Data partitioning and scalable coding techniques generally treat an entire image equally in spatial domain. However, many images have distinct spatial regions of interest. These regions could have better error protection than other areas in order to obtain a better subjective quality compared to coding and transport schemes that

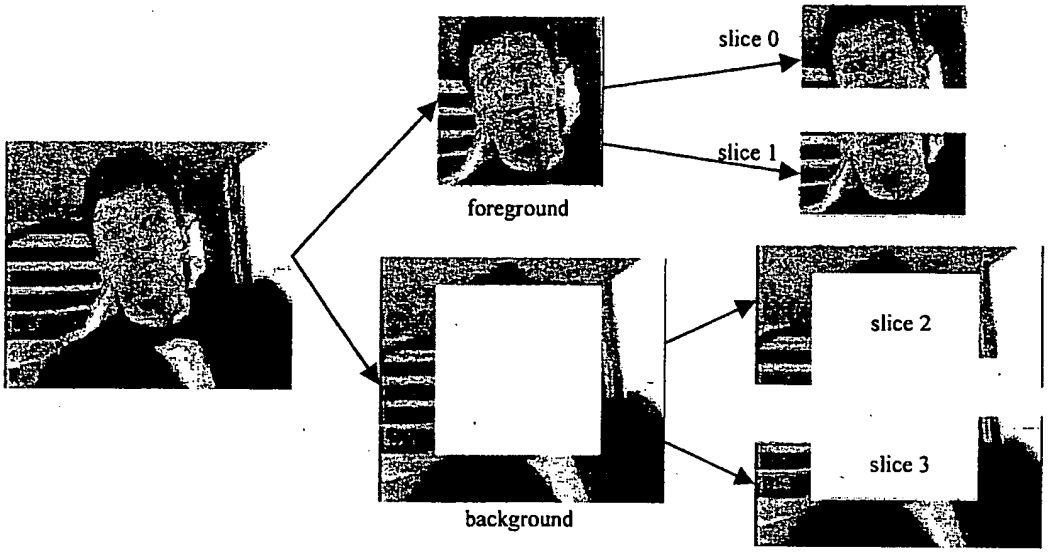

Figure 1. Example of picture, sub-picture, and slice structures.

treat all regions equally. Arbitrarily shaped objects [9], as defined in the MPEG-4 standard, can be used to extract the regions of interest. The object shape is represented by a binary alpha map and the object transparency can be represented by an alpha plane. Objects are then laid on top of each other to compose a picture to display.

1.3. Overview of the Paper

While MPEG-4 arbitrary shape coding has proven to be efficient in compression terms for many sequences, it often inherits relatively high processing requirements. This paper proposes a simple region-based coding method, called sub-picture coding, which is based on rectangular shapes. It can be considered as a simplification of arbitrary shape coding. While sub-picture coding does not provide means to define object boundaries accurately, it suits unequal error protection.

Section 2 of the paper presents the sub-picture coding method. The operation of the sub-picture coding method was simulated in multicast Internet streaming conditions, as explained in Section 3. The paper is concluded in Section 4.

2. SUB-PICTURE CODING

The proposal adds a sub-picture coding layer between picture and slice layers. Sub-pictures are rectangular except for the so-called background sub-picture, which consists of the picture area not falling to any of the rectangular sub-pictures. Rectangular sub-pictures are also referred to as foreground sub-pictures. Sub-pictures boundaries are aligned with macroblock boundaries, and sub-pictures do not overlap. A slice resides within one sub-picture only. A slice in a background sub-picture may not contain spatially adjacent macroblocks within a macroblock line, as it can be intervened by foreground sub-pictures. Figure 1 shows an example of a picture having one foreground sub-picture and one background sub-picture, both of which include two slices.

There are two coding modes associated with sub-pictures: normal prediction mode and independent sub-picture decoding mode. In the normal prediction mode, sub-picture boundaries are treated as slice boundaries. In the independent sub-picture decoding mode, boundaries of foreground sub-pictures are treated as image boundaries and sub-picture segmentation is static over a group of pictures similarly to H.263 Independent Segment Decoding. In other words, temporal and spatial prediction over sub-picture boundaries is prevented when coding rectangular sub-pictures. No such limitation exists when coding a background sub-picture, as the background sub-picture is considered to have a lower subjective importance and it is not protected against error propagation.

3. SIMULATIONS

3.1. Conditions

We selected multicast Internet streaming as a target application. As interactive error concealment cannot be used in large scale with IP multicast, forward error control methods have to be used. Thus, simulation conditions can

BEST AVAILABLE COPY

TML with sub-picture coding TML with ROI quantization TML with constant quantization

Figure 2. Example snapshots, 20 % packet loss rate.

be close to simulation conditions for IP video conferencing without interactive error control methods. We used the ITU-T Video Coding Experts Group (VCEG) common conditions for the low-delay Internet applications [10] as much as we considered appropriate. In addition, we applied transport coding level forward error correction according to RFC 2733 [3].

ITU-T VCEG has been working on the H.26L video codec project. A Joint Video Team (JVT) was recently established joining the experts from ITU-T VCEG and ISO/IEC Moving Picture Experts Group (MPEG). JVT develops a codec based on the draft H.26L design.

The sub-picture coding scheme was implemented in and tested with H.26L Test Model Long-Term (TML) version 8.6 [11][12]. A constant foreground sub-picture was selected, and a finer quantizer was used in the foreground region. The independent sub-picture decoding mode was in use. The scheme was compared to TML-8.6 with region-of-interest (ROI) quantization and to TML-8.6 with constant quantization. The quantization parameters for the ROI coding scheme were obtained in the same manner as for the sub-picture coding scheme but no sub-pictures were used.

The core of the simulator consisted of the following phases. First, the TML encoder was used to encode a sequence. The encoder generated an RTP packet stream. Then, a packet loss simulator erased some of the generated packets according to error patterns released in [13]. The resulting stream of packets was decapsulated and decoded using the TML decoder. Finally, the peak signal-to-noise ratio (PSNR) was calculated between each frame of the source sequence (at full frame rate) and the corresponding reconstructed frame.

Encapsulation into RTP packets was done as follows: In the sub-picture coding scheme, INTRA pictures were encapsulated into five packets. There were two packets for the foreground sub-picture: one packet contained odd macroblock rows and another packet contained even macroblock rows. This slice interleaving mechanism, introduced in [14], was used to obtain a better error concealment result. One parity FEC packet was generated for the two foreground packets according to RFC 2733. The background sub-picture was packetized into another two packets using slice interleaving method. Two consecutive INTER pictures consisted a group, and for each such group there were two foreground sub-picture packets, one parity FEC packet for the foreground packets, and two background sub-picture packets. A sub-picture packet contained data from two pictures: macroblocks from even rows of a certain frame and macroblocks from odd rows of the next frame or vice versa. When sub-picture coding was not in use, there were three packets for each INTRA and INTER frame: two packets for the entire picture (slice interleaving applied), and one parity FEC packet for the two packets.

As multicast Internet streaming was assumed, the coding and transport scheme was tailored for the worst expected case. We selected optimal coding parameters and encapsulation options by trial and error according to the PSNR performance in the 20 % packet loss rate. We tested several INTRA macroblock coding rates as well as several slice sizes to find the optimal ones. The packet stream obtaining the best PSNR performance was multicast virtually. The PSNR performance in 0, 3, 5, and 10 % packet loss rate was then simulated with the multicast packet stream. In order to obtain statistically significant results, each packet stream was virtually transported ten times for each packet loss rate. The first loss pattern position of a run starts from where the previous run ended.

3.2. Results

The experiments were done with the Carphone, Hall Monitor, and Coastguard sequences. We present the results for the Carphone sequence only due to lack of space. The results with the other sequences were consistent with the Carphone results.

Figure 2 shows an example snapshot of the Carphone sequence in 20 % packet loss rate. It can be seen that the sub-picture coding scheme maintains the best image quality. A clearly visible error hit the stream coded with the ROI quantization scheme. When constant quantization

BEST AVAILABLE COPY

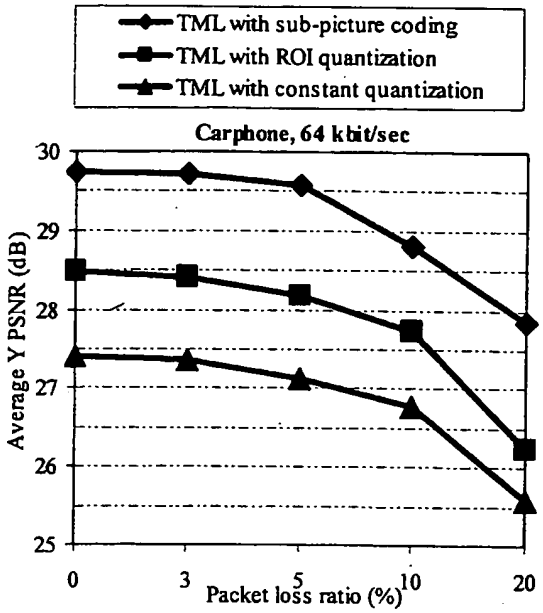

Figure 3. Average luminance PSNR of foreground.

was used, the foreground area was quantized more coarsely than in the other cases, which can be easily seen from Figure 2.

Figure 3 presents the average luminance PSNR of the foreground area of the Carphone sequence. These objective results confirm the subjective ones. Sub-picture coding improves the average luminance PSNR of the foreground area more than one decibel regardless of the packet loss rate. This improvement is gained at the expense of background image quality, which is degraded by coarser quantization and less error protection. In fact, the overall PSNR in the sub-picture coding case drops a little compared to the ROI quantization case and somewhat more compared to the constant quantization case. However, errors in the background are far less noticeable than errors in the foreground, and therefore the overall subjective quality is improved.

4. CONCLUSION

Many video communication systems can make use of unequal error protection to improve quality while maintaining or decreasing bit-rates. In order to apply unequal error protection, video bit-streams have to be organized in portions of different importance in terms of visual quality. Techniques achieving this goal include data partitioning scalable video coding, and region-based video coding. This paper introduced a simple region-based video coding method called sub-picture coding. It provides means for unequal error protection based on regions of interest. In sub-picture coding, a picture is partitioned to one or more rectangular foreground sub-pictures and to a hollow background sub-picture along macroblock boundaries, and sub-picture edges are treated as slice boundaries or as picture boundaries depending on the signaled coding mode. The sub-picture coding method was simulated in multicast Internet streaming conditions and it was found to be superior to conventional coding. Due to its simplicity and the obtained results, we think that sub-picture coding has some potential to become one of the key video coding tools for unequal error protection.

Title: Core Experiment Description of Sub-Picture Coding

Purpose: Information

---

1. INTRODUCTION

In the Pattaya meeting, VCEG/JVT decided to initiate a core experiment about the sub-picture coding technique presented in VCEG-O46, titled "New Image Segmentation Method". This document describes the core experiment. It also includes an executable simulation script, the source code, and some explanations to ease the experiment. The script and the source code are contained in the accompanying files "VCEG-O57_script.zip" and "VCEG-O57_src.zip", respectively.

Section 2 of the document reprints the description of the sub-picture coding method for convenience. The coding method is unchanged compared to VCEG-O46. The core experiment is targeted for Internet multicast. Section 3 describes the simulation conditions, which are essentially the same as in VCEG-O46 except for improved quantization parameter allocation. Section 4 provides instructions how to run the simulation script and some remarks on the source code.

2. SUB-PICTURE CODING

2.1 Sub-picture Layer

A sub-picture coding layer is added between picture and slice layers. Sub-pictures are rectangular except for the so-called background sub-picture, which consists of the picture area not falling to any of the rectangular sub-pictures. Rectangular sub-pictures are also referred to as foreground sub-pictures. Sub-pictures do not overlap. All sub-pictures are coded in scan-order. A slice resides within one sub-picture only. A slice in a background sub-picture may not contain spatially adjacent macroblocks within a macroblock line, as it can be intervened by foreground sub-pictures.

2.2 Coding Modes

There are two coding modes associated with sub-pictures: independent sub-picture coding and normal prediction mode.

In independent sub-picture coding, boundaries of rectangular segments are treated as image boundaries. Sub-picture segmentation is static over a group of pictures (or any similar grouping of pictures). Temporal and spatial prediction over sub-picture boundaries is prevented when coding rectangular sub-pictures. No such limitation exists when coding the background sub-picture, as the background sub-picture is considered to have a lower subjective importance and it is not protected against error propagation. Motion vectors shall not point outside rectangular sub-pictures. Spatial prediction or loop-filtering shall not be done across sub-picture boundaries.

In normal prediction mode, sub-picture boundaries are treated as slice boundaries. Motion vectors may point outside sub-pictures freely and loop-filtering is applied across sub-picture boundaries.

2.3 Bit-Stream Syntax

Slices (or data partitions) are considered the minimum separable unit for transport packetization. We did not want to introduce a competitive concept to slices in the bit-stream level, and therefore we included the sub-picture information in the slice header. Consequently, the transport packetization and depacketization process work the same way as previously regardless of whether sub-pictures are in use.

Use of sub-pictures is signaled in the parameter list of picture and sequence layer data (see VCEG-N72-R1).

When sub-pictures are in use, the slice header shall be as follows:

PictureID	As defined in VCEG-N72-R1.
SliceType	As defined in VCEG-N72-R1.
FirstMBInSliceX	The horizontal position (column) of the first macroblock in the slice relative to the sub-picture.
FirstMBInSliceY	The vertical position (row) of the first macroblock in the slice relative to the sub-picture.
InitialQP	As defined in VCEG-N72-R1.
SubPictureID	Unique identifier of the sub-picture. Each sub-picture is assigned an ID starting from zero and incremented by one in coding order. The count shall be reset for each picture. If independent sub-picture coding is in use, sub-picture ID shall remain the same for the spatially matching sub-pictures over a group of pictures.
SubPictureInfo	0: Sub-picture attributes are the same as the attributes of a sub-picture having the same ID in the previous picture. This value is useful especially in the independent sub-picture coding mode. 1: Sub-picture attributes are the same as the attributes of a sub-picture having the same ID in the same picture. This value is used if a sub-picture contains multiple slices. 2: Sub-picture location and size is defined in the following four codewords. If independent sub-picture coding is in use, the following four codewords shall remain the same within a group

of blocks. A repetition of the codewords is allowed for error resiliency purposes.
3: Background sub-picture. If one of the earlier sub-pictures for the same picture is lost and its location and size are not externally signaled (which is typical in normal prediction mode), decoder shall not decode the background sub-picture, as its shape is unknown.

Left — The coordinate of the left-most macroblock in the sub-picture (in macroblocks). The left-most macroblock column of the picture is assigned value zero.

Top — The coordinate of the top-most macroblock in the sub-picture (in macroblocks). The top-most macroblock row of the picture is assigned value zero.

Width — Width of the sub-picture. The codewords are assigned as follows:

Symbol no	UVLC code	Explanation
0	1	Guess = (RightMost - Left) / 2 + 1, where RightMost is the column address of the right-most macroblock of the picture and / stands for division by truncation. For example, for a QCIF picture and Left equal to 3, Width becomes (10-3)/2+1 = 4.
1	001	Guess + 1
2	011	Guess – 1
3	00001	Guess + 2
4	00011	Guess – 2
...	...	...

Height — Height of the sub-picture. The codewords are assigned similarly to Width.

3. SIMULATION CONDITIONS

3.1 Overview

The performances of three codecs are to be compared:

1) TML-8.6 with the sub-picture coding scheme proposed in VCEG-O46 (herein referred to as the RSP codec),

2) TML-8.6 with region-of-interest (ROI) quantization (ConvROI codec), and

3) the original TML-8.6 without ROI quantization (Conv codec).

Conditions simulating multicast Internet streaming are going to be applied. The conditions are based on the common conditions for the low-delay Internet applications (VCEG-N79R1). As interactive error concealment cannot be used in large-scale with IP multicast, parity FEC according to RFC 2733 is used for each codec.

The simulation procedure for each input sequence consists of two main phases:

1. As a single packet stream is transmitted in multicast Internet streaming, coding and transport parameters are optimized by trial and error for the worst expected case (20 %

packet loss rate). Several INTRA GOB update (IGU) rates as well as several slice sizes are tested. The packet stream obtaining the best PSNR performance is selected. Section 3.3 describes which algorithm is used in IGU rate and slice size optimization. Section 3.4 explains how the bit-rate is controlled and how quantization parameters are assigned.

2. The packet stream is multicast virtually, and the PSNR performance in 0, 3, 5, and 10 % packet loss rate is simulated.

Both main simulation phases include packetization, packet loss simulation according to VCEG-N79r1, and depacketization. Section 3.5 gives an insight into the packetization process.

Instead of encoding 4000 frames as specified in VCEG-N79R1, the PSNR of the decoded video is calculated for each of the 10 runs, the average PSNR plus the best and worst cases of the 10 runs should be shown, as proposed in VCEG-M77. This method is used to show the variation of the PSNR depending on the position of the loss pattern files. The first loss pattern position of a run starts from where the previous run ended. PSNR is calculated between each frame of the source sequence (at full frame rate) and the corresponding reconstructed frame, including repetitions of previous frames in place of skipped and lost frames.

Earlier, for VCEG-O46, we carried out simulations without transport-layer FEC coding too (results for Carphone included in VCEG-O46 and results for Coastguard and Hall presented in the Pattaya meeting). However, when FEC was applied, the results were considerably better than those were without FEC. Moreover, a system providing transport-layer unequal error protection is better to demonstrate the potential of the sub-picture coding method. Therefore, the core experiment is carried out with a system applying FEC according to RFC 2733.

3.2 Test Sequences

The sequences, picture sizes, frame rates, bit-rates, and segmentation of the foreground sub-pictures, described in this section are recommended in the core experiment.

Five QCIF sequences (Carphone, Coastguard, Foreman, Hall and News) and one CIF sequence (Irene), with different frame rates and bitrates, are simulated. Foreman sequence is simulated twice with different bitrates. Therefore, there are of totally seven simulation cases, as shown in Table 1. The foreground sub-picture position and size for each case are also shown in Table 1.

Table 1. The seven simulation cases.

Sequence	Bitrate (kbps)	Frame Rate (frame/s)	Num of Encoded Frames	Foreground Sub-picture Position & Size (Unit: MB)			
				Left	Top	Width	Height
Carphone	64	10	99	2	1	6	6
Coastguard	64	10	99	1	2	9	4
Foreman	64	7.5	75	2	2	7	6
Foreman	144	7.5	75	2	2	7	6
Hall	32	10	99	2	2	7	4
News	64	15	149	2	1	8	6
Irene	384	30	99	4	2	11	13

The foreground sub-picture for each sequence is obtained by manual segmentation, which tries to find the best common region of interest for all used frames in the sequence. The visual segmenting results of the six sequences can be roughly seen from Figure 1.

Figure 1. Sub-picture segmentation for the test sequences.

3.3 Optimization of Slice Size and IGU rate

For QCIF sequences, the slice size is selected from the set of 1, 3, or 9 GOBs/slice (the last means 1 slice/picture), and the IGU rate is 1 GOB per 1, 2, 3, 4, 5, or 0 pictures (the last means that no GOBs are forced to be intra-coded). For CIF sequences, the slice size is selected from the set of 1, 3, 9, or 18 GOBs/slice (the last means 1 slice/picture), and the range of possible IGU rates is the same as for QCIF sequences. It is commonly known that both smaller slice size and higher IGU rate typically result into better error resilience.

Since exhaustive optimization methods are too time-consuming, the following optimization strategy is applied:

- Foreground parameters are optimized first. Then, the background parameters are optimized while the foreground parameters are fixed to the ones found in the first phase. The underlying reason for this strategy is that background slices can be predicted from foreground slices, while foreground slices cannot be predicted from background slices. Therefore, background parameters cannot affect foreground coding very much. This rule only applies to the RSP codec.

- IGU rate is optimized before slice size. We think that IGU rate imposes a heavier effect on error resilience than slice size. When optimising IGU rate, the most error resilient slice size, i.e. 1 GOB/slice, is used.

- When optimizing a parameter (slice size or IGU rate), the parameter values are tested in descending order of error robustness, i.e., from 1 GOBs/slice to 9 GOBs/slice and from 1 forced intra GOB/picture to no forced intra GOBs. Each time the PSNR performance degrades compared to the previous parameter value, optimization of the parameter is stopped without testing the remaining parameter values.

PSNR values of both foreground sub-pictures and entire pictures are calculated for each codec. Since foreground is to be better protected, selection of better parameters cannot be PSNR of the entire pictures. Meanwhile, background should also be considered. Therefore, the following weighted PSNR is used in comparing different results:

$$wPSNR = (PSNRf * 3 + PSNRb) / 4$$

BEST AVAILABLE COPY

The parameter combination with the highest wPSNR is selected. Only the luminance component is considered.

3.4 Selection of Quantization Parameter

In VCEG-O46, adjusting QPs of the foreground and background for the RSP codec and the ConvROI codec focused only on good foreground PSNR performance. As a result, in the two sides of the foreground boundary, the QP difference was likely to be large, which caused annoying boundary effects in the decoded pictures. To reduce the boundary effects, a new scheme described in the following is applied.

The background QP, QPb, is fixed for all background MBs. The foreground QP is a function of the distance from edge between the foreground sub-picture and the background sub-picture. For QCIF sequences, if a macroblock is adjacent to the edge, its QP is QPb-1. If the distance between a macroblock and the edge is one macroblock, the QP of the macroblock is QPb-2. For other foreground macroblocks, the QP is QPb-3. An example is shown in Figure 2, where the highlighted MBs form the foreground sub-picture.

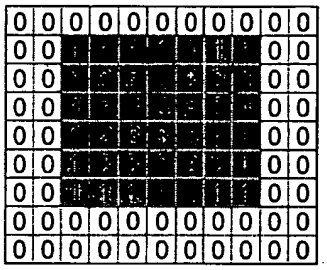

Figure 2. Example of the quantization scheme for QCIF sequences.

The scheme for CIF sequences is similar. If the distance between a macroblock and the foreground-background edge is zero or one, the QP of the macroblock is QPb-1. If the distance between a macroblock and the foreground-background edge is two or three, the QP of the macroblock is QPb-2. For other foreground macroblocks, the QP is QPb-3. An example is shown in Figure 3, where the highlighted MBs form the foreground sub-picture.

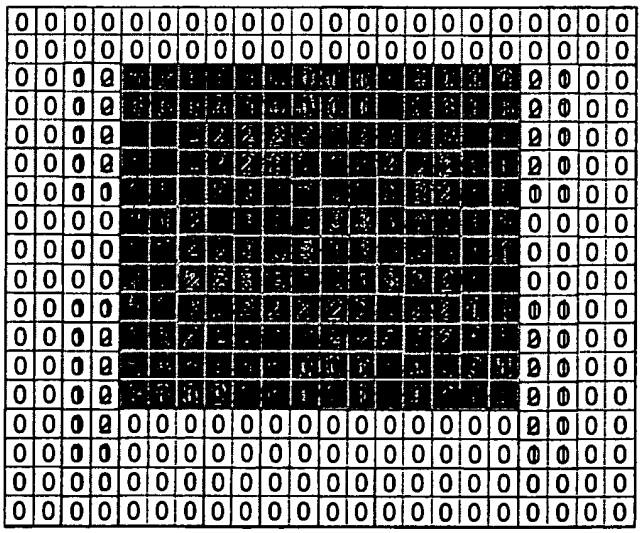

Figure 3. Example of the quantization scheme for CIF sequences.

BEST AVAILABLE COPY

Quantization parameters for the ConvROI codec are obtained in the same manner as for the sub-picture coding scheme.

3.5 Packetization

The packetization method is slightly different from what is described in VCEG-O46, as follows:

The RSP codec:

- For the intra picture, there are 5 packets: 2 packets for the foreground sub-picture, 1 parity FEC packet for the foreground packets, and 2 packet for the background sub-picture. The slice interleaving mechanism (one packet contains odd macroblock rows and another packet contains even macroblock rows) is applied in both the two kinds of sub-pictures.

- For inter pictures, each successive 2 frames consist a group. For each group, there are 2 foreground sub-picture packets, 1 parity FEC packet for the foreground packets, and 2 background sub-picture packets. Each sub-picture packet contains data from two pictures: macroblocks from even rows of frame n and macroblocks from odd rows of frame n+1 or vice versa.

The conventional codecs (the ConvROI codec and the Conv. codec):

- There are 3 packets for each intra and inter frame: 2 packets for the entire picture (slice interleaving applied), and 1 parity FEC packet.

4. PROVIDED SIMULATION SOFTWARE

4.1 Step-By-Step Guide to Run the Simulation

The executable script has been tested with Windows 2000 and NT4.

Having the file "VCEG-O57_script.zip", please do as the following steps:

1) Decompress the contained files to the directory that you want to be the working directory for the experiment.

2) Create/modify the input parameter files (e.g. "sim_foreman64.dat") for the sequences you are going to simulate. The explanation of each input parameter is provided in the example parameter files. You should prepare for each simulating case (a sequence with other parameters, e.g. bitrate, fixed) an input parameter file.

3) Modify the batch file "RSPvidcodsim.bat", to add all planned simulating cases.

4) Run the batch file to begin the simulation.

5) After the simulation process is finished, simulation results of all the simulating cases are saved in the sub-directories of the working directory:

   - Bitrates information (desired bitrate, available video bitrate, and the resulting video bitrate), QP, and optimized slicing method(s), IGU rate(s) are provided in the sub-directory of "parameters".

   - Objective results (PSNR values of foreground sub-pictures and entire pictures) are saved in the sub- directory "PSNR".

- The decoded sequences can be found in the sub- directory of "decSeq".
- Other sub-directories are for saving the error pattern files ("errorpattern"), the encoded bitstreams ("bitstream"), and the temporary foreground sub-picture sequences ("subSeq").

Note that enough free disk space should be provided for the experiment, mainly to save the decoded sequences. The amount of required disk space depends on how many simulating cases and how many frames to be encoded in each case.

4.2 Remarks on Source Code

4.2.1 Saving the Decoded Sequence

To compare the subjective results, decoded sequences should be saved. However, each encoded bitstream file with optimized parameters will be decoded 10 times, by applying 10 continuous runs of the used error pattern file. The decoded sequence of the run whose wPSNR is closest to the averaged wPSNR is saved.

In each decoded sequence, the number of frames is exactly the same as the number of encoded frames. That is, the corresponding reconstructed frames (repeat of the previous reconstructed frames) of lost frames are also saved. This is beneficial for comparing decoded sequences under different packet loss rate when evaluating the subjective results.

4.2.2 Considering Bits of FEC Packets in Resulting Bitrate

When FEC is used to protect the bitstream in transmission, the bits of FEC packets should be considered as part of the resulting video bitrate. As we know, the size of the parity FEC packet equals to the larger size of the two packets to be protected. This is implemented in the encoder function encode_one_frame(), after the current frame is encoded.

4.2.3 Lossy Channel Simulation

The method to apply the packet loss patterns to the bitstream files is really a "simulation". The packet loss simulator is implemented in the decoder software project, by the function Simulator_H26L_Slice() and some functions it calls. No packet is really formed. The simulator identifies to which packet each slice belongs according to the packetization method, and identifies whether a packet is lost according to the used packet loss pattern. The slices belong to the lost packets are discarded, and the slices belong to the received packets are written into the resulting bitstream file, which will be taken as input by the decoder.

4.2.4 Decoding and Sub-Picture Error Concealment Strategy in the RSP Codec

The order of the sub-pictures in the encoded bitsream is: SP0, B0, SP1, B1, SP2, B2, SP3, B3, SP4, B4, ... , where SPn and Bn means the foreground and background sub-picture, respectively, of frame n. The sub-picture error concealment strategy, therefore the framework of the decoder, is designed according to the current decoded sub-picture and the sub-picture losses, as described in the following:

- If current decoded sub-picture is a foreground sub-picture (SPn), the next sub-picture might be:

1) Bn
   No sub-picture is lost. The decoding steps are:
   a. Decode SPn, do error concealment if slice loss exists.
   b. Mark the status of the foreground sub-picture for the next received background sub-picture as "received". Note that the status of any foreground sub-picture SPx affects the error concealment process of its background sub-picture Bx.
2) SP(n+m), m is larger than 0 (1, 2, 3, ...)
   At least Bn is lost, and entire frames might be lost. The decoding steps are:
   a. Decode SPn, do error concealment if slice loss exists.
   b. For frame n, copy SPn to the foreground region of Bn, then mark the MBs of the background region as corrupted and do error concealment. Note that here the MBs of the foreground should be marked as received. The simplest method to form the decoded picture of frame n is to directly copy the background region from B(n-1), plus the foreground region from SPn. Since no bitstream exist for Bn, a virtual frame decoding function is called. This is implemented as the decoder function decode_one_frame_virtual().
   c. Adjust the reference buffers according to the number of entirely lost frames. This is implemented in the decoder function init_frame(), which will be called by the next sub-picture decoding process.
3) B(n+m), m is larger than 0 (1, 2, 3, ...)
   At least Bn and SP(n+1) are lost, and entire frames might be lost. The decoding steps are:
   a. All the three steps in the previous case.
   b. Mark the status of the foreground sub-picture for the next received background sub-picture as "lost". Therefore in the end the next decoding process for B(n+m), the foreground region could be error concealed.
4) End of sequence (EOS)
   Similar to case 2), carry out its first two steps.

- If current decoded sub-picture is a background sub-picture (Bn), the next subpicture might be:

1) SP(n+1)
   No sub-picture is lost. Therefore, the only decoding step is to decode Bn, do error concealment if slice loss exists.
2) B(n+m), m is larger than 0 (1, 2, 3, ...)
   At least SP(n+1) is lost, and entire frames might be lost. The decoding steps are:
   a. Decode Bn, do do error concealment if slice loss exists.
   b. Adjust the reference buffers according to the number of entirely lost frames.
   c. Mark the status of the foreground sub-picture for the next received background sub-picture as "lost".
3) SP(n+m), m is larger than 1 (2, 3, 4, ...)
   There are m-1 frames entirely lost. The decoding steps are the two steps in the previous case.
4) End of sequence (EOS)
   Entire frames might be lost. Nothing can be done more than to decode Bn and do error concealment if slice loss exists.

4.2.5 PSNR Calculation

According to VCEG-N79, PSNR should be calculated between each and every frame of the source sequence (at full frame rate) and the corresponding reconstructed frame, including repetitions of previous frames in place of skipped and lost frames. PSNR calculation for the skipped frames are implemented in the decoder function findSNR4skippedFrames() and findSNR4skippedFrames_s(), the later is for the foreground sub-picture. PSNR calculation for the lost frames are implemented in the decoder function init_frame().

4.2.6 Hacks

There are four hacks in the source code:

1) *Bitstream Syntax Implementation.* Since TML-8.6 does not follow VCEG-N72r1, the slice header syntax in the source code is not the same as described in subsection 2.3. Instead, the sub-picture position and size information are implemented in the picture header. This should not affect the results significantly.

2) *No packet Loss in the Intra frame.* Since only the first frame is intra coded for each encoded sequence, it is possible that one decoding case has lost a packet in the intra frame, while the others do not have. We feel that this might affect the objective and subjective results in an unfair way, as ten runs might not be enough to smooth out the quality drop. Therefore, in the decoded sequences, all the packets of the first frame (the Intra frame) are assumed to be correctly received. This is realized by the packet loss simulator. Each time when there is at least one packet loss in the Intra frame, the simulator will discard the obtained error patterns and read another set of error patterns from the used error pattern file.

3) *P_interval for PSNR calculation.* To calculate PSNR for the skipped frames, the number of skipped frames (therefore the variable P_interval in the source code of TML decoder) should be known at first. In the TML decoder, P_interval is calculated by subtracting the temporal reference (TR) of one P-frame/I-frame from the next P-frame. Therefore, it can be known only after the first P-frame (the second encoded frame) is received. In other words, P_interval cannot be known just after decoding of the first frame. As the result, PSNR of the skipped frames following the first frame cannot be calculated. In the provided software, P_interval is calculated by reading the skipped frames number from the input parameter file (e.g. "sim_foreman64.dat").

4) *Hack for "assert (coef_ctr < 4)".* There is a very "old" bug in the TML decoder, initiated from TML-8.0. That is, in the decoder function readCBPandCoeffsFromNAL(), which can be captured by the instruction line "assert (coef_ctr < 4);" in the function body. The bug occurs in very low frequency (therefore is difficult to debug and to fix). However, each times it occurs, it will cause "unfortunate" result and halt the program! Since the authors still have not found a fix, they implemented a hack: when the bug occurs, the decoding process is stopped, and the bitstream is discarded by transferring to the main simulating program an average PSNR value of 0 dB. We are hoping someone can fix this bug as soon as possible!

ны в левом верхнем углу матрицы. Наиболее эффективный метод считывания значений коэффициентов — зигзагообразное сканирование из верхнего левого в правый нижний угол (рис. 2.7), при котором сначала прочитываются все ненулевые, а затем нулевые коэффициенты. Для кодирования последних применяется описанный выше метод кодирования длин серий, при котором каждой непрерывной последовательности одинаковых символов (в данном случае нулей) приписываются отдельные кодовые слова.

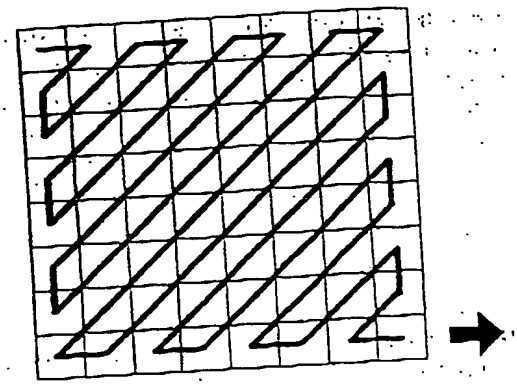

Рис. 2.7. Зигзагообразное сканирование коэффициентов ДКП

Статистическая вероятность появления различных значений коэффициентов неодинакова: некоторые появляются очень часто, другие редко. Эта особенность может быть использована для дальнейшего сокращения числа битов, если более часто встречающимся значениям присвоить более короткие последовательности символов, а более редким — более длинные. Эту задачу решают коды с переменной длиной, о которых мы упоминали выше.

В зависимости от сюжета изображения и скорости движения объектов доля устраняемой избыточности изменяется и среднее число битов, приходящееся на один отсчет, может варьироваться в широких пределах. В таких же пределах будет изменяться и скорость цифрового потока на выходе кодера сжатия. В то же время большинство каналов связи рассчитаны на передачу сигналов с постоянными скоростями. Как всегда в таких случаях, выручает буферная память. Буфер накапливает избыточные биты в критические для кодера моменты (смена сюжета, быстрое движение) и отдает их в канал в периоды относительного спокойствия, когда канал оказывается недогруженным текущими данными. Предусмотрен и механизм обратной связи на случай переполнения или, наоборот, опустошения буфера: изменяя адаптивно коэффициенты матрицы квантования, буфер может в определенных пределах управлять количеством поступающих битов и скоростью потока, разумеется, ценой соответствующего увеличения или уменьшения шага квантования и связанных с ним шумов квантования.

2.1.5. Некоторые действующие стандарты цифрового сжатия

Разработанные в конце 80-х годов эффективные методы цифрового сжатия изображений, описанные выше, вызвали к жизни большое число схем обработки, сочетающих различные методы и направленных на решение разных задач. Часть этих схем была принята стандартизирующими органами и получила статус международных стандартов. Рассмотрим наиболее эффективные из них, послужившие базой для стандартов семейства MPEG.

В 1982–1990 годах группой экспертов по кодированию неподвижных изображений (Joint Photographic Expert Group), образованной совместно МОС, МЭК и МСЭ, был разработан и затем принят одноименный стандарт кодирования неподвижных изображений [2.6]. Основной задачей было поставлено сокращение необходимого объема данных для передачи высококачественного изображения (до 0,25 бит/пикс. для «различимого» изображения, 1 бит/пикс. для «отличного» качества и 4 бит/пикс. для «неотличимого» от оригинала, при исходной точности квантования 8 бит/пикс.).

В ходе длительных исследований были опробованы многие алгоритмы цифрового

BEST AVAILABLE COPY

сжатия и выбрано ДКП как обеспечивающее наилучшее качество при минимальной скорости цифрового потока. В стандарте JPEG впервые были введены технические решения, вошедшие затем в последующие стандарты: обработка не исходных цветовых, а матрицированных сигналов яркости и цветоразностных сигналов, прореживание последних вдвое до формата «4:2:0», выбор размера блоков ДКП 8 x 8 пикс, зигзагообразное сканирование коэффициентов, раздельное квантование постоянной составляющей и остальных коэффициентов ДКП, энтропийное кодирование. По понятным причинам отсутствовала только компенсация движения.

Следующий представляющий интерес стандарт под названием H.261 был разработан в 1988–90 гг. предшественником нынешнего МСЭ-Т Международным консультативным комитетом по телеграфии и телефонии. Стандарт предназначался для передачи видеоизображений (видеотелефония, видеоконференции) со скоростями n x 64 кбит/с, где n = 1...30, формат изображения не мог превышать CIF. В этом стандарте уже использовалось кодирование с предсказанием и два типа кадров: I- и P-кадры. Предсказание движения осуществлялось сравнением с предшествующим кадром, в качестве критерия сопряжения был принят минимум абсолютной ошибки. Начальное окно поиска составляло прямоугольный участок размером 64 x 48 пикс., поиск мог осуществляться одним из трех способов: 1) полным перебором всей области поиска (медленный способ); 2) путем последовательного сужения окна, пока не достигалась требуемая точность сопряжения; 3) иерархической оценкой движения, при которой формируются несколько последовательных версий опорного и текущего кадров со все более низким разрешением, ищется наилучшее согласование в версии с самым низким разрешением и пересчитывается к исходному уровню путем последовательной модификации векторов перемещения. Как и в современных стандартах, макроблок размером 16 x 16 пикс. содержал 4 блока отсчетов сигнала яркости и по одному блоку цветоразностных сигналов.

Стандарты H.261 и JPEG легли в основу разработки MPEG-1.

Работа в этом направлении была продолжена, и в 1996 г. МСЭ-Т принял для тех же применений стандарт H.263, более приспособленный для низкоскоростного кодирования. В этом стандарте поддерживаются форматы от SQCIF до 16CIF (1408 x 1152 пикс.), присутствуют все три вида кадров I, P и B, область поиска сопряжения не ограничена, точность сопряжения 0,5 пикс. К основным улучшениям по сравнению с H.261 относятся: неограниченный диапазон изменения векторов перемещения (на границе они могут

Табл. 2.1. Некоторые форматы разложения, поддерживаемые стандартами H.261 и H.263

указывать за пределы области изображения), арифметическое кодирование квантованных коэффициентов ДКП, улучшенное предсказание (предсказываются 4 блока векторов 8 x 8 вместо одного размерностью 16 x 16 пикселов), кодирование PB-кадров (последовательные P- и B-кадр могут кодироваться вместе как один PB-кадр). Кодек H.263 вышел за границы скорости 64 кбит/с и стал кодеком широкого применения для низкоскоростного кодирования

В табл. 2.1 приведены некоторые параметры стандартов H.261 и H.263 для различных форматов изображения.

Появившаяся недавно вторая версия стандарта H.263, названная H.263+, содержит много дополнительных функций, делающих этот стандарт вполне современным и эффективным: усовершенствован режим внутрикадровой компрессии (деблокирование фильтра); предсказание делается на основе передискретизированного опорного изображения; введен режим обновления с пониженным разрешением; использованы реверсивные коды переменной длины; формат изображения и тактовые частоты могут устанавливаться по выбору пользователя; введен режим временной, пространственной масштабируемости и масштабируемости отношения сигнал-шум; повышена устойчивость к ошибкам благодаря структурированию слайсов.

Отметим, что стандарт H.263+ использовался при разработке визуальной части стандарта MPEG-4.

2.2. СЖАТИЕ ЗВУКОДАННЫХ

2.2.1. Эффект маскирования и психоакустическая модель слуха

Из-за повышенной чувствительности уха к искажениям сжатие звуковых сигналов оказывается более сложной задачей, чем видеокомпрессия. В то же время некоторые психофизиологические особенности слухового восприятия позволяют даже при существенной компрессии (6:1 и более) обеспечить «прозрачный» канал, т.е. канал, звучание выходного сигнала которого субъективно неотличимо от звучания сигнала источника. Для понимания этих особенностей познакомимся вкратце с механизмом слухового восприятия.

Известные нам из школьного курса анатомии барабанная перепонка и стремечко преобразуют звуки в механические вибрации и передают их на находящийся в улитке внутреннего уха кортиев орган — протяженную мембрану между двумя камерами, заполненными жидкостью. Звуки разной высоты возмущают различные участки мембраны, имеющие разные резонансные частоты, и через нервные окончания эти возбуждения передаются в мозг. Частотный диапазон восприятия простирается от 20 Гц до примерно 20 кГц, область наибольшей чувствительности лежит между 1 кГц и 5 кГц. Кривая чувствительности слуха в отсутствие громких звуков показана на рис. 2.8а. Как и во всякой системе с преобразованием из временной в частотную область, в слуховой системе имеется некоторая неопределенность в разделении двух событий: чем точнее известны характеристики сигнала во временной области, тем менее точно можно описать его спектральный состав, и наоборот. Несовершенное разделение по частоте приводит к тому, что ухо не в состоянии различить звуки с близкими частотами, этот эффект

The most effective method of reading the coefficient values is zigzag scanning from the upper left angle to the lower right angle (see Figure 2.7), comprising the steps of first counting all non-zero coefficients followed by reading zero coefficients. To encode the latter, the above-mentioned method of run-length coding is used that comprises assigning separate code words to each continuous sequence of identical symbols (zeroes in this case).

statistical probability for occurrence of different coefficient values is non-equal: some coefficients occur very frequently, others occur rarely. This aspect can be used for further reducing the number of bits, if shorter sequences of symbols are assigned to values occurring more frequently, and longer sequences of symbols are assigned to values occurring more rarely. This problem is solved by variable-length codes mentioned above.

Depending upon a picture subject and an object motion velocity, a fraction of redundancy to be removed varies, and the average number of bits per sample may vary in wide limits. A digital stream rate at an output of a compression encoder will wary within the same limits. At the same time, most communication channels are designed to transmit signals at constant rates. As usual in these cases, buffer memory helps. The buffer accumulates redundant bits at the moments (change of a subject, fast motion) critical for the encoders, and provides said bits to a channel during the periods of relative tranquility when the channel is underloaded with current data. There is provided a feedback mechanism as well – for the of the buffer overflow, or contrary, buffer underflow: by adaptively changing the quantization matrix coefficients, the buffer can control an incoming number of bits and a stream rate within certain limits, of course, due to respective increase or decrease in a quantization step and quantization noise associated therewith.

2.1.5 Some Current Digital Compression Standards

Effective methods for digitally compressing images, developed at the late eighties and described above, have given growth to a great number of processing schemes that combine different techniques and are directed to solution of different problems. A part of said schemes was adopted by standardization authorities and gained the status of international standards. Let us consider the most effective of them that became the basis for standards of the MPEG family.

In 1982 – 1990, the Joint Photographic Expert Group organized by ISO, IEC and ITU together developed and then adopted the standard with the same name for encoding still images [2.6]. The main problem stated was to reduce the amount of data necessary for transmission of a

BEST AVAILABLE COPY

high-quality picture (up to 0.25 bit/pixel for a "distinguishable" picture, 1 bit/pixel for "excellent" quality, and 4 bit/pixel for a picture "non-distinguishable" from the original one, at a starting quantization accuracy of 8 bit/pixel).

Many digital compression algorithms were tested during long studies, and the DCT was selected as the one providing the best quality at the minimum digital stream rate. The technical solutions included in the subsequent standards, namely, processing not original color signals but matrixed luminance signals and chrominance signals, and scaling the latter a half to the format "4:2:0", selecting the size of the DCT blocks to be 8 x 8 pixels, zigzag scanning the coefficients, separately quantizing constant components and other DCT coefficients, entropy encoding, were introduced first in the JPEG standard. Only motion compensation was lacking for understandable reasons.

The next standard of interest – H.261 – was developed in 1988-90 by the Consultative Committee or International Telephony and Telegraphy (CCITT) that was the precursor of the present ITU-T. The standard was designed for transmission of video images (video telephony, video conference) at the rates of n x 64 kbit/s, where n = 1...30, and the image format could not be higher that CIF. That standard already used the prediction encoding and two types of frames: I- and B-frames. The motion prediction was performed by comparison with a previous frame, and an absolute error minimum was taken as the match criterion. The original search window was a rectangular section with a size of 64 to 48 pixels, and the search could be performed by one of three methods: 1) complete searching the entire search area (a slow method); 2) sequential narrowing the window till the required match accuracy is attained; 3) hierarchical motion estimation that requires several sequences of versions of a reference frame and a current frame with progressively lower resolution, wherein the best match in the version with the lowest resolution is searched for and counted to the starting level by sequentially modifying the displacement vectors. Similar to the present standards, a macro block having the size of 16 x 16 pixels contained 4 blocks of luminance signal samples and one block per chrominance signal.

The H.261 and JPEG standards became the basis to develop MPEG-1.

The research in this direction continued, and in 1996 the ITU-T adopted the H.261 standard for the same applications, that was more appropriate for low-rate encoding. That standard supported formats from SQCIF to 16CIF (1408 x 1152 pixels), and dealt with all three

BEST AVAILABLE COPY

types of frames – I, P, and B, wherein the match search area was not limited, and the match accuracy was 0.5 pixel. The basic improvements as compared to H.261 were a non-limited range of variation of the displacement vectors (they could point beyond the picture area), arithmetical encoding of the quantized DCT coefficients, improved prediction (4 blocks of 8 x 8 vectors were predicted instead of one block having a size of 16 x 16 pixel), encoding PB-frames (the capability to encode sequential P- and B-frames together as one PB-frame). The H.262 codec exceeded the rate of 64 kbit/s and became a broadly used codec for low-rate encoding.

Table 2.1 contains several parameters of H.261 and H.263 standards for various picture formats.

Format	Number of luminance signal samples	Number of chrominance signal samples	H.261 standard	H.263 standard
SQCIF	128 x 96	64 x 88	optionally	supported
QCIF	176 x 144	88 x 72	supported	supported
CIF	352 x 288	176 x 144	optionally	optionally
4CIF	704 x 576	352 x 288	not supported	optionally
16CIF	1408 x 1152	704 x 576	not supported	optionally

The second version of the H.263 standard developed recently and named as H.263+ contains many additional functions that make this standard completely modern and effective: the intra-frame compression mode (filter unblocking) is improved; prediction is performed on the basis of a resampled reference picture; the low-resolution updating mode is introduced; reversible variable-length codes are used; a picture format and clock frequencies can be customized; the time, space and signal-to-noise scaling modes are introduced; the error resistance is improved due to structuring the slices.

Let us note that the H.263+ standard has been used in development of the visual part of the MPEG-4 standard.

Abstract: Many of the newer video coding/compression standards, including MPEG-4 and H.263+ support some form of temporal scalability as part of their layered codec concept. This is generally realized by using bi-directionally predicted pictures (B-pictures), which use both an earlier and a subsequent P-picture as reference (anchor) pictures. This paper introduces a new form of temporal scalability employing only P-pictures. This mechanism results in improved real-time behavior (particularly lower latency) and a more flexible layering structure, at the cost of less efficient coding. The P-picture based temporal scalability mechanism is particularly useful for interactive multimedia communication on networks that offer several independent transport streams (possibly with different quality of service), but have sub-optimal real-time characteristics. Typical applications include both the Internet and some forms of mobile communication. The 1998 version of H.263 (known as H.263+ in both academia and industry) offers a mechanism to support P-picture scalability within the bit-stream through the Reference Picture Selection mode [1] [2]. Other video coding standards, including those of the MPEG family, require slight modifications to the decoder in order to support the proposed mechanism.

INTRODUCTION

The concept of a layered codec is well known [3] [4] and recent video coding standards have incorporated support for such mechanisms. A layered video codec produces a representation of the video sequence at various resolutions and qualities. This allows for compatible and robust representations. A particular representation can be obtained by decoding a particular subset of the coded data. Typically, each representation is referred to as a layer. In a hierarchical scalable coding scheme, each layer is coded with respect to lower layer representations. These layers can then be transmitted in separate data streams. The base layer is the only self-contained representation of the sequence and is usually low quality, low resolution, and low bit-rate. Enhancement layers code the difference information or error between the base layer and a higher quality or resolution representation of the video sequence. Three forms of scalability are widely used:

- Temporal enhancement layers increase the frame-rate of the reproduced video by coding additional pictures.
- Spatial enhancement layers raise the spatial resolution of the coded picture by coding difference information between an up-scaled reference layer picture and a higher resolution representation of the original picture. Decoding the base layer produces a low spatial resolution representation, while decoding both the base and spatial enhancement layers produces a higher resolution representation.
- Signal-to-noise-ratio enhancement layers (SNR scalability) allow the transmission of additional precision of DCT coefficients (and/or motion vectors), thus leading to a higher quality reproduced image and consequently to an increase of the SNR of that reproduced image.

All different enhancement layer mechanisms can be used in combination, although some restrictions exist in the current standards. In H.263+, for example, it is possible to use a spatial enhancement layer to increase the spatial resolution of the representation. Using this higher resolution representation, temporal scalability can be employed to produce a higher frame-rate. However, it is not permitted to use the pictures of a temporal enhancement layer as a reference for subsequent SNR or spatial enhancement layers.

This paper focuses on temporal scalability only. It introduces a new form of temporal scalability employing P-pictures. The following section describes this P-picture scalability and distinguishes it from usual B-picture scalability, using H.263+ as an example. Simulation results for both are presented next. The final section describes the applicability of P-picture scalability to other video coding standards implementing inter picture prediction.

THE CONCEPT OF P-PICTURE BASED TEMPORAL SCALABILITY

When implementing a layered codec based on H.263+, the common solution is to employ H.263+'s Temporal, Spatial, and SNR Scalability optional mode (Annex O). In this mode, temporal scalability is realized through bi-directionally predicted pictures (B-pictures). B-pictures use the previous and the subsequent P-picture (or I-picture) as their anchor pictures. Figure 1 illustrates a base layer that is decodable at 10 fps and an B-picture enhancement layer that is decodable at 30 fps.

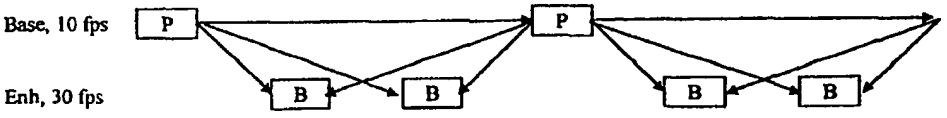

Figure 1: Base and temporal enhancement layer.

As stated above, H.263+ does not permit the B-pictures of the enhancement layer to be used as reference pictures for subsequent layers. Furthermore, with this mechanism it is necessary to decode two base layer pictures before it is possible to decode the B-pictures. Therefore, the overall latency of the base/enhancement layer combination and of the base layer itself are similar, although bits were spent in the enhancement layer to increase temporal resolution. The advantage of temporal scalability employing B-pictures is the comparably small size of B-pictures, leading to a high coding efficiency in the enhancement layer. This is in part due to the enhanced (bi-directional) prediction mechanisms for B-pictures. Additionally, a higher quantization step size is often used for the enhancement layer B-pictures compared to the base-layer P-pictures. This is possible because of the restriction that B-pictures not be used as references whatsoever. The result is high coding efficiency for the enhancement layer B-pictures and little noticeable impact on the reproduced video quality.

The proposed P-picture based temporal scalability mechanism is illustrated in Figure 2. The base layer is a usual sequence of P or I-pictures, as in the example above. The enhancement layer, however, consists only of P-pictures. In addition, the enhancement layer now uses previous pictures of the enhancement layer, as well as base layer pictures, as reference pictures. Two scenarios are shown:

- a base layer that is decodable at 15 fps with an enhancement layer that is decodable at 30 fps, and
- a base layer that is decodable at 10 fps with an enhancement layer that is decodable at 30 fps.

Note that the proposed mechanism can also employ a higher quantizer step-size in the enhancement layer P-pictures to increase coding efficiency with little noticeable impact. This is a particularly useful technique for the last picture of each enhancement layer sub-sequence.

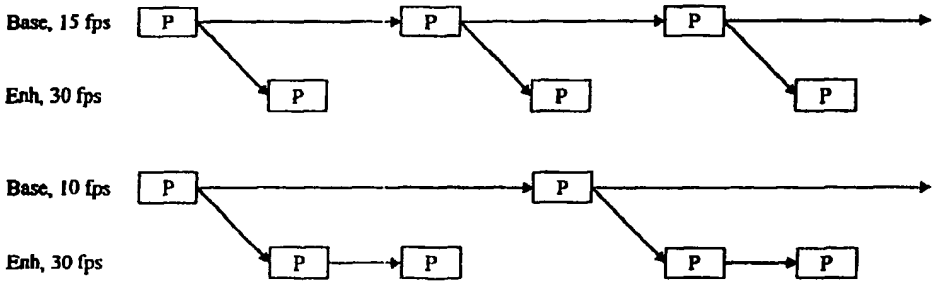

Figure 2: Principle of P-picture temporal scalability

Employing P-pictures for temporal scalability is not an explicitly defined optional mode in H.263+, or in any of the other popular video coding standards. However, in H.263+ it is possible to use the Reference Picture Selection optional mode

(Annex N) without a back channel to generate a standard-compliant bit stream containing scalable P-picture information. This optional mode allows, for each predicted picture, one of several recently transmitted pictures to be selected for use as the reference picture, as opposed to simply allowing the most recent picture to be used as the reference picture. This is signaled in the picture header by coding the temporal reference of the selected reference picture. An H.263+ decoder supporting this optional mode must store several previous reference pictures along with their associated temporal references.

The proposed P-picture based temporal scalability mechanism provides several advantages over the traditional B-picture based temporal scalability mechanism. First, the latency is reduced when spending bits for the enhancement layer. Since a P-picture can be decoded without backward prediction, the enhancement layer P-pictures can be decoded as soon as they are transmitted. At an enhancement layer frame rate of 30 fps, and a base layer frame rate of 10 fps, the overall latency can be 66 milliseconds shorter than using B-frame scalability (33 ms instead of 100 ms). Second, P-frames can be used as reference frames for subsequent enhancement layers. This provides more flexibility in the design of a layered codec. Third, error resilience is improved, as it is by using B-picture based temporal scalability. Any damage to an enhancement layer P-picture will not affect prediction starting from the next reference layer P-picture. The main disadvantage is the inferior coding efficiency of P-pictures relative to B-pictures. This reduced coding efficiency in the enhancement layer results in a slight increase in bit rate.

SIMULATION RESULTS

Using the University of British Columbia's H.263+ reference codec and our implementation of the Reference Picture Selection optional mode (Annex N), both B-picture based temporal scalability (using Annex O) and P-picture based temporal scalability (using Annex N) are simulated. A base layer decodable at 10 fps and an enhancement layer decodable at 30 fps are generated. Fixed quantizer step sizes of 13 and 16 are used for the base and enhancement layers respectively. The input sequences Foreman, Coastguard and Paris, at QCIF resolution, are employed. Several improved coding-efficiency oriented optional modes, Advanced Prediction mode (Annex F), Advanced Intra coding mode (Annex I), Deblocking Filter mode (Annex J) and Modified Quantization mode (Annex T) are used. This configuration produces representations at bit rates typical for Internet scenarios employing layered codecs. The resulting picture quality is far beyond what is achievable using current Internet applications (e.g. the popular Mbone tools).

The picture quality for B-picture based scalability and the proposed P-picture based scalability is comparable, with a PSNR difference of less than 0.1 dB. This result is expected as the same quantizer values are used for both sets of

simulations. Therefore, we compare the different layering mechanisms based on coding efficiency, using the data in Table 1. The first column shows the bit rate for a non-layered representation decodable at 10 fps. The second column shows the bit rate for a non-layered representation decodable at 30 fps. This bit-rate can be considered as the optimum for full temporal resolution (i.e. 30 fps) P-picture based coding. The third and fourth columns show the bit rate of the enhancement layers for layered representations decodable at 30 fps using B-picture based temporal scalability and P-picture based temporal scalability respectively. The fifth and sixth columns show the total bit rate of the base and enhancement layers combined for layered representations decodable at 30 fps using B-picture based temporal scalability and P-picture based temporal scalability respectively. This data provides an indication of the network load imposed by the different mechanisms. Of particular interest are columns 4 and 6, which illustrate the bit rate overhead of P-picture based temporal scalability as compared to B-picture based temporal scalability.

Sequence	Base 10 fps p--p--	Base 30 fps pppppp	Enhance -BB-BB-	Enhance -PP-PP-	Total pBBpBB	Total pPPpPP
Paris	58.6	106.6	25.3	60.5 139%	83.9	119.1 42%
Foreman	43.8	108.5	29.9	45.7 52%	73.7	89.5 21%
Coastguard	60.5	113.0	18.7	25.9 38%	79.2	86.4 9%

Picture types: p: base layer P, P: enhancement layer PB: enhancement-layer B

Table 1: Performance of the P-picture temporal scalability scheme relative to B-picture scalability

The data shows a sequence-dependent total bit rate increase of 9% to 42% when P-picture based temporal scalability is employed, as compared to B-picture based temporal scalability. The associated enhancement layer bit rate increase is 38% to 139%. For many applications, this increase in bit rate is tolerable, given that the benefits of a scalable bit stream are provided with significantly reduced latency using the proposed P-picture based temporal scalability mechanism.

USING P-PICTURE BASED TEMPORAL SCALABILITY OUTSIDE OF H.263+

H.263+ offers a mechanism for P-picture based temporal scalability through the Reference Picture Selection optional mode. The transport layer can then create a single P-picture based scalable bit stream from multiple transport streams (each of them conveying one layer) by using the temporal reference as the ordering criterion and concatenating the coded pictures. Unfortunately, other current video coding standards lack such a mechanism. This section provides a brief overview of how

to circumvent such limitations and implement a P-picture based temporal scalability mechanism in a non-H.263+ framework. In particular, the MPEG-family of ISO/IEC standards and ITU-T H.261 and H.263 version 1 are to be mentioned.

Using these standards, it is impossible to generate a standard compliant data stream that combines a base layer and a P-picture based temporal scalability layer without performing a complete decoding and re-encoding of the video sequence. However, it is possible to modify a decoder such that not only the most recently decoded P-picture is stored but also several recently decoded P-pictures are stored in a queue. The decoder can then use these stored P-pictures in the following manner:

- If the current picture belongs to the base layer, i.e. if it was conveyed over a base layer virtual transport channel, then use the most recently decoded base layer P-picture as a reference. This picture can easily be flagged in the decoded P-picture queue.
- If the current incoming picture belongs to the P-picture enhancement layer, i.e. if it was conveyed over an enhancement layer virtual transport channel, then use the most recently decoded P-picture (from any available source channel) as the reference.

The corresponding encoder operates in a similar manner:

- The base layer is coded in the usual manner, performing inter-picture prediction based on reference pictures from the low temporal resolution representation only.
- The enhancement layer is coded using the most recently coded P-picture as a reference.

We have implemented such a mechanism for a real-time commercial H.261 codec. The results are comparable to those presented above for the H.263+ case.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. §1.97(b))

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

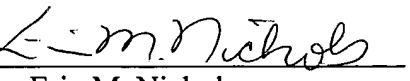
Dear Sir:

With regard to the above-identified application, the item of information listed on the enclosed Form 1449 is brought to the attention of the Examiner.

This statement should be considered because it is submitted either within three months of the filing date or before the first Office Action on the merits of the above-identified application. Accordingly, no fee is due for consideration of the item listed on the enclosed Form 1449.

In accordance with 37 C.F.R. §1.98(a)(2), and the 5 August 2003 Official Gazette Notice, only a copy of each foreign document or other non-patent published document listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached document do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.



No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. §1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the item listed is respectfully requested. Pursuant to the provisions of MPEP §609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

(54) СПОСОБЫ И УСТРОЙСТВА КОДИРОВАНИЯ ИЗОБРАЖЕНИЙ И НОСИТЕЛИ ИНФОРМАЦИИ ДЛЯ ЗАПИСИ ИЗОБРАЖЕНИЙ

(57) Реферат:

Электронная схема и последовательность операций, позволяющие кодировать входной видеосигнал путем выполнения, например, прогнозирующего кодирования, ДКП обработки (Дискретное Косинусное Преобразование), квантования данных с фиксированным шагом квантования, неравномерного кодирования (с переменной длиной) для вырабатывания первых кодированных данных и последующего определения (начисления) количества кодов, отводимых (задаваемых) для каждого кадра или каждой группы изображений ГИ на основе учета количества данных в каждый заранее задаваемый отрезок времени, например за время длительности каждого кадра или каждой СОР в объеме первых кодированных данных и общего количества данных, пригодных для кодирования входного видеосигнала в каждый заранее задаваемый отрезок времени на основе назначаемого количества кодов, для выработки вторых кодированных данных. Таким образом осуществляется кодирование с переменной скоростью, когда скорость кодирования изменяется в каждый заранее задаваемый отрезок времени. В результате, если даже имеет место последовательность изображений (кадров) сложного рисунка, нет возможности обеспечить столь же большое значение шага квантования для этих изображений, как в обычных устройствах. Благодаря этому можно достигнуть однородного изображения высокого качества в целом в самых различных случаях, что является достигаемым техническим результатом. Кроме того, поскольку вторые кодированные данные имеют переменную скорость, то в случае, когда такие данные регистрируются на носителе записанного изображения, ограниченный объем памяти может быть использован более эффективно, а время записи изображения может быть продлено. Наконец, данные изображения, имеющего высокое качество и однородность во всех возможных случаях, могут быть воспроизведены с носителя записанного изображения. 9 с. и 18 з.п.ф-лы, 12 ил.

(54) METHOD AND DEVICE FOR ENCODING IMAGES AND INFORMATION MEDIUM FOR STORING IMAGES

(57) Abstract:

FIELD: computer engineering, in particular, for encoding of input signal by running prediction encoding, discrete cosine transform, data sampling with constant quantization step, non-uniform encoding (with alternating length). SUBSTANCE: method involves encoding of first data group and subsequent detection (assigning) code length for allocation (setting) for each frame or each image group using data length in each given time interval, for example, for duration of each frame in first encoded data group and total length of data available for encoding of input video signal in each given time interval using assigned number of codes for generation of second group of encoded data. This results in possibility of alternating length encoding, when encoding rate alters in any given time interval. So, even if sequence of images (frames) for complex picture is given, there is not way to ensure large quantization step for these images as in state-of-the-art devices. This provides possibility to generate uniform image of high quality in various cases. In addition since second group of encoded data has alternating rate, then if such data are recorded onto information medium, a restricted size of buffer memory may be used with greater efficiency and information storage duration may be extended. Finally, image data of high quality and uniformity in all possible cases can be read from medium which stores this image. EFFECT: increased image quality, increased efficiency of buffer memory usage. 28 cl, 12 dwg

Фиг.1

RU 2123769 C1

RU 2123769 C1

Область применения.

Настоящее изобретение относится к способу кодирования подвижного изображения, к устройству кодирования подвижного изображения и к носителю информации в виде записанного подвижного изображения, а более конкретно оно относится к способу и устройству кодирования подвижного изображения, к носителю записанного подвижного изображения, который используется в системе для кодирования и последующего хранения, к видеосигналу подвижного изображения, к регистрации кодированного сигнала на носителе информации, таком как, например, оптический диск, магнитный диск или магнитная лента и т.п., а также к системам для передачи видеосигнала подвижного изображения через передающую среду.

Предпосылки создания изобретения.

До последнего времени в системах передачи видеосигнала подвижного изображения в удаленные точки, как, например, в телевизионных системах передачи с конференцией, в телевизионных телефонных системах и т.п., или в системах регистрации видеосигнала на таких носителях, как оптический диск, магнитный диск или магнитная лента и т.п., или при воспроизведении записанного видеосигнала подвижного изображения, была широко распространена так называемая схема эффективного кодирования при более эффективном использовании трассы передачи видеосигнала (или носителя записи изображения), когда за счет использования корреляции между строками или корреляции между кадрами видеосигнала снижается избыточность по пространственной оси и по временной оси, и передается только наиболее существенная информация, что увеличивает эффективность передачи.

Например, при обработке в виде кодирования в направлении пространственной оси (далее в тексте - внутрикадровое кодирование) корреляция между строками видеосигнала используется так, как показано на фиг. 7. При попытке передать соответствующие изображения PC1, PC2, PC3,... представляющие собой в моменты времени t1, t2, t3,... подвижные изображения, данные изображения, подлежащие обработке и передаче, подвергаются одномерному кодированию, например, в рамках одной и той же строки, или же изображение разбивается, например, на несколько блоков, что позволяет подвергнуть данные изображения в соответствующих блоках двумерному кодированию с тем, чтобы осуществить сжатие данных, что увеличивает эффективность передачи.

Кроме того, при обработке кодированием в направлении оси времени (далее также - внутрикадровое кодирование) внутрикадровая корреляция видеосигнала используется для определения (с помощью так называемого прогнозирующего кодирования) данных изображения PC12, PC23,... имеющих недостаток элементов (так называемых прогнозированных ошибок) в каждом из пикселей данных изображений, общих для смежных изображений PC1, PC2 и PC3, в последовательности этих данных PC12, PC23,... подлежащих передаче, осуществляя, таким образом, сжатие данных, а следовательно, и увеличивая эффективность передачи.

Таким образом, по сравнению со случаем, когда передаются все данные изображений PC1, PC2, PC3,... в данном случае видеосигнал может быть передан на основе значительно меньшего количества данных.

Кроме того, в процессе прогнозирующего кодирования во время описанного выше внутрикадрового кодирования применяется также прогнозируемая компенсация движения, например, в объеме массивов, состоящих из макроблоков, с тем, чтобы еще более увеличить эффективность. Например, когда персонаж в центральной части изображения движется, такое движение объекта на изображении обнаруживается с целью коррекции положения данных изображения, используемых для прогнозирования в предыдущем изображении путем выполнения прогнозируемого кодирования в предыдущем изображении, что также дает возможность увеличить эффективность кодирования. Однако, даже когда применяется такое прогнозирование на основе компенсации движения, большое количество данных по сравнению с той частью изображения, где объект движется и появляется на заднем фоне, должно быть передано. Ввиду этого, не только компенсация движения в описанном выше направлении вперед, но также и компенсация движения в направлении назад или даже в обоих направлениях - вперед и назад - используется совместно, что дает возможность еще более увеличить эффективность кодирования.

Фактически, как показано на фиг. 8, в макроблоках данных кадров F0, F1, F2, F3 нулевого, первого, второго, третьего,... кадров видеосигнала подвижного изображения, подлежащего передаче, и в случае, когда имеют место изменения в изображении, что соответственно указано векторами движения x0, x1, x2, x3, ... последовательно между кадрами, устройство на передающей стороне обозначает кадры в заранее заданном количестве интервалов (например, исключая каждый следующий кадр), т.е. второй, четвертый,... как кадры интерполяции для так называемой заранее задаваемой кадровой интерполяции, как показано на фиг. 8, с целью формирования данных для передачи в виде интерполированных кадров F2X, F4X. . . . Далее, в отношении неинтерполированных кадров, устройство на передающей стороне выполняет заранее задаваемое колирование кадров F1, F2, F3,... для формирования подлежащих передаче данных - неинтерполированных кадров F1X, F3X,....

Например, разность SP2 (прогнозируемая ошибка) между данными кадров с компенсацией движения F3 и F2, разность SP4 между данными кадров с компенсацией движения F1 и F2 и разность между данными кадров, полученных в результате интерполяции данных кадров с компенсацией движения F1 и FT3, а также данные кадра F2 соответственно определяются в массивах макроблоков для сравнения разности (данных) SP1 данных кадра F2 и этих разностей. Затем данные, в составе которых

RU 2123769 C1

RU 2123769 C1

имеется минимальное количество данных, сформированных на основе SP1, SP4, выводятся на передачу как интерполированные данные F2X в массивах макроблоков. Аналогично интерполированные для передачи данные F4X, ... генерируются на основе соответствующих кадров интерполяции. Далее, данные неинтерполированных кадров F1, F3,... подвергаются обработке ДКП (дискретное косинусное преобразование) и неравномерному кодированию для формирования подлежащих передаче данных неинтерполированных кадров F1X, F3X, ...

Данные неинтерполированных кадров F1X, F3X,... и данные интерполированных кадров F2X, F4X, . . . передаются в устройство на приемной стороне совместно с векторами движения x0, x1, x3,...

С другой стороны, устройство на приемной стороне выполняет обработку декодированием, соответствующим обработке кодированием на предающей стороне, перед передачей данных (передаваемые данные неинтерполированных кадров F1X, F3X, . . . передаваемые интерполированные данные кадров F2X, F4X,... данные векторов движения x0, x1, x3) с тем, чтобы воспроизвести данные кадров F0, F1, F2, F3, . .. В результате компенсации движения выполняются не только в направлении вперед, но и в направлении назад или даже в обоих направлениях - вперед и назад, что дает возможность увеличить еще более эффективность кодирования.

Ниже приводится описание устройств кодирования и декодирования, имеющих описанные выше функции.

Устройство кодирования содержит, как показано на фиг. 9, схему 61 предварительной обработки, разделяющую видеосигнал BC на сигнал яркости и цветоразностный сигнал, преобразовательные схемы 62a и 63б аналог/цифра (далее в тексте А/Ц схемы) для преобразования сигнала яркости и цветоразностного сигнала, соответственно поступающих со схемы 61, в цифровые сигналы, ЗУ кадровой памяти 63 для хранения данных яркости и цветоразностных данных (далее в тексте - данные изображения), поступающих со схем А-Ц 62a и 62б, схему 64 преобразования, схему 64 преобразования формата, служащую также для считывания данных из ЗУ 63 кадровой памяти в соответствии с блочным форматом, и кодирующее устройство (кодер) 65 для эффективного кодирования блока, поступающего со схемы 64 преобразования формата, в данные изображения.

В процессе работы схема 61 предварительной обработки разделяет входной видеосигнал BC на сигналы яркости и цветоразностный. А/Ц схемы преобразования 62a и 62б соответственно преобразуют сигнал яркости и цветоразностный в данные яркости и цветоразностные данные группами по 8 бит каждая. ЗУ 63 хранит эти данные.

Схема 64 преобразования формата считывает в соответствии с блочным форматом, данные изображения (данные яркости и цветоразностные данные, хранящиеся в ЗУ 63 кадровой памяти). Кодер 65 кодирует данные изображения, считывая их таким образом с заданной эффективностью кодирования в выходной поток бит.

Этот поток бит направляется в устройство 80 декодирования изобретения через передающую среду 70, которой может быть либо трасса распространения сигнала, либо носитель записи изображения, например оптический диск, магнитный диск или магнитная лента и т.п.

Это устройство декодирования 80 содержит, как показано на фиг. 9, декодер 81, соответствующий кодеру 65, схему преобразования формата 82, служащую для преобразования данных изображения, воспроизведенных декодером 81, в формат кадра, ЗУ 83 кадровой памяти для хранения данных изображения, подаваемых со схемы 82 преобразования формата, Ц/А преобразовательные схемы 84a, 84б для преобразования данных яркости и цветоразностных данных, которые были считаны из ЗУ 83 кадровой памяти, в аналоговые сигналы, и послеобработочная схема 85 для смешения сигнала яркости и цветоразностного сигнала, подаваемых со схем 84a, 84б Ц/А преобразования, в результате чего формируется выходной видеосигнал.

Декодер 81 декодирует поток бит, выполняя операцию декодирования, соответствующую эффективному кодированию в кодере 65, для воспроизведения данных изображения в блочном формате. Схема 82 преобразует эти данные изображения и в формате кадра передает их на хранение в ЗУ 83 кадровой памяти.

Ц/А преобразовательные схемы 84a, 84б соответственно преобразуют данные яркости и цветоразностные данные, считанные из ЗУ 83 кадровой памяти, в сигнал яркости и в цветоразностный сигнал. Послеобработочная схема 81 смешивает эти два сигнала, формируя таким образом выходной видеосигнал.

Фактически послеобработочная схема 61 и Ц/А преобразовательные схемы 62a, 62б преобразуют сигнал яркости и цветоразностный сигнал в цифровой сигнал так же, как это делается и описано выше для сокращения количества данных, так что количество пикселей становится равным половине пикселей сигнала яркости в верхнем и нижнем направлениях, а также в левом и правом направлениях по отношению к сигналу яркости при дальнейшем осуществлении мультиплексирования по оси времени вдобавок к выдаче данных яркости и цветоразностных данных, полученных таким образом, в ЗУ 63 кадровой памяти.

Из ЗУ кадровой памяти 63 данные яркости и цветоразностные данные считываются в соответствии с блочным форматом, как описано выше, а именно, например, данные изображения одного кадра разделяются на N секций, как показано на фиг. 10A. Каждая секция формируется так, чтобы в ней содержалось M макроблоков, как показано на фиг. 10B. Каждый макроблок составляется из данных яркости в виде четырех блоков яркости Y1, Y2, Y3, Y4, каждый из которых состоит из 8 x 8 пикселей, в верхнем и нижнем, а также в левом и правом

RU 2123769 C1

RU 2123769 C1

направлениях, и из цветоразностных данных Сб, Ср цветных блоков, состоящих из 8 х 8 пикселей, соответствующих по размерам блокам яркости. Из ЗУ 63 кадровой памяти данные яркости и цветоразностные данные считываются так, что данные изображения затем располагаются последовательно в массивах макроблоков в пределах секций и последовательно в порядке Y1, Y2, Y3, Y4, Сб, Ср внутри макроблока. Данные изображения, считанные таким образом в соответствии с блочным форматом, затем пересылаются в кодер 65.

Кодер 65 содержит схему 101 определения вектора движения, как показано на фиг. 11. Эта схема 101 обнаруживает (в массивах макроблоков) вектор движения данных изображения, передаваемых дополнительно в соответствии с блочным форматом. Схема 101 обнаружения вектора движения обнаруживает в массивах макроблоков вектор движения текущего изображения как опорного на основе исходных изображений в направлении вперед/назад, хранящихся в ЗУ 63 кадровой памяти. Обнаружение осуществляется так, что минимальный вектор сумм абсолютных значений разностей между кадрами в массивах макроблоков становится соответствующим вектору движения. Определенный таким образом вектор движения выдается на схему 113 компенсации движения и далее, а внутрикадровые разности в массивах макроблоков выдаются на схему внутрикадрового прогнозирования вперед/назад/в обоих направлениях 103.

Эта схема 103 определяет прогнозируемый вид образцового блока с тем, чтобы на основе значения его параметра управлять схемой 104 прогнозируемого кодирования, выполняя переключения внутрикадрового прогнозирования вперед/назад/в обоих направлениях в массивах макроблоков. Схема 104 прогнозирования кодирования содержит схемы суммирования 104а, 104б, 104в и селективный переключатель 104г, эта схема в том случае, когда прогнозируемый режим кодирования оказывается внутрикадровым режимом, она отбирает разности между всеми пикселями (далее в тексте - разностные данные) входных данных изображения относительно соответствующих прогнозируемых изображений, а затем выдает отобранные данные на схему 105 ДКП (Дискретное Косинусное Преобразование).

Схема 105 выполняет ДКП-обработку данных входного изображения или разностных данных в массивах блоков, используя двумерную корреляцию видеосигнала для определения данных коэффициента и последующей передачи его на схему 106 квантования.

Схема квантования 106 квантует данные коэффициента, соблюдая размер шага квантования (шкала квантования), определяемый для каждого макроблока или секции с тем, чтобы затем выдать полученные таким образом данные на схему 107 неравномерного кодирования (с переменной длиной) (далее по тексту - НК) и на инверсную схему 108 квантования. При определении шага квантования необходимо следить за тем, чтобы величина этого шага не стала причиной разрыва упорядоченности в буферной памяти 109 передачи, которая будет описана ниже, вследствие возможного образования обратной связи по остаточным данным этого буфера 109. Значение этого шага квантования также передается на схему НК 107 и на инверсную схему квантования 108.

Схема НК 107 выполняет неравномерное кодирование квантованных данных, имеющих определенный шаг, в прогнозируемом режиме с учетом вектора движения, передавая затем все эти параметры в буфер 109 в качестве данных, подлежащих передаче.

Буфер 109 передачи временно хранит данные, подлежащие передаче с тем, чтобы в определенный момент считать их с заранее заданной скоростью чтения битов и упорядоченно передать их на выход в виде потока битов, а также передает сигнал управления квантованием в массивах макроблоков обратно на схему 106 квантования в соответствии с количеством остаточных данных, остающихся в буферной памяти, и для управления значением шага квантования. Таким образом, буфер передачи 109 регулирует количество данных, формируемых в виде потока битов для поддержания надлежащего остаточного количества данных в памяти (остаточная емкость) с тем, чтобы не допустить переполнения буфера и недостатка данных. Например, когда количество остаточных данных в буфере передачи 109 увеличивается до допустимого верхнего предела, буфер увеличивает шаг квантования схемы 108 с помощью управляющего сигнала, снижая таким образом количество квантуемых данных. С другой стороны, когда количество остаточных данных в буфере передачи 109 уменьшается до нижнего допустимого предела, буфер 109 передачи уменьшает с помощью сигнала управления квантованием размер шага квантования схемы квантования 106, увеличивая тем самым количество квантуемых данных.

Таким путем поток битов с выхода буфера 109 подается на блок 80 декодирования изображения через среду передачи 70, которая может представлять собой либо трассу распространения сигналов в эфире, либо носитель записанного изображения, например оптический диск, магнитный диск или магнитную ленту, передача производится с заранее заданной скоростью следования битов, что было описано выше.

С другой стороны, схема 108 инверсного квантования в инверсном режиме квантует уже квантованные данные, поступающие со схемы квантования 106 с тем, чтобы воспроизвести коэффициентные данные (при этом добавляются искажения, вызываемые квантованием), соответствующие выходным данным описанной выше схемы 105 ДКП, и выдать затем эти данные на схему 110 Инверсного Дискретного Косинусного Преобразования (далее по тексту - ИДКП). Схема 110 и ДКП выполняет ИДКП-обработку коэффициентных данных для воспроизведения данных изображения, соответствующих входным данным изображения во внутри-кадровом режиме кодирования, а также воспроизвести разностные данные, соответствующие выходным данным схемы 104 в режиме

RU 2123769 C1

RU 2123769 C1

прогнозирования вперед/назад/в обоих направлениях, передавая их затем на схему 111 суммирования.

Когда режим кодирования является прогнозирующим режимом вперед/назад/в обоих направлениях, на схему суммирования 111 подаются прогнозированные данные изображения с компенсацией движения со схемы 113 компенсации движения, что будет описано ниже, для суммирования прогнозированных данных изображения с компенсацией движения и разностных данных, тем самым воспроизводя данные изображения, соответствующие входным данным изображения.

Воспроизведенные таким образом данные изображения хранятся в кадровой памяти 112. Фактически, схема 108 инверсного квантования и схема суммирования 111 составляют схему местного декодирования, которая локально декодирует квантованные данные с выхода схемы 106 квантования с тем, чтобы затем записать декодированное изображение, получаемое таким образом, в кадровую память в качестве вперед или назад прогнозированного изображения. Общая кадровая память состоит из множества более мелких ячеек памяти. Здесь осуществляется переключение банка кадровой памяти. В соответствии с изображением, подлежащим кодированию, на выход выдается одиночный кадр в качестве вперед или назад прогнозированных данных изображения. Более того, в случае прогнозирования в обоих направлениях, вперед и назад прогнозируемые данные изображения, например, усредняются и выдаются на выход. Эти прогнозируемые данные изображения представляют полностью такие же изображения, как и изображения, воспроизведенные декодером 81, что будет описано ниже. Следующее изображение, подлежащее обработке, подвергается прогнозируемому кодированию вперед/назад/в обоих направлениях на основе этого прогнозированного изображения.

Так, данные изображения, считанные из кадровой памяти 112, направляются в схему 113 компенсации движения. Эта схема 113 выполняет компенсацию движения прогнозируемых данных изображения на основе вектора движения, а затем передает прогнозированные данные изображения с компенсацией движения на схему 104 прогнозируемого кодирования и на суммирующую схему 111.

Далее рассматривается декодер 81.

На вход декодера 81 поток битов подается через передающую среду 70, а затем этот поток подается на схему 202 Инверсного Кодирования с Переменной Длиной (ИКПД) через приемный буфер 201. Схема 202 ИКПД воспроизводит квантованные данные, вектор движения, прогнозируемый режим и шаг квантования из потока бит. Эти квантованные данные и размер шага квантования передаются в схему 203 инверсного квантования. Вектор движения подается на схему 207 компенсации движения, а режим прогнозирования устанавливается в суммирующей схеме 205.

Схема 203 инверсного квантования и суммирующая схема 205 совместно работают аналогично схеме локального декодирования кодера 61, а ЗУ кадровой памяти 206 и схема 207 компенсации движения соответственно выполняют те же функции, что и кадровая память 112 и схема 113 компенсации движения кодера 61. Декодирование осуществляется на основе квантованных данных, вектора движения, режима прогнозирования и шага квантования. В результате данные воспроизведения изображения выдаются с выхода схемы суммирования 205.

Как упоминалось выше, в обычных устройствах такого типа скорость кодирования потока бит, генерируемого кодером 65, устанавливается фиксированной в соответствии со скоростью передачи через передающую среду 70. При таком ограничении количество генерируемых данных, т.е. шаг квантования в схеме 106 кодера 65, находится под контролем. Другими словами, например, управление осуществлялось таким образом, что когда идет последовательность сложных изображений, шаг квантования задается увеличенным для сокращения количества генерируемых данных, тогда как при наличии последовательности более простых изображений шаг квантования уменьшается для увеличения генерируемых данных с тем, чтобы буфер 109 не переполнялся или его содержимое не было ниже установленного предела, благодаря чему поддерживается фиксированная скорость передачи.

Соответственно в обычных (известных) устройствах при наличии последовательности сложных изображений шаг квантования увеличивается, и при этом ухудшается качество изображения, тогда как, если имеет место последовательность простых изображений, то шаг квантования уменьшается. Как результат этого, одинакового качества изображения во всех возможных случаях получить не удается.

Кроме того, в случае регистрации потока бит на носителе регистрируемого изображения ограниченной емкости (по количеству данных) во избежание значительного ухудшения качества изображения относительно сложных изображений для всех случаев устанавливают высокую фиксированную скорость, которая уже не сказывается на качестве сложных изображений, но при этом уменьшается время регистрации.

Сущность изобретения.

Для решения изложенных выше проблем первый способ кодирования изображения согласно настоящему изобретению включает операции кодирования по меньшей мере части входного видеосигнала для генерации первых кодированных данных, определения скорости кодирования в каждый заранее заданный момент на основе количества данных в каждый заранее заданный момент существования первых кодированных данных и общего количества используемых данных и кодирования входного видеосигнала в каждый заранее заданный момент на основе скорости кодирования с тем, чтобы генерировать вторые кодированные данные.

Второй способ кодирования изображений согласно настоящему изобретению отличается тем, что в первом способе кодирования изображения по меньшей мере часть входного видеосигнала квантуется с фиксированным шагом квантования для

RU 2123769 C1

RU 2123769 C1

генерации первых кодированных данных.

Третий способ кодирования изображений согласно настоящему изобретению отличается тем, что включает операции заранее определяемого прогнозируемого кодирования или заранее задаваемого преобразующего кодирования по меньшей мере части входного видеосигнала для генерации первых коэффициентов данных, квантования этих первых коэффициентов данных с фиксированным шагом для генерации (выработки) первых квантованных данных, что позволяет подвергнуть первые квантованные данные неравномерному кодированию (с переменной длиной) для формирования первого потока бит, определения скорости кодирования в каждый заранее заданный момент времени на основе количества данных в первом потоке бит и общего количества пригодных к использованию данных, выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразующего кодирования входного видеосигнала для генерации вторых коэффициентов данных, квантования этих вторых коэффициентов данных с шагом квантования, выбираемым на основе скорости кодирования в каждый заранее заданный момент времени, для генерации вторых квантованных данных и разрешения вторым квантованным данным подвергнуться неравномерному кодированию (с переменной длиной) для формирования второго потока бит.

Третий способ кодирования изображений согласно настоящему изобретению отличается тем, что в первом способе кодирования изображений общее количество пригодных для использования данных пропорционально распределяется в каждый заранее заданный момент времени, благодаря чему определяется скорость кодирования в каждый заранее заданный момент времени.

Пятый способ кодирования изображения согласно настоящему изобретению отличается тем, что при использовании четвертого способа кодирования изображений скорость кодирования определяется в каждом кадре на основе количества данных в каждом кадре первого потока бит и общего количества пригодных к использованию данных.

Шестой способ кодирования изображений согласно настоящему изобретению отличается тем, что при осуществлении четвертого способа кодирования изображений скорость кодирования определяется в каждой Группе Изображений (GOP) на основе количества данных из состава по меньшей мере части каждой GOP, состоящей из множества кадров из первого потока бит и общего количества пригодных к использованию данных.

Седьмой способ кодирования изображений согласно настоящему изобретению отличается тем, что при использовании шестого способа скорость кодирования в каждой ГИ определяется на основе количества данных, относящихся к изображению, закодированному внутри кадра, и прогнозируемому вперед кодированному изображению из состава ГИ.

Восьмой способ кодирования изображений согласно настоящему изобретению отличается тем, что при использовании четвертого способа кодирования общее количество пригодных данных пропорционально распределяется в зависимости от количества данных в первом потоке бит в каждый отрезок времени, на основе чего скорость кодирования определяется в каждый заданный отрезок времени.

Девятый способ кодирования изображений согласно настоящему изобретению включает операции определения предела кодирования в каждом заранее заданном массиве изображения во входном видеосигнале, установки скорости кодирования в каждом заранее заданном массиве изображения на основе предела кодирования и общего количества пригодных данных и выполнения кодирования входного видеосигнала таким образом, что скорости кодирования соответственных массивов изображения соответствуют установленной скорости кодирования для каждого массива изображения.

Десятый способ кодирования изображений согласно настоящему изобретению отличается тем, что при использовании девятого способа заранее задаваемым массивом изображения является кадр.

Одиннадцатый способ кодирования изображений согласно настоящему изобретению отличается тем, что при осуществлении девятого способа кодирования заранее заданным массивом изображения выбирается ГИ, состоящая из множества кадров.

Двенадцатый способ кодирования изображений согласно настоящему изобретению отличается тем, что при осуществлении девятого способа кодирования изображения выполняется заранее задаваемое прогнозирующее кодирование и/или заранее задаваемое преобразовательное кодирование по меньшей мере части входного видеосигнала для формирования коэффициентных данных и квантования этих данных с фиксированным шагом для определения предела кодирования.

Первое устройство для кодирования изображений согласно настоящему изобретению содержит первое кодирующее средство для кодирования по меньшей мере части входного видеосигнала и последующего генерирования первых кодированных данных, средство управления кодированием для определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе наличия в каждый заранее задаваемый момент количества первых кодированных данных, поступающих от первого кодирующего средства, и общего количества пригодных к использованию данных и вторые кодированные данные для кодирования входного видеосигнала в каждый заранее задаваемый отрезок времени на основе скорости кодирования, заранее задаваемой в каждый отрезок времени средством управления кодированием для генерирования вторых кодированных данных.

Второе устройство кодирования изображения согласно настоящему изобретению отличается тем, что в первом устройстве кодирования изображения первое кодирующее средство содержит средство

RU 2123769 C1

RU 2123769 C1

квантования, служащее для квантования по меньшей мере части входного видеосигнала с фиксированным шагом.

Третье устройство кодирования изображений согласно настоящему изображению отличается тем, что при используемом первом устройстве кодирования изображения средство управления кодированием осуществляет пропорциональное распределение общего количества пригодных данных в зависимости от наличия определенного количества данных в каждый заранее заданный момент (отрезок) времени с тем, чтобы определять скорость кодирования в каждый заранее задаваемый отрезок времени.

Четвертое устройство кодирования изображений согласно настоящему изобретению содержит средство кодирования, служащее для выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала для генерирования коэффициентных данных, первое квантующее средство для квантования первых коэффициентных данных, поступающих с первого кодирующего средства, с фиксированным шагом квантования для вырабатывания первых квантованных данных, первое средство неравномерного кодирования (с переменной длиной) для обеспечения возможности для квантованных данных, приходящих с первого средства квантования, подвергнуться неравномерному кодированию (с переменной длиной) для формирования первого потока бит, средство управления кодированием для определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества данных в первом потоке бит, поступающем с первого средства неравномерного кодирования (с переменной длиной), и общего количества пригодных для использования данных, второе кодирующее средство, служащее для выполнения заранее задаваемого прогнозирующего кодирования и/или прогнозирующего преобразовательного кодирования входного видеосигнала для выработки вторых коэффициентных данных, второе средство квантования, квантующее вторые коэффициентные данные с выхода второго средства кодирования с шагом квантования, задаваемым на основе скорости кодирования в каждый заранее задаваемый отрезок времени средством управления кодированием для выработки вторых квантованных данных, и второе средство неравномерного кодирования (с переменной длиной), позволяющее вторым квантованным данным с выхода квантующего средства пройти кодирование с переменной длиной для формирования второго потока бит.

Пятое устройство кодирования изображения согласно настоящему изобретению отличается тем, что при использовании четвертого устройства кодирования средство управления кодированием определяет скорость кодирования в каждом кадре на основе количества данных в каждом кадре первого потока бит и общего количества пригодных данных.

Шестое устройство кодирования изображений согласно настоящему изобретению отличается тем, что при использовании четвертого устройства кодирования средство управления кодированием определяет скорость кодирования в каждой ГИ на основе количества данных по крайней мере в части каждой ГИ, состоящей из множества кадров в первом потоке бит, и в общем количестве пригодных данных.

Седьмое устройство кодирования изображений согласно настоящему изобретению отличается тем, что при использовании шестого устройства кодирования изображений средство управления кодированием определяет скорость кодирования в каждой ГИ на основе количества данных в закодированном внутри кадра изображении и прогнозированно закодированном вперед изображении в ГИ.

Восьмое устройство кодирования изображений согласно настоящему изобретению средство управления кодированием пропорционально распределяет общее количество пригодных данных в зависимости от количества данных в первом потоке бит в каждый заранее задаваемый отрезок времени, определяя таким образом скорость кодирования в каждый задаваемый момент времени.

Девятое устройство кодирования изображения согласно настоящему изобретению содержит средство вычисления предела, служащее для расчета (определения) предела кодирования в каждом заранее задаваемом массиве изображения входного видеосигнала, средство установки скорости кодирования, служащее для установки скорости кодирования в каждом заранее задаваемом массиве изображения на основе показателей предела кодирования, поступающих со средства вычисления предела и общего количества пригодных к использованию данных, и кодирующее средство, дающее возможность входному видеосигналу пройти кодирование таким образом, что скорости кодирования соответствующих массивов изображения находятся в соответствии со скоростью кодирования каждого массива изображения, установленной средством установки скорости кодирования.

Десятое устройство кодирования изображения согласно настоящему изобретению отличается тем, что при использовании девятого устройства кодирования изображения средство вычисления помех определяет (предел) кодирования для каждого кадра.

Одиннадцатое устройство для кодирования изображений согласно настоящему изобретению отличается тем, что средство вычисления определяет (предел) кодированию для каждой ГИ, состоящей из множества кадров.

Двенадцатое устройство кодирования изображения согласно настоящему изобретению отличается тем, что при использовании девятого устройства кодирования изображения средство вычисления предела выполняет заранее задаваемое прогнозирующее кодирование и/или заранее задаваемое преобразовательное кодирование по меньшей мере части входного видеосигнала для вырабатывания коэффициентных данных

RU 2123769 C1

RU 2123769 C1

и последующего квантования этих данных при фиксированном шаге квантования, на основе чего вычисляется (определяется) предел кодирования.

Первый носитель информации для регистрации изображения согласно настоящему изобретению отличается тем, что регистрируется (записывается) второй поток бит, получаемый путем кодирования по крайней мере части входного видеосигнала для генерации первых кодированных данных, по которым определяют скорость кодирования в каждый заранее задаваемый отрезок времени на основе наличия в каждый заранее задаваемый отрезок времени количества первых кодированных данных и общего количества пригодных для использования данных с тем, чтобы кодировать входной видеосигнал в каждый заранее задаваемый отрезок времени на основе кодированных данных.

