capabilities advertised by the AP.
AssociationID	Integer	1–2007 inclusive	If the reassociation request result was SUCCESS, then AssociationID specifies the association ID value assigned to the peer MAC entity by the AP.
EDCAParameterSet	As defined in frame format	As defined in frame format	Specifies the EDCA parameter set that the STA should use. The parameter shall be present only if the MIB attribute dot11Qos-OptionImplemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

Additional parameters needed to perform the association response procedure are not included in the primitive parameter list since the MLME already has that data (maintained as internal state).

10.3.7.4.3 When generated

This primitive is generated by the SME of a STA that is within an AP as a response to an MLME-REASSOCIATE.indication primitive.

10.3.7.4.4 Effect of receipt

This primitive initiates transmission of a response to the specific peer MAC entity that requested reassociation.

Exhibit 1014
Page 001559

10.3.8 Disassociate

10.3.8.1 MLME-DISASSOCIATE.request

10.3.8.1.1 Function

This primitive requests disassociation with a specified peer MAC entity that is within an AP.

10.3.8.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-DISASSOCIATE.request(
PeerSTAAddress,
ReasonCode,
VendorSpecificInfo
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which to perform the disassociation process.
ReasonCode	As defined in frame format	As defined in frame format	Specifies the reason for initiating the disassociation procedure.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.8.1.3 When generated

This primitive is generated by the SME for a STA to establish disassociation with an AP.

10.3.8.1.4 Effect of receipt

This primitive initiates a disassociation procedure. The MLME subsequently issues an MLME-DISASSOCIATE.confirm that reflects the results.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001560

10.3.8.2 MLME-DISASSOCIATE.confirm

10.3.8.2.1 Function

This primitive reports the results of a disassociation procedure with a specific peer MAC entity that is within an AP.

10.3.8.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DISASSOCIATE.confirm(
                                    ResultCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, TIMEOUT, REFUSED	Indicates the result of the MLME-DISASSOCIATE.request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.8.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-DISASSOCIATE.request to disassociate with a specified peer MAC entity that is within an AP.

10.3.8.2.4 Effect of receipt

The SME is notified of the results of the disassociation procedure.

Page 001561

10.3.8.3 MLME-DISASSOCIATE.indication

10.3.8.3.1 Function

This primitive reports disassociation with a specific peer MAC entity.

10.3.8.3.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DISASSOCIATE.indication(
                                    PeerSTAAddress,
                                    ReasonCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which the association relationship was invalidated.
ReasonCode	As defined in frame format	As defined in frame format	Specifies the reason the disassociation procedure was initiated.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.8.3.3 When generated

This primitive is generated by the MLME as a result of the invalidation of an association relationship with a specific peer MAC entity.

10.3.8.3.4 Effect of receipt

The SME is notified of the invalidation of the specific association relationship.

10.3.9 Reset

This mechanism supports the process of resetting the MAC.

10.3.9.1 MLME-RESET.request

10.3.9.1.1 Function

This primitive requests that the MAC entity be reset.

10.3.9.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-RESET.request(
                        STAAddress,
                        SetDefaultMIB
                        )
```

Name	Type	Valid range	Description
STAAddress	MACAddress	Any valid individual MAC address	Specifies the MAC address that is to be used by the MAC entity that is being reset. This value can be used to provide a locally administered STA address.
SetDefaultMIB	Boolean	True, false	If true, all MIB attributes are set to their default values. The default values are implementation dependent. If false, the MAC is reset, but all MIB attributes retain the values that were in place prior to the generation of the MLME-RESET.request primitive.

10.3.9.1.3 When generated

This primitive is generated by the SME to reset the MAC to initial conditions. The MLME-RESET.request primitive must be used prior to use of the MLME-START.request primitive.

10.3.9.1.4 Effect of receipt

This primitive sets the MAC to initial conditions, clearing all internal variables to the default values. MIB attributes can be reset to their implementation-dependent default values by setting the SetDefaultMIB flag to true. The MLME subsequently issues a MLME-RESET.confirm that reflects the results.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001563

10.3.9.2 MLME-RESET.confirm

10.3.9.2.1 Function

This primitive reports the results of a reset procedure.

10.3.9.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-RESET.confirm(
ResultCode
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS	Indicates the result of the MLME-RESET.request.

10.3.9.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-RESET.request to reset the MAC entity.

10.3.9.2.4 Effect of receipt

The SME is notified of the results of the reset procedure.

Exhibit 1014
Page 001564

10.3.10 Start

This mechanism supports the process of creating a new BSS.

10.3.10.1 MLME-START.request

10.3.10.1.1 Function

This primitive requests that the MAC entity start a new BSS.

10.3.10.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-START.request(
SSID,
BSSType,
BeaconPeriod,
DTIMPeriod,
CF parameter set,
PHY parameter set,
IBSS parameter set,
ProbeDelay.
CapabilityInformation,
BSSBasicRateSet,
OperationalRateSet,
Country,
IBSS DFS Recovery Interval,
EDCAParameterSet,
VendorSpecificInfo
)

Name	Type	Valid range	Description
SSID	Octet string	1–32 octets	The SSID of the BSS.
BSSType	Enumeration	INFRASTRUCTURE, INDEPENDENT	The type of the BSS.
Beacon Period	Integer	≥ 1	The Beacon period of the BSS (in TU).
DTIM Period	Integer	As defined in 7.3.2.6	The DTIM Period of the BSS (in beacon periods).
CF parameter set	As defined in frame format	As defined in 7.3.2.5	The parameter set for CF periods, if the BSS supports CF mode. aCFPPeriod is modified as a side effect of the issuance of an MLME-START.request primitive.
PHY parameter sets	As defined in frame format	As defined in 7.3.2.3 or 7.3.2.4	The parameter sets relevant to the PHY.
IBSS parameter set	As defined in frame format	As defined in 7.3.2.7	The parameter set for the IBSS, if BSS is an IBSS.
ProbeDelay	Integer	N/A	Delay (in microseconds) to be used prior to transmitting a Probe frame during active scanning.
CapabilityInformation	As defined in frame format	As defined in 7.3.1.4	The capabilities to be advertised for the BSS.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001565

Name	Type	Valid range	Description
BSSBasicRateSet	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that must be supported by all STAs to join this BSS. The STA that is creating the BSS must be able to receive and transmit at each of the data rates listed in the set.
OperationalRateSet	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that the STA desires to use for communication within the BSS. The STA must be able to receive at each of the data rates listed in the set. This set is a superset of the rates contained in the BSSBasicRateSet parameter.
Country	As defined in the Country element	As defined in the Country element	The information required to identify the regulatory domain in which the STA is located and to configure its PHY for operation in that regulatory domain. Present only when TPC functionality is required, as specified in 11.8 or when dot11MultiDomainCapabilityEnabled is true.
IBSS DFS Recovery Interval	Integer	1–255	Present only if BSSType = INDEPENDENT. The time interval that is used for DFS recovery. Present only when DFS functionality is required, as specified in 11.9.
EDCAParameterSet (QoS only)	As defined in frame format	As defined in frame format	The initial EDCA parameter set values to be used in the BSS. The parameter shall be present only if the MIB attribute dot11QosOptionImplemented is true.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.10.1.3 When generated

This primitive is generated by the SME to start either an infrastructure BSS (with the MAC entity within an AP) or an IBSS (with the MAC entity acting as the first STA in the IBSS).

The MLME-START.request primitive must be generated after an MLME-RESET.request primitive has been used to reset the MAC entity and before an MLME-JOIN.request primitive has been used to successfully join an existing infrastructure BSS or IBSS.

The MLME-START.request primitive must not be used after successful use of the MLME-START.request primitive or successful use of the MLME-JOIN.request without generating an intervening MLME-RESET.request primitive.

10.3.10.1.4 Effect of receipt

This primitive initiates the BSS initialization procedure once the current frame exchange sequence is complete. The MLME subsequently issues an MLME-START.confirm that reflects the results of the creation procedure.

Exhibit 1014
Page 001566

10.3.10.2 MLME-START.confirm

10.3.10.2.1 Function

This primitive reports the results of a BSS creation procedure.

10.3.10.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-START.confirm(
ResultCode,
VendorSpecificInfo
)

Name	Type	Valid range	resetDescription
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, BSS_ALREADY_STARTED_OR_JOINED, RESET_REQUIRED_BEFORE_ START, NOT_SUPPORTED	Indicates the result of the MLME-START.request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.10.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-START.request to create a new BSS.

10.3.10.2.4 Effect of receipt

The SME is notified of the results of the BSS creation procedure.

10.3.11 Spectrum management protocol layer model

The layer management extensions for measurement and channel switching assume a certain partition of spectrum management functionality between the MLME and SME. This partitioning assumes that policy decisions (e.g., regarding measurement and channel switching) reside in the SME, while the protocol for measurement, switch timing, and the associated frame exchanges resides within the MLME (see Figure 10-2).

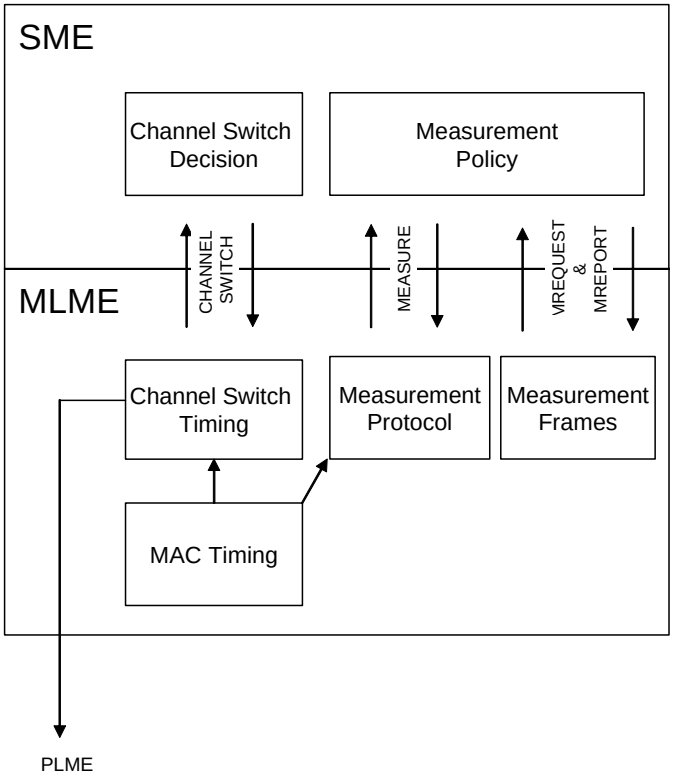

Figure 10-2—Layer management model

The informative diagrams within this subclause further illustrate the spectrum management protocol model adopted. Figure 10-3 and Figure 10-4 depict the measurement process for a peer STA to accept and reject a measurement request, respectively. Figure 10-5 illustrates the TPC adaptation process. Lastly, Figure 10-6 depicts the management process for a channel switch using a Channel Switch Announcement frame.

10.3.12 Measurement request

This set of primitives supports the signaling of measurement requests between peer SMEs.

10.3.12.1 MLME-MREQUEST.request

10.3.12.1.1 Function

This primitive requests the transmission of a measurement request to a peer entity.

10.3.12.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-MREQUEST.request(
                        Peer MAC Address,
                        Dialog Token,
                        Measurement Request Set,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
Peer MAC Address	MACAddress	Any valid individual or group MAC address	The address of the peer MAC entity to which the measurement request is set.
Dialog Token	Integer	1–255	The dialog token to identify the measurement transaction.
Measurement Request Set	Set of measurement requests, each as defined in the Measurement Request element	Set of measurement requests, each as defined in the Measurement Request element	A set of measurement requests, each containing a Measurement Token, Measurement Request Mode, Measurement Type, and Measurement Request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.12.1.3 When generated

This primitive is generated by the SME to request that a Measurement Request frame be sent to a peer entity to initiate one or more measurements.

10.3.12.1.4 Effect of receipt

On receipt of this primitive, the MLME constructs a Measurement Request frame containing the set of Measurement Request elements specified. This frame is then scheduled for transmission.

Exhibit 1014
Page 001573

10.3.12.2 MLME-MREQUEST.confirm

10.3.12.2.1 Function

This primitive reports the result of a request to send a Measurement Request frame.

10.3.12.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-MREQUEST.confirm(
                        ResultCode,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, or UNSPECIFIED_FAILURE	Reports the outcome of a request to send a Measurement Request frame.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.12.2.3 When generated

This primitive is generated by the MLME when the request to transmit a Measurement Request frame completes.

10.3.12.2.4 Effect of receipt

On receipt of this primitive, the SME evaluates the result code.

Page 001574

10.3.12.3 MLME-MREQUEST.indication

10.3.12.3.1 Function

This primitive indicates that a Measurement Request frame has been received requesting the measurement of one or more channels.

10.3.12.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-MREQUEST.indication(
Peer MAC Address,
Dialog Token,
Measurement Request Set,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Peer MAC Address	MACAddress	Any valid individual MAC address	The address of the peer MAC entity from which the measurement request was received.
Dialog Token	Integer	1–255	The dialog token to identify the measurement transaction.
Measurement Request Set	Set of measurement requests, each as defined in the Measurement Request element	Set of measurement requests, each as defined in the Measurement Request element	A set of measurement requests, each containing a Measurement Token, Measurement Request Mode, Measurement Type, and Measurement Request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.12.3.3 When generated

This primitive is generated by the MLME when a valid Measurement Request frame is received.

10.3.12.3.4 Effect of receipt

On receipt of this primitive, the SME either rejects the request or commences the requested measurements.

10.3.13 Channel measurement

This set of primitives supports the requesting and reporting of measurement data.

10.3.13.1 MLME-MEASURE.request

10.3.13.1.1 Function

This primitive is generated by the SME to request that the MLME initiate specified measurements.

10.3.13.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-MEASURE.request(
                        Dialog Token,
                        Measurement Request Set,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
Dialog Token	Integer	0–255	The Dialog Token to identify the measurement transaction.
Measurement Request Set	Set of measurement requests, each as defined in the Measurement Request element	Set of measurement requests, each as defined in the Measurement Request element	A set of measurement requests, each containing a Measurement Token, Measurement Request Mode, Measurement Type, and Measurement Request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.13.1.3 When generated

This primitive is generated by the SME to request that the MLME initiate the specified measurements.

10.3.13.1.4 Effect of receipt

On receipt of this primitive, the MLME commences the measurement process.

Exhibit 1014
Page 001576

10.3.13.2 MLME-MEASURE.confirm

10.3.13.2.1 Function

This primitive reports the result of a measurement.

10.3.13.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-MEASURE.confirm(
ResultCode,
Dialog Token,
Measurement Report Set,
VendorSpecificInfo
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, or UNSPECIFIED_FAILURE	The outcome of the measurement request.
Dialog Token	Integer	0–255	The dialog token to identify the measurement transaction.
Measurement Report Set	Set of measurement reports, each as defined in the Measurement Report element	Set of measurement reports, each as defined in the Measurement Report element	A set of measurement reports, each containing a Measurement Token, Measurement Report Mode, Measurement Type, and Measurement Report.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.13.2.3 When generated

This primitive is generated by the MLME to report the results when a measurement set completes.

10.3.13.2.4 Effect of receipt

On receipt of this primitive, the SME evaluates the result code and, if appropriate, stores the channel measurements pending communication to the requesting entity or for local use.

10.3.14 Measurement report

This set of primitives supports the signaling of measurement reports.

10.3.14.1 MLME-MREPORT.request

10.3.14.1.1 Function

This primitive supports the signaling of measurement reports between peer SMEs.

10.3.14.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-MREPORT.request(
Peer MAC Address,
Dialog Token,
Measurement Report Set,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Peer MAC Address	MACAddress	Any valid individual MAC address	The address of the peer MAC entity to which the measurement report is set.
Dialog Token	Integer	0–255	The dialog token to identify the measurement transaction. Set to 0 for an autonomous report.
Measurement Report Set	Set of measurement reports, each as defined in the Measurement Report element	Set of measurement reports, each as defined in the Measurement Report element	A set of measurement reports, each containing a Measurement Token, Measurement Report Mode, Measurement Type, and Measurement Report.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.14.1.3 When generated

This primitive is generated by the SME to request that a frame be sent to a peer entity to report the results of measuring one or more channels.

10.3.14.1.4 Effect of receipt

On receipt of this primitive, the MLME constructs a Measurement Report frame containing the set of measurement reports. This frame isthen scheduled for transmission.

Page 001578

10.3.14.2 MLME-MREPORT.confirm

10.3.14.2.1 Function

This primitive reports the result of a request to send a Measurement Report frame.

10.3.14.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-MREPORT.confirm(
                        ResultCode,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID PARAMETERS, or UNSPECIFIED FAILURE	Reports the outcome of a request to send a Measurement Request frame.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.14.2.3 When generated

This primitive is generated by the MLME when the request to transmit a Measurement Report frame completes.

10.3.14.2.4 Effect of receipt

On receipt of this primitive, the SME evaluates the result code.

Exhibit 1014
Page 001579

10.3.14.3 MLME-MREPORT.indication

10.3.14.3.1 Function

This primitive indicates that a Measurement Report frame has been received from a peer entity. This management report can be in response to an earlier measurement request (e.g., MLME-MREQUEST.request) or can be an autonomous report.

10.3.14.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-MREPORT.indication(
Peer MAC Address,
Dialog Token,
Measurement Report Set,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Peer MAC Address	MACAddress	Any valid individual MAC address	The address of the peer MAC entity from which the Measurement Report frame was received.
Dialog Token	Integer	0–255	The dialog token to identify the measurement transaction. Set to 0 for an autonomous report.
Measurement Report Set	Set of measurement reports, each as defined in the Measurement Report element	Set of measurement reports, each as defined in the Measurement Report element	A set of measurement reports, each containing a Measurement Token, Measurement Report Mode, Measurement Type, and Measurement Report.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.14.3.3 When generated

This primitive is generated by the MLME when a valid Measurement Report frame is received.

10.3.14.3.4 Effect of receipt

On receipt of this primitive, measurement data can be available for SME processes, such as channel selection.

Exhibit 1014
Page 001580

10.3.15 Channel switch

10.3.15.1 MLME-CHANNELSWITCH.request

10.3.15.1.1 Function

This primitive requests a switch to a new operating channel.

10.3.15.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-CHANNELSWITCH.request(
Mode,
Channel Number,
Channel Switch Count,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Mode	Integer	0, 1	Channel switch mode, as defined for the Channel Switch Announcement element.
Channel Number	Integer	As defined in 17.3.8.3.3	Specifies the new channel number.
Channel Switch Count	Integer	0–255	Specifies the number of TBTTs until the channel switch event, as described for the Channel Switch Announcement element.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.15.1.3 When generated

This primitive is generated by the SME to schedule a channel switch and announce this switch to peer entities in the BSS.

10.3.15.1.4 Effect of receipt

On receipt of this primitive, the MLME schedules the channel switch event and announces this switch to other STAs in the BSS using the Channel Switch Announcement frame or element. The MLME ensures the timing of frame transmission takes into account the activation delay. The actual channel switch can be achieved at the appropriate time through the MLME-PLME interface using the PLME-SET primitive of the dot11CurrentFrequency MIB attribute.

Exhibit 1014
Page 001581

10.3.15.2 MLME-CHANNELSWITCH.confirm

10.3.15.2.1 Function

This primitive reports the result of a request to switch channel.

10.3.15.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-CHANNELSWITCH.confirm(
                                    ResultCode,
                                    VendorSpecificInfo
                                    )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID PARAMETERS, or UNSPECIFIED FAILURE	Reports the result of a channel switch request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.15.2.3 When generated

This primitive is generated by the MLME when a channel switch request completes. Possible unspecified failure causes include an inability to schedule a channel switch announcement.

10.3.15.2.4 Effect of receipt

The SME is notified of the results of the channel switch procedure.

10.3.15.3 MLME-CHANNELSWITCH.indication

10.3.15.3.1 Function

This primitive indicates that a channel switch announcement has been received from a peer entity.

10.3.15.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-CHANNELSWITCH.indication(
Peer MAC Address,
Mode,
Channel Number,
Channel Switch Count,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Peer MAC Address	MACAddress	Any valid individual MAC address	The address of the peer MAC entity from which the Measurement Report frame was received.
Mode	Integer	0, 1	Channel switch mode, as defined for the Channel Switch Announcement element.
Channel Number	Integer	As defined in 17.3.8.3.3	Specifies the new channel number.
Channel Switch Count	Integer	0–255	Specifies the number of TBTTs until the channel switch event, as described for the Channel Switch Announcement element.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.15.3.3 When generated

This primitive is generated by the MLME when a valid Channel Switch Announcement frame is received.

10.3.15.3.4 Effect of receipt

On receipt of this primitive, the SME decides whether to accept the switch.

10.3.15.4 MLME-CHANNELSWITCH.response

10.3.15.4.1 Function

This primitive is used to schedule an accepted channel switch.

10.3.15.4.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-CHANNELSWITCH.response(
Mode,
Channel Number,
Channel Switch Count,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Mode	Integer	0, 1	Channel switch mode, as defined for the Channel Switch Announcement element.
Channel Number	Integer	As defined in 17.3.8.3.3	Specifies the new channel number.
Channel Switch Count	Integer	0–255	Specifies the number of TBTTs until the channel switch event. as described for the Channel Switch Announcement element.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.15.4.3 When generated

This primitive is generated by the SME to schedule an accepted channel switch request.

10.3.15.4.4 Effect of receipt

On receipt of this primitive, the MLME schedules the channel switch. The actual channel switch can be achieved at the appropriate time through the MLME-PLME interface using the PLME-SET primitive of the dot11CurrentFrequency MIB attribute.

10.3.16 TPC request

This set of primitives supports the adaptation of transmit power between peer entities as described in 11.8.4.

10.3.16.1 MLME-TPCADAPT.request

10.3.16.1.1 Function

This primitive supports the adaptation of transmit power between peer entities as specified in 11.8.4.

10.3.16.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-TPCADAPT.request(
Peer MAC Address,
Dialog Token,
VendorSpecificInfo
)

Name	Type	Valid range	Description
Peer MAC Address	MACAddress	Any valid individual or group MAC address	The address of the peer MAC entity to which the TPC request is set.
Dialog Token	Integer	1–255	The dialog token to identify the TPC transaction.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.16.1.3 When generated

This primitive is generated by the SME to request that a TPC Request frame be sent to a peer entity to request that entity to report transmit power and link margin information.

10.3.16.1.4 Effect of receipt

On receipt of this primitive, the MLME constructs a TPC Request frame. This frame is then scheduled for transmission.

10.3.16.2 MLME-TPCADAPT.confirm

10.3.16.2.1 Function

This primitive reports the result of the TPC adaptation procedure.

10.3.16.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-TPCADAPT.confirm(
ResultCode
Transmit Power,
Link Margin,
VendorSpecificInfo
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID PARAMETERS, or UNSPECIFIED FAILURE	Reports the outcome of a request to send a TPC Request frame.
Transmit Power	Integer	–127 to 127	Value of the Transmit Power field of the TPC Report element of the TPC Report frame.
Link Margin	Integer	–127 to 127	Value of the Link Margin field of the TPC Report element of the TPC Report frame.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.16.2.3 When generated

This primitive is generated by the MLME when the TPC adaptation procedure completes.

10.3.16.2.4 Effect of receipt

The SME is notified of the results of the TPC adaptation procedure.

Exhibit 1014
Page 001586

10.3.17 SetKeys

10.3.17.1 MLME-SETKEYS.request

10.3.17.1.1 Function

This primitive causes the keys identified in the parameters of the primitive to be set in the MAC and enabled for use.

10.3.17.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SETKEYS.request(
Keylist
)

Name	Type	Valid range	Description
Keylist	A set of SetKeyDescriptors	N/A	The list of keys to be used by the MAC.

Each SetKeyDescriptor consists of the following elements:

Name	Type	Valid range	Description
Key	Bit string	N/A	The temporal key value
Length	Integer	N/A	The number of bits in the Key to be used.
Key ID	Integer	0–3	Key identifier
Key Type	Integer	Group, Pairwise, PeerKey	Defines whether this key is a group key, pairwise key, or PeerKey.
Address	MACAddress	Any valid individual MAC address	This parameter is valid only when the Key Type value is Pairwise, when the Key Type value is Group and the STA is in IBSS, or when the Key Type value is PeerKey.
Receive Sequence Count	8 octets	N/A	Value to which the RSC(s) is initialized
Authenticator/Supplicant or Initiator/Peer	Boolean	True, false	Whether the key is configured by the Authenticator or Supplicant; true indicates Authenticator or Initiator.
Cipher Suite Selector	4 octets	As defined in the RSN information element format	The cipher suite required for this association.

10.3.17.1.3 When generated

This primitive is generated by the SME at any time when one or more keys are to be set in the MAC.

10.3.17.1.4 Effect of receipt

Receipt of this primitive causes the MAC to set the appropriate keys and to begin using them for future MA-UNITDATA.request and MA-UNITDATA.indication primitives provided the MLME-SETPROTECTION.request primitive has been issued.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001587

10.3.17.2 MLME-SETKEYS.confirm

10.3.17.2.1 Function

This primitive confirms that the action of the associated MLME-SETKEYS.request primitive has been completed.

10.3.17.2.2 Semantics of the service primitive

This primitive has no parameters.

10.3.17.2.3 When generated

This primitive is generated by the MAC in response to receipt of a MLME-SETKEYS.request primitive. This primitive is issued when the action requested has been completed.

10.3.17.2.4 Effect of receipt

The SME is notified that the requested action of the MLME-SETKEYS.request primitive is completed.

Page 001588

10.3.18 DeleteKeys

10.3.18.1 MLME-DELETEKEYS.request

10.3.18.1.1 Function

This primitive causes the keys identified in the parameters of the primitive to be deleted from the MAC and thus disabled for use.

10.3.18.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-DELETEKEYS.request(
Keylist
)

Name	Type	Valid range	Description
Keylist	A set of DeleteKeyDescriptors	N/A	The list of keys to be deleted from the MAC.

Each DeleteKeyDescriptor consists of the following elements:

Name	Type	Valid range	Description
Key ID	Integer	N/A	Key identifier.
Key Type	Integer	Group, Pairwise, PeerKey	Defines whether this key is a group key, pairwise key, or PeerKey.
Address	MACAddress	Any valid individual MAC address	This parameter is valid only when the Key Type value is Pairwise, or when the Key Type value is Group and is from an IBSS STA, or when the Key Type value is PeerKey.

10.3.18.1.3 When generated

This primitive is generated by the SME at any time when keys for a security association are to be deleted in the MAC.

10.3.18.1.4 Effect of receipt

Receipt of this primitive causes the MAC to delete the temporal keys identified by the Keylist Address, including Group, Pairwise and PeerKey, and to cease using them.

10.3.18.2 MLME-DELETEKEYS.confirm

10.3.18.2.1 Function

This primitive confirms that the action of the associated MLME-DELETEKEYS.request primitive has been completed.

10.3.18.2.2 Semantics of the service primitive

This primitive has no parameters.

10.3.18.2.3 When generated

This primitive is generated by the MAC in response to receipt of a MLME-DELETEKEYS.request primitive. This primitive is issued when the action requested has been completed.

10.3.18.2.4 Effect of receipt

The SME is notified that the requested action of the MLME-DELETEKEYS.request primitive is completed.

10.3.19 MIC (Michael) failure event

10.3.19.1 MLME-MICHAELMICFAILURE.indication

10.3.19.1.1 Function

This primitive reports that a MIC failure event was detected.

10.3.19.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-MICHAELMICFAILURE.indication (
Count,
Address,
Key Type,
Key ID,
TSC
)

Name	Type	Valid range	Description
Count	Integer	1 or 2	The current number of MIC failure events.
Address	MACAddress	Any valid individual MAC address	The source MAC address of the frame.
Key Type	Integer	Group, Pairwise, PeerKey	The key type that the receive frame used.
Key ID	Integer	0–3	Key identifier.
TSC	6 octets	N/A	The TSC value of the frame that generated the MIC failure.

10.3.19.1.3 When generated

This primitive is generated by the MAC when it has detected a MIC failure.

10.3.19.1.4 Effect of receipt

The SME is notified that the MAC has detected a MIC failure.

10.3.20 EAPOL

10.3.20.1 MLME-EAPOL.request

10.3.20.1.1 Function

This primitive is generated by the SME when the SME has an IEEE 802.1X EAPOL-Key frame to send.

10.3.20.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-EAPOL.request (
                    Source Address,
                    Destination Address,
                    Data
                    )
```

Name	Type	Valid range	Description
Source Address	MACAddress	N/A	The MAC sublayer address from which the EAPOL-Key frame is being sent.
Destination Address	MACAddress	N/A	The MAC sublayer entity address to which the EAPOL-Key frame is being sent.
Data	IEEE 802.1X EAPOL-Key frame	N/A	The EAPOL-Key frame to be transmitted.

10.3.20.1.3 When generated

This primitive is generated by the SME when the SME has a 802.1X EAPOL-Key frame to send.

10.3.20.1.4 Effect of receipt

The MAC sends this EAPOL-Key frame.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001592

10.3.20.2 MLME-EAPOL.confirm

10.3.20.2.1 Function

This primitive indicates that this EAPOL-Key frame has been acknowledged by the IEEE 802.11 MAC.

10.3.20.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-EAPOL.confirm (
                    ResultCode
                    )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, TIMEOUT	Indicates whether the EAPOL-Key frame has been acknowledged by the target STA.

10.3.20.2.3 When generated

This primitive is generated by the MAC as a result of an MLME-EAPOL.request being generated to send an EAPOL-Key frame.

10.3.20.2.4 Effect of receipt

The SME is always notified whether this EAPOL-Key frame has been acknowledged by the IEEE 802.11 MAC.

Exhibit 1014
Page 001593

10.3.21 MLME-PeerKeySTART

10.3.21.1 MLME- PeerKeySTART.request

10.3.21.1.1 Function

This primitive is generated by the SME when the SME wants to start a PeerKey Handshake with a peer.

10.3.21.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-PeerKeySTART.request (
                                    PeerSTAAddress,
                                    RSN
                                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	Any valid individual MAC address	Specifies the address of the peer MAC entity with which to perform the PeerKey Handshake process.
RSN	RSN information element	As defined in frame format	A description of the cipher suites supported by initiator STA.

10.3.21.1.3 When generated

This primitive is generated by the SME for a STA to initiate a PeerKey Handshake with a specified peer MAC entity in order to create a secure link between the two STAs.

10.3.21.1.4 Effect of receipt

This primitive initiates the SMK Handshake as part of PeerKey Handshake by sending an EAPOL-Key message.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001594

10.3.22 SetProtection

10.3.22.1 MLME-SETPROTECTION.request

10.3.22.1.1 Function

This primitive indicates whether protection is required for frames sent to and received from the indicated MAC address.

10.3.22.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SETPROTECTION.request(Protectlist)

Name	Type	Valid range	Description
Protectlist	A set of protection elements	N/A	The list of how each key is being used currently.

Each Protectlist consists of the following elements:

Name	Type	Valid range	Description
Address	MACAddress	Any valid individual MAC address	This parameter is valid only when the Key Type value is Pairwise or when the Key Type value is Group and is from an IBSS STA or PeerKey.
ProtectType	Enumeration	None, Rx, Tx, Rx_Tx	The protection value for this MAC.
Key Type	Integer	Group, Pairwise, or PeerKey	Defines whether this key is a group key, pairwise key, or PeerKey.

10.3.22.1.3 When generated

This primitive is generated by the SME when protection is required for frames sent to and received from the indicated MAC address.

10.3.22.1.4 Effect of receipt

Receipt of this primitive causes the MAC to set the protection and to protect data frames as indicated in the ProtectType element of the Protectlist parameter:

— None: Specifies that data frames neither from the MAC address nor to the MAC address is protected.

— Rx: Specifies that data frames from MAC address is protected.

— Tx: Specifies that data frames to MAC address is protected.

— Rx_Tx: Specifies that data frames to and from MAC address is protected.

Once it is specified that a data frame is protected to or from a MAC address, this is reset by the MLME-SETPROTECTION.request primitive. The MLME-SETPROTECTION.request primitive deletes the state by specifying None.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001595

10.3.22.2 MLME-SETPROTECTION.confirm

10.3.22.2.1 Function

This primitive indicates that the frame protection request is completed.

10.3.22.2.2 Semantics of the service primitive

There are no parameters for this primitive.

10.3.22.2.3 When generated

This primitive is generated by the MAC when the protection request is complete.

10.3.22.2.4 Effect of receipt

The SME is notified that the protection request is complete.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001596

10.3.23 MLME-PROTECTEDFRAMEDROPPED

10.3.23.1 MLME- PROTECTEDFRAMEDROPPED.indication

10.3.23.1.1 Function

This primitive notifies the SME that a frame has been dropped because a temporal key was unavailable.

10.3.23.1.2 Semantics of the service primitive

This primitive has two parameters, the MAC addresses of the two STAs.

The primitive parameters are as follows:

MLME-PROTECTEDFRAMEDROPPED.indication (
Address1,
Address2
)

Name	Type	Valid range	Description
Address1	MACAddress	Any valid individual MAC address	MAC address of SA.
Address2	MACAddress	Any valid individual MAC address	MAC address of RA.

10.3.23.1.3 When generated

This primitive is generated by the MAC when a frame is dropped because no temporal key is available for the frame.

10.3.23.1.4 Effect of receipt

The SME is notified that a frame was dropped. The SME can use this information in an IBSS to initiate a security association to the peer STA.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001597

10.3.24 TS management interface

This mechanism supports the process of adding, modifying, or deleting a TS in a BSS using the procedures defined in 11.4.

The primitives used for this mechanism are called *TS Management primitives*, which include MLME-ADDTS.xxx and MLME-DELTS.xxx primitives, where xxx denotes request, confirm, indication, or response. Each primitive contains parameters that correspond to a QoS Action frame. Requests and responses may cause the transmission of the corresponding QoS Action frames. Confirms and indications are issued upon the receipt of the appropriate QoS Action frame.

Table 10-1 defines which primitives are supported by which type of STA.

Table 10-1—Supported TS Management primitives

Primitive	Request	Confirm	Indication	Response
ADDTS	non-AP QoS STA	non-AP QoS STA	HC	HC
DELTS	non-AP QoS STA and HC	non-AP QoS STA and HC	non-AP QoS STA and HC	—

10.3.24.1 MLME-ADDTS.request

10.3.24.1.1 Function

This primitive requests addition (or modification) of a TS. It is valid at the non-AP STA and requests the HC to admit the new or changed TS.

10.3.24.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-ADDTS.request (
                        DialogToken,
                        TSPEC,
                        TCLAS,
                        TCLASProcessing,
                        ADDTSFailureTimeout,
                        VendorSpecificInfo
                        )
```

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001598

Name	Type	Valid range	Description
DialogToken	Integer	0–127	Specifies a number unique to the QoS Action primitives and frames used in adding (or modifying) the TS of concern.
TSPEC	As defined in frame format with the exception of the surplus bandwidth allowance, minimum PHY rate, and maximum and minimum SIs, which are optionally specified	As defined in frame format with the exception of the surplus bandwidth allowance, minimum PHY rate, and maximum and minimum SIs, which are optionally specified	Specifies the TSID, traffic characteristics, and QoS requirements of the TS of concern.
TCLAS (0 or more)	As defined in frame format	As defined in frame format	Specifies the rules and parameters by which an MSDU may be classified to the specified TS.
TCLASProcessing	As defined in frame format	As defined in frame format	Specifies how the TCLAS elements are to be processed when there are multiple TCLAS elements.
ADDTSFailure-Timeout	Integer	Greater than or equal to 1	Specifies a time limit (in TU) after which the TS setup procedure will be is terminated.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.24.1.3 When generated

This primitive is generated by the SME at a non-AP STA to request the addition of a new (or modification of an existing) TS in order to support parameterized QoS transport of the MSDUs belonging to this TS when a higher layer protocol or mechanism signals the STA to initiate such an addition (or modification).

10.3.24.1.4 Effect of receipt

The non-AP STA operates according to the procedures defined in 11.4.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001599

10.3.24.2 MLME-ADDTS.confirm

10.3.24.2.1 Function

This primitive reports the results of a TS addition (or modification) attempt.

10.3.24.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ADDTS.confirm(
ResultCode,
DialogToken,
TSDelay,
TSPEC,
Schedule,
TCLAS,
TCLASProcessing,
VendorSpecificInfo
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, REJECTED_WITH_SUGGESTED_ CHANGES, REJECTED_FOR_DELAY_PERIOD, TIMEOUT, TRANSMISSION_FAILURE	Indicates the results of the corresponding MLME-ADDTS.request primitive.
DialogToken	Integer	As defined in the corresponding MLME-ADDTS.request primitive	Specifies a number unique to the QoS Action primitives and frames used in adding (or modifying) the TS.
TSDelay	Integer	≥ 0	When the result code is REJECTED_FOR_DELAY_ PERIOD, provides the amount of time a STA should wait before attempting another ADDTS request frame.
TSPEC	As defined in frame format	As defined in frame format	Specifies the TS information, traffic characteristics, and QoS requirements of the TS.
Schedule	As defined in frame format	As defined in frame format	Specifies the schedule information, service start time, SI, and the specification interval.
TCLAS (0 or more)	As defined in frame format	As defined in frame format	Specifies the rules and parameters by which an MSDU may be classified to the specified TS.
TCLASProcessing	As defined in frame format	As defined in frame format	Specifies how the TCLAS elements are to be processed when there are multiple TCLAS elements.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001600

For the ResultCode value of SUCCESS, the TSPEC and the optional TCLAS parameters describe the characteristics of the TS that has been created (or modified); and the specified (nonzero) parameters [with the exception of Service Start Time, Medium Time, and any possibly unspecified minimum set of parameters (see 9.9.3.2) in the TSPEC in ADDTS Request frame] exactly match those of the matching MLME-ADDTS.request primitive.

For other values of ResultCode, no new TS has been created. In the case of REJECTED_WITH_ SUGGESTED_CHANGES, the TSPEC represents an alternative proposal by the HC. A TS is not created with this definition. If the suggested changes are acceptable to the non-AP STA, it is the responsibility of the non-AP STA to set up the TS with the suggested changes.

If this is the result of a modification of an existing TS, the status of that TS remains unchanged.

10.3.24.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-ADDTS.request primitive indicating the results of that request.

This primitive is generated when that MLME-ADDTS.request primitive is found to contain invalid parameters, when a timeout occurs, or when the non-AP STA receives a response in the form of an ADDTS Response frame in the corresponding QoS Action frame from the HC.

10.3.24.2.4 Effect of receipt

The SME is notified of the results of the TS addition (or modification) procedure.

The SME should operate according to the procedures defined in 11.4.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001601

10.3.24.3 MLME-ADDTS.indication

10.3.24.3.1 Function

This primitive reports to the HC SME the request for adding (or modifying) a TS.

10.3.24.3.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-ADDTS.indication (
                        DialogToken,
                        Non-APSTAAddress
                        TSPEC,
                        TCLAS,
                        TCLASProcessing,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
DialogToken	Integer	As defined in the received ADDTS request frame	Specifies a number unique to the QoS Action primitives and frames used in adding (or modifying) the TS.
Non-APSTAAddress	MACAddress		Contains the MAC address of the non-AP STA that initiated the MLME-ADDTS.request primitive.
TSPEC	As defined in frame format with the exception of the surplus bandwidth allowance, minimum PHY rate, and maximum and minimum SIs, which are optionally specified	As defined in the received ADDTS Request frame with the exception of the surplus bandwidth allowance, minimum PHY rate, and maximum and minimum SIs, which are optionally specified	Specifies the TSID, traffic characteristics, and QoS requirements of the TS.
TCLAS (0 or more)	As defined in frame format	As defined in frame format	Specifies the rules and parameters by which an MSDU may be classified to the specified TS.
TCLASProcessing	As defined in frame format	As defined in frame format	Specifies how the TCLAS elements are to be processed when there are multiple TCLAS elements.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

The TCLAS is optional at the discretion of the non-AP STA that originated the request. An HC shall be capable of receiving an ADDTS request frame that contains a TCLAS element and capable of generating an indication that contains this as a parameter.

10.3.24.3.3 When generated

This primitive is generated by the MLME as a result of receipt of a request to add (or modify) a TS by a specified non-AP STA in the form of an Add TS request in the corresponding QoS Action frame.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001602

10.3.24.3.4 Effect of receipt

The SME is notified of the request for a TS addition (or modification) by a specified non-AP STA.

This primitive solicits an MLME-ADDTS.response primitive from the SME that reflects the results of admission control at the HC on the TS requested to be added (or modified).

The SME should operate according to the procedures defined in 11.4.

The SME generates an MLME-ADDTS.response primitive within a dot11ADDTSResponseTimeout.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001603

10.3.24.4 MLME-ADDTS.response

10.3.24.4.1 Function

This primitive responds to the request for a TS addition (or modification) by a specified non-AP STA MAC entity.

10.3.24.4.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ADDTS.response (
ResultCode,
DialogToken,
Non-APSTAAddress,
TSDelay,
TSPEC,
Schedule,
TCLAS,
TCLASProcessing,
VendorSpecificInfo
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, REJECTED_WITH_ SUGGESTED_CHANGES, REJECTED_FOR_DELAY_ PERIOD	Indicates the results of the corresponding MLME-ADDTS.indication primitive.
DialogToken	Integer	As defined in the corresponding MLME-ADDTS.indication	DialogToken of the matching MLME-ADDTS.indication primitive.
Non-APSTAAddress	MACAddress		Contains the non-AP STA address of the matching MLME-ADDTS.indication primitive.
TSDelay	Integer	≥ 0	When the result code is REJECTED_FOR_DELAY_ PERIOD, provides the amount of time a STA should wait before attempting another ADDTS request.
TSPEC	As defined in frame format	As defined in frame format	Specifies the QoS parameters of the TS.
Schedule	As defined in frame format	As defined in frame format	Specifies the schedule information, service start time, SI, and the specification interval.
TCLAS (0 or more)	As defined in frame format	As defined in frame format	Specifies the rules and parameters by which an MSDU may be classified to the specified TS.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001604

Name	Type	Valid range	Description
TCLASProcessing	As defined in frame format	As defined in frame format	Specifies how the TCLAS elements are to be processed when there are multiple TCLAS elements.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

The DialogToken and non-APSTAAddress parameters contain the values from the matching MLME-ADDTS.indication primitive.

If the result code is SUCCESS, the TSPEC and (optional) TCLAS parameters contain the values from the matching MLME-ADDTS-indication.

If the result code is REJECTED_WITH_SUGGESTED_CHANGES, the TSPEC and TCLAS parameters represent an alternative proposed TS. The TS, however, is not created. The TSID and direction values within the TSPEC are as in the matching MLME-ADDTS.indication primitive. The difference may lie in the QoS (e.g., minimum data rate, mean data rate, and delay bound) values, as a result of admission control performed at the SME of the HC on the TS requested to be added (or modified) by the non-AP STA. If sufficient bandwidth is not available, the QoS values may be reduced. In one extreme, the minimum data rate, mean data rate, and delay bound may be all set to 0, indicating that no QoS is to be provided to this TS.

10.3.24.4.3 When generated

This primitive is generated by the SME at the HC as a result of an MLME-ADDTS.indication primitive to initiate addition (or modification) of a TS with a specified peer MAC entity or entities.

10.3.24.4.4 Effect of receipt

This primitive approves addition (or modification) of a TS requested by a specified non-AP STA MAC entity, with or without altering the TSPEC.

This primitive causes the MAC entity at the HC to send an ADDTS Response frame in the corresponding QoS Action management frame to the requesting non-AP STA containing the specified parameters.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001605

10.3.24.5 MLME-DELTS.request

10.3.24.5.1 Function

This primitive requests deletion of a TS with a specified peer MAC.

This primitive may be generated at either a non-AP STA or the HC.

10.3.24.5.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DELTS.request(
                    Non-APSTAAddress,
                    TSInfo,
                    ReasonCode,
                    VendorSpecificInfo
                    )
```

Name	Type	Valid range	Description
Non-APSTAAddress (HC only)	MACAddress		(At the HC only) Specifies the MAC address of the non-AP STA that initiated this TS.
TSInfo	As defined in frame format	As defined in frame format	Specifies the TS to be deleted.
ReasonCode	Enumeration	STA_LEAVING, END_TS, UNKNOWN_TS	Indicates the reason why the TS is being deleted.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.24.5.3 When generated

This primitive is generated by the SME at a STA to initiate deletion of a TS when a higher layer protocol or mechanism signals the STA to initiate such a deletion.

10.3.24.5.4 Effect of receipt

This primitive initiates a TS deletion procedure. The MLME subsequently issues an MLME-DELTS.confirm primitive that reflects the results.

This primitive causes the local MAC entity to send out a DELTS frame containing the specified parameters. If this primitive was generated at the HC, the frame is sent to the specified non-AP STA MAC address. If this primitive was generated at the non-AP STA, the frame is sent to its HC. In either case, the DELTS frame does not solicit a response from the recipient frame other than an acknowledgment to receipt of the frame.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001606

10.3.24.6 MLME-DELTS.confirm

10.3.24.6.1 Function

This primitive reports the transmission status of a TS deletion attempt with a specified peer MAC entity.

10.3.24.6.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DELTS.confirm (
                        ResultCode,
                        Non-APSTAAddress,
                        TSInfo,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, FAILURE	Indicates the results of the corresponding MLME-DELTS.request primitive.
Non-APSTAAddress (HC only)	MACAddress		(HC only) Contains the non-AP STA MAC address of the matching request.
TSInfo	As defined in frame format	As defined in frame format	Contains the TS information of the matching request.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.24.6.3 When generated

This primitive is generated by the MLME as a result of an MLME-DELTS.request primitive after the DELTS frame has been sent (or attempts to send it have failed) and any internal state regarding the use of the TS has been destroyed.

10.3.24.6.4 Effect of receipt

The SME is notified of the results of the TS deletion procedure.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001607

10.3.24.7 MLME-DELTS.indication

10.3.24.7.1 Function

This primitive reports the deletion of a TS by a specified peer MAC entity or deletion of the TS due to an inactivity timeout (HC only).

10.3.24.7.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DELTS.indication (
                        Non-APSTAAddress,
                        TSInfo,
                        ReasonCode,
                        VendorSpecificInfo
                        )
```

Name	Type	Valid range	Description
Non-APSTAAddress (HC only)	MACAddress		(HC only) Specifies the MAC address of the non-AP STA for which the TS is being deleted.
TSInfo	As defined in frame format	As defined in the received DELTS frame	Specifies the TS information of the TS of concern.
ReasonCode	Enumeration	STA_LEAVING, END_TS, UNKNOWN_TS, TIMEOUT	Indicates the reason why the TS is being deleted.
VendorSpecificInfo	A set of information elements	As defined in 7.3.2.26	Zero or more information elements.

10.3.24.7.3 When generated

This primitive is generated by the MLME as a result of receipt of an initiation to delete a TS by a specified peer MAC entity.

This primitive may also be generated by the MLME at the HC as a result of inactivity of a particular TS. Inactivity results when a period equal to the inactivity interval in the TSPEC for the TS elapses

— Without arrival of an MSDU belonging to that TS at the MAC entity of the HC via an MA-UNITDATA.request primitive when the HC is the source STA of that TS or

— Without reception of an MSDU belonging to that TS by the MAC entity of the HC when a non-AP STA is the source STA of that TS.

This primitive is generated after any other state concerning the TSID/direction within the MAC has been destroyed.

10.3.24.7.4 Effect of receipt

The SME is notified of the initiation of a TS deletion by a specified peer MAC entity.

10.3.25 Management of direct links

This subclause describes the management procedures associated with direct links.

10.3.25.1 MLME-DLS.request

10.3.25.1.1 Function

This primitive requests the setup of a direct link with a specified peer MAC entity.

10.3.25.1.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DLS.request (
                    PeerMACAddress,
                    DLSTimeoutValue,
                    DLSResponseTimeout
                    )
```

Name	Type	Valid range	Description
PeerMACAddress	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA that is the intended immediate recipient of the data flow.
DLSTimeoutValue	Integer	≥ 0	Specifies a time limit (in seconds) after which the direct link is terminated if there are no frame exchange sequences with the peer. A value of 0 implies that the direct link is never to be terminated based on a timeout.
DLSResponseTimeout	Integer	≥ 1	Specifies a time limit (in TU) after which the DLS procedure is terminated.

10.3.25.1.3 When generated

This primitive is generated by the SME at a non-AP STA to set up a direct link with another non-AP STA.

10.3.25.1.4 Effect of receipt

This primitive initiates a DLS procedure. The MLME subsequently issues an MLME-DLS.confirm primitive that reflects the results.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001609

10.3.25.2 MLME-DLS.confirm

10.3.25.2.1 Function

This primitive reports the results of a DLS attempt with a specified peer MAC entity.

10.3.25.2.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DLS.confirm (
                    PeerMACAddress,
                    ResultCode,
                    CapabilityInformation,
                    DLSTimeoutValue,
                    SupportedRates
                    )
```

Name	Type	Valid range	Description
PeerMACAddress	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA that is the intended immediate recipient of the data flow.
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, NOT_ALLOWED, NOT_PRESENT, NOT_QOS_STA, REFUSED, TIMEOUT	Indicates the results of the corresponding MLME-DLS.request primitive.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capability definitions to be used by the peer MAC entity.
DLSTimeoutValue	Integer	≥ 0	Specifies a time limit (in seconds) after which the direct link is terminated if there are no frame exchange sequences with the peer. A value of 0 implies that the direct link is never to be terminated based on a timeout.
SupportedRates	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that are supported by the peer MAC entity.

10.3.25.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-DLS.request primitive to establish a direct link with a specified peer MAC entity.

10.3.25.2.4 Effect of receipt

The SME is notified of the results of the DLS procedure.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001610

10.3.25.3 MLME-DLS.indication

10.3.25.3.1 Function

This primitive reports the establishment of a direct link with a specified peer MAC entity.

10.3.25.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-DLS.indication(
PeerMACAddress,
CapabilityInformation,
DLSTimeoutValue,
SupportedRates
)

Name	Type	Valid range	Description
PeerMACAddress	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA that is the sender of the data flow.
Capability-Information	As defined in frame format	As defined in frame format	Specifies the operational capability definitions to be used by the peer MAC entity.
DLSTimeoutValue	Integer	≥ 0	Specifies a time limit (in seconds) after which the direct link is terminated if there are no frame exchange sequences with the peer. A value of 0 implies that the direct link is never to be terminated based on a timeout.
SupportedRates	Set of integers	1–127 inclusive (for each integer in the set)	The set of data rates that are supported by the peer MAC entity.

10.3.25.3.3 When generated

This primitive is generated by the MLME as result of the establishment of a direct link with a specific peer MAC entity that resulted from a DLS procedure that was initiated by that specific peer MAC entity.

10.3.25.3.4 Effect of receipt

The SME is notified of the establishment of the DLS.

Exhibit 1014
Page 001611

10.3.25.4 MLME-DLSTeardown.request

10.3.25.4.1 Function

When initiated by a non-AP STA, this primitive requests the teardown of the direct link with a specified peer MAC entity. When initiated by an AP, this primitive requests the teardown of direct link between two specified MAC entities.

10.3.25.4.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-DLSTeardown.request(
PeerMACAddress1,
PeerMACAddress2,
ReasonCode
)

Name	Type	Valid range	Description
PeerMACAddress1	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA that is the intended immediate recipient of the teardown.
PeerMACAddress2	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA with which the DLS is being torn down. This parameter is applicable only at the AP.
ReasonCode	Enumeration	STA_LEAVING, END_DLS, PEERKEY_MISMATCH, UNKNOWN_DLS	Indicates the reason why the direct link is being torn down.

10.3.25.4.3 When generated

This primitive is generated by the SME at a STA for tearing down a direct link with another non-AP STA.

10.3.25.4.4 Effect of receipt

This primitive initiates a direct-link teardown procedure. The MLME subsequently issues an MLME-DLSTeardown.confirm primitive that reflects the results.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001612

10.3.25.5 MLME-DLSTeardown.confirm

10.3.25.5.1 Function

This primitive reports the results of a direct-link teardown attempt with a specified peer MAC entity.

10.3.25.5.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DLSTeardown.confirm(
                                    PeerMACAddress1,
                                    PeerMACAddress2,
                                    ResultCode
                                    )
```

Name	Type	Valid range	Description
PeerMACAddress1	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA that is the intended immediate recipient of the teardown.
PeerMACAddress2	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA with which the direct link is being torn down. This parameter is applicable only at the AP.
ResultCode	Enumeration	SUCCESS, FAILURE	Indicates the results of the corresponding MLME-DLSTeardown.request primitive.

10.3.25.5.3 When generated

This primitive is generated by the MLME as a result of an MLME-DLSTeardown.request primitive to tear down an established direct link with a specified peer MAC entity.

10.3.25.5.4 Effect of receipt

The SME is notified of the results of the direct-link teardown procedure.

Exhibit 1014
Page 001613

10.3.25.6 MLME-DLSTeardown.indication

10.3.25.6.1 Function

This primitive indicates the teardown of an already established direct link with a specific peer MAC entity.