Второй носитель информации для регистрации (записи) изображения согласно настоящему изобретению отличается тем, что регистрируется второй поток бит, получаемых путем выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования по крайней мере части входного видеосигнала для выработки первых коэффициентных данных и последующего квантования этих данных с фиксированным шагом квантования с тем, чтобы получить первые квантованные данные, которые получат возможность подвергнуться неравномерному кодированию (с переменной длиной) для формирования первого потока бит, по которому определяется скорость кодирования в каждый заранее задаваемый отрезок времени на основе количества данных в первом потоке бит и общего количества пригодных к использованию данных с тем, чтобы затем выполнить заранее задаваемое прогнозирующее кодирование и/или заранее задаваемое преобразовательное кодирование входного видеосигнала для выработки вторых коэффициентных данных и их последующего квантования с фиксированным шагом, задаваемым на основе скорости кодирования в каждый заранее задаваемый отрезок времени, и последующей выработки вторых квантованных данных, которые получат возможность пройти неравномерное кодирование (с переменной длиной).

Третий носитель информации для регистрации (записи) изображения согласно настоящему изобретению отличается тем, что на регистрацию выводятся кодирование данные, полученные при определении предела кодирования в каждом заранее задаваемом массиве изображения во входном видеосигнале с тем, чтобы установить скорость кодирования в каждом заранее задаваемом массиве изображения на основе показателей предела кодирования и количества пригодных к использованию данных и выполнить кодирование входного видеосигнала таким образом, чтобы скорости кодирования соответствующих массивов изображения находились в соответствии с установленной для каждого массива изображения скоростью кодирования.

В соответствии с первым способом кодирования изображения согласно настоящему изобретению скорость кодирования в каждый заранее заданный отрезок времени определяется на основе количества данных в каждый заранее задаваемый отрезок времени из числа первых кодированных данных, получаемых путем кодирования по крайней мере части входного видеосигнала, и общего количества пригодных данных для дальнейшего кодирования входного видеосигнала в каждый заранее задаваемый отрезок времени на основе определенной скорости кодирования и для последующего вырабатывания вторых кодированных данных.

В соответствии с третьим способом кодирования изображений согласно настоящему изобретению при осуществлении первого способа кодирования изображения общее количество пригодных данных пропорционально распределяется в зависимости от количества данных в каждый заранее задаваемый отрезок времени для определения скорости кодирования в каждый заранее заданный отрезок времени для дальнейшего кодирования входного видеосигнала в каждый заданный отрезок времени на основе определенной скорости кодирования и для вырабатывания вторых кодированных данных.

В соответствии с четвертым способом кодирования изображения согласно настоящему изобретению сначала по крайней мере только часть входного сигнала подвергается последовательно заранее задаваемому прогнозирующему кодированию и/или заранее задаваемому преобразовательному кодированию, обработке в виде квантования и неравномерному кодированию (с переменной длиной) при фиксированном шаге квантования для выработки первого потока бит и определения скорости кодирования на основе количества данных в первом потоке бит и общего количества пригодных данных. Затем для формирования второго потока бит весь входной видеосигнал подвергается обработке в виде заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования, квантования и кодированию с переменной длиной при фиксированном шаге квантования, устанавливаемого на основе скорости кодирования в каждый заранее задаваемый отрезок времени.

В соответствии с пятым способом кодирования изображений согласно настоящему изобретению при осуществлении четвертого способа кодирования изображений согласно настоящему изобретению скорость кодирования определяется в каждом кадре на основе количества данных в одном кадре потока бит и общего количества пригодных данных. Затем для формирования второго потока бит входной видеосигнал подвергается заранее задаваемому прогнозирующему кодированию и/или заранее задаваемому преобразовательному кодированию, а также обработке квантованием и неравномерным кодированием (с переменной длиной) при фиксированном шаге квантования, задаваемом на основе скорости кодирования в каждом кадре.

В соответствии с шестым способом кодирования изображений согласно настоящему изобретению берут за основу

RU 2123769 C1

RU 2123769 C1

четвертый способ кодирования изображения и определяют скорость кодирования в каждой ГИ на основе количества данных по меньшей мере в части каждой ГИ, состоящей из множества кадров первого потока бит, и общего количества пригодных данных.

В соответствии с седьмым способом кодирования изображений согласно настоящему изобретению за основу берут шестой способ кодирования изображения и определяют скорость кодирования в каждой ГИ на основе количества данных относительно закодированного внутри кадра изображения и прогнозированного вперед изображения в составе ГИ. Затем входной видеосигнал подвергается обработке в виде (для формирования второго потока бит) заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования, квантизации с фиксированным шагом, задаваемым на основе скорости кодирования в каждой ГИ, а также обработке кодированием с переменной длиной.

В соответствии с восьмым способом кодирования изображений согласно настоящему изобретению за основу берут четвертый способ кодирования изображений и общее количество пригодных к использованию данных пропорционально распределяют в зависимости от количества данных в первом потоке бит в каждый заранее задаваемый отрезок времени для определения скорости кодирования в каждый заранее задаваемый отрезок времени. Затем для формирования второго потока бит входной видеосигнал подвергается обработке в виде заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования, квантизации с фиксированным шагом квантизации, задаваемым на основе скорости кодирования в каждый заранее задаваемый отрезок времени и кодирования с переменной длиной.

В соответствии с девятым способом кодирования изображений согласно настоящему изобретению предел кодирования в каждом заранее задаваемом массиве изображения во входном видеосигнале определяют для установления скорости кодирования в каждом заранее задаваемом массиве изображения на основе показателей предела кодирования и общего количества пригодных к использованию данных. Затем входной видеосигнал кодируется таким образом, что скорости кодирования в соответствующих массивах изображения находятся в соответствии с установленной скоростью кодирования для каждого массива изображения.

В соответствии с десятым способом кодирования изображения согласно настоящему изобретению за основу берут девятый способ кодирования изображений и определяют помехи кодированию для каждого кадра входного видеосигнала для определения скорости кодирования в каждом кадре. Затем входной видеосигнал кодируется так, что скорости кодирования соответствующих кадров соответствуют установленной скорости кодирования в каждом кадре.

В соответствии с одиннадцатым способом кодирования изображений за основу снова берут девятый способ и определяют порог кодирования в каждой ГИ входного видеосигнала для определения скорости кодирования в каждой ГИ. Затем входной видеосигнал кодируется так, что скорости кодирования в Группах Изображений находятся в соответствии с установленной для каждой ГИ скоростью кодирования.

В соответствии с двенадцатым способом кодирования изображений согласно настоящему изобретению также за основу берут девятый способ кодирования изображений, и коэффициентные данные, получаемые путем заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала, квантуют с фиксированным шагом для определения таким образом предельных показателей. Затем входной видеосигнал кодируется так, что скорости кодирования соответствующих массивов изображений поддерживаются в соответствии со скоростью кодирования каждого массива изображения.

Далее, в соответствии с первым устройством кодирования изображений согласно настоящему изобретению скорость кодирования в каждый заранее задаваемый отрезок времени определяется на основе количества данных в каждый заданный отрезок времени в составе первых кодированных данных, полученных путем кодирования по меньшей мере части входного видеосигнала в каждый заранее задаваемый отрезок времени, и общего количества пригодных данных для дальнейшего кодирования всего входного видеосигнала в каждый заранее задаваемый отрезок времени на основе определенной скорости кодирования и последующей выработки вторых кодированных данных.

В соответствии с вторым устройством кодирования изображений согласно настоящему изобретению за основу берут первое устройство и по меньшей мере часть входного видеосигнала квантуется при фиксированном шаге квантования для выработки таким образом первых кодированных данных, по которым определяют скорость кодирования, с которой кодируется входной видеосигнал в каждый заранее задаваемый отрезок времени, в результате чего вырабатываются вторые кодированные данные.

В соответствии с третьим устройством кодирования изображений согласно настоящему изобретению используется первое устройство кодирования изображения, в котором общее количество пригодных для использования данных пропорционально распределяется в зависимости от количества данных в каждый заранее задаваемый отрезок времени для определения скорости кодирования в каждый заранее задаваемый момент времени и затем с этой скоростью кодируется входной видеосигнал в каждый заданный момент, в результате чего вырабатываются вторые кодированные данные.

В соответствии с четвертым устройством кодирования изображения согласно настоящему изобретению по меньшей мере часть входного видеосигнала подвергается обработке в виде заранее заданного

RU 2123769 C1

RU 2123769 C1

прогнозирующего кодирования и/или заранее заданного преобразовательного кодирования, а также квантования с фиксированным шагом и неравномерного кодирования (с переменной длиной) для формирования первого потока бит с тем, чтобы определить скорость в каждый заранее задаваемый отрезок времени на основе количества данных в первом потоке бит и общего количества данных, пригодных к использованию. Затем заранее задаваемому прогнозируемому кодированию и/или преобразовательному кодированию, а также квантованию и кодированию с переменной длиной с шагом квантования, задаваемым на основе скорости кодирования в каждый задаваемый отрезок времени, подвергается весь входной видеосигнал, в результате чего формируется второй поток бит.

В соответствии с пятым устройством кодирования изображения согласно настоящему изобретению во взятом за основу четвертом устройстве кодирования изображения скорость кодирования определяется в каждом кадре на основе количества данных в каждом кадре первого потока бит и общего количества пригодных данных. Затем обработке в виде заранее задаваемого прогнозирующего кодирования и/или прогнозирующего преобразовательного кодирования, а также квантования с шагом квантования, задаваемым на основе скорости кодирования в каждом кадре, и кодированию с переменной длиной подвергается весь входной видеосигнал, в результате чего формируется второй поток бит.

В соответствии с шестым устройством кодирования изображений согласно настоящему изобретению в принятом за основу четвертом устройстве кодирования изображений скорость кодирования определяется в каждой ГИ на основе количества данных по меньшей мере в части каждой ГИ, состоящей из множества кадров в первом потоке бит, и общего количества пригодных данных. Затем обработке подвергается весь входной видеосигнал, а именно заданному прогнозирующему кодированию и/или заданному преобразовательному кодированию, квантованию с шагом квантования, задаваемым на основе скорости кодирования в каждой ГИ, и кодированию с переменной длиной, в результате чего формируется второй поток бит.

В соответствии с седьмым устройством кодирования изображений согласно настоящему изобретению в принятом за основу шестом устройстве кодирования изображения скорость кодирования в каждой ГИ определяется на основе количества данных в изображениях, кодированных внутри кадра, и прогнозируемых вперед кодированных изображениях в составе ГИ. Затем входной видеосигнал подвергается обработке в виде заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования, квантования с шагом, определяемым скоростью кодирования в каждой ГИ, и кодирования с переменной длиной, в результате чего формируется второй поток данных.

В соответствии с восьмым устройством кодирования изображения согласно настоящему изобретению в принимаемом за основу четвертом устройстве кодирования изображения общее количество пригодных к использованию данных пропорционально распределяется в зависимости от количества данных в первом потоке бит в каждый заранее задаваемый отрезок времени для определения скорости кодирования в каждый задаваемый момент. Затем входной видеосигнал подвергается обработке в виде заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования, квантования с шагом, определяемым на основании скорости кодирования в каждый заранее заданный момент, и неравномерному кодированию (с переменной длиной), в результате чего формируется второй поток данных.

В соответствии с девятым устройством кодирования изображения согласно настоящему изобретению предел кодирования определяется в каждом задаваемом массиве изображения входного видеосигнала для установления скорости кодирования в каждом заданном массиве изображения на основе параметров предела кодирования и общего количества данных, пригодных к использованию. Затем входной видеосигнал кодируется так, что скорости кодирования соответственных массивов изображения поддерживаются в соответствии с установленной скоростью кодирования в каждом массиве изображения.

В соответствии с девятым устройством кодирования изображения согласно настоящему изобретению в принимаемом за основу девятом устройстве кодирования порог кодирования определяется в каждом кадре входного видеосигнала для определения скорости кодирования в каждом кадре. Затем входной видеосигнал кодируется так, что скорости кодирования в соответственных кадрах находятся в соответствии с установленной скоростью кодирования в каждом кадре.

В соответствии с одиннадцатым устройством кодирования изображения согласно настоящему изобретению за основу берут снова девятое устройство кодирования и помехи кодированию определяют в каждой ГИ входного видеосигнала для определения скорости кодирования в каждой GOP. Затем входной видеосигнал кодируется так, что скорости кодирования соответственных ГИ поддерживаются в соответствии со скоростью кодирования, установленной для каждой ГИ.

В соответствии с двенадцатым устройством кодирования изображений согласно настоящему изобретению за основу также берут девятое устройство кодирования, и коэффициентные данные, получаемые путем выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала, квантуют с фиксированным шагом для определения предела кодирования. Затем входной видеосигнал кодируется таким образом, что скорости кодирования соответственных массивов изображения находятся в соответствии со скоростью кодирования, установленной для каждого массива изображения.

Кроме того, в соответствии с первым носителем для регистрации (записи)

RU 2123769 C1

RU 2123769 C1

изображения согласно настоящему изобретению на регистрацию выводится второй поток бит, получаемых путем определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества данных в каждый момент или отрезок времени из состава первых кодированных данных, получаемых кодированием по меньшей мере части входного видеосигнала, и общего количества пригодных к использованию данных с тем, чтобы кодировать входной видеосигнал в каждый заранее задаваемый момент времени на основе определенной скорости кодирования.

В соответствии с вторым носителем информации для регистрации изображения согласно настоящему изобретению регистрируется второй поток бит, получаемый путем выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала, а также квантования и неравномерного кодирования (с переменной длиной) с фиксированным шагом для генерации первого потока бит с целью определения скорости кодирования в каждый заданный отрезок времени на основе количества данных в первом потоке бит и общего количества пригодных данных с тем, чтобы подвергнуть обработке входной видеосигнал, а именно заранее задаваемому прогнозирующему кодированию и/или заранее задаваемому преобразовательному кодированию, а также квантованию и кодированию с переменной длиной с шагом квантования, определяемым на основе скорости кодирования в каждый заранее задаваемый отрезок.

В соответствии с третьим носителем информации для регистрации изображения согласно настоящему изобретению на регистрацию выводятся кодированные данные, получаемые при определении предела кодирования в каждом заданном массиве изображения входного видеосигнала с тем, чтобы установить скорость кодирования каждого заранее задаваемого массива изображения на основе параметров предела кодирования и общего количества данных, пригодных для использования, чтобы кодировать входной видеосигнал таким образом, чтобы скорости кодирования соответственных массивов изображения были в соответствии со скоростью кодирования каждого массива изображения.

Краткое описание фигур.

Фиг. 1 - блок-схема, показывающая связи основных частей устройства кодирования изображений.

Фиг. 2 - блок-схема алгоритма, поясняющего работу первой кодирующей схемы, входящей в состав устройства кодирования по фиг. 1.

Фиг. 3 - блок-схема алгоритма, поясняющего работу второй схемы кодирования, входящей в состав устройства кодирования изображения по фиг. 1.

Фиг. 4 - относительное расположение изображений в составе группы изображений GOP.

Фиг. 5 - относительное расположение изображений и сигнал управления кодирования в каждой группе изображений GOP.

Фиг. 6 - блок-схема алгоритма, также поясняющего работу схемы кодирования, входящей в состав устройства кодирования изображений по фиг. 1.

Фиг. 7 - вид изображения для пояснения принципа прогнозирующего кодирования.

Фиг. 8 - диаграмма изображений, поясняющая принцип прогнозирующего кодирования с компенсацией движения.

Фиг. 9 - блок-схема устройства (блока) кодирования изображений и устройства (блока) декодирования изображений согласно настоящему изобретению.

Фиг. 10 - конфигурация кадра, макро-блока и секции.

Фиг. 11 - блок-схема обычного (известного) кодера.

Фиг. 12 - блок-схема обычного (известного) декодера.

Наилучший вариант реализации настоящего изобретения

Далее приводится описание со ссылкой на прилагаемые чертежи одного из вариантов способа кодирования изображений, устройства кодирования изображений и носителя информации для регистрации (записи) изображений согласно настоящему изобретению.

Устройство кодирования изображений согласно настоящему изобретению содержит, как показано на фиг. 10, например, первую схему кодирования 10 для кодирования входного видеосигнала и выработки первых кодированных данных, схему кодирования 30 изображений для определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества кодированных данных в каждый заранее задаваемый момент, поступающих с первой кодирующей схемы 10, и общего количества пригодных к использованию данных и вторую схему кодирования 40 для кодирования входного видеосигнала в каждый заранее задаваемый отрезок времени на основе скорости кодирования, определяемой схемой управления кодированием 30 и последующей выработки вторых кодированных данных.

Более конкретно, первая схема 10 кодирования содержит, как показано на фиг. 1, ЗУ 12 кадровой памяти для хранения входных данных изображений, представляющих собой входной видеосигнал, схему 11 определения вектора движения, служащую для обнаружения этого вектора во входных данных изображений, хранящихся в ЗУ 12 кадровой памяти, ЗУ 22 кадровой памяти, хранящее прогнозированные данные изображений, схему 23 компенсации движения, служащую для выполнения компенсации движения прогнозированных данных изображений, которые были считаны из ЗУ 22 кадровой памяти на основе данных о векторе движения, поступающих со схемы 11 обнаружения вектора движения, схему 14 прогнозирующего кодирования для кодирования входных данных изображения на основе прогнозированных данных изображений с компенсацией движения, поступающих со схемы 23 компенсации движения, схему 15 ДКП, выполняющую кодирование разностей в виде Дискретного Косинусного Преобразования (далее по тексту - ДКП) разностей и т.п., которые называют прогнозируемыми ошибками,

RU 2123769 C1

RU 2123769 C1

поступающих со схемы 14 прогнозирующего кодирования, схему 16 квантования для квантования коэффициентных данных со схемы 15 ДКП, с фиксированным шагом квантования для выработки квантованных данных, схему 17 неравномерного кодирования (с переменной длиной) (далее по тексту - НК), позволяющую квантованным данным со схемы 16 подвергнуться обработке НК с тем, чтобы выдать на выход кодированные с переменной длиной данные, схему 18 инверсного квантования данных, поступающих со схемы 16 квантования для воспроизведения коэффициентных данных, схему 20 Инверсного Дискретного Косинусного Преобразования (далее по тексту ИДКП), служащую для выполнения декодирования, например, в виде ИДКП обработки коэффициентных данных со схемы 18 инверсного квантования, и схему 21 суммирования для суммирования данных с выхода схемы 20 ИДКП и прогнозируемых данных изображения с компенсацией движения с выхода схемы 23 компенсации движения, в результате чего вырабатываются прогнозируемые данные, относящиеся к данным следующего изображения, передаваемых затем в ЗУ кадровой памяти 22.

Далее, вторая схема кодирования 40 содержит, как показано на фиг. 1, элемент задержки 43 для задержки входных данных изображения, ЗУ 52 кадровой памяти для хранения прогнозируемых данных изображения, схему 53 компенсации движения прогнозируемых данных изображения, которые были считаны из ЗУ 52 кадровой памяти с учетом вектора движения со схемы 11 обнаружения этого вектора, схему 44 прогнозирующего кодирования входных данных изображений, задержанных элементом задержки 43, на основе прогнозируемых данных изображений с компенсацией движения, поступающих со схемы 53 компенсации движения, схему 45 ДКП, выполняющую кодирование, например ДКП-обработку разностей и т.п., поступающих со схемы 44 прогнозирующего кодирования, для выработки коэффициентных данных, схему 33 установки шкалы квантования (шага квантования) на основе скорости кодирования, определяемой схемой 30 управления кодированием, схему 46 квантования коэффициентных данных, поступающих со схемы 45 ДКП, с шагом квантования, задаваемым схемой 33 установки шкалы квантования, схему 47 НК, дающую возможность подвергнуть квантованные данные со схемы 46 НК-обработке и вывести после этого данные на выход, буфер передачи 49 для временного хранения данных с выхода схемы 47 НК для последующего вывода их с фиксированной скоростью на передачу, схему 48 для инверсного квантования данных со схемы квантования 46 и дальнейшего воспроизведения коэффициентных данных, схему ИДКП 50, выполняющую декодирование, например, в виде ИДКП обработки коэффициентных данных с выхода схемы 48 инверсного квантования с целью воспроизведения разности, и схему 51 суммирования разности с выхода схемы 50 ИДКП и прогнозируемых данных с компенсацией движения с выхода схемы 53 компенсации движения с тем, чтобы выработать прогнозируемые данные изображений, относящиеся к следующим входным данным изображений, и передать эти прогнозируемые данные в ЗУ 52 кадровой памяти.

В настоящем варианте устройства кодирования обработке, которую выполняет первое средство кодирования 10, а именно прогнозирующему кодированию, ДКП-обработке, квантованию с фиксированным шагом и кодированию (с переменной длиной) подвергается входной видеосигнал, скорость кодирования битов определяется средством управления кодированием 30 на основе количества кодированных с переменной длиной данных, которые представляют собой первый получаемый поток бит, и емкости (по данным) носителя 55 записанного изображения, например оптического диска, магнитного диска или магнитной ленты и т.п., или же общего количества пригодных к использованию данных, определяемого скоростью передачи бит через передающую среду. Соответственно второе средство 40 кодирования выполняет прогнозирующее кодирование, ДКП-обработку, квантование и неравномерное кодирование (с переменной длиной) входных данных изображения во второй раз.

Как показано на фиг. 2, в настоящем варианте реализации изобретения в шаге алгоритма 1 схема квантования 16 из состава первого средства кодирования 10 устанавливает шаг квантования равным, например, 1 для квантования коэффициентных данных, переданных со схемы 15 ДКП для вырабатывания квантованных данных. Счетчик 31 средства управления кодированием 30 подсчитывает количество данных, кодированных с переменной длиной (первый поток данных), получаемых в случае представления возможности кодирования (с переменной длиной) квантованных данных в заранее задаваемый отрезок времени, например за время одного кадра, для определения количества формируемых в каждом кадре количества кодов, указывающих предел (порог) кодирования.

В шаге 2 алгоритма схема 32 вычисления скорости передачи битов определяет количество кодов, предназначенных для каждого кадра на основе предела или порога (количества формируемых кодов) каждого кадра и общего количества пригодных данных.

В шаге 3 алгоритма схема квантования 46, второго средства кодирования 40 квантует данные, приходящие со схемы 45 ДКП, с шагом квантования, задаваемым на основе количества кодов, предназначенных для вырабатывания квантованных данных.

Подаваемые на вход данные изображений временно хранятся в ЗУ 12 кадровой памяти, откуда они затем считываются в соответствии с блочным форматом, что описано в известных технических решениях.

Схема 11 обнаружения вектора движения считывает необходимые данные изображения из ЗУ 12 кадровой памяти массивами макроблоков для обнаружения вектора движения, что было описано выше. Эта схема 11 обнаруживает в массивах макроблоков

RU 2123769 C1

RU 2123769 C1

вектор движения текущего (опорного) изображения, используя расположенное впереди или позади исходное изображение из ЗУ 12 кадровой памяти. Здесь обнаружение вектора движения осуществляется так, что вектор движения, для которого, например, сумма абсолютных значений разностей между кадрами в массивах макроблоков становится минимальной, признается соответствующим искомому вектору движения. Обнаруженный вектор движения передается на схемы 23, 53 и т.п. компенсации движения, а сумма абсолютных значений разностей между кадрами в массивах макроблоков подается на схему 13 прогнозирования внутри кадра/вперед/назад/ в обоих направлениях (схема принятия решения).

Эта схема 13 определяет режим прогнозирования на основе упомянутого выше значения, используя его для управления схемой 14 прогнозирующего кодирования, которая переключает режимы прогнозирования "внутрикадровый/вперед/назад/в обоих направлениях" в массивах блоков.

Прогнозирующая кодирующая схема 14 содержит, как можно видеть из фиг. 1, схемы суммирования 14а, 14б, 14в и селекторный (смены режима) переключатель 14г. Когда работа идет во внутрикадровом режиме, этот переключатель манипулирует непосредственно входными данными изображения, но если же задан режим прогнозирования "вперед/назад/ в обоих направлениях", этот переключатель манипулирует разностями (далее по тексту - разностные данные) в каждом из пикселей входных данных изображения, относящихся к соответственным прогнозируемым изображениям. С селекторного переключателя 14 выбранные им данные подаются на схему 15 ДКП.

Схема 15 ДКП выполняет (в масштабе массивов блоков) ДКП-обработку входных данных изображений или разностных данных, приходящих с селекторного переключателя 14г, с использованием двумерной корреляции видеосигнала, а затем получаемые таким образом коэффициентные данные подаются на схему 16 квантования.

Схема 16 квантования квантует коэффициентные данные, поступающие со схемы 15 ДКП, с шагом квантования, установленным на значение 1 с тем, чтобы передать получаемые таким образом коэффициентные данные на схему НК 17 и схему 18 инверсного квантования.

Схема 17 НК выполняет кодирование с переменной длиной квантованных данных совместно с шагом квантования, параметрами прогнозирования и вектором движения и передает закодированные с переменной длиной данные на средство 30 управления кодированием в качестве первого потока бит.

Средство 30 управления кодированием содержит, как видно из фиг. 1, счетчик 31, служащий для подсчета в каждый задаваемый момент или отрезок времени количества кодированных с переменной длиной данных, поступающих со схемы 17 НК, и вычислительную схему 32, служащую для вычисления (определения) задаваемого (назначаемого) количества кодов на единицу времени на основе количества данных с выхода счетчика 31 и общего количества данных, пригодных к использованию. Счетчик 31 подсчитывает количество данных первого потока бит в каждый заранее задаваемый отрезок времени, например в течение каждого одного кадра, с тем, чтобы вычислять (определять) порог (предел насыщенности) каждого кадра и передать это пороговое значение на схему 32 вычисления скорости следования бит.

Схема 32 вычисляет (определяет) количество кодов, назначаемое для каждого кадра, т.е. среднюю скорость кодирования за время каждого кадра на основе предельной емкости кадра и общего количества пригодных к использованию (используемых) данных, и затем передает значение этого назначаемого количества кодов в схему 33 установки шкалы квантования из состава второго средства кодирования 40.

По существу, схема 32 вычисления скорости кодирования выполняет следующие расчеты. Пусть, например, количество всех кадров есть величина N, общее количество используемых данных есть B, предельная емкость (кодовая емкость) i-го, (i = 0, 1, 2,... N-1) кадра есть d_i и количество назначаемых кодов до i-го кода есть b_i, то когда в виде условия задается, что назначаемая кодовая величина b_i должна быть пропорциональна предельной кодовой емкости d_i, как будет указано в формуле (1), то общее количество данных B может быть вычислено путем сложения задаваемого количества кодов всех кадров, как указано ниже в формуле (2). Величина "a" в следующих формулах есть константа.

$$b_i = a \times d_i \quad ...(1)$$

$$B = \sum_{i=0} bi = \sum_{i=0} axdi = a \quad (2)$$

Соответственно, эта константа "a" может быть вычислена с помощью следующей формулы (3). После подстановки этой константы "a" в формулу (1) назначаемое количество кодов b_i до (относительно) i-го кадра может быть вычислено по формуле (4)

$$a = \frac{B}{\sum_{i=0}^{N-1}} \quad (3)$$

$$bi = di \times \frac{B}{\sum_{i=0}^{N-1}} \quad (4)$$

Таким образом, схема 32 вычисления скорости следования битов увеличивает кодовую величину b_i для кадров изображения сложного вида и уменьшает эту величину для кадров изображения более простого вида.

С другой стороны, схема 18 выполняет инверсное квантование уже квантованных в обычном режиме данных, поступающих со схемы 16 с шагом квантования, который устанавливают равным 1 для воспроизведения коэффициентных данных (при этом добавляются искажения, вызванные квантованием), с выхода схемы 15 ДКП и передачи затем этих данных на схему 20 ИДКП.

Схема 20 ИДКП выполняет обработку ИДКП коэффициентных данных для воспроизведения входных данных изображений, соответствующих выходным данным схемы прогнозирующего кодирования 14 во внутрикадровом режиме, и воспроизводит разностные данные во

RU 2123769 C1

RU 2123769 C1

внутрикадровом/вперед/назад/в обоих направлениях прогнозирующем режимах, передавая затем воспроизведенные данные на схему 21 суммирования.

Если установлен режим прогнозирования "вперед/назад/ в обоих направлениях", на схему 21 суммирования поступают прогнозируемые данные изображений с компенсацией движения со схемы 23 компенсации движения. Схема 21 суммирует эти прогнозированные данные изображения и разностные данные, переданные со схемы 20 ИДКП, в результате чего воспроизводятся данные изображения, соответствующие входным данным изображения.

Воспроизведенные таким образом данные изображения хранятся в ЗУ 22 кадровой памяти. По существу, схема 18 инверсного квантования и суммирующая схема 21 образуют локальную схему декодирования, обрабатывающую квантованные данные с выхода схемы 16 квантования на основе заданного режима прогнозирования с тем, чтобы записать полученные декодированные данные в ЗУ 22 кадровой памяти в качестве вперед или назад прогнозированных изображений. Это ЗУ 22 состоит из множества более мелких ячеек кадровой памяти. Здесь производится переключение банка кадровой памяти. В зависимости от параметров данных, подлежащих кодированию, один очный кадр, например, выдается на выход в качестве прогнозированных вперед или назад данных изображения. Далее, в случае прогнозирования "вперед/назад/ в обоих направлениях" прогнозируемые вперед данные изображения и прогнозируемые назад данные изображения, например, усредняются и эти усредненные данные выдаются на выход. Эти прогнозированные данные изображений представляют собой точно такие же данные, как и данные изображений, воспроизведенные устройством декодирования изображения, которое будет описано ниже. На основе этого прогнозированного изображения следующее подлежащее обработке изображение подвергается кодированию в режиме "вперед/назад/в обоих направлениях".

Ниже описывается работа второго кодирующего средства 40. Здесь следует отметить, что поскольку электронные схемы, за исключением схемы 33 установления шкалы квантования, элемента задержки 43, схемы квантования 46 и буфера передачи 49, образующие второе средство кодирования 40, выполняют те же самые операции, что и аналогичные схемы описанного ранее первого средства кодирования 10, то их описание опущено.

Элемент задержки 43 задерживает входные данные изображения, например, до того момента, когда сигнал управления кодированием пройдет на выход средства управления кодированием 30. Затем в схеме прогнозирующего кодирования 44 и схеме 45 ДКП задержанные входные данные изображения подвергаются обработке в виде прогнозируемого кодирования и ДКП, которые выполняются в соответствии в режимом прогнозирования, задаваемым схемой 13, работающей в режимах прогнозирования "внутрикадровом/вперед/назад/в обоих направлениях", и выполняющей функцию принятия решения. Таким образом вырабатываются коэффициентные данные.

Схема 33 установки шкалы квантования определяет (вычисляет) количество кодов, назначаемых для каждого макроблока (например, величину, получаемую путем деления количества кодов, назначаемых для каждого кадра, на число макроблоков в одном кадре) из переданного количества кодов для каждого кадра для выполнения сравнения между количеством кодов, сформированных в макроблоке, который обнаруживается в обратной связи буфера передачи 49, и количеством кодов, назначаемых для каждого макроблока. Работа схемы 33 установки шкалы квантования состоит в том, что она таким образом задает скорости следования битов при кодировании соответствующих кадров, чтобы они были как можно ближе к средним значениям скорости следования битов при кодировании за время каждого кадра. В том случае, когда количество кодов, сформированных в соответствующем макроблоке оказывается больше, чем количество назначенных (заданных) кодов для каждого макроблока, схема 33 устанавливает шаг квантования для следующего макроблока на большую величину для того, чтобы уменьшить количество кодов, которые будут сформированы в следующем макроблоке, и напротив, если количество кодов, сформированных в соответствующем макроблоке, оказывается меньше, чем количество кодов, заданное для каждого макроблока, эта схема 33 устанавливает уменьшенную величину шага квантования для следующего макроблока для увеличения числа формируемых кодов. Здесь следует отметить, еще одну функцию схемы 33, которая состоит в том, что когда в цепи обратной связи буфера передачи 49 появляются указания о том, что буфер 49 находится в состоянии, близком к переполнению, то эта схема 33 также увеличивает шаг квантования для предотвращения переполнения независимо от результатов сравнения заданного и формируемого фактически количества кодов. С другой стороны, если контур обратной связи буфера передачи 49 сигнализирует о том, что содержимое буфера близко к нижнему пределу, схема 33 установления шкалы квантования уменьшает величину шага квантования для увеличения числа формируемых кодов также независимо от результатов сравнения заданного и фактически формируемого количества кодов. Хотя выше было сказано, что сравнение количества заданных (назначаемых) кодов и фактически формируемых выполняется в каждом макроблоке для переключения величины шага квантования для каждого такого макроблока, подобное же переключение может быть выполнено и для каждой секции. Кроме того, хотя выше было указано, что количество фактически формируемых кодов определяют из содержимого буфера передачи 40, эти же показатели можно получить непосредственно с выхода схемы 47 неравномерного кодирования (с переменной длиной). Схема 33 установления шкалы квантования именно таким образом передает величину шага квантования в схему 46 квантования.

Эта схема квантования 46 квантует

RU 2123769 C1

RU 2123769 C1

коэффициентные данные, получаемые от схемы 45 ДКП, с шагом квантования, величина которого передается со схемы 33 установки шкалы для вырабатывания квантованных данных.

Схема НК 47 дает возможность подвергнуть квантованные данные, приходящие со схемы 46 квантования, неравномерному кодированию (с переменной длиной) с шагом квантования, величина которого передается со схемы 33 установки шкалы квантования, и в режиме прогнозирования "внутрикадрового/вперед/назад/в обоих направлениях", задаваемого схемой 13 прогнозируемого решения, а также с учетом вектора движения со схемы его обнаружения 11, после чего полученные таким образом данные кодирования с переменной длиной пересылаются в буфер 49 передачи как второй поток бит.

В настоящем варианте устройства кодирования изображений, как показано на фиг. 3, после ввода данных изображений через элемент задержки 43 в шаге 1 алгоритма, схема 33 установки шкалы получает от средства 30 управления кодированием значение количества кодов, задаваемых для кадра, подлежащего текущему кодированию в шаге 2 алгоритма, после чего обработка переходит к шагу 3.

В шаге 3 алгоритма схема 44 прогнозируемого кодирования совместно со схемой 47 НК выполняют обработку данных изображения в виде прогнозируемого кодирования и ДКП обработки, а затем квантуют коэффициентные данные с шагом квантования, задаваемым на основе количества задаваемых кодов, что дает возможность выполнить кодирование с переменной длиной. Затем обработка переходит к шагу 4.

В шаге 4 алгоритма, независимо от того, завершено или нет кодирование всех кадров (последовательности их), которые имеют один и тот же размер изображения или обрабатываются при одинаковой скорости передачи бит, принимается решение об окончании алгоритма. Если обработка все же на завершена, алгоритм возвращается к шагу 1. Таким образом реализуется кодирование с переменной скоростью, когда скорость кодирования изменяется в рамках массивов кадров. Соответственно, даже если изображения (кадры) сложного вида поступают в виде последовательности, невозможно обеспечить столь же большую величину шага квантования, как в обычных (известных) устройствах. Так обеспечивается однородное и высокое качество изображения во всех возможных ситуациях.

Буфер передачи 49 временно хранит данные кодирования с переменной длиной, чтобы затем выдать их на считывание с фиксированной скоростью следования бит, обеспечивая упорядоченный вывод кодированных с переменной длиной данных в виде потока бит. Поток бит с выхода буфера передачи 49 мультиплексируется, например, с кодированным аудиосигналом, сигналом синхронизации и т. п. Кроме того, сюда же добавляется код коррекции ошибок и модуляция с заранее заданными параметрами, пригодными для передачи или регистрации данных. Затем обработанный таким образом поток бит передается на устройство декодирования изображения либо через среду распространения, либо регистрируется на носителе записи изображения 55, представляющем собой оптический диск, магнитный диск или магнитную ленту, что уже упоминалось выше и показано на фиг. 1. Поскольку во втором средстве кодирования 40 производится такая обработка в виде кодирования с переменной скоростью, когда количество задаваемых кодов увеличивается при обработке изображений сложного вида и уменьшается при обработке изображений простого вида, то нет необходимости поддерживать высокую и фиксированную скорость во всех случаях во избежание значительного ухудшения качества изображений сложного вида, как это делается в обычных (известных) устройствах. Благодаря этому время регистрации изображения на носителе 55 может быть продлено.

С другой стороны, схема 48 выполняет инверсное квантование данных, квантованных обычным методом и переданных со схемы 46 квантования, причем величина шага квантования при этом та же, что и в схеме 46, что необходимо для воспроизведения коэффициентных данных (при этом добавляются искажения из-за квантования), соответствующих выходным данным схемы 45 ДКП, после чего эти коэффициентные данные пересылаются в схему 50 ИДКП. Кроме того, схема 48 инверсного квантования и суммирующая схема 51 образуют локальную схему декодирования, декодирующую квантованные данные, поступающие с выхода схемы квантования 46, после чего полученное таким образом декодированное изображение записывается в ЗУ 52 кадровой памяти как прогнозированное вперед или назад изображение. Данные изображения, хранящиеся в ЗУ 52, используются в качестве прогнозированного изображения для следующего подлежащего обработке изображения.

Следует отметить, что хотя в вышеупомянутом варианте реализации изобретения задаваемое количество кодов для заранее задаваемого отрезка времени, т. е. средняя скорость кодирования на протяжении заранее заданного отрезка времени, определяется для каждого кадра, причем за заданный отрезок времени принимается длительность кадра, оно (изобретение) не ограничивается только таким вариантом реализации. Например, в качестве заранее задаваемого отрезка времени может быть использована длительность GOP (Группы Изображений) в нормативах так называемой Экспертной Группы по Подвижным Изображениям (ЭГПИ). Название этой группы ЭГПИ (MPEG) используется и как наименование системы кодирования подвижных изображений, исследованной в Рабочей Группе (РГ) 11 Подкомитета 29 (ПК) Объединенного Технического Комитета (ОТК) в составе Международной Организации по Стандартизации (МОС) и Международного Электротехнического Комитета (МЭТК).

Согласно нормативам (ЭГПИ) группа изобаржений GOP содержит по меньшей мере одно так называемое I-изображение и множество P-изображений или B-изображений

RU 2123769 C1

RU 2123769 C1

(не I-изображения). Рассмотрим практический пример, когда GOP состоит из одиночного I-изображения, четырех P-изображений с периодом следования в 3 изображения и десять B-изображений, а схема управления кодированием 30 определяет количество задаваемых кодов для каждой GOP. Здесь I-изображение подвергается внутриполевому или внутрикадровому кодированию. P-изображение есть изображение, прогнозируемое только в направлении вперед и подлежащее внутриполевому или внутрикадровому кодированию.
B-изображение есть изображение, которое может прогнозироваться в направлениях вперед, назад и в обоих направлениях, оно подлежит внутриполевому или внутрикадровому кодированию.

Если далее предполагается, например, как показано на фиг. 5, что два последовательных произвольных изображения в составе ГИ, состоящем из определенного количества изображений, есть повторяющиеся периодически I-изображение и P-изображение, и величина шага квантования установлена равной, например, 1, то первое средство кодирования 10 может выполнить прогнозирующее кодирование, ДКП обработку и кодирование с переменной длиной данных этих I-изображения и P-изображения для выработки кодированных с переменной длиной данных, которые затем будут переданы на средство 30 управления кодированием. Два эти изображения именно типа I и P выбраны с целью проверки сложности рисунка изображения и степени корреляции между кадрами. По количеству формируемых кодов I-изображения возможно определить (оценить) сложность изображения. По количеству формируемых кодов P-изображения можно определить степень корреляции между кадрами. Поскольку последовательность множества кадров имеет в общем-то аналогичные пиктографические элементы, то даже по двум выбранным изображениям можно оценить тенденцию структуры GOP.

Средство 30 управления кодированием подсчитывает (вычисляет) количество данных I-изображений в каждой ГИ, обозначаемое как I_j бит, и количество данных P-изображений P_j бит, и определяет для каждой GOP фактический предел насыщенности (порог) (количество формируемых кодов d_j, где j = 0, 1, 2,...) на основе величин I_j и P_j, а также количество N P-изображений, составляющих GOP, как указано ниже в формуле (5).

$$\text{GOP } d_j = \text{бит } J_i + N^x \text{ бит } P_j \ldots (5)$$

Средство 30 управления кодированием определяет количество кодов, отведенное для каждой, на основе величины порога каждой GOP и общего количества используемых данных, а затем пересылает это значение количества задаваемых кодов к второму средству кодирования 40.

Если принять, что число групп изображений GOP есть M, общее количество пригодных к использованию данных есть B, задаваемое количество кодов применительно к j-му GOP есть GOP b_j, а также задать, что эта величина GOP b_j пропорциональна пороговому значению, как следует из приведенной ниже формулы (6), то общее количество данных B определяется путем суммирования величин b_i все, как записано в формуле (7). Величина a в формуле (6) есть константа.

$$\text{GOP } b_j = a \text{ GOP } d_j \ldots (6)$$

$$B = \sum_{j=0}^{M-1} \text{GOP } b_i = \sum_{j=0}^{M-1} a \text{GOP } d_j = a \sum_{j=0}^{M-1} \text{GOP } d_j \quad (7)$$

Эта константа a может быть определена из формулы (8). Подставляя эту константу в формулу (6), можно по формуле (9) определить задаваемое количество кодов ГИ b_j для j-го ГИ.

$$a = \frac{B}{\sum_{j=0}^{M-1} \text{GOP } d_j} \quad (8)$$

$$\text{GOP } b_j = \text{GOP } d_j \times \left(\frac{B}{\sum_{j=0}^{M-1} \text{GOP } d_j} \right) \quad (9)$$

Итак, средство 30 управления кодированием увеличивает величину количества задаваемых кодов GOP b_j в случае, например, группы изображений, в которых содержатся изображения со сложным рисунком или которые обладают низкой степенью корреляции между кадрами, и напротив, в группе изображений, включающих изображения с простым рисунком или имеющих высокую степень корреляции между кадрами, это средство 30 уменьшает предназначаемое для нее количество кодов.

Когда на второе средство кодирования 40 в шаге 1 алгоритма, приведенного на фиг. 6, через элемент задержки 43 поступают данные изображений, это средство 40 определяет, являются или нет эти данные начальными данными (шаг 2) группы изображений. Если это так, алгоритм обработки переходит к шагу 3. В противном случае алгоритм переходит к шагу 4.

В шаге 3 второе средство кодирования 40 получает от средства управления 30 значение числа кодов, предназначаемых для GOP, подвергаемой текущему кодированию. Затем алгоритм обработки переходит к шагу 4.

В шаге 4 второе кодирующее средство 40 выполняет прогнозирующее кодирование и ДКП-обработку, а также квантует коэффициентные данные с шагом, заданным на основе назначенного числа кодов, что дает возможность выполнить кодирование с переменной длиной. Затем алгоритм обработки переходит к шагу 5.

Здесь схема 33 установки шкалы квантования задает количество кодов для каждого кадра из числа переданного ему общего количества кодов, назначенных для каждой ГИ, принимая во внимание тип изображения (I-изображение, P-изображение, B-изображение) при конкретном кодировании, например тип изображения, показанный на фиг. 4. В практическом аспекте можно сказать, что количество кодов, назначаемых для I-изображений, увеличивается, количество кодов для B-изображений уменьшается, а количество кодов для P-изображений имеет промежуточное между ними значение.

В последующем шаге 5 независимо от того, завершено или нет кодирование всех тех кадров (их последовательности), для которых был задан одинаковый размер изображения

RU 2123769 C1

RU 2123769 C1

или одинаковая скорость передачи бит, принимается соответствующее решение. Если последовательность закончилась, то и обработка считается завершенной. В противном случае алгоритм возвращается к шагу 1. Так реализуется неравномерное кодирование (с переменной длиной), когда скорость кодирования изменяется в каждой GOP. Если даже имеет место последовательность изображений (кадров) со сложным рисунком, то все же нет возможности сделать шаг квантования достаточно большим для таких изображений, как в обычных (известных) устройствах. В результате появляется возможность формирования однородного изображения высокого качества в целом для всех ситуаций. Кроме того, поскольку задаваемое количество кодов для каждой GOP определяется в настоящем варианте устройства по двум изображениям, то по сравнению с вышеописанным вариантом может быть установлена более высокая скорость обработки. Осталось только отметить тот очевидный факт, что количество кодов соответственных групп изображений определяются на основе количества данных всех изображений в составе GOP.

Необходимо отметить, что настоящее изобретение не ограничивается описанными выше вариантами его. Хотя, например, в описанных выше вариантах для преобразовательного кодирования используется метод ДКП, преобразование Страто, преобразование Хаара или преобразование Вавелета также могут быть применены в описанных случаях.

Промышленное применение.

Как должно быть понятно из приведенного выше описания, в настоящем изобретении используется электронная схема и последовательность операций, позволяющие кодировать входной видеосигнал путем выполнения, например, прогнозирующего кодирования, ДКП-обработки и квантования данных с фиксированным шагом квантования, кодирования (с переменной длиной) для выработки первых кодированных данных и последующего определения (вычисления) количества кодов, отводимых (задаваемых) для каждого кадра или каждой GOP, на основе учета количества данных в каждый заранее заданный отрезок времени, например за время длительности каждого кадра или каждой ГИ из первых кодированных данных, и общего количества данных, пригодных для кодирования входного видеосигнала в каждый заранее задаваемый момент на основе назначаемого количества кодов для выработывания вторых кодированных данных. Таким образом осуществляется кодирование с переменной скоростью, когда скорость кодирования изменяется в заранее задаваемый отрезок времени. В результате, если даже имеет место последовательность изображений (кадров) сложного вида, нет возможности обеспечить такое большое значение шага квантования для этих изображений, как в обычных устройствах. Благодаря этому можно достигнуть однородного изображения высокого качества в целом в различных случаях.

Кроме того, поскольку вторые кодированные данные, формирование которых описано выше, имеют переменную скорость, то в случае, когда такие данные регистрируются на носителе записанного изображения, ограниченный объем памяти может быть использован более эффективно, а время регистрации изображения на носителе может быть продлено. Наконец, данные изображения, имеющего высокое качество и однородность во всех возможных случаях, могут быть воспроизведены с носителя записанного изображения.

Формула изобретения:

1. Способ кодирования изображений, включающий операции кодирования по меньшей мере части входного видеосигнала для выработки первых кодированных данных, определения скорости кодирования в каждый заранее задаваемый момент или отрезок времени на основе количества первых кодированных данных и общего количества пригодных к использованию данных, отличающийся тем, что предусматривает кодирование входного видеосигнала в каждый заранее задаваемый отрезок времени на основе скорости кодирования для выработки вторых кодированных данных.

2. Способ по п.1, отличающийся тем, что по меньшей мере часть входного видеосигнала квантуют с фиксированным шагом квантования для выработки первых кодированных данных.

3. Способ по п.1, отличающийся тем, что общее количество пригодных к использованию данных пропорционально распределяют в соответствии с требуемым количеством данных в каждый заранее задаваемый отрезок времени для определения таким образом скорости кодирования в каждый заранее задаваемый отрезок времени.

4. Способ кодирования изображений, включающий операции заранее задаваемого прогнозирующего кодирования или заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала для вырабатывания первых коэффициентных данных, квантования первых коэффициентных данных с фиксированным шагом квантования для вырабатывания первых квантованных данных, обеспечивая возможности обработки первых квантованных данных в виде неравномерного кодирования (с переменной длиной) для формирования первого потока бит, определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества данных в первом потоке бит и общего количества пригодных к использованию данных, отличающийся тем, что прогнозирующее кодирование и/или заранее задаваемое преобразовательное кодирование входного видеосигнала для генерации вторых коэффициентных данных, квантование вторых коэффициентных данных с шагом квантования, задаваемым на основе скорости кодирования в каждый заранее задаваемый отрезок времени для выработки вторых квантованных данных, и обеспечение возможности кодирования с переменной длиной вторых квантованных данных для формирования второго потока бит.

5. Способ по п.4, отличающийся тем, что скорость кодирования определяют в каждом кадре на основе количества данных в каждом кадре первого потока бит и общего количества пригодных к использованию

RU 2123769 C1

RU 2123769 C1

данных.

6. Способ по п.4, отличающийся тем, что скорость кодирования определяют в каждой группе изображений (ГИ) на основе по крайней мере количества части данных каждой группы изображений (ГИ), состоящей из множества кадров из первого потока бит, и на основе общего количества пригодных к использованию данных.

7. Способ по п.6, отличающийся тем, что скорость кодирования в каждой группе изображений (ГИ) определяют на основе количества данных в изображении с внутрикадровым кодированием и изображения, кодированного с прогнозированием вперед в составе группы изображений (ГИ).

8. Способ по п. 4, отличающийся тем, что общее количество пригодных к использованию данных распределяют пропорционально в зависимости от количества данных в первом потоке бит в каждый заранее задаваемый отрезок времени для определения скорости кодирования в каждый заранее задаваемый отрезок времени.

9. Способ кодирования изображений, включающий операции определения предела кодирования в каждом блоке изображения во входном видеосигнале, установки скорости кодирования в каждом заранее задаваемом блоке изображения на основе предела кодирования и общего количества данных, пригодных к использованию, отличающийся тем, что предусматривает кодирование входного видеосигнала таким образом, что скорости кодирования соответственных блоков изображения поддерживают в соответствии с установленной для каждого блока изображения скоростью кодирования.

10. Способ по п.9, отличающийся тем, что в качестве заранее задаваемого блока изображения задают кадр.

11. Способ по п.9, отличающийся тем, что в качестве заранее задаваемого блока изображения задают группу изображений (ГИ), состоящую из множества кадров.

12. Способ по п.9, отличающийся тем, что заранее задаваемому прогнозирующему кодированию и/или заранее задаваемому преобразовательному кодированию подвергают по крайней мере часть входного видеосигнала для выработки коэффициентных данных с тем, чтобы затем произвести квантование этих коэффициентных данных с фиксированным шагом квантования и определить таким образом предел кодирования.

13. Устройство кодирования изображений, содержащее первое средство кодирования по крайней мере части входного видеосигнала для вырабатывания первых кодированных данных, средство управления кодированием, служащее для определения скорости кодирования в заранее задаваемый отрезок времени на основе количества первых кодированных данных в каждый заранее задаваемый отрезок времени, поступающих от первого средства кодирования, и общего количества данных, пригодных для использования, отличающееся тем, что содержит второе средство кодирования входного видеосигнала в каждый заранее задаваемый отрезок времени на основе скорости кодирования в каждый заранее задаваемый отрезок времени, задаваемой средством управления кодированием, для выработки вторых кодированных данных.

14. Устройство по п.13, отличающееся тем, что первое средство кодирования содержит средство для квантования по крайней мере части входного видеосигнала с фиксированным шагом квантования.

15. Устройство по п.13, отличающееся тем, что средство управления кодированием выполняют функцию пропорционального распределения общего количества данных в зависимости от наличия данных в каждый заранее задаваемый отрезок времени, определяя таким образом скорость кодирования в каждый заранее задаваемый отрезок времени.

16. Устройство кодирования изображений, содержащее первое средство для выполнения заранее задаваемого прогнозирующего кодирования и/иди заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала для выработки первых коэффициентных данных, первое средство квантования первых коэффициентных данных с фиксированным шагом квантования для образования первых квантованных данных, первое средство неравномерного кодирования, обеспечивающее такую обработку квантованных данных, приходящих с первого средства квантования, для формирования первого потока бит, средство управления кодированием для определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества данных в первом потоке бит, поступающем с первого средства неравномерного кодирования, и общего количества используемых данных, отличающееся тем, что содержит второе средство кодирования для выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого прогнозирующего преобразовательного кодирования входного видеосигнала для выработки вторых коэффициентных данных, второе средство квантования для квантования вторых коэффициентных данных, поступающих со второго кодирующего средства, с шагом квантования, задаваемым с учетом скорости кодирования средством управления кодированием в каждый заранее задаваемый отрезок времени для вырабатывания вторых квантованных данных, и второе средство неравномерного кодирования, обеспечивающее такую обработку вторых квантованных данных, поступающих со второго средства квантования для формирования второго потока бит.

17. Устройство по п.16, отличающееся тем, что средство управления кодированием определяет скорость кодирования в каждом кадре на основе количества данных в каждом кадре первого потока бит и общего количества пригодных данных.

18. Устройство по п.16, отличающееся тем, что средство управления кодированием определяет скорость кодирования в каждой группе изображений (ГИ) на основе количества данных по меньшей мере в части каждой группы изображений (ГИ), состоящей из множества кадров первого потока бит, а также общего количества пригодных к

RU 2123769 C1

RU 2123769 C1

использованию данных.

19. Устройство по п.18, отличающееся тем, что средство управления кодированием определяет скорость кодирования в каждой группе изображений (ГИ) на основе количества данных в изображениях внутрикадрового кодирования и в изображениях, кодированных с прогнозированием вперед в составе группы изображений (ГИ).

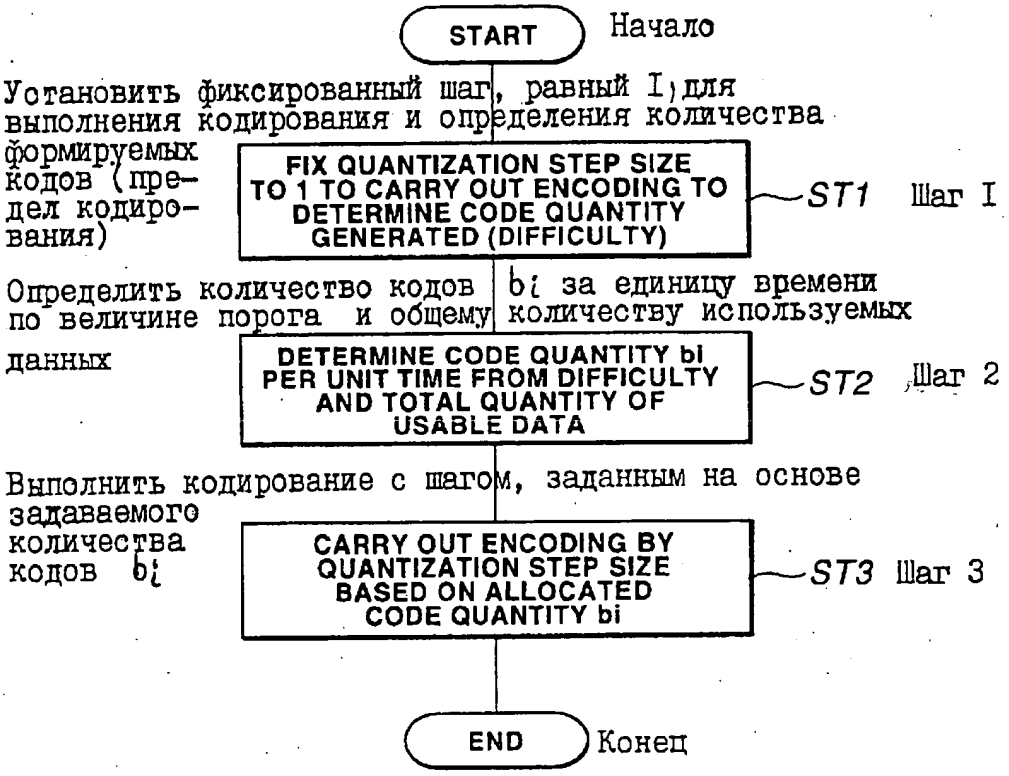
20. Устройство по п.16, отличающееся тем, что средство управления кодированием пропорционально распределяет общее количество пригодных к использованию данных в зависимости от количества данных в первом потоке бит в каждый заранее задаваемый отрезок времени, определяя таким образом скорость кодирования в каждый заранее задаваемый отрезок времени.

21. Устройство кодирования изображений, содержащее средство вычисления (определения) предела кодирования в каждом заранее задаваемом блоке изображений во входном видеосигнале, средство установки скорости кодирования в каждом заранее задаваемом блоке изображений на основе предельных параметров кодирования, получаемых от средства вычисления этих предельных параметров, с учетом общего количества пригодных к использованию данных, отличающееся тем, что содержит средство кодирования, обеспечивающее возможность такого кодирования входного видеосигнала, когда скорости кодирования соответственных блоков изображения соответствуют скорости кодирования каждого блока изображений, установленной средством установки скорости кодирования.

22. Устройство по п.21, отличающееся тем, что средство вычисления предела кодирования определяет эти параметры кодирования для каждого кадра.

23. Устройство по п.21, отличающееся тем, что средство вычисления предельных параметров кодирования определяет эти параметры для каждой группы изображений (ГИ), состоящей из множества кадров.

24. Устройство по п.21, отличающееся тем, что средство вычисления предела кодирования выполняет заранее задаваемое прогнозирующее кодирование и/или заранее задаваемое преобразовательное кодирование по крайней мере части входного видеосигнала для выработки коэффициентных данных и их последующего квантования с фиксированным шагом, в результате чего вычисляют (определяют) предел кодирования.



25. Носитель информации для записи изображений, на котором записан второй поток бит, полученный путем кодирования по крайней мере части входного видеосигнала для выработки первых кодированных данных, определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества первых кодированных данных в каждый заранее задаваемый отрезок времени, а также общего количества используемых данных, отличающийся тем, что второй поток бит получен в результате кодирования входного видеосигнала в каждый заранее задаваемый отрезок времени на основе скорости кодирования.

26. Носитель информации для записи изображений, на котором записан второй поток бит, полученный путем выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования по меньшей мере части входного видеосигнала, выработки первых коэффициентных данных и их квантования с фиксированных шагом для выработки первых квантованных данных, обеспечивания возможности неравномерного кодирования первых квантованных данных для формирования первого потока бит, определения скорости кодирования в каждый заранее задаваемый отрезок времени на основе количества данных в первом потоке данных и общего количества пригодных к использованию данных, отличающийся тем, что второй поток бит получен в результате выполнения заранее задаваемого прогнозирующего кодирования и/или заранее задаваемого преобразовательного кодирования входного видеосигнала для выработки вторых коэффициентных данных, квантования вторых коэффициентных данных с шагом квантования, задаваемым на основе скорости кодирования в каждый заранее задаваемый отрезок времени для выработки вторых квантованных данных и обеспечения возможности неравномерного кодирования этих вторых квантованных данных.

27. Носитель информации для записи изображений, на котором записаны кодированные данные, полученные путем определения предела кодирования в каждом заранее задаваемом блоке изображения входного видеосигнала, установления скорости кодирования в каждом заранее задаваемом блоке изображения, на основе величины предела кодирования и общего количества пригодных к использованию данных, отличающийся тем, что записанные данные получены в результате кодирования входного видеосигнала таким образом, что скорости кодирования в каждом из соответственных блоков изображения соответствуют скорости кодирования, установленной для каждого блока изображения.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

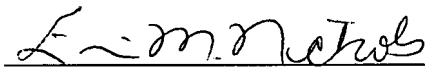
With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

These items were also first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached document do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.



No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

(54) Title: VIDEO COMPRESSION

(57) Abstract: The concept of B-frames gives the MPEG video compression standard its high encoding efficiency. However, B-frame encoding roughly doubles the complexity of an MPEG encoder. In view thereof, MPEG encoders have been developed which produce I-frames and P-frames only. They are less complex but also less efficient. To improve the efficiency of such "IPP encoders", selected P-frames are quantized more coarsely than other P-frames, for example, by multiplying the conventional quantization step size by 1.4. Although this results in isolated frames ("virtual B-frames") being encoded with a lower quality, the overall perceptual quality is not affected. It has been found that the gain in bit rate obtained by the coarser quantization is not lost in subsequent P-frames, even though the subsequent frames are encoded with reference to the lower quality frames.

WO 01/84850 A1

Video compression

FIELD OF THE INVENTION

The invention relates to a method of compressing a video signal, the method comprising predictively encoding frames of said video signal with reference to a prediction frame, calculating a quantization parameter for each encoded frame, and quantizing the encoded frames in accordance with said quantization parameter. The invention also relates to a compression arrangement, to a transmission or recording method and arrangement, to the compressed video signal and to a storage medium comprising that signal.

BACKGROUND OF THE INVENTION

A video compression method as defined in the opening paragraph has been standardized by the Motion Frames Expert Group and is well-known as MPEG1 or MPEG2. The known method includes transformation of video pixels into frequency coefficients, quantization of said coefficients, and variable-length coding of the quantized coefficients. The quantization is controlled so as to achieve a desired quality or bit rate of the compressed signal.

The MPEG compression method produces I, P and B-frames. I-frames are encoded autonomously, i.e. without reference to another frame. P-frames are predictively encoded with reference to a previous (possibly motion-compensated) I or P-frame. B-frames are bidirectionally predictively encoded with reference to a previous and a subsequent I or P frame. B-frames are not themselves used as reference for encoding other frames.

The concept of B-frames in MPEG provides maximum encoding efficiency. However, the use of B-frames roughly doubles the complexity, memory capacity and memory bandwidth. In view thereof, MPEG encoders have been developed which produce I and P-frames only ("IP encoders"). A disadvantage of IP encoders is their efficiency. They need approximately 10-20% more bit rate than IPB encoders.

OBJECT AND SUMMARY OF THE INVENTION

It is an object of the invention to provide an arrangement and method which overcomes the above-mentioned disadvantage of prior-art IP encoders.

To this end, the invention provides a video compression arrangement and method, a compressed signal, a storage medium, and a transmission or recording method and arrangement as defined in the independent claims. Advantageous embodiments are defined in the dependent claims.

The method in accordance with the invention quantizes selected P-frames more coarsely than other P-frames. This reduces the bit cost but degrades the image quality of said frames. The invention has a surprising effect. It was expected that the corresponding gain in bit cost would be lost in subsequent P-frames because the lower quality frames are used as prediction for subsequent P-frames. However, experiments have shown that this is not the case. It has been found that an IPPPP.. sequence of frames, in which the quantization parameter of every other P-frame is multiplied by a factor of 1.4, has substantially the same bit rate as a conventional IBPBP.. sequence having the same perceptual visual quality. In view thereof, the lower quality P-frames are also referred to as "virtual B-frames".

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 shows a schematic diagram of a preferred embodiment of an arrangement for compressing a video signal encoder in accordance with the invention;

Figs. 2A and 2B show diagrams illustrating the performance of the arrangement in accordance with the invention compared with the performance of a prior-art arrangement;

Fig. 3 shows a block diagram of embodiments of arrangements for transmitting and receiving a video signal; and

Fig. 4 shows a block diagram of embodiments of arrangements for recording a video signal on a storage medium and for playing back from the storage medium.

DESCRIPTION OF EMBODIMENTS

Fig. 1 shows a schematic diagram of an MPEG encoder in accordance with the invention. The Figure shows the encoder in the state in which P-frames are encoded. The encoder is a conventional MPEG encoder in the sense that it comprises a subtraction circuit **10**, a discrete cosine transformer (DCT) **11**, a quantizer (Q) **12**, a variable-length coder (VLC) **13**, a buffer (BUF) **14**, an inverse quantizer (iQ) **15**, an inverse discrete cosine transformer (iDCT) **16**, an adder **17**, a frame memory (MEM) **18**, a motion estimation and compensation circuit (ME/MC) **19**, and a quantization adapter (QA) **20**.

Briefly summarized, the known encoder operates as follows. The input video frame X is divided into blocks of 8×8 pixels. The difference between each pixel block of input frame X and the corresponding block of a prediction frame X_p is discrete cosine transformed into a block of 8×8 coefficients. The coefficients are subsequently quantized, by which perceptually irrelevant picture details are irreversibly removed (lossy compression). The quantized coefficients are variable-length encoded and stored in a buffer from which the signal is applied to a transmission channel or record carrier. The encoded frame is locally decoded by inverse quantization, inverse discrete cosine transformation, and addition to the prediction frame X_p. The reconstructed frame is stored in the frame memory and subjected to motion estimation and compensation so as to constitute the prediction frame for the next input frame.

The encoder includes a quantization adapter **20** for calculating the quantization steps with which the DCT-coefficients are quantized. In this embodiment, the MPEG2 quantization mechanism is used in which a predetermined quantization matrix, which defines the step sizes to be applied to the respective coefficients of an 8×8 coefficient block, is multiplied by a quantization scale factor q (herein further referred to as quantization parameter). The quantization parameter is adapted from frame to frame, but may be 'modulated' within a frame as a function of local image details. The quantization parameter may be controlled to represent a given image quality (resulting in a variable bit rate) or a given bit rate (resulting in a variable quality). Various embodiments of quantization adapters (also referred to as bit rate controllers) are known in the art and may be employed in the encoder according to the invention.

The arrangement in accordance with the invention increases the quantization parameter q for selected frames, thereby degrading the image quality of said frames but reducing their bit costs. In this embodiment, the arrangement includes a multiplier **23** which multiplies the quantization parameter q calculated by the quantization adapter **20** by a predetermined factor F (e.g. F=1.4). A switch **22** has a position P in which the conventional quantization parameter q is applied to the quantizer **12** and a position P' in which the coarser quantization parameter F.q is applied to the quantizer. The switch is controlled by a control circuit **22** in a predetermined manner. For example, the control circuit selects every other P-frame to be more coarsely quantized.

Fig. 2A shows a diagram illustrating the performance of a conventional MPEG2 encoder which produces a stream of IPPP.. frames (no B-frames). Each frame is quantized in accordance with the quantization parameter q as calculated by the quantization

adapter **20**. The lower row of figures denotes the bit cost of the respective frame, expressed as a percentage of the bit cost of the respective I-frame. The bit cost of P-frames appears to be 38% in this example.

Fig. 2B shows a similar diagram for an encoder in accordance with the invention. The quantization adapter **20** has been set to produce the same image quality as in Fig. 2A. In accordance therewith, the bit cost for I-frames is the same as in Fig. 2A. Every other P-frame (denoted P' in the Figure) is now quantized with the quantization parameter 1.4q. The bit cost of the P'-frames is thereby reduced from 38% to 26%. The image quality of said frames is reduced in proportion therewith. The surprising effect of the invention is that the gain in bit cost is not lost in the subsequent 'conventional' P-frames. As shown in Fig. 2B, the bit cost of 'conventional' P-frames increases only from 38% to 42%. The net result is a considerable reduction of the bit rate at the same perceptual image quality (or a higher perceptual quality at the same bit rate) of the encoded video stream. In a practical experiment, the bit rate of a typical video signal was reduced from 15.2 Mbit/sec to 12.9 Mbit/sec at the same perceptual quality.

It is to be noted that the bit stream produced by an MPEG encoder in accordance with the invention fully complies with the MPEG standard. It should also be noted that although the invention has been described with reference to an IPP.. encoder (no B-frames), the invention does not exclude B-frame encoding. For example, an encoder may produce an IBPBP.. sequence in which selected P-frames have been quantized with the coarser quantization parameter. The coarser quantization parameter may even be applied to I-frames to the extent that such I-frames are used as prediction frames for subsequent frames.

Fig. 3 shows embodiments of arrangements for transmitting and receiving a video signal. An encoder 100 receives an image signal I on input 102. The encoder 100 is preferably constructed in accordance with the embodiment of Fig. 1, but may be any kind of compressed video signal encoder that supplies compressed video signals including first quantization parameters (q) representing a first quality or bit rate for quantizing selected first frames (P) of predictively encoded frames, and second quantization parameters (F.q) representing a second quality or bit rate that is lower than the first quality or bit rate for quantizing selected second frames (P') of the video signal. The compressed video signal is supplied at output 106 to a transmitter 108. The transmitter 108 then converts the compressed video signal into a transmission signal and applies the transmission signal to a transmission medium 110. The transmitter 108 and the transmission medium 110 may take any known form, for example, in the case of a broadcast, the transmitter 108 modulates the compressed

video signal onto a radio frequency (RF) carrier wave, and the transmission medium 110 may comprise airwaves containing the radio waves, or a cable carrying the radio waves. Alternatively, it is known to supply digital signals via the Internet. As such, the transmitter 108 may comprises means for transmitting the compressed video signal over the transmission medium 110 comprising the Internet.

A receiver 112 coupled to the transmission medium 110 then receives the transmission signal and applies the image signal to a display device 118.

Fig. 4 shows a block diagram of embodiments of arrangements for recording and playing back a compressed video signal onto and from a record carrier. This arrangement is substantially similar to that shown in Fig. 3, except that the compressed video signal at the output 106 of the encoder 100 is applied to a recording device 120. The recording device 120 then converts the compressed video signal into a recording signal and records the recording signal onto the record carrier 122. The recording device 120 and the record carrier 122 may take any known form. For example, in the case of the record carrier 122 being a magnetic video tape, the recording device 120 may take the form of a helical scan video tape recorder. Alternatively, the record carrier 122 may be an optical disk, for example, CD-ROM, CD-R, DVD, DVD-ROM, DVD-R/W, etc. In that event, the recording device 120 would take the form of an optical disk recorder.

In order to play back the recording signal RS, the record carrier 122 is inserted into a playback device 124 which processes the recording signal RS and generates an image signal. As with the embodiment of Fig. 3, the playback device 124 applies the image signal to the display device 118.

The invention can be summarized as follows. The concept of B-frames gives the MPEG video compression standard its high encoding efficiency. However, B-frame encoding roughly doubles the complexity of an MPEG encoder. In view thereof, MPEG encoders have been developed which produce I-frames and P-frames only. They are less complex but also less efficient. To improve the efficiency of such "IPP encoders", selected P-frames are quantized more coarsely than other P-frames, for example, by multiplying the conventional quantization step size by 1.4. Although this results in isolated frames ("virtual B-frames") being encoded with a lower quality, the overall perceptual quality is not affected. It has been found that the gain in bit rate obtained by the coarser quantization is not lost in subsequent P-frames, even though the subsequent frames are encoded with reference to the lower quality frames.

It should be noted that the above-mentioned embodiments illustrate rather than limit the invention, and that those skilled in the art will be able to design many alternative embodiments without departing from the scope of the appended claims. In the claims, any reference signs placed between parentheses shall not be construed as limiting the claim. The word "comprising" does not exclude the presence of elements or steps other than those listed in a claim. The word "a" or "an" preceding an element does not exclude the presence of a plurality of such elements. The invention can be implemented by means of hardware comprising several distinct elements, and by means of a suitably programmed computer. In the device claim enumerating several means, several of these means can be embodied by one and the same item of hardware. The mere fact that certain measures are recited in mutually different dependent claims does not indicate that a combination of these measures cannot be used to advantage.

CLAIMS:

1. A method of compressing a video signal, the method comprising:

predictively encoding (10,11) frames (X) of said video signal with reference to a prediction frame (X_p),

calculating (20) a quantization parameter (q) for each encoded frame,

quantizing (12) the encoded frames in accordance with said quantization parameter,

characterized in that said step of calculating the quantization parameter includes calculating a first quantization parameter (q) representing a first quality or bit rate for quantizing selected first frames (P) of said predictively encoded frames, and a second quantization parameter (F.q) representing a second quality or bit rate that is lower than said first quality or bit rate for quantizing selected second frames (P') of the video signal, the method further including:

decompressing (15-18) the compressed second frames to constitute the prediction frame (X_p) for predictively encoding the first frames.

2. A method as claimed in claim 1, wherein the step of calculating the second quantization parameter includes calculating said first quantization parameter (q) and multiplying (23) said first quantization parameter by a given factor (F).

3. A method as claimed in claim 1, wherein said predictively encoded frames constitute a series of successive frames, the second selected frames being every other frame of said series.

4. An arrangement for compressing a video signal, the arrangement comprising:

encoding means (10,11) for predictively encoding frames (X) of said video signal with reference to a prediction frame (X_p),

calculation means (20) for calculating a quantization parameter (q) for each encoded frame,

a quantizer (12) for quantizing the encoded frames in accordance with said quantization parameter,

characterized in that said calculation means (20) are arranged to calculate a first quantization parameter representing a first quality or bit rate for quantizing selected first frames (P) of said predictively encoded frames, and a second quantization parameter (F.q) representing a second quality or bit rate that is lower than said first quality or bit rate for quantizing selected second frames (P') of the video signal, the arrangement further including:

means (15-18) for decompressing the compressed second frames to constitute said prediction frame (X_p) for predictively encoding first selected frames.

5. An arrangement as claimed in claim 4, wherein said calculation means (20) comprise a multiplier (23) for multiplying the first quantization parameter (q) by a given factor (F).

6. An arrangement as claimed in claim 4, wherein said predictively encoded frames constitute a series of successive frames, the second selected frames being every other frame of said series.

7. A compressed video signal, comprising:

a prediction frame (X_p),

predictively encoded (10,11) frames (X) that have been predictively encoded with reference to the prediction frame (X_p),

respective quantization parameters (q) for respective encoded frames, the encoded frames having been quantized (12) in accordance with said respective quantization parameters, the quantization parameters including first quantization parameters (q) representing a first quality or bit rate for quantizing selected first frames (P) of said predictively encoded frames, and second quantization parameters (F.q) representing a second quality or bit rate that is lower than said first quality or bit rate for quantizing selected second frames (P') of the video signal.

8. A storage medium (122) on which the compressed video signal of claim 7 has been stored.

9. A method of transmitting or recording a video signal, the method comprising:

generating the compressed video signal of claim 7; and

transmitting or storing the compressed video signal.

10. An arrangement for transmitting or recording a video signal, the arrangement comprising:

means (100) for generating the compressed video signal of claim 7; and

means (108, 120) for transmitting or recording the compressed video signal.

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

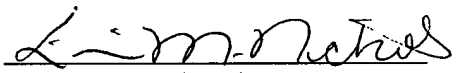
With regard to the above-identified application, the item of information listed on the enclosed Form 1449 is brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the item listed on the enclosed Form 1449.

This item was also first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

Applicant has not provided a copy of the U.S. publication/patent listed on the enclosed Form 1449 in accordance with 37 C.F.R. § 1.98(a)(2).

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to



establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

☑权利要求 1, 9-10 不符合专利法实施细则第 20 条的规定。
☐权利要求_____不符合专利法实施细则第 21 条的规定。
☐权利要求_____不符合专利法实施细则第 22 条的规定。
☑权利要求4-6, 8-9, 13-15, 17不符合专利法实施细则第 23 条的规定。
☐_____
☐分案的申请不符合专利法实施细则第 43 条第 1 款的规定。
上述结论性意见的具体分析见本通知书的正文部分。

6. 基于上述结论性意见，审查员认为：
☐申请人应按照通知书正文部分提出的要求，对申请文件进行修改。
☑申请人应在意见陈述书中论述其专利申请可以被授予专利权的理由，并对通知书正文部分中指出的不符合规定之处进行修改，否则将不能授予专利权。
☐专利申请中没有可以被授予专利权的实质性内容，如果申请人没有陈述理由或者陈述理由不充分，其申请将被驳回。
☐_____

7. 申请人应注意下述事项：
(1) 根据专利法第 37 条的规定，申请人应在收到本通知书之日起的贰个月内陈述意见，如果申请人无正当理由逾期不答复，其申请将被视为撤回。
(2) 申请人对其申请的修改应符合专利法第 33 条和实施细则第 51 条的规定，修改文本应一式两份，其格式应符合审查指南的有关规定。
(3) 申请人的意见陈述书和/或修改文本应邮寄或递交国家知识产权局专利局受理处，凡未邮寄或递交给受理处的文件不具备法律效力。
(4) 未经预约，申请人和/或代理人不得前来国家知识产权局专利局与审查员举行会晤。

第二次审查意见通知书正文

申请号：2006100093533

申请人于2008年10月13日提交了意见陈述书和经过修改的申请文件，审查员在阅读了上述文件后，对本申请继续进行审查，再次提出如下审查意见。

1.权利要求1请求保护一种用于解码压缩视频序列的方法，对比文件1（CN1173783A）公开了一种解码器，同时也公开了该解码器具体的解码过程，具体披露了以下技术特征（参见对比文件1说明书第6页第1行-第12行）：接收传输数据流，接收其中的一个不连续指示位（相当于该权利要求的不连续性的指示），将传输包的有效内容（相当于该权利要求的不连续性相应的多个图像帧）存入存储器（相当于该权利要求的缓冲存储器），通过解码器对存储器中的数据进行处理。可见，该权利要求所要求保护的技术方案与该对比文件所公开的内容相比，所不同的仅仅是文字表达方式上略有差别，其技术方案实质上是相同的，且两者属于相同的技术领域，并且采用相同的技术方案解决了同样的技术问题，并能产生相同的技术效果，因此该权利要求所要求保护的技术方案不具备专利法第二十二条第二款规定的新颖性。

2.权利要求10请求保护一种用于解码压缩视频序列的视频解码器，对比文件1（CN1173783A）公开了一种解码器，，具体披露了以下技术特征（参见对比文件1说明书第6页第1行-第12行）：接收传输数据流，接收其中的一个不连续指示位（相当于该权利要求的不连续性的指示），将传输包的有效内容（相当于该权利要求的不连续性相应的多个图像帧）存入存储器（相当于该权利要求的缓冲存储器），解码器与存储器相连，通过解码器对存储器中的数据进行处理。可见，该权利要求所要求保护的技术方案与该对比文件所公开的内容相比，所不同的仅仅是文字表达方式上略有差别，其技术方案实质上是相同的，且两者属于相同的技术领域，并且采用相同的技术方案解决了同样的技术问题，并能产生相同的技术效果，因此该权利要求所要求保护的技术方案不具备专利法第二十二条第二款规定的新颖性。

3.权利要求1和10中的出现了特征“所述图像帧”（参见上述权利要求的最后一行），在该特征之前多次出现过特征“图像帧”，并且在不同的步骤中，“图像帧”包含的内容也是不同的，因此，对该特征的引用是不清楚的，不能明确是引用那个部分的“图像帧”，因此导致了该权利要求的保护范围不清楚，不符合专利法实施细则第二十条第一款的规定。

4.权利要求9中的特征“参考”含义不清楚，不能确定参考数据的类型，因此导致该权利要求的保护范围不清楚，不符合专利法实施细则第二十条第一款的规定。

5.权利要求4-6，8-9，13-15，17本身是多项从属权利要求，其引用的权利要求中还包括多项从属权利要求，因此不符合专利法实施细则第二十三条第二款的规定。申请人应当对该权利要求的引用关系进行修改。

6.权利要求10，12，14-15，17-18，20中，在"还被安排来"之后没有任何标点，申请人应该对其进行修改、

基于上述理由，本发明专利申请按照目前的文本不能被授权。申请人应在本通知指定的答复期限内提交新修改的权利要求书（请全文替换并附上带有修改标记的修改草稿）。请在意见陈述书中详细论述已克服上述缺陷的理由。对申请文件的修改应当符合专利法第三十三条的规定，不得超出原说明书和权利要求书记载的范围。对申请文件进行的任何改动，务请详细说明修改没有超范围的理由。

THE PATENT OFFICE OF THE PEOPLE'S REPUBLIC OF CHINA

Address: 6 Xi Tu Cheng Lu, Haidian, Beijing 100088

Applicant:	**NOKIA CORPORATION**	
Attorney:	**Maohua WANG**	Date of Notification:
Application No.:	**200610009353.3**	Date13Month02Year2009
Title of the Invention:	**GROUPING OF IMAGE FRAMES IN VIDEO CODING**	

Notification of 2nd Office Action

1. ☒ The examiner received the response submitted by the applicant on_____ to the1stOffice Action and further examination as to substance has been carried out on the above-identified patent application for invention on this new basis.
   ☐ According to the Reexamination Decision made by the Patent Reexamination Board of the Patent Office on _____, examination as to substance on the above-identified application has been resumed.

2. Further examination as to substance has been carried out based on the documents as specified below:
   ☐ The amended application documents attached to the response to the previous Office Action.
   ☒ The application documents based on which the previous examination was carried out and the substitution pages attached to the response to the previous Office Action.
   ☐ The application documents based on which previous examination was carried out.
   ☐ The application documents confirmed by the Reexamination Decision.

3. ☐ No further reference documents are cited in this Office Action.
   ☒ Below is/are the reference document(s) cited in this Notification:

No.	Number(s) or Title(s) of Reference(s)	Date of Publication(or the filing date of conflicting application)
1	CN1173783A	Date:18Month:2Year: 1998
		Date: Month: Year:
		Date: Month: Year:
		Date: Month: Year:
		Date: Month: Year:

4. Conclusions of the Action:
   ☐ On the Specification:
   ☐ The amendments to the description do not comply with Article 33 of the Patent Law.
   ☐ The subject matter contained in the application is not patentable under Article 5 of the Patent Law.
   ☐ The description does not comply with Article 26 paragraph 3 of the Patent Law.
   ☐ The draft of the description does not comply with Rule 18 of the Implementing Regulations.

   ☒ On the Claims:

☐ The amendments to claims _____do not comply with Article 33 of the Patent Law.
☐ Claim(s)_____is/are not patentable under Article 25 of the Patent Law.
☐ Claim(s)_____does/do not comply with the definition of inventions prescribed by Rule 2 paragraph 1 of the Implementing Regulations.
☒ Claim(s) 1, 10 does/do not possess the novelty as required by Article 22 paragraph 2 of the Patent Law.
☐ Claim(s)_____does/do not possess the inventiveness as required by Article 22 paragraph 3 of the Patent Law.
☐ Claim(s)_____does/do not possess the practical applicability as required by Article 22 paragraph 4 of the Patent Law.
☐ Claim(s)_____does/do not comply with Article 26 paragraph 4 of the Patent Law.
☐ Claim(s)_____does/do not comply with Article 31 paragraph 1 of the Patent Law.
☒ Claim(s) 1, 9-10 does/do not comply with the provisions of Rules 20 of the Implementing Regulations.
☒ Claim(s) 4-6, 8-9, 13-15, 17 does/ do not comply with the provisions of Rules 23 of the Implementing Regulations..
☐ Claim(s) _____does/do not comply with the provisions of Rule 12 paragraph 1 of the Implementing Regulations.

The detailed explanation of the above conclusions is set forth in the text portion of the Notification.

5. In view of the conclusions set forth above, the Examiner is of the opinion that:
☐ The applicant should make amendments to the application documents as directed in the text portion of the Notification.
☒ The applicant should expound in the response reasons why the application is patentable and make amendments to the application where there are deficiencies as pointed out in the text portion of the Notification, otherwise, the application will be rejected.
☐ The application contains no allowable invention, and therefore, if the applicant fails to submit sufficient reasons to prove that the application does have merits, it will be rejected.
6. The followings should be taken into consideration by the applicant in making the response:
(1) Under Article 37 of the Patent Law, the applicant should respond to the office action within 2 months counting from the date of receipt of the Notification. If, without any justified reason, the time limit is not met, the application shall be deemed to have been withdrawn.
(2) Any amendment to the application should be in conformity with the provisions of Article 33 of the Patent Law and Rule 51 of the Implementing Regulations. Substitution pages should be in duplicate and the format of the substitution should be in conformity with the relevant provision contained in "The Examination Guidelines".
(3) The response to the Notification and/or revision of the application should be mailed to or handed over to the "Reception Division" of the Patent Office, and documents not mailed or handed over to the Reception Divisions have no legal effect.
(4) Without an appointment, the applicant and/or his agent shall not interview with the Examiner in the Patent Office.
7. This Notification contains a text portion of 2 pages and the following attachments:
☒ 1cited reference(s), totaling 37pages.

Examination Dept. 9 Examiner: 976H Seal of the Examination Department

Text of the Second Office Action

The applicant submitted the observations and amended application documents on October 13, 2008. After reading the above documents, the examiner continues examination on the present application and provides the following opinions:

1. Claim 1 is directed to a method for decoding a compressed video sequence. 1 (CN1173783A, corresponding to EP0798932A2 of the same patent family) discloses a decoder, and meanwhile discloses concrete decoding process of the decoder, and specifically discloses the following technical features (see page 5, lines 20-30 of the description, EP0798932A2): receiving transport data stream, receiving a discontinuity indicator (equivalent to discontinuity indication of claim 1) thereof, storing the transport packet payloads (equivalent to the number of image frames corresponding to a discontinuity of claim 1) in memory (equivalent to the buffer memory of claim 1), and processing by the decoder the data in the memory. It is seen that the technical solution for which protection is sought in the claim differs from the contents disclosed by D1 only slightly in difference, and their technical solutions are substantively identical. Further, claim 1 and D1 fall within the same technical field, solve the same technical problem by adopting the same technical solution and can achieve the same technical effect. Thus, the technical solution for which protection is sought in claim 1 lacks novelty under Article 22.2 of the Chinese Patent Law.

2. Claim 10 is directed to a video decoder for decoding a compressed video sequence. 1 (CN1173783A, corresponding to EP0798932A2 of the same patent family) discloses a decoder, and meanwhile discloses concrete decoding process of the decoder, and specifically discloses the following

technical features (see page 5, lines 20-30 of the description, EP0798932A2): receiving transport data stream, receiving a discontinuity indicator (equivalent to discontinuity indication of claim 10) thereof, storing the transport packet payloads (equivalent to the number of image frames corresponding to a discontinuity of claim 10) in memory (equivalent to the buffer memory of claim 10) connected to the decoder, and processing by the decoder the data in the memory. It is seen that the technical solution for which protection is sought in the claim differs from the contents disclosed by D1 only slightly in difference, and their technical solutions are substantively identical. Further, claim 10 and D1 fall within the same technical field, solve the same technical problem by adopting the same technical solution and can achieve the same technical effect. Thus, the technical solution for which protection is sought in claim 10 lacks novelty under Article 22.2 of the Chinese Patent Law.

3. In claims 1 and 10, there recites the wording "the image frames" (see the last line of the above claims). Since the feature "image frames" have been previously mentioned for several times, and in different steps, the contents contained in the "image frames" are different, citation of the feature is unclear and it is unclear which "image features" are cited. Thus the respective protection scope of the claims is unclear in the sense of Rule 20.1 of the Implementing Regulations of the Chinese Patent Law.

4. In claim 9, the wording "a reference" is unclear in meaning and it is unable to determine the type of reference data, which renders the protection scope of claim 9 unclear in the sense of Rule 20.1 of the Implementing Regulations of the Chinese Patent Law.

5. Claims 4-6, 8-9, 13-15 and 17 per se are multiple dependent claims, while

the claims to which they refer also contain multiple dependent claims, which therefore do not comply with Rule 23.2 of the Implementing Regulations of the Chinese Patent Law. Please be advised to amend the dependencies of the claims.

6. (A formality issue is omitted here, which will be attended to by this Attorney without your further input.)

To sum up, the present application can not be granted a patent right under the current application documents. The applicant should submit newly amended claims (please replace the whole text attached with the amended draft with marks) within the time limit for response as prescribed in the Office Action. Please state in detail the reasons why the above defects have been overcome in the observations. It should note that subject to Article 33 of the Chinese Patent Law, any amendments to the application documents should not go beyond the scope of the disclosure contained in the original description and claims. For any change to the application documents, please state reasons in detail why such amendments do not go beyond the original scope.

(54) MPEG-2 transport decoder

(57) A transport decoder 110, for receiving and processing a transport data stream using MPEG-2 formats, includes connections to a physical layer channel interface (channel interface) 112, a buffer memory 114, a host microprocessor 116, audio and video decoders 118/120, and clock signal circuitry 122. Upon receipt of a discontinuity indicator, the transport packet headers are parsed and transport packet payloads are stored in memory. Subsequently, upon receipt of a next program counter reference (PCR) value, a counter is loaded with the received program counter reference value. Next, the data stored in memory is searched for a time stamp and, when one is found, the time stamp is retrieved. Finally, a timer interrupt is set for a point in time approximately one frame time before the time stamp value, and, when the timer interrupt occurs, the program counter reference value is sent to the decoders, thereby providing sufficient time for the decoders to process data.

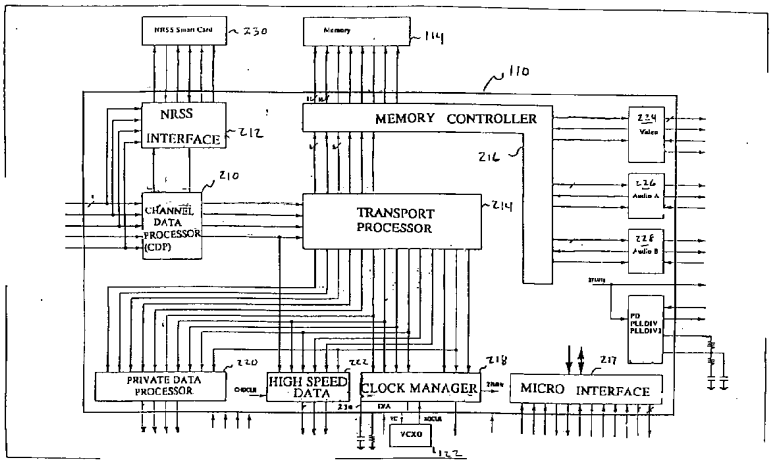

FIGURE 2A

EP 0 798 932 A2

Description

FIELD OF THE INVENTION

The present invention relates generally to data reception, processing and transmission of data encoded according to MPEG-2 standards and, more particularly, the present invention relates to the operation and interfacing of a transport decoder which handles an MPEG-2 format datastream.

BACKGROUND OF THE INVENTION

High Definition Television (HDTV) continues to make progress in its attempts to replace conventional television. Paving the way for this progress are various companies and associations working on standards to provide for a global market for HDTV.

One such group of companies is known as the "Digital HDTV Grand Alliance" including members such as AT&T, David Sarnoff Research Center, Massachusetts Institute of Technology and others. A comprehensive overview of the strides made by this group are presented in an article by Robert Hopkins entitled "Digital Terrestrial HDTV for North America: The Grand Alliance HDTV System" published in the IEEE Transactions on Consumer Electronics (Summer 1994). This article is herein incorporated by reference for all of its teachings regarding the background and basics of HDTV systems including the use of Program and Transport Packet Streams.

One standard that has been adopted by the Grand Alliance is the MPEG-2 standard for encoding video and audio information, developed by the Moving Pictures Expert Group (MPEG), a committee within the International Standards Organization (ISO). Accepted standards are periodically published such as, for example, the Video Section of Information Technology - Generic Coding of Moving Pictures and Associated Audio ISO/IEC 13818-2 (1995) (hereinafter "Video Section") and the Systems Section of Information Technology - Generic Coding of Moving Pictures and Associated Audio ISO/IEC 13818-1 (November 1994) (hereinafter "Systems Section") both of which are incorporated herein by reference for their teachings regarding established standards and formats.

The syntax for the MPEG-2 standard defines several layers of data records which are used to convey both audio and video data. To transmit information, a digital data stream, representing, for example, multiple video sequences, is divided into several smaller units and each of these units is encapsulated into a respective packetized elementary stream (PES) packet. For transmission, each PES packet is divided, in turn, among a plurality of fixed-length transport packets. Each transport packet contains data relating to only one PES packet. The transport packet also includes a header which holds control information, sometimes including an adaptation field, to be used in decoding the transport packet. However, PES data may include multiple elementary streams.

As set forth in the Systems Section, synchronization among multiple elementary streams is accomplished by periodically providing time stamps in the data stream. For instance, the decoding of N elementary streams is synchronized by adjusting the decoding of the streams to a common master time base rather than by adjusting the decoding of one stream to match that of another. The master time base may be the clock signal of one of the N decoders, or the clock signal of the data source, or it may be an externally supplied clock signal.

To aid in this synchronization process, included in the transport header of the MPEG-2 standard is a "discontinuity indicator". A syntax representation is provided in the Systems Section showing where in the transport header an exemplary "discontinuity indicator" resides. This syntax is re-presented below in Table I.

As described in the Systems Section, the discontinuity indicator resides within an adaptation field within the Transport Header. The discontinuity indicator is a 1 bit field which, when set to a logical '1', indicates that the discontinuity state is true for the current Transport Stream packet. When the discontinuity indicator is set to a logical '0' or is not present, the discontinuity state is false. The discontinuity indicator is used to indicate two types of discontinuities, system time-base discontinuities and continuity counter discontinuities.

A system time-base discontinuity is indicated by the use of the discontinuity indicator in Transport Stream program identification (PID) packets designated as a Program Clock Reference (PCR) PID (refer to Systems Section 2.4.4.9 on page 50). Subsequently, a PCR value (i.e., reference to a master clock signal) is received.

The discontinuity indicator bit is set, for example, when program material which was recorded with one time base is inserted into a data stream that was recorded with another time base. The difference in time base appears as an unexpected PCR value.

When the discontinuity state is true for a Transport Stream packet of a PID designated as a PCR PID, the next PCR in a Transport Stream packet with that same PID represents a sample of a new system time clock for the associated program. The system time-base discontinuity point is defined to be the instant in time when the first byte of a packet containing a PCR of a new system time-base arrives at the input of the System Target Decoder (STD).

It should be noted that an STD is well known in the art and, briefly, represents a hypothetical decoder which is conceptually connected to an output of a transport encoder. It is required that a datastream that conforms to the MPEG-2 standard shall not cause dataflow problems for the STD (including buffer overflow). Additional discussion of the STD is

provided in the Systems Section.