10.3.25.6.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DLSTeardown.indication(
                                    PeerMACAddress,
                                    ReasonCode
                                    )
```

Name	Type	Valid range	Description
PeerMACAddress	MACAddress	Any valid individual MAC address	Specifies the MAC address of the non-AP STA that is the sender of the data flow.
ReasonCode	Enumeration	STA_LEAVING, END_DLS, PEERKEY_MISMATCH, UNKNOWN_DLS, TIMEOUT	Indicates the reason why the direct link is being torn down.

10.3.25.6.3 When generated

This primitive is generated by the MLME as result of the teardown of a direct link with a specific peer MAC entity that resulted from a direct link teardown procedure that was initiated either by that specific peer MAC entity or by the local MAC entity.

10.3.25.6.4 Effect of receipt

The SME is notified of the teardown of the DLS.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001614

10.3.26 Higher layer synchronization support

This mechanism supports the process of synchronization among higher layer protocol entities residing within different wireless STAs. The actual synchronization mechanism in the higher layer is out of the scope of this standard. In principle, the MLME indicates the transmission/reception of frames with a specific multicast address in the Address 1 field of a data MPDU.

10.3.26.1 MLME-HL-SYNC.request

10.3.26.1.1 Function

This primitive requests activation of the synchronization support mechanism.

10.3.26.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-HL-SYNC.request(
GroupAddress
)

Name	Type	Valid range	Description
GroupAddress	MACAddress	A multicast MAC address	Specifies the multicast MAC address to which the synchronization frames are addressed. A synchronization frame is a data frame with higher layer synchronization information.

10.3.26.1.3 When generated

This primitive is generated by the SME when a higher layer protocol initiates a synchronization process.

10.3.26.1.4 Effect of Receipt

This request activates the synchronization support mechanism at the STA. The MLME subsequently issues an MLME-HL-SYNC.confirm primitive that reflects the results of the higher layer synchronization support request. If the request has been successful and the higher layer synchronization support mechanism has been activated, the MLME issues an MLME-HL-SYNC.indication primitive when a higher layer synchronization frame, which is a data frame with the specified multicast address in Address 1 field, is received or transmitted.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001615

10.3.26.2 MLME-HL-SYNC.confirm

10.3.26.2.1 Function

This primitive confirms the activation of the higher layer synchronization support mechanism.

10.3.26.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-HL-SYNC.confirm(
ResultCode,
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, NOT_SUPPORTED	Indicates the result of the MLME-HL-SYNC.request primitive.

10.3.26.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-HL-SYNC.request primitive to activate the higher layer synchronization support mechanism for a particular multicast address.

10.3.26.2.4 Effect of Receipt

The SME is notified of the activation of the higher layer synchronization support mechanism. The result code of NOT_SUPPORTED is issued if the MAC/MLME does not support the higher layer synchronization support mechanism or if the address provided by the MLME-HL-SYNC.request primitive is not a multicast address.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001616

10.3.26.3 MLME-HL-SYNC.indication

10.3.26.3.1 Function

This primitive indicates the last symbol on air of a higher layer synchronization frame, whether transmitted or received by the MAC.

10.3.26.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-HL-SYNC.indication(
SourceAddress,
SequenceNumber
)

Name	Type	Valid range	Description
SourceAddress	MACAddress	Any valid individual MAC address	Specifies the SA of the STA that transmitted the higher layer synchronization frame.
SequenceNumber	Integer	As defined in frame format	Specifies the sequence number of the higher layer synchronization frame received or transmitted.

10.3.26.3.3 When generated

This primitive is generated by the MLME when the successful reception or transmission of a higher layer synchronization frame is detected, as indicated by the PHY_RXEND.indication or PHY_TXEND.confirm primitives generated by the PHY. The higher layer synchronization frame is identified by the multicast MAC address registered by an earlier MLME-HL-SYNC.request primitive in the Address 1 field of a data frame.

10.3.26.3.4 Effect of Receipt

The SME is notified of the reception or transmission of a higher layer synchronization frame.

10.3.27 Block Ack

This mechanism supports the initiation (or modification) and termination of Block Ack.

The primitives used for this mechanism are called *Block Ack primitives*, which include MLME-ADDBA.xxx and MLME-DELBA.xxx primitives, where xxx denotes request, confirm, indication, or response. Each primitive contains parameters that correspond to a Block Ack Action frame body. Requests and responses may cause these frames to be sent. Confirms and indications are emitted when an appropriate Block Ack Action frame is received.

10.3.27.1 MLME-ADDBA.request

10.3.27.1.1 Function

This primitive requests the initiation (or modification) of Block Ack with a peer MAC entity.

10.3.27.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ADDBA.request(
PeerSTAAddress,
DialogToken,
TID,
BlockAckPolicy,
BufferSize,
BlockAckTimeout,
ADDBAFailureTimeout,
BlockAckStartingSequenceControl
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity with which to perform the Block Ack initiation (or modification).
DialogToken	Integer	0–255	Specifies a number unique to the Block Ack Action primitives and frames used in defining the Block Ack.
TID	Integer	0–15	Specifies the TID of the data.
BlockAckPolicy	Enumeration	Immediate, Delayed	Specifies the Block Ack policy.
BufferSize	Integer	0–127	Specifies the number of MPDUs that can be held in its buffer.
BlockAckTimeout	Integer	0–65 535	Specifies the number of TUs without a frame exchange between peers after which the Block Ack is considered to be torn down.
ADDBAFailure-Timeout	Integer	Greater than or equal to 1	Specifies a time limit (in TU) after which the Block Ack setup procedure is terminated.
BlockAckStarting-SequenceControl	As defined in frame format	As defined in frame format	Specifies the value of Block Ack starting sequence control.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001619

10.3.27.2 MLME-ADDBA.confirm

10.3.27.2.1 Function

The primitive reports the results of initiation (or modification) of the Block Ack attempt with the specified peer MAC entity.

10.3.27.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ADDBA.confirm(
PeerSTAAddress,
DialogToken,
TID,
ResultCode,
BlockAckPolicy,
BufferSize,
BlockAckTimeout
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity with which the Block Ack initiation (or modification) was attempted. This value must match the PeerSTAAddress parameter specified in MLME-ADDBA.request primitive.
DialogToken	Integer	0–255	Specifies a number unique to the Block Ack Action primitives and frames used in defining the Block Ack. This value must match the DialogToken parameter specified in MLME-ADDBA.request primitive.
TID	Integer	0–15	Specifies the TID of the data. This value must match the TID specified in MLME-ADDBA.request primitive.
ResultCode	Enumeration	SUCCESS, INVALID_ PARAMETERS, REFUSED, TIMEOUT	Indicates the result of the corresponding MLME-ADDBA.request primitive.
BlockAckPolicy	Enumeration	Immediate, Delayed	Specifies the Block Ack policy.
BufferSize	Integer	0–127	Specifies the maximum number of MPDUs in the block for the specified TID.
BlockAckTimeout	Integer	0–65 535	Specifies the number of TUs without a frame exchange between peers after which the Block Ack is considered to be torn down.

10.3.27.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-ADDBA.request primitive to indicate the results of that request.

10.3.27.2.4 Effect of receipt

The SME is notified of the results of the Block Ack initiation (or modification).

Exhibit 1014
Page 001620

10.3.27.3 MLME-ADDBA.indication

10.3.27.3.1 Function

This primitive reports the initiation (or modification) of Block Ack by a peer MAC entity.

10.3.27.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ADDBA.indication(
PeerSTAAddress,
DialogToken,
TID,
BlockAckPolicy,
BufferSize,
BlockAckTimeout
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity that requested the Block Ack initiation (or modification).
DialogToken	Integer	0–255	Specifies a number unique to the Block Ack Action primitives and frames used in defining the Block Ack.
TID	Integer	0–15	Specifies the TID of the data.
BlockAckPolicy	Enumeration	Immediate, Delayed	Specifies the Block Ack policy.
BufferSize	Integer	0–127	Specifies the number of MPDUs that can be held in peerSTAAddress buffer.
BlockAckTimeout	Integer	0–65 535	Specifies the number of TUs without a frame exchange between peers after which the Block Ack is considered to be torn down.

10.3.27.3.3 When generated

This primitive is generated by the MLME as a result of receipt of a Block Ack initiation (or modification) by the specified peer MAC entity in the form of an ADDBA Request frame.

10.3.27.3.4 Effect of receipt

The SME is notified of the initiation (or modification) of the Block Ack by the specified peer MAC entity.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001621

10.3.27.4 MLME-ADDBA.response

10.3.27.4.1 Function

The primitive responds to the initiation (or modification) by a specified peer MAC entity.

10.3.27.4.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-ADDBA.response(
PeerSTAAddress,
DialogToken,
TID,
ResultCode,
BlockAckPolicy,
BufferSize,
BlockAckTimeout
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity that attempted the Block Ack initiation (or modification). This value must match the Peer-STAAddress parameter specified in MLME-ADDBA.indication primitive.
DialogToken	Integer	0–255	Specifies a number unique to the Block Ack Action primitives and frames used in defining the Block Ack. This value must match the DialogToken parameter specified in MLME-ADDBA.indication primitive.
TID	Integer	0–15	Specifies the TID of the data. This value must match the TID specified in MLME-ADDBA.indication primitive.
ResultCode	Enumeration	SUCCESS, REFUSED, INVALID_ PARAMETERS, TIMEOUT	Indicates the result of the corresponding MLME-ADDBA.indication primitive.
BlockAckPolicy	Enumeration	Immediate, Delayed	Specifies the Block Ack policy. Undefined when the result code is REFUSED.
BufferSize	Integer	0–127	Specifies the maximum number of MPDUs in the block for the specified TID. Undefined when the result code is REFUSED.
BlockAckTimeout	Integer	0–65 535	Specifies the number of TUs without a frame exchange between peers after which the Block Ack is considered to be torn down.

10.3.27.4.3 When generated

This primitive is generated by the MLME as a result of an MLME-ADDBA.indication primitive to initiate Block Ack by the specified peer MAC entity.

10.3.27.4.4 Effect of receipt

The primitive causes the MAC entity to send an ADDBA Response frame to the specified peer MAC entity.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001622

10.3.27.5 MLME-DELBA.request

10.3.27.5.1 Function

This primitive requests the deletion of Block Ack with a peer MAC entity.

10.3.27.5.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DELBA.request(
                    PeerSTAAddress,
                    Direction,
                    TID,
                    ReasonCode
                    )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity with which to perform the Block Ack deletion.
Direction	Enumeration	Originator, Recipient	Specifies if the MAC entity initiating the MLME-DELBA.request primitive is the originator or the recipient of the data stream that uses the Block Ack.
TID	Integer	0–15	Specifies the TID of the MSDUs for which this Block Ack has been set up.
ReasonCode	Enumeration	STA_LEAVING, END_BA, UNKNOWN_BA	Indicates the reason why the Block Ack is being deleted.

10.3.27.5.3 When generated

This primitive is generated by the SME at a STA to request deletion of Block Ack with the specified peer MAC entity.

10.3.27.5.4 Effect of receipt

The STA sends the DELBA frame to the specified peer MAC entity.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001623

10.3.27.6 MLME-DELBA.confirm

10.3.27.6.1 Function

The primitive reports the transmission status of the Block Ack deletion attempt with a specified peer MAC entity.

10.3.27.6.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-DELBA.confirm(
PeerSTAAddress,
Direction,
TID,
ResultCode,
)

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity with which the Block Ack deletion was attempted. This value must match the PeerSTAAddress parameter specified in MLME-DELBA.request primitive.
Direction	Enumeration	Originator, Recipient	Specifies if the MAC entity initiating the MLME-DELBA.request primitive is the originator or the recipient of the data stream that uses the Block Ack.
TID	Integer	0–15	Specifies the TID of the MSDUs for which this Block Ack has been set up.
ResultCode	Enumeration	SUCCESS, INVALID_ PARAMETERS, FAILURE	Indicates the result of the corresponding MLME-DELBA.request primitive.

10.3.27.6.3 When generated

This primitive is generated by the MLME as a result of an MLME-DELBA.request primitive to indicate the results of that request.

10.3.27.6.4 Effect of receipt

The SME is notified of the results of the Block Ack deletion.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001624

10.3.27.7 MLME-DELBA.indication

10.3.27.7.1 Function

This primitive reports the deletion of Block Ack by a peer MAC entity.

10.3.27.7.2 Semantics of the service primitive

The primitive parameters are as follows:

```
MLME-DELBA.indication(
                        PeerSTAAddress,
                        Direction,
                        TID,
                        ReasonCode
                        )
```

Name	Type	Valid range	Description
PeerSTAAddress	MACAddress	N/A	Specifies the address of the peer MAC entity with which to perform the Block Ack deletion.
Direction	Enumeration	Originator, Recipient	Specifies if the MAC entity initiating the MLME-DELBA.request primitive is the originator or the recipient of the data stream that uses the Block Ack.
TID	Integer	0–15	Specifies the TID of the MSDUs for which this Block Ack has been set up.
ReasonCode	Enumeration	STA_LEAVING, END_BA, UNKNOWN_BA, TIMEOUT	Indicates the reason why the Block Ack is being deleted.

10.3.27.7.3 When generated

This primitive is generated by the MLME as a result of receipt of a Block Ack deletion by the specified peer MAC entity in the form of a DELBA frame.

10.3.27.7.4 Effect of receipt

The SME is notified of the deletion of the Block Ack by the specified peer MAC entity.

10.3.28 Schedule element management

This subclause describes the management procedures associated with the QoS Schedule element.

The primitives defined are MLME-SCHEDULE.request, MLME-SCHEDULE.confirm, and MLME-SCHEDULE.indication.

10.3.28.1 MLME-SCHEDULE.request

10.3.28.1.1 Function

This primitive requests transmission of a Schedule frame. It is valid at the HC.

10.3.28.1.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SCHEDULE.request(
Non-APSTAAddress,
Schedule
)

Name	Type	Valid range	Description
Non-APSTAAddress	MACAddress	Any valid individual address	MAC address of the non-AP STA to which the Schedule frame shall be sent.
Schedule	As defined in frame format	As defined in frame format	Specifies the schedule for the non-AP STA, including the SI (minimum and maximum), TXOP duration (minimum and maximum), and specification interval.

10.3.28.1.3 When generated

This primitive is generated by the SME at the HC to send the schedule information, in the form of a Schedule frame, to a specified non-AP STA when the schedule information for the non-AP STA is changed.

10.3.28.1.4 Effect of receipt

This primitive causes the MAC entity at the HC to send a Schedule frame to the non-AP STA specified in the primitive containing the specified Schedule parameters.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001626

10.3.28.2 MLME-SCHEDULE.confirm

10.3.28.2.1 Function

This primitive reports the transmission status of a MLME-SCHEDULE.request primitive.

10.3.28.2.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SCHEDULE.confirm(
ResultCode,
)

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, UNSPECIFIED_FAILURE	Indicates the results of the corresponding MLME-SCHEDULE.request primitive.

10.3.28.2.3 When generated

This primitive is generated by the MLME as a result of an MLME-SCHEDULE.request primitive when the action completes.

10.3.28.2.4 Effect of receipt

The SME is notified of the result of the MLME-SCHEDULE.request primitive. If the result code is SUCCESS, the Schedule element has been correctly sent by the HC to the non-AP STA in the Schedule frame.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001627

10.3.28.3 MLME-SCHEDULE.indication

10.3.28.3.1 Function

This primitive reports the reception of a new schedule by the non-AP STA in the form of a Schedule frame. It is valid at the non-AP STA.

10.3.28.3.2 Semantics of the service primitive

The primitive parameters are as follows:

MLME-SCHEDULE.indication(
Schedule
)

Name	Type	Valid range	Description
Schedule	As defined in frame format	As defined in frame format	Specifies the schedule for the non-AP STA, including the SI (minimum and maximum), TXOP duration (minimum and maximum), and specification interval.

10.3.28.3.3 When generated

This primitive is generated by the MLME as a result of receipt of a new schedule in the form of a Schedule frame.

10.3.28.3.4 Effect of receipt

The SME is notified of the receipt of QoS schedule in the form of a Schedule frame. The new Schedule parameters overwrite the previously stored values.

10.3.29 Vendor-specific action

This set of primitives supports the signaling of Vendor Specific Action frames between peer SMEs.

10.3.29.1 MLME-VSPECIFIC.request

10.3.29.1.1 Function

This primitive requests transmission of a Vendor Specific Action frame to a peer entity.

10.3.29.1.2 Semantics of the Service Primitive

The primitive parameters are as follows:

MLME-VSPECIFIC.request(
PeerMACAddress,
OUI,
VendorSpecificContent
)

Name	Type	Valid range	Description
PeerMACAddress	MACAddress	Any valid individual MAC address	The address of the peer MAC entity to which the Vendor Specific Action frame is sent.
OUI	3 octets	00-00-00 to FF-FF-FF	A public value assigned by the IEEE to identify the entity that has defined the content of the particular vendor-specific action.
VendorSpecificContent	Set of information elements and vendor-specific fields	Set of information elements and vendor-specific fields	A set of information elements as defined in 7.3.2. A set of vendor-specific fields specifying the required fields for the Vendor Specific Action frame.

10.3.29.1.3 When Generated

This primitive is generated by the SME to request that a Vendor Specific Action frame be sent to a peer entity.

10.3.29.1.4 Effect of Receipt

On receipt of this primitive, the MLME constructs a Vendor Specific Action frame containing the set of information elements and vendor-specific fields. The STA then attempts to transmit the frame to the peer entity.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001629

10.3.29.2 MLME-VSPECIFIC.confirm

10.3.29.2.1 Function

This primitive reports the result of a request to send a Vendor Specific Action frame to the peer entity.

10.3.29.2.2 Semantics of the Service Primitive

The primitive parameters are as follows:

```
MLME-VSPECIFIC.confirm(
                                    ResultCode
                                    )
```

Name	Type	Valid range	Description
ResultCode	Enumeration	SUCCESS, INVALID_PARAMETERS, TIMEOUT, TRANSMISSION_FAILURE, UNSPECIFIED_FAILURE	Indicates the result of the corresponding MLME-VSPECIFIC.request.

10.3.29.2.3 When Generated

This primitive is generated by the MLME when the request to transmit a Vendor Specific Action frame completes and indicates the results of the request.

10.3.29.2.4 Effect of Receipt

On receipt of this primitive, the SME evaluates the result code.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001630

10.3.29.3 MLME-VSPECIFIC.indication

10.3.29.3.1 Function

This primitive indicates that a Vendor Specific Action frame has been received from a peer entity.

10.3.29.3.2 Semantics of the Service Primitive

The primitive parameters are as follows:

MLME-VSPECIFIC.indication(
PeerMACAddress,
OUI,
VendorSpecificContent
)

Name	Type	Valid range	Description
PeerMACAddress	MACAddress	Any valid individual MAC address	The address of the peer MAC entity from which the Vendor Specific Action frame was received.
OUI	3 octets	00-00-00 to FF-FF-FF	A public value assigned by the IEEE to identify the entity that has defined the content of the particular vendor-specific action.
VendorSpecificContent	Set of information elements and vendor-specific fields	Set of information elements and vendor-specific fields	A set of information elements as defined in 7.3.2. A set of vendor-specific fields specifying the required fields for the Vendor Specific Action frame.

10.3.29.3.3 When Generated

This primitive is generated by the MLME when a valid Vendor Specific Action frame is received.

10.3.29.3.4 Effect of Receipt

On receipt of this primitive, the Vendor Specific Content can be made available for SME processes.

10.4 PLME SAP interface

The PHY management service interface consists of the generic PLMEGET and PLMESET primitives on PHY MIB attributes, as described previously, together with the PLME-RESET and PLME-CHARACTERISTICS primitives and the following specific primitives.

10.4.1 PLME-RESET.request

10.4.1.1 Function

This primitive is a request by the LME to reset the PHY. The PHY is always reset to the receive state to avoid accidental data transmission.

10.4.1.2 Semantics of the service primitive

The semantics of the primitive are as follows:
PLME-RESET.request( )

This primitive has no parameters.

10.4.1.3 When generated

This primitive is generated at any time to reset the PHY.

10.4.1.4 Effect of receipt

Receipt of this primitive by the PHY causes the PHY entity to reset both the transmit and the receive state machines and places the PHY into the receive state.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001632

10.4.2 PLME-CHARACTERISTICS.request

10.4.2.1 Function

This primitive is a request by the LME to provide the PHY operational characteristics.

10.4.2.2 Semantics of the service primitive

The semantics of the primitive are as follows:
PLME-CHARACTERISTICS.request( )

This primitive has no parameters.

10.4.2.3 When generated

This primitive is generated by the LME, at initialization time, to request the PHY entity to provide its operational characteristics.

10.4.2.4 Effect of receipt

The effect of receipt of this primitive by the PHY entity will be to generate a PLME-CHARACTERISTICS. confirm primitive that conveys its operational characteristics.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001633

10.4.3 PLME-CHARACTERISTICS.confirm

10.4.3.1 Function

This primitive provides the PHY operational parameters.

10.4.3.2 Semantics of the service primitive

The primitive provides the following parameters:

PLME-CHARACTERISTICS.confirm
(
aSlotTime,
aSIFSTime,
aCCATime,
aPHY-RX-START-Delay,
aRxTxTurnaroundTime,
aTxPLCPDelay,
aRxPLCPDelay,
aRxTxSwitchTime,
aTxRampOnTime,
aTxRampOffTime,
aTxRFDelay,
aRxRFDelay,
aAirPropagationTime,
aMACProcessingDelay,
aPreambleLength,
aPLCPHeaderLength,
aMPDUDurationFactor,
aMPDUMaxLength,
aCWmin,
aCWmax
)

The values assigned to the parameters is as specified in the PLME SAP interface specification contained within each PHY subclass of this standard. The parameter aMPDUDurationFactor is not used by all PHYs defined within this standard.

Name	Type	Description
aSlotTime	integer	The Slot Time (in microseconds) that the MAC will use for defining the PIFS and DIFS periods. See 9.2.10.
aSIFSTime	integer	The nominal time (in microseconds) that the MAC and PHY will require to receive the last symbol of a frame at the air interface, process the frame, and respond with the first symbol on the air interface of the earliest possible response frame. See 9.2.10.
aCCATime	integer	The minimum time (in microseconds) the CCA mechanism has available to assess the medium within every time slot to determine whether the medium is busy or idle.
aPHY-RX-START-Delay	integer	The delay, in microseconds, from a point in time specified by the PHY to the issuance of the PHY-RXSTART.indication primitive.
aRxTxTurnaroundTime	integer	The maximum time (in microseconds) that the PHY requires to change from receiving to transmitting the start of the first symbol. The following equation is used to derive the RxTxTurnaroundTime: aTxPLCPDelay + aRxTxSwitchTime + aTxRampOnTime + aTxRFDelay.
aTxPLCPDelay	integer	The nominal time (in microseconds) that the PLCP uses to deliver a symbol from the MAC interface to the transmit data path of the physical medium dependent (PMD).
aRxPLCPDelay	integer	The nominal time (in microseconds) that the PLCP uses to deliver the last bit of a received frame from the PMD receive path to the MAC.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001634

Name	Type	Description
aRxTxSwitchTime	integer	The nominal time (in microseconds) that the PMD takes to switch from Receive to Transmit.
aTxRampOnTime	integer	The maximum time (in microseconds) that the PMD takes to turn the Transmitter on.
aTxRampOffTime	integer	The nominal time (in microseconds) that the PMD takes to turn the Transmit Power Amplifier off.
aTxRFDelay	integer	The nominal time (in microseconds) between the issuance of a PMD_DATA.request to the PMD and the start of the corresponding symbol at the air interface. The start of a symbol is defined to be 1/2 symbol period prior to the center of the symbol for FH, or 1/2 chip period prior to the center of the first chip of the symbol for DS, or 1/2 slot time prior to the center of the corresponding slot for infrared (IR).
aRxRFDelay	integer	The nominal time (in microseconds) between the end of a symbol at the air interface to the issuance of a PMD_DATA.indicate to the PLCP. The end of a symbol is defined to be 1/2 symbol period after the center of the symbol for FH, or 1/2 chip period after the center of the last chip of the symbol for DS, or 1/2 slot time after the center of the corresponding slot for IR.
aAirPropagationTime	integer	Twice the propagation time (in microseconds) for a signal to cross the maximum distance between the most distant allowable STAs that are slot synchronized.
aMACProcessingDelay	integer	The maximum time (in microseconds) available for the MAC to issue a PHY-TXSTART.request primitive pursuant to a PHY-RXEND.indication primitive (for response after SIFS) or PHY-CCA.indication(IDLE) primitive (for response at any slot boundary following SIFS). This constraint on MAC performance is defined as a PHY-specific parameter because of its use, along with other PHY-specific time delays, in calculating the two PHY characteristics of primary concern to the MAC: aSlotTime and aSIFSTime. The relationship between aMACProcessingTime and the IFS and slot timing is described in 9.2.10 and illustrated in Figure 9-12.
aPreambleLength	integer	The current PHY's preamble length (in microseconds). If the actual value of the length of the modulated preamble is not an integral number of microseconds, the value is rounded up to the next higher value.
aPLCPHeaderLength	integer	The current PHY's PLCP header length (in microseconds). If the actual value of the length of the modulated header is not an integral number of microseconds, the value is rounded up to the next higher value.
aMPDUDurationFactor	integer	The overhead added by the PHY to the MPDU as it is transmitted through the WM expressed as a scaling factor applied to the number of bits in the MPDU. The value of aMPDUDurationFactor is generated by the following equation: Truncate[((PPDUbits/PSDUbits)–1) × 10^9)]. The total time to transmit a PPDU over the air is generated by the following equation rounded up to the next integer μs: aPreambleLength + aPLCPHeaderLength + (((aMPDUDurationFactor × 8 × PSDUoctets) / 10^9) + (8 × PSDUoctets)) / data rate where data rate is in Mb/s. The total time (in μs) to the beginning of any octet in a PPDU from the first symbol of the preamble can be calculated using the duration factor in the following equation: Truncate[aPreambleLength + aPLCPHeaderLength + (((aMPDUDurationFactor × 8 × N) / 10^9) + (8 × N)) / data rate] + 1, where data rate is in Mb/s and where *N* counts the number of octets in the PPDU prior to the desired octet, but does not count the number of octets in the preamble PLCP header.
aMPDUMaxLength	integer	The maximum number of octets in an MPDU that can be conveyed by a PLCP protocol data unit (PPDU).
aCWmin	integer	The minimum size of the CW, in units of aSlotTime.
aCWmax	integer	The maximum size of the CW, in units of aSlotTime.

10.4.3.3 When generated

This primitive will be issued by the PHY entity in response to a PLME-CHARACTERISTICS.request.

10.4.3.4 Effect of receipt

The receipt of this primitive provides the operational characteristics of the PHY entity.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001635

10.4.4 PLME-DSSSTESTMODE.request

10.4.4.1 Function

This primitive requests that the DSSS PHY entity enter a test mode operation. The parameters associated with this primitive are considered as recommendations and are optional in any particular implementation.

10.4.4.2 Semantics of the service primitive

The primitive parameters are as follows:

PLME-DSSSTESTMODE.request(
TEST_ENABLE,
TEST_MODE,
SCRAMBLE_STATE,
SPREADING_STATE,
DATA_TYPE,
DATA_RATE;
PREAMBLE_TYPE;
MODULATION_CODE_TYPE;
)

Name	Type	Valid range	Description
TEST_ENABLE	Boolean	True, false	If true, enables the PHY test mode according to the remaining parameters.
TEST_MODE	integer	1, 2, 3	TEST_MODE selects one of three operational states: 01 = transparent receive 02 = continuous transmit 03 = 50% duty cycle
SCRAMBLE_STATE	Boolean	True, false	If true, sets the operational state of the scrambler to ON.
SPREADING_STATE	Boolean	True, false	If true, selects the operational state of the chipping.
DATA_TYPE	integer	1, 2, 3	Selects one of three data patterns to be used for the transmit portions of the tests, e.g., all ones, all zeros, and random data patterns.
DATA_RATE	integer	2, 3, 4, 5, 6, 9, 11, 12, 18, 22, 24, 27, 36, 44, 48, 54, 66, 72, 96, 108	Selects among rates: 02 = 1 Mb/s 03 = 1.5 Mb/s 04 = 2 Mb/s 05 = 2.5 Mb/s 06 = 3 Mb/s 09 = 4.5 Mb/s 11 = 5.5 Mb/s 12 = 6 Mb/s 18 = 9 Mb/s 22 = 11 Mb/s 24 = 12 Mb/s 27 = 13.5 Mb/s 36 = 18 Mb/s 44 = 22 Mb/s 48 = 24 Mb/s 54 = 27 Mb/s 66 = 33 Mb/s 72 = 36 Mb/s 96 = 48 Mb/s 108 = 54 Mb/s

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001636

Name	Type	Valid range	Description
PREAMBLE_TYPE	Boolean	null, 0, 1	Selects the preamble length: 0 = long 1 = short Can be null.
MODULATION_CODE_TYPE	Integer	null, 0, 1, 2	Selects among modulation options: 0 = no optional modulation modes 1 = optional ERP-PBCC modes 2 = optional DSSS-OFDM modes Can be null.

The rate for DATA_Rate=05 is rounded up to the next higher 0.5 Mb/s value.

10.4.4.3 When generated

This primitive is generated at any time to enter the DSSS PHY test mode.

10.4.4.4 Effect of receipt

Receipt of this primitive by the PHY causes the DSSS PHY entity to enter the test mode of operation.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001637

10.4.5 PLME-DSSSTESTOUTPUT.request

10.4.5.1 Function

This optional primitive is a request by the LME to enable selected test signals from the PHY. The parameters associated with this primitive are considered as recommendations and are optional in any particular implementation.

10.4.5.2 Semantics of the service primitive

The primitive parameters are as follows:

```
PLME-DSSSTESTOUTPUT.request(
                                    TEST_OUTPUT,
                                    )
```

Name	Type	Valid range	Description
TEST_OUTPUT	Boolean	True, false	If true, enables the selected test signals for testing DS PHY.

TEST_OUTPUT enables and disables selected signals for debugging and testing the PHY. Some signals that can be available for output are PHY-TXSTART.request, PHY-RXSTART.indicate(RXVECTOR), PHY-CCA.indicate, the chipping clock, the data clock, the symbol clock, transmit (TX) data, and receive (RX) data.

10.4.5.3 When generated

This primitive is generated at any time to enable the test outputs when in the DSSS PHY test mode.

10.4.5.4 Effect of receipt

Receipt of this primitive by the DSSS PHY causes the DSSS PHY entity to enable the test outputs using the modes set by the most recent PLME-DSSSTESTMODE.request primitive.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001638

10.4.6 PLME-TXTIME.request

10.4.6.1 Function

This primitive is a request for the PHY to calculate the time that will be required to transmit onto the WM a PPDU containing a specified length MPDU, and using a specified format, data rate, and signalling.

10.4.6.2 Semantics of the service primitive

This primitive provides the following parameters:

PLME-TXTIME.request(TXVECTOR)

The TXVECTOR represents a list of parameters that the MAC sublayer provides to the local PHY entity in order to transmit an MPDU, as further described in 12.3.4.4 and 17.4 (which defines the local PHY entity).

10.4.6.3 When generated

This primitive is issued by the MAC sublayer to the PHY entity when the MAC sublayer needs to determine the time required to transmit a particular MPDU.

10.4.6.4 Effect of receipt

The effect of receipt of this primitive by the PHY entity is to generate a PHY-TXTIME.confirm primitive that conveys the required transmission time.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001639

10.4.7 PLME-TXTIME.confirm

10.4.7.1 Function

This primitive provides the time that will be required to transmit the PPDU described in the corresponding PLME-TXTIME.request.

10.4.7.2 Semantics of the service primitive

This primitive provides the following parameters:

PLME-TXTIME.confirm(TXTIME)

The TXTIME represents the time, in microseconds, required to transmit the PPDU described in the corresponding PLME-TXTIME.request. If the calculated time includes a fractional microsecond, the TXTIME value is rounded up to the next higher integer.

10.4.7.3 When generated

This primitive is issued by the local PHY entity in response to a PLME-TXTIME.request.

10.4.7.4 Effect of receipt

The receipt of this primitive provides the MAC sublayer with the PPDU transmission time.

11. MLME

11.1 Synchronization

All STAs within a single BSS shall be synchronized to a common clock using the mechanisms defined herein.

11.1.1 Basic approach

A Timing Synchronization Function (TSF) keeps the timers for all STAs in the same BSS synchronized. All STAs shall maintain a local TSF timer.

11.1.1.1 TSF for infrastructure networks

In an infrastructure BSS, the AP shall be the timing master for the TSF. The AP shall initialize its TSF timer independently of any simultaneously started APs in an effort to minimize the synchronization of the TSF timers of multiple APs. The AP shall periodically transmit special frames called *Beacon frames* that contain a copy of its TSF timer to synchronize the TSF timers of other STAs in a BSS. A receiving STA shall always accept the timing information in Beacon frames sent from the AP servicing its BSS. If a STA's TSF timer is different from the timestamp in the received Beacon frame, the receiving STA shall set its local TSF timer to the received timestamp value.

Beacon frames shall be generated for transmission by the AP once every dot11BeaconPeriod TUs.

11.1.1.2 TSF for an IBSS

The TSF in an IBSS shall be implemented via a distributed algorithm that shall be performed by all of the members of the BSS. Each STA in the IBSS shall transmit Beacon frames according to the algorithm described in this clause. Each STA in an IBSS shall adopt the TSF value received from any Beacon frame or probe response from the IBSS of which it is a member and which has a TSF value later than its own TSF timer.

11.1.2 Maintaining synchronization

Each STA shall maintain a TSF timer with modulus 2^{64} counting in increments of microseconds. STAs expect to receive Beacon frames at a nominal rate. The interval between Beacon frames is defined by the dot11BeaconPeriod parameter of the STA. A STA sending a Beacon frame shall set the value of the Beacon frame's timestamp so that it equals the value of the STA's TSF timer at the time that the data symbol containing the first bit of the timestamp is transmitted to the PHY plus the transmitting STA's delays through its local PHY from the MAC-PHY interface to its interface with the WM [e.g., antenna, light-emitting diode (LED) emission surface].

11.1.2.1 Beacon generation in infrastructure networks

The AP shall define the timing for the entire BSS by transmitting Beacon frames according to the dot11BeaconPeriod attribute within the AP. This defines a series of TBTTs exactly dot11BeaconPeriod TUs apart. Time zero is defined to be a TBTT with the Beacon frame being a DTIM and transmitted at the beginning of a CFP. At each TBTT, the AP shall schedule a Beacon frame as the next frame for transmission according to the medium access rules specified in Clause 9. The beacon period is included in Beacon and Probe Response frames, and STAs shall adopt that beacon period when joining the BSS.

NOTE—Though the transmission of a Beacon frame may be delayed because of CSMA deferrals, subsequent Beacon frames shall be scheduled at the undelayed nominal beacon interval. This is shown in Figure 11-1.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001642

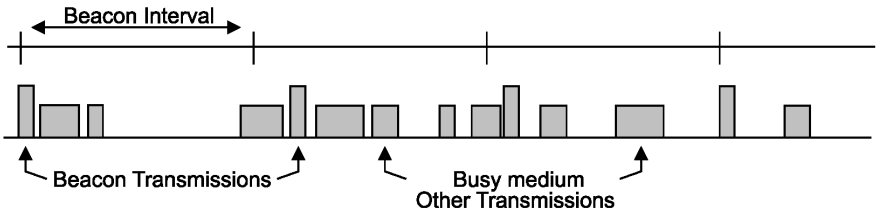

Figure 11-1—Beacon transmission on a busy network

11.1.2.2 Beacon generation in an IBSS

Beacon generation in an IBSS is distributed. The beacon period is included in Beacon and Probe Response frames, and STAs shall adopt that beacon period when joining the IBSS. All members of the IBSS participate in beacon generation. Each STA shall maintain its own TSF timer that is used for dot11BeaconPeriod timing. The beacon interval within an IBSS is established by the STA at which the MLME-START.request is performed to create the IBSS. This defines a series of TBTTs exactly dot11BeaconPeriod TUs apart. Time zero is defined to be a TBTT. At each TBTT the STA shall

a) Suspend the decrementing of the backoff timer for any pending nonbeacon or non-ATIM transmission,

b) Calculate a random delay uniformly distributed in the range between zero and twice aCWmin × aSlotTime,

c) Wait for the period of the random delay, decrementing the random delay timer using the same algorithm as for backoff,

d) Cancel the remaining random delay and the pending beacon transmission, if a Beacon frame arrives from the IBSS of which the STA is a member before the random delay timer has expired, at which time the ATIM backoff timer shall resume decrementing.

e) Send a Beacon frame if the random delay has expired and no Beacon frame has arrived from the IBSS of which the STA is a member during the delay period.

(See Figure 11-2.)

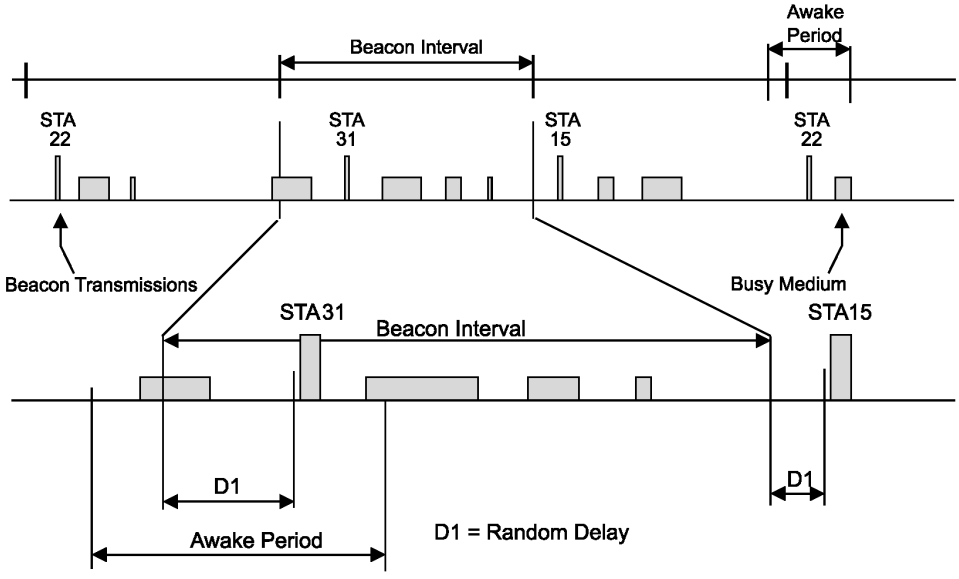

Figure 11-2—Beacon transmission in an IBSS

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001643

The beacon transmission shall always occur during the Awake Period of STAs that are operating in a low-power mode. This is described in more detail in 11.2.

11.1.2.3 Beacon reception

STAs shall use information from the CF Parameter Set element of all received Beacon frames, without regard for the BSSID, to update their NAV as specified in 9.3.2.2.

STAs in an infrastructure network shall only use other information in received Beacon frames, if the BSSID field is equal to the MAC address currently in use by the STA contained in the AP of the BSS.

STAs in an IBSS shall use other information in any received Beacon frame for which the IBSS subfield of the Capability field is set to 1, the content of the SSID element is equal to the SSID of the IBSS, and the TSF value is later than the receiving STA's TSF timer. Use of this information is specified in 11.1.4.

11.1.2.4 TSF timer accuracy

Upon receiving a Beacon frame with a valid FCS and BSSID or SSID, as described in 11.1.2.3, a STA shall update its TSF timer according to the following algorithm: The received timestamp value shall be adjusted by adding an amount equal to the receiving STA's delay through its local PHY components plus the time since the first bit of the timestamp was received at the MAC/PHY interface. In the case of an infrastructure BSS, the STA's TSF timer shall then be set to the adjusted value of the timestamp. In the case of an IBSS, the STA's TSF timer shall be set to the adjusted value of the received timestamp, if the adjusted value of the timestamp is later than the value of the STA's TSF timer. The accuracy of the TSF timer shall be no worse than ±0.01%.

11.1.3 Acquiring synchronization, scanning

A STA shall operate in either a Passive Scanning mode or an Active Scanning mode depending on the current value of the ScanMode parameter of the MLME-SCAN.request primitive.

Active scanning is prohibited in some frequency bands and regulatory domains. The MAC of a STA receiving an MLME-SCAN.request shall use the regulatory domain information it has to process the request and shall return a result code of NOT_SUPPORTED to a request for an active scan if regulatory domain information indicates an active scan is illegal.

Upon receipt of the MLME-SCAN.request primitive, a STA shall perform scanning. The SSID parameter indicates the SSID for which to scan. To become a member of a particular ESS using passive scanning, a STA shall scan for Beacon frames containing that ESS's SSID, returning all Beacon frames matching the desired SSID in the BSSDescriptionSet parameter of the corresponding MLME-SCAN.confirm primitive with the appropriate bits in the Capabilities Information field indicating whether the Beacon frame came from an infrastructure BSS or IBSS. To actively scan, the STA shall transmit Probe request frames containing the desired SSID. Upon completion of scanning, an MLME-SCAN.confirm is issued by the MLME indicating all of the BSS information received.

Upon receipt of an MLME-JOIN.request, the STA shall use the syncrhonization procedure described in 11.1.3.4.

Upon receipt of an MLME-SCAN.request with the SSID parameter set to the wildcard SSID, the STA shall passively scan for any Beacon frames, or actively transmit Probe request frames containing the wildcard SSID, as appropriate depending upon the value of ScanMode. Upon completion of scanning, an MLME-SCAN.confirm is issued by the MLME indicating all of the BSS information received.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001644

If a STA's scanning does not result in finding a BSS with the desired SSID and of the desired type, or does not result in finding any BSS, the STA may start an IBSS upon receipt of the MLME-START.request. The MAC of a STA receiving an MLME-START.request shall use the regulatory domain information it has to process the request and shall return a result code of NOT_SUPPORTED to the request if regulatory domain information indicates starting the IBSS is illegal.

When a STA starts a BSS, that STA shall determine the BSSID of the BSS. If the BSSType indicates an infrastructure BSS, then the STA shall start an infrastructure BSS and the BSSID shall be equal to the STA's dot11StationID. The value of the BSSID shall remain unchanged, even if the value of dot11StationID is changed after the completion of the MLME-START.request. If the BSSType indicates an IBSS, the STA shall start an IBSS, and the BSSID shall be an individual locally administered IEEE MAC address as defined in 5.2 of IEEE Std 802-1990. The remaining 46 bits of that MAC address shall be a number selected in a manner that minimizes the probability of STAs generating the same number, even when those STAs are subjected to the same initial conditions. The value SSID parameter shall be used as the SSID of the new BSS. It is important that designers recognize the need for statistical independence among the random number streams among STAs.

11.1.3.1 Passive scanning

If the ScanType parameter indicates a passive scan, the STA shall listen to each channel scanned for no longer than a maximum duration defined by the MaxChannelTime parameter.

11.1.3.2 Active scanning

Active scanning involves the generation of Probe request frames and the subsequent processing of received Probe Response frames. The details of the active scanning procedures are as specified in the following subclauses.

11.1.3.2.1 Sending a probe response

STAs, subject to criteria below, receiving Probe Request frames shall respond with a probe response only if

a) The SSID in the probe request is the wildcard SSID or the specific SSID of the STA,
b) The BSSID field in the probe request is the wildcard BSSID or the BSSID of the STA, and
c) The DA field in the probe request is the broadcast address or the specific MAC address of the STA.

Probe Response frames shall be sent as directed frames to the address of the STA that generated the probe request. The probe response shall be sent using normal frame transmission rules. An AP shall respond to all probe requests meeting the above criteria. In an IBSS, the STA that generated the last Beacon frame shall be the STA that responds to a probe request.

Only APs and STAs in an IBSS respond to probe requests. The procedures defined in this subclause ensure that in each BSS there is at least one STA that is awake at any given time to receive and respond to probe requests. A STA that sent a Beacon frame shall remain in the Awake state and shall respond to probe requests, subject to criteria in the next paragraph, until a Beacon frame with the current BSSID is received. If the STA is an AP, it shall always remain in the Awake state and always respond to probe requests, subject to criteria in the next paragraph. There may be more than one STA in an IBSS that responds to any given probe request, particularly in cases where more than one STA transmitted a Beacon frame following the most recent TBTT, either due to not receiving successfully a previous Beacon frame or due to collisions between beacon transmissions.

STAs receiving Probe Request frames shall respond with a probe response when the SSID in the probe request is the wildcard SSID or matches the specific SSID of the STA. Probe Response frames shall be sent as directed frames to the address of the STA that generated the probe request. The probe response shall be

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001645

sent using normal frame transmission rules. An AP shall respond to all probe requests meeting the above criteria. In an IBSS, the STA that generated the last Beacon frame shall be the STA that responds to a probe request.

11.1.3.2.2 Active scanning procedure

Upon receipt of the MLME-SCAN.request with ScanType indicating an active scan, a STA shall use the following procedure:

For each channel to be scanned,

a) Wait until the ProbeDelay time has expired or a PHYRxStart.indication has been received;

b) Perform the Basic Access procedure as defined in 9.2.5.1;

c) Send a probe request to the broadcast destination address, with the SSID and BSSID from the MLME-SCAN.request primitive;

d) Clear and start a ProbeTimer;

e) If PHY-CCA.indication (busy) has not been detected before the ProbeTimer reaches MinChannelTime, then clear NAV and scan the next channel, else when ProbeTimer reaches MaxChannelTime, process all received probe responses;

f) Clear NAV and scan the next channel.

See Figure 11-3.

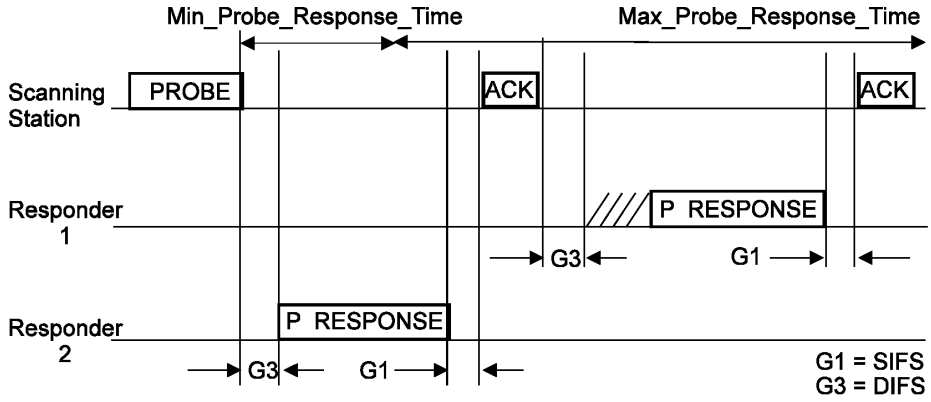

Figure 11-3—Probe response

When all channels in the ChannelList have been scanned, the MLME shall issue an MLME-SCAN.confirm with the BSSDescriptionSet containing all of the information gathered during the scan.

11.1.3.3 Initializing a BSS

Upon receipt of an MLME-START.request, a STA shall determine the BSS's BSSID (as described in 11.1.3), select channel synchronization information, select a beacon period, initialize and start its TSF timer, and begin transmitting Beacon frames. If the dot11MultiDomainCapabilityEnabled attribute is true, a STA shall not start a BSS, neither an infrastructure BSS nor an IBSS, unless a properly formed Beacon frame including a Country information element can be constructed, and the dot11CountryString attribute has been set.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001646

11.1.3.4 Synchronizing with a BSS

Upon receipt of an MLME-JOIN.request, a STA shall adopt the BSSID in the request. Upon receipt of a Beacon frame from the BSS, a STA shall adopt the channel synchronization information (applicable only if the STA contains an FH PHY), and TSF timer value of the parameters in the Beacon frame using the algorithm described in 11.1.2.4, and the MLME shall issue an MLME-JOIN.confirm indicating the operation was successful.

In addition to these synchronization parameters, a STA joining an infrastructure BSS will adopt each of the parameters found in the BssDescription of the MLME-JOIN.request except Local time, Capability Information, and BSSBasicRateSet parameters. Local time is not adopted but is used as a local variable in adopting the TSF as described in 11.1.2.4. The Capability Information reflects the capabilities of the sender and is not adopted but may be used to determine local configuration or behavior. The BSSBasicRateSet parameter is not adopted but may determine if the STA can join the BSS. A STA joining an IBSS will adopt the same parameters except the CF parameter set (since contention free period is not permitted in an IBSS).

If the JoinFailureTimeout timer expires prior to the receipt of a Beacon frame from the BSS, the MLME shall issue an MLME-JOIN.confirm indicating the operation was unsuccessful.

If the dot11MultiDomainCapabilityEnabled attribute is true, a STA receiving a Beacon or Probe Response frame containing a Country information element shall adopt the all parameters included in that Country information element when joining a BSS and the dot11RegDomainsSupportEntry shall be set to Other.

If a Hopping Pattern Parameters element is present in the Beacon or Probe Response frame, and if the dot11MultiDomainCapability-Enabled attribute is true, a STA shall adopt the pattern parameters in the element and calculate the hopping patterns using one of the algorithms defined in 7.3.2.10 or 7.3.2.11. Using the appropriate pattern, set, and index values from the FH Parameter Set element, the STA shall adopt the values in use by the BSS when joining. The dot11RegDomainsSupportedValue shall be set to Other when the STA is operating using Country information element settings

11.1.4 Adjusting STA timers

In an infrastructure BSS, STAs shall always adopt the TSF timer value in a Beacon frame or probe response coming from the AP in their BSS by using the algorithm in 11.1.2.4.

In response to an MLME-JOIN.request, a STA joining an IBSS shall initialize its TSF timer to 0 and shall not transmit a Beacon frame or probe response until it hears a Beacon frame or probe response from a member of the IBSS with a matching SSID. This ensures that such a STA will adopt the timer from the next Beacon frame or probe response from its IBSS.

All Beacon and Probe Response frames carry a Timestamp field. A STA receiving such a frame from another STA in an IBSS with the same SSID shall compare the Timestamp field with its own TSF time. If the Timestamp field of the received frame is later than its own TSF timer, the STA in the IBSS shall adopt all parameters contained in the Beacon frame, except the Capability bits, Supported Rates information element, and Extended Supported Rates information element.

11.1.5 Timing synchronization for FH PHYs

NOTE—This subclause pertains only to STAs using an FH PHY.

The TSF described here provides a mechanism for STAs in an FH system to synchronize their transitions from one channel to another (their “hops”). Every STA shall maintain a table of all of the hopping sequences that are used in the system. All of the STAs in a BSS shall use the same hopping sequence. Each Beacon

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001647

frame and probe response includes the channel synchronization information necessary to determine the hop pattern and timing for the BSS.

STAs shall use their TSF timer to time the aCurrentDwellTime. The aCurrentDwellTime is the length of time that STAs shall stay on each frequency in their hopping sequence. Once STAs are synchronized, they have the same TSF timer value.

STAs in the BSS shall issue an appropriate PLME service primitive for the PHY in use to tune to the next frequency in the hopping sequence when

TSF timer MOD aCurrentDwellTime = 0

11.2 Power management

11.2.1 Power management in an infrastructure network

STAs changing Power Management mode shall inform the AP of this fact using the Power Management bits within the Frame Control field of transmitted frames. The AP shall not arbitrarily transmit MSDUs to STAs operating in a PS mode, but shall buffer MSDUs and only transmit them at designated times.

The STAs that currently have buffered MSDUs within the AP are identified in a TIM, which shall be included as an element within all Beacon frames generated by the AP. A STA shall determine that an MSDU is buffered for it by receiving and interpreting a TIM.

STAs operating in PS modes shall periodically listen for Beacon frames, as determined by the STA's ListenInterval and the ReceiveDTIMs parameter in the MLME-POWERMGT.request primitive.

In a BSS operating under the DCF, or during the CP of a BSS using the PCF, upon determining that an MSDU is currently buffered in the AP, a STA operating in the *PS mode* shall transmit a short PS-Poll frame to the AP, which shall respond with the corresponding buffered MSDU immediately, or acknowledge the PS-Poll and respond with the corresponding MSDU at a later time. If the TIM indicating the buffered MSDU is sent during a CFP, a CF-Pollable STA operating in the PS mode does not send a PS-Poll frame, but remains active until the buffered MSDU is received (or the CFP ends). If any STA in its BSS is in PS mode, the AP shall buffer all broadcast and multicast MSDUs and deliver them to all STAs immediately following the next Beacon frame containing a DTIM transmission.

A STA shall remain in its current Power Management mode until it informs the AP of a Power Management mode change via a frame exchange that includes an acknowledgment from the AP. Power Management mode shall not change during any single frame exchange sequence, as described in 9.12.

A non-AP QoS STA may be in PS mode before the setup of DLS or Block Ack. Once DLS is set up with another non-AP STA, the non-AP STA suspends the PS mode and shall always be awake. When a STA enters normal (non-APSD) PS mode, any downlink Block Ack agreement without an associated schedule is suspended for the duration of this PS mode. MSDUs for TID without a schedule are sent using Normal Ack following a PS-poll as described in rest of this clause. Uplink Block Ack, Block Acks for any TID with a schedule, and any Block Acks to APSD STA continue to operate normally.

11.2.1.1 STA Power Management modes

A STA may be in one of two different power states:

— *Awake:* STA is fully powered.

— *Doze:* STA is not able to transmit or receive and consumes very low power.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001648

The manner in which a STA transitions between these two power states shall be determined by the STA's Power Management mode. These modes are summarized in Table 11-1.

Table 11-1—Power Management modes

Active mode or AM	STA may receive frames at any time. In Active mode, a STA shall be in the Awake state. A STA on the polling list of a PCF shall be in Active mode for the duration of the CFP.
PS	STA listens to selected Beacon frames (based upon the ListenInterval parameter of the MLME-ASSOCIATE.request primitive) and sends PS-Poll frames to the AP if the TIM element in the most recent Beacon frame indicates a directed MSDU buffered for that STA. The AP shall transmit buffered directed MSDUs to a PS STA only in response to a PS-Poll from that STA, or during the CFP in the case of a CF-Pollable PS STA. In PS mode, a STA shall be in the Doze state and shall enter the Awake state to receive selected Beacon frames, to receive broadcast and multicast transmissions following certain received Beacon frames, to transmit, and to await responses to transmitted PS-Poll frames or (for CF-Pollable STAs) to receive CF transmissions of buffered MSDUs.

The Power Management mode of a STA is selected by the PowerManagementMode parameter of the MLME-POWERMGT.request. Once the STA updates its Power Management mode, the MLME shall issue an MLME-POWERMGT.confirm indicating the success of the operation.

To change Power Management modes, a STA shall inform the AP through a successful frame exchange initiated by the STA. The Power Management bit in the Frame Control field of the frame sent by the STA in this exchange indicates the Power Management mode that the STA shall adopt upon successful completion of the entire frame exchange. The Power Managment bit shall not be set in any management frame, except an Action frame.

A STA that is changing from Doze to Awake in order to transmit shall perform CCA until a frame sequence is detected by which it can correctly set its NAV, or until a period of time equal to the ProbeDelay has transpired.