Continuing, the discontinuity indicator bit may also be set to '1' in Transport Stream packets of the same PCR PID prior to the packet which contains the new system time-base PCR. In this case, once the discontinuity indicator has been set to '1', it continues to be set to '1' in all Transport Stream packets of the same PCR PID up to and including the Transport Stream packet which contains the first PCR of the new system time-base. After the occurrence of a system time-base discontinuity, no fewer than two PCRs for the new system time-base will be received before another system time-base discontinuity can occur. Further, except when a trick mode status is true, data from no more than two system time-bases shall be present in the STD buffers for one program at any time.

A potential problem occurs when a time-base discontinuity requires that multiple System Time Constant (STC) values (e.g., in a Clock Manager of a Transport Decoder and in external video and audio decoders) be updated, particularly when a substantial latency may exist between data that is presently being decoded by external decoders and data that is being received and stored in the buffers of a transport decoder. That is, typically a transport decoder is coupled to external video and audio decoders each of which maintain an STC or equivalent thereof. Thus, when a change in system time-base occurs, adjusting all of the STC's at the same time may create system synchronization problems.

With this in mind, an important concern, addressed by the present invention, is how a transport decoder can efficiently handle the occurrence of a system time-base discontinuity between buffers and decoders.

SUMMARY OF THE INVENTION

The present invention involves a system designed for receiving a transport data stream which includes transport packets having headers and payloads, the headers include a discontinuity indicator. The system including at least one buffer for temporarily storing the received transport data stream and at least one external decoder for decoding data output from the buffer for presentation purposes. The present invention is designed to handle the receipt of a discontinuity indicator by, upon receiving a discontinuity indicator, parsing the transport packet header and storing the transport packet payloads in memory. Upon receiving a next program counter reference value, a counter is loaded with the received program counter reference value. The data stored is then searched for a time stamp and, when one is found, the time stamp is retrieved. Finally, a timer interrupt is set for a point in time based on the retrieved time stamp, and, when the timer interrupt occurs, the program counter reference value is sent to the decoder, providing the new time stamp value insufficient time for the decoder to process data having the new time base without interfering with the processing of data having the previous time base.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention is best understood from the following detailed description when read in connection with the accompanying drawing, in which:

Figure 1A shows a high-level functional block diagram of an exemplary digital transport decoder and its various interfaces.

Figure 1B shows a high-level flowchart illustrating the steps followed by one aspect of the present invention using the exemplary implementation shown in Figure 1A.

Figure 2A shows a high-level functional block diagram of an exemplary implementation of a the transport decoder shown in Figure 1A.

Figure 2B shows a high-level data/control flow block diagram of an exemplary implementation of the transport decoder shown in Figure 1A.

Figure 3 shows a functional block diagram of the memory controller used in the transport decoder shown in Figure 2.

Figure 4 shows an exemplary flowchart illustrating how the memory controller handles Pointers FIFO Entries.

Figure 5A shows an exemplary flowchart illustrating steps executed during the video decoder interface aspect of the present invention.

Figure 5B shows an exemplary flowchart illustrating steps executed during the audio decoder interface aspect of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Overview

As mentioned above, one important aspect of the present invention is how a transport decoder can efficiently handle a discontinuity indicator. Another aspect of the present invention is interfacing a transport decoder to a video decoder which can only handle elementary stream data. Still another aspect of the present invention involves interfacing a transport decoder to a bit rate-constrained audio decoder. To encompass the above listed aspects, the present invention includes a specially-designed MPEG-2 Transport Decoder.

To provide some context for the discontinuity aspect of the present invention, a real-world example of a time-base discontinuity would occur if a program were being broadcast, using MPEG-2 formats, via satellite to many receiving stations across the country. But, during the program, each station inserted its own respective commercials. In this situation, a discontinuity indicator would be set to indicate a gap or break in the time-base of the program in order to allow for the insertion of commercials, each having its own local time base. The program transmission from the satellite, however, would continue while the individual stations inserted their respective programs. Accordingly, the internal timing of the transport decoder for receiving the program broadcast from the local station with the inserted commercials would desirably track the appropriate time-bases when a discontinuity indicator is encountered.

Turning to the figures, Figure 1A shows a high-level functional block diagram of an exemplary digital transport decoder 110 and its various interfaces. As shown in Figure 1A, transport decoder 110 includes connections to a physical layer channel interface (channel interface) 112, buffer memory 114, a host microprocessor 116, external video and audio decoders 118 and 120, and clock signal circuitry (e.g., VCXO) 122. In the exemplary embodiment of the present invention, the transport decoder 110 supports one video interface and up to two audio interfaces (e.g., audio A and audio B).

Host microprocessor 116 is also coupled, external to transport decoder 110, to the video and audio decoders 118 and 120 by way of microbus 124. This connection may use parallel or serial data paths and depends on the requirements of the individual external decoders selected for use. In any event, as will be appreciated by those of ordinary skill in the art, this method of coupling the host microprocessor 116 to external decoders is well known.

Generally, the transport decoder 110 and each of the external video and audio decoders 118 and 120 include a System Time Constant (STC) value (not shown) maintained in a register or counter for the purpose of synchronizing the decoding and display of the received data stream.

As mentioned, a problem can occur when a time-base discontinuity occurs within the data stream, and the discontinuity requires STC values to be updated both in the transport decoder 110 and in the video and audio decoders 118 and 120. This is particularly a problem when a substantial latency may exist between data presently being decoded by the external decoders and data being received and stored in the transport processor 110.

In the present invention, microprocessor 116 has an important function in controlling the synchronization of the datastream and the operation of the video and audio decoders 118 and 120. In the present invention, microprocessor 116 has direct, memory-mapped access to various on-chip registers within the transport decoder 110. Microprocessor 116 also has access to buffer areas in the external memory 114 (through read, write and watermark pointers) and to on-chip 32-byte Read and Write FIFOs (shown in Figure 3). Microprocessor 116 is coupled to several internal functional blocks by an internal microbus 223 (shown in Figure 2B) and allows for various event and error conditions to be signaled via maskable interrupts.

Generally, as illustrated in the flowchart of Figure 1B, one aspect of the present invention, by way of the specially-designed transport decoder 110, performs the following steps after receiving of a discontinuity indicator, step 150:

1) because a discontinuity indicator is not necessarily in the same data packet as a next Program Clock Reference (PCR) value, when the next PCR value is received, a counter within Clock Management circuitry (shown in Figure 2A) contained within transport decoder 110 is loaded with the next PCR value, step 152;

3) subsequent packets, parsed and stored in memory, are searched for a time stamp and, when one is found, the time stamp value is retrieved, step 154;

4) a timer interrupt is set by the microprocessor 116 for a point in time that is just less than one frame time before the retrieved time stamp value, step 156; and

5) when this timer interrupt occurs, the current STC value is sent to the external video and audio decoders 118 and 120, step 158, thereby giving the external decoders sufficient time to process the data before the time stamp value in the datastream is compared to the counter value maintained in the video or audio decoders 118 or 120.

The implementation of these high level steps is described in detail below.

Figures 2A and 2B show high-level functional block diagrams of an exemplary implementation of the transport decoder 110 shown in Figure 1A. With reference to Figures 2A and 2B, the overall data flow in the transport decoder 110 is described.

As shown in the figures, the channel interface 112 of Figure 1A leads to a channel data processor (CDP) 210. Channel interface 112 also provides data to an NRSS interface 212 for purposes of decryption by the NRSS Smart Card 230. The EIA Standard for Conditional Access, Version 2.6, NRSS Committee (4/95) is hereby incorporated by reference for its teaching regarding the NRSS Smart Card.

The CDP 210 is provided to preprocess (e.g., detect, synchronize and validate) the packets in the received datastream. The CDP 210, after performing its processing, forwards its output data to transport processor (TPROC) 214 for further processing. TPROC 214 performs various processing, such as parsing, in accordance with a PID Table described below in detail.

The TPROC 214 interacts with several of the functional blocks within transport decoder 110 including a Memory Controller 216, a Clock Manager 218, a Private Data Processor 220, and a High Speed Data Port 222. As mentioned, the microprocessor 116 has direct access to various on-chip registers. This access is gained by way of a Micro Interface 217 and the internal microbus 223 (shown in Figure 2B). Memory Controller 216, in addition to being coupled to TPROC 214, is also coupled to external memory 114 and video and audio decoders 224, 226 and 228.

The details of the processing of the digital datastream, with respect to the individual functional blocks, is now described.

Channel Data Processor (CDP) 210

It is noted that the datastream from the channel interface 112 is passed to the CDP 210, after possible buffering (not shown).

The CDP 210 performs various preprocessing steps on the received datastream. In particular, CDP 210 determines the byte and frame boundaries in the datastream and converts the received datastream into an 8-bit parallel format. In the exemplary embodiment of the present invention, operations occurring in the transport decoder 110 subsequent to the CDP 210 are performed using a byte format.

To determine byte and frame boundaries, the CDP 210 synchronizes to a framing pattern contained in the header of a Transport Packet. In particular, this synchronization is achieved by searching for the MPEG-2 Transport Stream sync_byte (e.g., 47H) and verifying its occurrence at the start of a programmable number of consecutive transport packets.

In doing so, the CDP 210 checks for the sync_byte, "locks" on to the datastream and continues validating packets. When the sync_byte search is in progress, a Search_State bit is set in a CDP Status Register (not shown). When the sync_byte has been found and verification of successive occurrences is in progress, a Sync_State bit is set. Finally, a Lock_State bit is set when a predetermined search criterion is met. In the exemplary embodiment of the present invention, the search criterion is three consecutive validated packets. Also, a Sync_Hysterisis value, indicating the number of packets with corrupted sync_bytes that the CDP 210 is programmed to allow to pass through before declaring loss of Lock_State, is established. When this hysterisis value is exceeded, a loss of lock is declared. The CDP 210 then issues a Lock_Lost interrupt and transitions from the Lock_State back to the Search_State.

Additionally, if the channel interface 112 (shown in Figure 1A) provides a CHPSTRT signal, the transport decoder 110 may be configured to use this signal as a means to synchronize to the datastream by setting a Framing_Mode bit in a CDP Framing and Sync Control Register to logical "1". In this case, synchronization is achieved within one transport packet time after the CHPSTRT is asserted.

Alternatively, if an Ignore_Sync bit, in the CDP Framing and Sync Control Register, is set to logical "0", the CDP 210 verifies sync_byte integrity at the expected (first) byte location relative to the CHPSTRT signal transition and declares a lock condition if verification falls. If Ignore_Sync is set to 1, the CDP 210 does not verify sync integrity.

After achieving the Lock_State, the output of the CDP 210 can be passed to and processed by the TPROC 214, which further processes (e.g., filters, parses, and formats) the data now in byte format.

Transport Processor (TPROC) 214

Signals produced by the TPROC 214 control the flow of data to the Memory Controller 216, the Micro Interface 217, the Clock Manager 218, the Private Data Processor 220 and the High Speed Data Port 222.

In the exemplary embodiment of the present invention, the TPROC 214 processes the data stream under control of a PID Table. As described in the Systems Section, a PID is a 13-bit field in a Transport Stream Header, indicating the type of data stored in the packet payload. Some PID values are assigned and some are reserved. Additional details of the PID Table are described in Section 3.3 of the Systems Section of the above-referenced MPEG-2 specification.

Regarding the PID Table, the TPROC 214 is capable of concurrently processing up to 32 user-selectable PIDs. The PIDs which the transport decoder 110 is to process are specified in the PID Table. Bit fields in the PID Table specify

various processing options for the data.

In operation, the PID is extracted by the TPROC 214 from the header of an incoming transport packet and simultaneously compared to all of the entries in the PID Table. If a match is found, the data in the packet is processed according to the options set in the matching PID Table entry. If no PID Table entry matches, the packet is discarded.

Each location in the PID Table for which the Payload Format bits are not set to Discard (000), is associated with a channel number. In conjunction with the TPROC 214, the Memory Controller 216 is responsible for transferring data to a specific buffer area (channel) in RAM. Operation of the Memory Controller 216 is discussed in detail below with reference to Figures 2, 3 and 4.

In the exemplary embodiment of the present invention, the PID Table, maintained in TRPROC 214, is set up under software control by the microprocessor 116 via the internal microbus 223 during an initialization process.

Regarding PID Table entry format, a PID Table entry includes, among other information, 1) a 13-bit PID and 2) a 1-bit PCR PID field which, when set, indicates that this PID carries the PCR for the program being decoded. An exemplary PID Table entry also includes a 1 bit PES HDR bit which, when set, enables the RAM buffer address corresponding to a "Stream ID" in the PES header to be stored to a Pointers FIFO. An interrupt is issued by the Memory Controller 216 when it writes data to the Pointers FIFO. This interrupt is referred to as a DMA_MARK signal which serves to alert the microprocessor 116 of the delivery of the Stream_ID byte. In the exemplary embodiment of the present invention, Channel Numbers are assigned to PID Table entries in numerical order based on their location in the table, for example, the first entry is assigned DMA Channel 0, the next one DMA Channel 1 and so on.

The TPROC 214 indicates that transport packets with PCR PID should be processed by the Clock Manager 218 by placing a PCR_PID signal in the PID Table entry. The Clock Manager 218 then monitors the adaptation fields of such packets for a PCR_flag and extracts the PCR.

After separating the packets according to their PIDs, the TPROC 214 removes the headers of the transport packets and, in conjunction with the Memory Controller 216, stores packet payloads (e.g., portions of PES packets) for the respective PID's in sequential memory locations of the designated channel in the external memory 114. The data in the memory 114 represents PES packets.

The TPROC 214 also handles write operations to the external memory from the host microprocessor 116.

MEMORY CONTROLLER 216

The Memory Controller 216 stores the parsed payload of Transport Packets in external memory 114 and provides video, audio, PSI and other data (e.g., private data) upon demand to the Video Processor 224, up to two Audio Processors 226 and 228 and to the host microprocessor 116 (or microcontroller).

Figure 3 shows an exemplary functional block diagram of a Memory Controller suitable for use in the transport decoder 110 shown in Figures 2A and 2b. As shown in Figure 3, the Memory Controller 216 receives data from the TPROC 214 via a Transport In FIFO 310. Memory Controller 216 receives/transmits data from the microprocessor 116 via Micro Interface 217 including Micro-in FIFO 314 and Micro-out FIFO 316. It is noted that the Micro Interface 217, shown external to Memory Controller 216 in Figures 2A and 2B, is shown in Figure 3 for the sake of clearly illustrating its interrelationship with FIFOs 314 and 316.

The Memory Controller 216 also includes a Flow Control Unit 318 containing On Chip Memory, a DMA Controller 320, Datapath logic 322, and FIFOs 324, 326 and 328 for delivering data to the video and audio decoders 224, 226 and 228, respectively.

The Memory Controller 216 writes data into external memory from two sources: one is the TPROC 214 (through the Transport In FIFO 310) and the other is the microprocessor 116 (through the Micro In FIFO 314).

The Memory Controller 216 reads data from external memory and supplies it to the following four destinations 1) Video Interface (through the Video FIFO 324), 2) Audio A Interface (through the Audio A FIFO 326), 3) Audio B Interface (through the Audio B FIFO 328), and 4) microcontroller 116 (through the Micro Out FIFO 316).

The external memory space is divided into separate, non-overlapping buffer areas, one for each DMA Channel in use. Up to 32 channels can be used. A channel number is associated with data written into the two source FIFOs or read out of the four destination FIFOs.

Data provided by the TPROC 214 and written into the Transport In FIFO 310 carries a channel number tag. The channel number for each of the other FIFOs is defined by the microcontroller 116 in a DMA Interface Register. A 128-bit DMA Channel Configuration Register (Channel Register) is set up by the microprocessor 116 for each channel in use. The Channel Register contains configuration information such as the buffer space defined by Begin and End Addresses, whether the buffer is configured as a FIFO (read and write pointers wrap around, sometimes referred to as a circular queue) or as a Queue (read and write pointers do not wrap around), etc.

If the Channel Register allows, the DMA Controller 320 can obtain a new buffer when the one it is currently using becomes full. This feature is normally used only for buffers which store data that is destined for the host microprocessor 116, such as PSI sections. The Begin and End Addresses of these new buffers are stored in a New Buffer FIFO. Only the microprocessor 116 can write new buffers to this FIFO. Used buffer pointers and other types of pointers are written

by the DMA Controller 320 to the Pointers FIFO. In the exemplary embodiment of the present invention, only the microprocessor 116 can read the Pointers FIFO. These pointers are used by the microprocessor 116 to manage reading of buffer data and to return used buffers back to the New Buffer FIFO. The Pointers FIFO Entries Flowchart, shown in Figure 4, shows the entries to the Pointers FIFO for all possible signal conditions, Channel Register configurations and buffer conditions.

Continuing with Figure 3, the DMA Controller 320 and Datapath logic 322 provide all interface signals to the external memory. The Flow Control Unit 318 directs the DMA Controller 320 to service a specific interface FIFO (one of six) by providing the appropriate control signals to it. These include:

1. DMA Controller Start

This signal commands the DMA Controller 320 to start servicing a specific FIFO using the commands such as DMA Controller Operation, DMA Input FIFO Select and DMA Output FIFO Select. At the same time, Flow Control Unit 318 reads out the 128-bit Channel Register and makes it available on the data bus of the Channel Register (internal memory). The DMA Controller 320 reads this 128-bit word into its internal register and the Flow Control Unit 318 is then free to do other read/write operations as required on the internal memory.

2. DMA Controller Operation (1 bit)

This bit signals a Write or Read operation to be performed by the DMA Controller on the interface FIFOs.

3. DMA Input FIFO Select (1 bit)

Signals which of the two input FIFOs 310 or 314 to service.

4. DMA Output FIFO Select (2 bits)

Signals which of the four output FIFOs 316m 324, 326 or 328 to service.

5. Channel Data In Request/Channel Data/Channel Number/DMA Controller Stop:

Usually, the DMA Controller 320 continues to service a FIFO until it cannot service the FIFO any longer due to some condition such as a full interface FIFO, or no data in external memory, etc. When this type of condition occurs, the DMA Controller 320 asserts the Channel Data In Request to the Flow Control Unit 318 and provides the Channel Register data and Channel Number data to the Flow Control Unit 318. The Flow Control Unit 318 updates the Channel Register memory with the Channel Data (updated information includes, for example, the Write and Read Pointers) and directs the DMA Controller 320 to service the next FIFO in the loop, unless a specific FIFO needs emergency action (because, for example, it may be approaching a full or empty status).

Occasionally, the Flow Control Unit 318 may need to issue a DMA Controller Stop command to the DMA Controller 320 in response to a need to service another FIFO such as the Transport In FIFO which may have a higher priority. This command directs the DMA Controller 320 to stop servicing the FIFO it is currently servicing and write the Channel data to the Flow Control Unit 318.

The Channel Register is updated by the DMA Controller 320 with a Read Pointer, a Write Pointer and other information at the point at which it stops servicing a FIFO. Since the Flow Control Unit 318 writes this to the internal Channel Register memory, the DMA Controller 320 can resume service to the interrupted FIFO from the point at which it was interrupted.

With reference to the DMA Controller's participation in the overall operation of the discontinuity state aspect of the present invention, when a next PES packet containing a Stream ID byte is written to the Memory Controller 216 by TPROC 214, the Flow Control Unit 318 causes the DMA_MARK signal to go high. The transition of the DMA_MARK signal triggers an interrupt at microprocessor 116 and the address of the PES packet header is stored in an input pointer FIFO to which the microprocessor has access. Since this PES header may have a time-stamp, the microprocessor 116, responsive to the flag raised by the discontinuity indicator, searches the stored PES headers for a time stamp and, when it finds one, retrieves the time stamp value. Based on the retrieved timestamp value, microprocessor 116 sets a timer interrupt.

Referring back to Figure 3, in the exemplary embodiment of the present invention, internal memory of the Flow Control Unit 318 includes four blocks of 64x32 bits, each of which are assigned for Channel Registers, New Buffer FIFO and Pointers FIFO.

In the exemplary embodiment of the invention, each Channel Register has 128 bits and there may be a maximum of 32 channels, so up to 128x32 bits can be assigned to Channel Registers, in multiples of 128 bits.

Words of 32-bits are written to and read from the New Buffer and Pointers FIFOs. At least 128x32 bits of memory (i.e., 128 words) are available for the New Buffer and Pointer FIFOs. Additionally, if less than 32 channels are in use, unused capacity from the Channel Register memory can be allocated to the New Buffer and Pointer FIFOs.

Following are examples of memory allocation for 32 DMA channels and 16 DMA channels.

1) Memory allocation for 32 used channels

New Buffer FIFO=64x32 bits
Pointer FIFO=64x32 bits
Channel Registers=128x32 bits

2) Memory allocation for 16 used channels

New Buffer FIFO=64x32 bits
Pointer FIFO=128x32 bits
Channel Registers=128x16 bits

CLOCK MANAGER 218

The Clock Manager 218, shown in Figures 2A and 2B, of the transport decoder 110 synchronizes a local 27 MHz signal (generated by clock signal circuitry 122) using successive PCR values. The value of the counter in the Clock Manager 218 is referred to as the System Time Constant (STC) value. The microprocessor 116, in the exemplary embodiment of the present invention, has access to the STC value in the counter via the internal microbus 223.

The counter in the Clock Manager 218 is periodically synchronized to the PCRs carried in the transport data stream. When the first PCR in a data stream is encountered, the PCR is "jam loaded" in the counter to become the initial STC value. As subsequent PCR values are received, they are compared to the STC value to adjust the frequency of the clock signal circuitry 122 (e.g., VCXO). In the present invention, this is accomplished using a Digital-to-Analog converter (DAC) described in detail below. Once phase error adjustments are made, generally, the new PCR value is loaded as the STC value.

Normally PCR values occur once per frame. Under the MPEG-2 standard, they must occur at least in every third frame (one-tenth of a second).

The external video and audio decoders 118 and 120 are typically synchronized to the transport decoder 110 by updating the STC value in the external decoders based on the STC value maintained in the Clock Manager 218. The video and audio decoders 118 and 120 use the stored value to determine when data is to be decoded/displayed by comparing it to timestamps in the received PES datastream. It is noted that, in the exemplary embodiment of the present invention, the transport decoder 110, video decoder 118 and audio decoder 120 all receive the same 27 MHz clock signal generated by the Clock Manager 218.

The transport decoder 110 contains hardware support for locally generating a clock signal that is locked to the system clock signal for a selected program. As mentioned above, PCR values received on the specified PCR_PID are made available on a serial interface for use by other devices.

The Clock Manager 218 includes a System Time Counter (STC) (not shown), a System Time Clock Register (not shown), a Program Clock Reference Register(not shown), a Current STC Register (not shown), an Alarm Clock Interrupt Register (not shown) and logic (not shown) to latch PCRs extracted from the headers that are associated with a selected PID. It also contains the serial PCR interface, and a DAC Register for control of an external system clock signal control loop.

In the exemplary embodiment of the present invention, the STC is a 42-bit counter having a 9-bit base and 33-bit extension.

The STC base divides the nominal 27 MHz System Clock input signal by 300. The resulting 90 KHz signal drives the STC extension. The STC can be read or written by software executing on the microprocessor 116 at any time. Optionally, the STC can be automatically loaded with a received PCR after a discontinuity indicator has been encountered.

As mentioned above, PCRs may be automatically extracted from the incoming bit stream by setting the PCR_PID bit in a PID Table entry. Handling of the received PCRs depends upon options set by software and whether a discontinuity state exists for the current transport packet when the PCR is received.

A discontinuity state is recognized when a transport packet which contains the PCR_PID is received with a logic 1 in the discontinuity_indicator bit in the Transport header. The discontinuity state exists until either a transport packet containing the PCR_PID is received with a logic 0 in the discontinuity_indicator, or until the next PCR is found in a PCR_PID packet.

If enabled, the Clock Manager 218 automatically loads the received PCR into the STC when a PCR is received

while a discontinuity state exists. At this instant, an interrupt is issued to the host microprocessor 116.

The Clock Manager 218 contains an Initialize bit which, when set to logic 1 by software, causes the next PCR received to be loaded into the STC regardless of whether a discontinuity state exists or not. The Initialize bit is subsequently cleared automatically by the Clock Manager 218. The Initialize bit is set only when the STC does not contain a valid PCR (i.e., when a new PID has been selected.)

If no discontinuity state exists or if the automatic STC loading function is disabled, a received PCR is stored in the PCR register and (optionally) an interrupt is issued to the host microprocessor 116. At the same time that the PCR is captured, the current state of the STC is stored in the STC Register. The stored PCR and STC values are used to compute an error signal to control the external system clock signal (XOCLK).

When a Transport Packet is received which has a PID equal to the PCR_PID and which contains a PCR, the PCR is latched in the PCR Register. The current contents of the STC Counter are also latched in the STC Register at that time, and an interrupt is issued to the host microprocessor 116. Latching both values eliminates any uncertainty due to varying latency in the interrupt service routine. In the exemplary embodiment of the present invention, both registers consist of a 9 bit base and 33-bit extension. The base part is modulo 300, whereas the extension is binary. Before the register contents can be used in any calculations, they are converted to a single binary count by multiplying the extension by 300 and adding the base part to the result.

The Current STC Register is a read-only register which allows the microcontroller 116 to obtain the current contents of the STC at any time. The microcontroller 116 can initialize the STC of the Video Decoder or Audio Decoder with this value by way of the external microbus 124.

As described above, transport decoder 110 contains a 10-bit digital-to-analog converter (DAC) 230 for use in the clock adjustment control loop within the Clock Manager 218. The DAC 230 is write-only, i.e., software keeps a copy of the last value loaded into the DAC in memory. In operation, the DAC 230 is used to generate the control voltage for the external resonant crystal voltage controlled oscillator, VCXO 122, which is source of the system clock frequency (27 MHz nominal). By comparing the latched PCR and STC values, software can determine whether the local clock signal requires adjustment. For example, software may take the difference between the PCR and STC and add this error term to the current contents of the input register of DAC 230.

To review, the discontinuity aspect of the present invention includes:

1) The Channel Data Processor (CDP) 210 checks the synchronization byte in received transport packets to validate the packets. The Transport Processor (TPROC) 214 parses the transport header and passes the packet payloads to the proper location in the memory. Data is directed to different FIFO buffers (channels) in the memory based on the PID values in the transport headers.

2) Because a received discontinuity indicator is not necessarily in the same packet as the next PCR value, when the next PCR value is received, the TPROC 214 "jam loads" the counter in the Clock Manager 218.

3) When the next PES packet containing a Stream ID byte is written to the Memory Controller 216 by TPROC 214, the DMA_MARK signal goes high. This causes the Memory Controller 216 to interrupt the microprocessor 116 and store the address of the PES packet header in an input pointer FIFO. This PES header may have a time-stamp (either decode timestamp or presentation timestamp). The microprocessor 116, responsive to the interrupt from the Memory Controller 216, searches the PES headers for a time stamp and, when it finds one, retrieves the time stamp value.

4) The microprocessor 116 then sets a timer interrupt for a time that is just less than one frame time before the timestamp value.

5) When this timer interrupt occurs, the microprocessor 116 sends the new PCR value to the video and audio decoders by way of the external microbus 124. This gives the decoders sufficient time to process the data before its time-stamp is compared to the counter value in the video or audio decoder, without interfering with the processing of data that is reverenced to the prior PCR value.

VIDEO/AUDIO DECODERS 224, 226, 228

Once the transport packets are received, processed and stored, as mentioned above, Memory Controller 216 reads the PES packets out of memory 114 and forwards them to the external video and audio decoders. Before the PES packets reach the external decoders 118 and 120, however, they are processed by internal video and audio processors 224, 226 and 228.

An important role of these internal processors is to ensure that the stream of data leaving the transport decoder is compatible with the external decoders. That is, different external decoders have different data requirements.

For example, some currently available external video decoders can accept a stream of PES packets, including header and payload, essentially in the same form in which it is read out of memory. On the other hand, some external decoders can only accept for processing an elementary stream (i.e., PES packet payloads but no headers). Additionally, the latter type of decoder may require, in addition to the datastream, associated control information such as timestamps and byte counts. One such video decoder is the CL9100 made by C-Cube, the specification of which -- CL9100 Multimode Video Decoder User's Manual (10/94) -- is hereby incorporated by reference. Accordingly, video processor 224 is configurable, by way of microprocessor 116, to format the outgoing datastream to be compatible with the requirements of the selected external decoder.

With respect to handling the interface to an external video decoder such as a C-Cube CL9100, video processor 224 processes the stream of PES packets in order to strip off the PES header and extract, from the PES header, timestamp information. In addition, video processor 224 maintains a byte count, using a counter (not shown), for the PES packets forwarded to the external decoder. Thus, video processor 224 holds timestamp information, maintains a byte count and forwards the PES packet payloads on to the external video decoder. In order to get the timestamp and byte count information to the external decoder, video processor 224 sends an interrupt to microprocessor 116 which, when it responds, reads the timestamp and byte count information from the video processor 224 via the internal microbus 223 and delivers this control information to the external video decoder via the external microbus 124.

Sometimes, however, before microprocessor 116 is able to respond to the interrupt from video processor 224, another PES header with timestamp information arrives. This may occur, for example, if the microprocessor 116 was involved with a higher priority task for an extended period of time. In this case, video processor 224 stores the timestamp information along with a status. In particular, video processor 224 maintains a status register indicating whether microprocessor has "missed" any timestamps. When, in the exemplary embodiment of the invention, microprocessor 116 finally begins to read the timestamp information, if it has missed one or more timestamps as indicated in by the status, it only retrieves the most recent timestamp.

Additionally, since timestamp information and byte count information are to be provided to the external decoder, when the microprocessor 116 misses a timestamp, video processor 224 maintains a cumulative byte count for however many timestamps may arrive before microprocessor 116 reads the information. Thus, microprocessor 116 reads the most recent timestamp and cumulative byte count and delivers this information to the external video decoder. Subsequently, the status register and byte count may be reset.

As shown in the flowchart of Figure 5A, the headers of received data are stripped and parsed (step 510), timestamp information is stored and a byte count is maintained (step 512), an interrupt is issued by video processor 224 to microprocessor 116 alerting it that timestamp information is available for reading (step 514), if additional timestamp information is received before microprocessor reads the previous timestamp information, the new timestamp information is stored, the byte count continues to accumulate (step 516) and the video processor 224 issues another interrupt to the microprocessor 116, otherwise microprocessor reads the status register, the timestamp information and the byte count information and delivers it to the external video decoder (step 518).

Another example of accommodating particular external decoders involves the use of bit rate-constrained audio decoders such as the Zoran ZR38500 AC3 audio decoder, the Specification (10/94) for which is hereby incorporated by reference. Generally, most audio decoders present a data request indicating they can accept audio data and then the transport decoder 110, via the audio processors 226/228, supplies audio data until the external audio processor negates the requests. In other words, there exists a handshake mechanism.

Bit-rate constrained decoders, however, such as the Zoran AC3 audio decoder, require that audio AC3 data be delivered as audio data frames, each frame including a frame time and bit-rate in its header. Delivering data in excess of this predetermined bit rate can cause the internal buffers to overflow and, consequently, cause a loss of data. Furthermore, these bit-rate constrained decoders do not provide a Data-Ready signal to indicate that they are ready to accept additional audio data.

Thus, as with the video decoder 224, the audio processors 226 and 228, are configurable to accommodate the selected external audio decoder. It is noted that, in the exemplary embodiment of the present invention, audio processors 226 and 228, except for addresses which allow access by microprocessor 116, are essentially identical.

Accordingly, audio processors 226/228, when programmed to interface with this type of audio decoder, assumes that the decoder is always issuing a data request signal. However, as PES packet audio data is supplied to audio processors 226/228 from Memory Controller 216, the PES header of the received data is parsed by the audio processors. Contained in the parsed header is a frame size and bit rate for the audio data. From the frame size and bit rate, the audio processors 226/228 can determine the frame boundary (i.e., frame time). Having frame time information, audio processors 226/228 set a frame timer such that, when audio data is available, the timer is set, a frame of data is "burst" out to the external audio decoder then the audio processors 226/228 and then pause until the frame timer expires. When the timer expires, the cycle continues, one audio frame at a time, while additional frames are available for sending to the external audio decoder. Control information, such as timestamps, are retrieved by the microprocessor and delivered via the external microbus.

As shown in the flowchart of Figure 5B, PES packets are retrieved from memory (step 542), the headers of received

data are stripped and parsed (step 530), a frame time is determined (step 532), the timer begins running (step 534), audio processors 226/228 burst out a frame of data (step 536) and audio processors 226/228 pause until the timer expires (step 538), although, as shown, steps 542, 530 and 532 can be carried out during the pause. Then, the process can continue.

Although the invention is illustrated and described herein as embodied in a method and apparatus for updating the system time constant following a discontinuity in an MPEG-2 transport data stream, the invention is not intended to be limited to the details shown. Rather, various modifications may be made in the details within the scope and range of equivalents of the claims and without departing from the spirit of the invention.

Claims

1. A method for use in a transport decoder system designed for decoding a transport data stream which includes transport packets having headers and payloads, the headers including a discontinuity indicator, said system including at least one buffer for temporarily storing the received transport data stream and at least one decoder for decoding data output from the buffer for presentation purposes, each of said transport decoder and said decoder having separate counters, the method being a method for handling the receipt of a program counter reference (PCR) after a discontinuity state has been set comprising the steps of:

   parsing received transport packets and storing the data in memory;

   upon receiving a next PCR value, loading the transport decoder counter with the received program counter reference value;

   searching the data stored in memory which is received after the PCR value for a time stamp and retrieving the time stamp;

   setting a timer interrupt based on the retrieved time stamp value; and

   when the timer interrupt occurs, sending the PCR value to the counter of the decoder, thereby providing sufficient time for the decoder to process data.

2. The method of claim 1, wherein the timer interrupt is set for just less than one frame time before the time stamp value.

3. The method of claim 1, wherein the step of searching includes

   upon receipt of a transport packet which may contain a time stamp value, interrupting a host microcontroller to send the host microcontroller address information relating to the stored transport packet;

   subsequently, searching at the appropriate address location of the stored transport packet for a time stamp value.

4. The method of claim 1, further comprising the step of:

   before parsing, validating received transport packets by determining whether their boundaries correspond to predetermined packet boundaries and parsing only those packets which have been validated.

5. The method of claim 4, wherein the step of validating the received transport packet includes checking a synchronization byte in the received transport packet.

6. In a system designed for receiving a transport data stream which includes transport packets having headers and payloads, the headers including a discontinuity indicator, said system including at least one buffer for temporarily storing the received transport data stream and at least one decoder for decoding data output from the buffer for presentation purposes, each of said transport decoder and one decoder having separate counters, an apparatus for handling the receipt of a discontinuity indicator comprising the steps of:

   means for receiving and detecting a discontinuity indicator;

   means for parsing the transport packets and storing the data in memory;

means, upon receiving a next program counter reference value, for loading the transport decoder counter with the received program counter reference value;

means for searching the data stored in memory for a time stamp and, when one is found, for retrieving the time stamp;

means for setting a timer interrupt based on the time stamp value; and

means, when the timer interrupt occurs, for sending the program counter reference value to the counter of the one.

7. In a transport decoder system designed for decoding a transport datastream which includes transport packets having headers and payloads, the headers including a discontinuity indicator, said transport decoder coupled to at least one external decoder for decoding data output from the transport decoder, each of said transport decoder and said external decoders having separate counters for maintaining synchronization to the datastream, a method for handling the receipt of a discontinuity indicator comprising the steps of:

receiving the discontinuity indicator;

parsing the transport packet and storing the data in memory;

upon receiving a next program counter reference value, loading the transport decoder counter with the received program counter reference value;

searching the data stored in memory for a timestamp and, when one is found, retrieving the timestamp;

setting a timer interrupt for a point in time approximately one frame time before the time stamp value; and

when the timer interrupt occurs, sending the program counter reference value to the counter of the decoder, thereby providing sufficient time for the decoder to process data.

[54]发明名称 用于处理非连续程序数据的数字视频解码器

[57]摘要

接收和处理使用 MPEG-2 格式的传输数据流的传输解码器包括：与物理层通道接口的连接，缓冲存储器，主微处理器，音频和视频解码器，时钟信号电路。收到不连续性指示位时对传输包首部进行语法分析并将有效部分存于存储器。收到下一程序计数器参考（PCR）值时将其载入计数器。在存储器内搜索时间标记，若发出则将其恢复。在时间标记值前约一帧时刻设置定时器中断，该中断发生时，程序计数器参考值被送往解码器，为解码器提供足够数据处理时间。

(BJ)第 1456 号

权 利 要 求 书

1. 一种用于传输解码器系统的方法，所述系统用于对传输数据流解码，该数据流包括由首部和有效部分组成的传输包，首部包括不连续性指示位，所述系统包括至少一个缓冲区和至少一个解码器，前者用于临时存储接收到的传输数据流，后者用于对来自缓冲区的数据输出解码供显示之用，所述每个传输解码器和解码器都有各自的计数器，此方法用于在设定了不连续状态后处理程序计数器参考（PCR）的接收，其特征在于包括以下步骤：

对接收到的传输包进行语法分析，并将数据存入存储器；

一旦接收到下一个 PCR 值，将接收到的程序计数器参考值载入传输解码器计数器中；

对 PCR 值之后接收并储存在存储器中的数据进行数据标记搜索并将检索该数据标记值；

基于检索后的时间标记值设置定时器中断；以及

当定时器中断发生时，将 PCR 值传送给解码器的计数器，从而为解码器提供充足的时间处理数据。

2. 根据权利要求 1 所述的方法，其中，在时间标记值之前不足一帧的时间处设置定时器中断。

3. 根据权利要求 1 所述的方法，其中的搜索的步骤包括：

一旦接收到含有时间标记值的传输包，中断一台主微控制器以发出与存储的传输包相关的主微控制器地址信息；以及

接着，在存储的传输包的适当地址位置搜索时间标记值。

4. 根据权利要求 1 所述的方法，还包括以下步骤：

在进行语法分析之前，通过确定接收到的传输包的边界是否与预确定的包边界符合使它们生效，并且只对生效的包进行语法分析。

5. 根据权利要求 4 所述的方法，其中使接收到的传输包生效的步骤包括检查接收到传输包中的同步位。

6. 在用于接收传输数据流的系统中的一种处理不连续性指示位的接收的装置，该数据流包括由首部和有效部分组成的传输包，首部包括不连续性指示位，所述系统包括至少一个缓冲区和至少一个解码器，前者用于临时存储接收到的传输数据流，后者用于解码来自缓冲区的数据输出供显示之用，所述每个传输解码器和解码器都有分离的计数器，所述装置的特征在于包括：

接收和检测不连续性指示位装置；

对传输包进行语法分析并将数据存储在存储器中的装置；

一旦接收到下一个程序计数器参考值，将接收到的程序计数器参考值载入传输解码器计数器中的装置；

在存储器中存储的数据中搜索时间标记并在发现后检索时间标记值的装置；

基于时间标记值设置定时器中断的装置；以及

当定时器中断发生时，将程序计数器参考值发送到该计数器的装置。

7. 在一个用于解码传输数据流的传输解码器系统中，该数据流包括由首部和有效部分组成的传输包，首部包括不连续性指示位，所述传输解码器与至少一个外部解码器配合以解码来自传输解码器的数据输出，所述每个传输解码器和外部解码器都有分离的计数器以保持

与数据流同步，一种处理不连续性指示位的接收的方法包括以下步骤：

接收不连续性指示位；

对传输包进行语法分析并将数据存储在存储器中；

一旦接收到下一个程序计数器参考值，将接收到的程序计数器参考值载入传输解码器计数器中；

在存储器存储的数据中搜索时间标记并在发现后检索时间标记值；

在时间标记值前大概一帧的时间处设置定时器中断；以及

当定时器中断发生时，将程序计数器参考值发送到解码器的计数器中，从而为解码器提供充足的时间进行数据处理。

说 明 书

用于处理非连续程序数据的数字视频解码器

本发明涉及根据 MPEG-2 标准编码的数据进行数据接收、处理、及传输，具体来说，本发明涉及处理 MPEG-2 格式数据流的传输解码器的操作和接口。

高清晰度电视(HDTV)在试图替代传统的电视机方面继续取得进展。多家公司和协会正努力制定多种标准以供应 HDTV 的全球市场，从而为这种进展铺平道路。

其中有一个公司集团又被称为“数字高清晰度电视大联盟”，它包括 AT&T、David Sarnoff 研究中心、麻省工学院和其他一些机构。Robert Hopkins 在 1994 年夏季的《消费者电子 IEEE 交易》上发表了一篇以“北美数字陆地高清晰度电视：大联盟高清晰度电视系统”为名的文章，全面概述了该集团的长足进步。在此将引用该文章关于 HDTV 系统的背景和基础知识方面的教导以供参考，其中包括对程序和传输包流的使用。

大联盟采用由国际标准组织(ISO)下属的动态图像专家组(MPEG)开发的 MPEG-2 标准对视频和音频信息进行编码。被接受的标准定期发表在下列刊物上：动态图像和相关音频 ISO/IEC 13818 - 2(1995 年)的通用编码：信息工程的视频部分(下文简称为“视频部分”)，动态图像和相关音频 ISO/IEC 13818 - 1(1994 年 11 月)的信息工程的系统部分(下文简称为“系统部分”)。在此将引用二者关于已建立的标准和格式方面的教学资料以供参考。

MPEG-2 标准的语法定义了几种数据记录层，用来传送音频和视频数据。例如，为了传输信息，一个表示多视频序列的数字数据流被分为

多个较小的单元。每个单元被分别封装成多个打包的基本流(PES)包中。为了传输需要，每一个打包的基本流包被依次分割成多个定长传输包。每个传输包包含的数据只与一个打包的基本流包有关。传输包还包括一个首部，其中带有控制信息，有时也包括适应字段子段，用于对传输包解码。然而，打包的基本流数据也可能包括多种基本流。

正如在系统部分所述，多种基本流之间的同步是通过定期在数据流中提供时间标记实现的。例如，N 个基本流的解码是通过将流的解码校正到一个通用主时基的方式实现的，而不是调整一种流的解码以适应另一种流的解码。主时基可能是 N 个解码器中某一个的时钟信号，或者是数据源的时间信号，还可能是一个外部提供的时钟信号。

为了有助于该同步处理，MPEG-2 标准的传输首部中还包括一个不连续性指示位。系统部分提供了一种语法表示以显示一个典型的“不连续性指示位”在传输首部中的位置。该语法在以下的表 1 中有具体描述。

                    marker_bit                          1       bslbf
                }
                for (i=0;i<N;i++){
                    reserved                            8       bslbf
                }
            }
            for (i=0);i<N;i++){
                stuffing_byte                           8       bslbf
            }
        }
    }
```

如系统部分中所述，不连续性指示位在传输首部内的适应字段中。不连续性指示位是一个 1 位的字段，设为逻辑值“ 1 ”时，表示当前的传输流包的不连续性状态为真。当不连续性指示位设为逻辑值“ 0 ”或不存在时，不连续性状态为假。不连续性指示位用于表示下列两种不连续性状态：系统时基不连续和连续性计数器不连续。

通过在被指定为程序时钟参考（ Program Clock Reference — PCR ）程序标识 的传输流程序标识（ PID ）中使用不连续性指示位，可以指示系统时基的不连续性（参见系统部分第 50 页的 2.4.4.9 ）。接下来，可以接收到一个程序时钟参考（ PCR ）值（即所谓主时钟信号）。

例如，当使用一个时基记录的节目材料被插入采用另一个时基记录的数据流中时，设定不连续性指示位。时基中的差别表现为一个不可知的程序时钟参考（ PCR ）值。

当一个被指定为 PCR 程序标识 的程序标识 的传输流包的不连续状态为真时，使用同一个程序标识 的传输流包中下一个 PCR 表示相关节目的新系统时间时钟取样。当包括一个新系统时基的 PCR 的包的第一个字

节到达系统目标解码器（ STD ）的输入端时，系统时基不连续点被定义为这个时刻。

值得注意的是：系统目标解码器在先有技术中广为人知，简而言之，它是表示一个在概念上与传输编码器的输出端相连的假定解码器。要求的条件是符合 MPEG-2 标准的数据流不会引起系统目标解码器的数据溢出问题（其中包括缓冲区溢出）。对系统目标解码器的其他讨论在系统部分给出。

紧接着，在传输流包中不连续指示位也可能被置为“ 1 ”。这些传输包都属于包含新的系统时基 PCR 的包的前一个程序时钟参考 程序标识。在这种情况下，一旦不连续性指示位被置为“ 1 ”，在同一个程序 PCR 标识的所有传输流包中它都被置“ 1 ”，该程序 PCR 标识符合和包括包含新系统时基的第一个 PCR 的传输流包。当系统时基的不连续性发生时，新的系统时基的不少于两个 PCR 在另一个系统时基不连续性发生之前被接收。进一步来说，除非欺骗模式状态为真，否则来自不多于两个系统时基中的数据会在任意时间出现在一个程序的系统目标解码器缓冲区中。

当时基不连续性要求更新多系统时间常数（ STC ）值时（即在传输解码器的时钟管理器和在外部的视频和音频解码器中），特别是当等待时间可能存在于正被外部解码器解码的数据和正被接收并储存在传输解码器的缓冲区中的数据之间时。换句话说，典型的情况是一个传输解码器与外部的视频和音频解码器耦合，后者中每一个都保存一个 STC 或等价的值。因此，当系统时基发生改变时，同时校正所有的 STC 值就可能引发系统的同步问题。

考虑到这个因素，本发明所要解决的一个重要问题在于传输解码器怎样才能有效地处理缓冲器和解码器之间的系统时基不连续性问题。

本发明包括一个用于接收传输数据流的系统，该数据流包括具有不连续性指示位的首部和有效内容的传输包。该系统至少包括一个缓冲存储器和一个外部解码器，前者用于临时储存接收到的传输数据流，后者用于解码来自缓冲区的数据输出以供显示之用。本发明用于处理对不连续性指示位的接收，其手段是通过接收到不连续性指示位后对传输包的首部进行语法分析，以及将传输包的有效内容存入存储器。一旦接收到下一个程序计数器参考值，一个计数器中就会装入接收到的程序计数器参考值。然后在储存的数据中搜寻时间标记，一旦发现，就检索该时间标记。最后，基于已检索到的时间标记为某一个时间点设置一个定时器中断，并且当定时器中断发生时，将程序计数器参考值送往解码器，同时向解码器提供新时间标记值不充分时间，使之能处理含有新的时基的数据，而无需干扰对含有前一时基的数据的处理。

概述

如上文所述，本发明的一个重要方面在于解决传输解码器如何高效地处理不连续性指示位的问题。本发明的另一个重要方面在于处理传输解码器和仅能处理基本流数据的视频解码器之间的接口问题。另外，本发明还有一个方面涉及传输解码器和位速率限制音频解码器之间的接口问题。为了全面介绍以上的各个方面，本发明包括一个特别设计的 MPEG-2 传输解码器。

如果一个节目使用 MPEG-2 格式通过卫星向全国的多个接收站播放，一个时基不连续的实例就出现了。这就是为介绍本发明的不连续性部分提供的具体环境。但是，在节目播出的过程中，每个接收站会加入自己的商业广告节目。在这种情况下，应设置一个不连续性位来指示节目时基中的空白或间断，以便于自己拥有本地时基的商业广告的插入。

然而，当各个接收站插入各自的节目时，来自卫星的节目传输并不会中断。由此可知，当遇到不连续性指示位时，接收来自本地接收站并带有插入广告内容的节目的传输解码器的内部定时会跟踪适当的时基。

再看看附图，图 1A 示出了一个典型的数字传输解码器 110 的高级功能框图以及各种接口。如图 1A 所示，传输解码器 110 包括与以下各部分的连接：物理层通道接口（又叫通道接口） 112 、缓冲存储器 114 、主微处理器 116 、外部视频和音频解码器 118 和 120 以及时钟信号电路（例如 VCXO ） 122 。在本发明的典型实施例中，传输解码器 110 支持一个视频接口和多达两个音频接口（例如，音频接口 A 和 B ）。

处于传输解码器 110 外部的主微处理器 116 也通过微总线 24 与视频和音频解码器 118 和 120 耦合。这种连接可以使用并行或串行数据路径，并根据被选择使用的单个外部解码器的要求而变化。在任何情况下，将主微处理器 116 和外部解码器连接起来的方法都是众所周知的，同时也为拥有普通技艺的人员所理解。

一般来说，传输解码器 110 和每个外部视频和音频解码器 118 和 120 都包括一个的系统时间常数（ STC ）值（图中未给出）。该值储存在寄存器或计数器中用于使接收到的数据流的解码和显示同步。

如上所述，当时基不连续在数据流中发生时可能出现问题，而且这种不连续要求 STC 值在传输解码器 110 和视频及音频解码器 118 和 120 中同时更新。特别容易发生问题的时间是当等待时间可能存在于正被外部解码器解码的数据和正被接收并储存在传输处理器 110 中的数据之间时。

在本发明中，微处理器 116 在控制数据流的同步和视频及音频解码器 118 和 120 的运作方面起着十分重要的作用。在本发明中，微处理器 116 对传输解码器 110 中的多个芯片寄存器能进行直接的存储器映射式存取。微处理器 116 还能通过读、写、和水印指针对外部存储器 114 内的缓冲区和芯片上 32 位可读写 FIFO （如图 3 中所示）进行存取。微处理器 116 通过一个内部微总线 223（如图 2B 所示）与多个内部功能块连接，从而允许各种事件和错误状态通过可屏蔽中断用信号发出。

一般来说，如图 1B 所示的流程图中，本发明的一个方面通过特别设计的传输解码器 110 在接收到不连续性指示位（步骤 150 ）后执行以下步骤：

1) 由于不连续性指示位不必和下一个程序时钟参考值（ PCR)处于同一个数据包中，所以当下一个程序时钟参考 值被接收后，位于传输

解码器 110 中的时钟管理电路（如图 2A 中所示）内的计数器中将装载下一个程序时钟参考值（ PCR ）（步骤 152 ）；

3) 在经过语法分析并存储在存储器中的后续包中搜索时间标记，一旦找到某一个，则将检索时间标记值（步骤 154 ）；

4) 由微处理器 116 在某个时间点设置定时器中断，该时间点只比检索的时间标记值提前不到一帧的时间（步骤 156 ）；而且

5) 当定时器中断发生时，当前 STC 值被送往外部视频和音频解码器 118 和 120 （步骤 158 ），从而给外部解码器足够的时间以抢在数据流中的时间标记值与保存在视频或音频解码器 118 或 120 中的计数器值进行比较之前处理数据。

下文将详细介绍这些高级步骤的执行情况。

图 2A 和图 2B 示出了图 1A 所示的传输解码器 110 的典型执行过程的高级功能框图。下文参照图 2A 和 2B ，介绍传输解码器 110 中的总体数据流动情况。

如图所示，图 1A 的通道接口 112 与通道数据处理器（ CDP ） 210 相连。通道接口 112 还向 NRSS 接口 212 提供数据，以便用 NRSS 智能卡 230 加密。在此特结合 NRSS 委员会（ 4/95 ）的条件存取 EIA 标准 2.6 版关于 NRSS 智能卡的论述以为参考。

通道数据处理器 210 被提供用于预处理（如检测、同步、确认等）所接收数据流中的包。处理完毕后，通道数据处理器 210 将输出数据发送到传输处理器（ TPROC ） 214 中供进一步处理之用。传输处理器 214 根据下文详细描述的程序标识表进行多种处理，例如语法分析等。

传输处理器 214 与传输解码器 110 中的多个功能块进行交互。这些功能块包括：存储器控制器 216、时钟管理器 218，个人数据处理器 220 和高速数据端口 222。如上所述，微处理器 116 能对多个芯片寄存器直接存取。这种存取是通过微接口 217 和内部微总线 223（如图 2B 所示）获得的。存储器控制器 216 除了与传输处理器 214 连接外，还与外部存储器 114 和视频及音频解码器（224、226 和 228）相连。

现在介绍一下与单个功能块有关的数字数据流的处理细节。

通道数据处理器（CDP）210

值得指出的是来自通道接口 112 中的数据流经过可能的缓冲后（图中未给出）被送往通道数据处理器 210。

通道数据处理器 210 对接收到的数据流执行多种预处理步骤。具体来说，通道数据处理器 210 决定数据流中字节和帧的边界，并将接收到的数据流转换为 8 位的并行格式。在本发明的典型实施例中，在通道数据处理器 210 后在传输解码器 110 中进行的操作使用字节格式进行。

为了确定字节和帧的边界，通道数据处理器 210 与传输包首部包含的帧模式同步。具体来说，这种同步是通过搜索 MPEG-2 的传输流同步字节（sync_byte）（例如：47H）并确认它在可编程数目的连续传输包开始处发生而实现的。

在此过程中，通道数据处理器（210）核对同步字节，将数据流锁定并继续确认包。当同步位的搜索在进行中时，在 CDP 状态寄存器中设置搜索状态位（Search_State）（图中未给出）。一旦发现了同步字节并且对连续发生的确认在进行之中，同步状态位（Sync_State）就设定了。最后，当符合预先确定的搜索标准时，设定锁定状态位（Lock_State）。在本发明的典型实施例中，搜索标准是三个连续的确认过的包。同样，指示带有损坏同步位的包数目的同步滞后值被设定。对通道数据处理器

210 编程使这些同步位在宣布损失锁定状态之前就能通过。当这个滞后值被超过时，锁定的损失被宣布。通道数据处理器 210 然后发出一个锁定损失中断并且从锁定状态过渡回搜索状态。

另外，如果通道接口 112（如图 1A 所示）提供一个 CHPSTRT 信号，传输解码器 110 可能被设置以使用此信号作为一种手段来与数据流同步，方法是将通道数据处理器帧和同步控制寄存器中的帧模式位（Framing_Mode）设为逻辑值“1”。在此情况下，当 CHPSTRT 被确定后，在一个传输包时间内可获得同步。

另一种情况是，如果通道数据处理器帧和同步控制寄存器中的忽略同步位被置为逻辑值“0”，则通道数据处理器 210 在相对于 CHPSTRT 信号过渡过程的预定字节（第一个字节）处校验同步位的完整性，并当校验失败时宣布锁定状态。如果忽略同步（Ignore-Sync）设置为“1”，则通道数据处理器 210 不校验同步的完整性。

取得了锁定状态后，通道数据处理器 210 的输出被传输到传输处理器 214 并由其进行处理，后者以字节的格式对数据进行处理（例如，过滤、语法分析、格式化等）。

传输处理器（TPROC）214

由传输处理器 214 产生的信号控制数据流动去往：存储器控制器 216、微接口 217、时钟管理器 218、个人数据处理器 220、和高速数据端口 220。

在本发明的典型实施例中，传输处理器 214 在程序标识表的控制下处理数据流。如系统部分所述，一个程序标识是传输流首部中一个 13 位的字段，表明存储在包有效数据中的数据类型。一些程序标识值被分配，另一些则被保留。程序标识表的另一些细节在上文提到的 MPEG-2 规范中的系统部分的 3.3 节给出。

根据程序标识表，传输处理器 214 能同时处理多达 32 个用户可选择的程序标识。传输解码器 110 所处理的程序标识在程序标识表中均有规定。程序标识表中的位字段指定了各种数据处理选项。

在操作过程中，程序标识由传输处理器 214 从刚刚到达的传输包的首部中抽取出来，并同时与程序标识表中的所有项目比较。一旦发生匹配，就根据匹配程序标识表项中设定的选项对包中的数据进行处理。如果程序标识表项没有匹配的，就放弃该包。

有效部分格式位没有设定为放弃（000）的程序标识表中每一个地址都与一个通道号相连。存储器控制器 216 与传输处理器 214 相连，负责向 RAM 中特定的缓冲区（通道）传输数据。关于存储器控制器 216 的操作问题在下文中与图 2、3、4 有关的部分具体讨论。

在本发明的典型实施例中，保存于传输处理器 214 中的程序标识表由微处理器 116 在初始化过程中通过微总线 223 利用软件设置。

关于程序标识表项的格式，除了其他信息外，一个程序标识表项还包括：1) 一个 13 位的程序标识，和 2) 一个 1 位的 PCR 程序标识字段。后者一旦设定，就表明对于被解码的程序来说，此程序标识带有 PCR。一个典型的程序标识表项还包括一个 1 位的打包的基本流 HDR 位，它一旦设定，就使得与打包的基本流首部中的“流标识”对应的 RAM 缓冲区地址储存于指针 FIFO 中。当存储器控制器 216 向指针 FIFO 中写入数据时，它发出一个中断。这个中断又被称为一个 DMA_MARK 信号，用于提醒微处理器 116 发送流标识（Stream_ID）字节。在本发明的典型实施例中，以基于表中位置的数字顺序向程序标识表项分配通道号。例如，向第一项分配 DMA 通道 0，向下一项分配 DMA 通道 1 等等。

传输处理器 214 表明带有程序时钟参考程序标识的传输包应该由时钟管理器 218 通过在程序标识表项中放入 PCR_PID 信号进行处理。时钟管理器（218）监视带有 PCR_flag（标志）的包的适应字段，并抽取 PCR。

传输处理器 214 根据包的程序标识将它们分开，然后除去传输包的首部，并结合存储器控制器 216 将程序标识包的有效部分（例如，打包的基本流包的部分）分别存储在外部存储器 114 中指定通道的顺序排列存储区字段。存储器 114 中的数据表示打包的基本流包。

传输处理器 214 还处理从主微处理器 116 向外部存储器进行的写操作。

存储器控制器 216

存储器控制器 216 将传输包中经过语法分析的有效部分存储在外部存储器 114 中，并根据需要向视频处理器 224、多达两个音频处理器 226 和 228 以及主微处理器 116 或微控制器提供视频、音频、PSI 和其他数据（如个人数据）。

图 3 给出了适用于图 2A 和图 2B 中显示的传输解码器 110 的存储器控制器的典型功能框图。如图 3 中所示，存储器控制器 216 通过 FIFO310 从传输处理器 214 中获得数据。存储器控制器 216 通过由微输入 FIFO314 和微输出 FIFO316 组成的微接口 217 从微处理器 116 中取得和传输数据。值得指出的是，图 2A 和图 2B 的存储器控制器 216 外部的微接口 217 在图 3 中也给出了，以便清楚地表示它与 FIFO314 和 316 的相互关系。

存储器控制器 216 还包括一个流程控制单元 318，它包括芯片存储器、一个 DMA 控制器 320、数据路径（Datapath）逻辑 322，以及 用于向视频和音频解码器（224、226 和 228）分别发送数据的。

存储器控制器 216 将来自下列两个来源中的数据写入外部存储器：其一为传输处理器 214（通过 FIFO310 中的传输端口），其二为微处理器 116（通过 FIFO314 中的微端口）。

存储器控制器 216 从外部存储器中读取数据，并将其提供给以下四个部件：1) 视频接口（通过视频 FIFO324），2) 音频接口 A（通过音频接口 A 的 FIFO326），3) 音频接口 B（通过音频接口 B 的 FIFO328），4) 微控制器 116（通过微输出 FIFO316）。

外部存储空间被划分为多个分离的、互不重叠的缓冲区。其中每一个供一个 DMA 通道使用。可使用的通道多达 32 个之多。通道号与写入数据两个 FIFO 源或从四个目标 FIFO 中读出的数据相关连。

由传输处理器 214 提供并写入传入端口 FIFO310 的数据带有一个通道号标记。其它 FIFO 中每一个的通道号由微处理器 116 在 DMA 接口寄存器中定义。微处理器 116 为每一个被使用的通道设置一个 128 位的 DMA 通道配置寄存器（通道寄存器）。此通道寄存器含有由起始和结束地址定义的缓冲区空间等信息，而不管该缓冲区被设为 FIFO（读写指针互相缠绕，有时又叫环形队列）还是队列（ Queue ）（读写指针不会缠绕在一起），等等。

如果通道寄存器允许，DMA 控制器 320 能在当前使用的缓冲区已满时获得一个新的缓冲区。这种特性通常只适用于那些存储为主微处理器 116 所用的数据的缓冲区，如 PSI 区字段。这些新缓冲区的起始和结束地址储存在新的缓冲 FIFO 中。只有微处理器 116 能向此 FIFO 中写入新的缓冲区。已使用过的缓冲区指针和其他类型的指针由 DMA 控制器 320 写入指针 FIFO 中。在本发明的典型实施例中，只有微处理器 116 能读取指针 FIFO。这些指针被微处理器 116 用于管理对缓冲区数据的读取和向新的缓冲 FIFO 返回使用过的缓冲区。图 4 中的指针 FIFO 项流程图给出了

在所有可能的信号条件、通道寄存器设置和缓冲区条件下指针 FIFO 的项。

在接下去的图 3 中，DMA 控制器 320 和数据路径 322 为外部存储器提供所有的接口信号。流程控制单元 318 通过向 DMA 控制器 320 提供适当的控制信号，使其为六个特定的接口 FIFO 中的某一个服务。这些信号包括:

1. DMA 控制器开始信号:

本信号命令 DMA 控制器 320 开始为使用诸如 DMA 控制器操作、DMA 输入 FIFO 选择和 DMA 输出 FIFO 选择之类命令的特定 FIFO 服务。同时，流程控制单元 318 读出 128 位特定通道寄存器的内容，并使其在通道寄存器（内部存储器）的数据总线上可用。 DMA 控制器 320 将此 128 位的字读入它的内部寄存器，然后流程控制单元 318 被释放以根据内部存储器的需要执行其他的读/写操作。

2. DMA 控制器操作信号（ 1 位）:

该位发出一个读或写的信号，由接口 FIFO 上的 DMA 控制器执行。

3. DMA 输入 FIFO 选择信号（ 1 位）:

发出信号选择两个输入 FIFO （ 310 或 314 ）中的某一个提供服务。

4. DMA 输出 FIFO 选择信号（ 2 位）:

发出信号选择四个输出 FIFO （ 316 、 324 、 326 或 328 ）中的某一个提供服务。

5. 在请求/通道数据/通道号/DMA 控制器中的通道数据停止:

一般来说， DMA 控制器 320 持续为 FIFO 服务，直到因如接口 FIFO 满或外部存储器中无数据等原因不能继续服务为止。一旦这种情况发

生， DMA 控制器 320 分配请求的通道数据给流程控制单元 318 ，并且将通道寄存器数据和通道号数据提供给流程控制单元 318 。除非特定的 FIFO 需要急救行动（例如，因为它正接近满或空的状态），流程控制单元 318 使用通道数据更新通道寄存器存储器（例如，被更新的信息包括读写指针等），并指示 DMA 控制器 320 为回路中的下一个 FIFO 服务。

有些时候，流程控制单元 318 可能需要向 DMA 控制器 320 发送一个 DMA 控制器停止命令，作为对向另一个 FIFO 提供服务的需要作出的响应。该 FIFO 可能是拥有更高优先级的输入 FIFO 。这个命令指导 DMA 控制器 320 停止为当前正被其服务的 FIFO 服务，并将通道数据写入流程控制单元 318 。

DMA 控制器 320 使用以下信息更新通道寄存器：读指针、写指针和 DMA 控制器 320 停止为 FIFO 服务处的其他信息。由于流程控制单元 318 将这些信息写入了内部通道寄存器存储器， DMA 控制器 320 可以从中断点开始恢复为被中断的 FIFO 提供服务。

考虑到 DMA 控制器参与本发明不连续状态部分的整体运作过程，当包括一个流标识的字节的下一个 PES 包被 TPROC 214 写入存储器控制器 216 时，流程控制单元 318 引起 DMA_MARK 信号变高。 DMA_MARK 信号的过渡触发微处理器 116 处的中断，并且打包的基本流 包首部的地址被存储在微处理器已存取的输入指针 FIFO 中。由于这个打包的基本流首部可能有一个时间标记，所以对由不连续性指示位产生的标志位作出响应的微处理器 116 在储存的打包的基本流 首部中搜索时间标记。一旦发现，会检索此时间标记值。微处理器 116 基于检索到的时间标记值设置定时器中断。

再参看图 3 ，在本发明的典型实施例中，流程控制器单元 318 的内部存储器包括四个 64 × 32 位的块，每个块都分配给通道寄存器、新缓冲 FIFO 和指针 FIFO 。

在本发明的典型实施例中，每一个通道寄存器有 128 位并且最多有 32 个通道。所以有多达 128 × 32 个位以多个 128 位的格式分配给通道寄存器。

32 位的字被写入新缓冲区和指针 FIFO 或从它们中读出。至少 128 × 32 位的内存（即 128 个字）可用于新缓冲区和指针 FIFO 中。另外，如果使用的通道少于 32 个，通道寄存器中未使用的空间被分配给新的缓冲区和指针 FIFO 。

以下是 32 个 DMA 通道和 16 个 DMA 通道的存储器分配示例。

1) 32 个被使用的通道的存储器分配

新缓冲区 FIFO = 64 × 32 位

指针 FIFO = 64 × 32 位

通道寄存器 = 128 × 32 位

2)16 个被使用的通道的存储器分配

新缓冲区 FIFO = 64 × 32 位

指针 FIFO = 128 × 32 位

通道寄存器 = 128 × 16 位

时钟管理器 218

图 2A 和 2B 中所示的传输解码器 110 中的时钟管理器 218 使用连续 PCR 值同步本地 27MHz 的信号（由时钟信号电路 122 产生）。时钟管理器 218 中的计数器值被称为系统时间常数（ STC ）值。在本发明的典型实施例中，微处理器 116 通过内部微总线 223 存取计数器中的 STC 值。

时钟管理器 218 中的计数器定期与传输数据流中的 PCR 进行同步。当遇到数据流中的第一个 PCR 时，该 PCR 被“挤载”入计数器并成为初始 STC 值。当后来的 PCR 值被接收时，将它们与 STC 值相比较，以校

正时钟信号电路 122（例如， VCXO ）的频率。在本发明中，此过程是通过使用在下文中会详细介绍的数字模拟转换器（ DAC ）实现的。一旦进行了相位错误校正，通常是将新的 PCR 值作为 STC 值载入。

一般每帧产生一次 PCR 值。在 MPEG-2 的标准中，至少每三帧内（大概十分之一秒）会产生一次 PCR 值。

典型的情况是，外部视频和音频解码器（ 118 和 120 ）通过更新外部解码器中的 STC 值与传输解码器 110 保持同步，该过程的实现基于时钟管理器 218 中保存的 STC 值。视频和音频解码器（ 118 和 120 ）通过将数据和接收到的打包的基本流 数据流中的时间标记相比较，使用储存值来确定何时解码或显示数据。值得指出的是，在本发明的典型实施例中，传输解码器 110 、视频解码器 118 和音频解码器 120 都接收时钟管理器（ 218 ）产生的同一个 27MHz 的时钟信号。

传输解码器 218 包含对产生本地时钟信号的硬件支持。该信号对于某一个选定的程序来说是锁定在系统时钟信号上的。如上文所述，在特定的 PCR_PID 上接收的 PCR 值在串行接口上可为其他设备所用。

时钟管理器（ 218 ）包括一个系统时间计数器（ STC ）（图中未给出）、一个系统时间时钟寄存器（图中未给出）、一个程序时钟参考（ PCR — Program Clock Reference ）寄存器（图中未给出）、一个当前 STC 寄存器（图中未给出）、一个报警时钟中断寄存器（图中未给出）以及一个锁存从与选定的程序标识（ PID ）有关的首部中抽取的 PCR 值的逻辑部件（图中未给出）。它还包括串行 PCR 接口和用于控制外部系统时钟信号控制回路的 DAC 寄存器。

在本发明的典型实施例中， STC 是由 9 位基部和 33 位扩展部组成的 42 位计数器。

STC 基部将名义上的 27MHz 系统时钟输入信号分为 300 份。结果得到的 90KHz 信号驱动 STC 扩展。在任何时候， STC 都能被在微处理器 116 上运行的软件写或读。当遇到一个不连续性指示位后，可以将接收到的 PCR 值自动加载到 STC 中。

如上文所述，可以通过在程序标识表项中设定 PCR_PID 位，从刚到达的位流中自动抽取 PCR。处理接收到的 PCR 取决于软件设定的选项和接收 PCR 时当前传输包的不连续状态是否存在。

当包含 PCR_PID 的传输包被接收时，和传输首部中的不连续指示位为逻辑值 1 ，可以确认是不连续状态。该不连续状态将一直持续下去，直到包含 PCR_PID 的传输包被接收时不连续性指示位为逻辑值 0 ，或者当在 PCR_PID 包中发现下一个 PCR 为止。

如果设置为有效，当 PCR 被接收且不连续状态存在时，时钟管理器 218 自动将接收到的 PCR 载入 STC 中。此时，一个中断被发送到主微处理器 116 。

时钟管理器 218 包括一个初始化位。该位被软件置为 1 时，则无论不连续状态存在与否，下一个被接收到的 PCR 都将被载入 STC 中。然后初始化位被时钟管理器 218 自动清除。只有当 STC 不包含有效的 PCR 时（即，当选择了新的程序标识时），才设置初始化位。

如果没有不连续状态存在或自动 STC 载入功能被置为无效，接收到的 PCR 被储存在 PCR 寄存器中，并且可选择向主微处理器 116 发出一个中断。在获得 PCR 的同时， STC 的当前状态被保存在 STC 寄存器中。储存下来的 PCR 和 STC 值被用于计算错误信号，从而控制外部系统的时钟信号（ XOCLK ）。

当接收到的传输包包括一个与 PCR_PID 等同的 PID（程序标识）和一个 PCR 时，此 PCR 被锁存在 PCR 寄存器中。此时 STC 计数器的当前

内容也被锁存在 STC 寄存器中，并且向主微处理器 116 发出一个中断。将两个值都锁存起来就消除了由于中断服务例程中存在变化的等待时间而产生的不确定性。在本发明的典型实施例中，两个寄存器都包括一个 9 位的基部和一个 33 位的扩展部。基部在 300 模块中，扩展部是用二进制表示的。在寄存器的内容被用于任何计算之前，它们可以被转化成二进制数。转化方法是将扩展部乘以 300，然后将与基部相加。

当前的 STC 寄存器是一个只读寄存器，它允许微处理器 116 在任何时间获得 STC 的当前内容。通过外部微总线 124，微处理器 116 能用这个值初始化视频解码器或音频解码器的 STC 。

如上文所述，传输解码器 110 包括一个 10 位的数字模拟转换器（ DAC ） 230 ，它在时钟管理器 218 的时钟校正控制回路中使用。DAC230 是只读的，也就是说，软件在存储器中存有最后载入 DAC 的值的副本。在运作中， DAC230 被用于为外部谐振晶体电压控制振荡器 VCXO122 产生控制电压。后者是系统时钟频率（名义上是 27MHz ）的来源。通过比较锁存的 PCR 和 STC 值，软件能确定本地时钟信号是否需要校正。例如，软件能获取 PCR 和 STC 之间的差别，并将这个错误条件加到 DAC230 的输入寄存器的当前内容中去。

总体来说，本发明的不连续部分包括以下内容:

1) 通道数据处理器（ CDP ） 210 核查接收到的传输包中的同步字节，以使该包生效。传输处理器（ TPROC ） 214 对传输首部进行语法分析，并将包的有效内容传送到存储器中的适当位置。根据传输首部中的程序标识值，数据被发送到存储器中的不同 FIFO 缓冲区（通道）中。

2) 因为接收到的不连续性指示位不必和下一个 PCR 值在同一个包中，所以接收到下一个 PCR 值时， TPROC （ 214 ）将“挤载”时钟管理器（ 218 ）中的计数器。

3) 当包括一个流标识字节的下一个打包的基本流包被传输处理器 214 写入存储器控制器 216 中时， DMA_MARK 信号变高。这就导致存储器控制器 216 向微处理器 116 发出中断并将打包的基本流 包首部的地址储存在一个输入指针 FIFO 中。这个打包的基本流 首部可能有一个时间标记（可能是解码时间标记或显示时间标记）。对来自存储器控制器 216 的中断作出响应的微处理器 116 在打包的基本流 首部中搜索时间标记，一旦发现，就检索时间标记值。

4) 然后，微处理器 116 在时间标记值前略短于一帧的时间处设置一个定时器中断。

5) 当此定时器中断发生时，微处理器 116 通过外部微总线 124 向视频和音频解码器发送新的 PCR 值，从而给了解码器足够的时间处理数据。这种处理发生在时间标记与视频或音频解码器中的计数器值比较之前，并且不会干扰与前一个 PCR 值相参照的数据的处理。

视频/音频解码器 224 、 226 、 228

如上文所述，一旦传输包被接收、处理和存储起来，存储器控制器 216 从存储器 114 中读出打包的基本流包，并将它们发送到外部视频和音频解码器中。然而，在打包的基本流 包到达外部解码器（ 118 和 120 ）前，它们被内部视频和音频处理器（ 224 、 226 和 228 ）处理。

这些内部处理器的一个重要功能在于确保离开传输解码器的数据流与外部解码器兼容。也就是说，不同的外部解码器有不同的数据需求。

例如，一些现在市场上可见的外部视频解码器能接受包括首部和有效部分的打包的基本流包流。这些流的形式主要与它被读出存储器时相同。另一方面，有些外部解码器只能接受对基本流（例如，打包的基本流 包的有效部分而非首部部分）的处理要求。另外，后一种类型的解码器除了要求有数据流外，还要求相关的控制信息，如时间标记和字节计

数等。由 C - Cube 制造的 CL9100 就是这样一种视频解码器。在此特参考其规格说明——CL9100 多模式视频解码器用户手册（94 年 10 月）——加以介绍。由此，视频处理器 224 可通过微处理器 116 进行设置，以格式化输出的数据流，使之与选定的外部解码器的要求兼容。

在处理 C - Cube CL9100 等外部视频解码器的接口方面，视频处理器 224 对打包的基本流 包的流进行处理，从而去除打包的基本流 的首部并将时间标记信息从打包的基本流 首部中取出来。另外，视频处理器 224 通过使用计数器（图中未给出），对发送给外部解码器的打包的基本流包保持字节计数。那么，视频处理器 224 包含时间标记信息，保持字节计数并将打包的基本流 包的有效部分传输给外部视频解码器。为了获得传送给外部解码器的时间标记和字节计数信息，视频处理器 224 向微处理器 116 发出一个中断。后者进行响应时，会通过内部微总线 223 从视频处理器 224 中读取时间标记和字节计数信息，并通过外部微总线 124 将这个控制信息发送到外部视频解码器中。

然而，有时在微处理器 116 能对来自视频处理器 224 的中断作出响应之前，另一个带有时间标记信息的打包的基本流 首部就到达了。例如，当微处理器 116 在很长的时间里被更高优先级的任务占用时，这种情况就可能发生。在这种情况下，视频处理器 224 将时间标记信息和状态一起储存起来。具体来说，视频处理器 224 会保存一个状态寄存器，表明微处理器是否“丢失”了时间标记。在本发明的典型实施例中，微处理器 116 最后才开始读取时间标记信息，如果它象状态中表示的那样丢失了一个或多个时间标记，那么它将只能恢复最新的时间标记。

另外，既然时间标记信息和字节计数信息将被提供给外部解码器，那么当微处理器 116 丢失了一个时间标记时，视频处理器 224 保持一种累积式的字节计数，因为许多数据标记可能在微处理器 116 读取信息之前就到达了。然后，微处理器 116 读取最新的时间标记和累积式的字节

计数,并将这些信息发送到外部视频解码器中。接下来，状态寄存器和字节计数器可以被重置。

如图 5A 中的流程图所示，接受到的数据的首部被分离并进行语法分析（步骤 510 ）。时间标记信息被存储并且字节计数被保存（步骤 510 ），由视频处理器 224 向微处理器 116 发出一个中断，提醒它时间标记信息可供读取（步骤 514 ）。如果附加的时间标记信息在微处理器读取前一个时间标记信息之前就已收到，新时间标记信息被存储，字节计数器继续积累（步骤 516 ），视频处理器 224 向微处理器 116 发出另一个中断，否则，微处理器读取状态寄存器、时间标记信息和字节计数信息并将它发送到外部视频解码器中（步骤 518 ）。

调节某个外部解码器的另一个例子是使用位速率限制音频解码器，例如 Zoran ZR38500 AC3 音频解码器。在此特引用其技术说明书（ 1994 年 10 月）以供参考。一般说来，大多数音频解码器提供一个数据请求，表明它们能接受音频数据，然后传输解码器 110 通过音频处理器（ 226/228 ）提供音频数据，直到外部音频处理器取消此请求。换句话说，这里存在着一种信号交换机制。

然而，位速率限制解码器，例如 Zoran AC3 音频解码器，要求音频 AC3 数据能作为音频数据帧发送，每一帧在首部中都包括一个帧时间和位速率。以高于预先确定的位速率发送数据可能会引起内部缓冲区溢出，从而导致数据丢失。进一步说，这些位速率限制解码器并不提供数据就绪的信号以表明它们已经准备好接收附加的音频数据。

所以，和视频解码器 224 一样，音频处理器 226 和 228 可被设置以调节选定的外部音频解码器。值得指出的是：在本发明的典型实施例中，除非是对于微处理器 116 可以存取的地址，音频处理器（ 226/228 ）在本质上是相同的。

因此，当音频处理器（226/228）被编程用于与该类音频解码器接口时，它们假定解码器一直在发送数据请求信号。然而，当打包的基本流包音频数据从存储器控制器216中提供给音频处理器（226/228）时，接收到数据的打包的基本流 首部被音频处理器进行语法分析。音频数据的帧大小和位速率被包含在经分析过的首部中。根据帧的大小和位速率，音频处理器（226/228）能确定帧边界（即帧时间）。有了帧时间信息，音频处理器（226/228）设置帧定时器，使得音频数据可用时，定时器被设定，一帧数据被触发到外部音频解码器及音频处理器（226/228）中，然后暂停，直到帧定时器超过时效。当定时器超过时效时，循环继续下去，每次一个音频帧，而另外的帧可用于向外部音频解码器中输送附加帧。控制信息，例如时间标记，由微处理器恢复并通过外部微总线发送出去。

如图 5B 中的流程图所示，从存储器中恢复打包的基本流包（步骤542），去除接收到数据的首部并进行语法分析（步骤530），确定一个帧时间(步骤532),定时器开始工作(步骤534),音频处理器（226/228）触发出一帧数据（步骤536），音频处理器（226/228）暂停，直到定时器超过时效（步骤538），尽管如图中所示，步骤542、530和532能在暂停期间执行。然后，此过程延续下去。

尽管在上述特定的实施例中，对跟踪 MPEG-2 传输数据流不连续性的系统时间常数进行更新的方法和设备进行了描述。但本发明并不局限于所示的细节。另外，无需脱离权利要求的范畴和本发明的精神实质，可实现细节的多种变化。

拒絶理由通知書

原/

特許出願の番号	特願２００３－５６３２２９
起案日	平成２１年　３月２６日
特許庁審査官	坂本　聡生　　２９５４　５Ｃ００
特許出願人代理人	青木　篤（外　４名）　様
適用条文	第２９条第２項、第３６条、第３７条

この出願は、次の理由によって拒絶をすべきものです。これについて意見がありましたら、この通知書の発送の日から３か月以内に意見書を提出してください。

理　由

ａ．この出願は、下記の点で特許法第３７条に規定する要件を満たしていない。

記

請求項１－１２，１４－２４に記載される発明が解決しようとする課題は、本願明細書（特に第【００１２】段落－第【００１３】段落参照）に記載の「最初のＰフレームが、通常、再構成のために最も重要なものである。しかしながら、既知の符号化方法は、このような重要度の差異を信号伝送する簡単な方法を提供できていない」という課題、又は、「逸脱した画像番号を、喪失した画像フレームの信号として解釈して、喪失と疑われる画像フレームを再構成したりあるいはその再送信を要求したりするために不要な動作を開始してしまう」問題にあると認められるが、請求項１３に記載される発明が解決しようとする課題は、画像の再構成に関する課題を解決するものではなく、両者が同一であるとは認められない。

よって、請求項１－１２，１４－２４に記載される発明、請求項１３に記載される発明は、それぞれの解決しようとする課題が同一でなく、特許法第３７条第１号に規定する関係を有するとは認められない。

また、請求項１－１２，１４－２４に記載される発明の主要部と請求項１３に記載される発明の主要部が同一であるとも認められないから、特許法第３７条第２号に規定する関係を有すると認められない。

さらに、各発明は、特許法第３７条第３号、第４号、第５号に規定する関係のいずれを満たすものとも認められない。

この出願は特許法第３７条の規定に違反しているので、請求項１－１２，１４－２４以外の請求項に係る発明については特許法第３７条以外の要件についての審査を行っていない。

ｂ．この出願の下記の請求項に係る発明は、その出願前に日本国内又は外国において、頒布された下記の刊行物に記載された発明又は電気通信回線を通じて公衆に利用可能となった発明に基いて、その出願前にその発明の属する技術の分野における通常の知識を有する者が容易に発明をすることができたものであるから、特許法第２９条第２項の規定により特許を受けることができない。

記　　（引用文献等については引用文献等一覧参照）

請求項：１－１２，１４－１５，１８－２４
引用文献：１

備考：

引用文献１には、参照画像をＩピクチャとして符号化する手順と、予測画像をＰピクチャとして符号化する手順と、を有し、いずれの画像が予測画像のグループに属するかを示す参照関係情報を作成する点（特に第【００４８】段落－第【００５４】段落参照）が記載されている。

そして、階層符号化技術は周知であり、引用文献１記載の発明の符号化を階層符号化により行うことに格別の困難性は認められない。

ｃ．この出願は、特許請求の範囲の記載が下記の点で、特許法第３６条第６項第１号に規定する要件を満たしていない。

記

（１）請求項１には、「第１のサブシーケンス」、「第２のサブシーケンス」と記載されているが、単に「第１」と「第２」の記載のみでは、それぞれがベースレイヤとエンハンスメントレイヤに対応するのか否かなど、「第１のサブシーケンス」と「第２のサブシーケンス」とが、いずれのサブシーケンスを指すのか不

明確であるため、発明の詳細な説明との対応関係が不明確である。
　他の請求項における「第１のサブシーケンス」、「第２のサブシーケンス」の記載も同様に不明確である。

（２）請求項１には、「どのビデオフレームが前記第２のサブシーケンスに属するのかを指示する情報」と記載されているが、「どのビデオフレームが・・・属する」の記載のみでは、例えば、シーケンス全体のうち第２のサブシーケンスに属するフレームを列挙したような情報であるのか、各ビデオフレーム毎に自らがいずれのサブシーケンスに属するのかを示す情報であるのか、不明確である。

　また、「属するのか」の記載では、第２のサブシーケンスのビデオフレームであることを指示する情報であるのか、第２のサブシーケンスに依存するビデオフレームであることを指示する情報であるのか、不明確である。

　その結果、発明の詳細な説明との対応関係が不明確である。

　請求項１４，２２の記載も同様に不明確である。

（３）請求項４には、「依存性を、少なくともスケーラビリティレイヤの識別子及びサブシーケンスの識別子に基づいて定める」と記載されているが、「依存性を・・・（中略）・・・基づいて定める」の記載では、例えば、依存先のサブシーケンスを、スケーラビリティレイヤの識別子及びサブシーケンスの識別子を用いて示すことを意味するようにも解され、発明の詳細な説明との対応関係が不明確である。

ｄ．この出願は、特許請求の範囲の記載が下記の点で、特許法第３６条第６項第２号に規定する要件を満たしていない。

記

（１）請求項１には、「サブシーケンス」と記載されているが、該記載のみでは、いかなる単位のシーケンスであるのか、不明確である。
　他の請求項における「サブシーケンス」の記載も同様に不明確である。

（２）請求項３には、「ビデオシーケンスを、複数のスケーラビリティレイヤ内に符号化する」と記載されているが、「複数の・・・（中略）・・・内に」の記載では、複数のスケーラビリティレイヤからなる符号化データとして符号化することを意味するのか否か、不明確である。

（３）請求項３には、「第２のサブシーケンスのビデオフレームの前記依存性を、前記第２のサブシーケンスの少なくとも１つのビデオフレームが、高位のスケーラビリティレイヤのビデオフレームと、同じスケーラビリティレイヤ内の他の１つのサブシーケンスのビデオフレームと、を含むグループから予測されるように定める」と記載されているが、「依存性を・・・（中略）・・・予測されるように定める」の記載では、依存して予測することを意味するのか、依存性を示す情報をビデオシーケンス内に形成することを意味するのか、不明確である。

（４）請求項３には、「１つのビデオフレームが、高位のスケーラビリティレイヤのビデオフレームと、同じスケーラビリティレイヤ内の他の１つのサブシーケンスのビデオフレームと、を含むグループから予測される」と記載されているが、「高位」又は「同じ」の記載のみでは、いずれのビデオフレームより「高位」、又は、いずれのビデオフレームと「同じ」であるのか、不明確である。

（５）請求項３には、「高位のスケーラビリティレイヤのビデオフレームと、同じスケーラビリティレイヤ内の他の１つのサブシーケンスのビデオフレームと、を含むグループ」と記載されているが、該記載のみでは、グループが、請求項３に記載（高位の・・・（中略）・・・サブシーケンスのビデオフレーム）の上記ビデオフレームを含むビデオシーケンス全体であるのか、２枚の上記ビデオフレームのみからなるグループであるのかなど、グループがいかなる単位のグループであるのか、不明確である。

（６）請求項３には、「グループから予測される」と記載されているが、「グループ」の記載では、いずれのフレームから予測が行われるのか、不明確である。

（７）請求項１１には、「サブシーケンスのフレームの少なくともいくつかは、時間的に少なくとも部分的に重複」と記載されているが、該記載のみでは、異なるレイヤのサブシーケンスのフレームが重複するのか、同じレイヤのサブシーケンスのフレームが重複するのかなど、いずれのレイヤのフレームといずれのレイヤのフレームが重複するのか、不明確である。

請求項２０の「部分的に時間的に重複」の記載も、同様に、不明確である。

（８）請求項１６には、「喪失した画像番号に対応するいくつもの画像フレームを含む」と記載されているが、「いくつもの」の記載では、「いくつ」であるのか不明確であり、例えば、喪失した画像番号に対応する画像フレームであるのか否か、不明確である。

請求項１７の「いくつもの」の記載も同様に不明確である。

（９）請求項１９には、「独立して復号可能なサブシーケンスを定める」と記載されているが、「定める」の記載では、例えば、サブシーケンスを復号可能なものと見なすなどして、定めることを意味するのか、復号可能なサブシーケンスを探すなどして、特定することを意味するのか、不明確である。

（１０）請求項１９には、「画像番号値を０に設定」と記載されているが、該記載のみでは、符号化の時に設定するのか、復号の時に設定するのか、不明確である。

（１１）請求項２０には、「復号順序における最後の画像フレーム」と記載されているが、「最後」の記載のみでは、シーケンス全体の最後であるのかなど、いかなる単位の最後であるのか、不明確である。

（１２）請求項２０には、「部分的に時間的に重複した画像フレームのグループ」と記載されているが、「時間的に重複した画像フレームのグループ」の記載のみでは、該グループが、時間的に重複した画像フレームを含むシーケンス全体を意味するのか、レイヤが異なるサブシーケンスであって時間的に重複するものを集めたグループであるのかなど、具体的に、いかなるグループであるのか、不明確である。

（１３）請求項２２には、「符号化するコンピュータプログラムであって、・・・（中略）・・・予測されるコンピュータプログラムにおいて、該コンピュータプログラムは、・・・（中略）・・・するためのプログラムコードであって、・・・（中略）・・・されているプログラムコードと、・・・（中略）・・・たものであるプログラムコードと、・・・（中略）・・・ためのプログラムコードと、を含むことを特徴とするコンピュータプログラム。」と記載されているが、該記載のみでは、符号化を実行する主体が不明確であり、例えば、コンピュータに符号化処理を実行させるためのプログラムであるのか否か、不明確である。

また、「プログラムコードと、・・・（中略）・・・プログラムコードと」の記載では、各符号化手順を実行させるためのプログラムであるのか否か、不明確である。

したがって、上記記載では、コンピュータに、請求項２２に記載の各手順を実行させるためのプログラムであるのか否か、不明確である。

請求項２３の記載も同様に不明確である。

（１４）請求項２４には、「ビデオ信号」と記載されているが、該記載では、「

物」の発明であるのか、「方法の発明」であるのか特定できず、不明確である。

（１５）上記理由ｃ．で指摘の点については、同理由に記載の理由により、各請求項に係る発明が不明確である。

なお、補正の際には、新規事項の追加とならないように留意の上、意見書で、各補正が適法である理由について、根拠となる出願当初明細書の記載箇所とともに、主張されたい。

拒絶の理由が新たに発見された場合には拒絶の理由が通知される。

B046260 Dispatch Number: 199591 Mailing Date: March 31, 2009

NOTICE OF REASONS FOR REJECTION

Patent Application No. 2003-563229
Drafting Date: March 26, 2009
Patent Office Examiner: Satoo Sakamoto 2954 5C00
Attorney for Patent Applicant: Atsushi Aoki (and four others)
Applicable Provisions: Article 29, paragraph 2; Article 36; Article 37

It is deemed that the present application should be rejected for the following reasons. Any argument, if any, should be submitted within 3 months from the mailing date of this notice.

REASONS

(a) It is deemed that this application does not satisfy the requirements prescribed in Article 37 of the Patent Law on the following points.

NOTE

It is deemed that the problems to be solved by the inventions claimed in claims 1 to 12 and 14 to 24 are as described in "the first P-frames are usually the most significant ones for the reconstruction. However, known coding methods fail to provide a simple method for signaling such differences in significance" and "the deviating image

numbering is interrupted as a signal of lost image frames and unnecessary actions are started to reconstruct the image frames suspected as lost or to request a re-transmission thereof." However, the problem to be solved by the invention claimed in claim 13 is not to solve the problem regarding an image reconstruction and is not deemed to be the same as those of claims 1 to 12 and 14 to 24.

Therefore, it is not deemed that the inventions claimed in claims 1 to 12 and 14 to 24 and the invention claimed in claim 13 have the same "problems to be solved by the invention" and satisfy the relationship prescribed under Article 37, item 1, of the Patent Law.

Moreover, it is not deemed that the inventions claimed in claims 1 to 12 and 14 to 24 and the invention claimed in claim 13 have the same substantial part and satisfy the relationship prescribed under Article 37, item 2, of the Patent Law.

Furthermore, it is deemed that each invention of this application does not satisfy the relationship prescribed in any of Article 37, Items 3, 4 and 5.

As this application violates the provision of Article 37, an examination was not carried out regarding the requirements other than Article 37 of the Patent Law for the inventions claimed in claims other than claims 1 to 12 and 14 to 24.

(b) The inventions described in the following claims of this

application are deemed ones which could easily have been made, prior to the filing of the patent application, by a person with ordinary skill in the art to which the inventions pertain, on the basis of the inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 2, of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)

Claims Nos. 1 to 12, 14, 15, and 18 to 24
Reference No. 1

Remarks:

Reference 1 describes the feature that a step of encoding a reference image as the I-PICTURE and a step of encoding a predictive image as the P-PICTURE are provided to create the reference relationship information showing the images belonging to the group of predictive images (specially refer to paragraphs [0048] to [0054]).

A hierarchical coding technology is well known and it is not deemed that it is particularly difficult to perform encoding in the invention described in Reference 1 using a hierarchical coding.

(c) The description of the claims of this application does

not satisfy the requirements prescribed in Article 36, paragraph 6, item 1 of the Patent Law on the following points.

NOTE

(1) Claim 1 describes "a first sub-sequence" and "a second sub-sequence", however, the sub-sequences indicated by "a first sub-sequence" and "a second sub-sequence" are unclear only with "first" and "second", for example, whether or not the "first sequence" and the "second sequence" correspond to "the base layer" and "the enhancement layer" respectively is unclear. Accordingly, the relationship to the detailed explanation of the invention is unclear.

Likewise, "a first sub-sequence" and "a second sub-sequence" described in other claims are also unclear.

(2) Claim 1 describes "information indicating which video frames belong to the second sub-sequence", however, this description makes the invention unclear, for example, as to whether the information lists the frames which belong to the second sub-sequence among the all of the sequences, or indicates sub-sequences to which the respective video frames belong.

Moreover, the description "belong" make the invention unclear as to whether the information indicates that a video frame is a video frame of the second sub-sequence or is a video frame depending on the second sub-sequence.

As a result, the corresponding relationship to the

detailed explanation of the invention is unclear.

Likewise, the descriptions of claims 14 and 22 are unclear.

(3) Claim 4 describes "determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier", however, this description could be understood to mean that the depended sub-sequence is indicated using the scalability layer identifier and the sub-sequence identifier and, therefore, the corresponding relationship to the detailed explanation of the invention is unclear.

(d) The description of the claims of this application does not satisfy the requirements prescribed in Article 36, paragraph 6, item 2 of the Patent Law on the following points.

NOTE

(1) Claim 1 describes "sub-sequence", however, the unit of sequence is unclear.

Likewise, the descriptions "sub-sequence" in other claims are also unclear.

(2) Claim 3 describes "coding the video sequence into a plural number of scalability layers", however, this description is unclear as to whether or not the video sequence is coded into coded data consisting of a plurality of scalability layers.

(3) Claim 3 describes "determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising a video frame of a higher scalability layer, a video frame of another sub-sequence in the same scalability layer", however, this description is unclear as to whether prediction is performed dependently or information representing the dependency is formed in the video sequence.

(4) Claim 3 describes "one video frame of the second sub-sequence is predicted from a group comprising a video frame of a higher scalability layer, a video frame of another sub-sequence in the same scalability layer", however, from this description, the video frame to which a higher scalability layer or the same scalability layer is unclear.

(5) Claim 3 describes "a group comprising a video frame of a higher scalability layer, a video frame of another sub-sequence in the same scalability layer", however, from this description, the unit of the group, for example, whether the group is the entirety of the video sequence including the aforementioned video frame or consists only of the two aforementioned video frames is unclear.

(6) Claim 3 describes "predicted from a group", however, the description is unclear as to from which frame the prediction is performed.

(7) Claim 11 describes "at least some of the sub-sequence frames are temporally at least partly overlapping", however,

from this description, the layers whose frames overlap are unclear, for example, whether the frames of sub-sequence of different layer overlap, or the frames of sub-sequence of the same layer overlap.

Likewise, a description "partly temporally overlapping" in claim 20 is unclear.

(8) Claim 16 describes "comprise a number of image frames corresponding to the missing image numbers", however, the specific number represented by "a the number of" is unclear, for example, whether or not this description means image frames corresponding to the missing image numbers is unclear.

Likewise, the description "a number of" in claim 17 is also unclear.

(9) Claim 19 describes "determining an independently decodable sub-sequence", however, this description is unclear as to, for example, whether the sub-sequence is determined to be decodable, or the sub-sequence is identified by searching a decodable sub-sequence.

(10) Claim 19 describes "setting the value of the image number of the first video frame in the sub-sequence at zero", however, the description is unclear as to whether the setting is performed upon coding or decoding.

(11) Claim 20 describes "the last image frame in the decoding order", however, the description "last" is unclear as to whether the "last" is the last of entire sequence or the last of else.

(12) Claim 20 describes "group of said at least partly temporally overlapping image frames", however, this description is unclear as to whether the group means the entirety of the sequence including the temporally overlapped image frames, or a group of temporally overlapping sub-sequence having different layers, or else.

(13) Claim 22 describes "A computer program for coding ...(omitted)..., characterized in that the computer program comprises a program code for forming ...(omitted)...formed ...(omitted)... a program code for forming ...(omitted)... ; and a program code ...(omitted).", however, the subject which performs the coding is unclear, for example, whether or not the invention is directed to a program which directs the computer to perform the coding.

Moreover, the description "a program code ...(omitted)... and a program code" is unclear as to whether or not the program is used to perform each coding step.

Accordingly, the above description is unclear as to whether or not the program is used to direct the computer to perform each step described in claim 22.

Likewise, the description of claim 23 is unclear.

(14) Claim 24 is directed to "a video signal" and the category of the invention (a product invention or a process invention) for which patent is sought cannot be specified, thus, the invention is unclear.

(15) The invention claimed in each claim is unclear for the reason described in the Reason (c).

If an amendment is made, it should be noted that no new matter can be added, and, please assert in the argument that the amendments meet the requirements defined in the law, identifying the relevant descriptions of the original specification which support the amendments.

If another reason for rejection is found, a further notice of reasons for rejection will be issued.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

<u>New Applications Under 35 U.S.C. 111</u>
If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

<u>National Stage of an International Application under 35 U.S.C. 371</u>
If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

<u>New International Application Filed with the USPTO as a Receiving Office</u>
If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

(54)【発明の名称】　画像符号化装置と画像復号化装置

(57)【要約】

【課題】　被符号化画像群の符号化データに予測符号化の際の参照関係と撮影位置と符号化データ位置のテーブルを付加することで、効率のよく予測符号化でき、要求に効率よく対応できる復号化を実現する。

【解決手段】　複数の被符号化画像とその撮影位置データを入力とし、前記複数の被符号化画像を参照画像と参照画像から予測符号化される予測画像にグループ化する参照予測グループ化部１０５と、参照画像を符号化する参照画像符号化部１０６と、再構成参照画像を用いて予測画像を符号化する予測画像符号化部１０８と、参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する参照関係テーブル作成部１０９手段を備えたことを特徴とする。

1

【特許請求の範囲】

【請求項１】複数の被符号化画像とその撮影位置データを入力とし、前記複数の被符号化画像を参照画像と参照画像から予測符号化される予測画像にグループ化する参照予測グループ化手段と、参照画像を符号化する参照画像符号化手段と、再構成参照画像を用いて予測画像を符号化する予測画像符号化手段と、参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する参照関係テーブル作成手段を備えたことを特徴とする画像符号化装置。

【請求項２】再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と符号化データ位置を記述した参照関係テーブルを入力とし、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択する符号化データ選択手段と、符号化データを復号化し、再構成参照画像を出力する参照画像復号化手段と、符号化データを復号化し再構成予測画像を出力する予測画像復号化手段を備えたことを特徴とする画像復号化装置。

【請求項３】撮影位置と、参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、予測画像符号化データについては、参照画像に対する変形情報とこの変形情報を用いて変形された画像に対する残差情報で構成されることを特徴とする符号化データを入力とし、再生すべき画像要求を逐次監視する画像要求監視手段と、画像要求と画像復号化状況とデータ位置テーブルと符号化データから、復号化する符号化データを選択する符号化データ選択手段と、符号化データから再構成参照画像を復号化する再構成参照画像復号化手段と、再構成参照画像と符号化データの変形情報から変形参照画像を復号化する変形参照画像復号化手段と、変形画像と符号化データの残差情報から再構成予測画像を復号化する再構成予測画像復号化手段を備え、再構成参照画像復号化手段と変形参照画像復号化手段および再構成予測画像復号化手段の出力を選択的に出力することを特徴とする画像復号化装置。

【請求項４】再生すべき画像の要求と、撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、画像が符号化された符号化データを入力とし、復号化する符号化データを選択する符号化データ選択手段と、符号化データから参照画像を復号化する参照画像復号化手段と、再構成された参照画像を複数枚蓄積する再構成参照画像群蓄積手段と、符号化データから予測画像を復号化する予測画像復号化手段と、再構成された予測画像を複数枚蓄積する再構成予測画像群蓄積手段と、再生すべき画像の要求に応じて蓄積すべき画像の撮影位置を計算し、前記再構成参照画像群蓄積手段と再構成予測画像群蓄積手段に蓄積されている画像量を一定量以下に保つ画像蓄積検査手段を備え、

2

前記復号処理済みの蓄積されている画像から再生画像を出力することを特徴とする画像復号化装置。

【請求項５】撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、符号化データを入力とし、再生すべき画像の要求を逐次監視し、画像要求を出力する画像要求監視手段と、現在の画像要求と前回の画像要求と既に復号化され蓄積された画像の情報から、新たに復号化する符号化データを選択する符号化データ選択手段と、撮影位置に関して現在の画像要求近傍の画像の符号化データを選択する予測符号化データ選択手段と、符号化データを参照画像に復号化する参照画像復号化手段と、符号化データを予測画像に復号化する予測画像復号化手段と、復号化された参照画像を蓄積する再構成参照画像群蓄積手段と、復号化された予測画像を蓄積する再構成予測画像群蓄積手段とを有し、画像要求を監視し再生する一方で、現在の画像要求近傍の画像の符号化データを選択し復号を行なうことを特徴とする画像復号化装置。

【請求項６】複数の被符号化画像と画像撮影位置データを入力とし、前記複数の被符号化画像を参照画像と、参照画像から予測される予測画像にグループ化する参照予測グループ化手段と、参照画像と予測画像の間の変形拘束式を推定する変形拘束式推定手段と、参照画像を符号化する参照画像符号化手段と、変形拘束式に基づいて変形を拘束して予測画像を符号化する拘束予測画像符号化手段、参照予測グループの参照関係と符号化データ位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する参照関係テーブル作成手段を備えたことを特徴とする画像符号化装置。

【請求項７】再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と符号化データ位置を記述した参照関係テーブルを入力とし、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択する符号化データ選択手段と、参照画像符号化データを復号化し、再構成参照画像を出力する参照画像復号化手段と、変形拘束式に基づいて変形を拘束して予測画像符号化データを復号化し再構成予測画像を出力する拘束予測画像復号化手段を備えたことを特徴とする画像復号化装置。

【請求項８】複数の被符号化画像とその撮影位置データと光源位置データを入力とし、前記複数の被符号化画像を参照画像と参照画像から予測符号化される予測画像にグループ化する参照予測グループ化手段と、参照画像を符号化する参照画像符号化手段と、再構成参照画像を用いて予測画像を符号化する予測画像符号化手段と、参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する参照関係テーブル作成手段を備えたことを特徴とする画像符号化装置。

【請求項９】再生すべき画像の要求と、画像が符号化さ

れた符号化データと、参照予測関係と撮影位置と光源位置と符号化データ位置を記述した参照関係テーブルを入力とし、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択する符号化データ選択手段と、符号化データを復号化し、再構成参照画像を出力する参照画像復号化手段と、符号化データを復号化し再構成予測画像を出力する予測画像復号化手段を備えたことを特徴とする画像復号化装置。

【０００１】

【発明の属する技術分野】本発明は画像の伝送・蓄積のための画像符号化装置と画像復号化装置に関するものである。

【０００２】

【従来の技術】従来、３次元物体を計算機上で表現する際、物体の形状情報や表面の材質情報を計算機に入力し、見え方を計算し、シュミレーションする手法が取られているが、複雑な形状や細かな質感を表現するには、多くのデータを入力する必要があり、シュミレーションの計算量も膨大なものとなる。

【０００３】一方、より小さい計算量で３次元物体を表現するために、イメージベースドレンダリング（Image-BasedRendering）と呼ばれる、多くの視点からの画像をあらかじめ撮影・蓄積・伝送しておき、それらを要求に応じて表示する手法も取られている（「クイックタイムブイアール」（S. E. Chen、 "QuickTime VR — Animage-Based Approach to Virtual Environment Navigation"、 SIGGRAPH'90、 pp. 29—38、 1990））。

【０００４】

【発明が解決しようとする課題】Image-Based Rendering の手法では、多くの要求に応えるために、多くの視点からの画像をあらかじめ撮影しておくため、膨大なデータ量を蓄積・伝送しなければならない、これらのデータは画像として約１万枚、約２．４ギガバイトを越えることもある。したがって、これらの膨大なデータ量を、効率的に蓄積・伝送することが課題となっている。

【０００５】本発明は、従来のこのような課題を考慮し、蓄積・伝送すべき多数の画像の中から少数の代表画像を選び、各代表画像で複数枚の画像を表現し、その依存関係を付加することによって、効率的に複数の画像を符号化する画像符号化装置や、段階的な復号化や、次の要求の予測を行うことによって効率的に画像を符号化または復号化する方式とその装置を提供することを目的とする。

【０００６】

【課題を解決するための手段】第１の発明は、複数の被符号化画像とその撮影位置データを入力とし、前記複数の被符号化画像を参照画像と参照画像から予測符号化される予測画像にグループ化する参照予測グループ化手段と、参照画像を符号化する参照画像符号化手段と、再構

成参照画像を用いて予測画像を符号化する予測画像符号化手段と、参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する参照関係テーブル作成手段を備えたことを特徴とする画像符号化装置である。

【０００７】第２の発明は、再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と符号化データ位置を記述した参照関係テーブルを入力とし、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択する符号化データ選択手段と、符号化データを復号化し、再構成参照画像を出力する参照画像復号化手段と、符号化データを復号化し再構成予測画像を出力する予測画像復号化手段を備えたことを特徴とする画像復号化装置である。

【０００８】第３の発明は撮影位置と、参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、予測画像符号化データについては、参照画像に対する変形情報とこの変形情報を用いて変形された画像に対する残差情報で構成されることを特徴とする符号化データを入力とし、再生すべき画像要求を逐次監視する画像要求監視手段と、画像要求と画像復号化状況とデータ位置テーブルと符号化データから、復号化する符号化データを選択する符号化データ選択手段と、符号化データから再構成参照画像を復号化する再構成参照画像復号化手段と、再構成参照画像と符号化データの変形情報から変形参照画像を復号化する変形参照画像復号化手段と、変形画像と符号化データの残差情報から再構成予測画像を復号化する再構成予測画像復号化手段を備え、再構成参照画像復号化手段と変形参照画像復号化手段および再構成予測画像復号化手段の出力を選択的に出力することを特徴とする画像復号化装置である。

【０００９】第４の発明は、再生すべき画像の要求と、撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、画像が符号化された符号化データを入力とし、復号化する符号化データを選択する符号化データ選択手段と、符号化データから参照画像を復号化する参照画像復号化手段と、再構成された参照画像を複数枚蓄積する再構成参照画像群蓄積手段と、符号化データから予測画像を復号化する予測画像復号化手段と、再構成された予測画像を複数枚蓄積する再構成予測画像群蓄積手段と、再生すべき画像の要求に応じて蓄積すべき画像の撮影位置を計算し、前記再構成参照画像群蓄積手段と再構成予測画像群蓄積手段に蓄積されている画像量を一定量以下に保つ画像蓄積検査手段を備え、前記復号処理済みの蓄積されている画像から再生画像を出力することを特徴とする画像復号化装置である。

【００１０】第５の発明は、撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、符号化データを入力とし、再生すべ

5

き画像の要求を逐次監視し、画像要求を出力する画像要求監視手段と、現在の画像要求と前回の画像要求と既に復号化され蓄積された画像の情報から、新たに復号化する符号化データを選択する符号化データ選択手段と、撮影位置に関して現在の画像要求近傍の画像の符号化データを選択する予測符号化データ選択手段と、符号化データを参照画像に復号化する参照画像復号化手段と、符号化データを予測画像に復号化する予測画像復号化手段と、復号化された参照画像を蓄積する再構成参照画像群蓄積手段と、復号化された予測画像を蓄積する再構成予測画像群蓄積手段とを有し、画像要求を監視し再生する一方で、現在の画像要求近傍の画像の符号化データを選択し復号を行なうことを特徴とする画像復号化装置である。

【００１１】第６の発明は、複数の被符号化画像と画像撮影位置データを入力とし、前記複数の被符号化画像を参照画像と、参照画像から予測される予測画像にグループ化し、参照画像と予測画像の間の変形拘束式を推定し、参照画像を符号化し、変形拘束式に基づいて変形を拘束して予測画像を符号化し、参照予測グループの参照関係と符号化データ位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力することを特徴とする画像符号化装置である。

【００１２】第７の発明は、再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と符号化データ位置を記述した参照関係テーブルを入力とし、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択し、参照画像符号化データを復号化し、再構成参照画像を出力し、変形拘束式に基づいて変形を拘束して予測画像符号化データを復号化し再構成予測画像を出力することを特徴とする画像復号化装置である。

【００１３】第８の発明は、複数の被符号化画像とその撮影位置データと光源位置データを入力とし、前記複数の被符号化画像を参照画像と参照画像から予測符号化される予測画像にグループ化し、参照画像を符号化し、再構成参照画像を用いて予測画像を符号化し、参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力することを特徴とする画像符号化装置である。

【００１４】第９の発明は、再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と光源位置と符号化データ位置を記述した参照関係テーブルを入力とし、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択し、符号化データを復号化し再構成参照画像を出力し、符号化データを復号化し再構成予測画像を出力することを特徴とする画像復号化装置である。

【００１５】第１の発明に基づく画像符号化装置では、参照予測グループ化手段が、入力である複数の被符号化

6

画像とその撮影位置データから被符号化画像を参照画像と参照画像から予測符号化される予測画像からなる複数のグループに分ける。参照画像は参照画像符号化手段により符号化され、その再構成画像を用いて予測画像符号化手段が予測画像を符号化する。そして、参照関係テーブル作成手段が、参照画像に対する予測画像の参照関係、符号化データ位置、撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する。

【００１６】第２の発明に基づく画像復号化装置では、再生すべき画像の要求、画像符号化データおよび参照予測関係、撮影位置、符号化データ位置を記述した参照関係テーブルを入力とする。符号化データ選択手段は、要求される画像の復号化に必要な符号化データを参照関係テーブルに基づいて選択する。

【００１７】選択された符号化データが参照画像であれば、参照画像復号化手段により復号化され、再構成参照画像として出力される。また選択された符号化データが予測画像データであれば、予測画像復号化手段により復号化され再構成予測画像として出力される。

【００１８】第３の発明に基づく画像復号化装置では、撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、予測画像符号化データについては、参照画像に対する変形情報とこの変形情報を用いて変形された画像に対する残差情報で構成されることを特徴とする符号化データを入力とする。画像要求監視手段は再生すべき画像要求を逐次監視する。符号化データ選択手段は、画像要求と画像復号化状況に応じてデータ位置テーブルと符号化データから、復号化すべき符号化データを選択する。

【００１９】選択された符号化データが参照画像データであれば、再構成参照画像復号化手段がその符号化データから再構成参照画像を復号化する。また選択された符号化データが予測画像データであれば、変形参照画像復号化手段または再構成予測画像復号化手段が予測画像データを復号する。変形参照画像復号化手段によれば、再構成参照画像と符号化データの変形情報から変形参照画像が復元され、再構成予測画像復号化手段によれば、変形画像と符号化データの残差情報から再構成予測画像が復元される。再構成参照画像復号化手段と変形参照画像復号化手段および再構成予測画像復号化手段の出力は、画像要求と画像復号化状況に応じてデータ位置テーブルにより選択的に出力されることになる。

【００２０】第４の発明に基づく画像復号化装置では、再生すべき画像の要求と、撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、画像が符号化された符号化データを入力とする。

【００２１】符号化データ選択手段は再生すべき画像の要求を入力として復号化べき符号化データを選択する。

選択された符号化データが参照画像データであれば、参照画像復号化手段が、選択された符号化データが予測画像データであれば、予測画像復号化手段が画像の再構成を行ない、その結果はそれぞれ再構成参照画像群蓄積手段と再構成予測画像群蓄積手段に蓄積される。この時、画像蓄積検査手段が、再生すべき画像の要求に応じて蓄積すべき画像の撮影位置を計算し、前記再構成参照画像群蓄積手段と再構成予測画像群蓄積手段に蓄積されている画像量を一定量以下に保つよう廃棄する蓄積画像を決定する。出力画像は復号処理済みの蓄積されている画像から選択されて出力される。

【００２２】第５の発明に基づく画像復号化装置では、撮影位置と参照画像符号化データ位置と予測画像符号化データ位置を記述したデータ位置テーブルと、符号化データを入力とする。画像要求監視手段は、再生すべき画像の要求を逐次監視し、画像要求を出力する。符号化データ選択手段は、現在の画像要求と前回の画像要求と既に復号化され蓄積された画像の情報から、新たに復号化する符号化データを選択する。その一方で、予測符号化データ選択手段は、撮影位置に関して現在の画像要求近傍の画像の符号化データを選択する。以上の二つの選択手段で選ばれた符号化データは選択された符号化データが参照画像データであれば、参照画像復号化手段が、選択された符号化データが予測画像データであれば、予測画像復号化手段が画像の再構成を行ない、その結果はそれぞれ再構成参照画像群蓄積手段と再構成予測画像群蓄積手段に蓄積される。

【００２３】このように、画像要求を監視し再生する一方で、現在の画像要求近傍の画像の符号化データを選択し復号を行ない、画像を出力する。

【００２４】第６の発明に基づく画像符号化装置は、複数の被符号化画像と画像撮影位置データを入力とする。参照予測グループ化手段では、前記複数の被符号化画像を、参照画像と、参照画像から予測される予測画像にグループ化する。変形拘束式推定手段では、参照画像と予測画像の間の変形拘束式を推定する。

【００２５】参照画像符号化手段では、参照画像を符号化する。拘束予測画像符号化手段では、変形拘束式に基づいて変形を拘束して予測画像を符号化する。参照関係テーブル作成手段では、参照予測グループの参照関係と符号化データ位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する。

【００２６】第７の発明に基づく画像復号化装置では、再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と符号化データ位置を記述した参照関係テーブルを入力とする。符号化データ選択手段では、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択する。参照画像復号化手段では、参照画像符号化データを復号化し、再構成参照画像を出力する。拘束予測画像復号化手段では、変

形拘束式に基づいて変形を拘束して予測画像符号化データを復号化し再構成予測画像を出力する。

【００２７】第８の発明に基づく画像符号化装置では、複数の被符号化画像とその撮影位置データと光源位置データを入力とする。参照予測グループ化手段では、前記複数の被符号化画像を参照画像と参照画像から予測符号化される予測画像にグループ化する。参照画像符号化手段では、参照画像を符号化する。予測画像符号化手段では、再構成参照画像を用いて予測画像を符号化する。参照関係テーブル作成手段では、参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データを出力する。

【００２８】第９の発明に基づく画像復号化装置では、再生すべき画像の要求と、画像が符号化された符号化データと、参照予測関係と撮影位置と光源位置と符号化データ位置を記述した参照関係テーブルを入力とする。

【００２９】符号化データ選択手段では、参照関係テーブルから要求される画像の復号化に必要な符号化データを選択する。参照画像復号化手段では、符号化データを復号化し、再構成参照画像を出力する。予測画像復号化手段では、符号化データを復号化し再構成予測画像を出力する。

【００３０】

【発明の実施の形態】以下、本発明にかかる実施の形態について図面を参照しながら説明する。

【００３１】図１は本発明の第１の実施の形態である画像符号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【００３２】同図において、撮影位置制御型画像撮像部（１０１）は、対象物体の画像を撮影し、その撮影位置データと画像データを出力する。参照予測グループ部（１０５）は、撮影位置データと画像データを参照画像と一枚以上の予測画像からなる参照予測グループにグループ化し、参照画像を参照画像符号化部（１０６）に出力し、予測画像を予測画像符号化部（１０８）に出力する。

【００３３】参照画像符号化部（１０６）は、参照画像を符号化し、再構成参照画像を作成し、符号化データを参照関係作成部（１０９）に出力し、再構成参照画像を再構成参照画像蓄積部（１０７）に出力する。再構成参照画像蓄積部（１０７）は、再構成参照画像を蓄積し、予測画像符号化部（１０８）に再構成参照画像を出力する。

【００３４】予測画像符号化部（１０８）は、予測画像を符号化し、符号化データを参照関係作成部（１０９）に出力する。参照関係テーブル作成部（１０９）は、符号化データから参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データをデータ記録・伝送部（１１０）に出力する。データ記録・伝送部（１１０）は、用途に応じ

て記録・伝送する。

【００３５】以上のように構成された本実施の形態の画像符号化装置の動作を説明する。まず、撮影位置制御型画像撮像部（１０１）では、対象物体の周囲を網羅するように、異なる視点から画像を撮影する。計算機によってサーボモータ（１０２）を対象物体の正面から水平方向にρ度、水平面から垂直方向にθ度の位置にカメラ（１０３）を移動させ、撮影位置・画像データを計算機（１０４）によって取得する。画像データは、クロマキーによって対象物体を背景と分離し、透過度情報を示すアルファプレーンを付加し、輝度プレーン（２０１）、色差１プレーン（２０２）、色差２プレーン（２０３）、アルファプレーン（２０４）で構成する。

【００３６】ここで、ρ，θは、

【００３７】

【数１】

$$0 \leq \rho < 360,\ 0 \leq \theta \leq 90,\ (\rho,\theta\text{は整数})$$

【００３８】とする。このように取得された撮影位置・画像データは、図３に示すように、各画像データの先頭に水平方向撮影角度ρと、垂直方向撮影角度θを付加した書式で出力される。

【００３９】参照予測グループ化部（１０５）では、参照画像（４０１）によって類似した画像を予測画像（４０２）として予測符号化するために、$\rho-\theta$空間において＊て等間隔に参照画像を配置し、参照画像の近傍の画像をその参照画像より予測される予測画像にグループ化するため、撮影位置Ｐ＝（ρ，θ）を用いて、以下のように画像それぞれに参照画像か予測画像のフラグｆ（Ｐ）を割り当てる。

【００４０】

【数２】

$$f(\mathbf{P}) = \begin{cases} 0 & \mathbf{P}=(Sn,Sm)\ (n,m\text{は整数}) \\ 1 & \text{それ以外} \end{cases}$$

【００４１】さらに、以下のようにインデックスｎ（Ｐ）を割り当てる。

【００４２】

【数３】

$$n(\mathbf{P}) = \lceil \tfrac{359}{S} \rceil \times n + m,\ n,m = \min_{n,m} d(\mathbf{P},\mathbf{Q})$$

【００４３】以上において、Ｑ＝（Ｓｎ，Ｓｍ）である。Ｓは参照画像間の間隔でありＳ＝５である。「・」は、・を越えない整数を表わす。また、水平方向撮影位置で折り返すため、

【００４４】

【数４】

$$\mathbf{P}_1 = (\rho_1,\theta_1),\ \mathbf{P}_2 = (\rho_2,\theta_2)$$

【００４５】とすると、

【００４６】

【数５】

$$d(\mathbf{P}_1,\mathbf{P}_2) = \min((\rho_1-\rho_2)^2,(\rho_1-\rho_2-360)^2,(\rho_1-\rho_2+360)^2) + (\theta_1-\theta_2)^2$$

【００４７】である。これらを、インデックス順に図５の示す書式で、参照画像は参照画像符号化部（１０６）へ、予測画像は予測画像符号化部（１０７）へ出力する。

【００４８】参照画像符号化部（１０６）では、参照画像をその画像データのみで符号化もしくは、その符号化データのみで復号化出来るよう復号化しておく、アルファプレーンを含んだ、そのような符号化する方法には、ＭＰＥＧ４（MPEG Video Group、"MPEG-4 Video Verification Model Version 5.0"、ISO/IEC JTC1/SC29/WG11 Document N1469、 1996）で標準化が進められている動画像符号化方法のＩ－ＰＩＣＴＵＲＥ符号化方式がある。

【００４９】この方法を用いて、参照画像符号化部（１０６）で参照画像を符号化し、符号化データを参照関係テーブル作成部（１０９）に出力し、参照画像の再構成画像を作成し、再構成参照画像蓄積部（１０７）に出力する。図６に参照画像符号化部（１０６）のフローチャートを示す。

【００５０】再構成参照画像蓄積部（１０７）では、再構成参照画像を蓄積しておき、予測画像符号化部（１０８）に出力する。参照予測グループ化部（１０５）において、図５のように参照画像と予測画像が整列されて出力されるので、再構成参照画像蓄積部（１０８）は、画像１枚分の容量を持っていれば十分である。

【００５１】予測画像符号化部（１０８）では、予測画像を再構成参照画像を用いて符号化する。参照画像と同様に、アルファプレーンを含んだ予測画像符号化方法には、ＭＰＥＧ４による動画像符号化のＰ－ＰＩＣＴＵＲＥ符号化方式がある。この方法を用いて予測画像を符号化し、符号化データを参照関係テーブル作成部（１０９）に出力する。図７に参照画像符号化部（１０６）のフローチャートを示す。

【００５２】参照関係テーブル作成部（１０９）では、各符号化部より出力された図８のようなデータを順に走査し、図９のような参照関係テーブルと図１０のような符号化データを作成し、データ記録・伝送部（１１０）に出力する。

【００５３】データ記録・伝送部（１１０）では、参照関係テーブルと符号化データを磁気ディスクや光ディスクに蓄積しておいたり、ネットワークなどで伝送する。

【００５４】以上のように、本実施の形態では、異なる多くの視点から撮影された多視点画像を、撮影位置データが近傍の類似した画像である参照画像と１枚以上の予測画像にグループ化し、効率よく符号化することが可能である。さらに、画像を各参照予測グループで参照画像が先頭になるように整列して、符号化手段に出力することで、計算量と計算に必要な蓄積容量を少なくしている。また、その整列順に符号化データ位置を格納したテーブルを付加することで、ランダムアクセスに対応した

効率的な復号化が可能である。

【００５５】図１１は本発明の第２の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【００５６】同図において、データ記憶・伝送部（１１０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルと符号化データを符号化データ選択部（１１０２）に出力する。符号化データ選択部（１１０２）では、参照関係テーブルからデータの位置を検索し、符号化データから必要なデータを参照画像復号化部（１１０３）や予測画像復号化部（１１０５）に出力する。参照画像復号化部（１１０３）では、参照画像符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１１０４）に出力し、必要なら画像表示手段（１１０６）にも出力する。

【００５７】再構成参照画像蓄積部（１１０５）は、再構成参照画像を蓄積し、予測画像復号化部（１１０５）に出力する。予測画像復号化部（１１０５）では、予測画像符号化データを復号化し、再構成予測画像を画像表示部（１００６）に出力する。画像表示部（１１０６）は入力された画像を蓄積しておき、要求により表示する。

【００５８】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部（１１０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルと符号化データを符号化データ選択部（１１０２）に出力する。

【００５９】符号化データ選択部（１１０２）では、参照関係テーブルから符号化データ位置を検索し、データ記憶・伝送部（１１０１）から、符号化データ位置の符号化データを取得する。参照／予測フラグと参照符号化データを、参照画像復号化部（１１０３）に出力し、予測符号化データがあれば、予測画像復号化部（１１０５）に出力する。但し、参照画像復号化部（１１０３）に出力する参照符号化データが前回と同じ場合は、参照画像はすでに復号化され、蓄積されているので、参照画像復号化部（１１０３）への出力は省略する。参照画像復号化部（１１０３）では、参照画像が符号化された参照符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１１０４）に出力する。

【００６０】また、参照／予測フラグにおいて、参照画像であれば、画像表示部（１００６）に再構成参照画像を出力する。再構成参照画像蓄積部（１１０４）では、再構成された参照画像を蓄積し、予測画像復号化部（１１０５）に出力する。

【００６１】予測画像復号化部（１１０５）では、予測画像が符号化された予測符号化データを再構成参照画像を用いて復号化し、画像表示部（１１０６）に再構成予測画像を出力する。

【００６２】画像表示部（１１０６）では、復号化された画像を蓄積しておき、計算機に接続されたマウスにより検索し、表示する。

【００６３】以上のように、本実施の形態では、多くの異なる視点から撮影した画像を、撮影位置が近傍の画像をグループ化し、グループを予測符号化された符号化データを、その参照予測関係と符号化データ位置と撮影位置を記述したテーブルを用いることにより、効率的に復号化することが可能である。

【００６４】また、参照関係テーブルはグループ順に記述されているので、同一参照予測グループ内が連続的に復号化されるので、再構成参照画像を蓄積しておき、予測符号化データを復号化するだけで、効率的に画像を復号化することが可能である。

【００６５】図１２は本発明の第３の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【００６６】同図において、データ記憶・伝送部（１２０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルをランダムアクセステーブル作成部（１２０２）に出力し、符号化データを符号化データ選択部（１２０３）に出力する。画像要求部（１２０４）では、要求する画像の撮影位置を符号化データ選択部（１２０３）に出力する。ランダムアクセステーブル作成部（１２０２）では、撮影位置から符号化データに効率的にランダムアクセスできるように、テーブルを変更する。

【００６７】符号化データ選択部（１２０３）では、画像要求に基づいて、ランダムアクセステーブルから、必要なデータの位置を検索し、符号化データから必要なデータを参照画像復号化部（１２０５）や予測画像復号化部（１２０７）に出力する。参照画像復号化部（１２０５）では、参照画像符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１２０６）に出力し、必要なら画像表示部（１２０８）にも出力する。

【００６８】再構成参照画像蓄積部（１２０６）は、再構成参照画像を蓄積し、予測画像復号化部（１２０７）に出力する。予測画像復号化部（１２０７）では、予測画像符号化データを復号化し、再構成予測画像を画像表示部（１２０７）に出力する。画像表示部（１２０８）は入力された画像を表示する。

【００６９】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部（１２０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルをランダムアクセステーブル作成部（１２０２）に出力する。また、符号化データ選択部（１２０３）の要求により、符号化データを符号化データ選択部（１２０３）に出力する。

【００７０】画像要求部（１２０４）では、計算機に接続されたマウスを操作することによって、ユーザが見たい視点位置を指定し、その視点位置に対応する撮影位置

を符号化データ選択部（１２０３）に出力する。

【００７１】ランダムアクセステーブル作成部（１２０２）では、図９に示す参照関係テーブルを、撮影位置から符号化データ位置を効率的に検索できるよう、ランダムアクセステーブルを作成する。図９中の参照ヘッダと予測ヘッダは、図１３のようなランダムアクセスヘッダ（Ｎバイト）に変換され、撮影位置（ρ，θ）のランダムアクセスヘッダはランダムアクセステーブルの先頭から、

【００７２】

【数６】

$$(359\rho+\theta)N$$

【００７３】の位置に配置し、図１４に示すランダムアクセステーブルを作成する。ただし、参照画像の場合、予測符号化データ位置の欄は空欄にしておく。

【００７４】符号化データ選択部（１２０３）では、要求画像の撮影位置データ（α，β）を用いて、ランダムアクセステーブルの先頭から、

【００７５】

【数７】

$$(359\alpha+\beta)N$$

【００７６】の位置のランダムアクセスヘッダを検索し、データ記憶・伝送手段（１２０１）から、符号化データ位置の符号化データを取得する。参照／予測フラグと参照符号化データは、参照画像復号化部（１２０５）に出力し、予測符号化データがあれば、予測画像復号化部（１２０７）に出力する。

【００７７】ただし、参照画像復号化部（１２０５）に出力する参照符号化データが前回と同じ場合は、参照画像はすでに復号化され、蓄積されているので、参照画像復号化部（１２０５）への出力は省略する。

【００７８】参照画像復号化部（１２０５）では、参照画像が符号化された参照符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１２０６）に出力する。また、参照／予測フラグにおいて、参照画像であれば、画像表示部（１２０８）に再構成参照画像を出力する。

【００７９】再構成参照画像蓄積部（１２０６）では、再構成された参照画像を蓄積し、予測画像復号化部（１２０７）に出力する。

【００８０】予測画像復号化部（１１０７）では、予測画像が符号化された予測符号化データを再構成参照画像を用いて復号化し、画像表示部（１２０８）に再構成予測画像を出力する。画像表示部（１２０８）では、入力された画像を表示する。

【００８１】以上のように、本実施の形態では、多くの異なる視点から撮影した画像を、撮影位置が近傍の画像をグループ化し、効率的に予測符号化し、その参照予測関係と符号化データ位置と撮影位置を記述したテーブルを付加することにより、任意の撮影位置の画像を効率的に検索、復号化、表示することが可能である。また、連続的に要求される画像は、撮影位置が近傍のものが多く、同一参照予測グループ内である場合が多く、再構成参照画像を蓄積しておくことで、予測符号化データを復号化するだけで、効率的に画像を復号化、表示することが可能である。

【００８２】図１５は本発明の第４の実施の形態である画像符号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【００８３】同図において、撮影位置制御型画像撮像部（１５０１）は、対象物体の画像を撮影し、その撮影位置データと画像データを出力する。参照予測グループ部（１５０２）は、撮影位置データと画像データを画像データを参照画像と一枚以上の予測画像からなる参照予測グループにグループ化し、参照画像を参照画像符号化部（１５０３）に出力し、予測画像を予測画像符号化部（１５０５）に出力する。参照画像符号化部（１５０３）は、参照画像を符号化し、再構成参照画像を作成し、符号化データを参照関係テーブル作成部（１５０６）に出力し、再構成参照画像を再構成参照画像蓄積部（１５０４）に出力する。再構成参照画像蓄積部（１５０４）は、再構成参照画像を蓄積し、予測画像符号化部（１５０５）に再構成参照画像を出力する。予測画像符号化部（１５０５）は、予測画像を符号化し、符号化データを参照関係テーブル作成部（１５０６）に出力する。参照関係テーブル作成部（１５０６）は、符号化データから参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データをランダムアクセステーブル作成部（１５０７）に出力する。

【００８４】ランダムアクセステーブル作成部（１５０７）では、撮影位置から符号化データに効率的にランダムアクセスできるように、テーブルを変更し、ランダムアクセステーブルと符号化データをデータ記録・伝送部（１５０８）に出力する。データ記録・伝送部（１５０８）は、用途に応じて記録・伝送する。

【００８５】以上のように構成された本実施の形態の画像符号化装置の動作を説明する。まず、画像位置制御型画像撮像部（１５０１）は、画像位置制御型画像撮影部（１０１）と同様である。参照予測グループ化部（１５０２）は、参照予測グループ化部（１０５）と同様である。参照画像符号化部（１５０３）は、参照画像符号化部（１０６）と同様である。再構成参照画像蓄積部（１５０４）は、再構成参照画像蓄積部（１０７）と同様である。予測画像符号化部（１５０５）は、予測画像符号化部（１０８）と同様である。参照関係テーブル作成部（１５０６）は、参照関係テーブル作成部（１０９）と同様である。

【００８６】ランダムアクセステーブル作成部（１５０７）は、ランダムアクセステーブル作成部（１２０２）

と同様に、ランダムアクセステーブルを作成し、データ記録・伝送部（１１０）に符号化データとランダムアクセステーブルを出力する。

【００８７】データ記録・伝送部（１１０）では、ランダムアクセステーブルと符号化データを磁気ディスクや光ディスクに蓄積しておいたり、ネットワークなどで伝送する。

【００８８】以上のように、本実施の形態では、異なる多くの視点から撮影された多視点画像を、撮影位置データが近傍の類似した画像である参照画像と１枚以上の予測画像にグループ化し、効率よく符号化することが可能である。さらに、画像を各参照予測グループで参照画像が先頭になるように整列して、符号化手段に出力することで、計算量と計算に必要な蓄積容量を少なくしている。また、その撮影位置順に符号化データ位置を格納したテーブルを付加することで、ランダムアクセスに対応した効率的な復号化が可能である。

【００８９】図１６は本発明の第５の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【００９０】同図において、データ記憶・伝送部（１６０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルと符号化データを符号化データ選択部（１６０２）に出力する。画像要求部（１６０３）では、要求する画像の撮影位置を符号化データ選択部（１６０２）に出力する。

【００９１】符号化データ選択部（１６０２）では、画像要求に基づいて、ランダムアクセステーブルから、必要なデータの位置を検索し、符号化データから必要なデータを参照画像復号化部（１６０４）や予測画像復号化部（１６０６）に出力する。参照画像復号化部（１６０４）では、参照画像符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１６０５）に出力し、必要なら画像表示部（１６０７）にも出力する。

【００９２】再構成参照画像蓄積部（１６０５）は、再構成参照画像を蓄積し、予測画像復号化部（１６０６）に出力する。予測画像復号化部（１６０６）では、予測画像符号化データを復号化し、再構成予測画像を画像表示部（１６０７）に出力する。画像表示部（１６０７）は入力された画像を表示する。

【００９３】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部（１６０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルを符号化データ選択部（１６０２）に出力する。また、符号化データ選択部（１６０２）の要求により、符号化データを符号化データ選択部（１６０２）に出力する。

【００９４】画像要求部（１６０３）では、計算機に接続されたマウスを操作することによって、ユーザが見たい視点位置を指定し、その視点位置に対応する撮影位置を符号化データ選択部（１６０２）に出力する。符号化データ選択部（１６０２）は、符号化データ選択部（１２０３）と同様である。

【００９５】参照画像復号化部（１６０４）では、参照画像が符号化された参照符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１６０５）に出力する。また、参照／予測フラグにおいて、参照画像であれば、画像表示部（１６０７）に再構成参照画像を出力する。再構成参照画像蓄積部（１６０５）では、再構成された参照画像を蓄積し、予測画像復号化部（１６０６）に出力する。

【００９６】予測画像復号化部（１６０６）では、予測画像が符号化された予測符号化データを再構成参照画像を用いて復号化し、画像表示部（１６０７）に再構成予測画像を出力する。画像表示部（１６０７）では、入力された画像を表示する。

【００９７】以上のように、本実施の形態では、多くの異なる視点から撮影した画像を、撮影位置が近傍の画像をグループ化し、効率的に予測符号化し、その参照予測関係と符号化データ位置と撮影位置を記述したテーブルを付加することにより、任意の撮影位置の画像を効率的に検索、復号化、表示することが可能である。また、連続的に要求される画像は、撮影位置が近傍のものが多く、同一参照予測グループ内である場合が多く、再構成参照画像を蓄積しておくことで、予測符号化データを復号化するだけで、効率的に画像を復号化、表示することが可能である。

【００９８】図１７は本発明の第６の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【００９９】同図において、データ記憶・伝送部（１７０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルと符号化データを符号化データ選択部（１７０５）に出力する。画像要求監視部（１７０２）は、画像の要求を監視し画像要求蓄積部（１７０３）に出力する。

【０１００】画像要求蓄積部（１７０３）は、画像要求を蓄積する。復号化状況蓄積部（１７０４）は復号化の状況を蓄積する。符号化データ選択部（１７０５）は、復号化状況と画像要求とランダムアクセステーブルと符号化データから復号化すべき符号化データを選択し、参照画像復号化部（１７０６）や変形画像復号化部（１７０８）や予測画像復号化部（１７１０）や出力画像選択部（１７１２）に出力する。参照画像復号化部（１７０６）は、参照画像符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（１７０７）に出力する。

【０１０１】再構成参照画像蓄積部（１７０７）は再構成参照画像を蓄積する。変形参照画像復号化部（１７０８）は符号化データの動きベクトル部分と再構成参照画像から、変形参照画像を復号化し、変形参照画像蓄積部

（１７０９）に出力する。

【０１０２】変形参照画像蓄積部（１７０９）は、変形参照画像を蓄積する。予測画像復号化部（１７１０）は、符号化データの残差成分部分と変形参照画像から、予測画像を復号化し、予測画像蓄積部（１７１１）に出力する。予測画像蓄積部（１７１１）は、予測画像を蓄積する。出力画像選択部（１７１２）は、画像を選択し、画像表示部（１７１３）に出力する。画像表示部（１７１３）は、画像を表示する。

【０１０３】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。まず、データ記憶・伝送部（１７０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルを符号化データ選択部（１７０５）に出力する。また、符号化データ選択部（１７０５）により、符号化データが読み出される。

【０１０４】画像要求監視部（１７０２）は、マウスを持った計算機であり、ユーザがマウスを使ってする要求を常に監視し、画像要求蓄積部（１７０３）に蓄積する。画像要求蓄積部（１７０３）は、要求される画像の撮影位置を蓄積し、符号化データ選択部（１７０５）により読み出される。

【０１０５】復号化状況蓄積部（１７０４）では、復号化状況テーブル（１８０１）を蓄積し、符号化データ選択部（１７０４）により更新され、読み出される。復号化状況テーブル（１８０１）において、撮影位置は（ρ，θ）であり、復号化レベルは復号化の状況を示す。復号化レベルの意味を復号化レベルテーブル（１８０２）に示す。

【０１０６】符号化データ選択部（１７０５）は、要求する撮影位置とランダムアクセステーブルと復号化状況テーブルから、出力データと出力先と復号化状況テーブル更新方法を決定する。図１９に要求する撮影位置とランダムアクセステーブルと復号化状況テーブルの状態を列挙した状態テーブルを示す。ここで、Ｐは要求された画像の撮影位置、Ｑは要求された画像が予測画像の場合、その画像の復号化に必要な参照画像の撮影位置、Ｒは復号化状況テーブル（１８０１）に登録されている参照画像撮影位置、Ｓは復号化状況テーブル（１８０１）に登録されている予測画像撮影位置、Ｌは復号化状況テーブル（１８０１）に登録されている復号化レベルを表わす。

【０１０７】図２０に出力データ書式（２００１）と各状態に対応する出力データと出力先と更新後の復号化状況テーブルを列挙した出力データテーブル（２００２）を示す。出力データ書式（２００１）において出力画像フラグは最終的に出力されるべき画像を示すフラグであり、０は出力なし、１は再構成参照画像を出力、２は変形参照画像を出力、３は再構成予測画像を出力を示す。符号化データはランダムアクセステーブルより撮影位置に対応する符号化データ位置を検索し、データ記憶・伝送部（１７０１）より読み出す。

【０１０８】参照画像復号化部（１７０６）では、入力された出力画像フラグと符号化データを出力画像フラグは出力画像選択部（１７１２）に出力し、符号化データは参照画像に復号化し、再構成参照画像蓄積部（１７０７）に出力する。再構成参照画像蓄積部（１７０７）は、再構成参照画像を蓄積する。変形画像復号化部（１７０８）では、入力された出力画像フラグと符号化データを出力画像フラグは出力画像選択部（１７１２）に出力し、符号化データは符号化データの動きベクトル部分を復号化し、再構成参照画像を変形させて変形参照画像を作成し、変形参照画像蓄積部（１７０９）に出力する。変形参照画像蓄積部（１７０９）は、変形参照画像を蓄積する。

【０１０９】予測画像復号化部（１７１０）では、入力された出力画像フラグと符号化データを、出力画像フラグは出力画像選択部（１７１２）に出力し、符号化データは符号化データの残差成分部分を復号化し、変形参照画像に残差成分を加えて予測画像を作成し、再構成予測画像蓄積部（１７１１）に出力する。再構成予測画像蓄積部（１７１１）は、再構成予測画像を蓄積する。

【０１１０】出力画像選択部（１７１２）は、入力された出力画像フラグが、０ならば出力しない、１ならば再構成参照画像蓄積部（１７０６）より再構成参照画像を読み出し、画像表示部（１７１３）に出力する、２ならば変形参照画像蓄積部（１７０８）より変形参照画像を読み出し、画像表示部（１７１３）に出力する、３ならば再構成予測画像蓄積部（１７１１）より再構成予測画像を読み出し、画像表示部（１７１３）に出力する。画像表示部（１７１３）は、入力された画像を表示する。

【０１１１】以上のように、本実施の形態では、画像要求を監視し、蓄積する部と、復号化処理途中の変形画像を出力する部を備えており、画像要求の変化の速度と画像復号化処理の速度に対応して、自動的に変形画像か再構成予測画像を出力することにより、画像要求の変化が速いときや画像復号化処理の速度が遅いときは画質の良くない変形画像が、その逆のときには画質のよい再構成予測画像を表示することが可能である。

【０１１２】図２１は本発明の第７の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【０１１３】同図において、データ記憶・伝送部（２１０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルと符号化データを符号化データ選択部（２１０４）に出力する。画像要求部（２１０２）は、要求する画像の撮影位置を画像蓄積検査部（２１０３）に出力する。画像蓄積検査部（２１０３）では、再構成参照画像群蓄積部（２１０８）と再構成予測画像群蓄積部（２１０９）に蓄積され

ている画像の重要度を撮影位置に基づいて計算し、最大蓄積量を越えないように重要度の低い画像を消去する。符号化データ選択部（２１０４）では、蓄積された画像とランダムアクセステーブルに基づいて必要な符号化データを選択し、参照画像復号化部（２１０５）や予測画像復号化部（２１０６）や参照予測画像復号化部（２１０７）に出力する。

【０１１４】再構成参照画像群蓄積部（２１０８）では、複数枚の再構成参照画像と各画像の撮影位置を蓄積し、出力画像選択部（２１１０）に出力する。再構成予測画像群蓄積部（２１０９）では、複数枚の再構成予測画像と各画像の撮影位置を蓄積し、出力画像選択部（２１１０）に出力する。参照画像復号化部（２１０５）では、符号化データを参照画像に復号化し、再構成参照画像群蓄積部（２１０８）に出力し、要求画像の撮影位置を出力画像選択部（２１１０）に出力する。予測画像復号化部（２１０６）では、符号化データを再構成参照画像を用いて予測画像に復号化し、再構成予測画像群蓄積部（２１０９）に出力し、要求画像の撮影位置を出力画像選択部（２１１０）に出力する。参照予測画像復号化部（２１０７）では、符号化データを参照画像と予測画像に復号化し、再構成した参照画像を再構成参照画像群蓄積部（２１０８）に出力し、再構成した予測画像を再構成予測画像群蓄積部（２１０９）に出力し、要求画像の撮影位置を出力画像選択部（２１１０）に出力する。出力画像選択部（２１１０）は、要求画像の撮影位置に対応する画像を再構成参照画像群蓄積部（２１０８）と再構成予測画像群蓄積部（２１０９）の中から取得し、画像表示部（２１１１）に出力する。画像表示部（２１１１）では、入力された画像を表示する。

【０１１５】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部＊

＊（２１０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルを符号化データ選択部（２１０４）に出力する。また、符号化データ選択部（２１０４）により、符号化データが読み出される。

【０１１６】画像要求部（２１０２）は、マウスを持った計算機であり、ユーザがマウスを使って見たい画像を要求し、要求画像の撮影位置を画像蓄積検査手段（２１０３）に出力する。画像蓄積検査部（２１０３）では、要求された画像の撮影位置と、最大Ｎ枚蓄積できる再構成参照画像群蓄積部（２１０８）に蓄積された画像の撮影位置と最大Ｍ枚蓄積できる再構成予測画像群蓄積部（２１０９）に蓄積された画像の撮影位置により各画像に対する重要度を計算し、再構成参照画像群蓄積部（２１０８）に蓄積された画像のＮ番目に重要度が大きいものと再構成予測画像群蓄積部（２１０９）に蓄積された画像のＭ番目に重要度が大きいものを消去する。$\rho-\theta$空間上で距離の近いほど重要度は高いので、要求された画像の撮影位置をＰ、蓄積された画像の撮影位置をＱとすると、重要度はＷは、

【０１１７】

【数８】

$$W=\frac{1}{d(\mathbf{P},\mathbf{Q})}$$

【０１１８】で計算できる。ここで、

【０１１９】

【数９】

$$\mathbf{P}_1=(\rho_1,\theta_1),\ \mathbf{P}_2=(\rho_2,\theta_2)$$

【０１２０】とすると、

【０１２１】

【数１０】

$$d(\mathbf{P}_1,\mathbf{P}_2)=\min((\rho_1-\rho_2)^2,(\rho_1-\rho_2-360)^2,(\rho_1-\rho_2+360)^2)+(\theta_1-\theta_2)^2$$

【０１２２】である。符号化データ選択部（２１０４）では、図２２の状態テーブルに応じて図２３の出力データテーブルにしたがって、出力データを作成し、それぞれの出力先に出力する。図２２と図２３においてＰは要求画像の撮影位置であり、Ｑは要求画像が予測画像の場合に復号化に必要となる参照画像の撮影位置である。出力データは先頭に出力画像撮影位置データを配置し、続いて画像の再構成に必要なデータを配置している。

【０１２３】参照画像復号化部（２１０５）では、入力されたデータの先頭の出力画像撮影位置データを出力画像選択部（２１１０）に出力し、参照符号化データを参照画像に復号化し、再構成参照画像群蓄積部（２１０８）に出力する。

【０１２４】予測画像復号化部（２１０６）では、入力されたデータの先頭の出力画像撮影位置データを出力画像選択部（２１１０）に出力し、参照画像データを用いて予測符号化データを予測画像に復号化し、再構成予測画像群蓄積部（２１０９）に出力する。

【０１２５】参照予測画像復号化部（２１０７）では、入力されたデータの先頭の出力画像撮影位置データを出力画像選択部（２１１０）に出力し、参照符号化データを参照画像に復号化し、再構成された参照画像を用いて予測符号化データを予測画像に復号化し、再構成参照画像群蓄積部（２１０８）に再構成参照画像を出力し、再構成予測画像群蓄積部（２１０９）に再構成予測画像を出力する。

【０１２６】出力画像選択部（２１１０）では、入力された出力画像撮影位置データに対応する画像を再構成参照画像群蓄積部（２１０８）と再構成予測画像群蓄積部（２１０９）から取得し、画像表示部（２１１１）に出力する。

【０１２７】画像表示部（２１１１）では、入力された画像を表示する。以上のように、本実施の形態では、多視点画像復号化装置では、現在要求されている画像の撮

影位置の近傍の画像の要求頻度が高いことを利用し、要求された画像の撮影位置に近いものに高い重要度を与え、一度復号化した画像のうち重要度の高いものを蓄積しておくことで、効率的に画像を復号化することが可能である。

【０１２８】図２４は本発明の第８の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【０１２９】同図において、データ記憶・伝送部（２４０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルと符号化データを符号化データ選択部（２４０５）と予測符号化データ選択部（２４０９）に出力する。画像要求部（２４０２）は、要求する画像の撮影位置を画像要求蓄積部（２４０３）に出力する。画像要求蓄積部（２４０３）は、画像要求を蓄積し、符号化データ選択部（２４０５）により画像要求が読み出される。前回画像要求蓄積部（２４０４）は、前回処理した画像の撮影位置を蓄積し、符号化データ選択部（２４０５）によって、前回画像要求が読み出され、更新される。

【０１３０】符号化データ選択部（２４０５）は、前回処理した画像の要求や画像の蓄積の状態から復号化すべき符号化データを決定し、ランダムアクセステーブルと符号化データから必要な符号化データや画像データを選択し、参照予測画像復号化部１（２４０６）や参照画像復号化部１（２４０７）や予測画像復号化部１（２４０８）や画像表示部（２４１５）に出力する。

【０１３１】予測符号化データ選択部（２４０９）は、復号化されていない近傍の撮影位置を予測し、その位置の画像の復号化に必要なデータを、ランダムアクセステーブルと符号化データと画像データからを選択し、参照予測画像復号化部２（２４１０）や参照画像復号化部２（２４１１）や予測画像復号化部２（２４１２）に出力する。参照予測画像復号化部１（２４０６）は、符号化データから予測画像を復号化し、画像表示部（２４１５）に出力する。

【０１３２】参照画像復号化部１（２４０７）は、符号化データから参照画像を復号化し、画像表示部（２４１５）に出力する。予測画像復号化部１（２４０８）は、符号化データと画像データから予測画像を復号化し、画像表示部（２４１５）に出力する。参照予測画像復号化部２（２４１０）は、符号化データから参照画像と予測画像を復号化し、再構成参照画像群蓄積部（２４１３）と再構成予測画像群蓄積部（２４１４）に出力する。参照画像復号化部２（２４１１）は、符号化データから参照画像を復号化し、再構成参照画像群蓄積部（２４１３）に出力する。予測画像復号化部２（２４１２）は、符号化データと画像データから予測画像を復号化し、再構成予測画像群蓄積部（２４１４）に出力する。

【０１３３】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部（２４０１）では、ランダムアクセステーブルと符号化データを蓄積・伝送し、ランダムアクセステーブルを符号化データ選択部（２４０５）に出力する。また、符号化データ選択部（２４０５）により、符号化データを読み出される。画像要求部（２４０２）は、マウスを持った計算機であり、ユーザがマウスを使って見たい画像を要求し、要求画像の撮影位置を画像要求蓄積手段（２４０３）に出力する。画像要求蓄積部（２４０３）では、要求された画像の撮影位置を蓄積し、符号化データ選択部（２４０５）によって、撮影位置を読み出される。

【０１３４】前回要求画像蓄積部（２４０４）では、処理した撮影位置を蓄積し、符号化データ選択部（２４０５）によって、撮影位置を読み出される。符号化データ選択部（２４０５）では、図２５の状態テーブルに応じて図２６の出力データテーブルにしたがって、出力データを作成し、それぞれの出力先へ出力する。図２５と図２６においてＰは要求画像の撮影位置であり、Ｑは要求画像が予測画像の場合に復号化に必要となる参照画像の撮影位置であり、Ｒは前回処理された画像の撮影位置である。さらに、Ｒ≠Ｐならば、再構成予測画像群蓄積部（２４１３）と再構成参照画像群蓄積部（２４１４）に蓄積されている画像を消去し、Ｐを前回要求画像蓄積部（２４０４）に書き込む。

【０１３５】参照予測画像復号化部１（２４０６）は、参照符号化データと予測符号化データを予測画像に復号化し、画像表示部（２４１５）に出力する。参照画像復号化部１（２４０７）は、参照符号化データを参照画像に復号化し、画像表示部（２４１５）に出力する。予測画像復号化部１（２４０８）は、参照画像データと予測符号化データを予測画像に復号化し、画像表示部（２４１５）に出力する。

【０１３６】予測符号化データ選択部（２４０９）では、図２７の予測テーブルの上から順に、再構成参照画像群蓄積部（２４１３）と再構成予測画像群蓄積部（２４１４）に蓄積されていないか検索し、蓄積されていないものがあれば、その撮影位置を予測撮影位置としてＳとして、図２８の状態テーブルに応じて図２９の出力データテーブルにしたがって、出力データを作成しそれぞれの出力先へ出力する。図２８と図２９で、Ｔは、撮影位置Ｓの画像が予測画像の場合の復号化に必要な参照画像の撮影位置である。

【０１３７】参照予測画像復号化部２（２４１０）は、参照符号化データと予測符号化データを参照画像と予測画像に復号化し、参照画像は再構成参照画像群蓄積部（２４１３）に、予測画像は再構成予測画像群蓄積部（２４１４）に出力する。参照画像復号化部２（２４１１）は、参照符号化データを参照画像に復号化し、再構成参照画像群蓄積部（２４１３）に出力する。

【０１３８】予測画像復号化部２（２４１２）は、参照

画像データと予測符号化データを予測画像に復号化し、再構成予測画像群蓄積部（２４１４）に出力する。画像表示部（２４１５）は、入力された画像を表示する。

【０１３９】以上のように、本実施の形態では、多視点画像復号化装置では、現在要求されている画像の撮影位置の近傍の画像の要求頻度が高いことを利用し、画像の要求の変化がないときには、要求された画像の撮影位置に近いもの復号化しておくことで、効率的に画像を復号化することが可能である。

【０１４０】図３０は本発明の第９の実施の形態である画像符号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【０１４１】同図において、撮影位置制御型画像撮像部（３００１）は、対象物体の画像を撮影し、その撮影位置データと画像データを出力する。参照予測グループ部（３００５）は、撮影位置データと画像データを参照画像と一枚以上の予測画像からなる参照予測グループにグループ化し、参照画像を参照画像符号化部（３００６）に出力し、撮影位置データと参照画像と予測画像を変形拘束式推定部（３００８）に出力する。

【０１４２】参照画像符号化部（３００６）は、参照画像を符号化し、再構成参照画像を作成し、符号化データを参照関係作成部（３０１０）に出力し、再構成参照画像を再構成参照画像蓄積部（３００７）に出力する。再構成参照画像蓄積部（３００７）は、再構成参照画像を蓄積し、拘束予測画像符号化部（３００９）に再構成参照画像を出力する。拘束式推定部（３００８）は、拘束式を推定し、拘束予測画像符号化部（３００９）に出力する。

【０１４３】拘束予測画像符号化部（３００９）は、予測画像を符号化し、符号化データを参照関係作成部（３０１０）に出力する。参照関係テーブル作成部（３０１０）は、符号化データから参照関係と符号化データ位置と撮影位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データをデータ記録・伝送部（３０１１）に出力する。データ記録・伝送部（３０１１）は、用途に応じて記録・伝送する。

【０１４４】以上のように構成された本実施の形態の画像符号化装置の動作を説明する。まず、画像位置制御型撮像部（３００１）では、図１の画像位置制御型撮像部と同様に、対象物体の周囲を周囲を網羅するように、異なる視点から画像を撮影し、撮影位置・画像データを取得し、図３に示す書式で出力する。

【０１４５】参照グループ化部（３００５）では、図１の参照グループ化部（１０５）と同様に、参照画像とその近傍の画像を予測画像としてグループ化し、インデックス順に図５に示す書式で、参照画像符号化部（３００６）と変形拘束式推定部（３００８）へ出力する。参照画像符号化部（３００６）は、図１の参照画像符号化部（１０６）と同様である。再構成参照画像蓄積部（３００７）は、図１の再構成参照画像蓄積部（１０７）と同様である。

【０１４６】変形拘束式推定部（３００８）では、エピポーラ拘束と呼ばれる拘束式のパラメータ７つを推定する（「エピポラー　ジェオメトリ　イン　ステレオ　モーション　アンド　オブジェクト　レコグニション」"Epipolar Geometry in Stereo、 Motion and Object Recognition - A Unified Approach、" Gang Xu and Zheng you Zhang、 Kluwer Academic Publishers、 1996））。

【０１４７】図３１はエピポーラ拘束の説明図であり、３次元空間中の点Ｍを異なる視点から撮影した場合である。Ｃ１、Ｃ２はそれぞれの画像１と画像２を撮影したカメラの焦点を示し、Ｍは、画像１上ではｍ１に、画像２上ではｍ２に投影される。Ｃ２は画像１上のｅ１に、Ｃ１は画像２上のｅ２に投影され、ｅ１とｅ２はそれぞれの画像上のエピ極と呼ばれる。３次元空間中のＣ１とｍ１を通る直線を画像２上への投影した直線をエピポーラ線と呼び、エピポーラ線２として図３１に示す。

【０１４８】エピポーラ線２は、画像１を撮影したカメラの内部パラメータ（焦点距離、光軸）と視点位置、画像２を撮影したカメラの内部パラメータと視点位置、画像１上の点の座標により決定できる。エピポーラ線２を決定できれば、画像１上の点ｍ１に３次元空間で対応する画像２上の点ｍ２の位置は、Ｃ１からＭの距離が得られない場合でも、エピポーラ線２上に拘束できる。

【０１４９】図３２に示す二つの視点から撮影された画像１と画像２において、画像１上の点（ｘ１、ｙ１）に対応する画像２上のエピポーラ線は以下のように表わされる。

【０１５０】

【数１１】

$$(x_1, y_1, 1)\mathbf{F}(x, y, 1)^{\mathbf{T}} = 0$$

【０１５１】ここで、

【０１５２】

【数１２】

$$\mathbf{F} = \mathbf{A}^{-T}\mathbf{t}_{\times}\mathbf{R}\mathbf{A}^{-1}$$

【０１５３】

【数１３】

$$\mathbf{A} = \begin{pmatrix} f & 0 & ox \\ 0 & f & oy \\ 0 & 0 & 1 \end{pmatrix}$$

【０１５４】

【数１４】

25 26

$$R=\begin{pmatrix}1 & 0 & 0\\ 0 & \cos(\rho_2-\rho_1) & -\sin(\rho_2-\rho_1)\\ 0 & \sin(\rho_2-\rho_1) & \cos(\rho_2-\rho_1)\end{pmatrix}\begin{pmatrix}\cos\theta_2 & 0 & -\sin\theta_2\\ 0 & 1 & 0\\ \sin\theta_2 & 0 & \cos\theta_2\end{pmatrix}\begin{pmatrix}\cos\theta_1 & 0 & \sin\theta_1\\ 0 & 1 & 0\\ -\sin\theta_1 & 0 & \cos\theta_1\end{pmatrix}$$

【０１５５】

【数１５】

$$\mathbf{t}=\mathbf{R}(0,0,-d)^T+(0,0,d)^T$$

【０１５６】であり、ｏｘ、ｏｙはカメラの光軸の画像上の座標を表わし、ｆは焦点距離を示す。

【０１５７】（$\rho 1$，$\theta 1$）、（$\rho 2$，$\theta 2$）、ｄは、図３２に示す撮影位置を示し、×は、

【０１５８】

【数１６】

$$\begin{pmatrix}x_1\\ x_2\\ x_3\end{pmatrix}_\times=\begin{pmatrix}0 & -x_3 & x_2\\ x_3 & 0 & -x_1\\ -x_2 & x_1 & 0\end{pmatrix}$$

【０１５９】の演算を示す。カメラの内部パラメータであるｏｘ、ｏｙ、ｆは、予め求めておき、（$\rho 1$，$\theta 1$）、（$\rho 2$，$\theta 2$）、ｄは撮影システムにより与えられる。７つのパラメータｅは、

【０１６０】

【数１７】

$$\mathbf{F}=\begin{pmatrix}f_{11} & f_{12} & f_{13}\\ f_{21} & f_{22} & f_{23}\\ f_{31} & f_{32} & f_{33}\end{pmatrix}$$

【０１６１】とすると、

【０１６２】

【数１８】

$$\mathbf{e}=\begin{pmatrix}\frac{f_{32}f_{21}-f_{22}f_{31}}{f_{22}f_{11}-f_{21}f_{12}}\\ \frac{f_{31}f_{12}-f_{11}f_{32}}{f_{22}f_{11}-f_{21}f_{12}}\\ \frac{f_{23}f_{12}-f_{22}f_{13}}{f_{22}f_{11}-f_{21}f_{12}}\\ \frac{f_{13}f_{21}-f_{11}f_{23}}{f_{22}f_{11}-f_{21}f_{12}}\\ \frac{-f_{12}}{f_{21}}\\ \frac{f_{11}}{f_{21}}\\ \frac{-f_{22}}{f_{21}}\end{pmatrix}$$

【０１６３】で計算できる。予測画像の撮影位置を（$\rho 1$，$\theta 1$）とし、その予測画像を予測するための参照画像（同じインデックスのついた参照画像）の撮影位置（$\rho 2$，$\theta 2$）として用いて、それぞれの参照予測の組に対してエピポーラパラメータを推定する。入力である図５のデータの予測画像にエピポーラパラメータを付加し、図３３に示す書式で、拘束予測画像符号化部（３００９）へ出力する。

【０１６４】拘束予測画像符号化部（３００９）のフローチャートを図３４に示す。ブロック化ステップでは、予測画像データをブロックに分割する。

【０１６５】エピポーラ線計算ステップでは、各ブロックの中心点の座標を（ｘ１，ｙ１）とし、拘束式推定部（３００８）で推定されたエピポーラパラメータｅからＦを以下のように計算し、式１１を用いてブロックにエピポーラ線を求める。

【０１６６】

【数１９】

$$\mathbf{F}=\begin{pmatrix}b & a & -(ay_b+bx_b)\\ -1 & -c & (cy_b+bx_b)\\ y_a-bx_a & cy_a-ax_a & -(cy_b-x_b)y_a+(ay_b+bx_b)x_a\end{pmatrix}$$

【０１６７】ここで、

【０１６８】

【数２０】

27

$$e = \begin{pmatrix} x_a \\ y_a \\ x_b \\ y_b \\ a \\ b \\ c \end{pmatrix}$$

【０１６９】である。動き推定ステップでは、図３５に示すように、予測画像のブロックをエピポーラ線に沿って、再構成参照画像上を１次元的に移動させて、予測画像ブロックと再構成参照画像の画素値の差の絶対値の総和が最小になる１次元の移動量を求める。

【０１７０】ブロック残差計算ステップでは、予測画像ブロックと再構成参照画像の画素値の差の絶対値の総和が最小になる位置での、画素値の差を計算する。ＤＣＴステップでは、ブロック残差計算ステップで計算されたブロック残差をデジタルコサイン変換する。量子化ステップでは、ＤＣＴステップの出力結果を所定の量子幅で量子化する。

【０１７１】可変長符号化ステップでは、動き推定ステップで計算された１次元移動量と、量子化ステップの出力結果を可変長符号化し、符号化データとして図３６に示す書式で出力する。

【０１７２】参照関係テーブル作成部（３０１０）は、参照関係テーブル作成部（１０９）と同様である。データ記録・伝送部（３０１１）は、データ記録・伝送部（１１０）と同様である。

【０１７３】以上のように、本実施の形態では、多視点画像のように、動きのないシーンを与えられた視点から撮影した場合、２つの画像の対応点が撮影対象によらず、カメラの視点と内部パラメータから決定できるある直線上に拘束されることを利用して、符号化データに拘束パラメータを付加する一方で、２次元の動き情報を一次元の動き情報に減少させることで、効率の良い符号化が可能である。

【０１７４】図３７は本発明の第１０の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【０１７５】同図において、データ記憶・伝送部（３７０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルと符号化データを符号化データ選択部（３７０２）に出力する。符号化データ選択部（３７０２）では、参照関係テーブルからデータの位置を検索し、符号化データから必要なデータを参照画像復号化部（３７０３）や拘束予測画像復号化部（３７０５）に出力する。参照画像復号化部（１７０３）では、参照画像符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（３７０４）に出力し、必要なら画像表示手段（３７０６）にも出力する。

28

【０１７６】再構成参照画像蓄積部（３７０５）は、再構成参照画像を蓄積し、拘束予測画像復号化部（３７０５）に出力する。拘束予測画像復号化部（３７０５）では、予測画像符号化データを復号化し、再構成予測画像を画像表示部（３７０６）に出力する。画像表示部（３７０６）は入力された画像を蓄積しておき、要求により表示する。

【０１７７】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部（３７０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルと符号化データを符号化データ選択部（３７０２）に出力する。符号化データ選択部（３７０２）では、参照関係テーブルから符号化データ位置を検索し、データ記憶・伝送部（３７０１）から、符号化データ位置の符号化データを取得する。参照／予測フラグと参照符号化データを、参照画像復号化部（３７０３）に出力し、予測符号化データがあれば、予測画像復号化部（３７０５）に出力する。

【０１７８】ただし、参照画像復号化部（３７０３）に出力する参照符号化データが前回と同じ場合は、参照画像はすでに復号化され、蓄積されているので、参照画像復号化部（３７０３）への出力は省略する。

【０１７９】参照画像復号化部（３７０３）では、参照画像が符号化された参照符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（３７０４）に出力する。また、参照／予測フラグにおいて、参照画像であれば、画像表示部（３７０６）に再構成参照画像を出力する。

【０１８０】再構成参照画像蓄積部（３７０４）では、再構成された参照画像を蓄積し、拘束予測画像復号化部（３７０５）に出力する。拘束予測画像復号化部（３７０５）のフローチャートを図３８に示す。復号化ステップでは、可変長符号化されたエピポーラパラメータ、動き情報、残差情報を復号化する。

【０１８１】エピポーラ線計算ステップでは、ブロックの中心座標とエピポーラパラメータから、図３４のエピポーラ線計算ステップと同様にエピポーラ線を計算する。動き補償ステップでは、エピポーラ線に沿って、復号化された移動量だけ移動したところからブロックを得、変形画像を構成する。逆量子化ステップでは、残差情報を逆量子化する。逆ＤＣＴステップでは、逆量子化された残差情報を逆ＤＣＴし、画素の残差情報を得る。ブロック再構成ステップでは、逆ＤＣＴステップで得られた残差情報を、動き補償ステップで得られた変形画像に加えて予測画像データを再構成する。

【０１８２】以上のように予測符号化データを再構成参照画像を用いて復号化し、画像表示部（３７０６）に再構成予測画像を出力する。画像表示部（３７０６）では、復号化された画像を蓄積しておき、計算機に接続されたマウスにより検索し、表示する。

29

【０１８３】以上のように、本実施の形態では、多視点画像のように、動きのないシーンを与えられた視点から撮影した場合、２つの画像の対応点が撮影対象によらず、カメラの視点と内部パラメータから決定できるある直線上に拘束されることを利用して、符号化データに拘束パラメータを付加する一方で、２次元の動き情報を一次元の動き情報に減少させることで、効率の良く符号化した符号化データの復号化が可能である。

【０１８４】図３９は本発明の第１１の実施の形態である画像符号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【０１８５】同図において、撮影位置光源位置制御型画像撮像部（３９０１）は、対象物体の画像を撮影し、その撮影位置データと光源位置データと画像データを出力する。参照予測グループ部（３９０７）は、撮影位置データと光源位置データと画像データを参照画像と一枚以上の予測画像からなる参照予測グループにグループ化し、参照画像を参照画像符号化部（３９０８）に出力し、予測画像を予測画像符号化部（３９０８）に出力する。

【０１８６】参照画像符号化部（３９０８）は、参照画像を符号化し、再構成参照画像を作成し、符号化データを参照関係作成部（３９１１）に出力し、再構成参照画像を再構成参照画像蓄積部（３９０９）に出力する。再構成参照画像蓄積部（３９０９）は、再構成参照画像を蓄積し、予測画像符号化部（３９１０）に再構成参照画像を出力する。

【０１８７】予測画像符号化部（３９１０）は、予測画像を符号化し、符号化データを参照関係作成部（３９１１）に出力する。参照関係テーブル作成部（３９１１）は、符号化データから参照関係と符号化データ位置と撮影位置と光源位置を記述した参照関係テーブルを作成し、参照関係テーブルと符号化データをデータ記録・伝送部（３９１０）に出力する。データ記録・伝送部（３９１２）は、用途に応じて記録・伝送する。

【０１８８】以上のように構成された本実施の形態の画像符号化装置の動作を説明する。撮影位置光源位置制御型画像撮像部（３９０１）では、光源位置が対象物体の周囲を網羅するように、異なる光源位置で画像を撮影する。計算機（３９０４）によって、サーボモータ２（３９０４）を対象物体の正面から水平方向にρ１度、水平面から垂直方向にθ１度の位置に光源（３９０５）を移動させる。さらに、それぞれの光源位置について、カメラ位置が対象物体の周囲を網羅するように、異なる視点から画像を撮影する。

【０１８９】計算機（３９０４）によってサーボモータ１（３９０２）を対象物体の正面から水平方向にρｃ度、水平面から垂直方向にθｃ度の位置にカメラ（３９０３）を移動させ、撮影位置・光源位置・画像データを計算機（３９０４）によって取得する。ここで、得られる画像データは図２と同様に輝度プレーン、色差１プレーン、色差２プレーン、アルファプレーンで構成する。ここで、ρ１，θ１，ρｃ，θｃは、

30

【０１９０】

【数２１】

$$0 \leq \rho_c < 360,\ 0 \leq \theta_c \leq 90,\ (\rho_c, \theta_c \text{は整数})$$

【０１９１】

【数２２】

$$0 \leq \rho_l < 360,\ 0 \leq \theta_l \leq 90,\ (\rho_l, \theta_l \text{は10の倍数})$$

【０１９２】とする。このように取得された撮影位置・光源位置・画像データは、図４０に示すように、各画像データの先頭に水平方向撮影角度ρｃと、垂直方向撮影角度θｃと、水平方向撮影角度ρ１と、垂直方向撮影角度θ１を付加した書式で出力される。

【０１９３】参照予測グループ化部（３９０７）では、参照画像によって類似した画像を予測画像として予測符号化するために、ρ１－θ１－ρｃ－θｃ空間において、等間隔に参照画像を配置し、参照画像の近傍の画像をその参照画像より予測される予測画像にグループ化する。参照予測グループ化部（３９０７）での処理は、図１の参照予測グループ化部（１０５）の処理を４次元的に行う。グループ化された撮影位置・光源位置・画像データはインデックス順に図４１の示す書式で、参照画像は参照画像符号化部（３９０８）へ、予測画像は予測画像符号化部（３９１０）へ出力する。

【０１９４】参照画像符号化部（３９０８）では、参照画像を図１の参照画像符号化部（１０６）と同様に符号化し、符号化データを参照関係テーブル作成部（３９１１）に出力し、参照画像の再構成画像を作成し、再構成参照画像蓄積部（３９０９）に出力する。

【０１９５】再構成参照画像蓄積部（３９０９）では、再構成参照画像を蓄積しておき、予測画像符号化部（３９１０）に出力する。参照予測グループ化部（３９０７）において、図４１のように参照画像と予測画像が整列されて出力されるので、再構成参照画像蓄積部（３９０９）は、画像１枚分の容量を持っていれば十分である。

【０１９６】予測画像符号化部（３９１０）では、図１の予測画像符号化部（１０８）と同様に、予測画像を再構成参照画像を用いて符号化し、符号化データを参照関係テーブル作成部（３９１１）に出力する。参照関係テーブル作成部（３９１１）では、各符号化部より出力された図４２のようなデータを順に走査し、図４３のような参照関係テーブルと図４４のような符号化データを作成し、データ記録・伝送部（３９１２）に出力する。

【０１９７】データ記録・伝送部（３９１２）では、参照関係テーブルと符号化データを磁気ディスクや光ディスクに蓄積しておいたり、ネットワークなどで伝送する。

【０１９８】以上のように、本実施の形態では、異なる

多くの視点から異なる多くの光源位置で撮影された多視点画像を、撮影位置データが近傍の類似した画像である参照画像と１枚以上の予測画像にグループ化し、効率よく符号化することが可能である。さらに、画像を各参照予測グループで参照画像が先頭になるように整列して、符号化手段に出力することで、計算量と計算に必要な蓄積容量を少なくしている。また、その整列順に符号化データ位置を格納したテーブルを付加することで、ランダムアクセスに対応した効率的な復号化が可能である。

【０１９９】図４５は本発明の第１２の実施の形態である画像復号化装置の構成を示すブロック図であり、同図を用いて本実施の形態の構成を説明する。

【０２００】同図において、データ記憶・伝送部（４５０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルと符号化データを符号化データ選択部（４５０２）に出力する。符号化データ選択部（４５０２）では、参照関係テーブルから要求された画像のデータの位置を検索し、符号化データから必要なデータを参照画像復号化部（４５０３）や予測画像復号化部（４５０５）に出力する。

【０２０１】要求された光源位置の符号化データがなければ、近傍にある複数の光源位置の符号化データを選択し、それぞれを参照画像復号化部（４５０３）や予測画像復号化部（４５０５）に出力する。参照画像復号化部（４５０３）では、参照画像符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（４５０４）と中間画像生成部（４５０６）に出力する。再構成参照画像蓄積部（４５０５）は、再構成参照画像を蓄積し、予測画像復号化部（４５０５）に出力する。予測画像復号化部（４５０５）では、予測画像符号化データを復号化し、再構成予測画像を中間画像生成部（４５０６）に出力する。

【０２０２】中間画像生成部（４５０６）では、要求された光源位置の画像がなければ、近傍の光源位置の画像を用いて要求された光源位置の画像の画像を生成し、画像表示部（４５０７）に出力する。画像表示部（４５０７）は入力された画像を蓄積しておき、要求により表示する。

【０２０３】以上のように構成された本実施の形態の画像復号化装置の動作を説明する。データ記憶・伝送部（４５０１）では、参照関係テーブルと符号化データを蓄積・伝送し、参照テーブルと符号化データを符号化データ選択部（４５０２）に出力する。

【０２０４】符号化データ選択部（４５０２）では、要求された光源位置と撮影位置を参照関係テーブルから符号化データ位置を検索し、データ記憶・伝送部（４５０１）から、符号化データ位置の符号化データを取得する。参照／予測フラグと参照符号化データを、参照画像復号化部（４５０３）に出力し、予測符号化データがあれば、予測画像復号化部（４５０５）に出力する。

【０２０５】ただし、参照画像復号化部（４５０３）に出力する参照符号化データが前回と同じ場合は、参照画像はすでに復号化され、蓄積されているので、参照画像復号化部（４５０３）への出力は省略する。また、要求された光源位置のデータがない場合には、光源位置が近傍の４つの符号化データをそれぞれ参照画像復号化部（４５０３）と予測画像復号化部（４５０４）へ出力する。

【０２０６】要求された画像が、（$\rho 1$，$\theta 1$，ρc，θc）であり、参照関係テーブルに、光源位置が水平・垂直方向の角度が１０の倍数の画像しか無い場合、近傍の４つの符号化データ（$\rho 11$，$\theta 11$，ρc，θc）、（$\rho 11$，$\theta 12$，ρc，θc）、（$\rho 12$，$\theta 11$，ρc，θc）、（$\rho 12$，$\theta 12$，ρc，θc）は、以下の式によって得られる。

【０２０７】

【数２３】

$$\rho_{l1} = \lceil \rho_l \rfloor$$

【０２０８】

【数２４】

$$\rho_{l2} = \lceil \rho_l \rfloor + 10$$

【０２０９】

【数２５】

$$\theta_{l1} = \lceil \theta_l \rfloor$$

【０２１０】

【数２６】

$$\theta_{l2} = \lceil \theta_l \rfloor + 10$$

【０２１１】ここで、「・」は、・を越えない１０の倍数を示す。また、$\rho 12$が３６０になる場合は、$\rho 12 = 0$とする。

【０２１２】参照画像復号化部（４５０３）では、参照画像が符号化された参照符号化データを復号化し、再構成参照画像を再構成参照画像蓄積部（４５０４）に出力する。

【０２１３】また、参照／予測フラグにおいて、参照画像であれば、中間画像生成部（４５０６）に再構成参照画像を出力する。再構成参照画像蓄積部（４５０４）では、再構成された参照画像を蓄積し、予測画像復号化部（４５０５）に出力する。

【０２１４】予測画像復号化部（４５０５）では、予測画像が符号化された予測符号化データを再構成参照画像を用いて復号化し、中間画像生成部（４５０６）に再構成予測画像を出力する。中間画像生成部（４５０６）では、要求された光源位置と復号化された画像データの光源位置が等しければ、画像表示部（４５０６）へ出力する。等しくなければ、符号化データ選択部（４５０２）で選択された光源位置が近傍の画像より中間画像を生成する。

【０２１５】要求された画像の光源位置を（$\rho 1$，$\theta 1$，ρc，θc）とし、符号化データ選択部（４５０

33

２）で選択された画像の光源位置を（ρｌ１，θｌ１，ρｃ，θｃ）、（ρｌ１，θｌ２，ρｃ，θｃ）、（ρｌ２，θｌ１，ρｃ，θｃ）、（ρｌ２，θｌ２，ρｃ，θｃ）とする。それぞれの近傍画像をＩ１、Ｉ２、Ｉ３、Ｉ４とし、画像Ｉ１の座標（ｘ，ｙ）の画素値を＊Ｉ１（ｘ，ｙ）と表わすと、中間画像Ｉの画素値Ｉ（ｘ，ｙ）を以下の式で計算する。

34

【０２１６】

【数２７】

$$I(x,y) = r_3(r_1 I_1(x,y) + r_2 I_3(x,y) + r_4(r_1 I_2(x,y) + r_2 I_4(x,y)$$

【０２１７】ここで、

【０２１８】

【数２８】

$$r_1 = \frac{\rho_{l2} - \rho_l}{\rho_{l2} - \rho_{l1}}$$

【０２１９】

【数２９】

$$r_2 = \frac{\rho_l - \rho_{l1}}{\rho_{l2} - \rho_{l1}}$$

【０２２０】

【数３０】

$$r_3 = \frac{\theta_{l2} - \theta_l}{\theta_{l2} - \theta_{l1}}$$

【０２２１】

【数３１】

$$r_4 = \frac{\theta_l - \theta_{l1}}{\theta_{l2} - \theta_{l1}}$$

【０２２２】である。生成された中間画像は画像表示部（４５０７）へ出力される。画像表示部（４５０７）では、復号化された画像を蓄積し、表示する。

【０２２３】以上のように、本実施の形態では、多くの異なる視点から多くの異なる光源位置で撮影した画像を、撮影位置が近傍の画像をグループ化し、グループを予測符号化された符号化データを、その参照予測関係と符号化データ位置と撮影位置を記述したテーブルを用いることにより、効率的に復号化することが可能である。

【０２２４】また、参照関係テーブルはグループ順に記述されているので、同一参照予測グループ内が連続的に復号化されるので、再構成参照画像を蓄積しておき、予測符号化データを復号化するだけで、効率的に画像を復号化することが可能である。

【０２２５】さらに、要求された光源位置の画像が符号化されていない場合でも、光源位置が近傍の画像から要求された光源位置の画像を生成するので、要求画像を表示することが可能である。

【０２２６】

【発明の効果】本発明の画像符号化装置と復号化装置では、以下の理由により、従来の画像符号化技術を用いるよりも効率の良い符号化と復号化が可能となる。

【０２２７】１．画像符号化データに参照関係と撮影位置と符号化データ位置を記述したテーブルを付加することにより、参照画像から複数の予測画像に対して予測符号化を用いて符号化する。

【０２２８】２．画像符号化データに参照関係と撮影位置と符号化データ位置を記述したテーブルを参照することにより、要求する画像の符号化データ位置を直ちに検索でき、復号化できる。

【０２２９】３．画像再生の要求を監視しておき、それを参照することにより、高速な要求の変化や計算能力に応じて、自動的に、画質は悪いが計算負荷の小さい変形画像と画質は良いが計算負荷の大きい予測画像を段階的に復号化する。

【０２３０】４．蓄積すべき画像の撮影位置を計算し、復号化処理済みの一枚数の画像を蓄積しておき、復号化処理の回数を減らす。

【０２３１】５．再生すべき画像に変化がないときに、再生すべき画像の撮影位置と撮影位置が復号化する画像撮影位置を計算し、あらかじめ復号化処理しておき、再生すべき画像の変化に高速な応答をする。

【０２３２】６．撮影シーンに動きがない場合に、撮影対象によらず対応点が直線上に拘束できることを利用して、拘束パラメータと１次元的な動き情報で、画像を効率に符号化する。

【０２３３】７．撮影シーンに動きがない場合に、撮影対象によらず対応点が直線上に拘束できることを利用して、拘束パラメータと１次元的な動き情報で、画像を効率に符号化した符号化データを復号化する。

【０２３４】８．画像符号化データに参照関係と撮影位置と光源位置と符号化データ位置を記述したテーブルを付加することにより、多くの視点で多くの照明効果を持つ対象物体画像を、要求にたいして効率的に復号化可能な状態で符号化する。

【０２３５】９．画像符号化データに参照関係と撮影位置と光源位置と符号化データ位置を記述したテーブルが付加された、符号化データを、要求にたいして効率的に復号化する。さらに、要求される光源位置の画像が符号化データに無い場合でも、光源位置が近傍の画像から中間画像を生成する。

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Applicant:	HANNUKSELA	Examiner:	Unassigned
Serial No.:	11/338,996	Group Art Unit:	2613
Filed:	January 25, 2006	Docket No.:	TPO.004.C1
Confirmation No.:	5361	Customer No.:	76385
Title:	GROUPING OF IMAGE FRAMES IN VIDEO CODING		

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

The Japanese reference was first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), and the 05 August 2003 Official Gazette Notice, only a copy of the foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided. The U.S. patent (No. 6,266,158) is included as an English-language version of the cited Japanese reference. Also attached is a copy of the Japanese Office Action with an English translation thereof.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC
8009 34th Avenue South, Suite 125
Minneapolis, MN 55425

(54) VIDEO INFORMATION PROCESSING DEVICE AND METHOD

(57)Abstract:
PROBLEM TO BE SOLVED: To eliminate flickering or fluctuations of images caused when frame dropping occurs in an interlace frame processing and the dropped frame is supplemented by copying a frame or field immediately preceding or following the dropped frame.
SOLUTION: An interlace frame is converted once into a progressive frame 503 which is processed as an interlace frame 501. Thus, half of the time component of the interlace frame is discarded to prevent flickering of a frame-thinned part. The interlace frame is not always converted into a progressive frame but converted only when frame thinning occurs. As a result, the time component loss can be minimized and also computer resources are saved to deal with similar problems.

(57)【要約】

【課題】　インタレースフレームを処理する際に、コマ落ちが発生し、そのコマ落ちを直前あるいは直後のフレームあるいはフィールドをコピーして補う場合に発生する「ちらつき」や「ゆれ」といった問題を解決することを目的とする。

【解決手段】　インタレースフレームを一旦プログレッシブフレームに変換し、そのプログレッシブフレームをインタレースフレームとして処理することで、インタレースフレームが持つ時間成分を半分廃棄し、コマ落ち部分の「ちらつき」を防ぐ。また、常にプログレッシブフレームに変換するのではなく、コマ落ちが発生した時にのみ変換することで、時間成分の損失を最小にとどめ且つ計算機資源を節約して同様の問題に対処する。

1

【特許請求の範囲】

【請求項１】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換手段と、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出手段と、上記プログレッシブフレームを、n枚のフィールドから構成されるインタレースフレームとして符号化し、映像符号を出力する符号化手段であり、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ち部分にはコマ落ち部分の直前あるいは直後の上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化手段とを備えたことを特徴とする映像情報処理装置。

【請求項２】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記インタレースフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを、上記インタレースフレームを構成するn枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換手段と、上記インタレース映像出力手段が出力したインタレースフレームを符号化し、映像符号を出力する符号化手段であり、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームに代わり対応する上記プログレッシブフレームをn枚のフィールドから構成されるインタレースフレームとして符号化し、且つコマ落ち部分には上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化手段とを備えたことを特徴とする映像情報処理装置。

【請求項３】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記インタレースフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換した画像を示すダミーフレーム用符号を出力するダミー用符号出力手段と、上記インタレース映像出力手段が出力したインタレースフレームを符号化し、映像符号を出力する符号化手段であり、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ち部分に出力する符号として、上記ダミーフレーム用符号を出力することで映像符号とする映像符号化手段とを備えたことを特徴とする映像情報処理装置。

【請求項４】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、

2

上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換手段と、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ち部の画像として、コマ落ち部の直前あるいは直後の上記プログレッシブフレームをコピーして補うコマ落ち対処手段と、上記プログレッシブ変換手段及びコマ落ち対処手段とが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理手段とを備えたことを特徴とする映像情報処理装置。

【請求項５】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記インタレースフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換し、コマ落ち部の画像を該画像で補うコマ落ち対処手段と、上記インタレース映像出力手段及びコマ落ち対処手段とが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理手段とを備えたことを特徴とする映像情報処理装置。

【請求項６】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換ステップと、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出ステップと、上記プログレッシブフレームを、n枚のフィールドから構成されるインタレースフレームとして符号化し、映像符号を出力する符号化ステップであり、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ち部分にはコマ落ち部分の直前あるいは直後の上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化ステップとを備えたことを特徴とする映像情報処理方法。

【請求項７】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記インタレースフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを、上記インタレースフレームを構成するn枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換ステップと、上記インタレース映像出力ステップが出力するインタレースフレームを符号化し、映像符号を出力する符号化ステップであり、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ

落ちの直前あるいは直後の上記インタレースフレームに代わり対応する上記プログレッシブフレームをn枚のフィールドから構成されるインタレースフレームとして符号化し、且つコマ落ち部分には上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化ステップとを備えたことを特徴とする映像情報処理方法。

【請求項８】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記インタレースフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換した画像を示すダミーフレーム用符号を出力するダミー用符号出力ステップと、上記インタレース映像を符号化し、映像符号を出力する符号化ステップであり、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ち部分に出力する符号として、上記ダミーフレーム用符号を出力することで映像符号とする映像符号化ステップとを備えたことを特徴とする映像情報処理方法。

【請求項９】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換ステップと、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ち部の画像として、コマ落ち部の直前あるいは直後の上記プログレッシブフレームをコピーして補うコマ落ち対処ステップと、上記プログレッシブ変換ステップ及びコマ落ち対処ステップとが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理ステップとを備えたことを特徴とする映像情報処理方法。

【請求項１０】n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記インタレースフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換し、コマ落ち部の画像を該画像で補うコマ落ち対処ステップと、上記インタレース映像出力ステップ及びコマ落ち対処ステップとが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理ステップとを備えたことを特徴とする映像情報処理方法。

【０００１】

【発明の属する技術分野】本発明は映像情報を符号化する映像情報処理装置に構成に関する。

【０００２】

【従来の技術】近年のデジタル技術の発達により、従来ではアナログの形でしか扱えなかった、ビデオ映像のような映像情報も、デジタルの形で扱えるようになってきた。また、パーソナルコンピュータの高性能化により、デジタル化された映像情報を、パーソナルコンピュータによって処理できるようになってきた。

【０００３】NTSCのようなアナログ映像信号を、一般に販売されているパーソナルコンピュータ用の画像取り込み装置(以下、キャプチャーカード)でデジタルデータに変換したときのデータ構造を、図11で説明する。NTSC信号では、映像は偶数フィールドと、奇数フィールドで構成されている。偶数フィールドと奇数フィールドは、空間的には1ライン分のずれがあり、また時間的には、６０分の１秒分のずれがある。このようなNTSC信号の偶数フィールドと奇数フィールドを、通常のキャプチャーカードでは、奇数フィールドと偶数フィールドがライン毎に組み合わさった、1101のような１枚のフレームとして、３０分の１秒に一枚の間隔で、コンピュータ内に取り込む。このように、本来時間的にも空間的にもずれている二枚のフィールドを、一枚のフレームとして取り扱うとき、そのフレームを、インタレースフレームという。すなわち、現在普及しているキャプチャーカードでは、NTSC信号を、インタレースフレームとしてデジタル化してコンピュータ内に取り込む。

【０００４】上記したようなキャプチャーカードを用い、コンピュータ内に取り込んだインタレースフレームを符号化し、符号化映像情報として出力する映像情報処理装置の従来技術による例を、図を用いて説明する。図12は、従来技術による映像情報処理装置の構成を説明する図である。1201は、インターレース映像出力手段であり、インタレースフレームを出力するもので、一般にはキャプチャーカード等で実現され、NTSC信号を入力し、デジタル化した後にインタレースフレームとして出力するものである。1202は映像符号化手段であり、インタレース映像入力手段(1201)から入力されたインタレースフレームを、符号化し、符号化映像情報とするものである。本例では、インタレースフレームを、そのままインタレースフレームとして、符号化するものとする。例えば、MPEG2(Moving Picture ExpertGroup)の符号化規格によれば、符号化された映像情報が、インタレースフレームであることを示す符号が用意されているので、このような符号化手段を本例は想定している。しかし、それ以外の、例えば、インタレースフレームをフィールドに分割し、フィールド毎に符号化するような符号化手段を適用したとしても、従来技術を説明できる。このことは後に説明する。図13は、従来技術による映像情報処理

装置の動作を説明する図である。

【０００５】上記のように構成された従来技術による映像情報処理装置を、図12と図13を用いて説明する。まず、NTSC信号がインタレース映像出力手段(1201)に入力され、インタレース映像出力手段(1201)は、これをデジタル化し、インタレースフレームとして出力する。映像符号化手段(1202)は、上記インタレースフレームを符号化し、符号化されたインタレースフレームとして、出力する。これを繰り返す。

【０００６】上記のように出力された符号化されたインタレースフレームが復号化される様子を説明するのが、図14である。符号化されたインタレースフレームは、映像復号化手段によって、インタレースフレームに復元される。このインタレーストフレームを、NTSC出力手段が、偶数フィールドと奇数フィールドとに分割し、アナログ信号にして出力する。

【０００７】

【発明が解決しようとする課題】従来技術による映像情報処理装置は、前述の例で説明したように、インタレースフレームを、そのまま符号化するものであった。このような方式は、インタレース映像出力手段が、確実に、すべてのフレームを出力することが条件となる。もし、インタレース映像出力手段が、コマ落としなどをしてしまい、それを符号化しなければならない場合には、従来技術では本質的な問題を有している。

【０００８】図15は、上記の問題を説明するための図である。図15では、６枚のフィールドで構成されるNTSC信号がインタレース映像出力手段に入力されたものとする。６枚のフィールドの時間的な並びを示すため、1～6の番号を示した。1がもっとも過去の映像であり、6がもっとも新しい映像である。上記のごとく６枚のフィールド(1～6)が、インタレース映像出力手段に入力されたが、符号化の負荷が高く、デジタル化したインタレース映像のバッファが足らなくなった、等の理由により、コマ落ちし、６枚のフィールドのうち、中心の二枚(3,4)がインタレースフレームにならなかったものとする。すなわち、本来なら３枚のインタレースフレームが出力されるところが、２枚しか出力されなかった。そこで、映像符号化手段は、コマ落ちしたフレームに対して、「前回のフレームと同一」という符号を出力し(図15のb)、符号化映像情報とした。

【０００９】上記のごとく符号化された映像情報を復号化される様子を説明するのが、図16である。上記で符号化された映像情報は、映像復号化手段によりインタレースフレームに復号化されるが、符号化映像のbは、「前回のフレームと同一」という符号なので、最初の一枚のインタレースフレームが、コピーされ、二枚目のインタレースフレームとして使用される。このように復号化されたインタレースフレームを、NTSC出力手段が、偶数フィールドと奇数フィールドとに分割し、アナログ信号にして出力する。この時、最初のインタレースフレームは、「1,2」という時間的に変化するフィールドを持っており、２枚目のフレームは、最初のフレームを、コピーして使用するので、二枚目のフレームも、「1,2」と時間的に変化するフィールドを持つこととなる。これをNTSC信号として出力すると、最初、「1,2」とフィールドを出力した後に、もう一度、「1」のフィールドを出力する。これは、瞬間的にだが、「過去に戻る」こととなり、動きのある映像を出力すると、「1,2」と動いた映像が「1」で戻るので、映像が「ちらつく」という問題が発生してしまう。

【００１０】図16で示した問題を回避するため、図15におけるbを、「偶数、奇数フィールドとも、前回の偶数フィールドと同じ」という符号とする。すなわち、図16で示した問題は、そもそも時間的に異なる２つのフィールドを持つフレームを、そのままコピーして使用したことに起因するものであるから、単一のフィールドをコピーして使用すれば、問題は回避できるはずである。

【００１１】上記のごとく符号化された映像情報を復号化される様子を説明するのが、図17である。上記で符号化された映像情報は、映像復号化手段によりインタレースフレームに復号化されるが、符号化映像のbは、「偶数、奇数フィールドとも、前回の偶数フィールドと同じ」という符号なので、最初の一枚のインタレースフレームのうち、偶数フィールドのみコピーされ、二枚目のインタレースフレームとして使用される。このように復号化されたインタレースフレームを、NTSC出力手段が、偶数フィールドと奇数フィールドとに分割し、アナログ信号にして出力する。この時、２枚目のフレームは、最初のフレームのうち、偶数フィールドを二回コピーして使用するので、二枚目のフレームは、「2,2」と、時間的に変化しない、同一のフィールドを持つこととなる。これをNTSC信号として出力すると、時間的には、「1,2,2,2,5,6」となり、「過去に戻る」ことはなくなるので、図16のように、「ちらつく」という問題は回避できる。しかし、空間的には、本来、偶数フィールドにある画像を、奇数フィールド、すなわち１ライン上に表示することになるので(図17のX)、画像が上下に「ゆれる」という問題が発生する。これは、静止している映像を出力すると、特に顕著に知覚される問題である。

【００１２】上記した従来の技術による例では、映像符号化手段としては、インタレースフレームを、そのままインタレースフレームとして、符号化するものとしたが、それ以外の、例えば、インタレースフレームをフィールドに分割し、フィールド毎に符号化するような符号化手段を適用したとしても、上記と同様の問題が発生することは、いうまでもない。また、本例では、コマ落ちした部分に対して、「前回のフレームと同じ」あるいは「前回のフィールドと同じ」という符号を用いるものとしたが、符号を用いず、前回のフレーム、あるいはフィ

ールドと同じ映像をそのまま用いてコマ落ちした部分を符号化しても、当然ながら同様の問題が発生する。また、「前回のフレームと同じ」という符号ではなく、「次回のフレームと同じ」という符号を用いたとしても、やはり、同様の問題が発生する。すなわち、コマ落ちした部分を補うのに使用するフィールドが、コマ落ちした部分のフィールドと、偶数、奇数が異なれば、空間的な問題が発生し、偶数、奇数をあわせようとすると、時間的な問題が発生するのである。　本発明は、従来の映像情報処理装置が有していた前記の問題に鑑み、システムの負荷変動によりコマ落ちが発生しても、「ちらつき」や「ゆれ」といった問題を回避しつつ、コマ落ち部分を補うことを可能とすることを目的とするものである。

【００１３】

【課題を解決するための手段】上記目的を達成するために、請求項１、及び請求項４にかかる映像情報処理装置は、すべてのインタレースフレームを、一旦、フレームを構成するフィールドのうちの一枚をプログレッシブ変換することでプログレッシブフレームにし、そのプログレッシブフレームをインタレースフレームとして処理し、コマ落ち部にはコマ落ちの直前あるいは直後のフレームをコピーして補うことを特徴とするものである。

【００１４】また、請求項２にかかる映像情報処理装置は、コマ落ちがあった場合にのみ、コマ落ちの直前あるいは直後のインタレースフレームを、一旦、フレームを構成するフィールドのうちの一枚をプログレッシブ変換することでプログレッシブフレームにし、そのプログレッシブフレームをインタレースフレームとして処理し、コマ落ち部には、コマ落ちの直前あるいは直後のフレームをコピーして補うことを特徴とするものである。

【００１５】また、請求項３及び請求項５にかかる映像情報処理装置は、コマ落ちがあった場合にのみ、コマ落ちの直前あるいは直後のフィールドをプログレッシブ変換することでプログレッシブフレームにし、コマ落ち部には、このプログレッシブフレームをインタレースフレームとして処理することで補うことを特徴とするものである。

【００１６】また、請求項６、及び請求項９にかかる映像情報処理方法は、すべてのインタレースフレームを、一旦、フレームを構成するフィールドのうちの一枚をプログレッシブ変換することでプログレッシブフレームにし、そのプログレッシブフレームをインタレースフレームとして処理し、コマ落ち部にはコマ落ちの直前あるいは直後のフレームをコピーして補うことを特徴とするものである。

【００１７】また、請求項７にかかる映像情報処理方法は、コマ落ちがあった場合にのみ、コマ落ちの直前あるいは直後のインタレースフレームを、一旦、フレームを構成するフィールドのうちの一枚をプログレッシブ変換

することでプログレッシブフレームにし、そのプログレッシブフレームをインタレースフレームとして処理し、コマ落ち部には、コマ落ちの直前あるいは直後のフレームをコピーして補うことを特徴とするものである。

【００１８】また、請求項８及び請求項１０にかかる映像情報処理方法は、コマ落ちがあった場合にのみ、コマ落ちの直前あるいは直後のフィールドをプログレッシブ変換することでプログレッシブフレームにし、コマ落ち部には、このプログレッシブフレームをインタレースフレームとして処理することで補うことを特徴とするものである。

【００１９】

【発明の実施の形態】（実施の形態１）本発明の実施の形態１による映像情報処理装置は、すべてのインタレースフレームのフィールドを一旦プログレッシブフレームに変換し、それをインタレースフレームとして符号化するものである。

【００２０】図1は、本発明の第１の実施の形態における映像情報処理装置の構成図であり、図2は、同装置の動作を説明する図である。図中、101はインターレース映像出力手段であり、インターレースフレームを出力するもので、一般にはキャプチャーカード等で実現され、NTSC信号を入力し、デジタル化した後にインタレースフレームとして出力するものである。102は映像符号化手段であり、プログレッシブ変換手段(104)が変換したプログレッシブフレームを、インタレースフレームとして、符号化するものである。また、コマ落ち検出手段が(103)がプログレッシブ変換手段が出力したプログレッシブフレームのコマ落ちを検出すると、コマ落ち部分に、「コマ落ちの直前のインタレースフレームと同一」という符号を出力するものである。103はコマ落ち検出手段であり、プログレッシブ変換手段(104)が出力するプログレッシブフレームのコマ落ちを検出するものである。104は、プログレッシブ変換手段であり、インタレース映像出力手段(101)が出力したインタレースフレームを構成するフィールドのうち、一枚のフィールドを、プログレッシブフレームに変換するものである。ここで、フィールドをプログレッシブフレームに変換する様子を、図3で示す。図3では、フィールド２の、間隙となっているラインを補間することで、プログレッシブフレームに変換している。フィールド２のピクセルａは、隣あう上下のラインを構成するピクセルの平均をとることで作成している。これをフィールド内補間という。また、フィールド２のピクセルｂは、先立つフィールド１から、対応する位置のピクセルをコピーすることで作成している。これをフィールド間補間という。フィールド間補間をすれば厳密にプログレッシブフレームの解像度が倍になるが、動きのある部分でフィールド間補間をすると、像が２重となり、見ずらい画像となる。フィールド内補間の場合は、解像度は落ちるが、動きのある部分

でも適応できる。このように、フィールドをライン補間してプログレッシブフレームにする技術については、多くの研究がなされている。本例のプログレッシブ変換手段(104)は、いずれかの方法を用いて、インタレースフレームを構成するフィールドのうち、偶数フィールドを、プログレッシブフレームに変換するものとする。上記の例でもわかるように、変換されたプログレッシブフレームは、垂直解像度は倍になっているが、時間的には、偶数フィールドの時点での時間成分のみを持つものとなる。

【００２１】上記のように構成された第１の実施の形態における映像情報処理装置の動作を、図1と図2を用いて説明する。まず、NTSC信号がインタレース映像出力手段(101)に入力され、インタレース映像出力手段(101)は、これをデジタル化し、インタレースフレームとして出力する。ここでは、「1,2,3,4,5,6,7,8」の順序でフィールドが入力されたが、コマ落ちが起こり、本来ならば4枚出力されるはずのインタレースフレームが、「1,2」と、「3,4」と、「7,8」の時間要素を持つ三枚しか、出力されなかった。このインタレースフレームを、プログレッシブ変換手段(104)が、偶数フィールドのみ、プログレッシブフレームにする。偶数フィールドのみをプログレッシブフレームにするので、垂直解像度は倍だが、時間要素は「2」と「4」と「8」である、プログレッシブフレームが３枚出力される。このプログレッシブフレームを、映像符号化手段(102)が、インターレースフレームとして、符号化し、「a」と「b」と「d」を得る。また、コマ落ち検出手段(103)は、プログレッシブフレームに付与されたタイムスタンプを読み取ることで、コマ落ちが発生したことを検出する。コマ落ち検出手段(103)からの指示により、映像符号化手段(102)は、「b」と同一であるという、「c」という符号を出力する。

【００２２】上記のように出力された符号化されたインタレースフレームが復号化される様子を説明するのが、図4である。符号化されたインタレースフレームは、映像復号化手段によって、インタレースフレームに復元される。このインタレーストフレームを、NTSC出力手段が、偶数フィールドと奇数フィールドとに分割し、アナログ信号にして出力する。このとき、「c」は、「b」と同じであるという符号になっており、また、「a」と「b」と「d」は、一度プログレッシブフレームに変換した画像を、インタレースフレームとして符号化したものであるから、垂直解像度はフィールドの倍になっているものの、時間的要素は「2」と「4」と「8」しかない。したがって、再生される映像の時間的要素は、「2,2,4,4,4,4,8,8」となる。すなわち、従来の技術で問題となった、「時間が戻る」ことによる「ちらつき」の問題が解決でき、さらに、プログレッシブフレームに変換することで垂直解像度を補間しているので、本来偶数フィールドで表示すべき画像を奇数フィールドで表示することによる「ゆれ」の問題も解決できる。

【００２３】なお、本例では、偶数フィールドをプログレッシブ変換するものとしたが、これは、奇数フィールドをプログレッシブ変換することもできる。また、本例では、コマ落ち検出手段が、プログレッシブフレームに付与されたタイムスタンプを読み取ることでコマ落ちを検出するものとしたが、プログレッシブ変換手段、あるいはインタレース映像出力手段から、コマ落ちした情報を得ても実現できる。また、本例では、映像符号化手段としては、プログレッシブフレームを、インタレースフレームとして、符号化するものとしたが、それ以外の、例えば、プログレッシブフレームをライン毎に分割してフィールドとし、フィールド毎に符号化するような符号化手段を適用したとしても、本発明は適用できる。また、本例では、コマ落ちした部分に対して、「前回のフレームと同じ」という符号を用いるものとしたが、符号を用いず、前回のフレーム、と同じ映像をそのまま用いてコマ落ちした部分を符号化しても、当然ながら問題は解決できる。また、「前回のフレームと同じ」という符号ではなく、「次回のフレームと同じ」という符号を用いたとしても、やはり、問題は解決できる。

【００２４】さらに、本実施の形態では、出力されたインタレースフレームの処理として、画像の符号化を行うものとしたが、本発明はこのような処理に限定されるものではない。符号化処理ではなく、一般的な画像処理においても、本実施の形態で示したような本発明の実施が行えることはいうまでもない。その場合、コマ落ち部には、「直前、あるいは直後と同一」という符号を用いるのではなく、直前、あるいは直後のフレームをコピーし、コマ落ちを補う、コマ落ち対処手段、等を用意すればよい。

【００２５】（実施の形態２）本発明の実施の形態２による映像情報処理装置は、コマ落ちがあった時に、コマ落ちの直前あるいは直後のインタレースフレームのみ、フィールドを一旦プログレッシブフレームに変換し、それをインタレースフレームとして符号化し、且つ、コマ落ち部分には、プログレッシブフレームに変換した画像と同一であるという符号を出力するものでる。

【００２６】図5は、本発明の第２の実施の形態における映像情報処理装置の構成図であり、図6は、同装置の動作を説明する図である。図中、501は映像符号化手段であり、インタレース映像出力手段(101)が出力したインタレースフレームを符号化するものであり、且つ、コマ落ち検出部(502)がインタレースフレームのコマ落ちを検出すると、コマ落ちの直前のインタレースフレームに関してはこれを符号化せず、代わりにプログレッシブ変換手段(503)が出力したプログレッシブフレームを、インタレースフレームとして、符号化し、さらに、コマ落ち部分に関しては、「直前のインタレースフレームと同一」という符号を出力するものである。502はコマ落

ち検出手段であり、インタレース映像出力手段(101)が出力したインタレースフレームのコマ落ちを検出するものである。503は、プログレッシブ変換手段であり、コマ落ち検出手段(502)がコマ落ちを検出すると、コマ落ち部分の直前のインタレースフレームを構成するフィールドのうち、偶数フィールドを、プログレッシブフレームに変換し、出力するものである。フィールドをプログレッシブフレームに変換する方法については、実施の形態１で説明した方法と同じである。その他の構成要素については実施の形態１と同様であるので、説明は割愛する。

【００２７】上記のように構成された第２の実施の形態における映像情報処理装置の動作を、図5と図6を用いて説明する。まず、NTSC信号がインタレース映像出力手段(101)に入力され、インタレース映像出力手段(101)は、これをデジタル化し、インタレースフレームとして出力する。ここでは、「1,2,3,4,5,6,7,8」の順序でフィールドが入力されたが、コマ落ちが起こり、本来ならば４枚出力されるはずのインタレースフレームが、「1,2」と、「3,4」と、「7,8」の時間要素を持つ三枚しか、出力されなかった。このコマ落ちを、コマ落ち検出手段(502)が、インタレースフレームに付与されたタイムスタンプを読み取ることで検出し、プログレッシブ変換手段(503)に対して、変換の指示を出す。プログレッシブ変換手段(503)は、変換の指示を受けて、コマ落ち部分の直前のインタレースフレームの、偶数フィールドのみ、プログレッシブフレームにする。偶数フィールドのみをプログレッシブフレームにするので、垂直解像度は倍だが、時間要素は「4」である、プログレッシブフレームが一枚出力される。一方、映像符号化手段(501)は、コマ落ち検出手段(502)のコマ落ちの指示を受け、コマ落ち部分の直前のインタレースフレーム(3,4)に関しては符号化せず、代わりにプログレッシブ変換手段(503)が出力したプログレッシブフレームを、インタレースフレームとして、符号化する(図中の「b」)。また、コマ落ち部分に関しては、「直前のインタレースフレームと同一」という符号(図中の「c」)を出力する。さらに、その後のインタレースフレーム(7,8)については、通常どおり、インタレースフレームとして、符号化する(図中の「d」)。

【００２８】上記のように出力された符号化されたインタレースフレームが復号化される様子を説明するのが、図7である。符号化されたインタレースフレームは、映像復号化手段によって、インタレースフレームに復元される。このインタレーストフレームを、NTSC出力手段が、偶数フィールドと奇数フィールドとに分割し、アナログ信号にして出力する。このとき、「c」は、「b」と同じであるという符号になっており、また、「b」は、一度プログレッシブフレームに変換した画像を、インタレースフレームとして符号化したものであるから、垂直解像度はフィールドの倍になっているものの、時間的要素は「4」しかない。したがって、再生される映像の時間的要素は、「1,2,4,4,4,4,7,8」となる。すなわち、従来の技術で問題となった、「ちらつき」の問題が解決でき、さらに、プログレッシブフレームに変換することで垂直解像度を補間しているので、本来偶数フィールドで表示すべき画像を奇数フィールドで表示することによる「ゆれ」の問題も解決できる。さらに、実施の形態１では、すべてのフレームの偶数フィールドをプログレッシブ変換していたため、すべてのフレームの時間的要素が半分となり、コマ落ちが発生しなかったとしても、本来1/60秒に一回動くはずの映像が、1/30秒に一回となり、動きがカクカクするという問題を有していたが、本実施の形態では、コマ落ちが発生した場合にのみ、プログレッシブ変換を行うので、コマ落ちが発生しない限り、1/60秒の滑らかな再生が実現できる。さらに、コマ落ちが生じた時のみプログレッシブ変換を行うことで、毎フレームごとにプログレッシブ変換を行う場合に比べ、計算機資源の節約が図れるという利点もある。

【００２９】なお、本例では、偶数フィールドをプログレッシブ変換するものとしたが、これは、奇数フィールドをプログレッシブ変換することもできる。また、本例では、映像符号化手段としては、プログレッシブフレームを、インタレースフレームとして、符号化するものとしたが、それ以外の、例えば、プログレッシブフレームをライン毎に分割してフィールドとし、フィールド毎に符号化するような符号化手段を適用したとしても、本発明は適用できる。また、本例では、コマ落ちした部分に対して、「前回のフレームと同じ」という符号を用いるものとしたが、符号を用いず、前回のフレーム、と同じ映像をそのまま用いてコマ落ちした部分を符号化しても、当然ながら問題は解決できる。また、コマ落ち部分の直前のインタレースフレームをプログレッシブ変換するのではなく、コマ落ち部分の直後のインタレースフレームをプログレッシブ変換し、コマ落ち部分には、「前回のフレームと同じ」という符号ではなく、「次回のフレームと同じ」という符号を用いても、問題は解決できる。

【００３０】（実施の形態３）本発明の実施の形態３による映像情報処理装置は、コマ落ちがあった時に、コマ落ちの直前あるいは直後のインタレースフレームの、コマ落ち部分に時間的に近いフィールドを、一旦プログレッシブフレームに変換し、それをインタレースフレームとして符号化して、コマ落ち部分の符号として用いるものである。

【００３１】図8は、本発明の第２の実施の形態における映像情報処理装置の構成図であり、図9は、同装置の動作を説明する図である。図中、801は映像符号化手段であり、インタレース映像出力手段(101)が出力したインタレースフレームを符号化するものであり、且つ、コ

マ落ち検出部(502)がインタレースフレームのコマ落ちを検出すると、コマ落ち部分の符号として、ダミー用符号出力手段(802)が出力したダミー用の符号を用いるものである。802は、ダミー用符号出力手段であり、コマ落ち検出部(502)がインタレースフレームのコマ落ちを検出すると、コマ落ち部分の直前のインタレースフレームを構成するフィールドのうち、コマ落ち部に時間的に近いフィールド、すなわち、この場合は偶数フィールドを、プログレッシブフレームに変換し、その画像を符号化して、出力するものである。フィールドをプログレッシブフレームに変換する方法については、実施の形態１で説明した方法と同じである。その他の構成要素については実施の形態２と同様であるので、説明は割愛する。

【００３２】上記のように構成された第３の実施の形態における映像情報処理装置の動作を、図8と図9を用いて説明する。まず、NTSC信号がインタレース映像出力手段(101)に入力され、インタレース映像出力手段(101)は、これをデジタル化し、インタレースフレームとして出力する。ここでは、「1,2,3,4,5,6,7,8」の順序でフィールドが入力されたが、コマ落ちが起こり、本来ならば４枚出力されるはずのインタレースフレームが、「1,2」と、「3,4」と、「7,8」の時間要素を持つ三枚しか、出力されなかった。このコマ落ちを、コマ落ち検出手段(502)が、インタレースフレームに付与されたタイムスタンプを読み取ることで検出し、ダミー用符号出力手段(802)に対して、ダミー用符号出力の指示を出す。ダミー用符号出力手段(802)は、上記の指示を受けて、コマ落ち部分の直前のインタレースフレームの、偶数フィールドを、プログレッシブフレームにする。偶数フィールドのみをプログレッシブフレームにするので、垂直解像度は倍だが、時間要素は「4」である。このプログレッシブフレームを、インタレースフレームとして、符号化して、出力する。一方、映像符号化手段(801)は、コマ落ち検出手段(502)のコマ落ちの指示を受け、コマ落ち部分に、ダミー用符号出力手段(802)が出力したダミー用符号を出力する(図中の「c」)。さらに、その後のインタレースフレーム(7,8)については、通常どおり、インタレースフレームとして、符号化する(図中の「d」)。

【００３３】上記のように出力された符号化されたインタレースフレームが復号化される様子を説明するのが、図10である。符号化されたインタレースフレームは、映像復号化手段によって、インタレースフレームに復元される。このインタレーストフレームを、NTSC出力手段が、偶数フィールドと奇数フィールドとに分割し、アナログ信号にして出力する。このとき、「c」は、一度プログレッシブフレームに変換した画像を、インタレースフレームとして符号化したものであるから、垂直解像度はフィールドの倍になっているものの、時間的要素は「4」しかない。したがって、再生される映像の時間的要素は、「1,2,3,4,4,4,7,8」となる。すなわち、従来

の技術で問題となった、「ちらつき」の問題が解決でき、さらに、プログレッシブフレームに変換することで垂直解像度を補間しているので、本来偶数フィールドで表示すべき画像を奇数フィールドで表示することによる「ゆれ」の問題も解決できる。さらに、実施の形態２では、コマ落ちの直前のフィールドをプログレッシブフレームに変換していたため、コマ落ち部分と合わせて多くの時間成分が失われていたという問題を有していたが、本実施の形態では、コマ落ち部分のみ時間成分が失われるので、滑らかな再生が実現できる。

【００３４】なお、本例では、ダミー用符号出力手段と映像符号化手段としては、プログレッシブフレームを、インタレースフレームとして、符号化するものとしたが、それ以外の、例えば、プログレッシブフレームをライン毎に分割してフィールドとし、フィールド毎に符号化するような符号化手段を適用したとしても、本発明は適用できる。また、本例では、コマ落ちした部分に対して、まず、コマ落ちの直前のフィールドをプログレッシブフレームに変換し、その画像をインタレースフレームとして符号化した符号を用いていたが、本発明を実装する処理系に、「前回のフィールドをプログレッシブ変換したものと同一(あるいは、前回のフィールドのライン補間したものと同一)」という符号が用意されていれば、そのような符号をそのまま用いてもよい。また、コマ落ち部分の直前のフィールドをプログレッシブ変換するのではなく、コマ落ち部分の直後のフィールドをプログレッシブ変換し、それを符号化し、コマ落ち部分に用いても、問題は解決できる。その場合、変換するフィールドは、奇数フィールドとなる。

【００３５】さらに、本実施の形態では、出力されたインタレースフレームの処理として、画像の符号化を行うものとしたが、本発明はこのような処理に限定されるものではない。符号化処理ではなく、一般的な画像処理においても、本実施の形態で示したような本発明の実施が行えることはいうまでもない。その場合、ダミー用符号出力手段の代わりに、直前、あるいは直後のフィールドをプログレッシブ変換し、その画像をコマ落ちを補う、コマ落ち対処手段、等を用意すればよい。

【００３６】さらに、これまで述べた本発明の方法を、プログラム製品として実現し、それをフロッピーディスクやその他の記憶媒体などに格納して配布した場合や、コンピュータネットワーク等の媒体を通じて配布した場合などでも、本発明が有効であることは言うまでもない。

【００３７】

【発明の効果】以上のように、本発明の請求項１にかかる映像情報処理装置は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに

変換するプログレッシブ変換手段と、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出手段と、上記プログレッシブフレームを、n枚のフィールドから構成されるインタレースフレームとして符号化し、映像符号を出力する符号化手段であり、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ち部分にはコマ落ち部分の直前あるいは直後の上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化手段とを備えたことを特徴とすることで、インタレースフレームを符号化する際に、コマ落ちが発生し、そのコマ落ちを直前あるいは直後のフレームあるいはフィールドをコピーして補う場合に発生する「ちらつき」や「ゆれ」といった問題を解決することができる。

【００３８】請求項２にかかる映像情報処理装置は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記インタレースフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを、上記インタレースフレームを構成するn枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換手段と、上記インタレースフレームを符号化し、映像符号を出力する符号化手段であり、上記コマ落ち検出手段がコマ落ちを検出すると、上記インタレースフレームに代わり対応する上記プログレッシブフレームをn枚のフィールドから構成されるインタレースフレームとして符号化し、且つコマ落ち部分には上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化手段とを備えたことを特徴とすることで、コマ落ちがない部分は1/60fpsの滑らかな動きを保ちつつ、また、プログレッ　シブ変換のための計算機資源を節約した上で、請求項１で述べた効果を実現できる。

【００３９】請求項３にかかる映像情報処理装置は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記インタレースフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換した画像を示すダミーフレーム用符号を出力するダミー用符号出力手段と、上記インタレース映像を符号化し、映像符号を出力する符号化手段であり、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ち部分に出力する符号として、上記ダミー用符号を出力することで映像符号とする映像符号化手段とを備えたことを特徴とすることで、時間的成分の欠落をコマ落ち部分のみにとどめ、請求項１で述べた効果を実現できる。

【００４０】請求項４にかかる映像情報処理装置は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換手段と、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ち部の画像として、コマ落ち部の直前あるいは直後の上記プログレッシブフレームをコピーして補うコマ落ち対処手段と、上記プログレッシブ変換手段及びコマ落ち対処手段とが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理手段とを備えたことを特徴とすることで、インタレースフレームを処理する際に、コマ落ちが発生し、そのコマ落ちを直前あるいは直後のフレームあるいはフィールドをコピーして補う場合に発生する「ちらつき」や「ゆれ」といった問題を解決することができる。

【００４１】請求項５にかかる映像情報処理装置は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力手段と、上記インタレースフレームのコマ落ちを検出するコマ落ち検出手段と、上記コマ落ち検出手段がコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換し、コマ落ち部の画像を該画像で補うコマ落ち対処手段と、上記インタレース映像出力手段及びコマ落ち対処手段とが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理手段とを備えたことを特徴とすることで、時間的成分の欠落をコマ落ち部分のみにとどめ、請求項４で述べた効果を実現できる。

【００４２】請求項６にかかる映像情報処理方法は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換ステップと、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出ステップと、上記プログレッシブフレームを、n枚のフィールドから構成されるインタレースフレームとして符号化し、映像符号を出力する符号化ステップであり、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ち部分にはコマ落ち部分の直前あるいは直後の上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化ステップとを備えたことを特徴とすることで、インタレースフレームを符号化する際に、コマ落ちが発生し、そのコマ落ちを直前あるいは直後のフレームあるいはフィールドをコピーして補う場合に発生する「ちらつき」や「ゆれ」といった問題を解決することができる。

【００４３】請求項７にかかる映像情報処理方法は、ｎ枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記インタレースフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを、上記インタレースフレームを構成するn枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換ステップと、上記インタレースフレームを符号化し、映像符号を出力する符号化ステップであり、上記コマ落ち検出ステップがコマ落ちを検出すると、上記インタレースフレームに代わり対応する上記プログレッシブフレームをn枚のフィールドから構成されるインタレースフレームとして符号化し、且つコマ落ち部分には上記プログレッシブフレームと同一の画像であるとする符号を出力し映像符号とする映像符号化ステップとを備えたことを特徴とすることで、コマ落ちがない部分は1/60 fpsの滑らかな動きを保ちつつ、また、プログレッシブ変換のための計算機資源を節約した上で、請求項６で述べた効果を実現できる。

【００４４】請求項８にかかる映像情報処理方法は、ｎ枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記インタレースフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換した画像を示すダミーフレーム用符号を出力するダミー用符号出力ステップと、上記インタレース映像を符号化し、映像符号を出力する符号化ステップであり、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ち部分に出力する符号として、上記ダミー用符号を出力することで映像符号とする映像符号化ステップとを備えたことを特徴とすることで、時間的成分の欠落をコマ落ち部分のみにとどめ、請求項６で述べた効果を実現できる。

【００４５】請求項９にかかる映像情報処理方法は、ｎ枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記n枚のフィールドのうち1枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換するプログレッシブ変換ステップと、上記プログレッシブフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ち部の画像として、コマ落ち部の直前あるいは直後の上記プログレッシブフレームをコピーして補うコマ落ち対処ステップと、上記プログレッシブ変換ステップ及びコマ落ち対処ステップとが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理ステップとを備えたことを特徴とすることで、インタレースフレームを処理する際に、コマ落ちが発生し、そのコマ落ちを直前あるいは直後のフレームあるいはフィールドをコピーして補う場合に発生する「ちらつき」や「ゆれ」といった問題を解決することができる。

【００４６】請求項１０にかかる映像情報処理方法は、n枚のフィールドから構成されるインタレースフレームを出力するインタレース映像出力ステップと、上記インタレースフレームのコマ落ちを検出するコマ落ち検出ステップと、上記コマ落ち検出ステップがコマ落ちを検出すると、コマ落ちの直前あるいは直後の上記インタレースフレームを構成するn枚のフィールドのうち、時間的にコマ落ち部に近い一枚のフィールドをn倍ライン補間することでプログレッシブフレームに変換し、コマ落ち部の画像を該画像で補うコマ落ち対処ステップと、上記インタレース映像出力ステップ及びコマ落ち対処ステップとが出力したフレームを、インタレースフレームとして、画像処理を行う画像処理ステップとを備えたことを特徴とすることで、時間的成分の欠落をコマ落ち部分のみにとどめ、請求項９で述べた効果を実現できる。

NOTICE OF REASONS FOR REJECTION

Patent Application No.:	2006-120296
Drafting Date:	January 6, 2010
Patent Office Examiner:	Akiyo Sakamoto 2954 5C00
Attorney for Patent Applicant:	Atsushi Aoki (and four others)
Applicable Provisions:	Article 29, paragraph 2; Article 36

It is deemed that the present application should be rejected for the following reasons. An argument, if any, should be submitted within 3 months from the mailing date of this notice.

REASONS

a. The inventions described in the following claims of this application are deemed ones which could easily have been made, prior to the filing of the patent application, by a person with ordinary skill in the art to which the inventions pertain, on the basis of the inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 2, of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)
Claims: 1 to 26
Reference: 1
Remarks:

Reference 1 describes the use of a copied frame in decoding, when the code of "the same as the previous frame" relating to a dropped frame is decoded (specifically, refer to paragraphs [0008] and [0009]).

Therefore, the technology for inserting a decoded image into a buffer memory, and the technology for adding a frame number are both known. Thus, it is not deemed that there is a remarkable difficulty in inserting a decoded frame including the copied frame in a buffer memory, and adding a number to the frame in the invention described in Reference 1.

b. The description of the claims of this application does not satisfy the requirements prescribed in Article 36, paragraph 6, item 2 of the Patent Law on the following points.

Notes

(1) The feature "configuring the buffer memory to enter image frames" is described in claim 1, but whether the description of "configuring" simply means that the image frames enter the buffer memory, or the term "configuring" means performing any process in addition to the above meaning.

The same is true for other claims having the same descriptions.

(2) The feature "A computer program comprising code to be executed by a computer, the code including, code for..., code for..., code for..., and code for...,." is described in claim 18. However, whether or not the above description for example, means "A computer program to execute a procedure for..., a procedure for..., a procedure for, a procedure for...., and a procedure for ...." is unclear (refer to Part VII, Chapter 1, 1.1.1(2)(b) of Examination Guidelines for Patent and Utility Model).