11.2.1.2 AP TIM transmissions

The TIM shall identify the STAs for which traffic is pending and buffered in the AP. This information is coded in a *partial virtual bitmap*, as described in 7.3.2.6. In addition, the TIM contains an indication whether broadcast/multicast traffic is pending. Every STA is assigned an AID by the AP as part of the association process. AID 0 (zero) is reserved to indicate the presence of buffered broadcast/multicast MSDUs. The AP shall identify those STAs for which it is prepared to deliver buffered MSDUs by setting bits in the TIM's partial virtual bitmap that correspond to the appropriate AIDs.

11.2.1.3 TIM types

Two different TIM types are distinguished: TIM and DTIM. After a DTIM, the AP shall send out the buffered broadcast/multicast MSDUs using normal frame transmission rules, before transmitting any unicast frames.

The AP shall transmit a TIM with every Beacon frame. Every DTIMPeriod, a TIM of type *DTIM* is transmitted within a Beacon frame, rather than an ordinary TIM.

Figure 11-4 illustrates the AP and STA activity under the assumptions that no PCF is operating and that a DTIM is transmitted once every three TIMs. The top line in Figure 11-4 represents the time axis, with the beacon interval shown together with a DTIM Interval of three beacon intervals. The second line depicts AP

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001649

activity. The AP schedules Beacon frames for transmission every beacon interval, but the Beacon frames may be delayed if there is traffic at the TBTT. This is indicated as "busy medium" on the second line. For the purposes of this figure, the important fact about Beacon frames is that they contain TIMs, some of which are DTIMs. Note that the second STA with ReceiveDTIMs set to false does not power-on its receiver for all DTIMs.

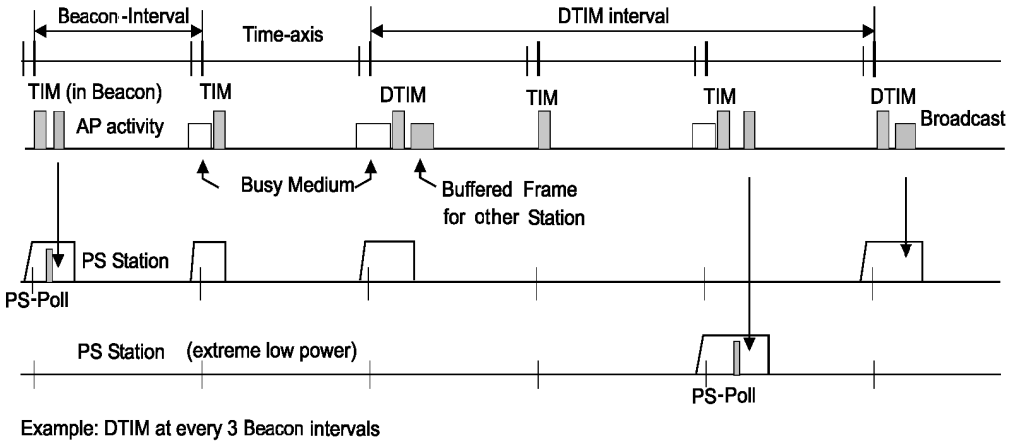

Figure 11-4—Infrastructure power management operation (no PCF operating)

The third and fourth lines in Figure 11-4 depict the activity of two STAs operating with different power management requirements. Both STAs power-on their receivers when they need to listen for a TIM. This is indicated as a ramp-up of the receiver power prior to the TBTT. The first STA, for example, powers up its receiver and receives a TIM in the first Beacon frame; that TIM indicates the presence of a buffered MSDU for the receiving STA. The receiving STA then generates a PS-Poll frame, which elicits the transmission of the buffered data MSDU from the AP. Broadcast and multicast MSDUs are sent by the AP subsequent to the transmission of a Beacon frame containing a DTIM. The DTIM is indicated by the DTIM count field of the TIM element having a value of 0.

11.2.1.4 Power management with APSD

QoS APs capable of supporting automatic power save delivery (APSD) shall signal this capability through the use of the APSD subfield in the Capability Information field in Beacon, Probe Response, and (Re)Association Response management frames.

Non-AP QoS STAs use the Power Management field in the Frame Control field of a frame to indicate whether it is in active or PS mode. As APSD is a mechanism for the delivery of downlink frames to power-saving STAs, the frames of a non-AP STA using APSD shall have the Power Management bit in the Frame Control field set to 1 for buffering to take place at the AP.

APSD defines two delivery mechanisms, namely *unscheduled APSD* (U-APSD) and *scheduled APSD* (S-APSD). Non-AP STAs may use U-APSD to have some or all of their frames delivered during unscheduled SPs. Non-AP STAs may use S-APSD to schedule delivery of some or all of their frames during scheduled SPs.

If there is no unscheduled SP in progress, the unscheduled SP begins when the AP receives a trigger frame from a non-AP STA, which is a QoS data or QoS Null frame associated with an AC the STA has configured to be trigger-enabled. An unscheduled SP ends after the AP has attempted to transmit at least one MSDU or MMPDU associated with a delivery-enabled AC and destined for the non-AP STA, but no more than the number indicated in the Max SP Length field if the field has a nonzero value.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001650

In order to configure an AP to deliver frames during an unscheduled SP, the non-AP STA designates one or more of its ACs to be delivery-enabled and one or more of its AC to be trigger-enabled. A non-AP STA may configure an AP to use U-APSD using two methods. First, a non-AP STA may set individual U-APSD Flag bits in the QoS Info subfield of the QoS Capability element carried in (Re)Association Request frames. When a U-APSD Flag bit is set, it indicates that the corresponding AC is both delivery- and trigger-enabled. When all four U-APSD Flag subfields are set to 1 in (Re)Association Request frames, all the ACs associated with the non-AP STA are trigger- and delivery-enabled during (re)association. When all four U-APSD Flag subfields are set to 0 in (Re)Association Request frames, none of the ACs associated with the non-AP STA is trigger- or delivery-enabled during (re)association.

Alternatively, a non-AP STA may designate one or more AC as trigger-enabled and one or more AC as delivery-enabled by sending an ADDTS Request frame per AC to the AP with the APSD subfield set to 1 and the Schedule subfield set to 0 in the TS Info field in the TSPEC element. APSD settings in a TSPEC request take precedence over the static U-APSD settings carried in the QoS Capability element. In other words, a TSPEC request overwrites any previous U-APSD setting of an AC. The request may be sent for ACs for which the ACM subfield is set to 0.

A non-AP STA may set an AC to be trigger- or delivery-enabled for its own use by setting up TSPECs with the APSD subfield set to 1 and the Schedule subfield set to 0 in the uplink or downlink direction, respectively. An uplink TSPEC plus a downlink TSPEC, or a bi-directional TSPEC with the APSD subfield set to 1 and the Schedule subfield set to 0, makes an AC both trigger- and delivery-enabled. An uplink TSPEC plus a downlink TSPEC, or a bi-directional TSPEC with the APSD and the Schedule subfields both set to 0, makes an AC neither trigger- nor delivery-enabled.

A scheduled SP starts at fixed intervals of time specified in the Service Interval field. In order to use a scheduled SP for a TS when the access policy is controlled channel access, a non-AP STA shall send an ADDTS Request frame to the AP with the APSD subfield of the TS Info field in the TSPEC element set to 1. To use a scheduled SP for a TS for a AC when the access policy is contention-based channel access, a non-AP STA shall send an ADDTS Request frame to the AP with the APSD and Schedule subfields of the TS Info field in the TSPEC element both set to 1. If the APSD mechanism is supported by the AP and the AP accepts the corresponding ADDTS Request frame from the non-AP STA, the AP shall respond to the ADDTS Request frame with a response containing the Schedule element indicating that the requested service can be accommodated by the AP. The first scheduled SP starts when the lower order 4 octets of the TSF timer equals the value specified in the Service Start Time field. A non-AP STA using scheduled SP shall first wake up to receive downlink unicast frames buffered and/or polls from the AP/HC. The STA shall wake up subsequently at a fixed time interval equal to the SI. The AP may modify the service start time by indicating so in the Schedule element in ADDTS Response frame and in Schedule frames.

A scheduled SP begins at the scheduled wakeup time that corresponds to the SI and the service start time indicated in the Schedule element sent in response to a TSPEC. The STA shall wake up at a subsequent time when

(TSF – service start time) mod minimum SI = 0.

If scheduled services periods are supported in a BSS, a STA may use both unscheduled and scheduled APSD on different ACs at the same time. When a non-AP STA establishes scheduled delivery for an AC, that AC shall be considered delivery-enabled. However, the AP shall not transmit frames associated with that AC during an SP that is initiated by a trigger frame, and it shall not treat frames associated with the AC that are received from the STA as trigger frames. The AP shall decline any ADDTS Request frame that indicates the use of both scheduled and unscheduled APSD to be used on the same AC at the same time.

APSD shall be used only to deliver unicast frames to a STA. Broadcast/multicast frame delivery shall follow the frame delivery rules defined for broadcast/multicast frames as defined in 11.2.1.6.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001651

11.2.1.5 AP operation during the CP

APs shall maintain a Power Management status for each currently associated STA that indicates in which Power Management mode the STA is currently operating. APs that implement and signal their support of APSD shall maintain an APSD and an access policy status for each currently associated non-AP STA that indicates whether the non-AP STA is presently using APSD and shall maintain the schedule (if any) for the non-AP STA. An AP shall, depending on the Power Management mode of the STA, temporarily buffer the MSDU or management frame destined to the STA. An AP implementing APSD shall, if a non-AP STA is using APSD and is in PS mode, temporarily buffer the MSDU or management frames destined to that non-AP STA. No MSDUs or management frames addressed directly to STAs operating in the Active mode shall be buffered for power management reasons.

a) MSDUs, or management frames destined for PS STAs, shall be temporarily buffered in the AP. MSDUs, or management frames, destined for PS STAs using APSD shall be temporarily buffered in the APSD-capable AP. The algorithm to manage this buffering is beyond the scope of this standard, with the exception that if the AP is QoS-enabled, it shall preserve the order of arrival of frames on a per-TID, per-STA basis.

b) MSDUs, or management frames destined for STAs in the Active mode, shall be directly transmitted to those STAs.

c) At every beacon interval, the AP shall assemble the partial virtual bitmap containing the buffer status per destination for STAs in the PS mode and shall send this out in the TIM field of the Beacon frame. At every beacon interval, the APSD-capable AP shall assemble the partial virtual bitmap containing the buffer status of nondelivery-enabled ACs (if there exists at least one nondelivery-enabled AC) per destination for non-AP STAs in PS mode and shall send this out in the TIM field of the Beacon frame. When all ACs are delivery-enabled, the APSD-capable AP shall assemble the partial virtual bitmap containing the buffer status for all ACs per destination for non-AP STAs.

d) If a non-AP STA has set up a scheduled SP, it shall automatically wake up at each SP. Therefore, the APSD-capable AP shall transmit frames associated with admitted traffic with the APSD subfield set to 1 in the TSPECs buffered for the non-AP STA during a scheduled SP. If the non-AP STA has set up to use unscheduled SPs, the AP shall buffer frames belonging to delivery-enabled ACs until it has received a trigger frame associated with a trigger-enabled AC from the non-AP STA, which indicates the start of an unscheduled SP. A trigger frame received by the AP from a non-AP STA that already has an unscheduled SP underway shall not trigger the start of a new unscheduled SP. The AP transmits frames destined for the non-AP STA and associated with delivery-enabled ACs during an unscheduled SP. The bit for AID 0 (zero) in the bit map control field of the TIM IE shall be set to 1 when broadcast or multicast traffic is buffered, according to 7.3.2.6.

e) All broadcast/multicast MSDUs, with the Order bit in the Frame Control field clear, shall be buffered if any associated STAs are in PS mode.

f) Immediately after every DTIM, the AP shall transmit all buffered broadcast/multicast MSDUs. The More Data field of each broadcast/multicast frame shall be set to indicate the presence of further buffered broadcast/multicast MSDUs. If the AP is unable to transmit all of the buffered broadcast/multicast MSDUs before the TBTT following the DTIM, the AP shall indicate that it will continue to deliver the broadcast/multicast MSDUs by setting the bit for AID 0 (zero) in the bit map control field of the TIM element of every Beacon frame, until all buffered broadcast/multicast frames have been transmitted.

g) A single buffered MSDU or management frame for a STA in the PS mode shall be forwarded to the STA after a PS-Poll has been received from that STA. For a non-AP STAs using U-APSD, the AP transmits one frame destined for the non-AP STA from any AC that is not delivery-enabled in response to PS-Poll from the non-AP STA. When all ACs associated with the non-AP STA are delivery-enabled, AP transmits one frame from the highest priority AC. The AP can respond with either an immediate Data frame or with an ACK, while delaying the responding Data frame.

   For a STA in PS mode and not using U-APSD, the More Data field of the response Data frame shall be set to indicate the presence of further buffered MSDUs or management frames for the polling

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001652

STA. For a non-AP STA using U-APSD, the More Data field shall be set to indicate the presence of further buffered MSDUs or management frames that do not belong to delivery-enabled ACs. When all ACs associated with the non-AP STA are delivery-enabled, the More Data field shall be set to indicate the presence of further buffered MSDUs or management frames belonging to delivery-enabled ACs. If there are buffered frames to transmit to the STA, the AP may set the More Data bit in a QoS +CF-Ack frame to 1, in response to a QoS data frame to indicate that it has one or more pending frames buffered for the PS STA identified by the RA address in the QoS +CF-Ack frame. An AP may also set the More Data bit in an ACK frame in response to a QoS data frame to indicate that it has one or more pending frames buffered for the PS STA identified by the RA address in the ACK frame, if that PS STA has set the More Data Ack subfield in the QoS Capability information element to 1.

Further PS-Poll frames from the same STA shall be acknowledged and ignored until the MSDU or management frame has either been successfully delivered or presumed failed due to maximum retries being exceeded. This prevents a retried PS-Poll from being treated as a new request to deliver a buffered frame.

h) At each scheduled APSD SP for a non-AP STA, the APSD-capable AP shall attempt to transmit at least one MSDU or MMPDU, associated with admitted TSPECs with the APSD and Schedule subfields both set to 1, that are destined for the non-AP STA. At each unscheduled SP for a non-AP STA, the AP shall attempt to transmit at least one MSDU or MMPDU, but no more than the value specified in the Max SP Length field in the QoS Capability element from delivery-enabled ACs, that are destined for the non-AP STA.

   The More Data bit of the directed data or management frame associated with delivery-enabled ACs and destined for that non-AP STA indicates that more frames are buffered for the delivery-enabled ACs. The More Data bit set in MSDUs or management frames associated with nondelivery-enabled ACs and destined for that non-AP STA indicates that more frames are buffered for the nondelivery-enabled ACs. For all frames except for the final frame of the SP, the EOSP subfield of the QoS Control field of the QoS data frame shall be set to 0 to indicate the continuation of the SP. An AP may also set the More Data bit to 1 in a QoS +CF-Ack frame in response to a QoS data frame to indicate that it has one or more pending frames buffered for the target STA identified by the RA address in the QoS +CF-Ack frame. If the QoS data frame is associated with a delivery-enabled AC, the More Data bit in the QoS +CF-Ack frame indicates more frames for all delivery-enabled ACs. If the QoS data frame is not associated with a delivery-enabled AC, the More Data bit in the QoS +CF-Ack frame indicates more frames for all ACs that are not delivery-enabled.

   The AP considers APSD STA to be in Awake state after it has sent a QoS +CF-Ack frame, with the EOSP subfield in the QoS Control field set to 0, to the APSD STA. If necessary, the AP may generate an extra QoS Null frame, with the EOSP set to 1. When the AP has transmitted a directed frame to the non-AP STA with the EOSP subfield set to 1 during the SP except for retransmissions of that frame, the AP shall not transmit any more frames using this mechanism until the next SP. The AP shall set the EOSP subfield to 1 to indicate the end of the SP in APSD.

i) If the AP does not receive an acknowledgment to a directed MSDU or management frame sent to a non-AP STA in PS mode following receipt of a PS-Poll from that non-AP STA, it may retransmit the frame for at most the lesser of the maximum retry limit and the MIB attribute dot11QAPMissingAckRetryLimit times before the next Beacon frame, but it shall retransmit that frame at least once before the next Beacon frame, time permitting and subject to its appropriate lifetime limit. If an acknowledgment to the retransmission is not received, it may wait until after the next Beacon frame to further retransmit that frame subject to its appropriate lifetime limit.

j) If the AP does not receive an acknowledgment to a directed MSDU sent with the EOSP subfield set to 1, it shall retransmit that frame at least once within the same SP, subject to applicable retry or lifetime limit. The maximum number of retransmissions within the same SP is the lesser of the maximum retry limit and the MIB attribute dot11QAPMissingAckRetryLimit. If an acknowledgment to the retransmission of this last frame in the same SP is not received, it may wait until the next SP to further retransmit that frame, subject to its applicable retry or lifetime limit.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001653

k) An AP can delete buffered frames for implementation-dependent reasons, including the use of an aging function and availability of buffers. The AP may base the aging function on the listen interval specified by the non-AP STA in the (Re)Association Request frame.

l) When an AP is informed that a STA changes to the Active mode, then the AP shall send buffered MSDUs and management frames (if any exist) to that STA without waiting for a PS-Poll. When an AP is informed that an APSD-capable non-AP STA is not using APSD, then the AP shall send buffered MSDUs and management frames (if any exist) to that non-AP STA according to the rules corresponding to the current PS mode of the non-AP STA.

11.2.1.6 AP operation during the CFP

APs shall maintain a Power Management status for each currently associated CF-Pollable STA that indicates in which Power Management mode the STA is currently operating. An AP shall, for STAs in PS mode, temporarily buffer the MSDU destined to the STA.

a) MSDUs destined for PS STAs shall be temporarily buffered in the AP. The algorithm to manage this buffering is beyond the scope of this standard.

b) MSDUs destined to STAs in the Active mode shall be transmitted as defined in Clause 9.

c) Prior to every CFP, and at each beacon interval within the CFP, the AP shall assemble the partial virtual bitmap containing the buffer status per destination for STAs in the PS mode, set the bits in the partial virtual bitmap for STAs the PC is intending to poll during this CFP, and shall send this out in the TIM field of the DTIM. The bit for AID 0 (zero) in the bit map control field of the TIM IE shall be set when broadcast or multicast traffic is buffered, according to 7.3.2.6.

d) All broadcast and multicast MSDUs, with the Order bit in the Frame Control field clear, shall be buffered if any associated STAs are in the PS mode, whether or not those STAs are CF-Pollable.

e) Immediately after every DTIM (Beacon frame with DTIM Count field of the TIM element equal to zero), the AP shall transmit all buffered broadcast and multicast frames. The More Data field shall be set in the headers of all but the final such frame to indicate the presence of further buffered broadcast/multicast MSDUs. If the AP is unable to transmit all of the buffered broadcast/multicast MSDUs before the TBTT following the DTIM, the AP shall indicate that it will continue to deliver the broadcast/multicast MSDUs by setting the bit for AID 0 (zero) in the bit map control field of the TIM element of every Beacon frame, until all buffered broadcast/multicast frames have been transmitted.

f) Buffered MSDUs or MMPDUs for STAs in the PS mode shall be forwarded to the CF-Pollable STAs under control of the PC. Transmission of these buffered MSDUs or management frames as well as CF-Polls to STAs in the PS mode that were indicated in the DTIM in accordance with paragraph c) of this subclause shall begin immediately after transmission of buffered broadcast and multicast frames (if any), and shall occur in order by increasing AID of CF-Pollable STAs. A CF-Pollable STA for which the TIM element of the most recent Beacon frame indicated buffered MSDUs or management frames shall be in the Awake state at least until the receipt of a directed frame from the AP in which the Frame Control field does not indicate the existence of more buffered MSDUs or management frames. After acknowledging the last of the buffered MSDUs or management frames, the CF-Pollable STA operating in the PS mode may enter the Doze state until the next DTIM is expected.

g) An AP shall have an aging function to delete pending traffic buffered for an excessive time period. The exact specification of the aging function is beyond the scope of this standard.

h) When an AP detects that a CF-Pollable STA has changed from the PS mode to the Active mode, then the AP shall queue any buffered frames addressed to that STA for transmission to that CF-Pollable STA as directed by the AP's PC.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001654

11.2.1.7 Receive operation for STAs in PS mode during the CP

STAs in PS mode shall operate as follows to receive an MSDU or management frame from the AP when no PC is operating and during the CP when a PC is operating.

a) STAs shall wake up early enough to be able to receive the first Beacon frame scheduled for transmission after the time corresponding to the last TBTT plus the STA's current ListenInterval.

b) When a STA detects that the bit corresponding to its AID is set in the TIM, the STA shall issue a PS-Poll to retrieve the buffered MSDU or management frame. The PS-Poll shall be transmitted after a random delay uniformly distributed between zero and aCWmin slots following a DIFS.

c) The STA shall remain in the Awake state until it receives the data or management frame in response to its poll or it receives another Beacon frame whose TIM indicates that the AP does not have any MSDUs or management frames buffered for this STA. If the bit corresponding to the STA's AID is set in the subsequent TIM, the STA shall issue another PS-Poll to retrieve the buffered MSDU or management frame(s). When a non-AP STA that is using U-APSD and has all ACs delivery-enabled detects that the bit corresponding to its AID is set in the TIM, the non-AP STA shall issue a trigger frame or a PS-Poll frame to retrieve the buffered MSDU or management frames.

d) If the More Data field in the received MSDU or management frame indicates that more traffic for that STA is buffered, the STA, at its convenience, shall Poll until no more MSDUs or management frames are buffered for that STA.

e) When ReceiveDTIMs is true, the STA shall wake up early enough to be able to receive every DTIM sent by the AP of the BSS. A STA that stays awake to receive broadcast/multicast MSDUs shall remain awake until the More Data field of the broadcast/multicast MSDUs indicates there are no further buffered broadcast/multicast MSDUs or until a TIM is received indicating there are no more buffered broadcast/multicast MSDUs. If a non-AP STA receives a QoS +CF-Ack frame from its AP with the More Data bit set to 1, then the STA shall operate exactly as if it received a TIM with its AID bit set. If a non-AP STA has set the More Data Ack subfield in QoS Capability information element to 1, then if it receives an ACK frame from its AP with the More Data bit set to 1, the STA shall operate exactly as if it received a TIM with its AID bit set. For example, a STA that is using the PS-Poll delivery method shall issue a PS-Poll frame to retrieve a buffered frame.

11.2.1.8 Receive operation for STAs in PS mode during the CFP

STAs in PS mode that are associated as CF-Pollable shall operate as follows in a BSS with an active PC to receive MSDUs or management frames from the AP during the CFP:

a) STAs shall enter the Awake state so as to receive the Beacon frame (which contains a DTIM) at the start of each CFP.

b) To receive broadcast/multicast MSDUs, the STA shall wake up early enough to be able to receive every DTIM that may be sent during the CFP. A STA receiving broadcast/multicast MSDUs shall remain awake until the More Data field of the broadcast/multicast MSDUs indicates there are no further buffered broadcast/multicast MSDUs, or until a TIM is received indicating there are no more broadcast/multicast MSDUs buffered.

c) When a STA detects that the bit corresponding to its AID is set in the DTIM at the start of the CFP (or in a subsequent TIM during the CFP), the STA shall remain in the Awake state for at least that portion of the CFP through the time that the STA receives a directed MSDU or management frame from the AP with the More Data field in the Frame Control field indicating that no further traffic is buffered.