If an amendment is made, it should be noted that no new matter can be added and if asserting that the amendment is obvious based on the descriptions of the specification, the relevant technological ground should be specifically identified.

If another reason for rejection is found, a further notice of reasons for rejection will be issued.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

<u>New Applications Under 35 U.S.C. 111</u>
If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

<u>National Stage of an International Application under 35 U.S.C. 371</u>
If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

<u>New International Application Filed with the USPTO as a Receiving Office</u>
If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

The Japanese reference was first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of the foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided. Also attached is a copy of the English translation of the Japanese Office Action.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

Issues in Multimedia scaling: the MPEG Video Streams Case

Omar Elloumi Hossam Afifi Laurent Toutain
Networks and Multimedia Services Department-Telecom Bretagne

Abstract:

Multimedia streams usually have an inherent hierarchy and an inter-inpendency of subsequent blocks in their data structures. Dealing with these features within the operating system and the network brings a global resource usage improvement. We propose in this paper a new method for media scaling based on two complementary techniques: Circular Buffers and Filtering. We describe an MPEG distributed application architecture built with the two combined techniques and show improvements in the received video quality.

1. Introduction

Scaling[1] [2],[3],[4],[10],[11] is a dynamic adjustment of traffic load by selective elimination in response to network overload or data buffers overflow. This is accomplished in end user system queues or in intermediate network nodes. Heterogeneity and multimedia multicast communications introduce bottlenecks and are major reasons for down scaling. We present a scaling mechanism that enables a weighted data flows multicast in heterogeneous environments. It fits into each capability and down-scales data streams only if this is really necessary. It can be implemented in intermediate and end-system nodes in a heterogeneous network in the presence of path bottlenecks. This paper focuses on scaling mechanism for end-system nodes[2]. We also describe its integration in the System V Streams[3] modules.

This paper is organized as follows: section 2. presents the MPEG video stream organization. Section 3. describes protocol stacks in UNIX systems and the Streams concept. The pilot application and the new protocol design are described in sections 4. and 5. Section 6. and 7. comment the performance results that we obtained and show the improvement when using the proposed scaling mechanism.

2. MPEG video streams properties

MPEG [1] streams are composed of sequences of coded frames grouped into GoPs (Group of Pictures). The video coding model uses three frame types: I (Intra-coded) frames are self-contained coded information; P (Predictive-coded) frames are the result of a motion compensated prediction, they depend upon the past I or P-picture; B (Bidirectional predictive-coded) frames are coded using motion compensated from a past and a future I or P-picture. A GoP video sequence can be decoded independently[4].

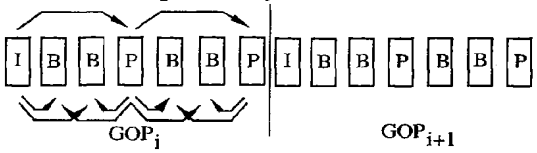

Figure 1 Frame dependency within one GOP

Figure 1 shows GoP internal dependencies. One can see that dropping any of the B pictures will not affect the GoP semantics. In contrast dropping a P picture leads to the drop of all dependent B or P pictures. This organization leads to many sub-GoP structures combination. Dropping one complete GoP do not affect the video stream structure. This induces two MPEG video features that will be used to design two scaling techniques[3]: 1) *Intra-GoP Scaling*: frame dropping within one GoP and *2) Inter-GoP scaling:* dropping complete GoPs eventually affected by *Intra-GoP scaling*.

Although a priority for each frame can be used (resulting on multiple Intra-GoP scaling possibilities), we attribute (to simplify the study) priority 1 to I frames, 2 to P frames and 3 to B ones.

3. Protocol stack design in UNIX systems

3.1. Queuing

Conventional Queuing in Unix hosts follows a simple FIFO policy [5]. New incoming data segments are stored in an input queue. When the queue is full, last incoming segments are dropped (also called Drop Tail technique) until an application consumes seg-

1. Also called *"down scaling"*
2. Hierarchical distributed scaling is studied in [8]
3. we note by Stream with capital S the protocol design architecture in the system V terminology
4. Except for Open GoPs.

3NSDOCID: <XP_____10164870A__I_>

ments from the queue head, releasing memory for future data arrival.

Such a queuing model is not suited to real time multimedia environments for two reasons. First, in order to keep an acceptable visual quality when dealing with video applications, it is better to drop older video data segments rather than newer incoming ones. And second, the Drop Tail policy can induce an incoherence in the video stream segmented on multiple datagrams (applications usually flush the buffer and wait for a synchronization point). We propose an application requirement oriented scalable dynamic mechanism. It emulates GoPs batch arrivals in order to be able to drop complete semantically correlated set of datagrams.

3.2. Data copying

Data copying introduces penalizing delays. A first copy happens from the network interface private memory to the kernel's memory. A second copy into the application space is necessary. Applications that are penalized with losses in the network or operating system are usually forced to drop additional data segments. This is preferably achieved before copying data from the kernel. Implementing scaling procedure before data is copied can thus remove unnecessary data that cannot be used by applications. This can be done in UNIX system V which proposes the Streams facility.

A Stream [7] is composed of a head of Stream, a set of modules and/or drivers and a device driver (network interface driver), all of them organized in a vertical stack. Data is hence processed in pipeline where each module introduces its treatment and handles data through pointers (logical copy) to the next module. This architecture advantage is that no copies are performed until data reaches the head of Stream for incoming data or the device driver for outgoing data.

4. Protocol stack architecture

This section describes an architecture intended to deal with *Inter-GoP* and *Intra-GoP* scaling. *Intra-GoP* is implemented through MPEG stream de-multiplexing on multiple weighted logical flows and a filtering mechanism at the receiver. *Inter-GoP* scaling is achieved through Circular Buffers (CB)[3].

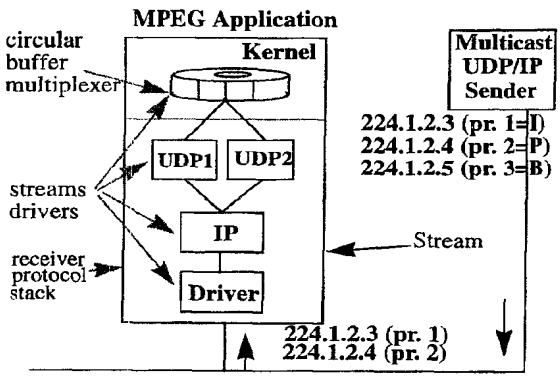

Figure 2 Streams Circular Buffer module for System V5

These two scaling techniques are described hereafter.

We have designed a priority based frame dropping mechanism using Circular Buffers. This mechanism was implemented for two different network protocols. In the first trial we used PTP Protocol [9] which offers a special field in the header for data priority. With the help of priorities we can apply filters in order to discard some logical flows. In the second trial, in order to implement a zero copy mechanism for the scaled data, we used different IP (Internet Protocol) Class D multicast addresses to differentiate data priorities. On Figure 2 priority 1 (I frames) is associated to class D 224.1.2.3 address. Application decides to filter, at the interface level, incoming flows by using the appropriate multicast addresses. Two fields are added, in order to be used by the CB module, to the datagrams (in the data part): Sequence Number and Information Unit (IU) number. The first is used to resolve desequencing that can be introduced either by the network, or by the scheduling of the UDP modules. The Information Unit (IU) number is used to emulate batch arrivals and hence to drop complete oldest GoPs[1] whenever the consumer application is slower than the arriving packets process. The whole implementation is inserted as a pseudo-driver multiplexer linked to the Stream (UDP protocol) (Figure 2).

The mechanism can easily be used for down-scaling on hosts acting as routers [8]. We only need to specify a priority for multi-

1. All datagrams within a GoP have the same IU number

BNSDOCID: <XP_____10164870A__I_>

casted packets. The multimedia router process will act as a filter and will transmit a reduced set of the incoming packets.

5. Application Design

Our application uses common Transport Layer Interface (TLI) of the Unix System V, to send datagrams over the previously mentioned priority class D UDP Streams. Each GoP is segmented on packets that have the size of the network Maximum Transfer Unit (MTU) minus protocols overhead. Three bytes are reserved at the beginning of each packet: one byte is used to indicate the Sequence Number and the two other bytes for IU.

Each Packet is sent on the correspondent Stream based on its priority.

The receiving application opens the CB Multiplexer and instantiates the multicast addresses corresponding to the flows it wants to receive. The multiplexer is linked to the UDP Stream. Coherent GoP structure is delivered to the CB when using increasing Class D addresses (and hence priorities).

6. Performance of a MPEG Receiver

A public domain MPEG player has been modified to deal with multicast facility.

The application instantiates UDP/IP Streams with the highest affordable priority (corresponding to multicast addresses) specified by the user. The interface discards all logical flows that have a higher priority (*Intra-GoP scaling*). In case of CPU bottleneck, the CB resolves overflow problems by overwriting, at the incoming data rate, complete oldest GoPs. This represents *Inter-GoP scaling* of IUs (corresponding each to a GoP eventually affected by the filtering: *Intra-GoP scaling*).

We concluded that priority improves video streams quality on loaded hosts. We have noticed that displaying the complete GoP on a loaded computer introduces important subsequent losses of complete GoPs. Using however a lower priority improves the regularity of the video stream. This effect was measured and plotted. Three operation zones are distinguished in the next section.

7. Performance measurements

This section studies how to improve the visual quality of the received stream when varying the CPU load. This is equivalent to varying the sending rate (incoming GoPs rate).

Scaling performance of the circular buffers module is shown in Figure 3 and Figure 4.

Figure 3 shows the percentage of GoP lost on a Sun Sparc Station 5 running Solaris 2.4 with circular buffer module inserted as mentioned in the UDP/IP Stream. Ethernet conventional interface was used in order to implement the multicast facility. The CIF video sequence has I:P:B ratio of 1:2:2 with a GoP of seven images (Figure 1).

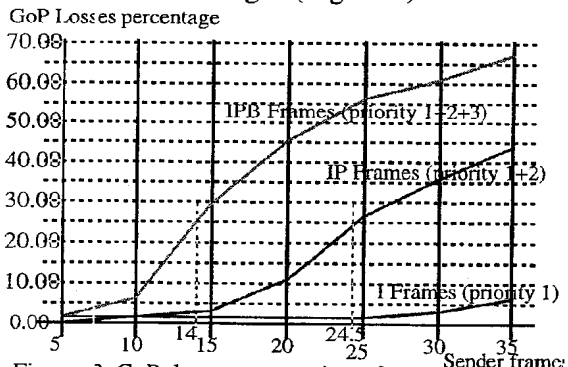

Figure 3 GoP losses at receiver for three increasing priorities

The horizontal axis shows the sender frame rate generation. The vertical axis gives the percentage of GoPs lost. Three curves are plotted with the three previously mentioned priorities. A high GoP loss percentage corresponds to a long visual irregularity in the video sequence. The first curve (priority 1) shows a very low percentage of lost GoPs. The second curve (priority 1+2) gives a larger number of subsequent decoded frames but also a larger number of losses. The third curve (priority 1+2+3) gives the highest number of GoP losses. We can conclude from this figure that when a loss happens in the network or in the operating system it will affect more seriously streams that have an IPB organization than streams that are less correlated like streams built on I frames only. Giving a lower priority for the latest stream can hence improve the global performance.

Figure 4 gives the ratio of the total captured and displayed frames for the different priorities.

BNSDOCID: <XP_____10164870A__I_>

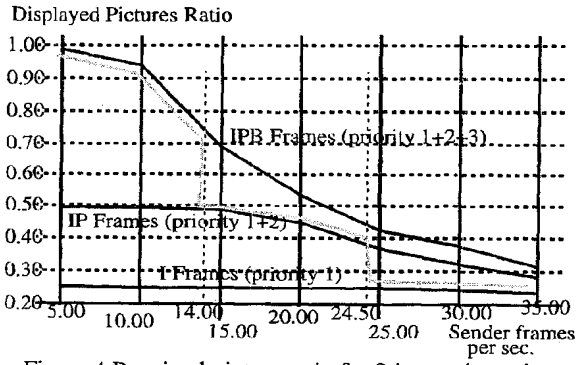

Figure 4 Received picture ratio for 3 increasing priority applications

It is clear from Figure 4 that the "IPB priority" decodes globally the largest number of frames. It is shown however that it suffers from large GoP losses when increasing the frame rate (interval 14->). It is hence visually better to choose a lower "IP priority" resulting in a smaller amount of decoded frames but with a greater visual regularity of pictures. This is depicted by the resulting gray broken curve in Figure 4. A simple model can hence be implemented in the application to receive the adequate number of priority streams. We can combine the two figures to implement a selective priority mechanism. From Figure 3, we can set arbitrarily a certain GoP loss threshold (e.g. 25%). This threshold divides the plots into three zones (at 14 and 24.5 frames per second). We then map these values on Figure 4. This also divides the plots into three working zones. The resulting mechanism will work with priority 1+2+3 up to 14 frames per second. When the decoder receives a larger amount of frames it will work with priority 1+2 and so on. It is to be mentioned that the chosen threshold can be studied taking into account psycho-visual considerations.

8. Conclusions

We have presented a scaling mechanism especially adapted for MPEG video coding. Two complementary methods are implemented in the system V Streams in order to prevent expensive kernel copies and to globally improve visual quality. The proposed scaling algorithm is used by MPEG receiver in a multicast environment. We show how scaling can be adapted to offer local QoS fitting at best with the CPU load. The scaling module can be used for all multimedia streams supporting hierarchical coding.

1. INTRODUCTION

1.1 Overview of the Paper

The paper is organized as follows. In the introductory part of the document, techniques utilizing scalable video coding or multiple representations of the same video content are presented in section 1.2 and a brief review to temporal scalability in video coding is given in section 1.3. The paper proposes means to signal temporal scalability based on chains of inter-dependent frames. An independently disposable chain of pictures is called a sub-sequence. The proposal is presented in section 2, and some examples of scalably coded bitstreams are given in section 3. After that, the document includes the patent disclosure form and some references.

The r1 revision of the document contains the proposal in the form that it was approved in the second JVT meeting. The changes compared to the original revision can be summarized as follows:

- The text for normative decoder operation was clarified and the terminology was fixed.
- The proposal does not require changes in transmitted packet or bit stream. A remark of that fact was added.
- The IPR statement was updated (a liberalizing comment on statement 2.2 was added).

1.2 Needs for Scalable Video Coding

1.2.1 Unequal Error Protection

Video streaming applications can often make use of unequal error protection (UEP). In order to apply UEP, video bitstreams have to be organized in portions of different importance in terms of visual quality. Techniques achieving this goal include data partitioning and scalable video coding. Examples of applicable UEP techniques are:

- Application-layer selective retransmission. Some commercial Internet streaming systems implement retransmission requests using proprietary protocols [1]. Work is going on in IETF to standardize a selective retransmission request mechanism as a part of RTP/RTCP [2][3].

BNSDOCID: <XP_____30005042A__I_>

A common feature for all of these retransmission request protocols is that they are not suitable for multicasting to a large number of players, as the network traffic may increase drastically. Consequently, multicast streaming applications cannot rely on interactive packet loss control.

- Transport-layer forward error control. Transmitters can add such redundancy to the transmitted packet stream that helps receivers to recover possibly lost data. Examples of such techniques are use of forward error correction (FEC) packets according to RFC 2733 [4] and transmission of redundant copies of selected packets.

- Guaranteed network Quality of Service (QoS). A stream might be transmitted through a number logical channels, each of which may have a different guaranteed QoS. Examples of such systems are the QoS architecture of Universal Mobile Telecommunication System (UMTS) [5] and System for Audio/Visual Live Services and Applications (SALSA) [6]. In UMTS (release 4 and later), an application can request for a certain QoS class (conversational, streaming, interactive, or background) and specific values for QoS parameters within the requested QoS class, such as guaranteed bit-rate and SDU error ratio. SALSA works on top of a CATV system. It provides a 100-kbps reliable channel and a 300-kbps best-effort channel per connection.

- Differentiated Services (DiffServ) [7][8]. In DiffServ, packets are classified and marked to receive a particular per-hop forwarding behavior on nodes along their path. While DiffServ is not available throughout the Internet, many private networks support it.

1.2.2 Rate Shaping

The objective of rate or traffic shaping is to match the bit-rate of a pre-compressed video bitstream to the target rate constraint. Many networks are not capable of providing channels with constant throughput. Thus, many streaming servers monitor the network conditions and adjust the transmitted bitstream accordingly. One way to control the bit-rate of the transmitted stream is to decide which enhancement layer to transmit. Another way is to switch between multiple representations of the same content each targeted for different bit-rate.

1.3 Temporally Scalable Video Coding

1.3.1 Individually Disposable Pictures

Conventionally, B pictures have not been used as prediction references. Consequently, they have provided a way to achieve temporal scalability. (In the JVT codec, B pictures can also be stored are referenced in other pictures.)

H.263 Annex U and JVT JM-1 allow signaling that a particular picture need not be stored in the buffer of reference pictures. Consequently, such a picture can be safely disposed.

1.3.2 Disposal of Picture Chains

A known method in today's streaming systems to cope with drastically dropped channel throughput is to transmit INTRA pictures only. When the network throughput is restored, INTER pictures can be transmitted again from the beginning of the next Group of Pictures (GOP).

Generally, any chain of INTER pictures can be safely disposed, if no other picture is predicted from them. This fact can be utilized to treat INTER pictures at the end of a prediction chains less important than other INTER pictures. In some cases, such INTER pictures represent contents of scene transitions, such as fades, and can be disposed without losing essential pictorial information.

3NSDOCID: <XP_____30005042A__I_>

Reference picture selection enables different kinds of temporal scalability schemes, which are herein referred to as layered temporal scalability. One example of such a scheme is proposed in [6]. It is called SALSA and depicted in Figure 1. The "base" layer has a relatively low temporal resolution enabling it to be transmitted in a 100-kbps reliable channel. For example, every 6th coded frame may belong to the "base" layer. The "enhancement" layer increases the temporal resolution and is transmitted in a 300-kbps best-effort channel.

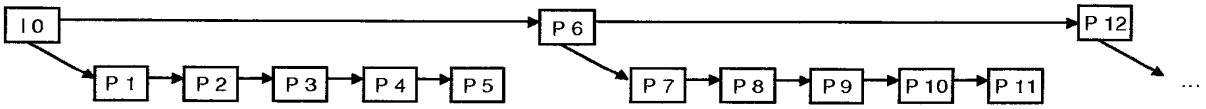

Figure 1. Temporal scalability proposed in SALSA.

A straightforward modification of the SALSA coding scheme targeted for rate shaping is illustrated in Figure 2. "SP 6" (and "SP 12") boxes indicate identical representations of frame 6 (and 12 respectively) based on different reference frames. A streaming server decides which coded SP frame is transmitted based on the temporal resolution of the previously transmitted section of the bitstream. The encoder may also switch to a lower or higher temporal resolution after such an SP frame. The compression efficiency of this kind of a coding scheme is nearly as good as in a non-scalable coding scheme as shown in VCEG-M73.

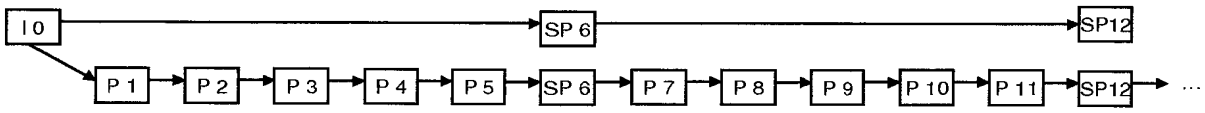

Figure 2. Temporal scalability for rate shaping.

In the JVT design, B pictures can be used as prediction references. Another example of temporal scalability scheme is illustrated in Figure 3, which presents an IBBP coding pattern, where the latter B picture is predicted from the former one. Pictures B3 and B6 can be disposed individually, whereas disposal of pictures B2 and B5 requires disposal of pictures B3 and B6 respectively.

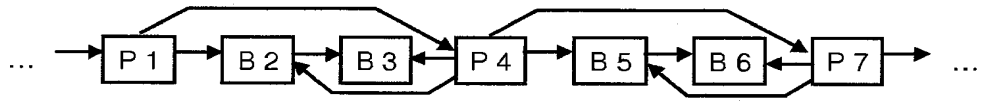

Figure 3. B pictures as motion compensation references in an IBBP coding pattern.

2. PROPOSAL

2.1 Overview

The proposal enhances the concept of independently decodable GOPs presented in JVT-B041 so that disposable chains of pictures can be easily identified and disposed. The proposal organizes pictures in temporal scalability layers and sub-sequences. A sub-sequence represents a number of inter-dependent pictures that can be disposed without affecting the decoding of any sub-sequence in any less enhanced scalability layer.

The result of sub-sequence or layer disposal must be a valid bitstream. Moreover, as the foreseen applications, namely unequal error protection and rate shaping, take place in a streaming server, no changes to Video Coding Layer syntax or any transport packetization syntax were seen necessary. Thus, we propose syntax changes only to the interim file format (VCEG-O58). The changes allow signaling of layers, sub-sequences and their dependencies. Appendix A of the document contains an updated version of the interim file format. The use of the proposed syntax changes is optional, i.e., non-scalable bitstreams can be created without signaling overhead. Furthermore, file format parsers can ignore the information related to scalability layers and sub-sequences safely.

Only entire sub-sequences and non-stored pictures should be disposed. When disposing a sub-sequence, any sub-sequence depending on the disposed one should be discarded as well. Otherwise, a mismatch in the multi-picture buffer contents may occur between the encoder and the decoder, which results into incorrectly reconstructed pictures in the decoder. Encoder constraints on multi-picture buffering are listed in section 2.3.

Decoders shall be informed if it is possible to dispose sub-sequences intentionally. This is done with a new flag in the parameter set (defined in VCEG-O58 and VCEG-N72r1). When intentional disposal is allowed, decoders shall not infer an unintentional picture loss immediately when a missing picture number is detected but rather update the multi-picture buffer so that the default index order remains the same as in the encoder. Detailed decoder operations are presented in section 2.4.

No changes in the transmitted packet or bit stream syntax are proposed. In other words, no information about layers and sub-sequences is transmitted.

The proposal is targeted for all "streaming" and "storage" applications.

2.2 Definition of a Layer and a Sub-Sequence

Layers can be ordered hierarchically based on their dependency on each other. The base layer is independently decodable. The first enhancement layer depends on some of the data in the base layer. The second enhancement layer depends on some of the data in the first enhancement layer and in the base layer and so on. The subjective quality increases along with the number of decoded enhancement layers.

A sub-sequence shall not depend on any other sub-sequence in the same or in a more enhanced scalability layer. In other words, it shall only depend on one or more sub-sequences in one or more less enhanced scalability layers. A sub-sequence in the base layer can be decoded independently of any other sub-sequences and prior long-term reference pictures. Thus, the beginning of a base layer sub-sequence can be used as a random access position.

A sub-sequence covers a certain period of time within the sequence. Sub-sequences within a layer and in different layers can partly or entirely overlap. A picture shall reside in one layer and in one sub-sequence only.

Pictures sharing the same display time in the same layer are considered alternative representations of the same picture content, and any representation of the picture can be used. These so-called sync pictures shall reside in the same sub-sequence, but their reference pictures can reside in any sub-sequence. Indication of the reference sub-sequence helps streaming servers to decide which coded sync frame to transmit.

A layer number is assigned to layers. Number zero stands for the base layer. The first enhancement layer is associated with number one and each additional enhancement layer increments the number by one.

A sub-sequence identifier is assigned to sub-sequences. Consecutive sub-sequences (within the same scalability layer) should not have the same identifier, but no other numbering rule for sub-sequence identifiers is necessary.

2.3 Constraints in Multi-Picture Buffering

If you are unfamiliar with multi-picture buffering, please refer to VCEG-O10r1 or to section 7 of TML-9 (VCEG-N83d1) to get an insight.

Any entity, such as a streaming server, disposing parts of a bitstream must make sure that the decoder is able to obtain essentially the same state of the multi-picture buffer as the encoder at any instant of time. Otherwise, the default picture order might differ in the decoder from the one used while encoding, and incorrect reference pictures may be used. Thus, the following constraints in memory management operations of the multi-picture buffer have to be followed when coding a bitstream according to the proposal:

- Marking a picture as "Unused" shall be done in a stored base-layer picture only. Otherwise, if a sub-sequence containing the assignment to "Unused" were disposed, the default index order of pictures might differ in the encoder and in the decoder.

- Resetting the multi-picture buffer shall be done in a stored base-layer picture only. Otherwise, the reset indication might be disposed and the contents of the multi-picture buffer would differ.

- Changing the number of long-term pictures shall be done in a stored base-layer picture only, as this operation affects the default index order.

- Assigning a long-term picture index to a short-term picture can be done in any picture in the same sub-sequence where the picture resides or in any of the sub-sequences used for predicting the current one, if the long-term picture index was already taken into use in one of these sub-sequences. Otherwise, if the long-term picture index was "Unused" or was taken into use in a sub-sequence independent from the current one, a long-term index shall be assigned in the base layer. (Re-using a long-term index does not change the default index order, whereas taking a fresh long-term index into use does.)

2.4 Decoder Operation

The defined reaction to a gap in picture numbers (a paragraph in section 7.6.2 of VCEG-N83d1) is as follows:

"If the decoder detects a missing picture, it may invoke some concealment process, and may insert an error-concealed picture into the multi-picture buffer. Missing pictures can be identified if one or several picture numbers are missing or if a picture not stored in the multi-picture buffer

BNSDOCID: <XP_____30005042A__I_>

is indicated in a transmitted ADPN or LPIR. Concealment may be conducted by copying the closest temporally preceding picture that is available in the multi-picture buffer into the position of the missing picture. The temporal order of the short-term pictures in the multi-picture buffer can be inferred from their default relative index order and PN fields. In addition or instead, the decoder may send a forced INTRA update signal to the encoder by external means (for example, Recommendation H.245), or the decoder may use external means or back-channel messages (for example, Recommendation H.245) to indicate the loss of pictures to the encoder. A concealed picture may be inserted into the multi-picture buffer when using the "Sliding Window" buffering type. If a missing picture is detected when decoding a Slice, the concealment may be applied to the picture as if the missing picture had been detected at the picture layer."

As the suggested reaction is correct for accidentally lost pictures only, we propose that the possibility of intentional sub-sequence disposal is indicated in the parameter set. We call the indication as the required picture number update behavior indication. The value of the indication (on or off) in the referred parameter set shall be the same as in the previously transmitted NAL packets, unless a multi-picture buffer reset is associated with the current NAL packet.

If the required picture number update behavior is signaled, a gap in picture numbers shall be treated as follows:

- Decoders shall not infer an accidental loss immediately.
- Decoders shall not invoke any immediate concealment.
- Decoders shall generate the default index order as if pictures corresponding to the lost picture numbers were inserted to the multi-picture buffer using the "Sliding Window" buffering type. An index corresponding to a missing picture number is called an "invalid" index.

Decoders shall infer an accidental picture loss if any "invalid" index is referred to in motion compensation or if an "invalid" index is re-mapped. As a reaction to a detected picture loss, decoders may invoke some concealment process similarly to what has been defined in section 7.6.2 of VCEG-N83d1. If the subject of a memory management control operation is a picture corresponding to an "invalid" index, the operation shall be carried out normally.

We propose that the paragraph in section 7.6.2 of VCEG-N83d1 is replaced with the following paragraph

"If the indicated parameter set in the latest received slice or data partition signals the required picture number update behavior, the decoder shall operate as follows. The default picture index order shall be updated as if pictures corresponding to missing picture numbers were inserted to the multi-picture buffer using the "Sliding Window" buffering type. An index corresponding to a missing picture number is called an "invalid" index. The decoder should infer an unintentional picture loss if any "invalid" index is referred to in motion compensation or if an "invalid" index is re-mapped.

If the indicated parameter set in the latest received slice or data partition does not signal the required picture number update behavior, the decoder should infer an unintentional picture loss if one or several picture numbers are missing or if a picture not stored in the multi-picture buffer is indicated in a transmitted ADPN or LPIR.

In case of an unintentional picture loss, the decoder may invoke some concealment process. If the required picture number update behavior was indicated, the decoder may replace the picture corresponding to an "invalid" index with an error-concealed one and remove the "invalid" indication. If the required picture number update behavior was not indicated, the decoder may insert an error-concealed picture into the multi-picture buffer assuming the "Sliding Window"

buffering type. Concealment may be conducted by copying the closest temporally preceding picture that is available in the multi-picture buffer into the position of the missing picture. The temporal order of the short-term pictures in the multi-picture buffer can be inferred from their default relative index order and PN fields. In addition or instead, the decoder may send a forced INTRA update signal to the encoder by external means (for example, Recommendation H.245), or the decoder may use external means or back-channel messages (for example, Recommendation H.245) to indicate the loss of pictures to the encoder."

2.5 Sub-Sequences Compared to Alternate Tracks

The interim file format (VCEG-O58) contains a mechanism to include multiple coded representations of the same uncompressed video sequence into the same file. These representations are referred to as alternate tracks. The interim file format also allows signaling of pictures that can be used to switch between alternate tracks.

Most (if not all) patterns of coded pictures, such as the one illustrated in Figure 2 can be expressed both using alternate tracks and using temporal scalability layers and sub-sequences. We propose that the alternate track mechanism would be used for rough bit-rate adjustment, as it does not provide means for indicating scalability layers, dependencies between pictures, and information about temporary bit- or frame rates. The sub-sequence mechanism can be considered more flexible in bit-rate scalability. It suits better for short-term, immediate, and accurate bit-rate adjustment.

3. EXAMPLES

The notation used in the figures is as follows: I stands for INTRA picture and P for INTER pictures. Picture type is followed by two digits separated by a dot (x.y). x stands for sub-sequence identifier and y stands for picture number. Relative capturing and displaying time runs from left to right. Scalability layers are on top of each other and indicated on the left.

Figure 4 shows an example of a scene transition, where the first scene is faded to black. The faded pictures are located in an enhancement layer, as they are not considered to contain any subjectively essential information. The former base layer sub-sequence happens to have identifier 0 and the latter one has identifier 1, whereas the sub-sequence in the enhancement layer happens to have identifier 3. Picture numbers run independently from sub-sequences but are reset to zero at the beginning of each base-layer sub-sequence as proposed in JVT-B041.

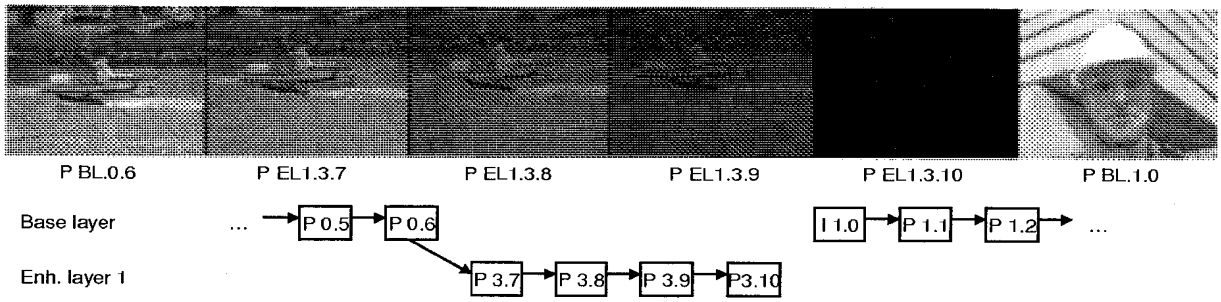

Figure 4. Fade to black.

Figure 5 shows how the temporal scalability scheme proposed in SALSA can be handled with layers and sub-sequences. Notice that even though the sub-sequence in the base layer and the first sub-sequence in the enhancement layer are given the same sub-sequence identifier, they can be distinguished from each other, since they reside in different layers.

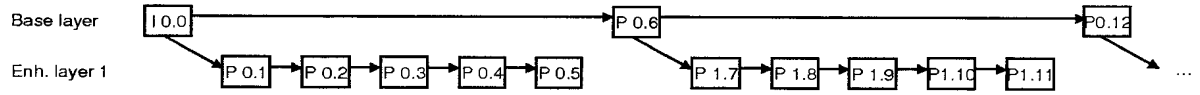

Figure 5. Temporal scalability proposed in SALSA.

Figure 6 shows an example of sub-sequence and picture numbering for a temporal scalability scheme for rate shaping purposes. Sub-sequence and picture numbering is similar to the previous example.

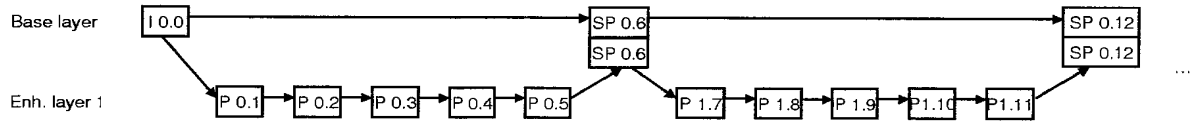

Figure 6. Temporal scalability for rate shaping.

Figure 7 shows an example of sub-sequence and picture numbering, when some B pictures are used as motion compensation reference pictures. Picture number 7 is assigned to both picture B EL1.1.7 and picture P BL.0.7, as the B picture is not stored in the multi-picture buffer. However, as picture B EL1.1.6 is stored in the multi-picture buffer, the picture number is incremented normally in the picture following it.

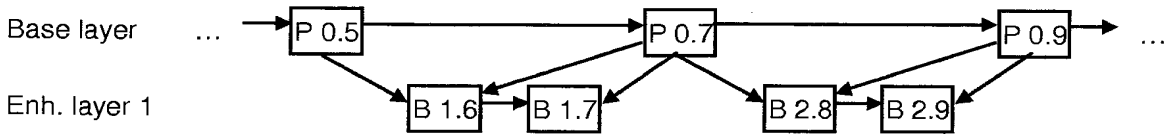

Figure 7. B pictures as motion compensation references in an IBBP coding pattern.

Abstract

We investigate the impact of multimedia applications on the cache behavior of desktop systems. Specifically, we consider the memory bandwidth and data cache challenges associated with MPEG-2 software decoding. Recent extensions to instruction set architectures, including Intel's MMX, address the computational aspects of MPEG decoding. The large amount of data traffic generated, however, has received little attention. Standard data caches consistently generate an excess of cache-memory traffic. Varying basic cache parameters only reduces traffic to double the minimum required at best. Incremental changes in cache size have a negligible effect for most feasible values. Increasing set associativity yields rapidly diminishing returns, and manipulating line size is similarly unproductive. Achieving higher efficiency requires understanding the composition and behavior of the decoder data set. We present a model of MPEG-2 decoder memory behavior and describe how to exploit this knowledge to minimize required memory bandwidth. Our results show that simply eliminating one component, video output data, from the cache can reduce traffic by as much as 50 percent.

1 INTRODUCTION

The capabilities of microprocessors are expanding to include multimedia functionality, supported by ISA extensions (e.g. Intel's MMX [7], Sun Microsystems' VIS [8] and Hewlett-Packard's MAX-2 [5]) and hardware enhancements. MPEG-2, the favored standard for video compression, is a popular target application for recent processor designs. These architectural modifications address the computational challenges of MPEG, yet the consequences for memory subsystems remain largely unexplored. The high data rate, large set sizes, and distinctive memory access patterns of MPEG exert a particular strain on caches. While miss rate levels are acceptable, standard caches, even very large ones, generate significant excess memory traffic.

We examine the traffic and data cache behavior of an MPEG-2 decoder running Main level streams on a general-purpose microprocessor. An analysis of the data types utilized by the decoder complements trace-driven cache simulations of representative streams. We show that there is a benefit to even small, simple caches. Unfortunately, manipulating standard parameters (cache size, associativity, and line size) fails to cost-effectively reduce excess memory traffic. These results suggest several architectural enhancements, which we outline. We also show that even relatively simple measures, such as selective caching of specific data types, can dramatically improve efficiency, reducing cache-memory traffic by up to 50%, and 25% on average, for a wide range of cache sizes.

The goal of this work is to establish how caches behave under the strain of software MPEG-2 decoding, and exploit that knowledge to achieve more efficient cache resource utilization. Successful application of these insights will raise the multimedia performance standard of microcomputers and support the deployment of numerous applications which are currently technologically infeasible. Facilitating the efficient utilization of resources can also enable the production of low-cost and even low-power portable systems, and a broader proliferation of digital video applications.

2 BACKGROUND

Consider the problem of decoding MPEG-2 in software on a general-purpose computing platform. The machine type of primary interest is a typical desktop PC or workstation, as envisioned in Figure 1. The diagram also illustrates the typical flow of video data in the system. Imagine the user is viewing, for example, an entry in a multimedia encyclopedia. Compressed data is transferred from the file system (e.g. CD-ROM or hard disk) by direct memory access (DMA) and buffered in the main memory. The CPU reads the data through its cache hierarchy and writes the decoded, dithered RGB video, one frame at a time, to main memory where it is stored in an image of the displayed video window. Finally, another DMA transfer brings the

BNSDOCID: <XP_____10251768A__I_>

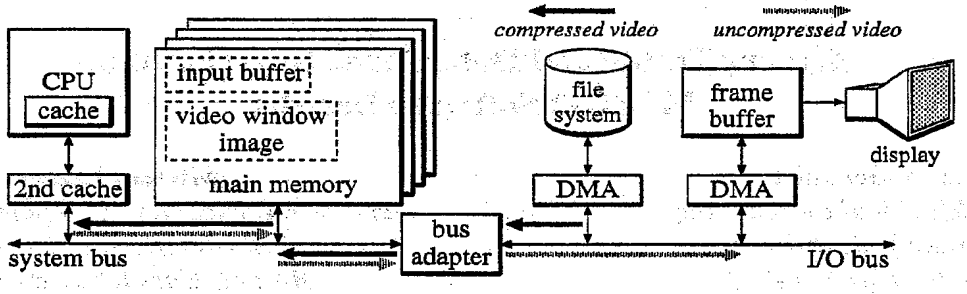

Figure 1: Typical desktop machine with software MPEG-2 decoding traffic

video data to the frame buffer where it eventually appears on the display.

It is clear that there is a large amount of data, much of it time-sensitive, being transferred through the system. Most of this is concentrated on the main system bus. At the very least, there are two streams each of encoded and decoded video being concurrently transferred in and out of main memory, amounting to a minimum sustained load of 63 Mbytes/s. This ignores the bandwidth required by other applications running on the system and sharing interconnect, main memory, and peripherals. Any excess memory traffic generated by cache inefficiency will further exacerbate this situation. Unfortunately, our simulations indicate that standard caches generate *at least* twice the minimum required level of cache-memory traffic, typically many times more, amounting to a significant strain on system capacity. The result is some combination of dropped frames, reduced frame rate, or degradation of overall system performance.

2.1 MPEG Overview

Appreciating the challenges of supporting video decoding requires some understanding of the MPEG standard [2]. MPEG attacks both the spatial and temporal redundancy of video signals to achieve compression. Video data is broken down into 8×8 pixel *Blocks* and passed through a discrete cosine transform (DCT). The resulting spatial frequency coefficients are quantized, run-length encoded, and then further compressed with an entropy coding algorithm. To exploit temporal redundancy, MPEG encoding uses motion compensation with three different types of frames. *I* (intra) frames contain a complete image, compressed for spatial redundancy only. *P* (predicted) MPEG frames are built from 16×16 fragments known as *macroblocks*. These consist primarily of pixels from the closest previous I or P frame (the *reference frame*), translated as a group from their location in the source. This information is stored as a vector representing the translation, and a DCT-encoded difference term, requiring far fewer bits then the original image fragment. *B* (bidirectional) frames can use the closest two I or P pictures – one before and one after in temporal order – as reference frames. Information not present in reference frames is encoded spatially on a block-by-block basis. All of data in P and B frames is also subject to run-length and entropy coding.

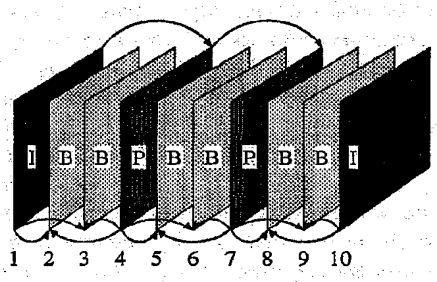

Figure 2: Typical sequence of MPEG frames, showing interframe dependencies

Figure 2 shows the interframe dependencies of the different frame types, superimposed on the displayed frame order. For decoding, these frames must be processed in the non-temporal order [1,4,2,3,7,5,6,10,8,9], which is a result of these dependencies. The dependencies between frames and the properties and and sequence of frame types determine in critical ways the flow pattern of MPEG data and the nature of hardware support required.

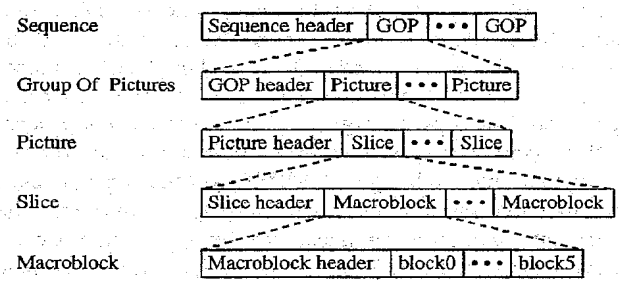

Figure 3: MPEG bitstream structure

The decoder reads the MPEG data as a stream of bits. Unique bit patterns, known as *startcodes* mark the division

BNSDOCID: <XP_____10251768A__I_>

between different sections of the data. The bitstream has a hierarchical structure, shown in simplified form in Figure 3. A *Sequence* (video clip) consists of *groups of pictures (GOP's)*. A GOP contains at least one I frame and typically a number P and B frames; Figure 2 shows a possible GOP of 9 frames (*pictures*) followed by the I frame of the subsequent GOP. Pictures consist of collections of macroblocks called *slices*. The "headers" shown at each level contain parameters relevant to each bitstream type, but no actual image data.

2.2 Experimental Model

For experimental purposes, we focus on a simplified machine model, limiting the microprocessor to a single level of caching, and assume that MPEG-2 decoding is the only active process. Our results come from trace-driven cache simulations of video stream decoding. The clips themselves are progressive MPEG-2 Main Level sequences, with a resolution of 704 × 480 pixels at 30 frames/second. The decoder is a version of mpeg2decode from the MPEG Software Simulation Group [1], running on a SPARC processor. We have modified the program to instrument it for trace generation with QPT2 (the Quick Profiler and Tracer) [4], a component of the Wisconsin Architectural Research Toolkit (WARTS). Our cache simulator, Pacino, is designed to support continuous media applications.

To limit the memory storage and CPU cycle requirements of simulation, we restrict each run to one GOP, the largest logical bitstream unit below a sequence. Simulations run as if at steady state – i.e. preceded and followed by a large number of other GOP's. This eliminates the side effects of program startup and termination.

Decoded video is sent to the frame buffer in 4:2:0 YCrCb form, the native representation of MPEG, rather than 4:4:4 RGB. YCrCb is a color representation with one luminance (grayscale) and two chrominance components per pixel, rather than one each of red, green, and blue. In 4:2:0 YCrCb, the chrominance components are subsampled in both dimensions. We assume that upsampling, color space conversion, and any dithering are done on the fly by the video display subsystem. These features are becoming common in workstations and budget PC video accelerators alike. According to prior work on MPEG-1 decoders, this processing can account for almost 25% of total execution time if performed in software [6]. In addition, the 4:2:0 representation of an image is only half the size of the 4:4:4 version, reducing the minimum sustained system bus load to 31.5 Mbytes/s.

3 Data Types and Definitions

The data set of an MPEG-2 decoder – the information that must be available to the program in the course of its execution – consists of several different types which serve distinct functions. As a result, they are quite heterogeneous with respect to the types and patterns of access utilized by the decoder, as well as the amount of memory space required. The following classes account for the global and static local values in user space.

- *Input.* The compressed MPEG-2 data stream, with data read in series from a fixed-size buffer and refreshed by system calls.
- *Output.* Uncompressed picture data in YCrCb format, stored in a video window image buffer. This data type is *write only* – written but never read by the CPU. System calls transfer each completed picture into the frame buffer.
- *Tabular.* Static, *read only* information used in the MPEG decoding process, such as various lookup tables.
- *Reference.* The current frame and the previously decoded frames used to reconstruct it (up to two for a B frame), in YCrCb form.
- *Block.* The DCT coefficient and pixel values for a single macroblock.
- *State.* Values incidental to the settings and operation of the decoder, yet not part of the image data *per se*.

This partitioning of data types may not be explicit within the decoder source, but represent an abstraction at a higher level of the data needed for decoder operation. Most of these data types are both read and written. The exceptions are the tabular data, which are *read only*, and the the output data which is *write only*. Within a memory hierarchy, reading and writing are not symmetric operations. Read misses and write misses in caches have very different latencies. The fact that some MPEG decoder data types are only read or written can be exploited for performance optimization.

Data Type	*Access Type*	*Size*	*Fraction of References*
Input	read/write	2 KB	2.7%
Output	write only	500 KB	3.9%
Tabular	read only	5 KB	5.5%
Reference	read/write	1500 KB	23.7%
Block	read/write	1.5 KB	31.4%
State	read/write	0.5 KB	25.6%

Table 1: Summary of decoder data types, sizes, access types, and proportion of memory references accounted for

3NSDOCID: <XP_____10251768A__I_>

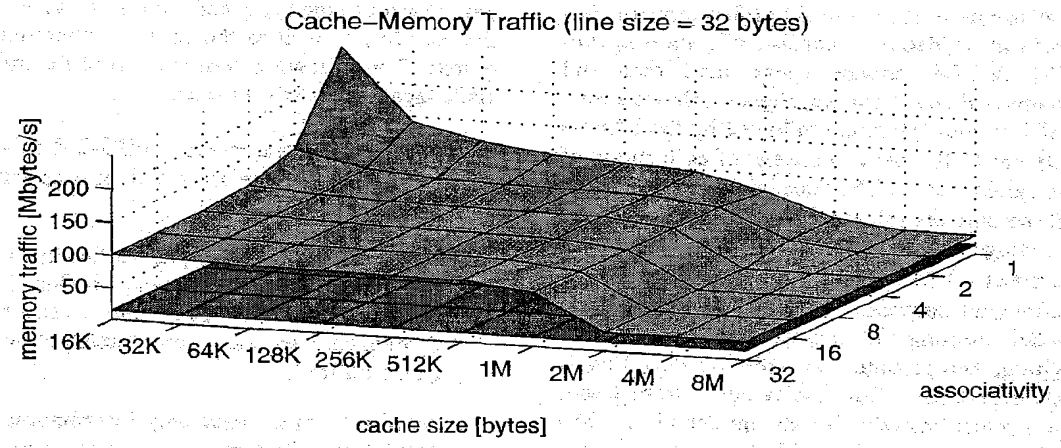

Figure 4: Typical cache-memory traffic for MPEG-2 Main Level decoding, over minimum possible traffic level

The essential properties of the different data types are summarized in Table 1. Note how in terms of size, the reference and output types completely dominate the others. With respect to caching, this means that their presence will tend to repeatedly expel the other types from the cache, except for very large data caches. It doesn't matter how many times the other values are re-used. Capacity limitations alone will insure that reference and output data, when updated, will throw the other data types out.

Curiously, ranking the data types in terms of the number of references rather than by size gives a very different picture. Block and state data account for by far the most memory requests. Reference data is next, but output data is in next to last place, accounting for 8 times fewer memory requests than block data. Note that the percentages don't add up to 100%; approximately 7.2% of data references are due to temporary variables and library functions.

4 Cache Simulation Results

Trace-driven cache simulations clarify how MPEG-2 decoder data requests translate into what traffic is seen by the memory. First of all, there is a distinct (albeit limited) benefit to caching video decoder data, even using naive, generic schemes. It has occasionally been suggested that caches are critically inefficient for video data. Accordingly, some special-purpose systems dispense with data caches altogether in favor of large register files [3]. Yet we have found that despite the large set sizes and the magnitude of data consumed and discarded, there is sufficient re-use of values for caching to significantly reduce the required memory bandwidth.

For example, decoding one Group Of Pictures from a typical MPEG-2 stream generates 2.1×10^8 memory requests. A 16 Kbyte, direct-mapped cache generates 3.9×10^7 words of memory traffic. If we estimate conservatively that each word of cache data represents a memory request, then even a relatively small, simple cache keeps almost 85% of traffic off of the memory bus. In fact, caches typically load several words at a time, while many CPU memory requests are for data types smaller than a word. Therefore, data caches can make far more efficient use of available memory bandwidth than registers alone. Even very clever register management would have trouble competing with anything but the smallest caches. The remainder of this section examines in more detail how the basic parameters of a simple cache affect memory traffic as well as misses.

4.1 Cache Size

The size of a cache is its most significant design parameter, certainly from a cost standpoint. Because cache size usually increases or decreases by factors of two, the decision of how large a cache to implement in a system is pivotal. For Main Level MPEG-2 decoding, the cache-memory traffic as a function of cache size and associativity shows little variation between video sequences. Figure 4 shows a representative plot, assuming a standard line size of 32 bytes. This is superimposed on a surface showing the minimum possible cache-memory traffic for the sequence, consisting of the encoded and decoded video streams combined.

The most prominent feature of the traffic function is a large plateau, at a level of 6.3 times the minimum value. Except for direct-mapped caches, which produce a peak of 16 times the minimum, cache-memory traffic changes little with increasing cache size for most of the range. Traffic starts to roll off at 1 Mbyte, and plummets at 2 Mbytes. This reflects the 2 Mbyte size of the decoder data set. Larger caches show negligible improvement, with the ad-

BNSDOCID: <XP_____10251768A__I_>

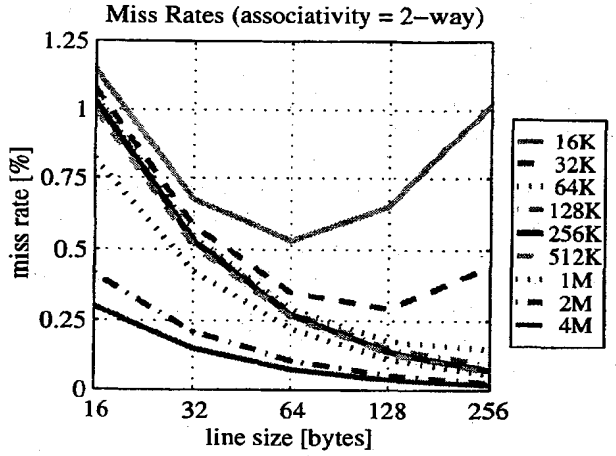

Figure 5: Typical miss rates for MPEG-2 Main Level decoding over different cache sizes

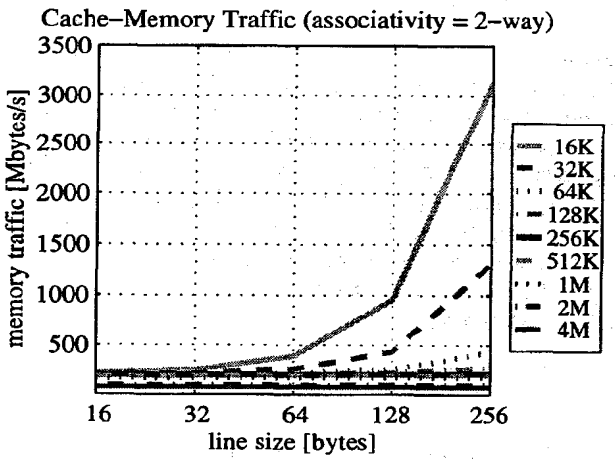

Figure 6: Typical cache-memory traffic for MPEG-2 Main Level decoding over different cache sizes

ditional space providing no extra benefit. However, the measured minimum is still almost 2 times higher than the minimum possible value.

These data imply that a 32 Kbyte cache is just as good (or bad) for MPEG-2 Main Level decoding as a 64 Kbyte or 128 Kbyte one, for example. Improving on cache-memory traffic requires a 1 Mbyte cache or higher, but a 2 Mbytes or larger cache only brings traffic down to double the absolute minimum, leaving plenty of room for improvement.

4.2 Associativity

Increasing set associativity is a popular method for getting higher performance out of smaller caches. The memory traffic effects of varying set associativity are also visible in Figure 4. Going from a direct-mapped cache to a 2-way set-associative one can reduce memory traffic by as much as 50% for small caches. Increasing associativity to 4 can squeeze out almost another 10% improvement over the direct-mapped case. Set sizes of greater than 4, however, show minimal benefit across all cache sizes. Since increasingly higher levels of associativity add considerably to cache cost, complexity and access time, such enhancements are not justified.

While memory traffic is the primary focus, we would prefer to not adversely affect miss rates. As a function of cache size and set associativity, miss rates show the same behavioral pattern as memory traffic. However, unlike for cache-memory traffic, the performance is more than satisfactory, with an average value below 0.5%.

4.3 Line Size

Line size, another fundamental parameter, is less costly to experiment with than cache size. Subblock placement can help decouple the size of cache lines and that of the memory bus. Unfortunately, there is contention between miss rate and memory traffic minimization. Low miss rates call for larger lines than the typical 32 bytes, as illustrated in Figure 5. Larger lines tend to provide superior spatial locality, but require more data to be read and possibly written back on a miss. For this reason, minimal memory traffic occurs with the smaller lines. This relationship is readily apparent in Figure 6, where for the smallest caches, the largest line sizes lead to cache-memory traffic almost 200 times the absolute minimum.

Balancing the demands of miss rates and memory traffic requires further investigation. For the time being, maintaining the ubiquitous 32 byte line size seems sensible. The interests of memory traffic reduction argue against a switch to larger values.

5 Architectural Solutions

It is clear that conventional cache techniques provide limited relief from excess cache-memory traffic. The simplest way to improve memory traffic and miss rates is to have a very large cache – but a large cache is not always feasible, and simulations show that improving MPEG-2 decoding performance requires very big caches. In any case, one would prefer to extract better performance from smaller, lower-cost resources. Hardware prefetching has been suggested as a remedy [9], yet primarily as a means to reduce miss rates and without much consideration of cache-memory traffic, which tends to increase with prefetching.

We advocate looking more closely at the internal dynamics of the decoder itself. Exploiting knowledge of individual data types, their sizes, access types, and access

3NSDOCID: <XP_____10251768A__I_>

patterns can suggest architectural solutions to cache inefficiency. In particular, there are great potential benefits in treating different data types distinctly. Write-only values, like video output data, are clearly a waste of cache space. While block and state data account for most of the memory requests their relatively small size means that larger data types, like reference data, systematically and relentlessly eject them from the cache. Preventing blatant cache pollution and the predation of small data types with high re-use can yield considerable cache-memory traffic savings. Therefore, we are investigating the following traffic-reduction techniques.

- *Selective Caching.* Exclude specific data from the cache.
- *Line Locking.* Reserve selected cache lines for particular data objects; lines are untouched by cache replacement while locked.
- *Locality Hints.* Flag data with poor temporal locality to guide cache replacement policies.
- *Scratch Memory.* Implement a small portion of addressable system memory on the processor – not as cache – for storage of small, frequently-used data.

As an example, consider selective caching, its rationale and implementation. Data objects with no possibility of re-use, like video output data, steal cache space from other data. Bypassing the cache entirely in favor of direct storage to main memory promises more efficient use. The UltraSPARC has block load and store instructions, which move groups of data directly between registers and main memory. The PowerPC architecture provides for marking areas of memory (i.e. pages) as non-cacheable. Once marked, data is transparently and automatically transferred between registers and memory buffers; the block load/store approach requires more explicit programming effort.

Preliminary results from simulation are promising. Excluding video output data alone from the cache reduces cache-memory traffic by up to 50%. Across the configurations considered, not caching video output yields a 25% reduction on average. Improvements in cache-memory traffic are global, yet the shape of the curve is not substantially modified. The plateau out to 512 Kbytes persists, as does the swift drop down at 2 Mbytes. Excluding output data is even more helpful for miss rates, which drop by a maximum of 85% from earlier levels, and 60% on average.

6 CONCLUSIONS

This paper has explained the memory traffic and data cache behavior of MPEG-2 decoding on a general-purpose computer. We have shown that even simple caches play a key role in reducing the required memory bandwidth. However, manipulating conventional cache parameters like cache size, associativity, and line size has a limited potential to reduce cache-memory traffic. Increasing cache size is ineffectual until the 1 Mbyte threshold, and even extremely large caches still generate double the absolute minimum required traffic. Enhanced set associativity becomes increasingly cost-ineffective above 4-way implementations, and deviating from a 32-byte line size leads to either increased traffic or miss rates. However, when driven by an understanding of decoder behavior, even relatively simple architectural enhancements, like selective caching, can dramatically improve cache efficiency. We anticipate that further refinement of this knowledge will lead to original and cost-effective ways of improving the decoding performance of general purpose microprocessors, and accelerate the deployment of digital video platforms and applications.

The examination is being carried out on the **following application documents**:

Description, Pages
1-33 as originally filed
Claims, Numbers
1-17 as originally filed
Drawings, Sheets
1/4-4/4 as originally filed

1. Reference is made to the following document; the numbering will be adhered to in the rest of the procedure:

   D1: ELLOUMI O ET AL: "Issues in multimedia scaling: the MPEG video streams case" EMERGING TECHNOLOGIES AND APPLICATIONS IN COMMUNICATIONS, 1996. PROCEE DINGS., FIRST ANNUAL CONFERENCE ON PORTLAND, OR, USA 7-10 MAY 1996, LOS ALAMITOS, CA, USA,IEEE COMPUT. SOC, US, 7 May 1996 (1996-05-07), pages 46-49, XP010164870 ISBN: 978-0-8186-7585-0

2. The present application is a divisional application of EP03700321 (from here on called the parent). In accordance with Article 76(1) EPC, the subject matter of a divisional application may not extend beyond the content of the parent application as filed. The present application adds subject-matter which goes beyond the parent application as filed, the reasons being as follows:

   The claims and the description of the parent application are directed to scalable coding of a video sequence, the video sequence being formed of a number of sub-sequences. Furthermore, the following feature is described as essential in the parent application: inserting information into the bitstream describing the interdependencies of the sub-sequences, i.e. information pertaining to which sub-sequence each subsequence has been predicted from (see. para. [0017] and [0033]).

   Present claim 1 relates to a method of encoding a video sequence, including encoding an indication of at least one image frame which is the first image frame, in decoding order, of an independent sequence. There is no mention of scalable coding or information describing the dependencies among different sub-

sequences. The same holds for claims 5, 9, 10, 13, 14 and 16.

The examiner finds no basis for this generalisation in the parent application as filed, whether in the claims or in the description. Features which were described as essential in the parent are not present in the divisional. Thus, subject-matter has been added with respect to the parent, contrary to Article 76(1) EPC.

3. In view of the above objections it is not at present practicable to carry out a full examination of the subject-matter of the claims. The applicant is therefore requested to file amended claims on which the further prosecution of the application is to be based. The applicant should indicate the passages of the parent application as filed on which the new claims are based.

4. It is also worth mentioning that claim 1 is not new (Article 52(1) and 54(1) and (2) EPC) with respect to an MPEG coded stream. An MPEG stream consists of a number of independent sequences called GOPs which start with an intra-frame (I) followed by a number of predicted frames (P) (see D1, para. 2). In the bitstream, there is an indication of the frame type (I or P) which, in the case of an I frame, identifies the start of an independent sequence. The same reasoning applies for claims 5, 9, 10, 13, 14 and 16, which are therefore not new either (Article 52(1) and 54(1) and (2) EPC).

The examination is being carried out on the **following application documents**:

Description, Pages
1-33 as originally filed
Claims, Numbers
1-31 as originally filed
Drawings, Sheets
1/4-4/4 as originally filed

1. Reference is made to the following document; the numbering will be adhered to in the rest of the procedure:

   D1: SODERQUIST P ET AL: "Memory traffic and data cache behavior of an MPEG-2 software decoder" COMPUTER DESIGN: VLSI IN COMPUTERS AND PROCESSORS, 1997. ICCD '97. PRO CEEDINGS., 1997 IEEE INTERNATIONAL CONFERENCE ON AUSTIN, TX, USA 12-15 OCT. 1997, LOS ALAMITOS, CA, USA,IEEE COMPUT. SOC, US, 12 October 1997 (1997-10-12), pages 417-422, XP010251768 ISBN: 978-0-8186-8206-3

2. The present application has six independent claims. Under Rule 43(2) EPC, an application may not contain more than one independent claim in a particular category unless the subject-matter claimed falls within one or more of the exceptional situations set out in sub-paragraph (a), (b) or (c).

   None of the exceptions apply in the present case. Although separate claims to an encoder and the corresponding decoder is allowed (Rule 43(2)(a) EPC), encoder claim 26 does not mirror the features of decoder claim 10. The same holds for device claim 28 and signal claim 30. The scope the independent claims varies slightly but there is a significant degree of overlap, which makes the claims as a whole unclear (Article 84 EPC). It is not even apparent that the claims are unified by a single general inventive concept.

3. The present application is a divisional application of EP03700321 (from here on called the parent). In accordance with Article 76(1) EPC, the subject matter of a divisional application may not extend beyond the content of the parent application as filed. The present application adds subject-matter which goes beyond the parent application as filed, the reasons being as follows:

The claims and the description of the parent application are directed to scalable coding of a video sequence, the video sequence being formed of a number of sub-sequences. Furthermore, the following feature is described as essential in the parent application: inserting information into the bitstream describing the interdependencies of the sub-sequences, i.e. information pertaining to which sub-sequence each subsequence has been predicted from (see. para. [0017] and [0033]).

Present claim 1 relates to the decoding of a video sequence where there is a discontinuity of numbering of the frames. There is no mention of sub-sequences and their relationship relative each other. Claim 1 is not even limited to predictive coding, let a lone scalable coding.

In Claims 26 and 28, the discontinuity is defined as frames being excluded from the video sequence. There is no mention of dependent sub-sequences or scalable coding.

The examiner finds no basis for this generalisation in the parent application as filed, whether in the claims or in the description. Features which were described as essential in the parent are not present in the divisional. Thus, subject-matter has been added with respect to the parent, contrary to Article 76(1) EPC.

4. In view of the above objections it is not at present practicable to carry out a full examination of the subject-matter of the claims. The applicant is therefore requested to file amended claims on which the further prosecution of the application is to be based. The applicant should indicate the passages of the parent application as filed on which the new claims are based.

5. It is also worth mentioning that claim 1 is not new (Article 54(1) and (2) EPC) with respect to standard MPEG decoding. The discontinuity in claim 1 covers B-frame decoding where the frames are processed in a non-temporal order (see e.g. D1, fig. 2 and the associated text). The requirements of Article 52(1) EPC are, therefore, not met.

(54) MOVING IMAGE ESTIMATING SYSTEM

(57) To achieve an encoding system including a highly efficient prediction performed in response to the content of a scene, a significance, and a motion characteristic of a moving picture and the like, memories a, b, c, motion compensator 5 responsive to an arbitrary transform parameter representing the motion of a prediction picture segment for generating a predicted picture by using arbitrary data stored in the memories a, b, c based upon the transform parameter, and memory update unit 15 for allowing the content of one or more of the memories to be updated at an arbitrary period of time, are provided.

Fig.1

EP 0 898 427 A1

Description

Technical Field

[0001] The present invention relates to the prediction of a moving picture implemented, for example, in

a moving picture encoder/decoder used in a portable/stationary video communication device and the like for visual communications in a video telephone system, a video conference system or the like,
a moving picture encoder/decoder used in a picture storage/recording apparatus such as a digital VTR and a video server, and
a moving picture encoding/decoding program implemented in the form of a single software or a firmware as a Digital Signal Processor (DSP).

Background Art

[0002] MPEG-4 (Moving Picture Experts Group Phase-4) Video Encoding/Decoding Verification Model (hereinafter referred to by the initials VM) whose standardization is in progress by ISO/IEC JTC1/SC29/WG11 may be introduced as a conventional type of predictive encoding/decoding in an encoding/decoding system of moving pictures. The VM continues to revise its contents according to the progress being made in standardization of MPEG-4. Here, Version 5.0 of the VM is designated to represent the VM and will be simply referred to as VM hereinafter.

[0003] The VM is a system for encoding/decoding each video object as one unit in view of a moving picture sequence being an aggregate of video objects changing their shapes time-/space-wise arbitrarily. Fig. 29 shows a VM video data structure. According to the VM, a time-based moving picture object is called a Video Object (VO), and picture data representing each time instance of the VO, as an encoding unit, is called a Video Object Plane (VOP). If the VO is layered in time/space, a special unit called a Video Object Layer (VOL) is provided between the VO and the VOP for representing a layered VO structure. Each VOP includes shape information and texture information to be separated. If the moving picture sequence includes a single VO, then the VOP is equated to a frame. There is no shape information included, in this case, and the texture information alone is then to be encoded/decoded.

[0004] The VOP includes alpha data representing the shape information and texture data representing the texture information, as illustrated in Fig. 30. Each data are defined as an aggregate of blocks (alphablocks/macroblocks), and each block in the aggregate is composed of 16x16 samples. Each alphablock sample is represented in eight bits. A macroblock includes accompanied chrominance signals being associated with 16x16 sample luminance signals. VOP data are obtained from a moving picture sequence externally processed outside of an encoder.

[0005] Fig. 31 is a diagram showing the configuration of a VOP encoder according to the VM encoding system. The diagram includes original VOP data P1 to be inputted, an alphablock P2 representing the shape information of the VOP, a switch P3a for passing the shape information, if there is any, of the inputted original VOP data, a shape encoder P4 for compressing and encoding the alphablock, compressed alphablock data P5, a locally decoded alphablock P6, texture data (a macroblock) P7, a motion detector P8, a motion parameter P9, a motion compensator P10, a predicted picture candidate P11, a prediction mode selector P12, a prediction mode P13, a predicted picture P14, a prediction error signal P15, a texture encoder P16, texture encoding information P17, a locally decoded prediction error signal P18, a locally decoded macroblock P19, a sprite memory update unit P20, a VOP memory P21, a sprite memory P22, a variable-length encoder/multiplexer P23, a buffer P24, and an encoded bitstream P25.

[0006] Fig. 32 shows a flowchart outlining an operation of the encoder.

[0007] Referring to the encoder of Fig. 31, the original VOP data P1 are decomposed into the alphablocks P2 and the macroblocks P7 (Steps PS2 and PS3). The alphablocks P2 and the macroblocks P7 are transferred to the shape encoder P4 and the motion detector P8, respectively. The shape encoder P4 is a processing block for data compression of the alphablock P2 (step PS4), the process of which is not discussed here further in detail because the compression method of shape information is not particularly relevant to the present invention.

[0008] The shape encoder P4 outputs the compressed alphablock data P5 which is transferred to the variable-length encoder/multiplexer P23, and the locally decoded alpha data P6 which is transferred sequentially to the motion detector P8, the motion compensator P10, the prediction mode selector P12, and the texture encoder P16.

[0009] The motion detector P8, upon reception of the macroblock P7, detects a local-motion vector on a macroblock basis using reference picture data stored in the VOP memory P21 and the locally decoded alphablock P6 (step PS5). Here, the motion vector is one example of a motion parameter. The VOP memory P21 stores the locally decoded picture of a previously encoded VOP. The content of the VOP memory P21 is sequentially updated with the locally decoded picture of a macroblock whenever the macroblock is encoded. In addition, the motion detector P8 detects a global warping parameter, upon reception of the full texture data of the original VOP, by using reference picture data stored in the sprite memory P22 and locally decoded alpha data. The sprite memory P22 will be discussed later in detail.

[0010] The motion compensator P10 generates the predicted picture candidate P11 by using the motion

parameter P9, which is detected in the motion detector P8, and the locally decoded alphablock P6 (step PS6). Then, the prediction mode selector P12 determines the final of the predicted picture P14 and corresponding prediction mode P13 of the macroblock by using a prediction error signal power and an original signal power (step PS7). In addition, the prediction mode selector P12 judges the coding type of the data either intra-frame coding or inter-frame coding.

[0011] The texture encoder P16 processes the prediction error signal P15 or the original macroblock through Discrete Cosine Transformation (DCT) and quantization to obtain a quantized DCT coefficient based upon the prediction mode P13. An obtained quantized DCT coefficient is transferred, directly or after prediction, to the variable-length encoder/multiplexer P23 to be encoded (steps PS8 and PS9). The variable-length encoder/multiplexer P23 converts the received data into a bitstream and multiplexes the data based upon predetermined syntaxes and variable-length codes (step PS10). The quantized DCT coefficient is subject to dequantization and inverse DCT to obtain the locally decoded prediction error signal P18, which is added to the predicted picture P14, and the locally decoded macroblock P19 (step PS11) is obtained. The locally decoded macroblock P19 is written into the VOP memory P21 and the sprite memory P22 to be used for a later VOP prediction (step PS12).

[0012] Dominant portions of prediction including a prediction method, a motion compensation, and the update control of the sprite memory P22 and the VOP memory P21 will be discussed below in detail.

(1) Prediction method in the VM

[0013] Normally, four different types of VOP encoding shown in Fig. 33 are processed in the VM. Each encoding type is associated with a prediction type or method marked by a circle on a macroblock basis. With an I-VOP, intra-frame coding is used singly involving no prediction. With a P-VOP, past VOP data can be used for prediction. With a B-VOP, both past and future VOP data can be used for prediction.

[0014] All the aforementioned prediction types are motion vector based. On the other hand, with a Sprite-VOP, a sprite memory can be used for prediction. The sprite is a picture space generated through a step-by-step mixing process of VOPs based upon a warping parameter set

$$\vec{a}=(a, b, c, d, e, f, g, h)$$

detected on a VOP basis (The mark $\rightarrow$ denotes a vector hereinafter). The warping parameter set is determined by the following parametric equations.

$$x'=(ax+by+c)/(gx+hy+1)$$

$$y'=(dx+ey+f)/(gx+hy+1)$$

The sprite is stored in the sprite memory P22.

[0015] Referring to the parametric equations, (x, y) represents the pixel position of an original VOP in a two-dimensional coordinate system. (x', y') represents a pixel position in the sprite memory corresponding to (x, y,) based upon a warping parameter. With the Sprite-VOP, the warping parameter set can be used uniformly with each macroblock to determine (x', y') in the sprite memory for prediction to generate a predicted picture. In a strict sense, the sprite includes "Dynamic Sprite" used for prediction and "Statistic Sprite" used for prediction as well as for another purpose of an approximate representation of VOP at a decoding station. In Figs. 34 through 37 below, "sprite" stands for Dynamic Sprite.

[0016] The motion detector P8 detects the motion vector and the warping parameter to be used for the aforementioned prediction types. The motion vectors and the warping parameters are generically called the motion parameter P9 hereinafter.

(2) Motion compensation

[0017] Fig. 34 is a diagram showing the configuration of the motion compensator P10 in detail. In the figure, a warping parameter P26, a motion vector P27, a global-motion compensator P28, a local-motion compensator P29, a warping-parameter based predicted picture candidate P30, and a motion-vector based predicted picture candidate P31 are shown. The warping-parameter and motion-vector based predicted picture candidates 30, 31 are generically called the predicted picture candidates P11 hereinafter.

[0018] Fig. 35 shows a flowchart outlining the operation of the motion compensator P10 including steps PS14 through PS21.

[0019] The motion compensator P10 generates the predicted picture candidate P11 using the warping parameter P26 of a full VOP detected on a macroblock P7 basis in the motion detector P8 or a macroblock based motion vector P27. The global-motion compensator P28 performs a motion compensation using the warping parameter P26, and the local-motion compensator P29 performs a motion compensation using the motion vector P27.

[0020] With the I-VOP, the motion compensator P10 does not operate. (The operating step proceeds to step PS21 from step PS14.) With a VOP other than the I-VOP, the local-motion compensator P29 reads out a predicted picture candidate PR1 from the locally decoded picture of a past VOP stored in the VOP memory P21 by using the motion vector P27 (step PS15). With the P-VOP, the predicted picture candidate PR1 is only available to be used.

[0021] When the B-VOP is identified in step PS16, the local-motion compensator P29 further reads out a predicted picture candidate PR2 from the locally decoded

picture of a future VOP stored in the VOP memory P21 by using the motion vector P27 (step PS17). In addition, an arithmetic mean of the predicted picture candidates PR1, PR2 obtained from the past and future VOP locally decoded pictures to obtain a predicted picture candidate PR3 (step PS18).

[0022] A predicted picture candidate PR4 is generated also through Direct Prediction (step PS19). (Direct Prediction is based upon a prediction method corresponding to B-Frame in an encoding method H.263, Recommendation ITU-T. A vector for B-Frame is produced based upon a group of P-VOP vectors, which is not discussed further here in detail.) In Fig. 34, the motion-vector based predicted picture candidates P31 is a generic term for all or part of the predicted picture candidates PR1 through PR4.

[0023] If a VOP is of neither I-VOP nor B-VOP, then the VOP is of Sprite-VOP. With the Sprite-VOP, the predicted picture candidate PR1 is read out from the VOP memory based upon the motion vector. In addition, the global-motion compensator P28 reads out the predicted picture candidate P30 from the sprite memory P22 based upon the warping parameter P26 in step PS20.

[0024] The global-motion compensator P28 calculates the address of a predicted picture candidate in the sprite memory P22 based upon the warping parameter P26, and reads out the predicted picture candidate P30 from the sprite memory P22 to be outputted based upon a resultant address. The local-motion compensator P29 calculates the address of a predicted picture candidate in the VOP memory P21 based upon the motion vector P27 and reads out the predicted picture candidate P31 to be outputted based upon a resultant address.

[0025] These predicted picture candidates P11 are evaluated along with an intra-frame coding signal of the texture data P7 in the prediction mode selector P12, which selects a predicted picture candidate having the least power of a prediction error signal along with a prediction mode.

(3) Updating of memories

[0026] The memory update unit P20 controls the VOP memory P21 and sprite memory P22 to be updated (step PS12). The contents of these memories are updated regardless of the prediction mode P13 selected on a macroblock basis.

[0027] Fig. 36 is a diagram showing the configuration of the memory update unit P20. Fig. 37 shows a flowchart including steps PS22 through PS28 illustrating the operation of the memory update unit P20.

[0028] In Fig. 36, an externally supplied VOP encoding type P32, an externally supplied sprite prediction identification flag P33 for indicating the use of the sprite memory for prediction, an externally supplied blend factor P34 used for prediction with the sprite memory, switches P35, P36, a sprite blender P37, a sprite transformer P38, a VOP memory update signal P39, and a sprite update signal P40 are shown.

[0029] Firstly, the use of the sprite with the current VO or VOL is examined if being designated by the sprite prediction identification flag P33 (step PS22). With no use of the sprite designated, the data are examined if being the B-VOP (step PS27). With the B-VOP, then no updating is performed with the VOP memory P21. With either the I-VOP or the P-VOP, then the VOP memory P21 is written over with the locally decoded macroblock P19 on a macroblock basis (step PS28).

[0030] With the use of the sprite designated in step PS22, then the VOP memory P21 is updated in the same manner as above (steps PS23, PS24), and in addition, the sprite memory PS22 is updated through the following procedure.

a) Sprite warping (step PS25)

[0031] In the sprite transformer P38, an area

$$M(\vec{R},t-1)$$

in the sprite memory P22 ($M(\vec{R},t-1)$ is an area having the same size as that of a VOP having the origin of the coordinates at a position in the sprite memory P22 with the VOP at a time t) is subject to warping (transformation) based upon a warping parameter

$$\vec{\alpha}=(a,b,c,d,e,f,g,h).$$

b) Sprite blending (step PS26)

[0032] By using a resultant warped picture from a) above, a new sprite memory area is calculated in the sprite blender P37 according to the following expression,

$$M(\vec{R},t)=(1-\alpha)\cdot W_b[M(\vec{R},t-1),\vec{\alpha}]+\alpha\cdot VO(\vec{r},t),$$

where α is the blend factor P34, $W_b[M,\vec{\alpha}]$ is the resultant warped picture, and $VO(\vec{r},t)$ is a pixel value of a locally decoded VOP with a location $\vec{r}$ and a time t.

[0033] With a non-VOP area in a locally decoded macroblock, it is assumed that

$$VO(\vec{r},t)=0.$$

As the blend factor α is assigned on a VOP basis, a locally decoded VOP is collectively blended into the sprite memory P22 based upon a weight α, regardless of the contents of a VOP area.

[0034] According to the aforementioned prediction system in the conventional encoding system, the video object is predicted by using the memory designed to be used for detecting the motion vector alone and the memory designed to be used for detecting the warping parameter alone, both of which are structurally allowed the maximum use of a single screen alone each. Thus,

the limited use of reference pictures is only available for prediction, thereby hindering a sufficient improvement in prediction efficiency.

[0035] Further, in such a system where two or more video objects are encoded concurrently, these memories only include a reference picture representing the past record of a video object to be predicted alone, which limits the variation of a reference picture and precludes the utilization of a correlation among video objects for prediction.

[0036] Further, the memories are updated regardless of such items as the internal structure, a characteristic, and the past record of the video object. This results in the insufficient storage of information lacking significant data for predicting a video object, thereby posing a problem of failing to enhance prediction efficiency.

[0037] The present invention is directed to solving the aforementioned problems. An objective of this invention is to provide the prediction system for encoding/decoding of picture data where two or more memories are provided to store the past record of the moving picture sequence effectively in consideration of the internal structure and characteristic of the moving picture sequence, thereby achieving a highly efficient prediction as well as encoding/decoding. In addition, the prediction system provides a sophisticated inter-video object prediction performing among two or more video objects.

Disclosure of the Invention

[0038] According to the present invention, a moving picture prediction system, for predicting a moving picture to be implemented in at least one of an encoder and a decoder, includes a plurality of memories for storing picture data for reference to be used for prediction, the plurality of memories being corresponding to different transform methods, respectively, and a prediction picture generation section for receiving a parameter representing a motion of a picture segment to be predicted, and for generating a predicted picture using the picture data stored in one of the plurality of memories used for the picture segment to be predicted based upon the parameter and one of the transform methods corresponding to the one of the plurality of memories.

[0039] The encoder generates a prediction memory indication information signal indicating the one of the plurality of memories used for generating the predicted picture and transmits the prediction memory indication information signal and the parameter to a decoding station so as to generate the predicted picture using the picture data stored in the one of the plurality of memories based upon the one of the transform methods corresponding to the one of the plurality of memories in the decoding station.

[0040] The decoder receives the parameter and a prediction memory indication information sinal indicating the one of the plurality of memories used for generating the predicted picture from an encoding station, wherein the prediction picture generation section generates the predicted picture using the picture data stored in the one of the plurality of memories based upon the parameter and the one of the transform methods corresponding to the one of the plurality of memories.

[0041] Further, according to the present invention, a moving picture prediction system, for predicting a moving picture to be implemented in at least one of an encoding and a decoding, includes a plurality of memories for storing picture data for reference to be used for prediction, the plurality of memories being assigned to different parameter effective value ranges, respectively, and a prediction picture generation section for receiving a parameter representing a motion of a picture segment to be predicted, for selecting one of the plurality of memories assigned to one of the parameter effective value ranges including a value of the parameter, and for generating a predicted picture using the picture data stored in a selected memory.

[0042] Still further, according to the present invention, a moving picture prediction system, for predicting a moving picture to be implemented in at least one of an encoding and a decoding, includes a plurality of memories for storing picture data for reference to be used for prediction and a prediction picture generation section including a motion compensator for receiving a parameter representing a motion of a picture segment to be predicted, and for generating a predicted picture by using the picture data stored in the plurality of memories based upon the parameter, and a memory update unit for updating the picture data stored in at least one of the plurality of memories at an arbitrary timing.

[0043] The moving picture prediction system predicts the moving picture in a moving picture sequence having first and second video objects, wherein the plurality of memories includes separate first and second pluralities of memories corresponding to the first and second video objects, respectively, and the prediction picture generation section includes separate first and second generators, respectively, corresponding to the first and second video objects, wherein the first generator uses the picture data stored in at least one of the first and second pluralities of memories to generate the predicted picture when predicting the first object, and generates information indicating a use of the second plurality of memories for predicting the first object, the information being added to the predicted picture.

[0044] The prediction picture generation section generates the predicted picture through a change of either one of a number and a size of the plurality of memories in response to a change in the moving picture at each time instance.

[0045] The prediction picture generation section generates the predicted picture in a limited use of memories for prediction in response to a change in the moving picture at each time instance.

[0046] The prediction picture generation section generates the predicted picture by calculating a plurality of

the predicted pictures generated by using the respective picture data stored in the plurality of memories.

[0047] The moving picture prediction system further includes a significance detector for detecting a feature parameter representing a significance of the picture segment to be predicted, wherein the prediction picture generation section generates the predicted picture by selecting at least one of choices of at least one of a plurality of prediction methods, the plurality of memories, and a plurality of memory update methods.

[0048] The moving picture prediction system further includes a significance detector for detecting a parameter representing at least one of an amount of bits available for coding the picture segment to be predicted, an amount of change of the picture segment at each time instance, and a significance of the picture segment, wherein the prediction picture generation section generates the predicted picture by selecting at least one of choices of at least one of a plurality of prediction methods, the plurality of memories, a plurality of memory update methods.

[0049] The moving picture prediction system predicts the moving picture on a video object basis, wherein the moving picture prediction system further includes a significance detector for detecting a parameter representing at least one of an amount of bits available for coding a video object to be predicted, an amount of change in the video object at each time instance, and a significance of the video object, wherein the prediction picture generation section generates the predicted picture by selecting at least one of choices of at least one of a plurality of prediction methods, the plurality of memories, and a plurality of memory update methods.

[0050] The moving picture prediction system further includes a prediction information encoder for encoding prediction relating information of the moving picture, wherein the prediction picture generation section counts times of a memory used for prediction and determines a rank of the plurality of memories based upon a counted number of the times, wherein the prediction information encoder allocates a code length to the prediction relating information to be encoded based upon the rank of a memory used for prediction.

[0051] The plurality of memories includes at least a frame memory for storing the picture data on a frame basis and a sprite memory for storing a sprite picture.

[0052] The sprite memory includes at least one of a dynamic sprite memory involving a regular updating, and a static sprite memory not involving the regular updating.

[0053] The one of the transform methods corresponding to the one of the plurality of memories is at least one of a parallel translation, an affine transformation, and a perspective transformation in an interchangeable manner.

[0054] Still further, according to the present invention, a method for predicting a moving picture to be implemented in at least one of an encoding or a decoding, includes the steps of storing picture data for reference to be used for prediction in a plurality of memories, corresponding different transform methods with the plurality of memories, respectively, receiving a parameter representing a motion of a picture segment to be predicted, and generating a predicted picture using the picture data stored in one of the plurality of memories used for predicting the picture segment based upon the parameter and one of the transform methods being corresponding to the one of the plurality of memories.

[0055] The method for predicting a moving picture further includes the steps of generating a prediction memory indication information signal indicating the one of the plurality of memories used for the picture segment to be predicted, and transmitting the prediction memory indication information signal and the parameter to a decoding station.

[0056] The method for predicting a moving picture is implemented in the decoding, and further includes the step of receiving a prediction memory indication information signal indicating the one of the plurality of memories used for generating the predicted picture and the parameter representing a motion of the picture segment to be predicted from an encoding station.

[0057] Still further, according to the present invention, a method, for predicting a moving picture to be implemented in at least one of an encoding and a decoding, includes the steps of storing picture data for reference to be used for prediction in a plurality of memories, assigning separate parameter effective value ranges to the plurality of memories, respectively, receiving a parameter representing a motion of a picture segment to be predicted, selecting one of the plurality of memories assigned to one of the parameter effective value ranges including a value of the parameter, and generating a predicted picture using the picture data stored in a selected memory.

[0058] Still further, according to the present invention, a method, for predicting a moving picture to be implemented in at least one of an encoding and a decoding, includes the steps of storing picture data for reference to be used for prediction in a plurality of memories, receiving a parameter representing a motion of a picture segment to be predicted, generating a predicted picture using the picture data stored in the plurality of memories based upon the parameter, and updating the picture data stored in at least one of the plurality of memories at an arbitrary timing.

Best mode for carrying out the invention

Embodiment 1.

[0060] Fig. 1 is a block diagram showing the configuration of an encoder according to a first embodiment and the following embodiments. The diagram illustrates an input moving picture signal 1, texture data 2, a motion detector 3, a motion parameter 4, a motion compensator 5, a predicted picture candidate 6, a prediction mode selector 7, a prediction mode 8, a predicted picture 9, a prediction error picture 10, a texture encoder 11, a quantized DCT coefficient 12, a locally decoded prediction error picture 13, a locally decoded picture 14, a memory update unit 15, a memory-a 16, a memory-b 17, a memory-c 18, a variable-length encoder/multiplexer 19, a transmission buffer 20, a bitstream 21, a scene-change detector 80, and a timer 81. Particularly, the motion compensator 5 and the memory update unit 15 forms a predicted picture generation section 100 which implemented a prediction system. Memories a, b, c forms a memory area 200. In the figure, portions not mentioned in this embodiment will be discussed in the

following embodiments. Fig. 2 shows a flowchart illustrating an operating flow of the encoder.

[0061] This embodiment is based upon the assumption that a plural number, e.g. three, of memories, are used adaptively according to the significance of an input moving picture based upon such characteristics of motion as an amount of motion and an intensity of color. It is also assumed that the content of an arbitrary memory (area), the memory-a for example, are updated at an arbitrary period of time and a moving picture sequence is received on a frame basis.

(1) Input signal

[0062] As aforementioned, the encoder inputs a frame representing a picture at each time instance of the moving picture sequence and decomposes the frame into the encoding units of macroblocks which are one example of picture segments subject to prediction (step S1).

(2) Adaptive use of memories

[0063] The memories store previously decoded pictures or previously provided fixed pictures. In this embodiment, the three memories are used adaptively according to the significance of a picture segment in a frame as follows.

[0064] The memory-a stores a least significant picture segment (i.e., a background-like picture segment whose motion is static or flat and the texture is flat.)

[0065] The memory-b stores a less significant picture segment (i.e., a picture segment of an object whose motion is relatively small.)

[0066] The memory-c stores a most significant picture segment (i.e., a picture segment of an object whose motion is complicated or drastic.)

[0067] The least significant picture segment to be stored in the memory-a may be a background picture segment in a video conference scene or the like. The least significant picture segment also corresponds to a background segment in a camera-work relating flat motion scene of a full screen including slightly moving objects. With this type of motion, it is efficient to obtain a frame based amount of a motion to substitute for a macroblock based motion, rather than to obtain a macroblock based amount of a motion. Specifically, a transform parameter corresponding to the sprite warping parameter discussed in the conventional art is obtained and the transform parameter of a full frame is then used as the motion parameter of a macroblock in the frame. The motion parameter may be selected from among a simple parallel translation parameter (=a motion vector), an affine motion parameter involving transformation, and a perspective motion parameter involving transformation. Here, a motion vector is one example of the motion parameter.

[0068] The less significant picture segment to be stored in the memory-b may be a picture segment of a moving figure who is not a speaker in a video conference scene or the like. This segment type of the object may be considered less attracting in the scene. The most significant picture segment to be stored in the memory-c may be a segment of an object attracting most attention in the video conference scene such as a speaker.

[0069] A picture segment stored in the memory-b or the memory-c representing a unique type of motion of an object should have a macroblock based unique motion parameter. The motion parameter of this case may be selected from among the simple parallel translation parameter (=a motion vector), the affine motion parameter involving transformation, the perspective motion parameter involving transformation, etc.

(3) Motion detection (step S2)

[0070] The motion detector 3 of this embodiment is designed to detect an arbitrary transform parameter of the respective three memories on a macroblock basis, involving no distinction between a motion vector and a warping parameter in the conventional art. The motion detector 3 is provided with additional functions of a global-motion parameter detection for detecting a frame based transform parameter using the memory-a and a local-motion parameter detection for detecting a macroblock based transform parameter using the memories a through c.

(4) Motion compensation (step S3)

[0071] Fig. 3 shows the configuration of the motion compensator 5 of this embodiment in detail. In the figure, a prediction picture memory address calculator 22, a prediction picture memory address 23, a memory reader 24, and a reference memory indicator signal 25 which is supplied externally are shown. In this embodiment, the reference memory indicator signal 25 indicates the use of the memory a, b, c. Fig. 4 shows a flowchart including steps S11 through S16 illustrating an operation of the motion compensator 5.

[0072] Initially, with an I(Intra)-frame, no motion compensation is performed (step S11). With a frame other than the I-frame, predicted picture candidates are generated based upon the global-motion and local-motion parameters corresponding to the respective memories detected in the motion detector 3 (steps S12 through S15). Specifically, the prediction picture memory address calculator 22 calculates the prediction picture memory address 23 of a predicted picture candidate in a memory identified by the reference memory indicator signal 25 based upon the motion parameter 4. Upon reception of the prediction picture memory address 23, the memory reader 24 reads out the predicted picture candidate 6 from a corresponding memory to be outputted.

[0073] In this embodiment, the global-motion and

local-motion parameters are obtained through the same transform method, thereby allowing the motion compensator 5 of Fig. 3 to be shared by both global-motion and local-motion parameter based approaches of generating a predicted picture. When generating the predicted picture candidate 6 through the global-motion parameter, the memory-a is always used as a reference memory (step S15).

(5) Prediction mode selection (step S4)

[0074] The prediction mode of this embodiment is assumed to include the following.

(a) a mode for using the memory-a,
(b) a mode for using the memory-b,
(c) a mode for using the memory-c, and
(d) a mode for using an intra-frame coding signal.

Similarly to the discussion in the conventional art, the prediction mode selector 7 selects the predicted picture candidate 6 having the least power (amplitude) of a prediction error signal, for example, from among all the predicted picture candidates 6 generated in the motion compensator 5 along with an intra-frame coding signal, and outputs a selected one of the predicted picture candidates 6 as the predicted picture 9 and an corresponding one of the prediction mode 8. The prediction mode 8 includes memory selection information indicating a memory used for predicting the selected predicted picture 9. The prediction mode 8 is transferred to the variable-length encoder/multiplexer 19 to be encoded with an allocated length of code in the bitstream 21 as prediction memory indication information 800.

(6) Memory updating

[0075] The memory update unit 15 controls the memories to be updated. Fig. 5 shows the configuration of the memory update unit 15 of this embodiment in detail. In the figure, an activity 26 used for updating the memory-a (which will be discussed later), a memory-a update judger 27, a reference memory selector 28, switches 29, 30, picture data 31 for updating the memory-a, picture data 32 for updating the memory-b, picture data 33 for updating the memory-c, and global prediction picture data 34 for updating the memory-a are shown. Fig. 6 shows a flow of a memory updating operation.

[0076] The memory updating operation of this embodiment has the following procedure. Upon reception of the locally decoded picture 14, the memory update unit 15 judges the necessity of updating the memory-a with a frame including the locally decoded picture 14 in the memory-a update judger 27 (step S17). The reference memory selector 28 selects a memory used for predicting the locally decoded picture based upon the prediction mode 8 (steps S18, S19). Then, a reference picture stored in a selected memory is updated with one of the picture data 31, 32, 33 for updating the memory-a, the memory-b, the memory-c, respectively, and the global prediction picture data 34 for updating the memory-a of the locally decoded picture 14 based upon the following rule. A memory is assumed to be updated each frame on a prediction unit (macroblock) basis.

(1) Frame based regular updating of the memory-b and the memory-c (steps S20, S21):

[0077] The locally decoded picture 14 is written into either the memory-b or the memory-c used for predicting the picture.

(2) Frame based adaptive updating of the memory-a (steps S22, S23):

[0078] The locally decoded picture 14 is written into the memory-a used for predicting the picture for an arbitrary frame only or at an arbitrary period of time based upon a memory-a update judgement 1000 obtained in step S17.

[0079] The content of memory-a is the past record of a time-unvarying picture segment such as a background picture. This removes the necessity of the regular updating of the content of memory unless a full-screen involved complicated or drastic movement such as a scene change occurs to cause a drastic change in the content of a picture segment.

[0080] As aforementioned, a frame based regular updating is performed with a complicated or drastic area of an object, whereas a longer-term based updating is performed with the content of the memory-a, thereby achieving an effective prediction with a background picture half visible among moving objects.

[0081] Viewed in this light, the memory-a is updated in an arbitrary period of time in this embodiment. Specifically, possible arbitrary update criteria are as follows.

a. A full-screen content is updated all at once with a global-motion parameter indicating a complicated or drastic motion, whereas no updating operation is performed with the parameter indicating a rather static motion.
b. A full-screen content is updated all at once on a predetermined period basis, regardless of a frame based period of time.
c. A full-screen content is updated all at once only with a frame immediately after a scene change detected.

[0082] In this embodiment, data as the arbitrary update criteria are generically called as the activity 26 used for updating memory-a. Initially, the memory-a update judger 27 judges whether to update the content of memory-a based upon the activity 26 (step S17). Specifically, the activity 26 corresponds to a value of the

global-motion parameter detected in the motion detector 3 with the arbitrary update criterion-a, a time stamp of the current frame from the timer 81 with the arbitrary update criterion-b, and a flag indicating a scene change detection outputted from the scene-change detector 80 with the arbitrary update criterion-c.

[0083] When the content of memory-a is judged to be updated, the content of the locally decoded picture 14 is outputted as the global prediction picture data 34 for updating the content of the memory-a (step S23). When no updating is judged with the content of the memory-a, then no updating is performed with the memory-a.

[0084] The memory-a update judgement 1000 of a frame is multiplexed in the bitstream 21 to be transmitted to a decoding station so that the same updating of the memory-a can be performed with the frame in the decoding station.

[0085] Fig. 20 is a diagram illustrating the bitstream 21 of this embodiment.

[0086] Fig. 20 is a conceptual diagram showing how frame data are encoded in sequence to be transmitted. Each frame data is provided with header information at the front as a frame based additional information. The header information has the memory-a update judgement 1000 multiplexed to be transmitted to a decoding station. The header information is followed by the component macroblock data of the frame. The macroblock data include the prediction memory indication information 800 indicating a memory used for predicting the macroblock data. In a counterpart decoder, a memory for predicting a predicted picture is specified based upon the prediction memory indication information 800 of macroblock data to generate the predicted picture.

[0087] Although not shown in the figures, the memory-b update information or/and the memory-c update information may be transmitted to the decoding station along with, or alternatively to, the memory-a update judgement 1000.

[0088] The aforementioned encoder thus provides the adaptive and efficient use of two or more memories in response to the content of a moving picture sequence, thereby enhancing prediction efficiency. Specifically, a moving picture sequence is predicted based upon an arbitrary transform parameter through an adaptive use of two or more memories in response to the content and characteristic of a moving picture sequence. This enables an efficient prediction of a moving picture in response to a local characteristic of a picture by even covering complicated motion. With the enhanced prediction efficiency, the encoder is allowed to reduce an amount of encoded data without deteriorating encoded picture quality. The same prediction system may be employed by the counterpart decoder for decoding a bitstream encoded through the prediction system of this invention.

[0089] This embodiment has thus disclosed the encoder performing on a frame basis. The same effect may be expected with an alternative encoder performing on an arbitrary shaped video object (VOP) basis.

[0090] Further, this embodiment has thus disclosed the encoder performing on a macroblock basis as the macroblock being a picture segment subjected to prediction. The same effect can be expected with an alternative encoder for encoding a picture on such a picture segment basis as an arbitrary shaped picture segment and a variable shaped block including fixed-size block components.

[0091] Further, this embodiment has thus disclosed the global-motion parameter detection using the memory-a. Alternatively, a single use of the local-motion parameter detection is of course applicable involving no global-motion parameter detection. With no global-motion detection, no necessity occurs for transmitting prediction information indicating a global/local prediction as the prediction mode.

[0092] Further, this embodiment may include a special memory for prediction which stores reference picture data previously generated based upon the content of the moving picture sequence. The special memory is not updated during an encoding operation.

[0093] Further, this embodiment has thus disclosed the case that memories a, b, c store a picture segment each time and the memory update unit 15 updates one of the memories a, b, c each time. If two or all of the memories a, b, c share to store a picture in part or fully, then the memory update unit 15 updates the two or all of the memories a, b, c. In the case of the memory-a being a frame memory for storing a frame of reference picture data, the memory-b being a static sprite memory involving the adaptive updating, and the memory-c being a dynamic sprite memory involving the regular updating, the memory update unit 15 does not update the memory-b as the static sprite memory for storing previously fixed reference picture data but updates the memory-a and the memory-c concurrently when the memories store the same reference picture segment. Thus, if a duplicated storage of the reference picture data occurs with the memories a, b, c, then the memory update unit 15 updates a duplicated segment stored in each memory.

[0094] The aforementioned can also be applied to the following embodiments.

[0095] Further, this embodiment has thus disclosed the use of three memories a, b, c, but alternatively, two of the memories may be utilized.

[0096] Further, a counterpart decoder may be provided with the prediction picture generation section 100 including the same components as the motion compensator 5 and the memory update unit 15 discussed in this embodiment. A motion compensator provided in the decoder, having no necessity of generating all the three predicted picture candidates, generates a single predicted picture alone based upon a decoded motion parameter.

Embodiment 2.

[0097] A second embodiment shows an encoder with a single replacement of the motion compensator 5 of the encoder shown in Fig. 1. The configuration and operation of a motion compensator 5a of the second embodiment are now described.

[0098] Fig. 7 shows the configuration of the motion compensator 5a of this embodiment in detail. The figure includes a reference memory determiner 35. Fig. 8 shows a flowchart illustrating a detailed operation of the motion compensator 5a.

[0099] Initially, with the I-frame, no compensation is performed (step S24). With a frame other than the I-frame, the reference memory determiner 35 determines a reference memory based upon a value of the motion parameter 4 (step S25). The reference memory determiner 35 holds effective motion parameter value ranges (which will be discussed later in detail) allocated, respectively, to the memories a, b, c. The reference memory determiner 35 compares the respective effective motion parameter value ranges with the value of the motion parameter 4 to judge which memory is designated by the motion parameter 4 and outputs a reference memory indicator signal 25a for identifying the respective memories a, b, c.

[0100] The effective motion parameter value ranges are effective search ranges allocated to the respective memories for detecting a motion vector, for example. Specifically, if ±15 pixels are assumed to be given for a total search value range, then the memory-a is chosen to be used for prediction in a range of ±0 to 3 pixels, the memory-b is used in a range of ±4 to 8 pixels, and the memory-c is used in a range of ±9 to 15 pixels, for example. Here, the reference memory determiner 35 operates only when the local-motion parameter is used for prediction, because the memory-a is exclusively used as a reference memory when the predicted picture candidate is generated based upon the global-motion parameter. This motion-vector value based approach of identifying a memory to be used for prediction is based upon the assumption that a background picture should include a static motion and a most attractive picture should include a complicated or drastic motion. This motion-vector value based approach of identifying a memory for prediction involves no necessity of encoding the prediction mode to be transmitted.

[0101] Next, the predicted picture candidate 6 is generated based upon the reference memory indicator signal 25a of a selected memory (steps S26 through S30). Specifically, the prediction picture memory address calculator 22 calculates the prediction picture memory address 23 of the predicted picture candidate 6 in an identified memory by the reference memory indicator signal 25a based upon the motion parameter 4. Based upon the prediction picture memory address 23, the memory reader 24 reads out the predicted picture candidate 6 from the memory to be outputted.

[0102] As the global-motion and local-motion parameters of this embodiment are based upon the same transform method, both parameter based approaches can share the motion compensator 5a of Fig. 7 for generating the predicted picture candidate. When reading out the predicted picture candidate 6 based upon the global-motion parameter (step S31), the memory-a is always used as a reference memory.

[0103] The effective motion parameter value ranges may be fixed on a moving picture sequence basis, and alternatively, changed on a frame basis, for example. With the frame based changes, the effective motion parameter value ranges assigned to the respective memories of the frame are multiplexed in a bitstream to be transmitted to a decoding station to perform the same memory selection.

[0104] Fig. 21 is a diagram showing the bitstream 21 of this embodiment.

[0105] The bitstream is provided with header information added at the front on a moving picture sequence basis. The header information includes effective motion parameter value range indication information of the respective memories. By thus designating the effective motion parameter value range indication information at the front of a moving picture sequence, the moving picture sequence is predicted with the fixed effective motion parameter value ranges in a counterpart decoder.

[0106] When varying the effective motion parameter value ranges each frame, the effective motion parameter indication information is to be included in the header information added on a frame basis.

[0107] Thus, the efficient and adaptive use of the memories in response to the magnitude of a local motion of a frame can be provided by the encoder including the motion compensator 5a, thereby enhancing prediction efficiency.

[0108] This embodiment has thus disclosed the encoder performing on a frame basis. The same effect may be expected with an alternative encoder performing on an arbitrary shaped video object (VOP) basis.

[0109] Further, this embodiment has thus disclosed the encoder performing on a macroblock basis. The same effect may be expected with an alternative encoder for encoding a picture on such a picture segment basis as an arbitrary shaped picture segment and a variable shaped block including fixed-size block components.

[0110] Further, this embodiment has thus disclosed the global-motion parameter detection using the memory-a. Alternatively, a single use of the local-motion parameter detection is of course applicable involving no global-motion parameter detection. No global-motion detection involves no necessity for transmitting information indicating a global/local prediction as the prediction mode.

[0111] Further, a counterpart decoder may be provided with the prediction picture generation section 100

including the same component as the motion compensator 5 discussed in this embodiment. In the decoder, a motion compensator only generates a single predicted picture based upon a decoded motion parameter.

Embodiment 3.

[0112] Another embodiment shows an encoder having a single replacement of the motion compensator 5 of the encoder of Fig. 1. The configuration and operation of a motion compensator 5b are now described. A motion detector 3a employed in this embodiment is assumed to output an amount of the parallel translation, the affine parameter, and the perspective parameter as motion parameters 4a.

[0113] Further, the memory-a of this embodiment is assumed to be a frame memory for storing a reference picture frame, the memory-b is assumed to be a static sprite memory, and the memory-c is assumed to be a dynamic sprite memory.

[0114] Fig. 9 shows the configuration of the motion compensator 5b of this embodiment in detail. In the figure, a parallel translation amount 36 (i.e., a motion vector), an affine parameter 37, a perspective parameter 38, a parallel-translation based prediction picture memory address calculator 39, an affine parameter based prediction picture memory address calculator 40, and a perspective parameter based prediction picture memory address calculator 41 are shown. Fig. 10 is a flowchart illustrating the operation of the motion compensator 5b in detail.

[0115] Initially, with the I-frame, no prediction is performed (step S33). With a frame other than the I-frame, the prediction picture memory address calculators 39 through 41 calculate the respective prediction picture memory addresses 23 based upon the respective values of the motion parameters 4a (step S34).

[0116] The memory address calculators 39, 40, 41 calculate addresses based upon picture transform methods assigned, respectively, to the corresponding memories. In this embodiment, the parallel translation is assigned to the memory-a, the affine parameter involving such a simple transformation as a rotation and an expansion/contraction is assigned to the memory-b, and the perspective parameter involving a three-dimensional complicated motion is assigned to the memory-c. These transform methods may be expressed by the following transform expressions.

[Parallel translation]

[0117] Amount of parallel translation (a, b):

$$x'=x+a$$

$$y'=y+b$$

(Affine transform]

[0118] Affine parameter (a,b,c,θ):

$$x'=a(\cos\theta)x+a(\sin\theta)y+b$$

$$y'=a(-\sin\theta)x+a(\cos\theta)y+c$$

[Perspective transform]

[0119] Perspective parameter (a,b,c,d,e,f):

$$x'=(ax+by+c)/(gx+hy+1)$$

$$y'=(dx+ey+f)/(gx+hy+1)$$

[0120] Here, (x, y) in a two-dimensional coordinate system represents a pixel location of an original macroblock. (x', y') represents a pixel location in a memory corresponding to (x, y,) based upon each of the parameters. That is a location in a memory (x', y') is calculated based upon these parameters. Through this mechanism, a memory most suitable for the characteristic of a motion can be chosen to be used for prediction on a macroblock basis. With calculated prediction picture memory addresses 23 based upon the respective motion parameters 36, 37, 38, the memory reader 24 reads out the predicted picture candidates 6 from corresponding memories to be outputted (steps S35 through S39).

[0121] The transform methods assigned to the respective memories of the frame are multiplexed in the bitstream 21 to be transmitted to a decoding station as a motion detection method indication information so that the same motion compensation can be performed in the decoding station.

[0122] Fig. 22 is a diagram showing the bitstream 21 of this embodiment.

[0123] Header information added at the front of a moving picture sequence includes the motion detection method indication information. In the encoder, the transformation types to be used in the respective memories are interchangeable, and thus the motion detection method indication information indicating a memory-transform method relation is to be transmitted to the counterpart decoder as the header information of the moving picture sequence. Thus, transformation types assigned to be used with the respective memories can be identified in the decoder.

[0124] In the decoder, the identified transformation types are dynamically assigned to the respective memories.

[0125] Thus, the efficient and adaptive use of the memories in response to the characteristic of a local motion of a frame is provided by the encoder including the motion compensator 5b, thereby enhancing prediction efficiency.

[0126] This embodiment has thus disclosed the

encoder performing on a frame basis. The same effect may be expected with an alternative encoder performing on an arbitrary shaped video object (VOP) basis.

[0127] Further, this embodiment has thus disclosed the encoder performing on a macroblock basis. The same effect may be expected with an alternative encoder for encoding a picture on such a picture segment basis as an arbitrary shaped picture segment and a variable shaped block including fixed-size block components.

[0128] Further, this embodiment has thus disclosed the global-motion parameter detection using the memory-a. Alternatively, a single use of the local-motion parameter detection is of course applicable involving no global-motion parameter detection. No global-motion detection involves no necessity of transmitting information of a global/local prediction as the prediction mode.

[0129] Further, this embodiment has thus disclosed the use of the memories a, b, and c. Alternatively, the use of memories a and b alone, memories a and c alone, or memories b and c alone, is also applicable.

[0130] Further, a decoder may be provided with the prediction picture generating section 100 including the same component as the motion compensator 5b discussed in this embodiment. A motion compensator in a decoder only generates a single predicted picture based upon a decoded motion parameter.

Embodiment 4.

[0131] Another embodiment shows an encoder which receives a plural number, two for example, of different video objects, having shape information, intermingled in a moving picture sequence for a collective encoding. Fig. 11 shows the configuration of the encoder of this embodiment.

[0132] In the figure, an input picture frame 42, an object separator 43, object data 44a, 44b, shape blocks 45a, 45b, switches 46a, 46b, shape encoders 47a, 47b, compressed shape block data 48a, 48b, locally decoded shape blocks 49a, 49b, texture data (macroblocks) 50a,50b, motion detectors 51a, 51b, motion parameters 52a, 52b, motion compensators 53a, 53b, predicted picture candidates 54a, 54b, prediction mode selectors 55a, 55b, prediction mode information 56a, 56b, predicted pictures 57a, 57b, prediction error signals 58a, 58b, texture encoders 59a, 59b, compressed texture data 60a, 60b, locally decoded prediction error signals 61a, 61b, locally decoded macroblocks 62a, 62b, a memory update unit 63, memory-a 64, memory-b 65, memory-c 66, memory-d 67, memory-e 68, memory-f 69, variable-length encoders 70a, 70b, a multiplexer 71, a buffer 72, a bitstream 73, a memory section 94, an object-A encoder 88a for encoding an object-A, and an object-B encoder 88b for encoding an object-B are shown. The object encoders 88a, 88b are structurally identical to each other with the identical components.

[0133] This encoder inputs the picture frame 42, which is decomposed into the encoding units of objects in the object separator 43. The object separator 43 is assumed to be assigned a processing method arbitrarily.

[0134] The shape information of an object is transferred to the shape encoder 47a, 47b in a form of the shape block 45a, 45b to be encoded, and then transferred to the variable-length encoder 70a, 70b as the compressed shape block data 48a, 48b.

[0135] The motion detector 51a, 51b detects a motion parameter based upon the locally decoded shape block 49a, 49b in the same manner as that of the VM encoding system. A motion parameter can be detected on a macroblock basis by using all the memories a through f.

[0136] As a rule, however, the memories a through c are designed to be used for an object-A to be encoded in the object-A encoder 88a, and the memories d through f are designed to be used for an object-B to be encoded in the object-B encoder 88b.

[0137] Also, as for a motion type, an arbitrary transform parameter is assumed to be detected on a macroblock basis with all the memories in the memory section 94, involving no distinction between the motion vector and the warping parameter.

[0138] The motion compensator 53a, 53b generates all the predicted picture candidates 54a, 54b based upon the respective motion parameters 52a, 52b. Then, in the prediction mode selector 55a, 55b, the predicted picture 57a, 57b is obtained along with the prediction mode information 56a, 56b. The predicted picture 57a, 57b is then differentiated from an original signal or the texture data 50a, 50b to obtain the prediction error signal 58a, 58b, which is encoded in the texture encoder 59a, 59b to be transmitted to the variable-length encoder 70a, 70b. The locally decoded prediction error signal 61a, 61b is added to the predicted picture 57a, 57b to obtain the locally decoded macroblock 62a, 62b to be stored into the memories a through f in accordance with an indication by the memory update unit.

[0139] Object A/B data when encoded in the object-A/B encoder 88a, 88b are multiplexed in the bitstream 73 at the multiplexer 71 to be transmitted via the buffer 72.

[0140] The prediction of this embodiment is discussed below focusing on the motion compensator 53a, 53b playing a primary role in the prediction.

[0141] The motion compensator 53a, 53b of this embodiment generates a predicted picture candidate based upon the motion parameter 52a, 52b detected in the motion detector 51a, 51b. Fig. 12 shows the configuration of the motion compensator 53a in detail. Fig. 13 shows a flowchart illustrating the operation of the motion compensator 53a in the object-A encoder 88a.

[0142] In Fig. 12, an object-B reference judger 74a and an object-B reference indicator flag 75a are shown.

[0143] The motion parameter 52a includes memory information used for detection. A predicted picture can-

didate is generated based upon a parameter value through the prediction picture memory address calculator 22a and a memory reader 24a in the same manner as that stated in the first embodiment (step S44 through step S49). The object-B reference judger 74a judges if the memories assigned to object-B are used for predicting the current macroblock based upon the reference memory information included in the motion parameter 52a (step S43).

[0144] The object-B reference judger 74a outputs a judged result as the object-B reference indicator flag 75a, which is multiplexed in the bitstream 73 to be transmitted to a decoding station so as to be used for deciding whether the object can be reproduced in a single use of the memories a, b, c of self in the decoding station. In order to secure the single use of the memories of self when reproducing the object in the decoding station, a limited use of the memories (a, b, c alone) of self for prediction can be controlled by an externally supplied signal 85a at the time of encoding the object.

[0145] Thus, the efficient and adaptive use of the memories in response to the characteristic of a local motion of a frame is provided by the encoder including the motion compensator 53a, 53b, thereby achieving an efficient prediction.

[0146] This embodiment has thus disclosed the encoder for encoding an object on a macroblock basis. The same effect may be expected with an alternative encoder for encoding a picture on such a picture segment basis as an arbitrary shaped picture segment and a variable shaped block including fixed-size block components.

[0147] Further, a decoder may be provided with the same components as the motion compensator 53a, 53b of this embodiment. A motion compensator 53 of the decoder only generates a single predicted picture based upon a decoded motion parameter. Further, if the decoder is structured so as to acknowledge whether a decoding object can be reproduced by itself by way of decoding a bit corresponding to object reference indicator flag 75a, 75b of the other object in a bitstream, then an error-free secured reproduction of decoded object data can be achieved.

Embodiment 5.

[0148] Another embodiment shows an encoder where the number of memories or the size of a memory can be varied flexibly in response to a change in a video object at each time instance. The encoder of a fifth embodiment modifies the encoder of Fig. 1 with a replacement of the memory update unit 15.

[0149] Fig. 14 shows the configuration of a memory update unit 15a of this embodiment in detail. In the figure, a memory expansion judger 76, a memory expansion indicator signal 77, and a memory contraction judger 78, and a memory contraction indicator signal 79 are shown. Fig. 15 shows an operating flow (step S51 through S63) of the memory update unit 15a.

[0150] A picture substantially different from the past record of a moving picture sequence stored in the memories may occur due to a scene change or the like. This may cause a deterioration of prediction efficiency after the scene change if reference pictures stored in the existing memories are the only available. For such an occasion, the scene-change detector 80 detects a scene change, a frame appearing immediately after the detected scene change is subject to intra-frame coding or the like, and resultant intra-frame coded data are stored additionally in a memory as new reference data, thereby enhancing prediction efficiency thereafter.

[0151] Further, in consideration of the physical limitation of storage capacity, a flexible approach of contracting the portions which are rarely used for prediction of the reference pictures stored in the memories is introduced. Specifically, the frequency in use of memory areas for prediction of the respective memories a, b, c is examined in the memory update unit 15a based upon the prediction mode 8. Consequently, the memory update unit releases a memory area identified low in frequency from an area for use. For example, with a software based implementation of this encoder, limited RAM resources may be used effectively.

[0152] Viewed in this light, the memory update unit 15a of this embodiment is provided with a function of expanding a memory area in response to each time instance of a time-varying moving picture sequence and contracting a memory area including a reference picture rarely used for prediction.

[0153] The memory-a, similarly to the first embodiment, is judged in the memory-a update judger 27 whether to be updated (step S50). When updating the memory-a, the locally decoded picture 14 is written into the memory-a (steps S56, S57). The locally decoded picture 14 is written into the other memories as well in accordance with the prediction mode 8 (step S51 through S55).

[0154] The updating of the contents of the memories involves the judgement of memory expansion/contraction. The memory expansion judger 76 judges whether to expand the size of the memory-a (or the memory-b, or the memory-c) based upon the activity 26 used for updating the memory-a (steps S58 through S60). When a positive judgement is made due to a scene change or the like, the expansion of the memory is indicated by the memory expansion indicator signal 77. The memory contraction judger 78 counts the times of a memory area used for prediction based upon the prediction mode 8. With a memory area counted less than a predetermined number in use for prediction, the contraction of the memory area is indicated by the memory contraction indicator signal 79 (steps S61 through S63).

[0155] Thus, a highly efficient prediction can be achieved in response to each time instance of a time-varying moving picture sequence by the encoder including the memory update unit 15a. In addition, the

dynamic allocation of memory areas required for prediction contributes to the enhancement of prediction efficiency and the effective use of memory resources.

[0156] This embodiment has thus disclosed the encoder performing on a frame basis. The same effect may be expected with an alternative encoder performing on an arbitrary shaped video object (VOP) basis.

[0157] Further, this embodiment has thus disclosed the encoder for encoding a frame on a macroblock basis. The same effect can be expected with an alternative encoder for encoding a picture on such a picture segment basis as an arbitrary shaped picture segment and a variable shaped block including fixed-size block components.

[0158] Further, a counterpart decoder may be provided with the same component as the memory update unit 15a discussed in this embodiment.

Embodiment 6.

[0159] With reference to the respective previous embodiments, the memories to be used for prediction are changed on a macroblock basis. Alternatively, the memories to be used for prediction can be changed on a frame or a video object basis. This eliminates the necessity of encoding memory relating information to be encoded on a frame or a video object basis and memory selection information (which is included in the prediction mode 8) to be encoded on a macroblock basis, thereby achieving an efficient encoding.

[0160] With reference to the encoder of Fig. 1 of the first embodiment, for example, the macroblock based changes of the memories used for prediction create the necessity of transmitting additional information identifying a memory used for prediction on a macroblock basis. According to this embodiment, the changing unit of the memories to be used for prediction is limited to a frame or a video object, thereby eliminating the additional information to be transmitted on a macroblock basis effectively. Fig. 23 shows a difference of the transmission bitstream 21 of this embodiment from the transmission bitstream 21 of Fig. 20 of the first embodiment. The bitstream of Fig. 23 represents a frame based change of the memories to be used for prediction with the prediction memory indication information 800 included in frame based header information. The bitstream of Fig. 23 may be effective, for example, in the case that the picture characteristic of a moving picture sequence changes infrequently including little changes locally on a macroblock level. Further, a decoder may be provided so as to decode the thus encoded bitstream to reproduce a frame or a video object.

Embodiment 7.

[0161] With reference to the previous embodiments, two predicted picture candidates read out from an arbitrary plural number, two (e.g., memories a and b) for example, of the memories are subject to an arithmetic mean to obtain a picture as a member of the predicted picture candidates 6 or as the predicted picture 9. Further, a decoder may be provided so as to decode the thus encoded bitstream to reproduce a frame or a video object.

Embodiment 8.

[0162] With reference to the encoders of the previous embodiments, a previously detected feature parameter representing the spatial complexity, perceptual significance and the like of a picture segment as a prediction unit may be utilized as tools for deciding a prediction mode and for judging the updating of the memories.

[0163] For example, a moving picture is assumed to include a motion too complicated to encode data in an acceptable quality within a given amount of encoding. In this case, significance is examined on a prediction picture segment (e.g., a macroblock, an arbitrary shaped picture segment, an arbitrary shaped block) basis. Consequently, a low quality encoding is assigned to some extent to a less significant segment in order to save some amount of encoding for a more significant segment, thereby improving an overall picture quality. With the encoders of this invention where two or more memories are switched interchangeably at an arbitrary timing to be used for prediction, a more adaptive prediction can be achieved in response to the characteristic of a picture, through detecting a feature parameter representing the significance of a prediction picture segment and then determining the use of the memories dynamically based upon a detected feature parameter. For example, as shown in Fig. 16, a segment-significance detector 95 is provided for detecting the feature parameter on a segment basis to determine the significance of the segment. The segment-significance detector 95 transfers a segment-significance to a prediction mode selector 7a and a quantization parameter based upon the segment-significance to a texture encoder 11a. With a segment judged more significant in the segment-significance detector 95, a most complex mode among two or more prediction modes available is used for prediction. Specifically, reference pictures from the respective memories a, b, c are used to obtain the motion parameters and the predicted pictures, respectively, based upon a complex motion model. In the prediction mode selector 7a, a prediction mode having the highest prediction efficiency is selected from among modes including an arbitrary combination (e.g., an arithmetic mean) of the predicted pictures. At the same time, reference pictures of all the memories used for prediction are updated. The texture encoder 11a performs an encoding using a quantization parameter having a smaller quantization step size. With a less significant segment, a simplified prediction mode (i.e., a parallel translation amount detection using a single memory) is employed for prediction and a quantization parameter having a larger

quantization step size is utilized for encoding, regardless of the amplitude of an obtained prediction error signal, so that an amount of encoding be reduced. Through this control, a less significant segment reduces its picture quality to some extent and a more significant segment maintains its quality through a high-quality prediction, thereby improving an overall quality within a given amount of encoding.

Embodiment 9.

[0164] In an encoder where a moving picture sequence is predicted and encoded by using two or more memories, a parameter representing an amount of encoding available for the moving picture sequence at each time instance, an amount of a change in a scene at a certain time instance (e.g., a scene change detection), or the feature parameter or significance of a prediction picture segment described in the eighth embodiment may be detected previously. The values of these parameters may be used for predicting a picture at a particular time instance in a prediction system. Alternatively, these values may be utilized as judging tools for selecting a reference memory area in a prediction system. A frame-significance detector 96 may be provided for determining the significance on a frame basis as shown in Fig. 17. The frame-significance detector 96 detects, for example, an amount of a change in a motion between the current and the previous frame (e.g., a scene change detection by the scene change detector 80), the appearance of a new object or the disappearance of an object or the like. A final significance of the current frame is determined in consideration of an amount of encoding available for the current frame informed by the transmission buffer 20. Based upon the final significance, a more significant frame may be predicted by using all the prediction methods and reference memory areas available for the maximum possible improvement of prediction efficiency, whereas a less significant frame is predicted in a limited use of the prediction methods and the reference memory areas for a simplified encoding so as to reduce the throughput. An alternative encoder for performing intra-frame coding alone involving no prediction at a scene change may be possible. In addition, a more sophisticated quality control may be achieved with a joint use of the segment-significance detector 95 discussed in the eighth embodiment. Through this control, a less significant frame reduces its quality to some extent and a more significant frame maintains its quality by a high-quality prediction, thereby improving an overall picture quality within a given amount of encoding.

[0165] The idea of this embodiment is also applicable to a software based encoding being associated with unsteady transaction processes and unsteady size of available storage in order to achieve an efficient encoding in the maximum use of available resources. This reduces a throughput with a less significant frame, thereby accelerating a general processing speed.

Embodiment 10.

[0166] In an encoder where a moving picture sequence including two or more video objects is predicted and encoded by using two or more memories, as shown in Fig. 11, a parameter representing a gross amount of encoding available for the sequence, an available amount of encoding of a video object at each time instance, an amount of a change in a video object at each particular time instance (e.g., the appearance/disappearance of an object), a level of significance/attention of a video object in a particular scene, or the feature parameter or significance of a prediction picture segment discussed in the eighth and ninth embodiments may be detected previously. The values of these parameters may be utilized for predicting a video object at each particular time instance. Alternatively, these values may be utilized as judging tools for selecting a reference memory area.

[0167] For example, as shown in Fig. 18, significance detectors 97a through 97n responsive, respectively, to objects 1 through n may be provided for detecting a parameter representing an amount of a change in an object at each time instance, or the appearance/disappearance of an object. In addition, the significance of an object at each time instance is determined in consideration of the occupational proportion of a buffer 72x for storing the encoded data of all the objects and the occupational proportion of virtual buffers 72a through 72n for the respective objects. When a new type of segment appears as a result of an object having another object overlapped in part, for example, then the following control may be applied to this type of segment because this type of segment has a great influence on prediction efficiency thereafter. A higher significance may be assigned to this type of segment to obtain an encoded picture in high quality even without enough space available for storage in the corresponding virtual buffer of the object. Significance detected in the significance detectors 97a through 97n is transferred to object 1 through N encoders 98a through 98n, where a full use of the prediction methods and the reference memory areas available is allowed to a more significant object so as to improve prediction efficiency to the maximum, whereas a limited use of the prediction methods and the reference memory areas is assigned to a less significant object so as to simplify the encoding, thereby reducing the throughput. Further, with an encoder for encoding objects decomposed from a frame through a real time separation, when a considerable amount of a change occurs in the contents of the object due to the appearance of a new object or the disappearance of an existing object, the object may be subject to intra-frame coding alone with no prediction involved. A more sophisticated quality control may be achieved on a prediction segment basis of an object in a joint use of the object 1

through N encoders 98a through 98n and the segment-significance detector 95 discussed in the eighth embodiment. Through this control, a less significant object is reduced in quality to some extent and a more significant object manages to maintain its quality through a sophisticated prediction, thereby improving an overall quality within a given amount of encoding.

Embodiment 11.

[0168] An alternative encoder may be provided with a prediction information encoder 91 for allocating a code (encoding) to prediction relating encoding information (e.g., a reference memory number) as shown in Fig, 19.

[0169] In the encoder where a moving picture sequence or a video object is predicted and encoded by using the memories a, b, c, the memories may be ranked based upon frequency in use for prediction with ranks being updated dynamically during an encoding operation. Consequently, a code allocation is performed to the prediction relating encoding information (e.g., a reference memory number) based upon the ranks of the respective memories used for prediction in the prediction information encoder 91.

[0170] For example, in the encoder of Fig. 19, the memory update unit 15b may be provided with a counter 92 which counts the times of the respective memories a, b, c to be used for prediction, ranks the memories a, b, c based upon counted values, and outputs resultant ranking information 90. This ranking may be performed on a picture (VOP) basis at a particular time instance of a frame or a video object, and alternatively, on a smaller unit basis of a prediction picture segment (e.g., a macroblcok, an arbitrary shaped segment, and an arbitrary shaped block).

[0171] This shows how often the respective memories are used for prediction. A memory in a frequent use for prediction is the most significant for prediction, and thus, a high frequency in use for reference corresponding to a high rank.

[0172] When encoding information on the frequency in use for prediction of the memories on a prediction picture segment basis, a memory in a frequent use for reference (i.e., a high-rank memory) is allocated a short code to enhance encoding efficiency.

[0173] In addition, if the motion parameter detected on a prediction picture segment basis is allocated a code length in response to the rank of a memory used for reference, then a shorter code may be assigned to a motion parameter value generated frequently, thereby achieving an efficient encoding of the prediction information. This may be materialized with an alternative encoder where the prediction information encoder 91 in the variable-length encoder/multiplexer 19 receives the ranks of the respective memories from the counter 92 in the memory update unit 15b and encodes the prediction information using a variable-length code based upon the ranking information 90.

Embodiment 12.

[0174] Fig. 24 shows the configuration of a picture decoder where an encoded digital picture through compression is reproduced through expansion according to another embodiment. In the figure, the encoded bitstream 21, a variable-length decoder 119, the quantized DCT coefficient 12, a quantization orthogonal transform coefficient 12a, a quantization step 12b, a texture decoder 111, a dequantizer 111a, an inverse orthogonal transformer 111b, a decoding adder 190, a decoded picture 101, a display controller 191, the prediction mode 8, memory-b update information 1001, memory-c update information 1002, the motion vector 4 (a motion parameter), the prediction memory indication information 800, an in-screen location 195 of a prediction picture segment, a motion compensator 105, a memory-a 116, a memory-b 117, a memory-c 118, a memory update unit 115, and a predicted picture 106 are shown. The motion compensator 105 and the memory update unit 115 form a prediction picture generation section 100a. The memories a, b, c form a memory area 200a.

[0175] According to this embodiment, the memory-a is assumed to be a frame memory designed to store a frame of picture data, the memory-b is assumed to be a static sprite memory, and the memory-c is assumed to be a dynamic sprite memory. The decoder of this embodiment is assumed to receive the bitstream 21 of Fig. 22. Although not shown in Fig. 22, the memory-b update information 1001 and the memory-c update information 1002 are assumed to be transmitted in the bitstream. The memory-b update information 1001 is assumed to include an update indication for a full updating of the static sprite memory and picture data for the full updating. Similarly, the memory-c update information 1002 is assumed to include an update indication for a full updating of the dynamic sprite memory and picture data for the full updating.

[0176] The operation of the thus configured decoder is described below. The variable-length decoder 119 analyzes the bitstream 21 and decomposes it into separate encoded data. The quantization orthogonal transform coefficient 12a is transferred to the dequantizer 119a to be dequantized by using the quantization step 12b. A dequantized result is subject to inverse orthogonal transformation in the inverse orthogonal transformer 111b to obtain a decoded texture, which is transferred to the decoding adder 190. Orthogonal transformation employed here is the same as that employed in an encoding station such as Discrete Cosine Transformation (DCT).

[0177] The motion compensator 105 inputs the motion vector 4, the prediction memory indication information 800, and information indicating the in-screen location 195 of a prediction picture segment included in the bitstream 21, all of which are decoded in the variable-length decoder 119. The motion compensator 105 reads out a right predicted picture from reference pic-

tures stored in the memories a, b, c based upon the three kinds of information. The in-screen location 195 of a prediction picture segment can be obtained by counting the number of macroblocks, other than from the information included in the bitstream. The process of generating a predicted picture will be discussed in a later section for describing the operation of the motion compensator 105 in detail.

[0178] The decoding adder 190, based upon the information of the prediction mode 8, outputs an output from the inverse orthogonal transformer 111b directly as the decoded picture 101 with a block through intra-frame coding, and, with a block through inter-frame coding, adds an output from the inverse orthogonal transformer 111b to the predicted picture 106 to be outputted as the decoded picture 101. The decoded picture 101 is transferred to the display controller 191 to be outputted to a display device and also transferred to the memories a, b, c to be stored as a reference picture for a later use in decoding. A memory writing operation is controlled by the memory update unit 115 based upon the prediction mode 8.

[0179] A predicted picture generation performed in the motion compensator 105 in the prediction picture generation section 100a is now discussed. According to this embodiment, the prediction method of a picture is determined based upon the prediction memory indication information 800. The decoder of this embodiment generates a predicted picture using a reference picture through predetermined coordinate transformation and interpolation based upon the motion vector 4 and the prediction memory indication information 800. Coordinate transform methods are assigned previously to the respective memories to be used for prediction. For example, the following approaches are possible similar to the picture transform methods described in the third embodiment.

(1) the memory-a used for prediction (with the prediction memory identification information 800 indicating the use of the memory-a)

[0180] The coordinates of each pixel of a prediction segment are translated based upon the motion vector and picture data at a corresponding location in the memory-a is read out as the predicted picture.

(2) the memory-b used for prediction (with the prediction memory identification information 800 indicating the use of the memory-b)

[0181] An affine transform expression is found based upon the motion vector, the coordinates of each pixel of a prediction segment are displaced based upon the transform expression, and picture data at a corresponding location in the memory-c is read out as a predicted picture.

(3) the memory-c used for prediction (with the prediction memory identification information 800 indicating the use of the memory-c)

[0182] A perspective transform expression is found based upon the motion vector, the coordinates of each pixel of a prediction segment are displaced based upon the transform expression, and picture data at a corresponding location in the memory-b is read out as a predicted picture.

[0183] Fig. 25 shows the configuration of the motion compensator 105 in detail. In the figure, a switch 161, a corresponding point determiner 162 for the memory-a, a corresponding point determiner 163 for the memory-b, a corresponding point determiner 164 for the memory-c, a memory read address generator 165, a switch 166, and an interpolator 167 are shown. Fig. 26 is a flowchart illustrating the optation of the motion compensator 105.

[0184] The operation of the motion compensator 105 of this embodiment is described below with reference to Figs. 25 and 26.

1) Determining a corresponding point

[0185] Initially, the corresponding point determiner of a corresponding memory is selected by the switch 161 based upon the prediction memory indication information 800. The vector 4 is then inputted to a selected corresponding point determiner. In this section, a predicted picture location corresponding to each memory is calculated, which is explained below with each memory.

1-1) the memory-a indicated by the prediction memory indication information 800 (step S100)

[0186] A predicted picture location is calculated through parallel translation based upon a motion vector (step S101). Specifically, a predicted picture location (x',y') corresponding to a pixel at a prediction picture segment location (x,y) is determined based upon a motion vector (a, b) according to the following expression.

$$x' = x + a$$

$$y' = y + b$$

A determined predicted picture location is outputted to the memory read address generator 165.

1-2) the memory-b indicated by the prediction memory indication information 800 (step S103)

[0187] An affine transform expression is determined based upon the motion vector 4. Specifically, an affine parameter (a, b, c, θ) of the following expression is determined by using the motion vector of a vertex of a rectangular area enclosing a prediction picture seg-

ment,

$$x' = a(\cos\theta)x + a(\sin\theta)y + b$$

$$y' = a(-\sin\theta)x + a(\cos\theta)y + c$$

thereby obtaining the predicted picture location (x',y') corresponding to a pixel at the location (x,y) of a prediction picture segment to be outputted to the memory read address generator 165 (step S104).

1-3) the memory-c indicated by the prediction memory indication information 800 (step S106)

[0188] A perspective transform expression is determined based upon a motion vector. Specifically, a perspective parameter (a, b, c, d, e, f) of the following expression is determined by using the motion vector of a vertex of a rectangular area enclosing a prediction picture segment,

$$x' = (ax + by + c) / (gx + hy + 1)$$

$$y' = (dx + ey + f) / (gx + hy + 1)$$

thereby obtaining the predicted picture location (x',y') corresponding to a pixel at the location (x,y) of a prediction picture segment to be outputted to the memory read address generator (step S107).

2) Reading out data for generating a predicted picture

[0189] Based upon the predicted picture location (x', y') outputted from a selected corresponding point determiner, the memory read address generator 165 generates a memory address for specifying the location of picture data required for generating a predicted picture in a reference picture stored in a memory, and reads out the data for generating a predicted picture (steps S102, 105, 108).

3) Generating a predicted picture

[0190] Among the component pixels of a predicted picture, with a pixel at an integer pixel location, the data for generating a predicted picture is used directly as a component pixel of a predicted picture, and with a pixel at a real number precision pixel location, the data for generating a predicted picture is subject to interpolation in the interpolator 167 to generate an interpolated pixel value (steps S109, S110, S111). Fig. 26 illustrates an interpolated pixel value generation. In Fig. 26, (i_0, j_p) denotes an integer pixel location, (j^p, j^p) denotes a real number precision pixel location, and w denotes a weight.

4) Updating a memory (a reference picture)

[0191] Fig. 28 shows a flowchart illustrating a control operation of the memory update unit 115. The memory update unit 115 controls an updating of the respective memories on a readout unit basis (e.g., a macroblock) of a predicted picture based upon the prediction mode 8 (or the prediction memory indication information 800). With the memory-a used for prediction (step S112), the contents of the memory-a and the memory-c are updated regularly with the decoded picture 101 (step S113). With the memory-b used for prediction (step S114), the reference picture of the memory-b is not updated on a readout unit basis of a predicted picture because of the memory-b being a static sprite memory, whereas the contents of the memory-a and the memory-c are updated regularly with the decoded picture 101 (step S115). When receiving the update indication by the memory-b update information 1001, then the memory update unit updates a full content of the memory-b with received picture data included in the memory-b update information 1001 (step S116). With the memory-c used for prediction (step S117), the contents of the memory-a and the memory-c are updated regularly by using the decoded picture 101 (step S118). When receiving the update indication by the memory update information, the memory update unit updates the content of the memory-c with received picture data included in the memory-c update information 1002 (step S119).

[0192] The use of the three memories a, b, c of this embodiment may be replaced by the use of two memories thereof, for example, with the memories a and b, that is, a frame memory and a static sprite memory. Alternatively, the memories a and c, that is, a frame memory and a dynamic memory, may be used.

[0193] As aforementioned, according to the decoder of this embodiment, the bitstream 21 encoded through an efficient prediction using the various kinds of motion parameters in response to the motion of a picture can be decoded. In addition, the decoder is applicable to the arbitrary updating approach of the contents of a reference picture at a timing determined in the encoding station, thereby achieving a more adaptive decoding in response to the characteristic of a picture.

[0194] According to this embodiment, if the bitstream includes a prediction error signal encoded through encoding other than orthogonal transform encoding, the same effect may be obtained by replacing a component for decoding a prediction error signal, other than the motion compensator and memory update unit.

[0195] Further, this embodiment may be applied not only to a decoder for decoding data on a fixed-size block basis, e.g., for decoding a normal television signal on a frame basis, but also to a decoder for decoding an arbitrary shaped video object (e.g., a Video Object Plane disclosed in ISO/IEC JTC1/SC29/WG11/N1902) as a unit without limiting a prediction segment to a fixed-size

block.

Industrial Feasibility

[0196] As discussed above, the memory areas provided for storing reference pictures according to this embodiment enables the adaptive use of the memories for storing data based upon the characteristic of the moving picture sequence. In addition, the contents of one or more of the memory areas can be updated at an arbitrary timing, so that the content of a time-unvarying picture, such as a background picture, is controlled to be updated on a longer-term basis, and the contents of a locally changing picture segment is controlled to be updated on a regular or sequential basis. This achieves an efficient prediction by reflecting the past record of the moving picture sequence.

[0197] Further, the transform parameter value ranges are assigned to the memory areas for making the respective memory areas effective, and the memory areas are switched to be used for prediction among them based upon the value of the transform parameter of a prediction picture segment, thereby achieving an efficient prediction in response to the magnitude of a local/global motion of the moving picture sequence. At the same time, the motion parameters to be encoded on a prediction picture segment basis can be encoded efficiently within the effective motion parameter value ranges of the reference memory areas.

[0198] Further, to the respective memory areas, the transform methods becoming effective in the respective memories are assigned, and the memories are switched to be used for prediction among them in response to the type of the transform parameter of a prediction picture segment, thereby achieving an efficient prediction in response to the complexity of a local/global motion of the moving picture sequence. At the same time, the transform method can be selected adaptively in response to the characteristic of a prediction picture segment, thereby achieving an efficient encoding of the motion parameter.

Claims

1. A moving picture prediction system for predicting a moving picture to be implemented in at least one of an encoder and a decoder, the moving picture prediction system comprising:

   a plurality of memories for storing picture data for reference to be used for prediction, the plurality of memories corresponding to different transform methods, respectively; and
   a prediction picture generation section for receiving a parameter representing a motion of a picture segment to be predicted, and for generating a predicted picture using the picture data stored in one of the plurality of memories used for the picture segment to be predicted based upon the parameter and one of the transform methods corresponding to the one of the plurality of memories.

2. The moving picture prediction system of claim 1, wherein the encoder generates a prediction memory indication information signal indicating the one of the plurality of memories used for generating the predicted picture and transmits the prediction memory indication information signal and the parameter to a decoding station so as to generate the predicted picture using the picture data stored in the one of the plurality of memories based upon the one of the transform methods corresponding to the one of the plurality of memories in the decoding station.

3. The moving picture prediction system of claim 1, wherein the decoder receives the parameter and a prediction memory indication information sinal indicating the one of the plurality of memories used for generating the predicted picture from an encoding station,

   wherein the prediction picture generation section generates the predicted picture using the picture data stored in the one of the plurality of memories based upon the parameter and the one of the transform methods corresponding to the one of the plurality of memories.

4. A moving picture prediction system for predicting a moving picture to be implemented in at least one of an encoding and a decoding, the moving picture prediction system comprising;

   a plurality of memories for storing picture data for reference to be used for prediction, the plurality of memories being assigned to different parameter effective value ranges, respectively; and
   a prediction picture generation section for receiving a parameter representing a motion of a picture segment to be predicted, for selecting one of the plurality of memories assigned to one of the parameter effective value ranges including a value of the parameter, and for generating a predicted picture using the picture data stored in a selected memory.

5. A moving picture prediction system for predicting a moving picture to be implemented in at least one of an encoding and a decoding, the moving picture prediction system comprising:

   a plurality of memories for storing picture data for reference to be used for prediction; and
   a prediction picture generation section includ-

ing

a motion compensator for receiving a parameter representing a motion of a picture segment to be predicted, and for generating a predicted picture by using the picture data stored in the plurality of memories based upon the parameter, and
a memory update unit for updating the picture data stored in at least one of the plurality of memories at an arbitrary timing.

6. The moving picture prediction system of claim 1, 4, or 5, wherein the moving picture is predicted in a moving picture sequence having first and second video objects,

wherein the plurality of memories includes separate first and second pluralities of memories corresponding to the first and second video objects, respectively, and the prediction picture generation section includes separate first and second generators, respectively, corresponding to the first and second video objects,

wherein the first generator uses the picture data stored in at least one of the first and second pluralities of memories to generate the predicted picture when predicting the first object, and generates information indicating a use of the second plurality of memories for predicting the first object, the information being added to the predicted picture.

7. The moving picture prediction system of claim 1, 4 or 5, wherein the prediction picture generation section generates the predicted picture through a change of either one of a number and a size of the plurality of memories in response to a change in the moving picture at each time instance.

8. The moving picture prediction system of claim 1, 4 or 5, wherein the prediction picture generation section generates the predicted picture in a limited use of memories for prediction in response to a change in the moving picture at each time instance.

9. The moving picture prediction system of claim 1, wherein the prediction picture generation section generates the predicted picture by calculating a plurality of the predicted pictures generated by using the respective picture data stored in the plurality of memories.

10. The moving picture prediction system of claim 1 further comprising:

a significance detector for detecting a feature parameter representing a significance of the picture segment to be predicted,

wherein the prediction picture generation section generates the predicted picture by selecting at least one of choices of at least one of a plurality of prediction methods, the plurality of memories, and a plurality of memory update methods.

11. The moving picture prediction system of claim 1 or 5 further comprising:

a significance detector for detecting a parameter representing at least one of an amount of bits available for coding the picture segment to be predicted, an amount of change of the picture segment at each time instance, and a significance of the picture segment;

wherein the prediction picture generation section generates the predicted picture by selecting at least one of choices of at least one of a plurality of prediction methods, the plurality of memories, a plurality of memory update methods.

12. The moving picture prediction system of claim 1 or 5, wherein the moving picture is predicted on a video object basis,

wherein the moving picture prediction system further comprising:

a significance detector for detecting a parameter representing at least one of an amount of bits available for coding a video object to be predicted, an amount of change in the video object at each time instance, and a significance of the video object;

wherein the prediction picture generation section generates the predicted picture by selecting at least one of choices of at least one of a plurality of prediction methods, the plurality of memories, and a plurality of memory update methods.

13. The moving picture prediction system of claim 1 or 5 further comprising:

a prediction information encoder for encoding prediction relating information of the moving picture;

wherein the prediction picture generation section counts a number of times of a memory used for prediction and determines a rank of the plurality of memories based upon a counted number of the times,

wherein the prediction information encoder allocates a code length to the prediction relating information to be encoded based upon the rank of a memory used for prediction.

14. The moving picture prediction system of claim 1, wherein the plurality of memories includes at least a frame memory for storing the picture data on a frame basis and a sprite memory for storing a sprite picture.

15. The moving picture prediction system of claim 14, wherein the sprite memory includes at least one of a dynamic sprite memory involving a regular updating, and a static sprite memory not involving the regular updating.

16. The moving picture prediction system of claim 14, wherein the one of the transform methods corresponding to the one of the plurality of memories is at least one of a parallel translation, an affine transformation, and a perspective transformation in an interchangeable manner.

17. A method for predicting a moving picture to be implemented in at least one of an encoding or a decoding, the method comprising the steps of:

storing picture data for reference to be used for prediction in a plurality of memories;
corresponding different transform methods with the plurality of memories, respectively;
receiving a parameter representing a motion of a picture segment to be predicted; and
generating a predicted picture using the picture data stored in one of the plurality of memories used for predicting the picture segment based upon the parameter and one of the transform methods being corresponding to the one of the plurality of memories.

18. The method for predicting a moving picture of claim 17, further comprising the steps of:

generating a prediction memory indication information signal indicating the one of the plurality of memories used for the picture segment to be predicted; and
transmitting the prediction memory indication information signal and the parameter to a decoding station.

19. The method for predicting a moving picture of claim 17 to be implemented in the decoding, the method further comprising the step of:

receiving a prediction memory indication information signal indicating the one of the plurality of memories used for generating the predicted picture and the parameter representing a motion of the picture segment to be predicted from an encoding station.

20. A method for predicting a moving picture to be implemented in at least one of an encoding and a decoding, the method comprising the steps of:

storing picture data for reference to be used for prediction in a plurality of memories;
assigning separate parameter effective value ranges to the plurality of memories, respectively;
receiving a parameter representing a motion of a picture segment to be predicted;
selecting one of the plurality of memories assigned to one of the parameter effective value ranges including a value of the parameter; and
generating a predicted picture using the picture data stored in a selected memory.

21. A method for predicting a moving picture to be implemented in at least one of an encoding and a decoding, the method comprising the steps of:

storing picture data for reference to be used for prediction in a plurality of memories;
receiving a parameter representing a motion of a picture segment to be predicted;
generating a predicted picture using the picture data stored in the plurality of memories based upon the parameter; and
updating the picture data stored in at least one of the plurality of memories at an arbitrary timing.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/JP98/00232

A. CLASSIFICATION OF SUBJECT MATTER
Int.Cl[6] H04N7/32

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
Int.Cl[6] H04N7/24-H04N7/68

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched
Jitsuyo Shinan Koho 1957-1998
Kokai Jitsuyo Shinan Koho 1975-1998

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	JP, 8-172631, A (Matsushita Electric Industrial Co., Ltd.), July 2, 1996 (02. 07. 96) & EP, 719049, A2	1-3, 5, 9, 17-19, 21

A		1-13, 17-21

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:
"A" document defining the general state of the art which is not considered to be of particular relevance
"E" earlier document but published on or after the international filing date
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O" document referring to an oral disclosure, use, exhibition or other means
"P" document published prior to the international filing date but later than the priority date claimed
"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"&" document member of the same patent family

TRANSMITTAL

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

We are submitting herewith the following:

- ☒ Transmittal Sheet containing certificate under 37 CFR 1.8.
- ☒ Response to Restriction Requirement (11 pages).
- ☒ Petition for Extension of Time
- ☒ Information Disclosure Statement, PTO Form 1449, and reference.
- ☒ 1 Return Postcard

Authorization is given to charge/credit Deposit Account No. 50-3581 (TAPA.004PA) for any deficiencies/overpayments associated with this filing.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC
8009 34th Avenue South, Suite 125

PETITION FOR EXTENSION OF TIME

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Sir:

In accordance with the provisions of 37 C.F.R. § 1.136, it is respectfully requested that a one-month extension of time be granted in which to file the attached Restriction Response. Please charge Deposit Account No. 50-3581 (TAPA.004PA) in the amount $120.00 to cover the extension fee for a large entity. Authority is given to charge/credit necessary fees/overages to deposit account number 50-3581 (TAPA.004PA) as required by this filing.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC
8009 34th Avenue South, Suite 125

RESPONSE TO RESTRICTION REQUIREMENT AND PRELIMINARY AMENDMENT

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Examiner's requirement for restriction dated March 16, 2006, the claims of Group I (Claims 1-13 and 15-25) are provisionally elected *with traverse*. The Applicant respectfully requests reconsideration and withdrawal of the requirement for restriction, for reasons set forth below. The Applicant respectfully requests reconsideration and allowance of all pending claims.

Claims 26 and 27 have been added. Authorization is given to charge Deposit Account No. 50-3581 (TAPA.004PA) in the amount of $300.00 for the two additional claims added by this filing. Authorization is also given to charge/credit Deposit Account No. 50-3581 (TAPA.004PA) for any deficiencies/overpayments.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 10 of this paper.

Listing of Claims:

1. (Original) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence.

2. (Original) A method according to claim 1, further comprising

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

3. (Original) A method according to claim 2, further comprising

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

- a video frame of a higher scalability layer,
- a video frame of another sub-sequence in the same scalability layer.

4. (Original) A method according to claim 3, further comprising

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame on the basis of the image number.

9. (Original) A method according to claim 7, further comprising

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. (Original) A method according to claim 7, further comprising

adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence.

11. (Original) A method according to claim 1, wherein

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

12. (Original) A method according to claim 1, further comprising

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

13. (Original) A method according to claim 1, further comprising

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

14. (Original) An element in a streaming system, such as a streaming server or a network element in a telecommunications system, wherein said element is arranged to

transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission,

control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

- at least one sub-sequence is removed from the video sequence,
- at least one sub-sequence is added to the video sequence.

15. (Original) A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame

of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

16. (Original) A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

17. (Original) A method according to claim 16, wherein video frames are entered into a sliding buffer memory in connection with decoding, further comprising

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

18. (Original) A method according to claim 17, further comprising

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

19. (Original) A method according to claim 16, further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

20. (Original) A method according to claim 16, further comprising

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

21. (Original) A method according to claim 16, further comprising

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

22. (Original) A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video

frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. (Original) A computer program for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

24. (Original) A computer program for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second

frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

25. (Original) A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

26. (New) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format;

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence, wherein subsequence information is different from picture type information.

27. (New) A method according to claim 26, wherein

a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly.

REMARKS/ARGUMENTS

The election/restriction requirement dated March 16, 2006, has been considered. The Examiner contends that the claims are drawn to two inventions, namely Group I (Claims 1-13 and 15-25) and Group II (Claim 14) and asserts that restriction to one of claim Groups I-II is required under 35 U.S.C. §121. The claims of **Group I (Claims 1-13 and 15-25)** are provisionally elected *with traverse*. The Applicant traverses the restriction requirement as it fails to satisfy the requirements for maintaining such a restriction requirement and accordingly requests reconsideration and withdrawal of the restriction requirement.

The election/restriction requirement asserts that the claims of Groups I and II are unrelated. It appears that the Examiner is asserting that the claims of the two Groups are independent based upon the reliance on §§802.01 and 806.06 of the MPEP. Specifically, §806.06 indicates that two inventions are independent if there is no disclosed relationship between the inventions, that is, they are unconnected in design, operation, and effect. The standard for showing that two inventions are independent is difficult to prove, for example, a specific process of molding would be independent from a molding apparatus so long as the apparatus cannot be used to practice the specific process. The Examiner's assertion that the claims of Group I are directed to forming a scalable, compressed video sequence, whereas the claim of Group II is directed to control of the bit rate of the compressed video packets for transmission, fails to identify how the two alleged inventions are disclosed as not capable of use together. The Examiner fails to provide any evidence to support the conclusion that the two alleged inventions are independent. Without any such evidence, the restriction requirement is improper. Accordingly, the Applicant requests that the restriction requirement be withdrawn.

New Claims 26 and 27 have been added. Claim 26 largely replicates Claim 1 and is believed to be directed to a similar invention if the above election/restriction requirement is maintained; therefore, the new claims are believed to be associated with the Examiner's asserted Group I.

CONCLUSION

In view of the above, the Applicant respectfully requests reconsideration and withdrawal of the requirement for restriction. If the Examiner would find it helpful to discuss this issue by telephone, the undersigned attorney of record invites the Examiner to contact the attorney of record.

Respectfully submitted,

AMENDMENT & RESPONSE UNDER 37 C.F.R. §1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office Action mailed March 13, 2007, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. §1.111.

Claims 1-24, 26 and 27 remain pending in the application. Claims 1, 2 and 26 have been amended. Claim 25 has been canceled, and no claims have been added. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 10.

AMENDMENTS TO THE CLAIMS:

This listing of claims replaces all prior versions, and listings, of claims in the application.

1. (Currently amended) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

encoding~~forming into~~ the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

encoding~~forming into~~ the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

encoding~~forming~~ into the video sequence information indicating which video frames belong to the second sub-sequence.

2. (Currently amended) A method according to claim 1, further comprising

determining ~~into the video sequence~~ the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence; and

encoding said interdependency into the video sequence.

3. (Original) A method according to claim 2, further comprising

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

- a video frame of a higher scalability layer,
- a video frame of another sub-sequence in the same scalability layer.

4. (Original) A method according to claim 3, further comprising

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame on the basis of the image number.

9. (Original) A method according to claim 7, further comprising

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. (Original) A method according to claim 7, further comprising

adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence.

11. (Original) A method according to claim 1, wherein

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

12. (Original) A method according to claim 1, further comprising

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

13. (Original) A method according to claim 1, further comprising

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

14. (Withdrawn) An element in a streaming system, such as a streaming server or a network element in a telecommunications system, wherein said element is arranged to

transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission,

control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

- at least one sub-sequence is removed from the video sequence,

- at least one sub-sequence is added to the video sequence.

15. (Original) A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

16. (Original) A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

17. (Original) A method according to claim 16, wherein video frames are entered into a sliding buffer memory in connection with decoding, further comprising

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

18. (Original) A method according to claim 17, further comprising

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

19. (Original) A method according to claim 16, further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

20. (Original) A method according to claim 16, further comprising

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

21. (Original) A method according to claim 16, further comprising

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

22. (Original) A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. (Previously presented) A computer program product, stored on a computer readable medium and executable in a data processing device, for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

24. (Previously presented) A computer program product, stored on a computer readable medium and executable in a data processing device, for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

25. (Canceled)

26. (Currently amended) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

encoding~~forming into~~ the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format;

encoding~~forming into~~ the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

encoding~~forming~~ into the video sequence information indicating which video frames belong to the second sub-sequence, wherein subsequence information is different from picture type information.

27. (Previously presented) A method according to claim 26, wherein

a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly.

REMARKS/ARGUMENTS

The rejection presented in the Office Action dated March 13, 2007 (hereinafter Office Action) has been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

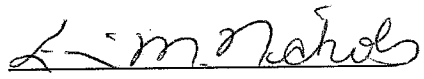
Claims 3-10, 12, 13 and 15-24 are not mentioned, or identified as being rejected, in the instant Office Action; therefore these claims are believed to be allowable. Applicant notes that MPEP §707.07(d) indicates that where a claim is refused the word "reject" must be used and the statutory basis for any ground of rejection should be designated by an express reference in the opening sentence of each ground of rejection. As the Office Action does not indicate that these claims are rejected, Applicant accordingly requests that each of these claims be identified as being allowable. If this was not the Examiner's intention, Applicant requests clarification, an opportunity to respond, and that any future rejections comply with MPEP §707.07(d).

With respect to the rejection of Claim 25, Claim 25 has been canceled thereby rendering the rejection moot. Applicant accordingly requests that the rejection be withdrawn.

Regarding the §101 rejection of Claims 1, 2, 11, 26 and 27, Applicant respectfully traverses because the claimed invention is directed to statutory subject matter. Independent Claims 1 and 26 are directed to processes for coding video frames, and expressly recite at least one specific utility in that the coding is "for the purpose of forming a scalable, compressed video sequence." It has not been asserted or shown that the claimed coding constitutes a judicial exception to the statutory categories of subject matter such as an abstract idea. Moreover, MPEP §2106(IV)(C)(2) indicates that a claimed invention is directed to a practical application of a judicial exception when it produces a useful, concrete and tangible result, and MPEP §2106(IV)(C)(2)(2) further indicates that the focus is on whether the final result achieved by the claimed invention is useful, tangible, and concrete. While the Examiner has previously acknowledged that the claims have useful and concrete results, Applicant notes that MPEP §2106(IV)(C)(2)(2)(b) does not limit a "real-world result" to a physical object. The claimed subject matter produces as a result, an encoded

video sequence of video frames having information indicating which frames belong to a second sub-sequence. The resulting encoded video sequence is used for the practical application of forming a scalable, compressed video sequence. As it has not been shown that the claimed scalable, compressed video sequence is not a practical application of encoded video frames, Applicant maintains that the claimed invention is directed to statutory subject matter and requests that the rejection be withdrawn.

Applicant has also amended Claims 1, 2 and 26 to more clearly characterize that the video sequence is encoded. These changes merely incorporate subject matter that was implicit in the previous claim language and therefore the changes do not introduce new matter. Each of these claims is believed to be patentable for the reasons discussed above.



Applicant also notes that as of August of 2006, the Interim Guidelines referred to at page two of the Office Action were incorporated into MPEP §2106.

Authorization is given to charge Deposit Account No. 50-3581 (TAPA.004PA) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office Action mailed April 9, 2009, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1-13, 15-24, 26, and 27 remain pending in the application. Claims 1, 16, and 26 have been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 10.

AMENDMENTS TO THE CLAIMS:

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

encoding, at the encoder, into the video sequence information indicating which video frames belong to the second sub-sequence.

2. (Previously presented) A method according to claim 1, further comprising

determining the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence; and

encoding said interdependency into the video sequence.

3. (Original) A method according to claim 2, further comprising

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

- a video frame of a higher scalability layer,

- a video frame of another sub-sequence in the same scalability layer.

4. (Original) A method according to claim 3, further comprising

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame on the basis of the image number.

9. (Original) A method according to claim 7, further comprising

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. (Original) A method according to claim 7, further comprising

adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence.

11. (Original) A method according to claim 1, wherein

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

12. (Original) A method according to claim 1, further comprising

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

13. (Original) A method according to claim 1, further comprising

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

14. (Canceled)

15. (Original) A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

16. (Currently amended) A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

decoding, at a decoder, a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding, at the decoder, at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining, at the decoder, dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing, at the decoder, at least part of the video sequence on the basis of the dependencies of the sub-sequences.

17. (Original) A method according to claim 16, wherein video frames are entered into a sliding buffer memory in connection with decoding, further comprising

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

18. (Original) A method according to claim 17, further comprising

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

19. (Original) A method according to claim 16, further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

20. (Original) A method according to claim 16, further comprising

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

21. (Original) A method according to claim 16, further comprising

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

22. (Original) A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video

frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. (Previously presented) A computer program product, stored on a computer readable medium and executable in a data processing device, for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

24. (Previously presented) A computer program product, stored on a computer readable medium and executable in a data processing device, for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other

video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

25. (Canceled)

26. (Currently amended) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format;

encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

encoding, at the encoder, into the video sequence information indicating which video frames belong to the second sub-sequence, wherein subsequence information is different from picture type information.

27. (Previously presented) A method according to claim 26, wherein

a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly.

REMARKS/ARGUMENTS

The rejection presented in the Office Action dated April 9, 2009, (hereinafter Office Action) has been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Applicant appreciates the indication of allowance for Claims 15 and 22-24.

With particular respect to the § 101 rejection of Claims 1-13, 16-21, 26, and 27, independent Claims 1, 16, and 26 have been amended to indicate that the claimed methods are performed at either an encoder or a decoder thereby tying the methods to another statutory category of subject matter as evidenced by the allowance of Claims 15 and 22. Although the subject matter of these changes was implicitly present in the claims, further support for these changes may be found, for example, in original Claims 15 and 22; therefore, these changes do not introduce new matter. Since the changes are believed to overcome the rejection, Applicant requests that the rejection be withdrawn and each of the pending claims be allowed.

Authorization is given to charge Deposit Account No. 50-3581 (TAPA.004PA) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

AMENDMENT & RESPONSE UNDER 37 C.F.R. §1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office Action mailed August 10, 2006, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. §1.111.

Claims 1-27 remain pending in the application. Claims 23 and 24 have been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 11.

AMENDMENTS TO THE CLAIMS:

This listing of claims replaces all prior versions, and listings, of claims in the application.

1. (Original) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence.

2. (Original) A method according to claim 1, further comprising

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

3. (Original) A method according to claim 2, further comprising

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

- a video frame of a higher scalability layer,

- a video frame of another sub-sequence in the same scalability layer.

4. (Original) A method according to claim 3, further comprising

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame on the basis of the image number.

9. (Original) A method according to claim 7, further comprising