d) If the More Data field in the Frame Control field of the last MSDU or management frame received from the AP indicates that more traffic for the STA is buffered, then, when the CFP ends, the STA may remain in the Awake state and transmit PS-Poll frames during the CP to request the delivery of additional buffered MSDU or management frames, or may enter the Doze state during the CP (except at TBTTs for DTIMs expected during the CP), awaiting the start of the next CFP.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001655

11.2.1.9 Receive operation for non-AP STAs using APSD

A non-AP STA using APSD shall operate as follows to receive an MSDU or management frame from the AP:

a) If a scheduled SP has been set up, the non-AP STA wakes up at its scheduled start time. (The non-AP STA shall wake up early enough to receive transmissions at the scheduled SP.)

b) If the non-AP STA is initiating an unscheduled SP, the non-AP STA wakes up and transmits a trigger frame to the AP. When one or more ACs are not delivery-enabled, the non-AP STA may retrieve MSDUs and MMPDUs belonging to those ACs by sending PS-Poll frames to the AP.

c) The non-AP STA shall remain awake until it receives a QoS data frame addressed to it, with the EOSP subfield in the QoS Control field set to 1.

d) The non-AP STA may send additional PS-Poll frames if the More Data subfield is set to 1 in downlink unicast data or management frames that do not belong to any deliver-enabled ACs. The non-AP STA may send additional trigger frames if the More Data subfield is set to 1 in downlink unicast data or management frames that belong to delivery-enabled ACs.

11.2.1.10 STAs operating in the Active mode

A STA operating in this mode shall have its receiver activated continuously; such STAs do not need to interpret the TIM information elements in Beacon frames.

11.2.1.11 AP aging function

Any AP aging function shall not cause the buffered traffic to be discarded after any period that is shorter than the ListenInterval of the STA for which the traffic is buffered. The exact specification of the aging function is beyond the scope of this standard.

11.2.2 Power management in an IBSS

This subclause specifies the power management mechanism for use within an IBSS.

11.2.2.1 Basic approach

The basic approach is similar to the infrastructure case in that the STAs are synchronized, and multicast MSDUs and those MSDUs that are to be transmitted to a power-conserving STA are first announced during a period when all STAs are awake. The announcement is done via an ad hoc ATIM sent in an ATIM Window. A STA in the PS mode shall listen for these announcements to determine if it needs to remain in the Awake state. The presence of the ATIM window in the IBSS indicates if the STA may use PS Mode. To maintain correct information on the power save state of other STAs in an IBSS, a STA needs to remain awake during the ATIM window. At other times the STA may enter the Doze state except as indicated in the following procedures

The basic approach is similar to the infrastructure case in that the STAs are synchronized, and multicast MSDUs and those MSDUs that are to be transmitted to a power-conserving STA are first announced during a period when all STAs are awake. The announcement is done via an ad hoc ATIM sent in an ATIM Window. A STA in the PS mode shall listen for these announcements to determine if it needs to remain in the Awake state. The presence of the ATIM window in the IBSS indicates if the STA may use PS Mode. To maintain correct information on the power save state of other STAs in an IBSS, a STA needs to remain awake during the ATIM window. At other times the STA may enter the Doze state except as indicated in the following procedures.

When an MSDU is to be transmitted to a destination STA that is in a PS mode, the transmitting STA first transmits an ATIM frame during the ATIM Window, in which all the STAs including those operating in a

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001656

PS mode are awake. The ATIM Window is defined as a specific period of time, defined by the value of the ATIM Window parameter in the IBSS Parameter Set supplied to the MLME-START.request primitive, following a TBTT, during which only Beacon or ATIM frames shall be transmitted. ATIM transmission times are randomized, after a Beacon frame is either transmitted or received by the STA, using the backoff procedure with the CW equal to aCWmin. Directed ATIMs shall be acknowledged. If a STA transmitting a directed ATIM does not receive an acknowledgment, the STA shall execute the backoff procedure for retransmission of the ATIM. Multicast ATIMs shall not be acknowledged.

If a STA receives a directed ATIM frame during the ATIM Window, it shall acknowledge the directed ATIM and stay awake for the entire beacon interval waiting for the announced MSDU(s) to be received. If a STA does not receive an ATIM, it may enter the Doze state at the end of the ATIM Window. Transmissions of MSDUs announced by ATIMs are randomized after the ATIM Window, using the backoff procedure described in Clause 9.

It is possible that an ATIM may be received from more than one STA, and that a STA that receives an ATIM may receive more than a single MSDU from the transmitting STA. ATIM frames are only addressed to the destination STA of the MSDU.

An ATIM for a broadcast or multicast MSDU shall have a destination address identical to that of the MSDU.

After the ATIM interval, only those directed MSDUs that have been successfully announced with an acknowledged ATIM, and broadcast/multicast MSDUs that have been announced with an ATIM, shall be transmitted to STAs in the PS mode. Transmission of these frames shall be done using the normal DCF access procedure.

Figure 11-5 illustrates the basic PS operation.

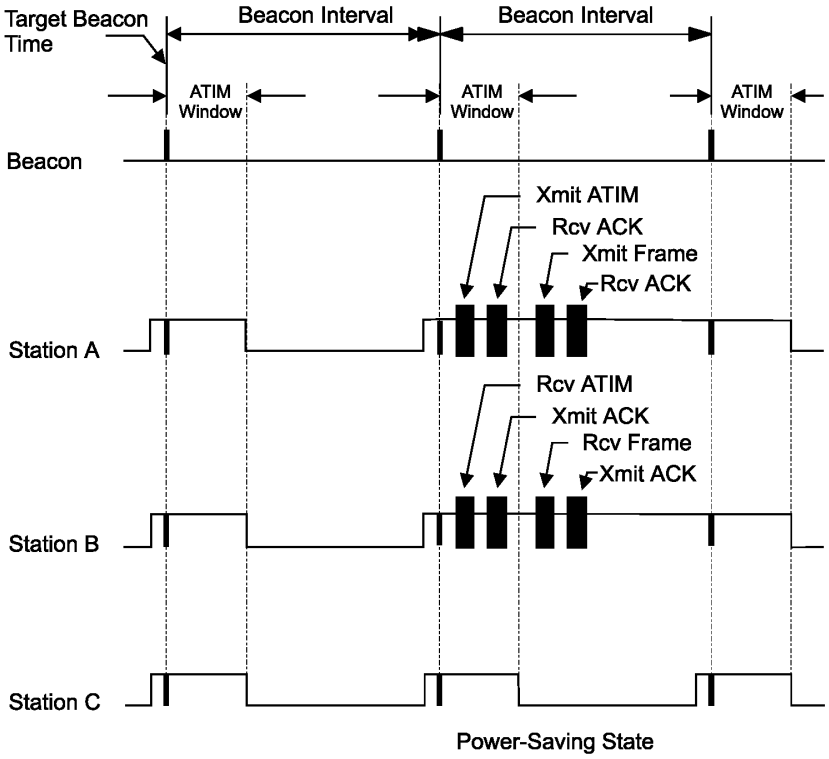

Figure 11-5—Power management in an IBSS—basic operation

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001657

The estimated power-saving state of another STA may be based on the power management information transmitted by that STA and on additional information available locally, such as a history of failed transmission attempts. The use of RTS/CTS in an IBSS may reduce the number of transmissions to a STA that is in PS mode. If an RTS is sent and a CTS is not received, the transmitting STA may assume that the destination STA is in PS mode. The method of estimating the power management state of other STAs in the IBSS is outside the scope of this standard.

11.2.2.2 Initialization of power management within an IBSS

The following procedure shall be used to initialize power management within a new IBSS, or to learn about the power management being used within an existing IBSS.

a) A STA joining an existing IBSS by the procedure in 11.1.3.3 shall update its ATIM Window with the value contained in the ATIM Window field of the IBSS Parameter Set element within the Beacon or Probe Response management frame received during the scan procedure.

b) A STA creating a new IBSS by the procedure in 11.1.3.3 shall set the value of the ATIM Window field of the IBSS Parameter Set element within the Beacon management frames transmitted to the value of its ATIM Window.

c) The start of the ATIM Window shall be the TBTT, defined in 11.1.2.2. The end of the ATIM Window shall be defined as

   TSF timer MOD dot11BeaconInterval = ATIMWindow, where ATIMWindow is the value of the ATIM Window parameter of the IBSS Parameter Set from the MLME-Start.request or MLME-JOIN.request primitives.

d) The ATIM Window period shall be static during the lifetime of the IBSS.

e) An ATIM Window value of zero shall indicate that power management is not usable within the IBSS.

11.2.2.3 STA power state transitions

A STA may enter PS mode if and only if the value of the ATIM Window in use within the IBSS is greater than zero. A STA shall set the Power Management subfield in the Frame Control field of MSDUs that it transmits using the rules in 7.1.3.1.6.

A STA in PS mode shall transition between Awake and Doze states according to the following rules:

a) If a STA is operating in PS mode, it shall enter the Awake state prior to each TBTT.

b) If a STA receives a directed ATIM management frame containing its individual address, or a multicast ATIM management frame during the ATIM Window it shall remain in the Awake state until the end of the next ATIM Window.

c) If a STA transmits a Beacon or an ATIM management frame, it shall remain in the Awake state until the end of the next ATIM Window regardless of whether an acknowledgment is received for the ATIM.

d) If the STA has not transmitted an ATIM and does not receive either a directed ATIM management frame containing its individual address, or a multicast ATIM management frame during the ATIM Window, it may return to the Doze state following the end of the current ATIM Window.

11.2.2.4 ATIM and frame transmission

If power management is in use within an IBSS, all STAs shall buffer MSDUs for STAs that are known to be in PS mode. The algorithm used for the estimation of the power management state of STAs within the IBSS is outside the scope of this standard. MSDUs may be sent to STAs in Active mode at any valid time.

a) Following the reception or transmission of the Beacon frame, during the ATIM Window, the STA shall transmit a directed ATIM management frame to each STA for which it has one or more

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001658

buffered unicast MSDUs. If the STA has one or more buffered multicast MSDUs, with the Strictly Ordered bit clear, it shall transmit an appropriately addressed multicast ATIM frame. A STA transmitting an ATIM management frame shall remain awake for the entire current beacon interval.

b) All STAs shall use the backoff procedure defined in 9.2.5.2 for transmission of the first ATIM following the Beacon frame. All remaining ATIMs shall be transmitted using the conventional DCF access procedure.

c) ATIM management frames shall only be transmitted during the ATIM Window.

d) A STA shall transmit no frame types other than RTS, CTS, and ACK Control frames and Beacon and ATIM management frames during the ATIM Window.

e) Directed ATIM management frames shall be acknowledged. If no acknowledgment is received, the ATIM shall be retransmitted using the conventional DCF access procedure. Multicast ATIM management frames shall not be acknowledged.

f) If a STA is unable to transmit an ATIM during the ATIM Window, for example due to contention with other STAs, the STA shall retain the buffered MSDU(s) and attempt to transmit the ATIM during the next ATIM Window.

g) Immediately following the ATIM Window, a STA shall begin transmission of buffered broadcast/multicast frames for which an ATIM was previously transmitted. Following the transmission of any broadcast/multicast frames, any MSDUs and management frames addressed to STAs for which an acknowledgment for a previously transmitted ATIM frame was received shall be transmitted. All STAs shall use the backoff procedure defined in 9.2.5.2 for transmission of the first frame following the ATIM Window. All remaining frames shall be transmitted using the conventional DCF access procedure.

h) A buffered MSDU may be transmitted using fragmentation. If an MSDU has been partially transmitted when the next Beacon frame is sent, the STA shall retain the buffered MSDU and announce the remaining fragments by transmitting an ATIM during the next ATIM Window.

i) If a STA is unable to transmit a buffered MSDU during the beacon interval in which it was announced, for example due to contention with other STAs, the STA shall retain the buffered MSDU and announce the MSDU again by transmitting an ATIM during the next ATIM Window.

j) Following the transmission of all buffered MSDUs, a STA may transmit MSDUs without announcement to STAs that are known to be in the Awake state for the current beacon interval due to an appropriate ATIM management or Beacon frame having been transmitted or received.

k) A STA may discard frames buffered for later transmission to power-saving STAs if the STA determines that the frame has been buffered for an excessive amount of time or if other conditions internal to the STA implementation make it desirable to discard buffered frames (e.g., buffer starvation). In no case shall a frame be discarded that has been buffered for less than dot11BeaconPeriod. The algorithm to manage this buffering is beyond the scope of this standard.

11.3 STA authentication and association

A STA keeps two state variables for each STA with which direct communication via the WM is needed:

— *Authentication state:* The values are unauthenticated and authenticated.

— *Association state:* The values are unassociated and associated.

These two variables create three local states for each remote STA:

— *State 1:* Initial start state, unauthenticated, unassociated.

— *State 2:* Authenticated, not associated.

— *State 3:* Authenticated and associated.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001659

The relationships between these STA state variables and the services are given in Figure 11-6.

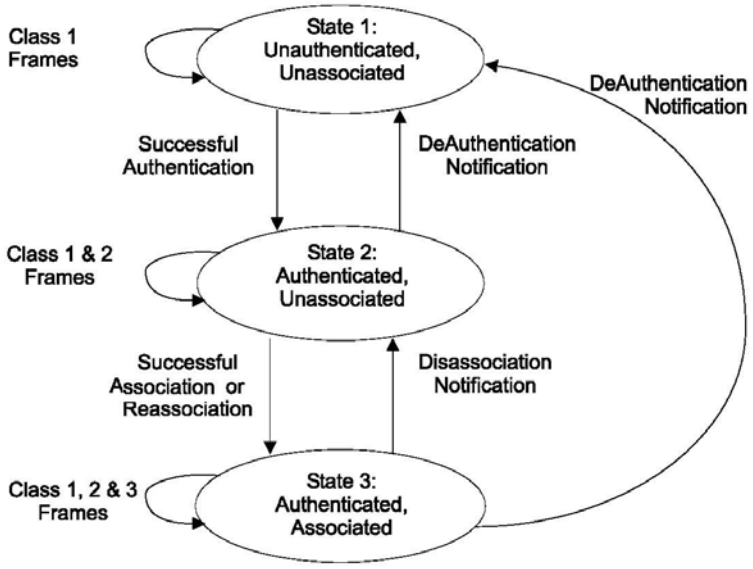

Figure 11-6—Relationship between state variables and services

The current state existing between the source and destination STAs determines the IEEE 802.11 frame types that may be exchanged between that pair of STAs (see Clause 7). The state of the sending STA given by Figure 11-6 is with respect to the intended receiving STA. The allowed frame types are grouped into classes and the classes correspond to the STA state. In State 1, only Class 1 frames are allowed. In State 2, either Class 1 or Class 2 frames are allowed. In State 3, all frames are allowed (Classes 1, 2, and 3). The frame classes are defined as follows:

a) Class 1 frames (permitted from within States 1, 2, and 3)
   1) Control frames
      i) Request to send (RTS)
      ii) Clear to send (CTS)
      iii) Acknowledgment (ACK)
      iv) Contention-Free (CF)-End+ACK
      v) CF-End
   2) Management frames
      i) Probe request/response
      ii) Beacon
      iii) Authentication: Successful authentication enables a STA to exchange Class 2 frames. Unsuccessful authentication leaves the STA in State 1.
      iv) Deauthentication: Deauthentication notification when in State 2 or State 3 changes the STA's state to State 1. The STA shall become authenticated again prior to sending Class 2 frames. Deauthentication notification when in State 3 implies disassociation as well.
      v) Announcement traffic indication message (ATIM)
      vi) Spectrum Management Action: Within an IBSS, action frames are Class 1.
   3) Data frames
      i) Data: Data frames between STAs in an IBSS with frame control (FC) bits "To DS" and "From DS" both false.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001660

b) Class 2 frames (if and only if authenticated; allowed from within States 2 and 3 only)
   1) Management frames
      i) Association request/response: Successful association enables Class 3 frames. Unsuccessful association leaves STA in State 2.
      ii) Reassociation request/response: Successful reassociation enables Class 3 frames. Unsuccessful reassociation leaves the STA in State 2 (with respect to the STA that was sent the reassociation message). Reassociation frames shall only be sent if the sending STA is already associated in the same ESS.
      iii) Disassociation: Disassociation notification when in State 3 changes a STA's state to State 2. This STA shall become associated again if it wishes to utilize the DS.

   If STA A receives a Class 2 frame with a unicast address in the Address 1 field from STA B that is not authenticated with STA A, STA A shall disallow the received Class 2 frame and send a deauthentication frame to STA B.

c) Class 3 frames (if and only if associated; allowed only from within State 3)
   1) Data frames
      i) Data subtypes: Data frames allowed, i.e., either the "To DS" or "From DS" FC bits may be set to true to utilize the DSS.
      ii) QoS data subtypes allowed to/from non-AP STA(s) that are associated with AP(s).
      iii) Data frames between STAs in a BSS with FC bits "To DS" and "From DS" both false.
   2) Management frames
      i) QoS, DLS, and Block Ack Action
   3) Control frames
      i) Power save (PS)-Poll
      ii) Action: Within an infrastucture BSS, action frames are Class 3.
      iii) Block Ack (BlockAck)
      iv) Block Ack Request (BlockAckReq)

   If STA A receives a Class 3 frame with a unicast address in the Address 1 field from STA B that is authenticated but not associated with STA A, STA A shall disallow the received Class 3 frame and send a disassociation frame to STA B.

   If STA A receives a Class 3 frame with a unicast address in the Address 1 field from STA B that is not authenticated with STA A, STA A shall disallow the received Class 3 frame and send a deauthentication frame to STA B.

   (The use of the word "receive" in this subclause refers to a frame that meets all of the filtering criteria specified in Clause 8 and Clause 9.)

11.3.1 Authentication and deauthentication

This subclause describes the procedures used for IEEE 802.11 authentication and deauthentication. The states used in this description are defined in 11.3.

11.3.1.1 Authentication—originating STA

Upon receipt of an MLME-AUTHENTICATE.request primitive, the originating STA shall authenticate with the indicated STA using the following procedure:

a) In an ESS, or optionally in an IBSS, the STA shall execute the authentication mechanism described in 8.2.2.2.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001661

b) If the authentication was successful, the state variable for the indicated STA shall be set to State 2.

c) The STA shall issue an MLME-AUTHENTICATE.confirm primitive to inform the SME of the result of the authentication.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using MLME-DELETEKEYS.request primitive (see 8.4.10) before invoking MLME-AUTHENTICATE.request primitive.

11.3.1.2 Authentication—destination STA

Upon receipt of an Authentication frame with authentication transaction sequence number equal to 1, the destination STA shall authenticate with the indicated STA using the following procedure:

a) The STA shall execute the authentication mechanism described in 8.2.2.2.

b) If the authentication was successful, the state variable for the indicated STA shall be set to State 2.

c) The STA shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) upon receiving a MLME-AUTHENTICATE.indication primitive.

If the STA is in an IBSS, if the SME decides to initiate an RSNA, and if the SME does not know the security policy of the peer, it may issue a unicast Probe Request frame to the peer by invoking an MLME-SCAN.request to discover the peer's security policy.

11.3.1.3 Deauthentication—originating STA

Upon receipt of an MLME-DEAUTHENTICATE.request primitive, the originating STA shall deauthenticate with the indicated STA using the following procedure:

a) If the state variable for the indicated STA is in State 2 or State 3, the STA shall send a Deauthentication frame to the indicated STA.

b) The state variable for the indicated STA shall be set to State 1.

c) The STA shall issue an MLME-DEAUTHENTICATE.confirm primitive to inform the SME of the completion of the deauthentication.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) and by invoking MLME-SETPROTECTION.request(None) before invoking the MLME-DEAUTHENTICATE.request primitive.

11.3.1.4 Deauthentication—destination STA

Upon receipt of a Deauthentication frame, the destination STA shall deauthenticate with the indicated STA using the following procedure:

a) The state variable for the indicated STA shall be set to State 1.

b) The STA shall issue an MLME-DEAUTHENTICATE.indication primitive to inform the SME of the deauthentication.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) and by invoking MLME-SETPROTECTION.request(None) upon receiving an MLME-DEAUTHENTICATE.indication primitive.

11.3.2 Association, reassociation, and disassociation

This subclause defines how a STA associates and reassociates with an AP and how it disassociates from it.

The states used in this description are defined in 11.3.

11.3.2.1 STA association procedures

Upon receipt of an MLME-ASSOCIATE.request primitive, a STA shall associate with an AP via the following procedure:

a) The STA shall transmit an Association Request frame to an AP with which that STA is authenticated. If the MLME-ASSOCIATE.request primitive contained an RSN information element with only one pairwise cipher suite and only one authenticated key suite, this RSN information element shall be included in the Association Request frame.

b) If an Association Response frame is received with a status value of "successful," the STA is now associated with the AP. The state variable shall be set to State 3, and the MLME shall issue an MLME-ASSOCIATE.confirm primitive indicating the successful completion of the operation.

c) If an Association Response frame is received with a status value other than "successful" or the AssociateFailureTimeout expires, the STA is not associated with the AP. The MLME shall issue an MLME-ASSOCIATE.confirm primitive indicating the failure of the operation. The status code returned in the Association Response frame indicates the cause of the failed association attempt. Any misconfiguration or parameter mismatch, e.g., data rates required as basic rates that the STA did not indicate as supported in the STA's Supported Rates information element, shall be corrected before the SME issues an MLME-ASSOCIATE.request for the same AP. If the status code indicates the association failed because of a reason that is not related to configuration, e.g., the AP is unable to support additional associations, the SME shall not issue an MLME-ASSOCIATE.request for the same AP until a period of at least 2 s has elapsed.

d) The SME shall establish an RSNA, or it shall enable WEP by calling MLME-SETPROTECTION.request primitive with ProtectType set to "Rx_Tx," or it shall do nothing if it does not wish to secure communication.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using MLME-DELETEKEYS.request primitive (see 8.4.10) before invoking MLME-ASSOCIATE.request primitive.

11.3.2.2 AP association procedures

When an Association Request frame is received from a STA, the AP shall associate with the STA using the following procedure:

a) If the STA is not authenticated, the AP shall transmit a Deauthentication frame to the STA and terminate the association procedure.

b) In an RSNA, the AP shall check the values received in the RSN information element to see whether the values received match the AP's security policy. If not, the association shall not be accepted.

c) Upon receipt of an MLME-Associate.response service primitive, the AP shall transmit an Association Response with a status code as defined in 7.3.1.9. If the status value is "successful," the association identifier assigned to the STA shall be included in the response.

d) When the status value of the association is not successful, the AP shall indicate a specific reason for the failure to associate in the status code of the Association Response frame. If any status code value from Table 7-23 in 7.3.1.9 is an appropriate reason for the failure to associate, the AP shall indicate that status code value. The use of the unspecified reason value of the status code shall indicate the association failed for a reason that is unrelated to every other defined status code value in Table 7-23.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001663

e) When the Association Response frame with a status value of "successful" is acknowledged by the STA, the STA is considered to be associated with this AP. The state variable for the STA shall be set to State 3.

f) The SME shall establish an RSNA, or it shall enable WEP by calling MLME-SETPROTECTION.request primitive with ProtectType set to "Rx_Tx," or it shall do nothing if it does not wish to secure communication.

g) The SME will inform the DS of the new association.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using MLME-DELETEKEYS.request primitive (see 8.4.10) upon receiving a MLME-ASSOCIATE.indication primitive.

11.3.2.3 STA reassociation procedures

Upon receipt of an MLME-REASSOCIATE.request primitive, a STA shall reassociate with an AP via the following procedure:

a) If the state variable is in State 1, the STA shall inform the SME of the failure of the reassociation by issuing an MLME-REASSOCIATE.confirm primitive.

b) The STA shall transmit a Reassociation Request frame to the new AP. If the MLME-REASSOCIATE.request primitive contained an RSN information element with only one pairwise cipher suite and only one authenticated key suite, this RSN information element shall be included in the Reassociation Request frame.

c) If a Reassociation Response frame is received with a status value of "successful," the STA is now associated with the new AP. The state variable shall be set to State 3, and the MLME shall issue an MLME-REASSOCIATE.confirm primitive indicating the successful completion of the operation.