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. (Original) A method according to claim 7, further comprising

adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence.

11. (Original) A method according to claim 1, wherein

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

12. (Original) A method according to claim 1, further comprising

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

13. (Original) A method according to claim 1, further comprising

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

14. (Withdrawn) An element in a streaming system, such as a streaming server or a network element in a telecommunications system, wherein said element is arranged to

transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission,

control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

- at least one sub-sequence is removed from the video sequence,
- at least one sub-sequence is added to the video sequence.

15. (Original) A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

16. (Original) A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

17. (Original) A method according to claim 16, wherein video frames are entered into a sliding buffer memory in connection with decoding, further comprising

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

18. (Original) A method according to claim 17, further comprising

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

19. (Original) A method according to claim 16, further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

20. (Original) A method according to claim 16, further comprising

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

21. (Original) A method according to claim 16, further comprising

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

22. (Original) A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. (Currently amended) A computer program product, stored on a computer readable medium and executable in a data processing device, for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

24. (Currently amended) A computer program product, stored on a computer readable medium and executable in a data processing device, for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

25. (Original) A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

26. (Previously presented) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format;

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence, wherein subsequence information is different from picture type information.

27. (Previously presented) A method according to claim 26, wherein

a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly.

REMARKS/ARGUMENTS

The rejections presented in the Office Action dated August 10, 2006 (hereinafter Office Action) have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

While the Examiner has indicated that the restriction requirement has been made final, Applicant maintains the traversal of the requirement and reserves the right to petition for reversal of the requirement.

Applicant appreciates the indication of allowability for claims 17-18 and 20.

Regarding the rejection of Claims 1, 2, 11, 23, 24, 26 and 27 under 35 U.S.C. §101 as allegedly not being directed to statutory subject matter, Applicant respectfully traverses. First, the Examiner asserts that Claims 1, 2, 11, 26 and 25 do not indicate what to do with formed sub-sequences. Applicant fails to recognize how such an assertion relates to a rejection based on allegedly non-statutory subject matter and is unsure as to the basis for such an assertion. The claims clearly teach that "at least part of a first sub-sequence" and "at least a second sub-sequence" are formed "into the video sequence." *See, e.g.*, Claim 1.

Second, the Examiner asserts that Claims 1, 2, 11, 26 and 25 have useful and concrete results, but lack tangible results and therefore do not provide a practical application. Applicant fails to recognize how claimed subject matter may be directed to concrete results without being directed to tangible results, especially since "the courts have yet to define the terms useful, concrete, and tangible in the context of the practical application requirement." *See, e.g.*, MPEP §2106(II)(A). Notwithstanding, the claims are directed to a process for forming a scalable compressed video sequence, which includes coding video frames having video data. Such a manipulation of video data is a practical application in compliance with MPEP §2106(IV)(B)(2)(b). Thus, Applicant submits that Claims 1, 2, 11, 26 and 25 are directed to statutory subject matter and requests that the rejection be withdrawn. If the Examiner were to maintain the rejection, Applicant requests further clarification and an opportunity to respond.

With respect to Claims 23 and 24, Applicant has amended the claims to be directed to a computer program product, stored on a computer readable medium and executable in a data processing device. Such a computer program product constitutes statutory subject matter as it is directed to a practical application of forming a scalable compressed video sequence. *See, e.g.*, MPEP §2106(IV)(B)(2)(b). Applicant accordingly submits that Claims 23 and 24 are directed to statutory subject matter and requests that the rejection be withdrawn.

With respect to the prior art (§§102(e) and 103(a)) rejections based on U.S. Patent No. 6,614,936 to Wu *et al.* (hereinafter "Wu"), Applicant respectfully traverses because Wu does not teach or suggest each of the claimed limitations. For example, Wu does not teach at least forming into a video sequence, information indicating which video frames belong to a second sub-sequence, as claimed. In an attempt to show correspondence to such limitations, the Examiner asserts that information indicating that the second through third frames (asserted as corresponding to a second sub-sequence and shown in Fig. 11) belong to a first layer is transmitted to a decoder. However, the Examiner has not identified where Wu teaches that such information is formed into a video sequence or provided any other evidence in support of such assertion. Without a presentation of correspondence to each of the claimed limitations, the prior art rejections are improper.

With particular respect to the §102(e) rejection, Applicant notes that to anticipate a claim, the asserted reference must teach every element of the claim. "A claim is anticipated only if each and every element as set forth in the claim is found, either expressly or inherently described, in a single prior art reference." *Verdegaal Bros. v. Union Oil Co. of California*, 2 USPQ2d 1051, 1053 (Fed. Cir. 1987). The identical invention must be shown in as complete detail as is contained in the patent claim; *i.e.* every element of the claimed invention must be literally present, arranged as in the claim. *Richardson v. Suzuki Motor Co.*, 9 USPQ2d 1913, 1920 (Fed. Cir. 1989). Therefore, all claim elements, and their limitations, must be found in the prior art reference to maintain the rejection based on 35 U.S.C. §102. Applicant respectfully submits that Wu does not teach every element of

independent Claims 1, 15, 16 and 22-26 in the requisite detail and therefore fails to anticipate Claims 1-9, 11-13, 15-16, 19 and 22-27.

Even if Wu teaches transmitting information indicating that the second through third frames belong to a first layer, such teaching fails to correspond to the claimed limitations. For example, the fact that the relied-upon second through third frames belong to a first layer does not indicate that they belong to a second sub-sequence. The Examiner has not identified how the second through third frames are formed into a video sequence and at least part of the second through third frames was formed by coding using a second frame format. As multiple sub-sequences may be present within a layer (*see, e.g.*, Applicant's Fig. 2), the Examiner has not shown that the second through third frames correspond to the claimed second sub-sequence. Also, the Examiner has not shown that information indicating where the second through third frames belong is formed into a video sequence. The Examiner has not shown that Wu teaches each of these claim limitations in as complete detail as contained in the claims to maintain a §102 rejection. Applicant accordingly requests that the rejection be withdrawn.

Dependent Claims 2-9, 11-13, 19 and 27 depend from independent Claims 1, 16 and 26, respectively, and also stand rejected as being anticipated by Wu. While Applicant does not acquiesce with the particular rejections to these dependent claims, including any assertions concerning inherency, these rejections are moot in view of the remarks made above in connection with independent Claims 1, 16 and 26. These dependent claims include all of the limitations of independent Claims 1, 16 and 26 and any intervening claims, and recite additional features which further distinguish these claims from the cited references. Therefore, the rejection of dependent Claims 2-9, 11-13, 19 and 27 is improper and should be withdrawn.

With particular respect to the rejection of dependent Claim 7, Applicant respectfully traverses because Wu does not teach each of the claimed limitations. The Examiner has not identified where Wu teaches any determination of unique identifiers for each video frame. Moreover, the Examiner's assertion that the first frame of the base layer is known as base layer, first sub-sequence, first frame, is entirely unsupported since Wu does not use the term

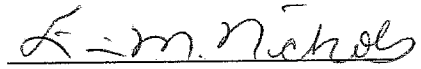
"sub-sequence" anywhere in its teachings. Without a presentation of correspondence to each of the claimed limitations, the §102(e) rejection is improper and should not be maintained.

With particular respect to the §103(a) rejection of dependent Claim 10, Applicant respectfully traverses because the asserted modification of Wu would not correspond to the claimed limitations and is unsupported. As discussed above in connection with dependent Claim 7, Wu does not teach determining a unique identifier, thus Wu must also not teach adding the identifier to Supplemental Enhancement Information. It would appear that the Examiner is impermissibly taking official notice that the elements of Claim 10, in view of Wu, constitute facts outside of the record which are capable of instant and unquestionable demonstration as being well known or obvious to one skilled in the art. Applicant respectfully disagrees and requests that the Examiner produce a reference that supports the Examiner's assertion that Claim 10 is obvious.

In determining the differences between the prior art and the claims, the question under 35 U.S.C. §103 is not whether the differences themselves would have been obvious, but whether the claimed invention as a whole would have been obvious. Taking official notice of the above-discussed "facts" disregards the requirement of analyzing Applicant's claimed subject matter "as a whole." Applicant respectfully reiterates the legal tenet that facts so noticed should not comprise the principle evidence upon which a rejection is based. *See*, MPEP §2144.03.

It is to be understood that Applicant does not acquiesce to the Examiner's characterization of the asserted art or Applicant's claimed subject matter, nor of the Examiner's application of the asserted art or combinations thereof to Applicant's claimed subject matter. Moreover, Applicant does not acquiesce to any explicit or implicit statements or conclusions by the Examiner concerning what would have been obvious to one of ordinary skill in the art, obvious design choices, alternative equivalent arrangements, common knowledge at the time of Applicant's invention, officially noticed facts, and the like. Applicant respectfully submits that a detailed discussion of each of the Examiner's rejections beyond that provided above is not necessary, in view of the clear absence of

teaching and suggestion of various features recited in Applicant's pending claims and a lack of evidence of motivation to modify the asserted teachings. Applicant, however, reserves the right to address in detail the Examiner's characterizations, conclusions, and rejections in future prosecution.



The Examiner has not shown that, nor does, Wu teach or suggest each of the claimed limitations. Thus, each of the prior art rejections are improper and should not be maintained. Applicant accordingly requests that each of the rejections be withdrawn.

Authorization is given to charge Deposit Account No. 50-3581 (TAPA.004PA) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact her at the number below to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 1 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☐ Responsive to communication(s) filed on _____.

2a)☐ This action is **FINAL**. 2b)☐ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) 1-25 is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☐ Claim(s) _____ is/are rejected.

7)☐ Claim(s) _____ is/are objected to.

8)☒ Claim(s) 1-25 are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☐ The drawing(s) filed on _____ is/are: a)☐ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☐ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☐ Certified copies of the priority documents have been received in Application No. _____.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

5) ☐ Notice of Informal Patent Application (PTO-152)
6) ☐ Other: _____.

DETAILED ACTION

Election/Restrictions

1. Restriction to one of the following inventions is required under 35 U.S.C. 121:

   I. Claims 1-13, 15-25, drawn to a method of coding video frame for forming a scalable, compressed video sequence, classified in class 375, subclass 240.12.

   II. Claim 14, drawn to a method of transmitting compressed video sequence and to control the transferred bit rate, classified in class 375, subclass 240.16.

The inventions are distinct, each from the other because of the following reasons:

Inventions I and II are unrelated. Inventions are unrelated if it can be shown that they are not disclosed as capable of use together and they have different designs, modes of operation, and effects (MPEP § 802.01 and § 806.06). In the instant case, the different inventions of group I requires the forming of a scalable, compressed video sequence whereas, the invention of group II relates to a control of the bit rate of the compressed video packets for transmission.

Because these inventions are independent or distinct for the reasons given above and have acquired a separate status in the art in view of their different classification, restriction for examination purposes as indicated is proper.

Because these inventions are independent or distinct for the reasons given above and the inventions require a different field of search (see MPEP § 808.02), restriction for examination purposes as indicated is proper.

Because these inventions are independent or distinct for the reasons given above and have acquired a separate status in the art because of their recognized divergent subject matter, restriction for examination purposes as indicated is proper.

2. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free).

DETAILED ACTION

Claim Rejections - 35 USC § 101

1. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

2. Claims 1-2, 11, 25-27 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter.

Regarding claims 1-2, 11, 26-27: Claims 1-2, 11, 26-27 claim a method for coding video frames for the purpose of forming a scalable, compressed video sequence. Since the method claim of claims 1-2, 11, 26-27 do not have substantial practical application as required in the Interim Guidelines, in particular, the tangible requirement does require that the claims must recite more than a 101 judicial exception, in that the process claim must set forth a practical application of that 101 judicial exception to produce a real-world result. Regarding to claims 1-17, the claims are determined lacking tangible result since all the steps cited in the claims, only manipulate data, evaluating data, incorporating new data ; however, at the end, the result is not used to provide any real-world application. With regard to the applicants argument that "Applicants fails to recognize how claimed subject matter may be directed to concrete results without being directed to tangible results (page 11, ln. 17-18). The examiner respectfully suggests the applicant to review the Interim Guidelines for examination of Patent Applications for Patent Subject Matter Eligibility, specially pages 19-22.

Regarding claim 25: Claim 25 recites nothing but the physical characteristics of a form of energy and as such are nonstatutory natural phenomena and further more, it

does not appear that a claim reciting a signal encoded with functional descriptive material falls within any of the categories of patentable subject matter set forth in section 101 (Interim Guidelines, Annex IV page 55).

Conclusion

3. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

DETAILED ACTION

Election/Restrictions

1. This application is in condition for allowance except for the presence of claim 14 directed to an invention non-elected with traverse in the reply filed on 5/8/2006. Applicant is given ONE MONTH or THIRTY DAYS from the date of this letter, whichever is longer, to cancel the noted claims or take other appropriate action (37 CFR 1.144). Failure to take action during this period will be treated as authorization to cancel the noted claims by Examiner's Amendment and pass the case to issue. Extensions of time under 37 CFR 1.136(a) will not be permitted since this application will be passed to issue.

The prosecution of this case is closed except for consideration of the above matter.

Allowable Subject Matter

2. Claims 1-13, 15-24 and 26-27 are allowed.

Conclusion

3. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *08 May 2006*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-27* is/are pending in the application.

4a) Of the above claim(s) *14* is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☐ Claim(s) *1-3,15,16,19 and 21-27* is/are rejected.

7)☒ Claim(s) *17,18 and 20* is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *29 November 2002* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☒ Certified copies of the priority documents have been received.

2.☐ Certified copies of the priority documents have been received in Application No. _____.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

6) ☐ Other: _____.

DETAILED ACTION

Election/Restrictions

1. Applicant's election without traverse of 1-13 and 15-25 in the reply filed on 5/8/2006 is acknowledged. The traversal is on the ground(s) that the examiner fails to identify how the two alleged inventions are disclosed as not capable of use together. This is not found persuasive because as indicated in the election requirement, Claims 1-13, 15-25, drawn to a method of coding video frame for forming a scalable, compressed video sequence, classified in class 375, subclass 240.12 and these claims exclusively claim the steps of forming into the video sequence comprising of a first sub-sequence, a second sub-sequence, the interdependency of the first and the second sub-sequence and forming into the video sequence information indicating which video frames belong to the sub-sequences. Basically, group I has nothing to do with bit rate control but the interdependency of the sub-sequences and group II drawn to a method of transmitting compressed video sequence and to control the transferred bit rate, classified in class 375, subclass 240.16. Therefore, the inventions are distinct, and because these inventions are independent or distinct for the reasons given above and have acquired a separate status in the art in view of their different classification, and the inventions require a different field of search (see MPEP § 808.02) and have acquired a separate status in the art because of their recognized divergent subject matter restriction for examination purposes as indicated is.

The requirement is still deemed proper and is therefore made FINAL.

Claim Rejections - 35 USC § 101

2. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

3. Claims 1-2, 11, 23-24 and 26-27 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter.

Regarding claims 1-2, 11, 23 and 26: The method claim of the above claims comprises the steps of forming sub-sequences and the interdependency of these sub sequences without claiming what to do with the formed sub-sequences. The claims, although have useful and concrete results, lack tangible result and therefore these claims do not provide a practical application and are directed to non-statutory subject matter.

Regarding claims 23-24: Claims 23-24 direct to "A computer program for encoding and decoding ..., wherein the computer program comprises program codes...". Since the computer program comprising program codes as claimed does not specify that the computer program is stored (or encoded or embedded) in the computer readable medium and when executed by the computer, the computer program code forming ....The claim computer program of claims 23-24 is therefore a computer per se and is directed to non-statutory subject matter.

Claim Rejections - 35 USC § 102

4. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (e) the invention was described in a patent granted on an application for patent by another filed in the United States before the invention thereof by the applicant for patent, or on an international application

> by another who has fulfilled the requirements of paragraphs (1), (2), and (4) of section 371(c) of this title before the invention thereof by the applicant for patent.

The changes made to 35 U.S.C. 102(e) by the American Inventors Protection Act of 1999 (AIPA) and the Intellectual Property and High Technology Technical Amendments Act of 2002 do not apply when the reference is a U.S. patent resulting directly or indirectly from an international application filed before November 29, 2000. Therefore, the prior art date of the reference is determined under 35 U.S.C. 102(e) prior to the amendment by the AIPA (pre-AIPA 35 U.S.C. 102(e)).

5. Claims 1-9, 11-13, 15-16, 19, 22-27 are rejected under 35 U.S.C. 102(e) as being anticipated by Wu et al (US 6,614,936).

Wu et al discloses a system and method for robust video coding using progressive fine-granularity scalable coding comprising the same method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second fame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video fames (col. 7, ln. 63 – col. 8, ln. 5), the method comprising:

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format (figure 11, base layer 332); and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and

at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence (2nd – 3rd frames of the 1st layer 334); and forming into the video sequence information indicating which video frames belong to the second sub-sequence (2nd – 3rd frames belong to the 1st layer and this information is transmitted to the decoding side of the system so decoder can decode) as specified in claims 1, 15, 23 and 25-26; claims 16, 22, 24 are rejected as a reverse process of the encoding process of claim 1); further comprising determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence (arrow between 1st frame of base layer and 2nd frame of 1st layer determines the interdependency between two subsequences) as specified in claim 2; further comprising coding the video sequence into a plural number of scalability layers; and determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising: a video frame of a higher scalability layer, a video frame of another sub-sequence in the same scalability layer (fig. 11, base layer to 5th layer and arrow between 1st frame of base layer and 2nd frame of 1st layer determines the interdependency between two subsequences) as specified in claim 3; 4. (Original) A method according to claim 3, further comprising determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier (the dependency of the 3rd frames to the 2nd frame (sub-sequence) of the 1st layer (a scalability layer) as specified in claim 4; further comprising coding the first scalability layer of the video sequence to

comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence (is frame of the base layer) as specified in claim 5; further comprising coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format (1st frame, 2nd and 3rd fames of the base layer) as specified in claim 6; further comprising determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number; or determining a unique identifier for each video frame on the basis of the image number (1st frame of the base layer is known as base layer, 1st sub-sequence and 1st frame) as specified in claims 7-8; further comprising adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence (inherently included so decoder at the decoding side would know how to reconstruct the images) as specified in claim 9; wherein the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image (is frame of the base layer and 2nd frame of the 1 layer) as specified in claim 11; further comprising coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping (1st frame of the base layer to 1st frame of the 1st layer and 1st frame of the base layer to 2nd frame of the 1st layer to 3rd frame of the 1st layer) as specified in claim 12; further comprising coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific (col. 7, ln. 63-64) as specified in claim 13; further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence or wherein a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly (frames 1-5 of the base layer can be decoded without the need of decoding sub0sequence of frames 2-3 of the 1st layer and therefore the removal of this subsequence does not have any effect in decoding frames 1-5 of the 1st layer) as specified in claims 19 and 27.

Claim Rejections - 35 USC § 103

6. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

7. Claims 10 and 21 are rejected under 35 U.S.C. 103(a) as being unpatentable over Wu et al.

As applied to claim 7 above, it is noted that Wu et al does not particularly disclose the step of adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence. Since SEI mechanism is known to proves data delivery that is transferred synchronously with the video data content and therefore, it would have been obvious to one of ordinary skilled in the art at the time the invention was made to modify the system of Wu et al by using SEI mechanism to transfer any identifier data.

With regard to claim 21: Since, the H.26L standard defines a picture order count as a picture position in output order. The decoding process specified in the H.26L

standard uses picture order counts to determine default index orderings for reference pictures in B slices, to represent picture order differences between frames and fields for vector scaling in motion vector prediction and for implicit mode weighted prediction in B slices, and to determine when successive slices in decoding order belong to different pictures. The picture order count is coded and transmitted for each picture. Therefore, it would have been obvious to one of ordinary skilled in the art having both Wu et al and the teaching of the H.26L in front of him/her would have found it obvious to use the picture order count to identify at least partly temporally overlapping sub-sequence frames from the video sequence, and to output from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

Allowable Subject Matter

8. Claims 17-18 and 20 is objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

The following is a statement of reasons for the indication of allowable subject matter: The various prior art of record does not anticipate or render obviousness steps of entering video frames into a sliding buffer memory in connection with decoding, further comprising decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional, configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers

and continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers as specified in claim 20 and steps of initiating the decoding from a random point in the video sequence; determining an independently decodable sub-sequence that is next after the random point, and setting the value of the image number of the first video frame in the sub-sequence at zero as specified in claim 20.

Conclusion

9. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

a. Harza (US 6,510,553) discloses a method of streaming video from multiple sources over a network.

b. Radha et al (US 6,639,943) discloses a hydrid temporal-SNR fine granular scalability video coding.

c. Tillman et al (US 6,496,980) discloses a method of providing replay on demend for streaming digital multimedia.

10. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone

number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *12 March 2009*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-13,15-24,26 and 27* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☒ Claim(s) *15 and 21-24* is/are allowed.

6)☒ Claim(s) *1-13,16-21,26 and 27* is/are rejected.

7)☐ Claim(s) _____ is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *11/29/2002* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☒ Certified copies of the priority documents have been received.

2.☐ Certified copies of the priority documents have been received in Application No. _____.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

4) ☐ Interview Summary (PTO-413) Paper No(s)/Mail Date. _____.
5) ☐ Notice of Informal Patent Application
6) ☐ Other: _____.

DETAILED ACTION

1. Claim 14 is cancelled as per paragraph of the previous Office Action mailed out on 9/11/2007.

Claim Rejections - 35 USC § 101

2. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

3. Claims 1-13, 16-21 and 26-27 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter.

Regarding to claims 1-13, 16-21 and 26-27, which are method claims, and that the claims do not fall within one of the four statutory categories of inventions. Supreme Court precedent and recent Federal Circuit decisions indicate a statutory "process" under 35 U.S.C. 101 must (1) be tied to another statutory category (such as a particular apparatus), or (2) transform underlying subject matter (such as an article or material) to a different state or thing. While the instant claim(s) recite a series of steps or acts to be performed, it is considered that none of the steps in the claims positively recites the other statutory class (the thing or product) to which it is tied, for example, by identifying the apparatus that accomplishes the method steps, In re Bilski, 88 USPQ2d 1385 (Fed. Cir. 2008).

Allowable Subject Matter

4. Claims 15, 22-24 are allowed.

Conclusion

5. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437

EXAMINER	
DIEP, NHON THANH	
ART UNIT	PAPER NUMBER
2621	

DATE MAILED: 12/07/2009

APPLICATION NO.	FILING DATE	FIRST NAMED INVENTOR	ATTORNEY DOCKET NO.	CONFIRMATION NO.
10/306,942	11/29/2002	Miska Hannuksela	TAPA.004PA	3642

TITLE OF INVENTION: GROUPING OF IMAGE FRAMES IN VIDEO CODING

APPLN. TYPE	SMALL ENTITY	ISSUE FEE DUE	PUBLICATION FEE DUE	PREV. PAID ISSUE FEE	TOTAL FEE(S) DUE	DATE DUE
nonprovisional	NO	$1510	$300	$0	$1810	03/08/2010

THE APPLICATION IDENTIFIED ABOVE HAS BEEN EXAMINED AND IS ALLOWED FOR ISSUANCE AS A PATENT. PROSECUTION ON THE MERITS IS CLOSED. THIS NOTICE OF ALLOWANCE IS NOT A GRANT OF PATENT RIGHTS. THIS APPLICATION IS SUBJECT TO WITHDRAWAL FROM ISSUE AT THE INITIATIVE OF THE OFFICE OR UPON PETITION BY THE APPLICANT. SEE 37 CFR 1.313 AND MPEP 1308.

THE ISSUE FEE AND PUBLICATION FEE (IF REQUIRED) MUST BE PAID WITHIN THREE MONTHS FROM THE MAILING DATE OF THIS NOTICE OR THIS APPLICATION SHALL BE REGARDED AS ABANDONED. THIS STATUTORY PERIOD CANNOT BE EXTENDED. SEE 35 U.S.C. 151. THE ISSUE FEE DUE INDICATED ABOVE DOES NOT REFLECT A CREDIT FOR ANY PREVIOUSLY PAID ISSUE FEE IN THIS APPLICATION. IF AN ISSUE FEE HAS PREVIOUSLY BEEN PAID IN THIS APPLICATION (AS SHOWN ABOVE), THE RETURN OF PART B OF THIS FORM WILL BE CONSIDERED A REQUEST TO REAPPLY THE PREVIOUSLY PAID ISSUE FEE TOWARD THE ISSUE FEE NOW DUE.

HOW TO REPLY TO THIS NOTICE:

I. Review the SMALL ENTITY status shown above.

If the SMALL ENTITY is shown as YES, verify your current SMALL ENTITY status:

A. If the status is the same, pay the TOTAL FEE(S) DUE shown above.

B. If the status above is to be removed, check box 5b on Part B - Fee(s) Transmittal and pay the PUBLICATION FEE (if required) and twice the amount of the ISSUE FEE shown above, or

If the SMALL ENTITY is shown as NO:

A. Pay TOTAL FEE(S) DUE shown above, or

B. If applicant claimed SMALL ENTITY status before, or is now claiming SMALL ENTITY status, check box 5a on Part B - Fee(s) Transmittal and pay the PUBLICATION FEE (if required) and 1/2 the ISSUE FEE shown above.

II. PART B - FEE(S) TRANSMITTAL, or its equivalent, must be completed and returned to the United States Patent and Trademark Office (USPTO) with your ISSUE FEE and PUBLICATION FEE (if required). If you are charging the fee(s) to your deposit account, section "4b" of Part B - Fee(s) Transmittal should be completed and an extra copy of the form should be submitted. If an equivalent of Part B is filed, a request to reapply a previously paid issue fee must be clearly made, and delays in processing may occur due to the difficulty in recognizing the paper as an equivalent of Part B.

III. All communications regarding this application must give the application number. Please direct all communications prior to issuance to Mail Stop ISSUE FEE unless advised to the contrary.

IMPORTANT REMINDER: Utility patents issuing on applications filed on or after Dec. 12, 1980 may require payment of maintenance fees. It is patentee's responsibility to ensure timely payment of maintenance fees when due.

PTOL-85 (Rev. 08/07) Approved for use through 08/31/2010.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), to: Mail **Mail Stop ISSUE FEE**
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450
or Fax (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence including the Patent, advance orders and notification of maintenance fees will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications.

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

76385 7590 12/07/2009

Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

Certificate of Mailing or Transmission
I hereby certify that this Fee(s) Transmittal is being deposited with the United States Postal Service with sufficient postage for first class mail in an envelope addressed to the Mail Stop ISSUE FEE address above, or being facsimile transmitted to the USPTO (571) 273-2885, on the date indicated below.

This collection of information is required by 37 CFR 1.311. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, Virginia 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450.

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

DATE MAILED: 12/07/2009

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b)
(application filed on or after May 29, 2000)

The Patent Term Adjustment to date is 791 day(s). If the issue fee is paid on the date that is three months after the mailing date of this notice and the patent issues on the Tuesday before the date that is 28 weeks (six and a half months) after the mailing date of this notice, the Patent Term Adjustment will be 791 day(s).

If a Continued Prosecution Application (CPA) was filed in the above-identified application, the filing date that determines Patent Term Adjustment is the filing date of the most recent CPA.

Applicant will be able to obtain more detailed information by accessing the Patent Application Information Retrieval (PAIR) WEB site (http://pair.uspto.gov).

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Customer Service Center of the Office of Patent Publication at 1-(888)-786-0101 or (571)-272-4200.

/Nhon T Diep/
Primary Examiner, Art Unit 2621

REASONS FOR ALLOWANCE

1. The following is an examiner's statement of reasons for allowance: The present invention relates to a coding of a video sequence comprising of a plurality of sub-sequence formed therein, at least part of the sub-sequence being formed by coding the intra (I) frames of the at least first frame format, and at least the second frame format, at least part of which is formed by coding video frame of the at least second frame format (P frames), and the identifying of data of the video frames comprised by at least the second sub-sequence are determined into the video sequence in question, and the sub-sequence will comprise information of all sub-sequences that have been directly used for predicting the image frame comprised by the sub-sequence in question, and this information is signaled in the bit stream of the video sequence, separate from the actual image information. The various prior art of record fails to anticipate or render obviousness the encoding of a first sub-sequence information to indicate the interdependency between sub-sequences or to indicate the type of frames, the type of layer, the number of sub-sequence in the layer, the order of frames in the sub-sequence (information of all sub-sequences that have been directly used for predicting the image frame comprised by the sub-sequence in question), and a similar second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from the at least one video frame of the first sub-sequence, and encoding into the video sequence information indicating which video frames belong to the second sub-sequence as specified in claims 1, 15, 16, 22, 23, 24 and 26.

Any comments considered necessary by applicant must be submitted no later than the payment of the issue fee and, to avoid processing delays, should preferably accompany the issue fee. Such submissions should be clearly labeled "Comments on Statement of Reasons for Allowance."

2. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of the foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided. Also attached is a copy of the English translation of the Japanese Office Action.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to

establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC
8500 Normandale Lake Blvd., Suite 320

NOTICE OF REASONS FOR REJECTION

(TRANSLATION)

Patent Application No.:	2006-120297
Drafting Date:	February, 2010
Patent Office Examiner:	Toshio Sakamoto 2954 5C00
Attorney for Patent Applicant:	Atsushi Aoki (and four others)
Applicable Provisions:	Article 29, paragraph 1; Article 29, paragraph 2; Article 36

It is deemed that the present application should be rejected for the following reasons. An argument, if any, should be submitted within 3 months from the mailing date of this notice.

Reasons

a. The inventions described in the following claims of this application are inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 1, item 3 of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)

Claims: 1, 5, 9 to 10, and 13 to 14
Reference: 1

Remarks:

It is deemed that there is no difference between the inventions according to claims 1, 5, 9 to 10, 13, and 14 of the present application and the invention described in Reference 1 (refer to Reason b. below).

b. The inventions described in the following claims of this application are deemed ones which could easily have been made, prior to the filing of the patent application, by a person with ordinary skill in the art to which the inventions pertain, on the basis of the inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 2, of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)

Claims: 1 to 14
Reference: 1

Remarks:

Reference 1 describes a coder apparatus for interframe

predictive coding, wherein information of an editable point, which is the first coded picture of a closed GOPs, is multiplexed in a header area (specifically refer to paragraphs [0001] to [0003], [0032], and [0064]).

c. This application does not satisfy the requirements prescribed in Article 36, Paragraph 6, Item 2 of the Patent Law on the following point.

NOTE

(1) Claim 1 describes "at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order", however, it is unclear as to what image frame is referred by the "previous" image frame, therefore, the referential relationship as well as the temporal relationship among "at least one reference image frame", "the previous reference image frame in decoding order", and "at least one previous image frame" are unclear.

Specifically, it is unclear as to whether the above description means that one reference image frame is predictable from an image frame that is earlier in decoding order than said reference image frame, or that one reference image frame is predictable from an earlier image frame in decoding order, and said earlier image in decoding order is also predictable from an earlier image frame in decoding order.

The descriptions in claims 5, 9 to 10, 13, and 14 are likewise unclear.

(2) Claim 1 describes "the first image frame is an image frame of the independently decodable sequence of image frames which is to be decoded first in decoding order", however, it is unclear as to in what "first" is, for example, whether "first" means "first" in "the independently decodable sequence" or not, etc.

The descriptions in claims 3, 5, 7, 9, 10, and 12 to 14 are likewise unclear.

(3) Claim 9 describes "A computer program comprising computer program code for use with a computer, the computer program code comprising ... (snip) ..., wherein ... (snip) ..., characterized in that the computer program comprises code for ... (snip) ..., and wherein ... (snip) ...,being included in the sequence." However, it is unclear as to (i) how the terms "program" and "code" are distinguished from one another, and (ii) whether or not "program" is used to cause a computer to execute a process (refer to "Examination Guidelines for Patent and Utility Model" PART VII, Chapter 1, 1.1.1(2)(b)).

The same is true for claim 14.

Note that, if the above description of claim 9 is amended to read "A program in accordance with which a computer executes a process of coding ... (snip) ..., wherein the process comprises a step for V-ing ... (snip) ...", the above objection will overcome.

The same is true for claim 14.

If an amendment is made, it should be noted that no new matter can be added, and in an argument, the reasons that the amendments meet the requirements of the Patent Law should be

stated, identifying the relevant descriptions of the original specification on which the amendments are based.

If another reason for rejection is found, a further notice of reasons for rejection will be issued.

H04N 7/26 (2006.01)

H04L 13/08 (2006.01)

(57)

1. A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, characterized by

decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames;

configuring in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. A method according to claim. 1, characterized in that said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional.

3. A method according to claim 1, characterized by further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

4. A method according to claim 1, characterized in that the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. A method according to claim 1 characterized by further comprising

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames.

6. A method according to claim 1, characterized by further comprising

entering into the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames.

7. A method according to claim 6 characterized in that said filler frames are designated by an identifier indicating that the filler frames do not belong to the actual video sequence.

8. A method according to claim 1, characterized in that the step of configuring the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. A. method according to claim 3 or 6, characterized by further comprising

detecting an error in the compressed video sequence on the basis of a reference in the decoding process to an image frame corresponding to a discontinuity in the numbering of image frames.

10. A video decoder for decoding a compressed video sequence,

the video decoder being, connected to a buffer memory wherein image frames are entered in connection with the decoding, characterized in that the video decoder is arranged to

decode from the video sequence an indication related to at least one discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. A video decoder according to claim 10, characterized in that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

12. A video decoder according, to claim 10, characterized in that the video decoder is further arranged to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

13. A video decoder according to claim 10 characterized in that the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. A video decoder according to claim 10, characterized in that the video decoder is further arranged to

continue the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames.

15. A video decoder according to claim 10, characterized in that the video decoder is further arranged to

enter into the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames.

16. A video decoder according to claim 15, characterized in that

said filler frames are designated by an identifier indicating that the filler frames do not belong to the actual video sequence.

17. A video decoder according to any of the claims 10, characterized in that the video decoder is further arranged to

configure the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. A computer readable medium having computer program code stored thereon and executable in a data processing device, the computer program code for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, characterized in that the computer program code comprises

a computer program code for decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. A computer readable medium according to claim 18, characterized in that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

20. A computer readable medium according to claim 18, characterized in that the computer program product further comprises

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

21. A computer readable medium according to claim 18, characterized in that the computer program product further comprises

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. A computer readable medium according to claim 18, characterized in that the computer readable medium, further comprises

a computer program code for continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames.

23. A computer readable medium according to claim 18, characterized in that the computer readable medium further comprises

a computer program code for entering into the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames.

24. A computer readable medium according to claim 23 characterized in that the computer readable medium further comprises

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the actual video sequence.

26. A computer readable medium according to claim 18, characterized in that the computer readable medium further comprises a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image frames by memory indications, whereby no data is enterer, into the buffer memory.

28. A video encoder for encoding a video sequence, characterized in that the video encoder is arranged to

encode the video sequence such that at least one image frame is excluded from the video sequence, causing a discontinuity in the numbering of image frames, and

encode into the video sequence an indication related to the discontinuity of numbering of the image frames.

27. A video encoder according to claim 26, characterized in that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

28. A device for adjusting bit rate of a video sequence, the device being arranged to receive an encoded video sequence, characterized in that the device is further arranged to

exclude at least one image frame from the video sequence, thereby causing a discontinuity in the numbering of image frames, and

include into the video sequence an indication related to the discontinuity of numbering of the image frames.

29. A device according to claim 28, characterized in that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

30. A video signal comprising a compressed video sequence comprising image frames, characterized in that the video signal comprises

an indication related to the discontinuity of numbering of the image frames in the transmitted video signal,

wherein the indication informs a decoder to use in a decoding process a number of image frames corresponding to the discontinuity in the numbering of the image frames.

31. A video signal according to claim 30, characterized in that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

(54) GROUPING OF IMAGE FRAMES IN VIDEO CODING

Abstract

(57) The invention relates to the grouping multimedia files, in particular, video files for using in streaming. The technical result is to provide possibility for decoder to take into account frames which a coder has deleted. The indicated technical result is achieved by that the method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding. The video sequence includes an indication related to at least one discontinuity of numbering of the image frames; the indication is decoded from the video sequence. Further in response to the indication, the buffer memory is configured to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames, and the image frames are used in the buffer memory in the decoding process. Preferably the indication informs that at least one discontinuity in the numbering of the image frames in the video sequence is intentional, and the number of image frames is used in the buffer memory in place of image frames that do not exist at a decoder.

1. Способ декодирования сжатой видеопоследовательности, при этом кадры изображения вводятся в буферную память в связи с декодированием, отличающийся тем, что содержит этапы, на которых декодируют из видеопоследовательности индикацию, относящуюся к по меньшей мере одному разрыву в нумерации кадров изображения; конфигурируют, в ответ на эту индикацию, буферную память так, чтобы она обеспечивала количество кадров изображения, соответствующее разрыву в нумерации кадров изображения; и используют кадры изображения в буферной памяти в процессе декодирования.

2. Способ по п.1, отличающийся тем, что упомянутая индикация информирует о том, что по меньшей мере один разрыв в нумерации кадров изображения в видеопоследовательности является преднамеренным.

3. Способ по п. 1, отличающийся тем, что дополнительно содержит этап, на котором используют упомянутое количество кадров изображения в буферной памяти вместо кадров изображения, которых нет на декодере вследствие разрывов в нумерации кадров изображения.

4. Способ по п. 1, отличающийся тем, что упомянутое количество кадров изображения в буферной памяти используется при буферизации кадров изображения по принципу скользящего окна.

5. Способ по п. 1, отличающийся тем, что дополнительно содержит этап, на котором продолжают ввод в буферную память кадров изображения, содержащихся в рассматриваемой видеопоследовательности, начиная с правильного номера кадра изображения, после того как буферная память сконфигурирована так, чтобы она обеспечивала количество кадров изображения, соответствующее разрывам в нумерации кадров изображения.

6. Способ по п. 1, отличающийся тем, что дополнительно содержит этап, на котором вводят в буферную память количество заполняющих кадров, соответствующее разрывам в нумерации кадров изображения.

7. Способ по п. 6, отличающийся тем, что упомянутые заполняющие кадры обозначены идентификатором, указывающим, что заполняющие кадры не принадлежат фактической видеопоследовательности.

8. Способ по п. 1, отличающийся тем, что этап конфигурирования буферной памяти так, чтобы она обеспечивала количество кадров изображения, соответствующее разрывам в нумерации кадров изображения, выполняют посредством индикаторов памяти, при этом никакие данные в буферную память не вводятся.

9. Способ по п. 3 или 6, отличающийся тем, что дополнительно содержит этап, на котором обнаруживают ошибку в сжатой видеопоследовательности на основе ссылки в процессе декодирования на кадр изображения, соответствующий разрыву в нумерации кадров изображения.

10. Видеодекодер для декодирования сжатой видеопоследовательности, при этом видеодекодер соединен с буферной памятью, в которую вводятся кадры изображения в связи с декодированием, отличающийся тем, что выполнен с возможностью декодирования из видеопоследовательности индикации, относящейся к по меньшей мере одному разрыву в нумерации кадров изображения; конфигурирования, в ответ на эту индикацию, буферной памяти так, чтобы она обеспечивала количество кадров изображения, соответствующее разрыву в нумерации кадров изображения; и использования кадров изображения в буферной памяти в процессе декодирования.

11. Видеодекодер по п. 10, отличающийся тем, что упомянутая индикация информирует о том, что разрывы в нумерации кадров изображения в видеопоследовательности являются преднамеренным.

12. Видеодекодер по п. 10, отличающийся тем, что дополнительно выполнен с возможностью использования упомянутого количества кадров

изображения в буферной памяти вместо кадров изображения, которых нет на декодере вследствие разрывов в нумерации кадров изображения.

13. Видеодекодер по п. 10, отличающийся тем, что упомянутое количество кадров изображения в буферной памяти используется при буферизации кадров изображения по принципу скользящего окна.

14. Видеодекодер по п. 10, отличающийся тем, что дополнительно выполнен с возможностью продолжать ввод в буферную память кадров изображения, содержащихся в рассматриваемой видеопоследовательности, начиная с правильного номера кадра изображения, после того как буферная память сконфигурирована так, чтобы она обеспечивала количество кадров изображения, соответствующее разрывам в нумерации кадров изображения.

15. Видеодекодер по п.10, отличающийся тем, что дополнительно выполнен с возможностью ввода в буферную память количества заполняющих кадров, соответствующего разрывам в нумерации кадров изображения.

16. Видеодекодер по п.15, отличающийся тем, что упомянутые заполняющие кадры обозначены идентификатором, указывающим, что заполняющие кадры не принадлежат фактической видеопоследовательности.

17. Видеодекодер по п.10, отличающийся тем, что дополнительно выполнен с возможностью конфигурирования буферной памяти так, чтобы она обеспечивала количество кадров изображения, соответствующее разрывам в нумерации кадров изображения, посредством индикаторов памяти, при этом никакие данные в буферную память не вводятся.

18. Машиночитаемый носитель, на котором хранится исполняемый в устройстве обработки данных компьютерный программный код, предназначенный для декодирования сжатой видеопоследовательности, при этом кадры изображения упомянутой видеопоследовательности вводятся буферную память в связи с декодированием, отличающийся тем, что компьютерный программный код содержит компьютерный программный код для декодирования из видеопоследовательности индикации, относящейся к по меньшей мере одному разрыву в нумерации кадров изображения; компьютерный

программный код для конфигурирования, в ответ на эту индикацию, буферной памяти так, чтобы она обеспечивала количество кадров изображения, соответствующее разрыву в нумерации кадров изображения; и компьютерный программный код для включения кадров изображения в буферную память в процессе декодирования.

19. Машиночитаемый носитель по п.18, отличающийся тем, что упомянутая индикация информирует о том, что разрывы в нумерации кадров изображения в видеопоследовательности являются преднамеренным.

20. Машиночитаемый носитель по п.18, отличающийся тем, что дополнительно содержит компьютерный программный код для включения упомянутого количества кадров изображения в буферную память вместо кадров изображения, которых нет на декодере вследствие разрывов в нумерации кадров изображения.

21. Машиночитаемый носитель по п. 18, отличающийся тем, что дополнительно содержит компьютерный программный код для использования упомянутого количества кадров изображения в буферной памяти при буферизации кадров изображения по принципу скользящего окна.

22. Машиночитаемый носитель по п.18, отличающийся тем, что дополнительно содержит компьютерный программный код для продолжения ввода в буферную память кадров изображения, содержащихся в рассматриваемой видеопоследовательности, начиная с правильного номера кадра изображения, после того как буферная память сконфигурирована так, чтобы она обеспечивала количество кадров изображения, соответствующее разрывам в нумерации кадров изображения.

23. Машиночитаемый носитель по п. 18, отличающийся тем, что дополнительно содержит компьютерный программный код для ввода в буферную память количества заполняющих кадров, соответствующего разрывам в нумерации кадров изображения.

24. Машиночитаемый носитель по п.23, отличающийся тем, что дополнительно содержит компьютерный программный код для обозначения

упомянутых заполняющих кадров идентификатором, указывающим, что заполняющие кадры не принадлежат фактической видеопоследовательности.

25. Машиночитаемый носитель по п.18, отличающийся тем, что дополнительно содержит компьютерный программный код для конфигурирования буферной памяти так, чтобы она обеспечивала количество кадров изображения, соответствующее разрывам в нумерации кадров изображения, посредством индикаторов памяти, при этом никакие данные в буферную память не вводятся.

26. Видеокодер для кодирования видеопоследовательности, отличающийся тем, что выполнен с возможностью кодирования видеопоследовательности так, что по меньшей мере один кадр изображения исключен из видеопоследовательности, что приводит к разрыву в нумерации кадров изображения, и кодирования в видеопоследовательность индикации, относящейся к упомянутому разрыву в нумерации кадров изображения.

27. Видеокодер по п. 2 6, отличающийся тем, что упомянутая индикация информирует о том, что разрывы в нумерации кадров изображения в видеопоследовательности являются преднамеренным.

28. Устройство для регулирования скорости передачи в битах видеопоследовательности, выполненное с возможностью приема закодированной видеопоследовательности, отличающееся тем, что дополнительно выполнено с возможностью исключения по меньшей мере одного кадра изображения из видеопоследовательности, тем самым обуславливая разрыв в нумерации кадров изображения, включения в видеопоследовательность индикации, относящейся к упомянутому разрыву в нумерации кадров изображения.

29. Устройство по п. 28, отличающееся тем, что упомянутая индикация информирует о том, что разрывы в нумерации кадров изображения в видеопоследовательности являются преднамеренным.

30. Видеосигнал, содержащий сжатую видеопоследовательность, содержащую кадры изображения, отличающийся тем, что содержит индикацию, относящуюся к разрыву в нумерации кадров изображения в передаваемом

видеосигнале, при этом данная индикация информирует декодер о необходимости использования количества кадров изображения, соответствующего упомянутому разрыву в нумерации кадров изображения, в процессе декодирования.

31. Видеосигнал по п. 30, отличающийся тем, что упомянутая индикация информирует о том, что разрывы в нумерации кадров изображения в видеопоследовательности являются преднамеренным.

(54) ГРУППИРОВАНИЕ КАДРОВ ИЗОБРАЖЕНИЯ НА ВИДЕО КОДИРОВАНИИ

Реферат

(57) Изобретение относится к группированию мультимедийных файлов, в частности, видео файлов для использования в потоковой передачи. Техническим результатом является обеспечение декодеру возможности учитывать кадры изображения, которые кодер намеренно удалил. Указанный технический результат достигается тем, что способ декодирования сжатой видеопоследовательности, при этом кадры изображения вводятся в буферную память в связи с декодированием. Видеопоследовательность включает в себя индикацию, относящуюся к по меньшей мере одному разрыву в нумерации кадров изображения, причем данная индикация декодируется из видеопоследовательности. Далее, в ответ на эту индикацию буферная память конфигурируется так, чтобы она обеспечивала количество кадров изображения, соответствующее разрыву в нумерации кадров изображения, и кадры изображения в буферной памяти используются в процессе декодирования. Предпочтительно, упомянутая индикация информирует о том, что по меньшей мере один разрыв в нумерации кадров изображения в видеопоследовательности является преднамеренным, и упомянутое количество кадров изображения используется в буферной памяти вместо кадров изображения, которых нет на декодере. 6 н.п., 25 з.п. ф-лы, 14 ил.

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *25 January 2006*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-31* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *1-6 and 10-31* is/are rejected.

7)☒ Claim(s) *7-9* is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *25 January 2006* is/are: a)☐ accepted or b)☒ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☒ Certified copies of the priority documents have been received in Application No. 10/306942.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

DETAILED ACTION

Claim Objections

1. Claims 1, 5, 9, 10, 14, 18, 22, 24, 26, 28, and 30 are objected to because of the following informalities:

(1) Regarding claim 1:

Line 4 recites “decoding from the video sequence an indication”; the examiner assumes "the video sequence" is referring to the compressed video sequence in line 1. The examiner suggests changing "the video sequence" in line 4 to "the **compressed** video sequence” for clarification.

Lines 7-8 recites “corresponding to a discontinuity in the numbering of the image frames”; the examiner assumes “a discontinuity in the numbering” is refer to the “at least one discontinuity of numbering” referred in lines 4-5. The examiner suggests changing “a discontinuity” in line 7 to “the discontinuity”.

(2) Regarding claim 5:

Lines 2-3 recite “the video sequence in question”; there is a lack of antecedent basis for this imitation.

Line 3 recites “the correct image frame number”; there is a lack of antecedent basis for this limitation.

(3) Regarding claim 9:

Line 2 recites “the basis” there is a lack of antecedent basis for this limitation.

(4) Regarding claim 10:

Line 5 recites “decoding from the video sequence an indication”; the examiner assumes "the video sequence" is referring to the compressed video sequence in line 1. The examiner suggests changing "the video sequence" in line 4 to "the **compressed** video sequence” for clarification.

Lines 8-9 recites “corresponding to a discontinuity in the numbering of the image frames”; the examiner assumes “a discontinuity in the numbering” is refer to the “at least one discontinuity of numbering” referred in lines 4-5. The examiner suggests changing “a discontinuity” in line 7 to “the discontinuity”.

(5) Regarding claim 14:

Lines 3-4 recite “the video sequence in question”; there is a lack of antecedent basis for this imitation.

Line 4-5 recite “the correct image frame number”; there is a lack of antecedent basis for this limitation.

(6) Regarding claim 18:

Line 11 recites “corresponding to a discontinuity in the numbering of the image frames”; the examiner assumes “a discontinuity in the numbering” is refer to the “at least one discontinuity of numbering” referred in lines 7. The examiner suggests changing “a discontinuity” in line 7 to “the discontinuity”.

(7) Regarding claim 22:

Line 4 recites “the video sequence in question”; there is a lack of antecedent basis for this limitation.

Line 5 recites “the correct image frame number”; there is a lack of antecedent basis for this limitation.

(8) Regarding claim 24:

Lines 4-5 recite “the actual video sequence”; there is a lack of antecedent basis for this limitation.

(9) Regarding claim 26:

Lines 4-5 recite "the numbering of image frames"; there is a lack of antecedent basis for this limitation.

(10) Regarding claim 28

Line 5 recites "the numbering of image frames"; there is a lack of antecedent basis for this limitation.

(11) Regarding claim 30:

Line 3 recites “the discontinuity of numbering of the image”; there is a lack of antecedent basis for this limitation.

Line 4 recites “the transmitted video signal”; there is a lack of antecedent basis for this limitation.

Appropriate correction is required.

Drawings

2. The drawings are objected to because Figure 1 does not have sufficiently descriptive labels. Blank boxes in drawings should be labeled descriptively unless it is a well-known component. For example, the blank box, "100" should be labeled as

"Multimedia Source". Corrected drawing sheets in compliance with 37 CFR 1.121(d) are required in reply to the Office action to avoid abandonment of the application. Any amended replacement drawing sheet should include all of the figures appearing on the immediate prior version of the sheet, even if only one figure is being amended. The figure or figure number of an amended drawing should not be labeled as "amended." If a drawing figure is to be canceled, the appropriate figure must be removed from the replacement sheet, and where necessary, the remaining figures must be renumbered and appropriate changes made to the brief description of the several views of the drawings for consistency. Additional replacement sheets may be necessary to show the renumbering of the remaining figures. Each drawing sheet submitted after the filing date of an application must be labeled in the top margin as either "Replacement Sheet" or "New Sheet" pursuant to 37 CFR 1.121(d). If the changes are not accepted by the examiner, the applicant will be notified and informed of any required corrective action in the next Office action. The objection to the drawings will not be held in abeyance.

Claim Rejections - 35 USC § 101

3. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

Claims 10-17 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "video decoder" is non-structural per se and because the specification discloses a "software" embodiment (page 6,

paragraph 0015 and page 33, paragraph 0097). Therefore, a reasonable interpretation in light of the specification leads to the conclusion that the claim video decoder as pure software, which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claims 18-25 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claim is drawn to a "computer program product stored in a computer readable medium". The specification does not define the computer readable medium, therefore, it includes transitory and non-transitory computer readable medium. The broadest reasonable interpretation of the claim in light of the specification concludes that the claim as a whole covers a transitory signal, which does not fall within the definition of a process, machine, manufacture, or composition of matter (In re Nuijten). Therefore, claim 18-25 do not fall within a statutory category (the rejection can be overcome by specifying the computer readable medium as "non-transitory computer readable medium").

Claims 26-27 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "video encoder" is non-structural per se and because the specification discloses a "software" embodiment (page 6, paragraph 0015 and page 33, paragraph 0097). Therefore, a reasonable interpretation in light of the specification leads to the conclusion that the claim video decoder as pure

software, which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claims 28-29 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "device" is non-structural per se and because the specification discloses a "software" embodiment (page 6, paragraph 0015 and page 33, paragraph 0097). Therefore, a reasonable interpretation in light of the specification leads to the conclusion that the claim video decoder as pure software, which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claims 30-31 are directed to a "video signal"; a signal is not limited to that which falls within a statutory category of invention because it is not limit to a process, machine, manufacture, or a composition of matter. Instead, it includes a form of energy. Energy does not fall with in a statutory category since it is clearly not a series of steps or acts to constitute a process, not a mechanical device or combination of mechanical device to constitute a machine, not a tangible physical article or object which is some form of matter to be a product and constitute a manufacture, and not a composite of two or more substances to constitute a composite of matter.

Claim Rejections - 35 USC § 112

4. The following is a quotation of the first paragraph of 35 U.S.C. 112:

> The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the

art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

Claims 26-27 are rejected under 112, 1st paragraph as being a single component (video encoder) claim, i.e., where a single component (video encoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Claims 28-29 are rejected under 112, 1st paragraph as being a single component (device) claim, i.e., where a single component (device) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Double Patenting

5. The nonstatutory double patenting rejection is based on a judicially created doctrine grounded in public policy (a policy reflected in the statute) so as to prevent the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees. A nonstatutory obviousness-type double patenting rejection is appropriate where the conflicting claims are not identical, but at least one examined application claim is not patentably distinct

from the reference claim(s) because the examined application claim is either anticipated by, or would have been obvious over, the reference claim(s). See, e.g., *In re Berg*, 140 F.3d 1428, 46 USPQ2d 1226 (Fed. Cir. 1998); *In re Goodman*, 11 F.3d 1046, 29 USPQ2d 2010 (Fed. Cir. 1993); *In re Longi*, 759 F.2d 887, 225 USPQ 645 (Fed. Cir. 1985); *In re Van Ornum*, 686 F.2d 937, 214 USPQ 761 (CCPA 1982); *In re Vogel*, 422 F.2d 438, 164 USPQ 619 (CCPA 1970); and *In re Thorington*, 418 F.2d 528, 163 USPQ 644 (CCPA 1969).

A timely filed terminal disclaimer in compliance with 37 CFR 1.321(c) or 1.321(d) may be used to overcome an actual or provisional rejection based on a nonstatutory double patenting ground provided the conflicting application or patent either is shown to be commonly owned with this application, or claims an invention made as a result of activities undertaken within the scope of a joint research agreement.

Effective January 1, 1994, a registered attorney or agent of record may sign a terminal disclaimer. A terminal disclaimer signed by the assignee must fully comply with 37 CFR 3.73(b).

6. Claims 1-5 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim	Instant application	Claim	Co-pending application 10/306942

1	A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising: decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and using the image frames in the buffer memory in the decoding process.	17	(including limitation of claim 16) Claim 16 A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising: decoding, at a decoder, a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format; decoding, at the decoder, at least a second sub-sequence of the

10	A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being arranged to decode from the video sequence an indication related to at least one discontinuity of numbering of the image frames; configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and use the image frames in the buffer memory in the decoding process.		video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; determining, at the decoder, dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and reconstructing, at the decoder, at least part of the video sequence on the basis of the dependencies of the sub-sequences. Claim 17 A method according to claim 16, **wherein video frames are entered into a sliding buffer**

			memory in connection with decoding, further comprising: **decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional**; **configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers**; and continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to

			the missing image numbers.

(1) Regarding claim 1:

Claim 17 of the copending application discloses decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; and configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames (the bold and underlined part in the above table).

The co-pending application does not explicitly disclose using the image frame in the buffer memory in the decoding process.

However, claim 17 also discloses wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

(2) Regarding claim 2:

Claim 17 further disclose wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

(3) Regarding claim 3:

The co-pending application does not explicitly discloses using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

However, claim 17 discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

As the video frames are enter into a sliding buffer memory in connection with decoding, it is obvious that the comprise number of image frames corresponding to the missing image number are used in the decoding process in place of the missing frame number to provide a benefit of performing decoding with a continuous sequence number.

(4) Regarding claim 4:

Claim 17 further disclose the number of image frames in the buffer memory are used in sliding window buffering of image frame (wherein video frames are entered into a sliding buffer memory in connection with decoding).

(5) Regarding claim 5:

Clam 17 further discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames (continuing the entering of the image frames comprised by the video sequence in

question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, claim 17).

7. Claim 6 is provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 18 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim 17 discloses all subject matter as discussed in above and claim 18 of the co-pending application depends on claim 17 and further disclose entering onto the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames (entering into the buffer memory a number of filler frames corresponding to the missing image number, claim 18).

8. Claims 10-14 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending Application No. 10/306942.

(1) Regarding claim 10:

Claim 17 of the copending application discloses decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; and configuring, in response to the indication, the buffer memory to provide a

number of image frames corresponding to a discontinuity in the numbering of the image frames (the bold and underlined part in the above table).

The co-pending application does not explicitly disclose (a) using the image frame in the buffer memory in the decoding process; and (b) the decoding method is performed by a decoder.

With respect to (a), claim 17 also discloses wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

With respect to (b), since the claim is non-structural per se, and claim 17 discloses the decoding steps, it is inherently that the decoding method is performed by a decoder.

(2) Regarding claim 11:

Claim 17 further disclose wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

(3) Regarding claim 12:

The co-pending application does not explicitly discloses using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

However, claim 17 discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

As the video frames are enter into a sliding buffer memory in connection with decoding, it is obvious that the comprise number of image frames corresponding to the missing image number are used in the decoding process in place of the missing frame number to provide a benefit of performing decoding with a continuous sequence number.

(4) Regarding claim 13:

Claim 17 further disclose the number of image frames in the buffer memory are used in sliding window buffering of image frame (wherein video frames are entered into a sliding buffer memory in connection with decoding).

(5) Regarding claim 14:

Clam 17 further discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames (continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, claim 17).

9. Claim 15 is provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 18 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim 17 of the co-pending application discloses all subject matter as discussed in above and claim 18 of the co-pending application depends on claim 17 and further disclose entering onto the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames (entering into the buffer memory a number of filler frames corresponding to the missing image number, claim 18, since the claim is non-structural per se, and claim 17 discloses the decoding steps, it is inherently that the decoding method is performed by a decoder).

10. Claims 30-31 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending Application No. 10/306942.

(1) Regarding claim 30 (the examiner interprets the claimed signal as the received video sequence in claim 17 of the co-pending application):

Claim 17 of the copending application discloses an indication related to the discontinuity of numbering of the image frames in the transmitted video signal (decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence),

Claim 17 does not explicitly disclose the indication informs a decoder to use in a decoding process a number of image frames corresponding to the discontinuity in the numbering of the image frames.

However, claim 17 also discloses configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

(2) Regarding claim 31:

Claim 17 further disclose wherein said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

11. Claims 18-22 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending

Application No. 10/306942 in view of Langberg et al. (US 5,852,630, hereinafter Langberg).

(1) Regarding claim 18:

Claim 17 of the copending application discloses decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; and configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames (the bold and underlined part in the above table).

The co-pending application does not explicitly disclose (a) using the image frame in the buffer memory in the decoding process; and (b) the decoding method is perform by a computer program product stored on a computer readable medium and having program code to perform the method.

With respect to (a), claim 17 also discloses wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

With respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or

method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of claim 17 of the co-pending application would have been implemented in software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software in as taught by Langberg to implement the method of the co-pending application in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 19:

Claim 17 further disclose wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

(3) Regarding claim 20:

The co-pending application does not explicitly discloses using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

However, claim 17 discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

As the video frames are enter into a sliding buffer memory in connection with decoding, it is obvious that the comprise number of image frames corresponding to the

missing image number are used in the decoding process in place of the missing frame number to provide a benefit of performing decoding with a continuous sequence number.

(4) Regarding claim 21:

Claim 17 further disclose the number of image frames in the buffer memory are used in sliding window buffering of image frame (wherein video frames are entered into a sliding buffer memory in connection with decoding).

(5) Regarding claim 22:

Clam 17 further discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames (continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, claim 17).

12. Claim 23 is provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 18 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim 17 and Langberg discloses all subject matter as discussed in above and Claim 18 of the co-pending application depends on claim 17 and disclose entering onto the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames (entering into the buffer memory a number of filler frames corresponding to the missing image number, claim 18, since the claim is non-structural per se, and claim 17 discloses the decoding steps, it is inherently that the decoding method is performed by a decoder).

Claim Rejections - 35 USC § 103

13. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

14. Claims 26 and 27 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2).

Apostolopoulos discloses a video encoder for encoding a video sequence, the video encoder being arranged to:

encode the video sequence such that at least one image frame is exclude from the video sequence, causing a discontinuity in the numbering of image frames (encode 314 in figure 3 encode the odd frame of the original video frame 115, therefore, excluding the even frame of the original video frame 115 and causing a discontinuity in

the numbering of image frames, for example I_1, P_3, P_5, column 7, line 59 - column 8, lines 12).

Apostolopoulos does not explicitly disclose encode into the video sequence an indication related to the discontinuity of numbering of the image frames.

However, Apostolopoulos discloses that if encode block 316 generates P-frames in the encoded even frames 356 that carry motion estimation and error information according to prediction loop, then the decode block 320 uses the motion estimation and error information from the received P-frames in its own prediction loop to generate the reconstructed even video frames (column 8, lines 50-55) and encode block 314 generates the encoded odd frames 354 in response to the odd video frames 350, the encoded odd frames 354 includes I frames and P frames. In response to the example series $frame_1$, $frame_3$, $frame_5$, the encode block 314 may generate an I-frame I_1, follow by P-frames P_3, P_5, P_3 depends on I_1, and P_5 depends on P_3, column 7, lines 59-65.

Although Apostolopoulos does not explicitly disclose encode into the video sequence an indication related to the discontinuity of numbering of the image frames (missing of the even frames), it is obvious that the odd sequence would include an indication in the odd frame sequence for the dependency of P_3 to be depend on I_1, and P_5 depends on P_3, for the compensation for the missing even frames in the odd frame sequence, and also used in the decoding process.

It is desirable to encode into the video sequence an indication related to the discontinuity of numbering of the image frames because it enables diversity transmission of video stream. Therefore, it would have been obvious to one of ordinary

skill in the art at the time of invention to have an indication in the odd and even frame for the discontinuity of the numbering of frames to enable diversity transmission and improve reliability of the transmission (column 3, lines 42-44).

(2) Regarding claim 27:

Apostolopoulos further discloses that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional (for diversity transmission of video signal, even frames and odd frames are separated into two streams, therefore, it is intentional for the separation of frames, column 7, lines 38-52).

(3) Regarding claim 28:

Apostolopoulos discloses a device for being arranged to:

receive an encoded video sequence (frame separate 312 received the original video frame 115 as shown in figure 3, column 7, lines 38-45; the examiner interprets the original video frame as a encode video sequence);

exclude at least one image frame from the video sequence, thereby causing a discontinuity in the numbering of image frames (original video sequence is separated into odd frames and even frames and forward the odd frames to encode 314 as shown in figure 3, column 3, lines 62-65).

Apostolopoulos does not explicitly disclose include into the video sequence an indication related to the discontinuity of numbering of the image frames.

However, Apostolopoulos discloses that if encode block 316 generates P-frames in the encoded even frames 356 that carry motion estimation and error information according to prediction loop, then the decode block 320 uses the motion estimation and

error information from the received P-frames in its own prediction loop to generate the reconstructed even video frames (column 8, lines 50-55) and encode block 314 generates the encoded odd frames 354 in response to the odd video frames 350, the encoded odd frames 354 includes I frames and P frames. In response to the example series $frame_1$, $frame_3$, $frame_5$, the encode block 314 may generate an I-frame I_1, follow by P-frames P_3, P_5, P_3 depends on I_1, and P_5 depends on P_3, column 7, lines 59-65.

Although Apostolopoulos does not explicitly disclose encode into the video sequence an indication related to the discontinuity of numbering of the image frames (missing of the even frames), it is obvious that the odd sequence would include an indication in the odd frame sequence for the dependency of P_3 to be depend on I_1, and P_5 depends on P_3, for the compensation for the missing even frames in the odd frame sequence, and also used in the decoding process.

It is desirable to encode into the video sequence an indication related to the discontinuity of numbering of the image frames because it enables diversity transmission of video stream. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to have an indication in the odd and even frame for the discontinuity of the numbering of frames to enable diversity transmission and improve reliability of the transmission (column 3, lines 42-44).

(4) Regarding claim 29:

Apostolopoulos further discloses that said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional (for diversity

transmission of video signal, even frames and odd frames are separated into two streams, therefore, it is intentional for the separation of frames, column 7, lines 38-52).

Allowable Subject Matter

15. Claims 7-9 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Conclusion

16. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

Cuccia (US 2002/0051621 A1) discloses an instant replay of digital video optimized using non MPEG tags.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE *3* MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *31 March 2010*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-13,15-24,26 and 27* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *1-13,15,16,19,20,22,24,26 and 27* is/are rejected.

7)☒ Claim(s) *17,18 and 21* is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *29 December 2002* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

DETAILED ACTION

Claim Rejections - 35 USC § 112

1. The following is a quotation of the first paragraph of 35 U.S.C. 112:

> The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

2. Claims 2-10 are rejected under 35 U.S.C. 112, first paragraph, as failing to comply with the enablement requirement. The claim(s) contains subject matter which was not described in the specification in such a way as to enable one skilled in the art to which it pertains, or with which it is most nearly connected, to make and/or use the invention. Claim 2 recites “encoding said interdependency into the video sequence”, and because the claimed subject matter was not described in the specification in such a way as to enable one skilled in the art to which it pertains, or with which it is most nearly connected, to make and/or use the invention, Therefore the claims fail to comply with 35 U.S.C. 112, first paragraph.

Claim Rejections - 35 USC § 102

3. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.

4. Claims 1, 11-13, 15-16, 19-20, 22-24 and 26-27 are rejected under 35 U.S.C. 102(b) as being anticipated by Nitta et al (US 6,363,208 B2).

Nitta et al discloses a digital signal reproduction method and apparatus comprising the same method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format (fig. 2A, I = Intra coding; and P = inter coding), the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames (1st format: I and/or P; 2nd format P and/or B), the method comprising:

encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format (1ST frame of the GOP is intra-frame coded of fig. 2A);

encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence(2 nd frame of the GOP is inter-frame coded); and

encoding, at the encoder, into the video sequence information indicating which video frames belong to the second sub-sequence (any inter-coded frame (P or B) is considered belonging to the second sub-sequence and col. 1, ln. 44-56) as specified in claims 1, 15-16, 22-24 and 26; wherein the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference

image (MPEG-2 GOP, I, P, B frames) as specified in claim 11; further comprising: coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping (Forward and/or backward P frame(s) and B frame(s)) as specified in claim 12; further comprising: coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific (MPEG-2 Predictive Coding uses 8 X 8 macroblock) as specified in claim 13; further comprising: initiating the decoding from a random point in the video sequence (beginning of any GOP); determining an independently decodable sub-sequence that is next after the random point (Intra-coded frame and/or inter-coded frames), and setting the value of the image number of the first video frame in the sub-sequence at zero (the 1st frame of the GOP is identified as I sub 0) as specified in claim 20; and a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly (removal of P or B frame would not cause the incorrect decoding of I frame) as specified in claims 19 and 27.

Allowable Subject Matter

5. Claims 17-18 and 21 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Conclusion

6. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

DETAILED ACTION

Claim Rejections - 35 USC § 112

1. The following is a quotation of the first paragraph of 35 U.S.C. 112:

> The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

2. Claims 2-10 are rejected under 35 U.S.C. 112, first paragraph, as failing to comply with the enablement requirement. The claim(s) contains subject matter which was not described in the specification in such a way as to enable one skilled in the art to which it pertains, or with which it is most nearly connected, to make and/or use the invention. Claim 2 recites "encoding said interdependency into the video sequence", and because the claimed subject matter was not described in the specification in such a way as to enable one skilled in the art to which it pertains, or with which it is most nearly connected, to make and/or use the invention, Therefore the claims fail to comply with 35 U.S.C. 112, first paragraph.

Claim Rejections - 35 USC § 102

3. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.

4. Claims 1, 11-13, 15-16, 19-20, 22-24 and 26-27 are rejected under 35 U.S.C. 102(b) as being anticipated by MPEG-2 Predictive Coding Protocol.

MPEG-2 Predictive Coding discloses the same method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format (MPEG-2 Predictive Coding, Intra and inter coding), the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames (1st format: I and/or P; 2nd format P and/or B), the method comprising:

encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format (1ST frame of the GOP is intra-frame coded);

encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence(2 nd frame of the GOP is inter-frame coded); and

encoding, at the encoder, into the video sequence information indicating which video frames belong to the second sub-sequence (any inter-coded frame (P or B) is considered belonging to the second sub-sequence) as specified in claims 1, 15-16, 22-24 and 26; wherein the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image (MPEG-2 GOP, I, P, B frames) as specified in claim 11; further comprising: coding the sub-sequences in

such a way that at least some of the sub-sequence frames are temporally at least partly overlapping (Forward and/or backward P frame(s) and B frame(s)) as specified in claim 12; further comprising: coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific (MPEG-2 Predictive Coding uses 8 X 8 macroblock) as specified in claim 13; further comprising: initiating the decoding from a random point in the video sequence (beginning of any GOP); determining an independently decodable sub-sequence that is next after the random point (Intra-coded frame and/or inter-coded frames), and

setting the value of the image number of the first video frame in the sub-sequence at zero (the 1st frame of the GOP is identified as Io) as specified in claim 20; and a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly (removal of P or B frame would not cause the incorrect decoding of I frame) as specified in claims 19 and 27.

Allowable Subject Matter

5. Claims 17-18 and 21 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Conclusion

6. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

a. Lyons et al (US 6,330,286) discloses a flow control, latency control, and bitrate conversions in a timing correction and frame synchronization apparatus.

b. Radha et al (US 6,806,909) discloses seamless splicing of MPEG-2 multimedia data streams.

7. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). DETAILED ACTION

1. Claim 14 is cancelled as per paragraph of the previous Office Action mailed out on 9/11/2007.

Claim Rejections - 35 USC § 101

2. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

3. Claims 1-13, 16-21 and 26-27 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter.

Regarding to claims 1-13, 16-21 and 26-27, which are method claims, and that the claims do not fall within one of the four statutory categories of inventions. Supreme Court precedent and recent Federal Circuit decisions indicate a statutory "process" under 35 U.S.C. 101 must (1) be tied to another statutory category (such as a particular apparatus), or (2) transform underlying subject matter (such as an article or material) to a different state or thing. While the instant claim(s) recite a series of steps or acts to be performed, it is considered that none of the steps in the claims positively recites the other statutory class (the thing or product) to which it is tied, for example, by identifying the apparatus that accomplishes the method steps, In re Bilski, 88 USPQ2d 1385 (Fed. Cir. 2008).

Allowable Subject Matter

4. Claims 15, 22-24 are allowed.

Conclusion

5. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Nhon T. Diep whose telephone number is 571-272-7328. The examiner can normally be reached on m-f.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Mehrdad Dastouri can be reached on 571-272-7418. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

RESPONSE TO RESTRICTION REQUIREMENT AND PRELIMINARY AMENDMENT

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Examiner's requirement for restriction dated March 16, 2006, the claims of Group I (Claims 1-13 and 15-25) are provisionally elected *with traverse*. The Applicant respectfully requests reconsideration and withdrawal of the requirement for restriction, for reasons set forth below. The Applicant respectfully requests reconsideration and allowance of all pending claims.

Claims 26 and 27 have been added. Authorization is given to charge Deposit Account No. 50-3581 (TAPA.004PA) in the amount of $300.00 for the two additional claims added by this filing. Authorization is also given to charge/credit Deposit Account No. 50-3581 (TAPA.004PA) for any deficiencies/overpayments.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 10 of this paper.

Listing of Claims:

1. (Original) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence.

2. (Original) A method according to claim 1, further comprising

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

3. (Original) A method according to claim 2, further comprising

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

- a video frame of a higher scalability layer,
- a video frame of another sub-sequence in the same scalability layer.

4. (Original) A method according to claim 3, further comprising

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame on the basis of the image number.

9. (Original) A method according to claim 7, further comprising

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. (Original) A method according to claim 7, further comprising

adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence.

11. (Original) A method according to claim 1, wherein

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

12. (Original) A method according to claim 1, further comprising