d) If a Reassociation Response frame is received with a status value other than "successful" or the AssociateFailureTimeout expires, the STA is not associated with the AP. The MLME shall issue an MLME-REASSOCIATE.confirm primitive indicating the failure of the operation. The status code returned in the Reassociation Response frame indicates the cause of the failed reassociation attempt. Any misconfiguration or parameter mismatch, e.g., data rates required as basic rates that the STA did not indicate as supported in the STA's Supported Rates information element, shall be corrected before the SME issues an MLME-REASSOCIATE.request for the same AP. If the status code indicates the reassociation failed because of a reason that is not related to configuration, e.g., the AP is unable to support additional associations, the SME shall not issue an MLME-REASSOCIATE.request for the same AP until a period of at least 2 s has elapsed.

e) The SME shall establish an RSNA, or it shall enable WEP by calling MLME-SETPROTECTION.request primitive with ProtectType set to "Rx_Tx," or it shall do nothing if it does not wish to secure communication.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using MLME-DELETEKEYS.request primitive (see 8.4.10) before invoking MLME-REASSOCIATE.request primitive.

11.3.2.4 AP reassociation procedures

Whenever a Reassociation Request frame is received from a STA, the AP uses the following procedure to support reassociation:

a) If the STA is not authenticated, the AP shall transmit a Deauthentication frame to the STA and terminate the reassociation procedure.

b) In an RSNA, the AP shall check the values received in the RSN information element to see whether the values received match the AP's security policy. If not, the association shall not be accepted.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001664

c) Upon receipt of an MLME-Associate.response service primitive, the AP shall transmit a Reassociation Response frame with a status code as defined in 7.3.1.9. If the status value is "successful," the association identifier assigned to the STA shall be included in the response.

d) When the Reassociation Response frame with a status value of "successful" is acknowledged by the STA, the STA is considered to be associated with this AP. The state variable for the STA shall be set to State 3.

e) When the status value of the reassociation is not successful, the AP shall indicate a specific reason for the failure to reassociate in the status code of the Reassociation Response frame. If any status code value from Table 7-23 in 7.3.1.9 is an appropriate reason for the failure to reassociate, the AP shall indicate that status code value. The use of the unspecified reason value of the status code shall indicate the reassociation failed for a reason that is unrelated to every other defined status code value in Table 7-23.

f) The SME shall establish an RSNA, or it shall enable WEP by calling MLME-SETPROTECTION.request primitive with ProtectType set to "Rx_Tx," or it shall do nothing if it does not wish to secure communication.

g) The SME will inform the DS of the new association.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using MLME-DELETEKEYS.request primitive (see 8.4.10) upon receiving a MLME-REASSOCIATE.indication primitive.

11.3.2.5 STA disassociation procedures

Upon receipt of an MLME-DISASSOCIATE.request primitive, an associated STA shall disassociate from an AP using the following procedure:

a) The STA shall transmit a Disassociation frame to the AP with which that STA is associated.

b) The state variable for the AP shall be set to State 2 if and only if it was not State 1.

c) The MLME shall issue an MLME-DISASSOCIATE.confirm primitive indicating the successful completion of the operation.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) and by invoking MLME-SETPROTECTION.request(None) before invoking the MLME-DISASSOCIATE.request primitive.

11.3.2.6 Non-AP STA disassociation receipt procedure

Upon receipt of a Disassociation frame, a STA shall operate as follows:

a) The MLME shall issue an MLME-DISASSOCIATE.indication with the ReasonCode parameter set to the value of the reason code received in the Disassociation frame.

b) The state variable for the AP shall be set to State 2 if and only if it was not State 1.

c) If the reason code indicates a configuration or parameter mismatch as the cause of the disassociation, the STA shall not attempt to associate or reassociate with the AP sending the Disassociation frame until the configuration or parameter mismatch has been corrected.

d) If the reason code indicates the STA was disassociated for a reason other than configuration or parameter mismatch, the STA shall not attempt to associate or reassociate with the AP sending the Disassociation frame until a period of 2 s has elapsed.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) and by invoking MLME-SETPROTECTION.request(None) before invoking the MLME-DISASSOCIATE.request primitive.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001665

11.3.2.7 AP disassociation initiation procedure

Upon receipt of an MLME-DISASSOCIATE.request, an AP shall use the following procedure when disassociating a STA:

a) The AP shall send a Disassociation frame to the STA being disassociated.

b) The AP shall indicate a specific reason for the disassociation in the Reason Code field of the Disassociation frame. If any reason code value other than the unspecified reason code from Table 7-22 of 7.3.1.7 is appropriate for indicating the reason for the disassociation, the AP shall indicate that reason code value. The use of the unspecified reason value shall indicate the STA was disassociated for a reason unrelated to all defined reason code values defined in Table 7-22.

c) The state variable for the STA shall be set to State 2.

d) The SME shall update the DS.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) and by invoking MLME-SETPROTECTION.request(None) upon receiving a MLME-DISASSOCIATE.indication primitive.

11.3.2.8 AP disassociation receipt procedure

Upon receipt of a Disassociation frame from an associated STA, the AP shall disassociate the STA via the following procedure:

a) The state variable for the STA shall be set to State 2.

b) The MLME shall issue an MLME-DISASSOCIATE.indication primitive to inform the SME of the disassociation.

c) The SME will update the DS.

The STA's SME shall delete any PTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 8.4.10) and by invoking MLME-SETPROTECTION.request(None) upon receiving a MLME-DISASSOCIATE.indication primitive.

11.4 TS operation

11.4.1 Introduction

A TSPEC describes the traffic characteristics and the QoS requirements of a TS. The main purpose of the TSPEC is to reserve resources within the HC and modify the HC's scheduling behavior. It also allows other parameters to be specified that are associated with the TS, such as a traffic classifier and acknowledgment policy.

A TS may have one or more TCLAS (within the discretion of the STA that sets up the stream) associated with it. The AP uses the parameters in the TCLAS elements to filter the MSDUs belonging to this TS so that they can be delivered with the QoS parameters that have been set up for the TS.

TSPEC and the optional TCLAS elements are transported on the air by the ADDTS, in the corresponding QoS Action frame and across the MLME SAP by the MLME-ADDTS primitives.

Following a successful negotiation, a TS is created, identified within the non-AP STA by its TSID and direction, and identified within the HC by a combination of TSID, direction, and non-AP STA address.

It is always the responsibility of the non-AP STA to initiate the creation of a TS regardless of its direction.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001666

In the direct-link case, it is the responsibility of the non-AP STA that is going to send the data to create the TS. In this case, the non-AP STA negotiates with the HC to gain TXOPs that it uses to send the data. There is no negotiation between the originator and recipient non-AP STAs concerning the TS: the originator can discover the capabilities of the recipient (rates, BlockAck) using the DLS.

In the case of traffic relayed by an AP, the sending and receiving non-AP STAs may both create individual TS for the traffic. Any traffic classifier created for the downlink TS applies equally regardless of whether the source is in the same BSS or reached through the DS.

A non-AP STA may simultaneously support up to eight TSs from the HC to itself and up to eight TSs from itself to other STAs, including the HC. The actual number it supports may be less due to implementation restrictions.

A HC may simultaneously support up to eight downlink TSs and up to eight uplink TSs per associated non-AP STA. The actual number it supports may be less due to implementation restrictions.

The traffic admitted in context of a TSPEC can be sent using EDCA or HCCA or HEMM. This depends on the access policy set in the TS Info field in the TSPEC. A TSPEC request may be set so that both HCCA and EDCA mechanisms (i.e., HEMM) are used.

11.4.2 TSPEC construction

TSPECs are constructed at the SME, from application requirements supplied via the SME, and with information specific to the MAC layer. There are no normative requirements on how any TSPEC is to be generated. However, in K.3.2, a description is given on how and where certain parameters may be chosen.

11.4.3 TS lifecycle

Figure 11-7 summarizes the TS lifecycle (using the HMSC syntax defined in ITU-T Recommendation Z.120 (2004).

Initially a TS is inactive. A STA shall not transmit any QoS data frames using an inactive TS.

Following a successful TS setup initiated by the non-AP STA, the TS becomes active, and either the non-AP STA or the HC may transmit QoS data frames using this TSID (according to the Direction field).

While the TS is active, the parameters of the TSPEC characterizing the TS can be renegotiated, when the renegotiation is initiated by the non-AP STA. This negotiation can succeed, resulting in a change to the TSPEC, or can fail, resulting in no change to the TSPEC.

An active TS becomes inactive following a TS deletion process initiated at either non-AP STA or HC. It also becomes inactive following a TS timeout detected at the HC. When an active TS becomes inactive, all the resources allocated for the TS are released.

An active TS may become suspended if no activity is detected for a duration of a suspension interval. Upon detection of activity, the TS may be reinstated. While the TS is in the suspended state, the HC shall not reclaim the resources assigned to the TS.

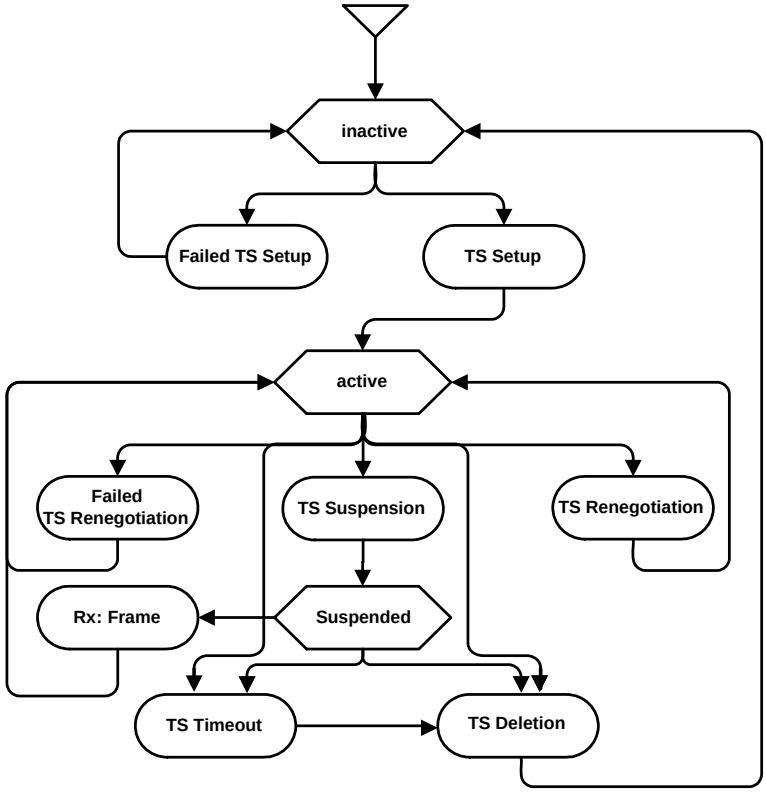

Figure 11-7—TS lifecycle

11.4.4 TS setup

Figure 11-8 shows the sequence of messages occurring at a TS setup. This message sequence in this figure and in the subsequent figures does not show the acknowledgment.

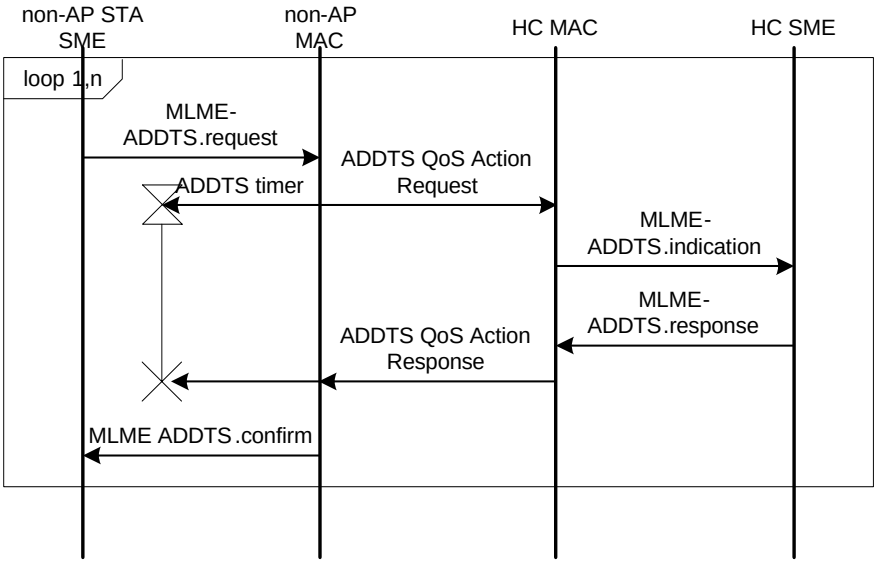

Figure 11-8—TS setup

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001668

The non-AP STA SME decides that a TS needs to be created. How it does this, and how it selects the TSPEC parameters, is beyond the scope of this standard. The SME generates an MLME-ADDTS.request primitive containing a TSPEC. A TSPEC may also be generated autonomously by the MAC without any initiation by the SME. However, if a TSPEC is generated subsequently by the SME, the TSPEC containing the same TSID generated autonomously by the MAC shall be overridden. If one or more TSPECs are initiated by the SME, the autonomous TSPEC shall be terminated.

The non-AP STA MAC transmits the TSPEC in an ADDTS Request frame to the HC and starts a response timer called *ADDTS timer* of duration dot11ADDTSResponseTimout.

The HC MAC receives this management frame and generates an MLME-ADDTS.indication primitive to its SME containing the TSPEC.

The SME in the HC decides whether to admit the TSPEC as specified, refuse the TSPEC, or not admit but suggest an alternative TSPEC. The SME then generates an MLME-ADDTS.response primitive containing the TSPEC and a ResultCode value. The contents of the TSPEC and Status fields contain values specified in 10.3.24.4.2.

The HC MAC transmits an ADDTS Response frame containing this TSPEC and status. The encoding of the ResultCode values to Status Code field values is defined in Table 11-2.

Table 11-2—Encoding of ResultCode to Status Code field value

ResultCode	Status code
SUCCESS	0
INVALID_PARAMETERS	38
REJECTED_WITH_SUGGESTED_CHANGES	39
REJECTED_FOR_DELAY_PERIOD	47

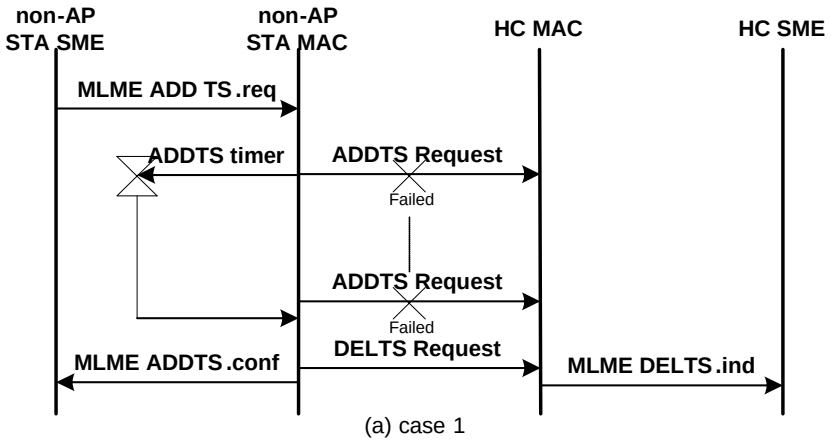
The non-AP STA MAC receives this management frame and cancels its ADDTS timer. It generates an MLME-ADDTS.confirm primitive to its SME containing the TSPEC and status.

The non-AP STA SME decides whether the response meets its needs. How it does this is beyond the scope of this standard. If the result code is SUCCESS, the TS enters into an active state. Otherwise, the whole process can be repeated using the same TSID and direction and a modified TSPEC until the non-AP STA SME decides that the granted TXOP is adequate or inadequate and cannot be improved.

The parameters that are set for a TS can be renegotiated in a similar manner, when such a request is generated by the SME through ADDTS.request primitive. When a request for the modification of the TS parameters is accepted by the HC, it shall reset both the suspension interval and the inactivity interval timers.

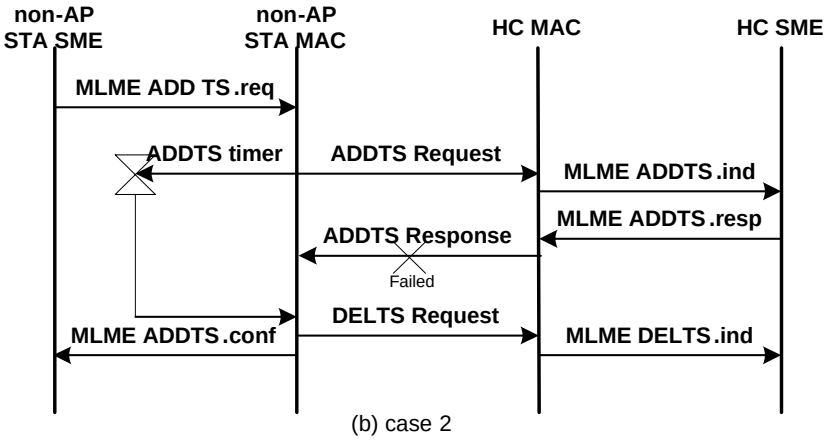
If the AP/HC grants a TXOP for an ADDTS Request frame with the Ack Policy subfield set to Block Ack and the Direction field set to either downlink or bidirectional, then it shall initiate a Block Ack negotiation by sending an ADDBA Request frame to the non-AP STA that originated the ADDTS Request frame. If a non-AP STA is granted a TXOP for an ADDTS Request frame with the Ack Policy subfield set to Block Ack and the Direction field set to other than downlink, then it shall initiate a Block Ack negotiation by sending an ADDBA Request frame to the recipient of the TS.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001669



11.4.5 Failed TS setup

There are two possible types of failed TS setup:



a) The transmission of ADDTS Request frame failed.

b) No ADDTS Response frame is received from the HC (e.g., because of delay due to congestion or because the response frame cannot be transmitted).

Figure 11-9 summarizes the remaining two cases. The MLME shall issue an MLME-ADDTS.confirm primitive, with a result code of TRANSMISSION_FAILURE in the former case and TIMEOUT in the latter case. In both cases, if the request is not for an existing TS, the non-AP STA MAC shall send a DELTS to the HC specifying the TSID and direction of the failed request just in case the HC had received the request and it was the response that was lost.

(a) case 1

(b) case 2

Figure 11-9—Failed TS setup detected within non-AP STA MAC

11.4.6 Data transfer

After the setup of a TSPEC, MSDUs are classified above the MAC and are sent to the MAC through the MAC_SAP using the service primitive MA-UNITDATA.request with the priority parameter encoded to the TSID. The MAC delivers the MSDUs based on a schedule using QoS data frames. In the case of a non-AP STA, the MSDUs are transmitted using QoS data frames, when the non-AP STA is polled by the HC.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001670

The generation of the associated TSID is done by a classifier above the MAC, and it may use the associated TCLAS elements if any are present. When there are multiple TCLASs and if the Processing subfield of TCLAS Processing information element is set to 0, the priority parameter in the associated MA-UNITDATA.request primitive is set to TSID if the classifier can match the parameters in all the TCLAS elements associated with the TS. When there are multiple TCLASs and if the Processing subfield of the TCLAS Processing information element is set to 1, the priority parameter in the associated MA-UNITDATA.request primitive is set to TSID if the classifier can match the parameters in at least one of the TCLAS elements associated with the TS. When there is no TCLAS element and if the Processing subfield of the TCLAS Processing information element is set to 2, the priority parameter in the associated MA-UNITDATA.request primitive is set to TSID if the classifier cannot match the parameters to any of the TCLAS elements.

When the Processing subfield of the TCLAS Processing information element is set to 1, then the receiver cannot recover the original UP unless it does a reverse mapping based on the TCLAS parameters. When the Processing subfield of the TCLAS Processing information element is set to 2, then the receiver cannot recover the original UP.

When an MSDU arrives from the MAC_SAP with a TSID for which there is no associated TSPEC, then the MSDUs shall be sent using EDCA using the access category AC_BE.

11.4.7 TS deletion

There are two types of TS deletion: non-AP STA-initiated and HC-initiated. In both cases, the SME entity above the MAC generates an MLME-DELTS.request primitive specifying the TSID and direction of the TS to be deleted and the reason for deleting the TS. This causes the MAC to send a DELTS Action frame. The encoding of ReasonCode values to Reason Code field (see 7.3.1.7) values is defined in Table 11-3.

Table 11-3—Encoding of ReasonCode to Reason Code field value for DELTS

ReasonCode	Reason Code field
STA_LEAVING	36
END_TS	37
UNKNOWN_TS	38
TIMEOUT	39

The TS is considered inactive within the initiating MAC when the ACK frame to the Action frame is received. No Action frame response is generated.

Figure 11-10 shows the case of TS deletion initiated by the non-AP STA and the case of TS deletion initiated by the HC.

An HC should not delete a TSPEC without a request from the SME except due to inactivity (see 11.4.8).

All TSPECs that have been set up shall be deleted upon disassociation and reassociation. Reassociation causes the non-AP STA and AP to clear their state, and the non-AP STA will have to reinitiate the setup.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001671

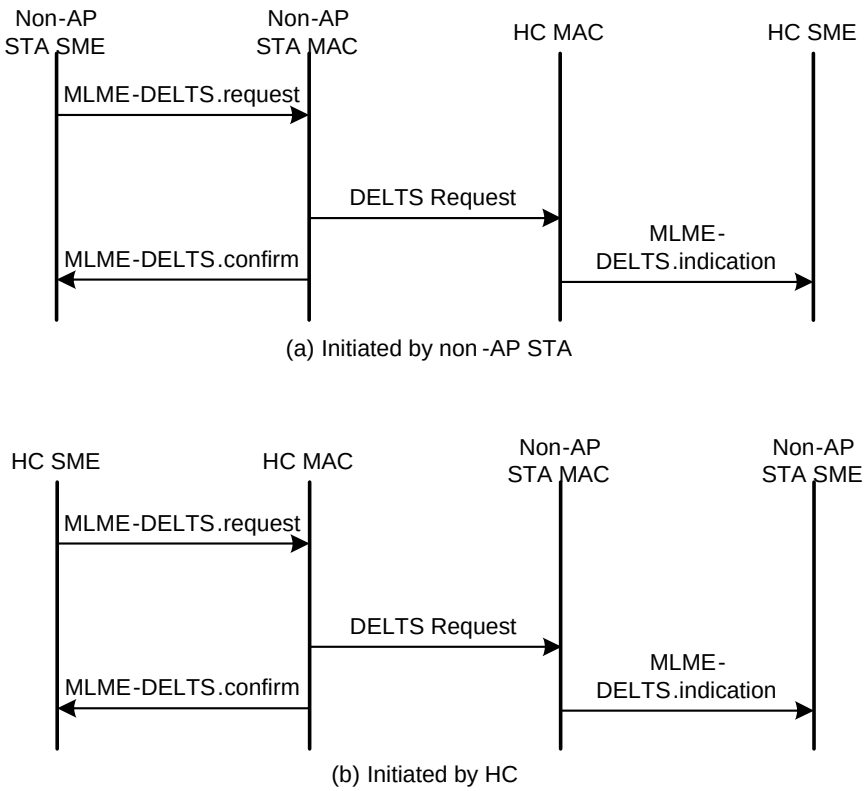

Figure 11-10—TS deletion

11.4.8 TS timeout

TS timeout is detected within the HC MAC when no traffic is detected on the TS within the inactivity timeout specified when the TS was created.

For an uplink TS, the timeout is based on the arrival of correctly received MSDUs that belong to the TS within the MAC after any decryption and reassembly.

For a downlink TS, the timeout is based on the following:

— Arrival of valid MA-UNITDATA.request primitives using this TS at the MAC_SAP when the QoS data frames are sent with the Ack Policy subfield set to No Ack.

— Confirmation of correctly sent MSDUs that belong to the TS within the MAC when the QoS data frames are sent with the Ack Policy subfield set other than to No Ack.

For a direct-link TS, inactivity is considered to have happened if one of the two following happens:

— Returning QoS Null immediately after SIFS interval that contains a zero Queue Size subfield in the QoS Control field in response to a QoS CF-Poll frame.

— No QoS Null frame indicating the queue size for related TSID within a TXOP. This is to ensure that the non-AP STA is actually using the assigned TXOP for the given TSID.

Any other use of a polled TXOP delivered to the non-AP STA is considered to be activity on all direct-link TS associated with that non-AP STA. Detection of inactivity of this type is optional.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001672

In response to an inactivity timeout, the HC shall send a DELTS frame to the non-AP STA with the result code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive.

The case of uplink TS timeout is shown in Figure 11-11.

11.4.9 TS suspension

TS suspension occurs within the HC MAC when no traffic is detected on the TS within the suspension interval specified when the TS was created. In the suspended state, the generation of QoS (+)CF-Poll frames is stopped for the related TS.

11.4.10 TS Reinstatement

A suspended TS may be reinstated following activity for that TS.

For uplink and direct link, a suspended TS may be reinstated by a non-AP STA by sending a QoS data or QoS Null frame. This frame may be sent at the highest priority using EDCA. The generation of successive QoS (+)CF-Poll frames shall then be resumed by the HC.

For downlink, a suspended TS is reinstated by the HC when the AP receives an MSDU from a higher layer.

11.5 Block Ack operation

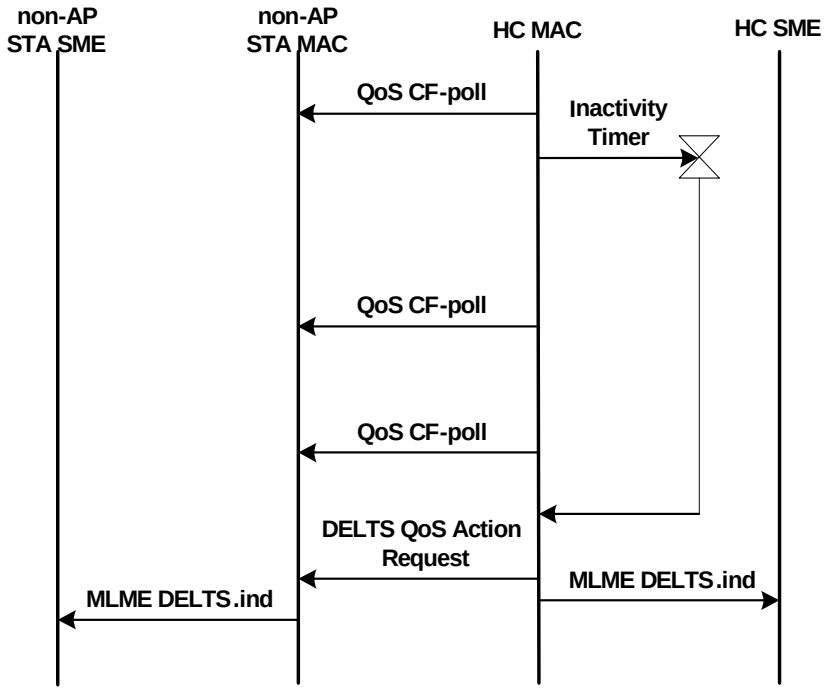
Block Ack may be set up at the MAC (see 9.10.2) or by the initiation of SME. The setup and deletion of Block Ack at the initiation of the SME is described in this subclause.

11.5.1 Setup and modification of the Block Ack parameters

The procedures for setting up and modifying the Block Ack parameters are described in 11.5.1.1 and 11.5.1.2, respectively, and illustrated in Figure 11-12.

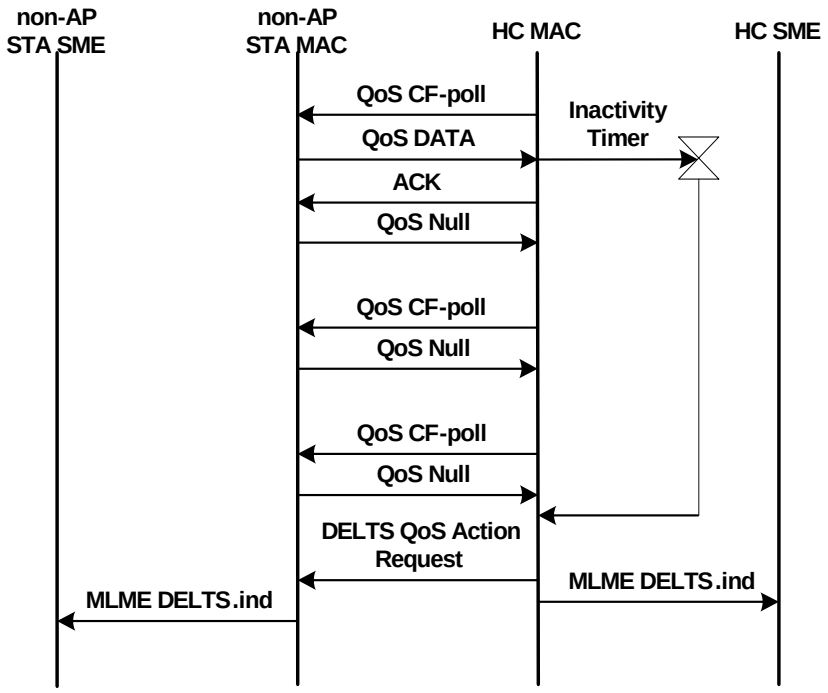
11.5.1.1 Procedure at the originator

Upon receipt of an MLME-ADDBA.request primitive, an initiating STA that intends to send QoS data frames under the Block Ack mechanism shall set up the Block Ack using the following procedure:



a) Check whether the intended peer STA is capable of participating in the Block Ack mechanism by discovering and examining its “Delayed Block Ack” and “Immediate Block Ack” capability bits. If the recipient is capable of participating, the originator sends an ADDBA frame indicating the TID and the buffer size.

b) If an ADDBA Response frame is received with the matching dialog token and the TID and with a status code set to a value of 0, the STA has established a Block Ack mechanism with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive indicating the successful completion of the Block Ack setup.



c) If an ADDBA Response frame is received with the matching dialog token and the TID and with a status code set to a value other than 0, the STA has not established a Block Ack mechanism with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive indicating the failure of the Block Ack setup.

d) If there is no response from the recipient within dot11ADDBAFailureTimeout, the STA has not established a Block Ack mechanism with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive with a result code of TIMEOUT.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001674

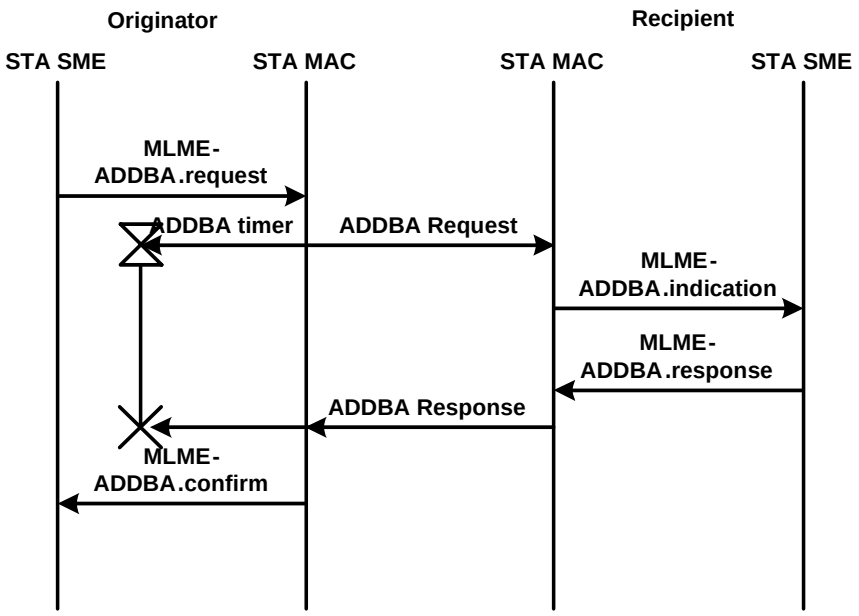

Figure 11-12—Block Ack setup

11.5.1.2 Procedure at the recipient

A recipient shall operate as follows in order to support Block Ack initialization and modification:

a) When an ADDBA Request frame is received from another STA, the MLME shall issue an MLME-ADDBA.indication primitive.

b) Upon receipt of the MLME-ADDBA.response primitive, the STA shall respond by an ADDBA Response frame with a result code as defined in 7.4.4.2.

   1) If the result code is SUCCESS, the Block Ack is considered to be established with the originator. Contained in the frame are the type of Block Ack and the number of buffers that have been allocated for the support of this block.

   2) If the result code is REFUSED, the Block Ack is not considered to have been established.

The encoding of ResultCode values to Status Code field values is defined in Table 11-4.

Table 11-4—Encoding of ResultCode to Status Code field value

ResultCode	Status Code field
SUCCESS	0
REFUSED	37
INVALID_PARAMETERS	38

11.5.2 Teardown of the Block Ack mechanism

The procedure at the two STAs is described in 11.5.2.1 and 11.5.2.2 and illustrated in Figure 11-13.

Exhibit 1014
Page 001675

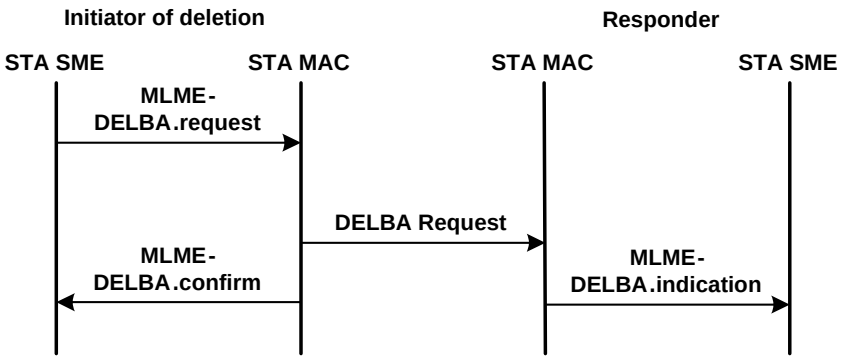

Figure 11-13—Block Ack deletion

11.5.2.1 Procedure at the initiator of the Block Ack teardown

Upon receipt of an MLME-DELBA.request primitive, the STA MAC/MLME shall tear down the Block Ack using the following procedure:

a) The STA shall transmit a DELBA frame.

b) Upon the receipt of an acknowledgment to the DELBA frame, the MLME issues an MLME-DELBA.confirm primitive.

The encoding of ReasonCode values to Reason Code field (see 7.3.1.7) values is defined in Table 11-5.

Table 11-5—Encoding of ReasonCode to Reason Code field value for DELBA

ReasonCode	Reason Code field
STA_LEAVING	36
END_BA	37
UNKNOWN_BA	38
TIMEOUT	39

11.5.2.2 Procedure at the recipient of the DELBA frame

A STA shall issue a MLME-DELBA.indication primitive with the parameter ReasonCode having a value of REQUESTED when a DELBA frame is received.

11.5.3 Error recovery upon a peer failure

Every STA shall maintain an inactivity timer for every negotiated Block Ack setup. The inactivity timer at a recipient is reset when MPDUs corresponding to the TID for which the Block Ack policy is set are received and the Ack Policy subfield in the QoS Control field of that MPDU header is set to Block Ack. The inactivity timer is not reset when MPDUs corresponding to other TIDs are received. The inactivity timer at the recipient is also reset when a BlockAckReq frame corresponding to the TID for which the Block Ack policy is set is received. The inactivity timer at the originator is reset when a BlockAck frame corresponding to the TID for which the Block Ack policy is set is received. When a timeout of BlockAckTimeout is detected, the STA shall send a DELBA frame to the peer STA with the Reason Code field set to TIMEOUT

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001676

and shall issue a MLME-DELBA.indication primitive with the ReasonCode parameter having a value of TIMEOUT. The procedure is illustrated in Figure 11-14.

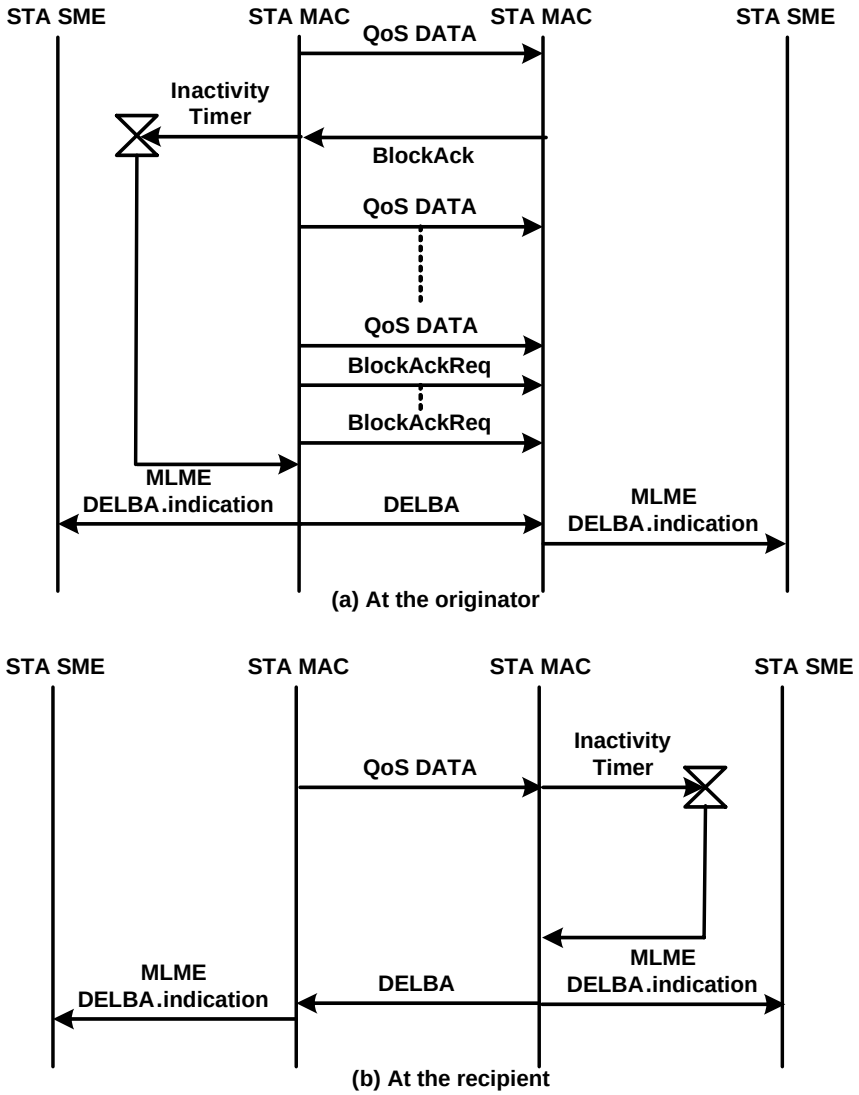

Figure 11-14—Error recovery by the receiver upon a peer failure

When a recipient does not have an active Block ack for a TID, but receives data MPDUs with the Ack Policy subfield set to Block Ack, it shall discard them and shall send a DELBA frame using the normal access mechanisms. If such a STA receives a BlockAckReq frame, it may respond with an ACK frame and shall respond with a DELBA frame using the normal access mechanisms. The originator may attempt to set up the use of Block Ack or may send the MPDUs using an alternative acknowledgment mechanism. When the recipient transmits a DELBA frame, it shall set the last sequence number received value to the sequence number of the last received MPDU, regardless of the acknowledgment policy used in that frame. When the originator receives a DELBA frame, it shall

a) Discard any MPDU that has been transmitted and not acknowledged, with the possible exception if it was the last MPDU to be sent and it was not a retransmission, and

b) Set the sequence number to either that of the last MPDU that is sent if it intends to retransmit or one beyond the last MPDU sent.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001677

The originator STA may send an ADDBA Request frame in order to update Block ACK Timeout Value. If the updated ADDBA Request frame is accepted, both STAs initialize the timer to detect Block ACK timeout. Even if the updated ADDBA Request frame is not accepted, the original Block ACK setup remains active.

11.6 Higher layer timer synchronization

11.6.1 Introduction

Higher layer timer synchronization is beyond the scope of this standard. However, explanation on how the constructs in this standard can be used to support such capabilities may be useful to the designer.

One way to accomplish synchronization across a BSS is by multicasting synchronization (Sync) packets from the higher layers containing a time stamp and a sequence number. These packets would be opaque to the MAC and would be transported in the same way as any other MSDU (most likely addressed to the multicast address). Sync packets would be treated as a type of management packet by the higher layers. The time stamp in the Sync packet would contain the higher layer clock value at the time when the previous Sync packet was transmitted. The sequence number parameter has a value equal to the sequence number of the MSDU in which the time stamp is provided.

The reason the packet would contain the time stamp for the previous Sync packet (rather than the current packet) is that hardware and layering constraints would prohibit the ability to provide a time stamp for the exact instant the current packet is transmitted within that packet. However, a MLME-HL-SYNC.indication primitive allows the transmitting STA to know exactly when each Sync packet is transmitted. A receiving STA can similarly note the time when each Sync packet is received as well as the sequence number for that frame. The receiving STA would save this receive time indication for each packet along with its sequence number and compare the indication of the previously received Sync packet to the time stamp in the most currently received packet. This comparison allows the STA to compute an offset, which can be used to adjust its time reference to match that of the synchronization source. The sequence number would ensure that the correct packet is being used for time stamp comparison. It is possible a packet is lost; in this case, the received time stamp for the lost packet should be discarded.

The last symbol of the Sync frame is indicated by the PHY using the PHY-TXEND.confirm and PHY-RXEND.indication primitives in the transmitter and receiver of the Sync frame, respectively. Practical limits on the coincidence of this indication and the last symbol of the Sync frame are implementation dependent. The accuracy of this technique also depends on the propagation delay between the source and receiving channel. However, both the time difference (between the PHY indication and the last symbol of the Sync frame) and the propagation delay can be considered as fixed-delay components. Therefore, they contribute only to the fixed time difference between the transmitter and receiver STAs' clocks and do not contribute to jitter. An implementation-dependent scheme can be used to cancel or minimize this fixed time difference.

The Sync frame may also be relayed through the AP. In this case, the non-AP STA that generates the time stamps notes the reception of the multicast Sync frame from the AP as the indication to save the higher clock value for the next Sync frame. Receiving STAs would also similarly note the time when each Sync packet is received from the AP. The sequence number would include a value corresponding to the frame received from the AP.

This is an example implementation using the higher layer timer synchronization feature. Other implementations are possible.

Exhibit 1014
Page 001678

11.6.2 Procedure at the STA

A MAC that supports the MLME-HL-SYNC primitives shall respond to a MLME-HL-SYNC.request primitive with an MLME-HL-SYNC.confirm primitive containing a result code of SUCCESS. This confirms to the requesting application that the specified group address has been entered into a MAC table of group addresses for which MLME-HL-SYNC.indication primitive shall be provided.

In order to determine whether to provide an MLME-HL-SYNC.indication primitive for a particular data frame, a MAC that supports MLME-HL-SYNC primitives compares the Address 1 field in a data frame's MAC header against a list of group addresses previously registered by an MLME-HL-SYNC.request primitive. If the MAC and the transmitter of the Sync frame are collocated within the same STA, the MLME-HL-SYNC.indication primitive shall occur when the last symbol of a matching data frame is transmitted. Otherwise, the indication shall occur when the last symbol of the matching data frame is received. In both cases, the MLME-HL-SYNC.indication primitive provided is simultaneous (within implementation-dependent delay bounds) with the indication provided to other STAs within the BSS for the same data frame.

11.7 DLS operation

In general, STAs are not allowed to transmit frames directly to other STAs in a BSS and should always rely on the AP for the delivery of the frames. However, STAs with QoS facility may transmit frames directly to another STA by setting up such data transfer using DLS. The need for this protocol is motivated by the fact that the intended recipient may be in PS mode, in which case it can be awakened only by the AP. The second feature of DLS is to exchange rate set and other information between the sender and the receiver.

This protocol prohibits the STAs going into PS mode for the duration of the direct stream as long as there is an active DLS between the two STAs.

DLS does not apply in an IBSS, where frames are always sent directly from one STA to another.

The handshake involved in the setup is illustrated in Figure 11-15 and involves the four steps listed after the figure.

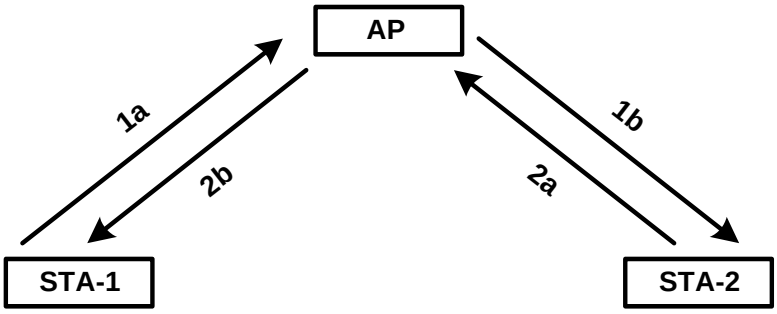

Figure 11-15—The four steps involved in direct-link handshake

a) A STA, STA-1, that intends to exchange frames directly with another non-AP STA, STA-2, invokes DLS and sends a DLS Request frame to the AP (step 1a in Figure 11-15). This request contains the rate set, capabilities of STA-1, and the MAC addresses of STA-1 and STA-2.

b) If STA-2 is associated in the BSS, direct streams are allowed in the policy of the BSS, and STA-2 is indeed a QoS STA, then the AP forwards the DLS Request frame to the recipient, STA-2 (step 1b in Figure 11-15).

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001679

c) If STA-2 accepts the direct stream, it sends a DLS Response frame to the AP (step 2a in Figure 11-15), which contains the rate set, (extended) capabilities of STA-2, and the MAC addresses of STA-1 and STA-2.

d) The AP forwards the DLS Response frame to STA-1 (step 2b in Figure 11-15), after which the direct link becomes active and frames can be sent from STA-1 to STA-2 and from STA-2 to STA-1.

When a STA transitions to a differnent AP after a DLS is set up, the DLS shall be torn down as described in 11.7.4.

11.7.1 DLS procedures

The DLS message flow is illustrated in Figure 11-16.

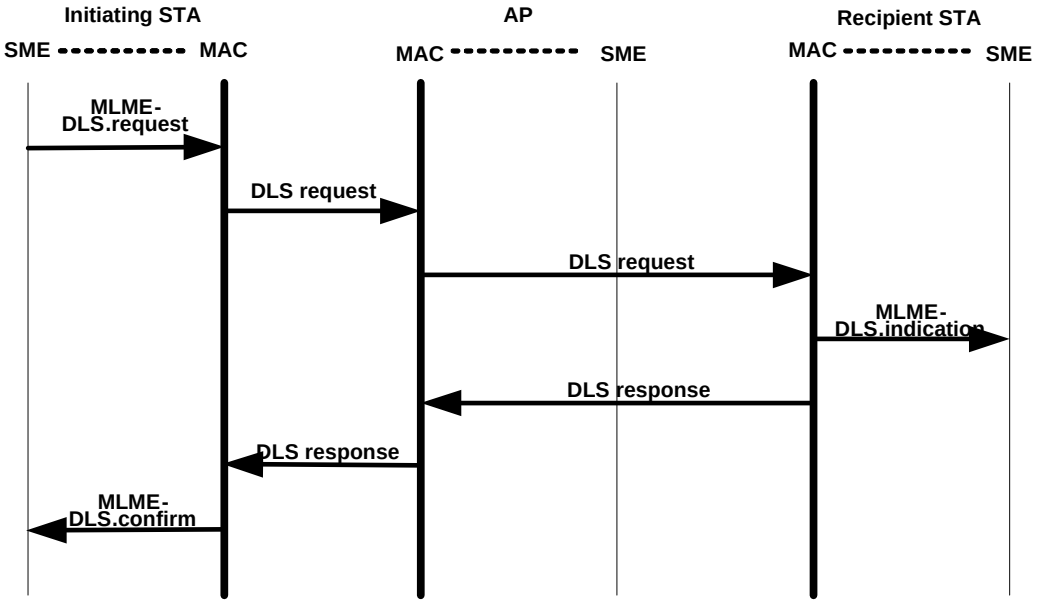

Figure 11-16—DLS message flow

11.7.1.1 Setup procedure at the QoS STA

A STA shall maintain a list of all STAs with which a direct link has been established.

Upon receipt of an MLME-DLS.request primitive from the SME, the STA shall do one of the following actions:

— Issue an MLME-DLS.confirm primitive with a result code of SUCCESS if the peer MAC address of MLME-DLS.request primitive is in the list of STAs with which direct link has been established; or

— Initiate the setup of the direct link by sending the DLS Request frame to the AP (step 1a in Figure 11-15). If the STA does not receive a DLS Response frame within DLSResponseTimeout after sending the DLS Request frame, the STA shall issue an MLME-DLS.confirm primitive with the result code of TIMEOUT.

Upon receipt of the DLS Request frame from the AP (step 1b in Figure 11-15), the STA MAC shall send to the AP a DLS Response frame (step 2a in Figure 11-15) with a result code of

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001680

— SUCCESS if the STA is willing to participate in the direct link with the source STA. The STA shall also issue an MLME-DLS.indication primitive to the SME and shall add the source STA to the list of the STAs, if not already present, with which direct link has been established.

— REFUSED if the STA is not willing to participate in the direct link.

Upon receipt of the DLS Response frame from the AP (step 2b in Figure 11-15), the STA shall issue an MLME-DLS.confirm primitive.

— If the result code is SUCCESS, the direct link is considered to be established with the destination STA in the DLS Response frame, and the STA MAC shall add the destination STA to the list of STAs with which direct link has been established.

— If the result code is REFUSED, the direct links is not considered to have been established.

11.7.1.2 Setup procedure at the AP

Upon receipt of the DLS Request frame (step 1a in Figure 11-15), the AP shall

— Send DLS Response frame to the STA that sent the DLS Request frame with a result code of Not Allowed in the BSS, if direct links are not allowed in the BSS (step 2b in Figure 11-15).

— Send DLS Response frame to the STA that sent the DLS Request frame with a result code of Not Present, if the destination STA is not present in the BSS (step 2b in Figure 11-15).

— Send DLS Response frame to the STA that sent the DLS Request frame with a result code of Not a STA, if the destination STA does not have QoS facility (step 2b in Figure 11-15).

— Send the DLS Request frame, with all fields having the same value as the DLS Request frame received by the AP, to the destination STA (step 1b in Figure 11-15).

Upon receipt of the DLS Response frame from a STA (step 2a in Figure 11-15), the AP shall send DLS Response frame to the source STA (step 2b in Figure 11-15).

The mapping of Status Code field values to ResultCode parameter values in an MLME-DLS.confirm primitive is defined in Table 11-6.

Table 11-6—Mapping of Status Code field value to ResultCode

ResultCode	Status Code field
SUCCESS	0
REFUSED	37
INVALID_PARAMETERS	38
NOT_ALLOWED	48
NOT_PRESENT	49
NOT_QOS_STA	50

11.7.2 Data transfer after setup

Both the STAs may use direct link for data transfers using any of the access mechanisms defined in this standard. STAs may also set up Block Ack if needed. If needed, the STAs may set up TSs with the HC to ensure they have enough bandwidth or use polled TXOPs for data transfer. A protective mechanism (such as transmitting using HCCA, RTS/CTS, or the mechanism described in 9.13) should be used to reduce the probability of other STAs interfering with the direct-link transmissions.

Exhibit 1014
Page 001681

11.7.3 DLS teardown

The DLS teardown procedure is divided into STA-initiated and AP-initiated DLS teardown. The STA-initiated DLS teardown message flow is illustrated in Figure 11-17.

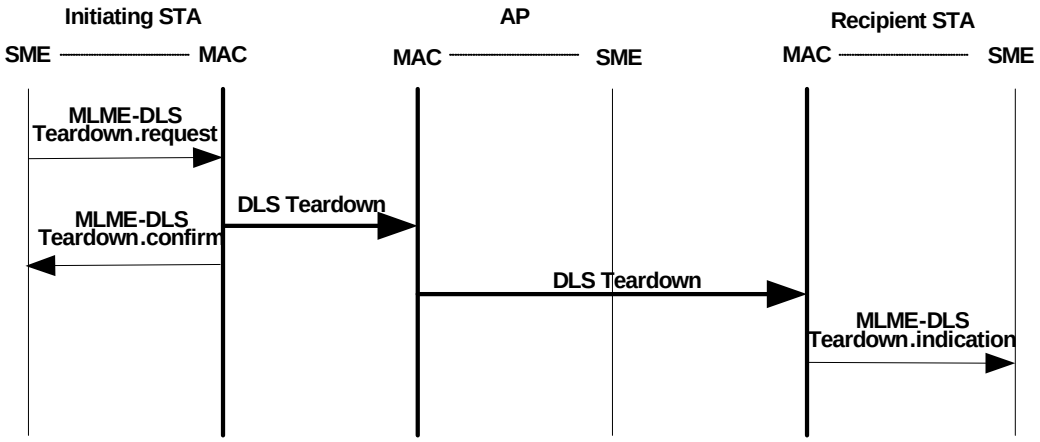

Figure 11-17—STA-initiated DLS teardown message flow

11.7.3.1 STA-initiated DLS teardown procedure

Upon receipt of MLME-DLSTeardown.request primitive from the SME, the STA shall initiate the teardown of the direct link by sending the DLS Teardown frame to the AP. The applicable values of ReasonCode and their encoding to the Reason Code field (see 7.3.1.7) values are defined in Table 11-7.

Table 11-7—Encoding of ReasonCode to Reason Code field value for DLS teardown

ReasonCode	Reason Code field	Applicable at
STA_LEAVING	36	Non-AP STA
END_DLS	37	Non-AP STA
UNKNOWN_DLS	38	Non-AP STA
TIMEOUT	39	Non-AP STA
PEERKEY_MISMATCH	45	AP
PEER_INITIATED	46	AP and Non-AP STA
AP_INITIATED	47	Non-AP STA

If the transmission of the frame is successful, it shall issue an MLME-DLSTeardown.confirm primitive with a result code of SUCCESS. If the frame could not be transmitted, it shall issue an MLME-DLSTeardown.confirm primitive with a result code of FAILURE.

Upon receipt of the DLS Teardown frame (from the AP), the STA shall issue an MLME-DLSTeardown.indication primitive to the SME and shall delete the STA from the list of the STAs with which direct link has been established.

The DLS teardown procedure shall apply to a specific DLS session, as each STA may have multiple simultaneous DLS sessions with other STAs.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001682

Prior to disassociation/deauthentication from the AP, the STA (STA1) shall initiate the teardown of any direct links it has by sending a DLS Teardown frame to the AP. If the DLS Teardown frame's Max Retry Limit was reached with no response from the AP, the STA shall send a DLS Teardown frame to its peer DLS STA (STA2).

A recipient STA (STA2), either on expiry of its DLSResponseTimeout or on receipt of a DLS Teardown frame with ReasonCode set to PEER_INITIATED (from STA1), shall send a DLS Teardown frame to the AP with ReasonCode set to PEER_INITIATED.

An AP that receives a DLS Teardown frame with ReasonCode set to PEER_INITIATED should send a DLS Teardown frame to any STAs that have a DLS link established with STA1.

NOTE—The failed STA may reestablish its DLS link according to 11.7.

11.7.3.2 Teardown procedure at the AP

Upon receipt of the DLS Teardown frame from a STA, the AP shall send a DLS Teardown frame to the destination STA.

Upon receipt of MLME-DLSTeardown.request primitive from the SME, the AP shall announce the tearing down of the direct link by sending the DLS Teardown frame to the two STAs using the direct link. The only applicable values of the ReasonCode are PeerKey_MISMATCH and STA_LEAVING. The encoding to Reason Code field values is defined in Table 11-7.

If the transmission of the frame is successful, it shall issue an MLME-DLSTeardown.confirm primitive with a result code of SUCCESS. If the frame could not be transmitted, it shall issue an MLME-DLSTeardown.confirm primitive with a result code of FAILURE.

11.7.3.3 AP-initiated DLS teardown procedure

The AP-initiated DLS teardown procedure may be used in cases where the STA is unable to initiate the DLS teardown. The AP should initiate a DLS teardown procedure when the AP detects that either end of a DLS link has left the BSS without teardown of the DLS link, e.g., through receipt of a deauthentication frame or receipt of a deassociation frame.

If there are one or more STAs with open DLS connections with the STA being removed, the AP shall send a DLS Teardown frame to each such STA with ReasonCode AP_INITIATED.

NOTE—The AP can also initiate DLS teardown for implementation-dependent reasons.

11.7.4 Error recovery upon a peer failure

Every STA shall maintain an inactivity timer for every negotiated direct link (i.e., STAs on both sides of the link maintain these timers). The DLS inactivity timer shall be reset for every successful frame transmission or reception for that direct link. The direct link becomes inactive when no frames have been exchanged as part of the direct link for the duration of DLS timeout value, if the DLS Timeout Value field is set to a nonzero value during the DLS. When the direct link becomes inactive due to the timeout, the MAC issues an MLME-DLSTeardown.indication primitive to the SME and sends a DLS Teardown frame to the AP, with the peer MAC address as the destination MAC address and the reason code set to TIMEOUT. All frames shall henceforth be sent via the AP. The procedure is illustrated in Figure 14-9.

If there has been a TS setup for the data transfer, it is the responsibility of the STAs to renegotiate the parameters of the TSPEC with the HC.

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001683

When two STAs have set up a direct link, either STA may send DLS Request frames in order to update the DLS timeout value. If the updated DLS Request frame is accepted, both STAs initialize the timer to detect DLS timeout. Even if the updated DLS Request frame is not accepted, the original direct link remains active.

11.7.5 Secure DLS operation

PeerKey Handshake, defined in 8.5.8, is used to establish the keys needed to enable secure DLS. The PeerKey message exchange shall be commenced after the DLS establishment and completed prior to initiation of the DLS data frame exchange.

The STKSA remains valid even if the STA disassociates from the originating AP, but the STKSA shall be deleted before a STA attempts another association or reassociation. If an AP transmits a Deauthenticate or Disassociate message to a STA, the AP shall also initiate teardowns for any existing DLS. The DLS STKs shall be deleted when the DLS teardown messages is sent or received.

11.8 TPC procedures

Regulations that apply to the 5GHz band in most regulatory domains require RLANs operating in the 5 GHz band to use transmitter power control, involving specification of a regulatory maximum transmit power and a mitigation requirement for each allowed channel, to reduce interference with satellite services. This standard describes such a mechanism, referred to as transmit power control (TPC).

This subclause describes TPC procedures that may satisfy needs in many regulatory domains and other frequency bands and may be useful for other purposes (e.g., reduction of interference, range control, reduction of power consumption).

STAs shall use the TPC procedures defined in this subclause if dot11SpectrumManagementRequired is true. dot11SpectrumManagementRequired shall be set to TRUE when regulatory authorities require TPC. It may also be set to TRUE in other circumstances. The TPC procedures provide for the following:

— Association of STAs with an AP in a BSS based on the STAs' power capability (see 11.8.1).

— Specification of regulatory and local maximum transmit power levels for the current channel (see 11.8.2).

— Selection of a transmit power for each transmission in a channel within constraints imposed by regulatory and local requirements (see 11.8.3).

— Adaptation of transmit power based on a range of information, including path loss and link margin estimates (see 11.8.4).

For the purposes of TPC, the following statements apply:

— A STA with dot11SpectrumManagementRequired set to TRUE shall not operate in a BSS or IBSS unless the Spectrum Management bit is set to 1 in the Capability Information field in Beacon frames and Probe Response frames received from other STAs in the BSS or IBSS, *with the following exception*.

— A STA may operate when the Spectrum Management bit is set to 0 if the STA can determine that it is in a regulatory domain that does not require TPC or can ensure that it will meet regulatory requirements even if TPC is not employed. Potential methods for determining the regulatory domain include receiving a country indication in the Beacon frame, user confirmation, or configuration information within the device. Potential methods to ensure regulations are met even if TPC is not employed include using a transmit power that is below the legal maximum (including any mitigation factor).

— A STA shall set dot11SpectrumManagementRequired to TRUE before associating with a BSS or IBSS in which the Spectrum Management bit is set to 1 in the Capability Information field in Beacon frames and Probe Response frames received from the BSS or IBSS.

Copyright © 2007 IEEE. All rights reserved.

Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001684

— APs may allow association of devices that do not have the Spectrum Management bit set to 1 in the Capability Information field in Association Request frames and Reassociation Request frames received from the STA to account for the existence of legacy devices that do not support TPC, but do meet regulatory requirements.

11.8.1 Association based on transmit power capability

A STA shall provide an AP with its minimum and maximum transmit power capability for the current channel when associating or reassociating, using a Power Capability element in Association Request frames or Reassociation Request frames.

An AP may use the minimum and maximum transmit power capability of associated STAs as an input into the algorithm used to determine the local transmit power constraint for any BSS it maintains. The specification of the algorithm is beyond the scope of this standard.

An AP may reject an association or reassociation request from a STA if it considers the STA's minimum or maximum transmit power capability is unacceptable. For example, a STA's power capability might be unacceptable if it violates local regulatory constraints or increases the probability of hidden STAs by a significant degree. The criteria for accepting or rejecting an association or reassociation on the basis of transmit power capability are beyond the scope of this standard.

11.8.2 Specification of regulatory and local maximum transmit power levels

A STA shall determine a regulatory maximum transmit power for the current channel. The STA shall use the minimum of the following:

— Any regulatory maximum transmit power received in a Country element from the AP in its BSS or another STA in its IBSS and

— Any regulatory maximum transmit power for the channel in the current regulatory domain known by the STA from other sources.

A STA shall determine a local maximum transmit power for the current channel. The STA shall use the minimum of the following:

— Any local maximum transmit power received in the combination of a Country element and a Power Constraint element from the AP in its BSS or another STA in its IBSS and

— Any local maximum transmit power for the channel regulatory domain known by the STA from other sources.

Any calculation of the local maximum transmit power for the channel shall ensure the mitigation requirements for the channel in the current regulatory domain can be satisfied. The conservative approach is to set the local maximum transmit power level equal to the regulatory maximum transmit power level minus the mitigation requirement. However, it may be possible to satisfy the mitigation requirement using a higher local maximum transmit power level. A lower local maximum transmit power level may be used for other purposes (e.g., range control, reduction of interference).

The regulatory and local maximum transmit powers may change in a STA during the life of a BSS. However, network stability should be considered when deciding how often or by how much these maximums are changed. The regulatory and local maximum transmit powers shall not change during the life of an IBSS.

An AP in a BSS and a STA in an IBSS shall advertise the regulatory maximum transmit power for the current channel in Beacon frames and Probe Response frames using a Country element. An AP in a BSS and a STA in an IBSS shall advertise the local maximum transmit power for the current channel in Beacon

Copyright © 2007 IEEE. All rights reserved.
Hewlett Packard, et al. v. Cobblestone Wireless
Exhibit 1014
Page 001685

frames and Probe Response frames using the combination of a Country element and a Power Constraint element.

11.8.3 Selection of a transmit power

A STA may select any transmit power for transmissions in a channel within the following constraints:

— A STA shall determine a regulatory maximum transmit power and a local maximum transmit power for a channel in the current regulatory domain before transmitting in the channel.

— An AP shall use a transmit power less than or equal to the regulatory maximum transmit power level for the channel. However, the AP shall also ensure the regulatory mitigation requirement is met.

— A STA that is not an AP shall use a transmit power less than or equal to the local maximum transmit power level for the channel.

11.8.4 Adaptation of the transmit power

A STA may use any criteria, and in particular any path loss and link margin estimates, to dynamically adapt the transmit power for transmissions of an MPDU to another STA. The adaptation methods or criteria are beyond the scope of this standard.

A STA may use a TPC Request frame to request another STA to respond with a TPC Report frame containing link margin and transmit power information. A STA receiving a TPC Request frame shall respond with a TPC Report frame containing the power used to transmit the response in the Transmit Power field and the estimated link margin in a Link Margin field.

An AP in a BSS or a STA in an IBSS shall autonomously include a TPC Report element with the Link Margin field set to 0 and containing transmit power information in the Transmit Power field in any Beacon frame or Probe Response frame it transmits.

11.9 DFS procedures

Regulations that apply to the 5GHz band in most regulatory domains require RLANs operating in the 5 GHz band to implement a mechanism to avoid co-channel operation with radar systems and to ensure uniform utilization of available channels. This standard describes such a mechanism, referred to as dynamic frequency selection (DFS).

This subclause describes DFS procedures that can be used to satisfy these and similar future regulatory requirements. The procedures may also satisfy comparable needs in other frequency bands and may be useful for other purposes.