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

13. (Original) A method according to claim 1, further comprising

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

14. (Original) An element in a streaming system, such as a streaming server or a network element in a telecommunications system, wherein said element is arranged to

transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission,

control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

- at least one sub-sequence is removed from the video sequence,
- at least one sub-sequence is added to the video sequence.

15. (Original) A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame

of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

16. (Original) A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

17. (Original) A method according to claim 16, wherein video frames are entered into a sliding buffer memory in connection with decoding, further comprising

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

18. (Original) A method according to claim 17, further comprising

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

19. (Original) A method according to claim 16, further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

20. (Original) A method according to claim 16, further comprising

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

21. (Original) A method according to claim 16, further comprising

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

22. (Original) A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video

frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. (Original) A computer program for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

24. (Original) A computer program for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second

frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

25. (Original) A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

26. (New) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format;

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence, wherein subsequence information is different from picture type information.

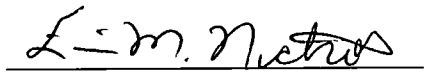
27. (New) A method according to claim 26, wherein

a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly.

REMARKS/ARGUMENTS

The election/restriction requirement dated March 16, 2006, has been considered. The Examiner contends that the claims are drawn to two inventions, namely Group I (Claims 1-13 and 15-25) and Group II (Claim 14) and asserts that restriction to one of claim Groups I-II is required under 35 U.S.C. §121. The claims of **Group I (Claims 1-13 and 15-25)** are provisionally elected *with traverse*. The Applicant traverses the restriction requirement as it fails to satisfy the requirements for maintaining such a restriction requirement and accordingly requests reconsideration and withdrawal of the restriction requirement.

The election/restriction requirement asserts that the claims of Groups I and II are unrelated. It appears that the Examiner is asserting that the claims of the two Groups are independent based upon the reliance on §§802.01 and 806.06 of the MPEP. Specifically, §806.06 indicates that two inventions are independent if there is no disclosed relationship between the inventions, that is, they are unconnected in design, operation, and effect. The standard for showing that two inventions are independent is difficult to prove, for example, a specific process of molding would be independent from a molding apparatus so long as the apparatus cannot be used to practice the specific process. The Examiner's assertion that the claims of Group I are directed to forming a scalable, compressed video sequence, whereas the claim of Group II is directed to control of the bit rate of the compressed video packets for transmission, fails to identify how the two alleged inventions are disclosed as not capable of use together. The Examiner fails to provide any evidence to support the conclusion that the two alleged inventions are independent. Without any such evidence, the restriction requirement is improper. Accordingly, the Applicant requests that the restriction requirement be withdrawn.



New Claims 26 and 27 have been added. Claim 26 largely replicates Claim 1 and is believed to be directed to a similar invention if the above election/restriction requirement is maintained; therefore, the new claims are believed to be associated with the Examiner's asserted Group I.

CONCLUSION

In view of the above, the Applicant respectfully requests reconsideration and withdrawal of the requirement for restriction. If the Examiner would find it helpful to discuss this issue by telephone, the undersigned attorney of record invites the Examiner to contact the attorney of record.

Respectfully submitted,

Spatially Scalable Video Compression Employing Resolution Pyramids

Klaus Illgner and Frank Müller

Abstract— **In this paper, a spatially scalable video coding scheme for low bit rates is proposed. The codec is especially well suited for communications applications because it is based on motion-compensated predictive coding which provides the necessary low-delay property. The frames to be coded are decomposed into a Gaussian pyramid. Motion estimation and compensation are performed between corresponding pyramid levels of successive frames. We show that, to fulfill specific needs of spatial scalability, the motion compensation on each level must result in compatible prediction errors (displaced frame differences, DFD). Compatibility of the prediction errors means that the pyramid formed by independently obtained DFD's (the DFD pyramid) is close to a Gaussian pyramid decomposition of the DFD of the highest resolution level. From the DFD pyramid, a least squares Laplacian pyramid is derived, which is quantized and coded. The DFD encoder outputs an embedded bit stream. Thus, the coder control may truncate the bit stream at any point, and can keep a fixed rate. The motion vector fields obtained at the different resolution levels are also encoded by employing a pyramid approach. Simulation results show that the proposed coder achieves a coding gain compared to simulcast coding.**

Index Terms—**Laplacian pyramid, multiresolution pyramid, scalable motion compensation, spline filter, video compression.**

I. Introduction

THE rapid development of networks leads to increasing interest in video communications. All current standards for communications-related video compression (H.261, H.263) are based on a single resolution hybrid (i.e., motion-compensated predictive) coding scheme. However, bandwidth limitations, multipoint operation with receivers of different capabilities, and bandwidth-dependent charging are good reasons to use scalable coding schemes. Also, MPEG-4 announced strong demands for scalable video coding algorithms.

The term *scalability* is ambiguous because it is used in a spatial, temporal, or SNR context. In this paper, the focus is on spatial multiresolution schemes since this is an essential prerequisite to provide the property of *spatial* scalability. This means that the receiver can reconstruct frames of smaller spatial resolution using only a subset of the complete bit stream, thus fulfilling the above-mentioned demands.

In search of an appropriate coding principle, spatiotemporal subband or wavelet approaches are problematic because the coding delay must be kept as small as possible for communications applications. A promising approach is therefore to extend the classical hybrid coding principle, which is the basis of most coding schemes for communications, to fulfill the needs of spatial scalability.

Known multiresolution approaches based on the hybrid coding principle utilize several DPCM loops on different resolution levels. The design objective of a spatially scalable video codec is to find optimal predictions for each resolution level. However, this task cannot be solved straightforwardly because the prediction errors have to be coded efficiently. This can be accomplished only by exploiting the dependencies between the different resolution levels. The degree of coupling between the DPCM loops makes for the main difference between various schemes.

A straightforward approach is to decompose the frames into multiple resolution frames, and to code each resolution level independently. However, this approach results in significant coding overhead. The scalable codec described in [1] is based on MPEG-II, and employs several DPCM loops on different resolution levels. There exists a slight interconnection between the layers since motion estimation is performed in a hierarchical fashion.

A tighter interconnection is realized in [2], where a two-layer scalable pyramid codec based on two DPCM loops is described. Hierarchical motion estimation is employed in combination with a hierarchical VQ on the displaced frame differences. There exist also various two-dimensional (2-D) wavelet-based and subband schemes [3]–[5]. Motion estimation and compensation turn out to be difficult in the wavelet/subband domain. One difficulty arises from the shift variance of downsampling in the wavelet domain [3]. Another reason is decreased efficiency of motion compensation on bandpass frames since the high-pass signal components are disturbed due to noise and aliasing. Therefore, most approaches perform motion compensation on low-pass subbands.

In this paper, a hybrid spatially scalable video coding algorithm is presented which is based on a Gaussian pyramid decomposition. Motion estimation and compensation are performed between each pyramid level such that the resulting prediction errors are close to a Gaussian pyramid decomposition of the prediction error at the highest resolution level. For coding of the displaced frame differences (DFD) as well as the motion vector fields, the statistical dependencies between the pyramid levels (corresponding to the different resolutions) are utilized by coding jointly all resolutions with a compact Laplacian pyramid representation. More specifically, the DFD is decomposed into a centered Laplacian least squares spline pyramid (construction and properties of this kind of pyramid are derived in this paper), and subsequently coded in an embedded fashion.

One of the most efficient embedded image coding algorithms has been developed by Shapiro [6], and is called the embedded zero-tree wavelet (EZW) coding algorithm. It consists of a transformation of the image into a wavelet domain, and subsequent embedded coding with the zero-tree algorithm, which starts with coarse quantizations and refines the wavelet coefficients in subsequent passes. Taubman [7] developed a three-dimensional (3-D) subband video coder, which (restricted to 2-D) resembles the EZW coder in the aspects of decomposition and layered quantization. Instead of using zero-trees for coding of significance maps, he used a conditioning context to predict zeros in dominant passes. He shows that this kind of general prediction context provides significant gain over the zero-tree coding method. In both cases, a wavelet decomposition has been used. In a previous work [8], we adapted the EZW coding scheme to a Laplacian pyramid decomposition, and discussed the usage of conditional arithmetic coding in a Laplacian pyramid. We showed there that the conditional arithmetic coder outperforms the pyramid zero-tree coder.

In this paper, we adapt the Laplacian pyramid coding of displaced frame differences to a spatially scalable coding scheme. We have to deal with two DFD's per frame, corresponding to the base layer and the refinement layer of the codec. The DPCM loops for both layers are coupled such that the DFD in the base layer is "close" to a reduced version of the DFD of the refinement layer. This requires a careful design of the filter operators which accomplish the transition between the different resolutions. Requirements for these filters are given in this paper, together with a new filter design which fulfills these requirements.

The paper is organized as follows. In the next section, an overview of the hybrid spatially scalable coding concept is given. The third section discusses motion compensation for scalable video coding in general, and mentions particular implementation issues of the proposed scheme. In the fourth section, desirable properties for the reduce and expand operators (which define the pyramid decompositions) are summarized. While most of these properties can be fulfilled with any least squares pyramid [9], employment in the scalable codec makes the *centering* a desired feature. The derivation of such pyramids is included in the Appendix. The fifth and sixth sections describe DFD coding and vector field coding in detail, and the last two sections are devoted to simulation results and some conclusions.

II. Design of a Spatially Scalable Coding Scheme

We start with a discussion of the motion-compensated predictive coder shown in Fig. 1. The current frame is denoted by g_n and the prediction of g_n by $\hat{g}_n$. The DFD $d_n = g_n - \hat{g}_n$ is decomposed into a Gaussian pyramid. A Laplacian pyramid is derived from the Gaussian pyramid and coded in embedded fashion using arithmetic coding. The prediction $\hat{g}_n$ is calculated as a motion-compensated version of the previously reconstructed frame $\tilde{g}_{n-1}$ using overlapping blocks. For motion estimation between the frames g_n and $\tilde{g}_{n-1}$, a gain–cost criterion is employed. The motion vector field v_n is

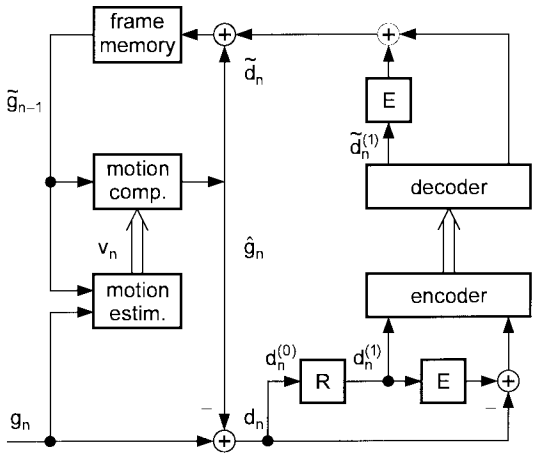

Fig. 1. Block diagram of *PYRACO*, a predictive multiresolution video coding scheme (nonscalable version).

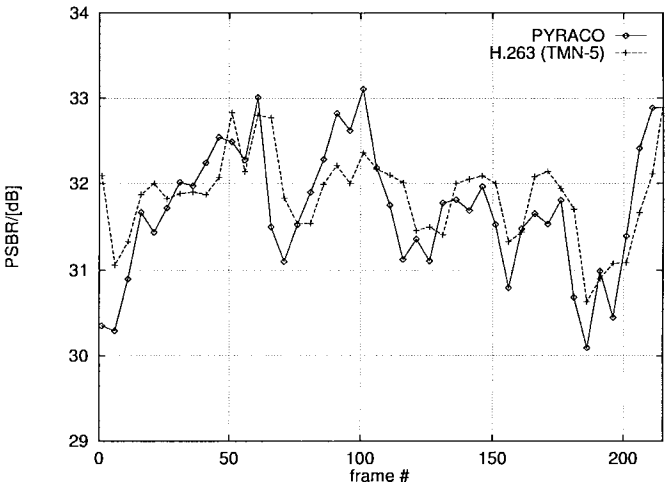

Fig. 2. PSNR of sequence *foreman* coded at 48 kbit/s and 5 fps (fixed).

coded losslessly in a hierarchical fashion [10]. Fig. 2 shows[1] that this coding approach, which is termed PYRACO, reaches approximately the same coding performance as the currently best reference coder H.263 (TMN-5 implementation) [11]. An important difference is that PYRACO outputs a constant bit rate per frame, which simplifies coder control and reduces coding delay, while TMN generates a significantly varying rate.

The multiresolution image representation as a Gaussian pyramid offers a natural design choice for a spatially scalable coding scheme with multiple resolution levels. For simplicity of presentation, we consider in the following only two resolution levels. A block diagram of the spatially scalable hybrid encoder is depicted in Fig. 3. The *base layer* coder emits the lower spatial resolution, and follows the same coding principle as the coder in Fig. 1. A temporally predictive coding approach is also used for encoding of the *refinement layer*, which provides the higher spatial resolution.

[1]The test sequence has been obtained from the CCIR sequence using spline filters [9] for preserving sharpness. The TMN codec runs with all options except PB frames.

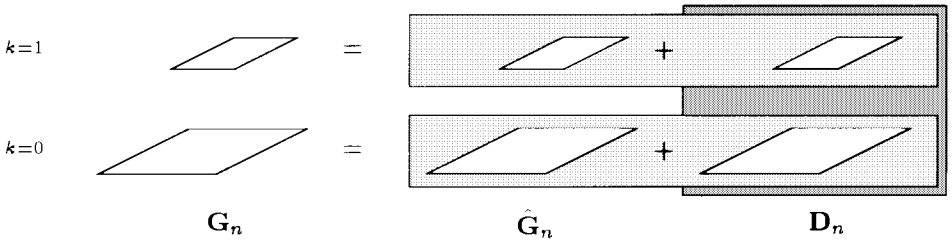

Fig. 4. Relations between two resolutions in a predictive video coding scheme.

A. Aim for Motion Compensation to Achieve Scalability

The first step is a decomposition of the current frame g_n into a Gaussian pyramid $\boldsymbol{G}_n$ of two levels[2]

$$\boldsymbol{G}_n = (g_n^{(0)}, g_n^{(1)}) = (g_n, R(g_n)). \tag{1}$$

$R(\cdot)$ denotes the so-called reduce operator, which consists of a linear low-pass filter followed by subsampling of the image in each dimension by a factor of 2. The aim is now to employ a predictive video compression scheme for both resolution levels of the frame to be coded. Hence, both levels are decomposed into a predicted frame and the prediction error, which is depicted in Fig. 4 reading the figure horizontally. However, reading Fig. 4 vertically, the prediction errors of both resolution levels form a pyramid. This pyramid can be coded efficiently [8] if it is a Gaussian-type pyramid.

Hence, the idea for the design of a spatially scalable predictive video compression scheme is to calculate predictions $\hat{g}_n^{(k)}$ for each level k

$$d_n^{(k)} = g_n^{(k)} - \hat{g}_n^{(k)}, \qquad k = 0, 1$$

such that the relation

$$R\left(d_n^{(0)}\right) \stackrel{!}{=} g_n^{(1)} - \hat{g}_n^{(1)} \tag{2}$$

holds, which is equivalent to the condition

$$R\left(\hat{g}_n^{(0)}\right) \stackrel{!}{=} \hat{g}_n^{(1)}. \tag{3}$$

The predicted levels are obtained by motion compensation of the corresponding level of the previous frame:

$$\hat{g}_n^{(k)} = \mathrm{MC}\left(\tilde{g}_{n-1}^{(k)}, v_n^{(k)}\right).$$

If the predictions satisfy (3), the prediction errors in Fig. 4 indeed constitute a Gaussian pyramid $\boldsymbol{D}_n$.

In a spatially scalable coding scheme, the prediction for the base layer needs to be calculated *without* considering the higher resolution level. This constraint is the central difficulty in the design.

Since the operator $\mathrm{MC}(\cdot)$ is nonlinear and space variant, motion compensation and low-pass filtering cannot be interchanged in general. Furthermore, subsampling is a shift-variant operation causing additional aliasing errors. Therefore, the low-pass filtered prediction from level $k = 0$ differs from the prediction on level $k = 1$, even if the motion is known exactly at level 0 [13]. Hence, equality in (3) cannot be obtained in general.

In order to achieve high compression efficiency, the aim is to find predictors for each scalable level such that (3) is approximated sufficiently accurate

$$R\left(\hat{g}_n^{(0)}\right) \approx \hat{g}_n^{(1)}. \tag{4}$$

[2] Throughout the paper, we use the convention that level 0 corresponds to the refinement layer, and level 1 to the base layer.

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

The design objective is to make the prediction of the base layer similar to the *reduced* prediction of the higher resolution level. The approach followed in this paper calculates the base layer prediction on an expanded frame, and subsequently applies a reduce operator. It is shown in Section III that by appropriately selecting the expand and reduce filters, (4) can be achieved sufficiently accurate. It turns out that the *same* filters as for the DFD pyramid coding are suitable.

B. Pyramid Decomposition of the Base Layer DFD

The base layer DFD $d^{(1)}$ is decomposed into a Laplacian pyramid using centered cubic splines (see Appendix B), which results in high energy concentration into the higher pyramid levels. The decomposition follows the *Gaussian–Laplacian* pyramid approach [12]. First, an intermediate pyramid structure, the Gaussian DFD pyramid $\boldsymbol{D}'$, is generated. The pyramid is initialized at the lowest level $l = 1$ with the original base layer DFD we want to code. From this level, a coarse approximation is derived by applying a reduce operator $R(\cdot)$. This procedure is iterated, resulting in the base layer Gaussian pyramid

$$\boldsymbol{D}' = \left\{ \left(d^{(1)}, \cdots, d^{(L-1)} \right) | d^{(k)} = R\left(d^{(k-1)} \right), \quad k = 2, \cdots, L-1 \right\} \tag{5}$$

consisting of $L-1$ levels.[3]

For computation of the corresponding Laplacian pyramid, an expand operator $E(\cdot)$ is defined, which predicts a level of the Gaussian pyramid from the next higher level, thus expanding the size again by a factor of 2 for each dimension. The expand operator consists of upsampling and subsequent filtering with a linear interpolation filter. The Laplacian pyramid $\boldsymbol{L}'$ captures the loss of information occurring through the reduction of the spatial resolution by means of the difference between a Gaussian image at level k and the expanded version of the Gaussian image at level $k+1$:

$$\boldsymbol{L}' = \left(l^{(1)}, l^{(2)}, \cdots, l^{(L-1)} \right) \tag{6}$$

where

$$l^{(k)} = d^{(k)} - E\left(d^{(k+1)} \right), \qquad k = 1, \cdots, L-2.$$

The top level of $\boldsymbol{L}'$ is "initialized" with the top level of $\boldsymbol{D}'$

$$l^{(L-1)} = d^{(L-1)}.$$

Knowledge of the Laplacian pyramid is sufficient to reconstruct the base layer DFD $d^{(1)}$. Thus, an encoder can build up a coarse representation and successive refinements (the Laplacian levels) of an image, and a decoder can reconstruct the original from this information.

[3]According to our convention, the complete pyramid consists of L levels, and therefore the base layer pyramid has $L-1$ levels.

C. Approach for DFD and Vector Field Coding

As is depicted in the block diagram of the spatially scalable hybrid encoder in Fig. 3, motion estimation and compensation are performed on the resolution levels 0 and 1, yielding a prediction error for the base and the refinement layer. The base layer prediction error is decomposed further into a Gaussian pyramid according to (5). Because the receiver needs only to know about the expand operator, the levels of the pyramid can be decomposed by employing different reduce operators, which may even be nonlinear. Therefore, the complete Gaussian pyramid of the prediction errors $\boldsymbol{D}$ is obtained by concatenating the prediction error of the refinement layer and the Gaussian pyramid of the base layer

$$\boldsymbol{D} = (d^{(0)}, \boldsymbol{D}'). \tag{7}$$

From this pyramid, the *complete* Laplacian pyramid

$$\boldsymbol{L} = \left\{ \left(l^{(0)}, l^{(1)}, \cdots, l^{(L-1)} \right) | l^{(k)} = d^{(k)} - E\left(d^{(k+1)} \right), \quad k = 0, \cdots, L-2, \; l^{(L-1)} = d^{(L-1)} \right\} \tag{8}$$

is calculated, which is sufficient for reconstruction of the DFD at the refinement layer decoder. The base layer decoder needs only to decode the truncated Laplacian pyramid $\boldsymbol{L}'$. The Laplacian pyramid is quantized with a layered quantization scheme. The coefficients are selected and quantized according to their amplitude in decreasing order. Due to the energy concentration, mainly coefficients from higher levels are coded first. The resulting symbol streams are coded using conditioning contexts and adaptive arithmetic coding [8]. Since the context choice depends only on the current or higher levels, scalability is retained. A detailed description of the coding scheme and the filters is given in Section V.

The open-loop approach, where the Laplacian pyramid levels are quantized independently, simplifies layered quantization, and allows for embedded coding. Furthermore, as is shown in (41) in Appendix A, the feedback of the quantization errors of the Laplacian pyramid within the DPCM loop does not degrade the performance since the current level $l_n^{(k)}$ is affected only by the quantization noise of the corresponding level of the previous frame $l_{n-1}^{(k)}$.

The Laplacian pyramid coding principle is adopted for coding of the motion vector fields. The main differences are that for both vector field components independent Laplacian pyramids are calculated, and the pyramids are coded losslessly. The vector field of the base layer is decomposed into Laplacian pyramids, and to obtain the complete pyramid, the motion vector differences of the refinement layer are added as level 0. Since the vector field components have finite precision, quantization is replaced by bit plane coding. This topic is elaborated in Section VI.

III. Motion Estimation and Compensation

The motion model used for this coder concept assumes that the motion of the 3-D objects can be described completely by displacements $v_n(\boldsymbol{x})$ on the image plane. Denoting the location of the pixels on the image grid by $\boldsymbol{x} = (x, y)^T$, frame g_n is related to g_{n-1} by

$$g_n(\boldsymbol{x} + v_n(\boldsymbol{x})) = g_{n-1}(\boldsymbol{x})$$

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

neglecting occlusions, uncovered background, and global illumination changes. The displacement vector field for frame g_n is the set of all displacement vectors v_n.

The aim of motion estimation in the context of coding is to find displacements $\hat{v}_n(\boldsymbol{x})$ with respect to the previously decoded frame $\tilde{g}_{n-1}$

$$\hat{v}_n = \mathrm{ME}(g_n, \tilde{g}_{n-1})$$

such that the prediction error

$$e_{\mathrm{DFD}} = \sum_{\boldsymbol{x}} \|g_n(\boldsymbol{x}) - \hat{g}_n(\boldsymbol{x})\| \tag{9}$$

becomes minimal according to a norm. The prediction signal $\hat{g}_n$ is obtained typically by displacing pixels of the previous frame, which may be weighted additionally (e.g., overlap block motion compensation) using a weighting function w_i

$$\hat{g}_n(\boldsymbol{x}) = \sum_i w_i(\boldsymbol{x}) \cdot \tilde{g}_{n-1}(\boldsymbol{x} - \hat{v}_n(\boldsymbol{x}_i)) = \mathrm{MC}(\tilde{g}_{n-1}, \hat{v}_n). \tag{10}$$

A. Optimal Motion Compensation for the Base Layer

For the moment, we assume that the original previous frame is used for "motion compensation." On the base layer, motion compensation is performed on low-pass filtered and downsampled frames, which limits the prediction performance even if the motion is known. One reason is that subsampling causes aliasing errors. Another one is that motion compensation and low-pass filtering cannot be interchanged in general

$$f_R\Big(\mathrm{MC}\Big(g_{n-1}^{(k)}, v^{(k)}\Big)\Big) \approx \mathrm{MC}\Big(f_R\Big(g_{n-1}^{(k)}\Big), v^{(k)}\Big) \tag{11}$$

because the low-pass filter $f_R(\cdot)$ weights and sums up spatially neighbored pixels. Thus, the filtered pixels are different if the original pixels are displaced prior to filtering [13]. An exception is the case of constant displacements $v(\boldsymbol{x}) = \text{const.}$, where all pixels undergo the same displacement. Low-pass filtering and motion compensation are then interchangeable, and equality holds in (11).

A deeper analysis reveals that motion can be interpreted as a shearing of the image spectrum into a hyperplane along the ω_t axis in the 3-D frequency space, and motion compensation reverts the shearing [14]. Therefore, low-pass filtering prior to motion compensation causes degradations since the hyperplane rather than the plane of the original image spectrum is multiplied by the filter transfer function. This interpretation also reveals why motion compensation prior to filtering results in more accurate predictions than compensation after filtering.

According to our motion model, where the moving scene content results in displacements of pixels in the image plane of the camera, the next frame is generated by displacing the pixels of the previous frame followed by filtering and subsampling. Therefore, for motion compensation of the base layer using a given motion vector field $v_n^{(0)}$, the low-pass filtered prediction from the highest available resolution level results in a higher prediction gain than calculating the prediction on the lower resolution level [13]

$$\hat{g}_{n,\mathrm{opt}}^{(k)} = R^k\Big(\mathrm{MC}\Big(g_{n-1}^{(0)}, v_n^{(0)}\Big)\Big), \qquad k = 0, 1. \tag{12}$$

This type of prediction is termed in the following *optimum prediction*. The superscript k denotes that the reduce function is applied k times. In principle, (12) holds also if the *reconstructed* previous frame is used for motion compensation. Hence, the Gaussian-type pyramid $\boldsymbol{D}_n$ formed by the displaced frame differences

$$d_n^{(k)} = g_n^{(k)} - \hat{g}_{n,\mathrm{opt}}^{(k)}, \qquad k = 1 \cdots L-1$$

has minimal energy. Furthermore, due to the linearity of the reduce operator

$$\begin{aligned} R(d_n^{(k)}) &= R\Big(g_n^{(k)} - \hat{g}_{n,\mathrm{opt}}^{(k)}\Big) \\ &= R\Big(g_n^{(k)}\Big) - R\Big(\hat{g}_{n,\mathrm{opt}}^{(k)}\Big) \\ &= g_n^{(k+1)} - \hat{g}_{n,\mathrm{opt}}^{(k+1)} \\ &= d_n^{(k+1)} \end{aligned}$$

holds for each level of $\boldsymbol{D}_n$. Thus, $\boldsymbol{D}_n$ is identical to the pyramid obtained by decomposing the prediction error of level $k = 0$. It is shown in [8] that such a pyramid can be coded efficiently.

B. Scalable Motion Compensation

This is the crucial part in a spatially scalable coding scheme since the prediction for the base layer needs to be calculated without considering the refinement level. The design aim with respect to (2) is to achieve equality of

$$R\Big(\mathrm{MC}\Big(g_{n-1}^{(0)}, v_n^{(0)}\Big)\Big) \approx \mathrm{MC}\Big(R\Big(g_{n-1}^{(0)}\Big), v_n^{(1)}\Big) \tag{13}$$

with $v_n^{(1)}$ being a suitably reduced version of $v_n^{(0)}$. Due to (11), an optimal prediction for the base layer $g_n^{(1)}$ cannot be obtained from $g_{n-1}^{(1)}$ in general. Therefore, the aim is to approximate $\hat{g}_{n,\mathrm{opt}}^{(1)}$ as closely as possible which, with respect to (12), is equivalent to approximating the refinement layer $g_{n-1}^{(0)}$ as accurately as possible. The idea is to interpolate the base layer frame $g_{n-1}^{(1)}$ such that the distance to the refinement layer $g_{n-1}^{(0)}$ is minimized in the least squares sense:

$$\Big|g_{n-1}^{(0)} - E\Big(g_{n-1}^{(1)}\Big)\Big|^2 \longrightarrow \min. \tag{14}$$

In real coders, only the *coded* previous frame $\tilde{g}_{n-1}^{(k)} = g_{n-1}^{(k)} + q'^{(k)}_{n-1}$ is available, where q' denotes the quantization error (Appendix A). However, (14) remains valid since the quantization error of level 0 is fixed

$$\tilde{g}_{n-1}^{(0)} - E\Big(\tilde{g}_{n-1}^{(1)}\Big) = g_{n-1}^{(0)} - E\Big(g_{n-1}^{(1)}\Big) + q_{n-1}^{(0)}.$$

Motion compensation is performed on the expanded frames, and the final prediction is obtained by reducing the compensated, expanded frame

$$\hat{g}_n^{(k)} = R\Big(\mathrm{MC}\Big(E\Big(\tilde{g}_{n-1}^{(k)}\Big), v_n^{(k)}\Big)\Big), \qquad k = 0, 1. \tag{15}$$

Since the equation can be interpreted for the base layer as half-pel motion compensation (assuming interger valued $v_n^{(0)}$), the same technique is also applicable for the refinement layer

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

$k = 0$. The vector fields $v_n^{(k)}$ are obtained by motion estimation on the expanded frames

$$v_n^{(k)} = \mathrm{ME}\Big(E\Big(g_n^{(k)}\Big), E\Big(\tilde{g}_{n-1}^{(k)}\Big)\Big), \qquad k = 0, 1. \tag{16}$$

Note that (15) depends on no particular method for motion estimation and compensation.

To achieve a good approximation of $\hat{g}_{n,\mathrm{opt}}^{(1)}$, the operator pair $E(\cdot), R(\cdot)$ needs to meet further constraints. The chain of operators must equal the identity operator

$$R\Big(E\Big(g_{n-1}^{(k)}\Big)\Big) = g_{n-1}^{(k)}.$$

This characteristic ensures that filtering effects do not distort the prediction. Furthermore, for the special case of global constant translational motion, the optimum prediction can be obtained.

Additionally, the filters must account for the fact that motion is a local property. Hence, the filters should be spatially localized or, in other words, the impulse response of the filters should have compact support.

The required properties are provided by centered third-order spline filters, a modified version of the cubic spline filters described in [15]. The class of spline filters allows for a tradeoff between spatial localization and aliasing since they include the Haar filter as a filter of order 0 as well as the sinc interpolator for infinite order. The distinctive feature of the proposed filters is the centering of the lower resolution grid with respect to the higher resolution grid. The advantage for scalable motion compensation is that the centered spline filters do not introduce a half-pel shift, and displacements remain at the same location in different levels. In Section IV, the filter design is linked to the Laplacian pyramids, and a detailed description is given in Appendix B.

C. Implementation Aspects

Since in a scalable video coding scheme the refinement level is not available to the base layer encoder, motion estimation is performed top down starting at the base layer. The method for motion estimation and compensation can be chosen freely in principle. However, an approach based on block matching is simple and robust. Another advantage of a block-oriented scheme is that low-pass filtering and motion compensation are interchangeable for $v_n^{(k)} = \mathrm{const}$. (11). Therefore, locally using a translational motion model is advisable.

To obtain a smooth vector field, a gain–cost criterion is evaluated as distance measure for each block j [16]

$$v_n(j) = \underset{v \in \mathcal{V}}{\operatorname{argmin}} \left\{ \log\Big(e_j^2(v)\Big) + \lambda \cdot \sum_{i \in \mathcal{N}_j} \|v - v_n(i)\| \right\} \qquad \lambda = \mathrm{const}. \tag{17}$$

with $\mathcal{N}_j$ denoting the set of neighbored blocks of block j. The calculation of the prediction error e_j for block j according to (9) employs overlapping blocks; hence, (17) includes overlap block motion estimation. Furthermore, motion compensation causes no blocking artifacts. The factor λ controls the smoothness by penalizing large vector differences. Due to the interaction with neighbored blocks, the vector field needs to be calculated iteratively. However, the computational load is still less than for full search block matching since the test vector set $\mathcal{V}$ is very small (18 candidates), and only about four iterations are sufficient. Since estimating motion at the expanded frames (16) can be interpreted as half-pel motion estimation, no additional half-pel motion estimation procedure like bilinear interpolation is needed.

At the refinement layer, the same gain–cost constrained block matching scheme applies. The vector field $v_n^{(1)}$ from the base layer is taken into consideration. Due to the constraint of (2), the predictions must be consistent across scales. Hence, the size of the blocks is increased by a factor of 2. A block size of 16×16 at level 0 corresponds to a block size of $16 \cdot 2^{-k} \times 16 \cdot 2^{-k}$ at level k. As a consequence, the vector field sizes of the scalable resolution levels are *equal*. The vector field $\hat{E}_v(v_n^{(1)})$ serves as an initial estimate for motion estimation, calculated by an appropriate scaling function $\hat{E}_v$. Since the number of vectors at both levels is the same, $\hat{E}_v$ scales only the amplitudes of the vector components by 2. Regarding $v_n^{(k)}$ as average motion, the motion vector field $v_n^{(k-1)}$ can be written as

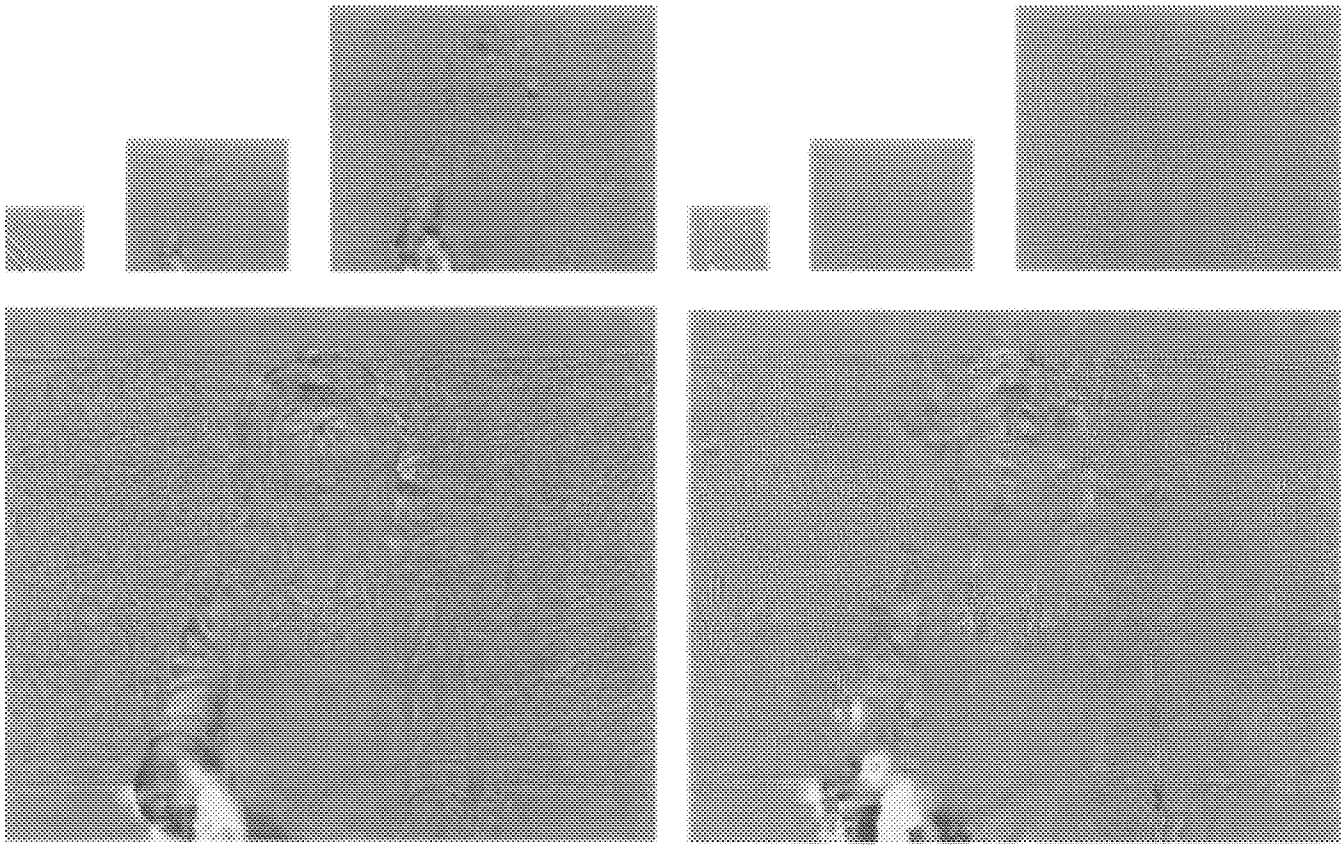
$$v_n^{(k-1)} = \hat{E}_v\Big(v_n^{(k)}\Big) + \Delta v_n^{(k-1)} \tag{18}$$

where $\Delta v_n^{(k-1)}$ denotes the refinement. The gain–cost criterion constrains the motion estimate to smooth vector fields eliminating spurious vectors. Finally, a hierarchy of motion vector fields has been obtained, and needs to be coded (Section VI).

IV. Choice of Reduce and Expand Operators

The choice of the reduce operator $R(\cdot)$ and the expand operator $E(\cdot)$ is the key issue to achieve efficient multiresolution motion estimation and compensation, as well as efficient coding of the Laplacian pyramid of the displaced frame differences.

In the previous section, we compiled operator conditions for multiresolution motion compensation. First, the interpolation of the base layer should approximate the refinement layer in the least squares sense. Furthermore, the operator chain $E(\cdot)$ followed by $R(\cdot)$ should be the identity operator.



For DFD coding, the main objective for the filter design with respect to the Laplacian pyramid is to shift the signal energy into the higher pyramid levels. Concentration of the energy in only few pixels results in the desired coding gain. This is equivalent to the objective of minimizing the energy of the lower levels of the Laplacian pyramid. A useful criterion is that the approximation operator [$R(\cdot)$ followed by $E(\cdot)$] should be optimal in the least squares sense.

Comparing both sets of conditions, it turns out that they are identical for both tasks. Hence, one set of filters suffices. We chose spline filters, and found that centered third-order filters performed best. In Appendix B, the filters are described in detail, and it is proven that they provide the desired properties.

V. DFD Pyramid Coding

The two-layer scalable coding scheme under consideration outputs two displaced frame differences $d^{(0)}, d^{(1)}$ for each coded frame. The base layer DFD $d^{(1)}$ is decomposed into

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

(a) (b)

Fig. 5. Least squares Laplacian pyramid (LSLP) decomposition of DFD 11 of sequence *Silent*. For display, the amplitudes have been multiplied by two for the Gaussian and by four for the Laplacian pyramid. (a) Gaussian DFD pyramid $\boldsymbol{D}$. (b) Laplacian DFD pyramid $\boldsymbol{L}$.

a Laplacian pyramid. As explained in Section II, a Laplacian level $l^{(0)}$ is derived from the refinement layer DFD $d^{(0)}$, and this level builds together with the truncated pyramid $\boldsymbol{L}'$ the complete Laplacian pyramid of both DFD's.

This results in energy concentration into the higher (low-pass) levels of the pyramid, which consist of considerably fewer pixels than the original image. Usually, the energy is not equally distributed within the levels. This is due to the nature of motion compensation: some areas in the original sequence may contain complex motion where the motion compensation fails, while other areas contain no or only simple translational motion. The DFD energy will be the highest in areas where motion compensation failed. The severely limited bit budget for DFD coding in low bit-rate coders only allows encoding of selected areas of the DFD. Most DFD coding schemes encode the address information as overhead (addressing the areas, which are actually coded) separately from the quantized data. We use instead a layered coding method, where address information and data are encoded jointly in significance maps.

The coding gain which can be achieved with the Laplacian pyramid depends strongly on the employed filters. We have chosen a centered version of the cubic spline *least squares Laplacian pyramid* (LSLP) because this set of filters performed best of all investigated linear filters (see Appendix B).

In Fig. 5, the LSLP decomposition is shown for the frame difference between frame 11 and the motion-compensated prediction for this frame obtained from the reconstructed frame 6 of the image sequence "silent." The lowest level of the pyramid consists of 352 × 288 pixels (common interchange format, CIF). In Fig. 5(a), the Gaussian DFD pyramid $\boldsymbol{D}$ is given; in Fig. 5(b), the corresponding Laplacian pyramid $\boldsymbol{L}$ is given. The top three images in each subfigure constitute the truncated pyramids $\boldsymbol{D}'$ and $\boldsymbol{L}'$ (base layer DFD and Laplacian pyramid). The large images $d^{(0)}$ and $l^{(0)}$ belong to the refinement layers.

One can see that the base layer decomposition of $d^{(1)}$ into the truncated pyramid $\boldsymbol{L}'$ yields energy compaction into the higher pyramid levels. The design objective $R(d^{(0)}) \approx d^{(1)}$ does not hold with equality; therefore, $l^{(0)}$ contains more energy than the other levels of the Laplacian pyramid. Especially where strong motion appears (the raising hand), $d^{(0)}$ cannot be predicted well from $d^{(1)}$. On the other hand, $l^{(0)}$ contains much less energy than $d^{(0)}$, which indicates that predicting $d^{(0)}$ from $d^{(1)}$ is better than no prediction at all. Doing without prediction leads to the simulcast case (independent coding of base and refinement layer), which is used for comparison in Section VII.

A. Layered Quantization

Let $l^{(l)}(i,j)$ denote the pixel value at location (i,j) of level l of the pyramid $\boldsymbol{L}$. The range of the indexes is $i \in 0 \cdots I/2^l - 1$, $j \in 0 \cdots J/2^l - 1$, and $l \in 0 \cdots L-1$, where I and J are the dimensions of the original frame. The pyramid is scanned top down (starting with $l = L-1$ down to $l = 0$), resulting in a

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

sequence of pyramid values $x[i]$. The scan order inside each level is a simple line scan.

Scalability is achieved by progressive quantization in a sequence of up to N layers. Each layer can be described by the associated quantizer. It is convenient to differentiate between two sets of quantizers $\mathcal{Q}_0^D, \cdots, \mathcal{Q}_{N-1}^D$ and $\mathcal{Q}_1^S, \cdots, \mathcal{Q}_{N-1}^S$. The first set of quantizers belongs to the *dominant passes*, and the second to the *subordinate passes* of the coding algorithm. These passes alternate, starting with a dominant pass. Hence, during the coding process, the sequence $\mathcal{Q}_0^D$, $\mathcal{Q}_1^S$, $\mathcal{Q}_1^D$, $\mathcal{Q}_2^S$, $\mathcal{Q}_2^D, \cdots$ of quantizers is employed.

Each quantizer $\mathcal{Q}_n$ is defined by a set of disjoint quantization intervals $\mathcal{I}_{n,k_1}, \mathcal{I}_{n,k_2}, \cdots$ and the quantization function

$$\mathcal{Q}_n^D(x) = k, \qquad \text{for } x \in \mathcal{I}_{n,k}^D \tag{19}$$

$$\mathcal{Q}_n^S(x) = k, \qquad \text{for } x \in \mathcal{I}_{n,k}^S \tag{20}$$

which maps each input value x to an index k.

In order to allow efficient layered quantization, the sequence of quantization intervals must form a set of nested intervals.

The "dominant" intervals $\mathcal{I}_{n,k}^D$ are symmetric around zero, and are uniformly spaced with a dead zone twice as large as all of the other quantization intervals. From layer to layer, each quantization interval is halved. Thus, the intervals are specified with a single parameter Δ_0 as follows:

$$\mathcal{I}_{n,k}^D = \begin{cases} (-\Delta_n, \Delta_n), & \text{if } k = 0 \\ [k\Delta_n, (k+1)\Delta_n), & \text{if } k > 0 \\ ((k-1)\Delta_n, k\Delta_n], & \text{if } k < 0 \end{cases} \tag{21}$$

with

$$\Delta_n = \Delta_{n-1}/2, \qquad \text{for } n > 0. \tag{22}$$

The "subordinate" intervals $\mathcal{I}_{n,k}^S$ are refinements of the intervals $\mathcal{I}_{n-1,k}^D$. More precisely, each interval $\mathcal{I}_{n-1,k}^D$ contains two intervals $\mathcal{I}_{n,k}^S$ of equal width, except for $k = 0$, where $\mathcal{I}_{n-1,0}^D = \mathcal{I}_{n,0}^S$. Hence, the "subordinate" intervals are symmetric around zero, uniformly spaced with a dead zone four times larger than the other intervals

$$\mathcal{I}_{n,k}^S = \begin{cases} \mathcal{I}_{n-1,0}^D, & \text{if } k = 0 \\ \emptyset, & \text{if } k \in \{-1, 1\} \\ \mathcal{I}_{n,k}^D, & \text{if } k \notin \{-1, 0, 1\}. \end{cases} \tag{23}$$

Note that each quantization interval $\mathcal{Q}_n^D$ is contained in some quantization interval of $\mathcal{Q}_{n-1}^D$. Moreover, the intervals $\mathcal{I}_{n,0}^D$ contain the *three* intervals $\mathcal{I}_{n+1,-1}^D$, $\mathcal{I}_{n+1,0}^D$, $\mathcal{I}_{n+1,1}^D$, whereas all other intervals $\mathcal{I}_{n,k}^D$ (with $k \neq 0$) contain *two* intervals $\mathcal{I}_{n+1,2k}^D$, $\mathcal{I}_{n+1,2k+1}^D$. (Similar properties exist for the "subordinate" intervals since these are defined through (23) via the dominant intervals.) This is the only condition on the quantization intervals which must be imposed. However, specifying the intervals as in (21) is very convenient because the set of quantization functions is defined by Δ_0 and N alone.

B. Symbol Stream Generation

We define two sets of sequences $\sigma_n'[i]$ and $\delta_n'[i]$ as follows:

$$\sigma_n'[i] = \mathcal{Q}_n^D(x[i]) \tag{24}$$

$$\delta_n'[i] = \mathcal{Q}_n^S(x[i]) \pmod 2. \tag{25}$$

Since the quantization intervals form a set of nested intervals, all information necessary to recover the current quantization intervals is contained in these sequences. Moreover, if these sequences are ordered in the same way as the quantizers, i.e., $\sigma_0'[i]$, $\delta_1'[i]$, $\sigma_1'[i], \cdots$, a part of this sequence is still redundant. Particularly, 1) every $\delta_n'[i]$ for which $\sigma_{n-1}'[i] = 0$, and 2) every value $\sigma_n'[i] \notin \{-1, 0, 1\}$ can be predicted from previous parts of the alternating sequence $\sigma_0'[i]$, $\delta_1'[i]$, $\sigma_1'[i], \cdots$.

Thus, the variable length strings σ_0, δ_1, $\sigma_1, \cdots$ contain the same information as the strings $\sigma_0'[i]$, $\delta_1'[i]$, $\sigma_1'[i], \cdots$, if we denote by σ_n and δ_n the strings obtained by removal of the redundant entries of $\sigma_n'[i]$ and $\delta_n'[i]$, respectively.

Removal of the redundant entries works the same way as in Shapiro's EZW coder [6]. In the first dominant pass, all entries are scanned; thus, σ_0' equals σ_0. The first subordinate pass deals only with the samples which have become significant in the first dominant pass. In accordance with condition 1), those values of $\delta_1'[i]$, for which $\sigma_0'[i]$ has been zero (insignificant), are omitted in δ_1. Condition 2) means that all samples which have become significant during previous dominant passes are not regarded in any subsequent dominant pass.

The symbol stream consisting of the concatenation of the strings σ_0, $\delta_1, \cdots$ is encoded arithmetically, which is described in the next subsection.

C. Conditional Arithmetic Coding

The strings δ_n are binary, and show only very little correlation between the letters. Thus, they are encoded with an adaptive arithmetic coder without regarding any context.

The three-valued strings σ_n are encoded with an arithmetic coder conditioned on context [17], which is collected from previously reconstructed values of $\sigma_n'[i]$. For this task, a conditioning sequence $\kappa_n[i]$ is constructed from $\sigma_n'[i]$ by thresholding

$$\kappa_n[i] = \begin{cases} -1, & \text{if } \sigma_n'[i] < 0 \\ 0, & \text{if } \sigma_n'[i] = 0 \\ +1, & \text{if } \sigma_n'[i] > 0. \end{cases} \tag{26}$$

Denote by (j, k) the coordinates and by l the pyramid level of the pixel belonging to the index i. For convenience, we set $\kappa_n^l(j, k) = \kappa_n[i]$. Then the values of $\kappa_n^l(j-1, k)$ and $\kappa_n^l(j, k-1)$ are used to build a local conditioning context. Additionally, the significance information of $\kappa_n^{l+1}(j/2, k/2)$ (i.e., $|\kappa_n^{l+1}(j/2, k/2)|$) is used to utilize correlations of significance across scales. The implementation of the arithmetic coder follows the paper of Witten *et al.* [18].

D. Inverse Quantization at the Decoder

Until now, the pyramid encoder has been described. The decoder receives an arithmetically encoded bit stream, decodes it into a stream of symbols, and reconstructs from this symbol stream successively refined quantization intervals. For each coefficient, a value of the current interval must be chosen as the reconstruction value (inverse quantization). The reconstructed Laplacian levels are suitably expanded and summed up, giving the base and refinement layer DFD's $d^{(1)}$ and $d^{(0)}$.

There are several possibilities for designing the inverse quantization function. In Shapiro's original EZW coder, the

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

reconstruction values are chosen in the middle of the current interval. Since our pyramid decomposition is overcomplete, there is some redundancy in the unquantized pyramid. This means that not all possible combinations are consistent with the employed reduce and expand operators. We utilize this redundancy in the pyramid for quantization error reduction.

Theorem 1: Denote by $l_{Q'}^{(k)}$ the kth Laplacian level with independently quantized values. Then the quantized Laplacian levels

$$l_Q^{(k)} = l_{Q'}^{(k)} - E\Big(R\Big(l_{Q'}^{(k)}\Big)\Big), \qquad k = 1, \cdots, L-2 \tag{27}$$

are, in general, closer (in the mean-squared sense) to the unquantized levels $l^{(k)}$ than the levels $l_{Q'}^{(k)}$.

Proof: For least squares pyramids, the concatenation of reduce and expand operators yields the identity operator or an orthogonal projection operator P (depending on the order)

$$R(E(x)) = x$$

and

$$P(x) := E(R(x)) = P(P(x)), \qquad \forall x. \tag{28}$$

These properties are derived in Appendix B.

All "true" Laplacian levels (i.e., the levels $l^{(k)}$, $k = 1, \cdots, L-2$) have the form $l^{(k)} = d^{(k)} - E(R(d^{(k)})) = d^{(k)} - P(d^{(k)})$. Keeping this in mind, it is easy to see that the projection of an unquantized Laplacian level is zero

$$P(l) = E(R(l)) = 0. \tag{29}$$

Denote by $l_{Q'}$ a Laplacian level with independently quantized values. We now decompose these levels into a sum of the true Laplacian level and a quantization error

$$l_{Q'} = l + q. \tag{30}$$

Application of the projection operator P on both sides leads to

$$P(l_{Q'}) = P(q) \tag{31}$$

and

$$l_{Q'} - P(l_{Q'}) = l_{Q'} - P(q) = l + q - P(q). \tag{32}$$

Thus, application of (27) projects the quantization error q linearly into the null space of P. Hence, for the new quantization error $q - P(q)$, we have $\|q - P(q)\| \leq \|q\|$ with equality if and only if q belongs to the null space of P. ■

To utilize the above-mentioned redundancy of the pyramid decomposition, we first choose reconstruction values independently based on the quantization intervals known to the decoder. Then we project the quantization error into the vector space of admissible Laplacian levels by applying (27).

VI. Displacement Vector Field Coding

An efficient and elegant coding method is derived by adopting the pyramid approach for coding of displaced frame differences. Specific aspects are that vector fields need to be coded lossless, and each vector consists of two components. The concept of conditioning contexts is employed because it is much more flexible and even more efficient than zerotree coding [10]. The flexibility is especially important for the scalable codec.

At first, coding of the base layer motion vector field $v_n^{(1)}$ is described. Similar to the coding approach for the prediction error, both components v_x and v_y of the motion vector field $v_n^{(1)}$ are decomposed separately into a Laplacian pyramid $\boldsymbol{L}_x$ and $\boldsymbol{L}_y$ of $L_v - 1$ levels, respectively. For simplicity, only one component is mentioned in the following, where no ambiguity can occur. The levels of the pyramid are obtained by

$$\begin{aligned} l_x^{(k)} &= v_x^{(k)} - E_v\Big(v_x^{(k+1)}\Big), \qquad k = 1, \cdots, L_v - 2 \\ l_x^{(L_v-1)} &= v_x^{(L_v-1)} \end{aligned} \tag{33}$$

where

$$v_x^{(k)} = R_v\Big(v_x^{(k-1)}\Big), \qquad k = 2, \cdots, L_v - 1 \tag{34}$$

denotes the levels of the intermediate Gaussian pyramid. The reduce and expand operators $R_v(\cdot)$, $E_v(\cdot)$ need to be designed carefully to obtain optimal compression. On the one hand, a high energy concentration into the higher pyramid levels should be achieved; on the other hand, one should be able to code the remaining residuals at lower levels efficiently. The two important properties of the coding technique of significance maps are that zero coefficients can be coded efficiently, and that one large residual coefficient is more expensive to code than two small coefficients.

The operators $R_v(\cdot)$ and $E_v(\cdot)$ have a 2×2 support to obtain a quadtree-like pyramid structure. As expand operator $E_v(\cdot)$, simple repetition is employed. The nonlinear operator $R_v(\cdot)$ used for reduction termed *closest couple* provides the best performance in our experiments. To achieve that at least one coefficient of the Laplacian pyramid becomes zero, this operator outputs one element of a block of 2×2 vector components. The selection criterion maximizes the number of small coefficients by first searching for the coefficient pair which has the smallest difference. The coefficient of the pair which has the smallest difference to the remaining two values is taken as output. Since half-pel motion compensation is used, the vector field components are scaled by a factor of 2 and treated as integers. Hence, the coefficients of the Laplacian pyramid also have integer precision.

The vector fields must be coded lossless, and the integer precision allows for simple bit plane coding, which could also be interpreted as a specialized version of layered "quantization." Instead of calculating a threshold Δ as for DFD coding, the position of the most significant bit is calculated. Halving of the threshold is equivalent to switching to the next lower bit plane. Significant coefficients are the coefficients with a bit set in the currently selected bit plane. Therefore, similar to DFD coding, a significance sequence σ_n is obtained for each bit plane, which is coded employing conditioning contexts followed by adaptive arithmetic coding [18]. The formulation of the different contexts is based on the conditioning sequence $\kappa_n[i]$.

Due to the quadtree structure, one class of contexts depends only on conditioning symbols $\kappa_n[i]$ within a 2×2 block. To keep the context causal, unavailable conditioning symbols $\kappa_n[i]$ are taken from the previous layer $\kappa_{n-1}[i]$. From the

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

3^3 possible states, the seven most frequently occurring states (experimentally determined) are used. Since, in the most significant bit plane, only a few coefficients become significant while most coefficients become significant later, the set of contexts is switched after scanning the second bit plane. In the case that all coefficients for a block are insignificant, the corresponding conditioning symbol of the next higher level is taken into account.

Finally, a different set of contexts is defined for the top level of the pyramid, which has a low-pass characteristic and no block structure, in contrast to the band-pass characteristic of the lower levels. This set is the same as used for DFD coding, except that no information on higher levels is available.

Regarding the scalable video codec, a hierarchy of the vector fields is generated (Section III-C). The vector fields do not form a pyramid since $v^{(0)}$ and $v^{(1)}$ have the same number of vectors. For calculating the refinement level $l_x^{(0)}$ of the Laplacian pyramid in (33), (18) is directly applicable

$$l_x^{(0)} = v_x^{(1)} - 2 \cdot \left(v_x^{(1)} \right) \tag{35}$$

replacing the expand function E_v by the scaling function $\hat{E}_v$. Since the decoder knows the motion vector field resolution anyway, the refinement vector field can be reconstructed from the Laplacian "pyramid." For coding, the concept of conditioning contexts is still well suited because the symbols denoting the bit plane (quantization interval) can be calculated independently of the higher resolution levels. Moreover, the conditioning contexts for entropy coding of the symbol stream are designed such that they depend only on elements from the same level.

VII. Simulation Results

First, the suitability of the motion estimation and compensation scheme (15) in the context of the proposed scalable coder is demonstrated. Frames 6, 11, and 16 of the sequence *foreman*[4] have been coded with a nonscalable codec as well as with a scalable codec. The base layer prediction error has been decomposed into a Gaussian pyramid of four levels. Correspondingly, in the nonscalable coder, the DFD has been decomposed into five levels. For both codecs, the highest spatial resolution is CIF, hence, the base layer (level 1) has QCIF resolution. For motion estimation and compensation, blocks of 32 × 32 are matched on the refinement level; thus, the block size on level 1 is 16 × 16. Both coders run at the same bit rate of 96 kbit/s at 5 frames/s (fps), and since the coder control assigns a constant bit budget to each frame, the coding results can be compared. The first frame (1) has been coded with 48 kbits.

In the nonscalable coder, the prediction for the "base level" is obtained by reducing the prediction of the "refinement level," according to (12). This is equivalent to a reduction of the reconstructed refinement layer to obtain the reconstructed base layer frame. The prediction gains measured in decibels for the nonscalable and the scalable codec in Table I are comparable.

[4]The sequences are obtained from the original CCIR sequences using least squares cubic spline filters.

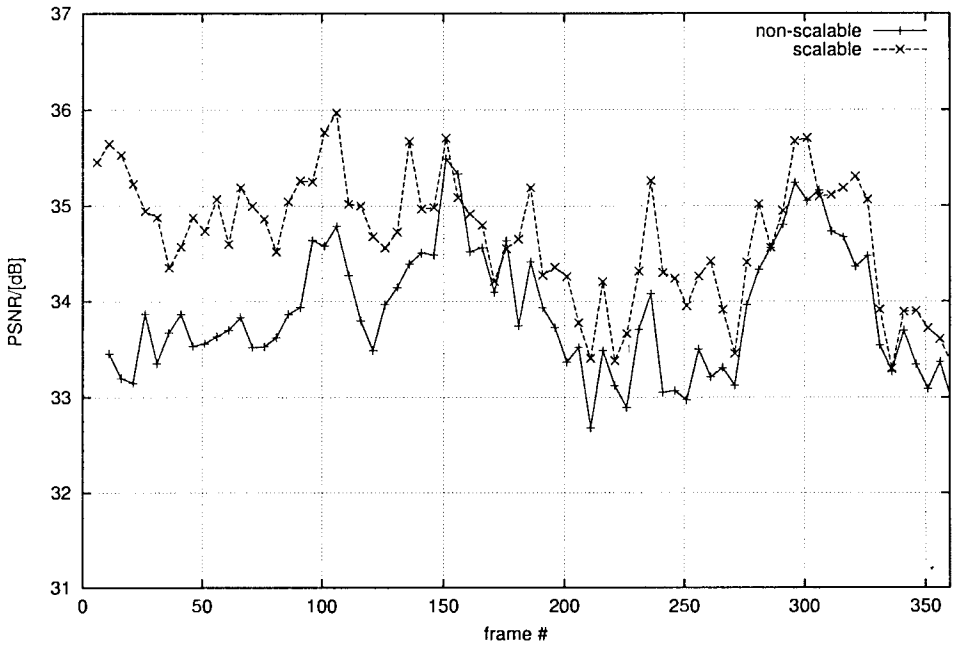
TABLE I
PSNR in Decibels of the Resolution Levels After Motion Compensation

Frame	Level	Nonscalable	Scalable
6	0	26.9	27.1
	1	27.7	27.9
11	0	28.7	28.5
	1	30.2	29.8
16	0	29.8	29.2
	1	31.6	30.9

The diagrams in Fig. 6 show the overall coding performance for the sequence *silent*, coded at 96 kbit/s and 5 fps with both a scalable coder as well as a nonscalable coder. The base layer DFD is decomposed into four levels. For motion compensation, blocks of 8 × 8 on the base layer and 16 × 16 on the refinement layer have been used. The pyramid for coding the base layer vector field has three levels.

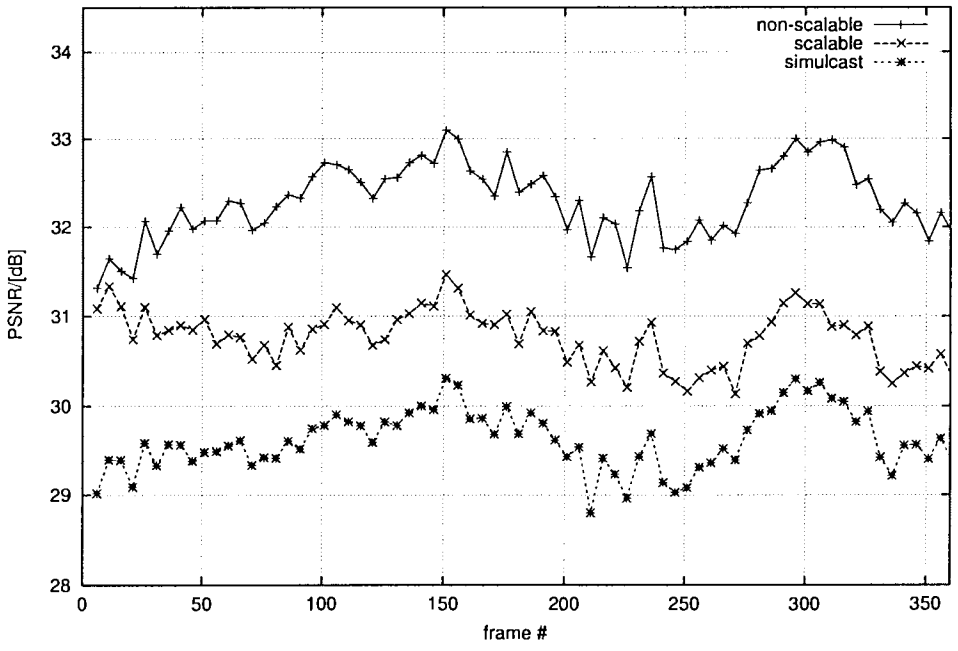
The PSNR of the base layer compared to the coding performance of a nonscalable coder (QCIF) running at the same average bit rate as the scalable coder (56 kbit/s) is given in Fig. 6(a). Except for the first frames, the performance is similar, as expected. For the refinement layer, the PSNR values are shown in Fig. 6(b). The comparison with the nonscalable coder running at the same total bit rate of 96 kbit/s indicates an upper bound. Furthermore, the results are compared with the simulcast case. The average bit rate of 40 kbit/s devoted to the refinement layer in the scalable coder is used to code the CIF sequence with the nonscalable coder independently.

On hand of the following diagrams, the coder is analyzed in more detail. Regarding the rate allocation shown in Fig. 6(c), the bit rate per frame is absolutely constant, while a varying part is allocated by the base layer. The difference is the rate available for the refinement layer. With only about 40 kbit/s, the additional refinement layers can be transmitted at a sufficient quality. As an example, the coded refinement layer image 61 is shown in Fig. 7.



The diagram in Fig. 8(a) shows solely the motion compensation performance of the base layer compared to a nonscalable QCIF coder. Both coders run in a closed loop at a fixed bit rate including update coding, but only the PSNR after motion compensation before update coding is shown. As expected, the gain is similar. In Fig. 8(b), the performance of the refinement layer compared to a nonscalable CIF coder running at 96 kbit/s is given. Although the curves differ due to different bit allocations, the overall motion compensation gain is comparable.

As is shown in Fig. 9, coding the CIF sequence *container* at 48 kbit/s and 5 fps with the scalable coding scheme also results in a gain compared to the simulcast case, where the refinement level coder runs at 25 kbit/s.



VIII. Characteristics of the Proposed Coding Method

The proposed scheme for a spatially scalable coder relies on a predictive motion-compensated approach. In contrast to spatiotemporal coding methods which utilize correlations of more than two frames (e.g., 3-D subband coding or motion estimation with more than one frame), such coders do not necessarily introduce a delay of more than one frame. The update information (the coded DFD) is calculated on a frame-by-

frame basis, thus retaining this low-delay property. Therefore, the proposed coder is especially suited for communications applications.

One key feature is the decomposition of the displaced frame differences into a Laplacian pyramid. In connection with overlap block motion compensation, the coder produces no blocking artifacts. The artifacts are similar to the artifacts of subband coders and are dependent on the used filters.

There is no need for a special start-up procedure since rough (low-pass) approximations of large areas are possible with a constrained bit rate. On the other hand, if most parts of the DFD are close to zero, the available bit rate can be spent in small regions, thus allowing an update of fine details. This property simplifies coder control considerably after a scene cut. Furthermore, there is no need for an explicit inter/intraswitch because the Laplacian pyramid is suited for static image statistics as well.

If only still images are transmitted (or if there is only slight motion present), the reconstructed image at the receiver will converge to a perfect reconstruction. This means that still images are automatically progressively coded (see Appendixes A–B).

(a) (b)

Fig. 7. Frame 61 of test sequence *silent* coded with the scalable coder (CIF, 96 kbit/s, 5 fps). (a) Coded refinement layer of frame 61 at 40 kbit/s. (b) Close up.

The DFD coder outputs an embedded bit stream, which eases coder control and adds flexibility. The sequence coder control may truncate the bit stream at *any* point (usually when the available bit budget is exhausted, or the buffer exceeds a given threshold). Thus, the coder has the ability to code frames at a *constant* bit rate, eliminating the need for a buffer, and thus reducing the delay. Since there is no separate encoding of address information and quantized data, the algorithm works efficiently in a wide range of bit rates.

IX. Discussion and Summary

A new spatially scalable predictive video coding scheme is described in this paper. The basic feature is a predictive coding approach for the base layer as well as for the refinement layer, such that the displaced frame differences can be decomposed into a *single* Laplacian pyramid.

One major aspect of the paper is the specific design of motion estimation and compensation. Motion compensation is performed such that the displaced frame difference of the base layer becomes similar to the reduced prediction error of the refinement layer. Therefore, motion is estimated and compensated on interpolated frames approximating the higher resolution level in the least square sense. As filters, centered cubic spline filters are chosen. The relation of the motion-compensated predictions on the base and the refinement layer determines the complete coder performance. Further research is directed to the improvement of the robustness when the predictions differ significantly.

Motion is estimated in a hierarchical fashion, taking into account the motion vector field of the next lower resolution level. Since the difference between levels represents an additional refinement information, a similar approach as for coding of the displaced frame differences is designed to encode the vector fields efficiently using a Laplacian pyramid coding approach employing conditioning contexts.

The second main aspect is the design of an improved Laplacian pyramid decomposition of the base layer. It turns out that centered cubic spline filters are among the best linear

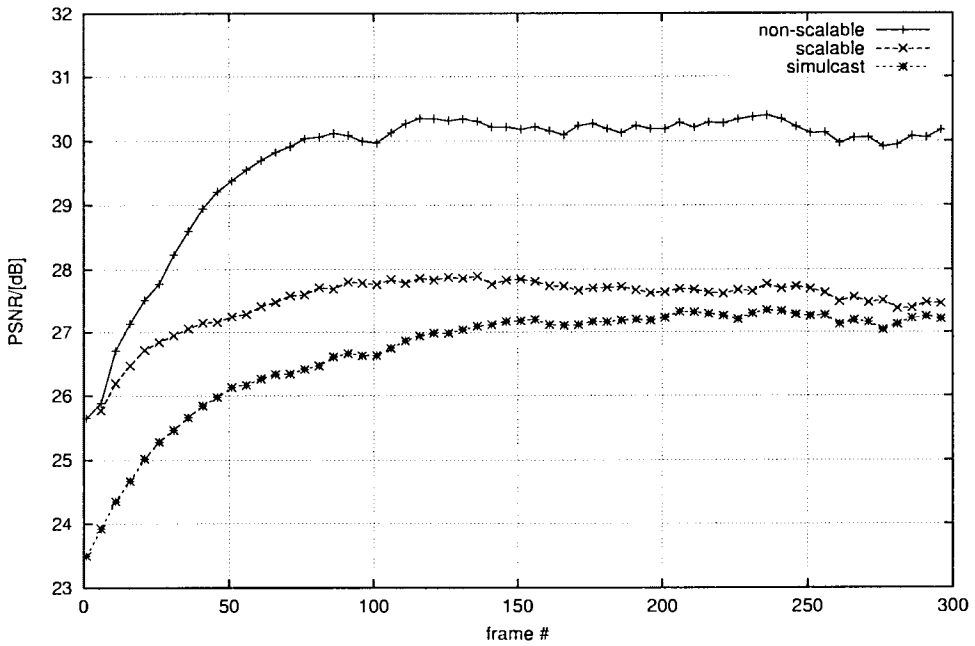

Fig. 9. Coding performance of the scalable coder for the sequence *container* at 5 fps.

filters fulfilling the desired design objectives. Interestingly, the *same* filters meet the constraints for scalable motion compensation as well as for efficient pyramid decomposition.

Furthermore, a rate-distortion efficient embedded DFD coding method using conditioning contexts for coding is developed, which allows for progressive transmission and simplifies coder control significantly. Simulation results are provided for the complete hybrid video coder.

APPENDIX A
ANALYSIS OF THE QUANTIZATION ERRORS

A. Open-Loop Quantization

The effects of quantizing the Laplacian DFD pyramid $\boldsymbol{L}$ in an open loop are analyzed in the following. In an open-loop approach the quantization error $q^{(k)}$ at level k is independent of quantization errors at other levels $q^{(i)}, i \neq k$

$$\tilde{l}^{(k)} = l^{(k)} + q^{(k)} \tag{36}$$

The coded displaced frame difference $\tilde{d}^{(k)}$ at level k is then given by

$$\begin{aligned}\tilde{d}^{(k)} &= \tilde{l}^{(k)} + E\left(\tilde{d}^{(k+1)}\right) \\ &= l^{(k)} + q^{(k)} + \sum_{i=k+1}^{L-1} E^{i-k}\left(l^{(i)}\right) + \sum_{i=k+1}^{L-1} E^{i-k}\left(q^{(i)}\right).\end{aligned}$$

With the convention $E^0(x) = x$, this leads to

$$\tilde{d}^{(k)} = d^{(k)} + \sum_{i=k}^{L-1} E^{i-k}\left(q^{(i)}\right). \tag{37}$$

Thus, the quantization error $q'^{(k)}$ of the displaced frame

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

difference at level k is given by

$$q'^{(k)} := \tilde{d}^{(k)} - d^{(k)} = \sum_{i=k}^{L-1} E^{i-k}\left(q^{(i)}\right). \tag{38}$$

Based on this relation, the quantization error for the coded frame is given by

$$\begin{aligned}\tilde{g}^{(k)} &= \hat{g}^{(k)} + \tilde{d}^{(k)} \\ &= g^{(k)} + q'^{(k)}.\end{aligned} \tag{39}$$

Therefore, the difference between the coded refinement image (level 0) and the coded and expanded base layer (level 1) is affected only by the quantization error of the refinement layer

$$\begin{aligned}\tilde{g}^{(0)} - E\left(\tilde{g}^{(1)}\right) &= g^{(0)} + q'^{(0)} - E\left(g^{(1)} + q'^{(1)}\right) \\ &= g^{(0)} - E\left(g^{(1)}\right) + q^{(0)}.\end{aligned} \tag{40}$$

B. Quantization Error Feedback

Furthermore, the quantization error feedback due to the predictive coding structure can be analyzed. Therefore, we assume no motion compensation (all displacement vectors are zero). Hence, the prediction is just the previously coded frame $\hat{g}_n^{(k)} = \tilde{g}_{n-1}^{(k)}$. The refinement level of the Laplacian pyramid to be coded

$$\begin{aligned}l_n^{(0)} &= d_n^{(0)} - E\left(d_n^{(1)}\right) \\ &= g_n^{(0)} - \hat{g}_n^{(0)} - \left(E\left(g_n^{(1)}\right) - E\left(\hat{g}_n^{(1)}\right)\right) \\ &= g_n^{(0)} - \tilde{g}_{n-1}^{(0)} - \left(E\left(g_n^{(1)}\right) - E\left(\tilde{g}_{n-1}^{(1)}\right)\right)\end{aligned}$$

depends on the reconstructed previous base and refinement level. Using (40) reveals

$$l_n^{(0)} = g_n^{(0)} - E\left(g_n^{(1)}\right) - \left(g_{n-1}^{(0)} - E\left(g_{n-1}^{(1)}\right)\right) - q_{n-1}^{(0)} \tag{41}$$

that $l_n^{(0)}$ is affected only by the quantization error $q_{n-1}^{(0)}$ of this level. No shift of quantization errors across scales occurs. Therefore, coding of still images and unchanged regions between subsequent frames converges to lossless coding.

Appendix B
Derivation of the Reduce and Expand Operators

In this Appendix, reduce and expand operators are derived, which are based on spline approximations. The derivation follows in its main aspects [15], [9], and is given in terms of discrete one-dimensional operators. For construction of the pyramids used for motion estimation and for DFD coding, these operators are extended to the 2-D case by separable application along the rows and columns of the frames.

The main difference between [9] and our approach is the centering of the lower resolution grid with respect to the high-resolution grid. This yields several advantages compared to the classical approach. First, the centering leads to a quadtree-like topology of the pyramid. Thus, each pixel on a coarse pyramid level belongs to four corresponding pixels of the next finer level, which is advantageous for the propagation of block-based motion vector fields across the differing resolutions. Second, consistent boundary conditions are obtained by mirrored extension of the finite signals, while the uncentered pyramid requires periodic extension which degrades the coding performance at signal support boundaries.

A. Discrete Least Squares Approximation

We consider the construction of a dyadic pyramid in a purely discrete framework. The basic operation is the approximation from a fine space S_1 onto a coarse space S_2 at twice the scale. For convenience, we focus first on sequences of infinite length. Implications of the finite support of the signals are discussed in the following subsection. Thus, we set $S_1 = l_2$ (the space of squared summable sequences), and consider the coarser subspace $S_2 \subset l_2$ generated from the even integer translates of a generating sequence h:

$$\begin{aligned}S_2 &= \operatorname{span}\{h[k-2l]\}_{l\in\mathbb{Z}} \\ &= \left\{\tilde{s}_1 | \tilde{s}_1[k] = \sum_{k\in\mathbb{Z}} s_2[l]h[k-2l], s_2 \in l_2\right\}.\end{aligned} \tag{42}$$

We may think of $s_2[k]$ as being samples of some pyramid level. Then $\tilde{s}_1[k]$ are the samples of the corresponding interpolated (expanded) level. We therefore define the (one-dimensional) expand operator E as

$$E : l_2 \to l_2; \quad s_2 \mapsto E(s_2) = [s_2]_{\uparrow 2} * h \tag{43}$$

and S_2 becomes simply the image of E

$$S_2 = \{\tilde{s}_1 | \tilde{s}_1 = E(s_2), s_2 \in l_2\}. \tag{44}$$

Note that the generating sequence h has a twofold meaning here: 1) it generates the Riesz basis $\{h[k-2l]\}_{l\in\mathbb{Z}}$ of S_2, and hence serves as a scaling function, and 2) it equals the impulse response of the synthesis filter, thus defining the expand operator.

The reduce operator R consists of an antialiasing filter (or analysis filter) with impulse response $\overset{\circ}{h}$ followed by a subsampler:

$$R : l_2 \to l_2; \quad s_1 \mapsto s_2 = R(s_1) = \left[s_1 * \overset{\circ}{h}\right]_{\downarrow 2}. \tag{45}$$

The concatenation of R and E approximates any sequence $s_1 \in l_2$ with a sequence $\tilde{s}_1 = E(R(s_1)) \in S_2$. A prefilter $\overset{\circ}{h}$ is called *optimal* in the least squares sense with respect to a synthesis filter h when the energy $\Sigma_{k\in\mathbb{Z}}(s_1[k] - \tilde{s}_1[k])^2$ of the approximation error becomes minimal.

Theorem 2: The optimal prefilter with respect to a synthesis filter with z transform $H(z)$ is given by

$$\overset{\circ}{H}(z) = \frac{2H(z^{-1})}{H(z)H(z^{-1}) + H(-z)H(-z^{-1})}. \tag{46}$$

Proof: The least squares approximation is achieved when the error $s_1[k] - \tilde{s}_1[k]$ is orthogonal to S_2 or, equivalently

$$\langle h[k-2l], s_1[k]\rangle = \left\langle h[k-2l], \sum_{n\in\mathbb{Z}} s_2[n]h[k-2n]\right\rangle, \quad \forall l \in \mathbb{Z}.$$

With $h^T[k] = h[-k]$, we can rewrite the inner products as convolutions

$$[h^T * s_1]_{\downarrow 2} = [h^T * h]_{\downarrow 2} * s_2.$$

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

Application of the inverse of $[h^T * h]_{\downarrow 2}$ on both sides (which exists because we require h constituting a Riesz basis) yields

$$\begin{aligned} s_2 &= ([h^T * h]_{\downarrow 2})^{-1} * [h^T * s_1]_{\downarrow 2} \\ &= \left[\left[([h^T * h]_{\downarrow 2})^{-1}\right]_{\uparrow 2} * h^T * s_1\right]_{\downarrow 2} \\ &= \left[\overset{\circ}{h} * s_1\right]_{\downarrow 2}. \end{aligned}$$

Thus, the optimal prefilter has the impulse response $\overset{\circ}{h} = [([h^T * h]_{\downarrow 2})^{-1}]_{\uparrow 2} * h^T$, whose z transform is given by (46). ■

Theorem 3: Least squares pyramids have the property that reduction of an expanded signal leaves the signal unchanged.

Proof: By definition, the reduce operator R of a least squares pyramid is chosen such that the energy of the approximation error is minimized. This being true, the concatenated operator

$$P : l_2 \to S_2, \quad s \mapsto \tilde{s} = E(R(s))$$

must be an orthogonal projector from l_2 into S_2. This implies $P(P(s)) = P(s)$. For the reduce and expand operators, this means that $E(R(E(R(s)))) = E(R(s))$, and

$$R(E(s)) = s, \qquad \forall s \in l_2 \tag{47}$$

follows immediately. ■

This property is crucial for the scalable coding scheme described in this paper.

B. Centered Spline Approximation

Until now, we have not specified the space S_2 and the filter h. We confine ourselves to spline pyramids mainly for to reasons. First, splines have excellent approximation properties [19], [20]. Second, the spline framework allows for a progressive transition between the piecewise constant and the band-limited model. The spline of degree zero leads to the Haar wavelet (best time localization), and the cardinal spline filters converge to the sinc interpolator for high degrees [21]. So it can be expected that a reasonable tradeoff between time localization and aliasing can be found inside the class of spline filters.

Usually, the generating kernel h is symmetric, and the coarser grid points are positioned on the even integers. We propose instead to shift the sampling grid of the approximating function such that the samples "sit" centered between the samples of the high-resolution grid. Using the formalism developed in [15], it is not difficult to derive the z transform $H_\Delta(z)$ of the cardinal spline interpolator corresponding to a shift Δ

$$H_{\Delta(z)} = \frac{B^n_{2,\Delta}(z)}{B^n_{1,0}(z)} \tag{48}$$

where the sampled B-spline filter kernels $B^n_{m,\Delta}(z)$ are defined as

$$B^n_{m,\Delta}(z) = \sum_{k\in\mathbb{Z}} \beta^n\left(\frac{k-\Delta}{m}\right) z^{-k} \tag{49}$$

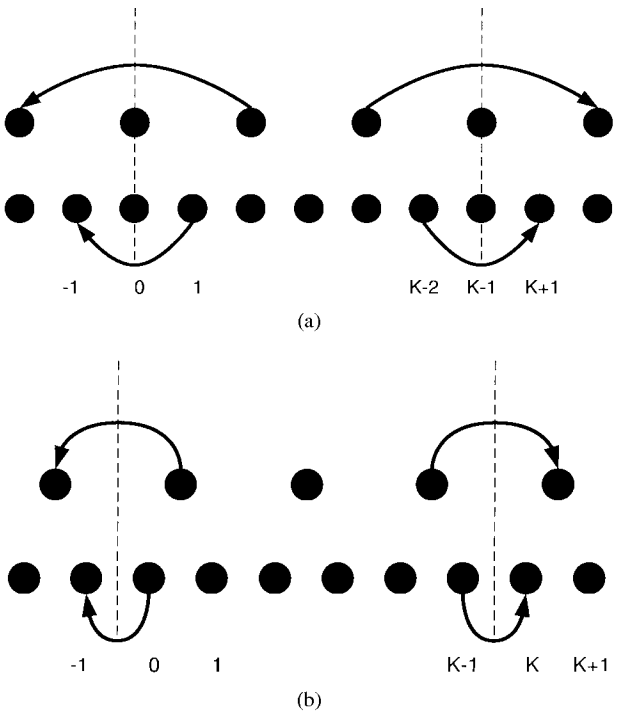

Fig. 10. Odd and even mirroring of a discrete signal. (a) Odd mirroring in case of a traditional pyramid. (b) Even mirroring in case of a centered pyramid.

and $\beta^n(x)$ is the symmetrical B spline of degree n, defined by

$$\beta^n(x) = \beta^0(x) * \beta^{n-1}(x)$$

with

$$\beta^0(x) = \mathrm{rect}(x) = \begin{cases} 1, & \text{for } |x| \le 1/2 \\ 0, & \text{for } |x| > 1/2. \end{cases}$$

For the shift parameter $\Delta = 0$, the pyramid equals the one derived in [9], and corresponds to the traditional formulation of the discrete wavelet transform. For $\Delta = 1$, the samples of the coarse grid sit on the odd integers, and for $\Delta = 1/2$, we end up with the *centered* pyramid which we use for the compression algorithm. In Fig. 10, the positioning of the sampling grids is depicted for the traditional ($\Delta = 0$) and the centered ($\Delta = 1/2$) case. The centered pyramid allows us to assign each sample on the fine grid the closest sample on the coarse grid, whereas this is possible in the traditional pyramid only for the even samples.

Until now, only infinite signals have been considered. In the case of finite signals, we have to impose suited boundary conditions. In signal processing, such boundary conditions are usually formulated in terms of signal extensions across the boundaries. It is easy to show that in the case of the uncentered spline approximation, consistent boundary conditions are given by periodic repetition of the signals. However, this introduces unnatural discontinuities at the boundaries, which degrade the performance of most signal processing applications. Therefore, a symmetric extension by mirroring is preferred in many applications, as depicted in Fig. 11 for continuous signals.

If the length of the signal K is even, a proper symmetric extension is impossible as long as we stay with the uncentered grid. On the other hand, if we use a centered grid as proposed

Authorized licensed use limited to: Rennae Johnson. Downloaded on August 10,2010 at 17:06:52 UTC from IEEE Xplore. Restrictions apply.

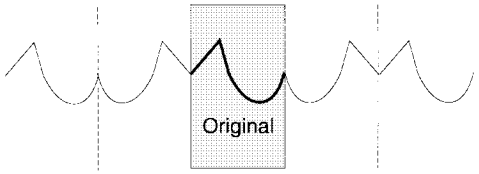

Fig. 11. Symmetric boundary extension of a continuous signal with finite support.

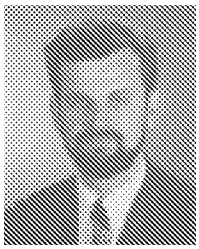
in this paper, we can use the "even" mirroring

$$s[-k-1] = s[k], \qquad k = 0 \cdots K-1$$
$$s[k] = s[2K-1-k], \qquad k = K \cdots 2K-1$$



without distorting property (47).

ACKNOWLEDGMENT

The authors would like to thank Prof. Dr.-Ing. H. D. Lüke, Aachen University of Technology, Germany, for his support of the underlying research, and also the anonymous referees for their valuable comments.

Klaus Illgner received the Dipl. degree (M.S.) in electrical engineering from Aachen University of Technology (RWTH), Germany, in 1991.

Since then, he has been with the Institut für Elektrische Nachrichtentechnik, RWTH Aachen, as a Scientific Assistant. His research interests cover all aspects of low-bit-rate video coding and video communications, where his main focus at present is on motion compensation and multiresolution video.

Mr. Illgner is a member of the IEEE Signal Processing Society, the IEEE Communications Society, and the German Electrical Engineering Association (VDE).

Frank Müller received the Dipl. degree (M.S.) in electrical engineering from Aachen University of Technology (RWTH), Germany, in 1991.

Since then, he has been with the Institut für Elektrische Nachrichtentechnik, RWTH Aachen, as a Scientific Assistant. His current interests are hierarchical and multiresolution approaches to image and video compression, and source coding theory.

Mr. Müller is a member of the IEEE Signal Processing Society, the IEEE Information Theory Society, the German Electrical Engineering Association (VDE), and the German Computer Society (Gesellschaft für Informatik (GI)).

Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 3.

In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this part of ISO/IEC 13818 may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights.

International Standard ISO/IEC 13818-1 was prepared by Joint Technical Committee ISO/IEC JTC 1, *Information technology*, Subcommittee SC 29, *Coding of audio, picture, multimedia and hypermedia information*, in collaboration with ITU-T. The identical text is published as ITU-T Rec. H.222.0.

This second edition cancels and replaces the first edition (ISO/IEC 3818-1:1996), which has been technically revised.

ISO/IEC 13818 consists of the following parts, under the general title *Information technology — Generic coding of moving pictures and associated audio information*:

— *Part 1: Systems*

— *Part 2: Video*

— *Part 3: Audio*

— *Part 4: Conformance testing*

— *Part 5: Software simulation*

— *Part 6: Extensions for DSM-CC*

— *Part 7: Advanced Audio Coding (ACC)*

— *Part 9: Extension for real time interface for systems decoders*

— *Part 10: Conformance extensions for Digital Storage Media Command and Control (DSM-CC)*

Annex A forms a normative part of this part of ISO/IEC 13818. Annexes B to S are for information only.

Introduction

The systems part of this Recommendation | International Standard addresses the combining of one or more elementary streams of video and audio, as well as other data, into single or multiple streams which are suitable for storage or transmission. Systems coding follows the syntactical and semantic rules imposed by this Specification and provides information to enable synchronized decoding of decoder buffers over a wide range of retrieval or receipt conditions.

System coding shall be specified in two forms: the **Transport Stream** and the **Program Stream**. Each is optimized for a different set of applications. Both the Transport Stream and Program Stream defined in this Recommendation | International Standard provide coding syntax which is necessary and sufficient to synchronize the decoding and presentation of the video and audio information, while ensuring that data buffers in the decoders do not overflow or underflow. Information is coded in the syntax using time stamps concerning the decoding and presentation of coded audio and visual data and time stamps concerning the delivery of the data stream itself. Both stream definitions are packet-oriented multiplexes.

The basic multiplexing approach for single video and audio elementary streams is illustrated in Figure Intro. 1. The video and audio data is encoded as described in ITU-T Rec. H.262 | ISO/IEC 13818-2 and ISO/IEC 13818-3. The resulting compressed elementary streams are packetized to produce **PES packets**. Information needed to use PES packets independently of either Transport Streams or Program Streams may be added when PES packets are formed. This information is not needed and need not be added when PES packets are further combined with system level information to form **Transport Streams** or **Program Streams**. This systems standard covers those processes to the right of the vertical dashed line.

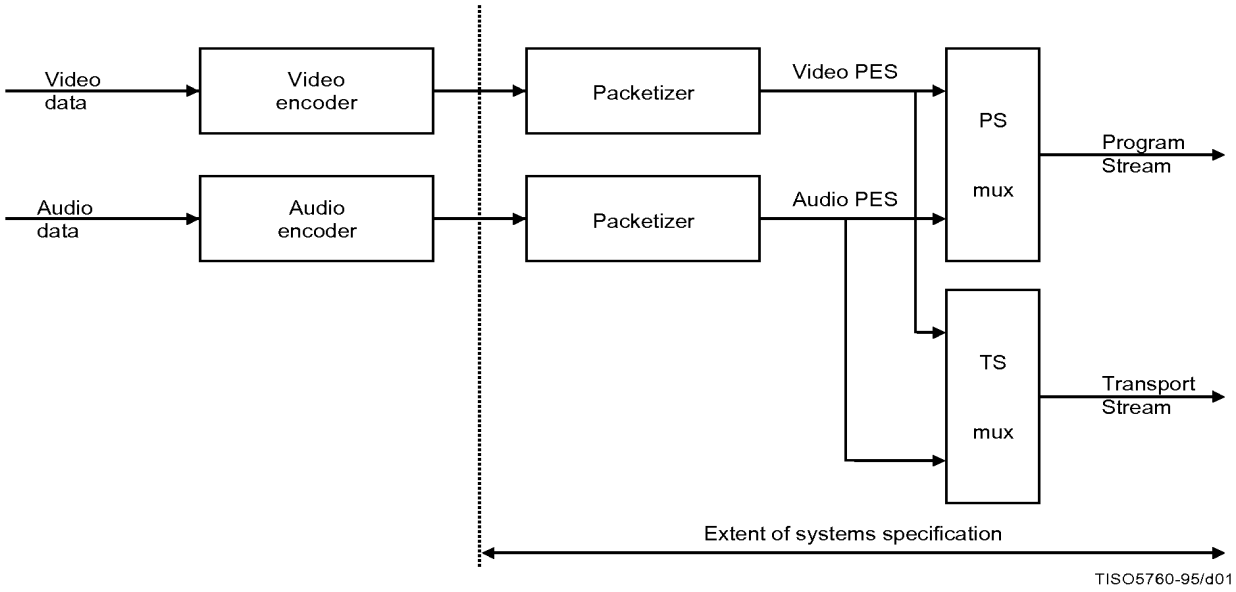

Figure Intro. 1 – Simplified overview of the scope of this Recommendation | International Standard

The **Program Stream** is analogous and similar to ISO/IEC 11172 Systems layer. It results from combining one or more streams of PES packets, which have a common time base, into a single stream.

For applications that require the elementary streams which comprise a single program to be in separate streams which are not multiplexed, the elementary streams can also be encoded as separate Program Streams, one per elementary stream, with a common time base. In this case the values encoded in the SCR fields of the various streams shall be consistent.

Like the single Program Stream, all elementary streams can be decoded with synchronization.

© ISO/IEC 2000 – All rights reserved

The Program Stream is designed for use in relatively error-free environments and is suitable for applications which may involve software processing of system information such as interactive multi-media applications. Program Stream packets may be of variable and relatively great length.

The **Transport Stream** combines one or more programs with one or more independent time bases into a single stream. PES packets made up of elementary streams that form a program share a common timebase. The Transport Stream is designed for use in environments where errors are likely, such as storage or transmission in lossy or noisy media. Transport Stream packets are 188 bytes in length.

Program and Transport Streams are designed for different applications and their definitions do not strictly follow a layered model. It is possible and reasonable to convert from one to the other; however, one is not a subset or superset of the other. In particular, extracting the contents of a program from a Transport Stream and creating a valid Program Stream is possible and is accomplished through the common interchange format of PES packets, but not all of the fields needed in a Program Stream are contained within the Transport Stream; some must be derived. The Transport Stream may be used to span a range of layers in a layered model, and is designed for efficiency and ease of implementation in high bandwidth applications.

The scope of syntactical and semantic rules set forth in the systems specification differ: the syntactical rules apply to systems layer coding only, and do not extend to the compression layer coding of the video and audio specifications; by contrast, the semantic rules apply to the combined stream in its entirety.

The systems specification does not specify the architecture or implementation of encoders or decoders, nor those of multiplexors or demultiplexors. However, bit stream properties do impose functional and performance requirements on encoders, decoders, multiplexors and demultiplexors. For instance, encoders must meet minimum clock tolerance requirements. Notwithstanding this and other requirements, a considerable degree of freedom exists in the design and implementation of encoders, decoders, multiplexors, and demultiplexors.

Intro. 1 Transport Stream

The Transport Stream is a stream definition which is tailored for communicating or storing one or more programs of coded data according to ITU-T Rec. H.262 | ISO/IEC 13818-2 and ISO/IEC 13818-3 and other data in environments in which significant errors may occur. Such errors may be manifested as bit value errors or loss of packets.

Transport Streams may be either fixed or variable rate. In either case the constituent elementary streams may either be fixed or variable rate. The syntax and semantic constraints on the stream are identical in each of these cases. The Transport Stream rate is defined by the values and locations of Program Clock Reference (PCR) fields, which in general are separate PCR fields for each program.

There are some difficulties with constructing and delivering a Transport Stream containing multiple programs with independent time bases such that the overall bit rate is variable. Refer to 2.4.2.2.

The Transport Stream may be constructed by any method that results in a valid stream. It is possible to construct Transport Streams containing one or more programs from elementary coded data streams, from Program Streams, or from other Transport Streams which may themselves contain one or more programs.

The Transport Stream is designed in such a way that several operations on a Transport Stream are possible with minimum effort. Among these are:

1) Retrieve the coded data from one program within the Transport Stream, decode it and present the decoded results as shown in Figure Intro. 2.

2) Extract the Transport Stream packets from one program within the Transport Stream and produce as output a different Transport Stream with only that one program as shown in Figure Intro. 3.

3) Extract the Transport Stream packets of one or more programs from one or more Transport Streams and produce as output a different Transport Stream (not illustrated).

4) Extract the contents of one program from the Transport Stream and produce as output a Program Stream containing that one program as shown in Figure Intro. 4.

5) Take a Program Stream, convert it into a Transport Stream to carry it over a lossy environment, and then recover a valid, and in certain cases, identical Program Stream.

© ISO/IEC 2000 – All rights reserved

Figure Intro. 2 and Figure Intro. 3 illustrate prototypical demultiplexing and decoding systems which take as input a Transport Stream. Figure Intro. 2 illustrates the first case, where a Transport Stream is directly demultiplexed and decoded. Transport Streams are constructed in two layers:

– a system layer; and

– a compression layer.

The input stream to the Transport Stream decoder has a system layer wrapped about a compression layer. Input streams to the Video and Audio decoders have only the compression layer.

Operations performed by the prototypical decoder which accepts Transport Streams either apply to the entire Transport Stream ("multiplex-wide operations"), or to individual elementary streams ("stream-specific operations"). The Transport Stream system layer is divided into two sub-layers, one for multiplex-wide operations (the Transport Stream packet layer), and one for stream-specific operations (the PES packet layer).

A prototypical decoder for Transport Streams, including audio and video, is also depicted in Figure Intro. 2 to illustrate the function of a decoder. The architecture is not unique – some system decoder functions, such as decoder timing control, might equally well be distributed among elementary stream decoders and the channel specific decoder – but this figure is useful for discussion. Likewise, indication of errors detected by the channel specific decoder to the individual audio and video decoders may be performed in various ways and such communication paths are not shown in the diagram. The prototypical decoder design does not imply any normative requirement for the design of a Transport Stream decoder. Indeed non-audio/video data is also allowed, but not shown.

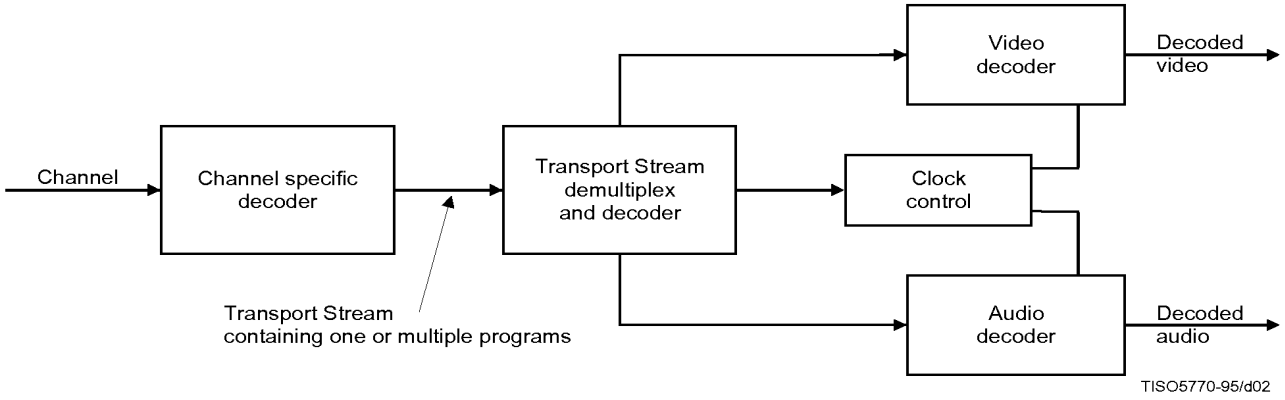

Figure Intro. 2 – Prototypical transport demultiplexing and decoding example

Figure Intro. 3 illustrates the second case, where a Transport Stream containing multiple programs is converted into a Transport Stream containing a single program. In this case the re-multiplexing operation may necessitate the correction of Program Clock Reference (PCR) values to account for changes in the PCR locations in the bit stream.

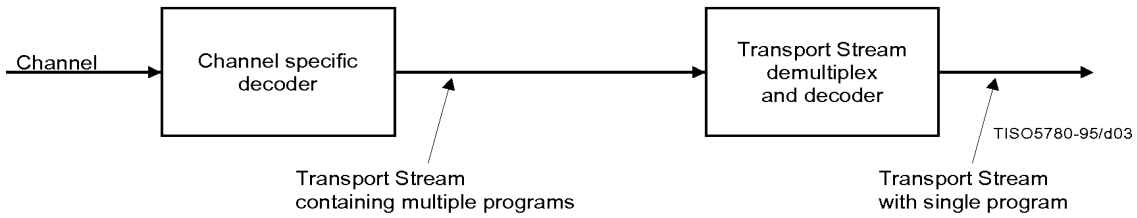

Figure Intro. 3 – Prototypical transport multiplexing example

 © ISO/IEC 2000 – All rights reserved

Figure Intro. 4 illustrates a case in which a multi-program Transport Stream is first demultiplexed and then converted into a Program Stream.

Figures Intro. 3 and Intro. 4 indicate that it is possible and reasonable to convert between different types and configurations of Transport Streams. There are specific fields defined in the **Transport Stream** and **Program Stream** syntax which facilitate the conversions illustrated. There is no requirement that specific implementations of demultiplexors or decoders include all of these functions.

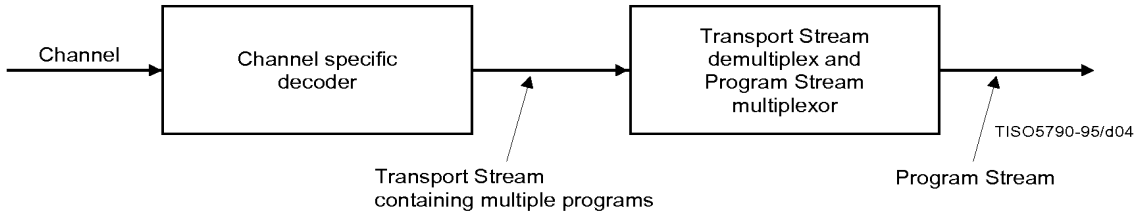

Figure Intro. 4 – Prototypical Transport Stream to Program Stream conversion

Intro. 2 Program Stream

The Program Stream is a stream definition which is tailored for communicating or storing one program of coded data and other data in environments where errors are very unlikely, and where processing of system coding, e.g. by software, is a major consideration.

Program Streams may be either fixed or variable rate. In either case, the constituent elementary streams may be either fixed or variable rate. The syntax and semantics constraints on the stream are identical in each case. The Program Stream rate is defined by the values and locations of the System Clock Reference (SCR) and mux_rate fields.

A prototypical audio/video Program Stream decoder system is depicted in Figure Intro. 5. The architecture is not unique – system decoder functions including decoder timing control might as equally well be distributed among elementary stream decoders and the channel specific decoder – but this figure is useful for discussion. The prototypical decoder design does not imply any normative requirement for the design of an Program Stream decoder. Indeed non-audio/video data is also allowed, but not shown.

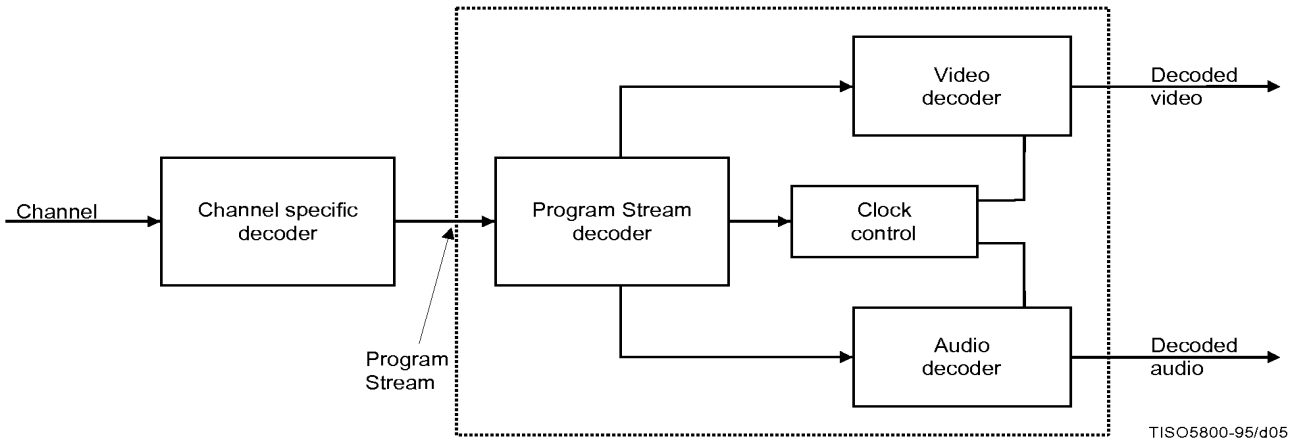

Figure Intro. 5 – Prototypical decoder for Program Streams

© ISO/IEC 2000 – All rights reserved

The prototypical decoder for Program Streams shown in Figure Intro. 5 is composed of System, Video, and Audio decoders conforming to Parts 1, 2, and 3, respectively, of ISO/IEC 13818. In this decoder, the multiplexed coded representation of one or more audio and/or video streams is assumed to be stored or communicated on some channel in some channel-specific format. The channel-specific format is not governed by this Recommendation | International Standard, nor is the channel-specific decoding part of the prototypical decoder.

The prototypical decoder accepts as input a Program Stream and relies on a Program Stream Decoder to extract timing information from the stream. The Program Stream Decoder demultiplexes the stream, and the elementary streams so produced serve as inputs to Video and Audio decoders, whose outputs are decoded video and audio signals. Included in the design, but not shown in the figure, is the flow of timing information among the Program Stream decoder, the Video and Audio decoders, and the channel-specific decoder. The Video and Audio decoders are synchronized with each other and with the channel using this timing information.

Program Streams are constructed in two layers: a system layer and a compression layer. The input stream to the Program Stream Decoder has a system layer wrapped about a compression layer. Input streams to the Video and Audio decoders have only the compression layer.

Operations performed by the prototypical decoder either apply to the entire Program Stream ("multiplex-wide operations"), or to individual elementary streams ("stream-specific operations"). The Program Stream system layer is divided into two sub-layers, one for multiplex-wide operations (the pack layer), and one for stream-specific operations (the PES packet layer).

Intro. 3 Conversion between Transport Stream and Program Stream

It may be possible and reasonable to convert between **Transport Streams** and **Program Streams** by means of PES packets. This results from the specification of **Transport Stream** and **Program Stream** as embodied in 2.4.1 and 2.5.1 of the normative requirements of this Recommendation | International Standard. PES packets may, with some constraints, be mapped directly from the payload of one multiplexed bit stream into the payload of another multiplexed bit stream. It is possible to identify the correct order of PES packets in a program to assist with this if the program_packet_sequence_counter is present in all PES packets.

Certain other information necessary for conversion, e.g. the relationship between elementary streams, is available in tables and headers in both streams. Such data, if available, shall be correct in any stream before and after conversion.

Intro. 4 Packetized Elementary Stream

Transport Streams and **Program Streams** are each logically constructed from PES packets, as indicated in the syntax definitions in 2.4.3.6. PES packets shall be used to convert between Transport Streams and Program Streams; in some cases the PES packets need not be modified when performing such conversions. PES packets may be much larger than the size of a Transport Stream packet.

A continuous sequence of PES packets of one elementary stream with one stream ID may be used to construct a PES Stream. When PES packets are used to form a PES stream, they shall include Elementary Stream Clock Reference (ESCR) fields and Elementary Stream Rate (ES_Rate) fields, with constraints as defined in 2.4.3.8. The PES stream data shall be contiguous bytes from the elementary stream in their original order. PES streams do not contain some necessary system information which is contained in Program Streams and Transport Streams. Examples include the information in the Pack Header, System Header, Program Stream Map, Program Stream Directory, Program Map Table, and elements of the Transport Stream packet syntax.

The PES Stream is a logical construct that may be useful within implementations of this Recommendation | International Standard; however, it is not defined as a stream for interchange and interoperability. Applications requiring streams containing only one elementary stream can use Program Streams or Transport Streams which each contain only one elementary stream. These streams contain all of the necessary system information. Multiple Program Streams or Transport Streams, each containing a single elementary stream, can be constructed with a common time base and therefore carry a complete program, i.e. with audio and video.

Intro. 5 Timing model

Systems, Video and Audio all have a timing model in which the end-to-end delay from the signal input to an encoder to the signal output from a decoder is a constant. This delay is the sum of encoding, encoder buffering, multiplexing, communication or storage, demultiplexing, decoder buffering, decoding, and presentation delays. As part of this timing model all video pictures and audio samples are presented exactly once, unless specifically coded to the contrary, and the inter-picture interval and audio sample rate are the same at the decoder as at the encoder. The system stream coding

 © ISO/IEC 2000 – All rights reserved

contains timing information which can be used to implement systems which embody constant end-to-end delay. It is possible to implement decoders which do not follow this model exactly; however, in such cases it is the decoder's responsibility to perform in an acceptable manner. The timing is embodied in the normative specifications of this Recommendation | International Standard, which must be adhered to by all valid bit streams, regardless of the means of creating them.

All timing is defined in terms of a common system clock, referred to as a System Time Clock. In the Program Stream this clock may have an exactly specified ratio to the video or audio sample clocks, or it may have an operating frequency which differs slightly from the exact ratio while still providing precise end-to-end timing and clock recovery.

In the Transport Stream the system clock frequency is constrained to have the exactly specified ratio to the audio and video sample clocks at all times; the effect of this constraint is to simplify sample rate recovery in decoders.

Intro. 6 Conditional access

Encryption and scrambling for conditional access to programs encoded in the Program and Transport Streams is supported by the system data stream definitions. Conditional access mechanisms are not specified here. The stream definitions are designed so that implementation of practical conditional access systems is reasonable, and there are some syntactical elements specified which provide specific support for such systems.

Intro. 7 Multiplex-wide operations

Multiplex-wide operations include the co-ordination of data retrieval of the channel, the adjustment of clocks, and the management of buffers. The tasks are intimately related. If the rate of data delivery of the channel is controllable, then data delivery may be adjusted so that decoder buffers neither overflow nor underflow; but if the data rate is not controllable, then elementary stream decoders must slave their timing to the data received from the channel to avoid overflow or underflow.

Program Streams are composed of packs whose headers facilitate the above tasks. Pack headers specify intended times at which each byte is to enter the Program Stream Decoder from the channel, and this target arrival schedule serves as a reference for clock correction and buffer management. The schedule need not be followed exactly by decoders, but they must compensate for deviations about it.

Similarly, Transport Streams are composed of Transport Stream packets with headers containing information which specifies the times at which each byte is intended to enter a Transport Stream Decoder from the channel. This schedule provides exactly the same function as that which is specified in the Program Stream.

An additional multiplex-wide operation is a decoder's ability to establish what resources are required to decode a Transport Stream or Program Stream. The first pack of each Program Stream conveys parameters to assist decoders in this task. Included, for example, are the stream's maximum data rate and the highest number of simultaneous video channels. The Transport Stream likewise contains globally useful information.

The Transport Stream and Program Stream each contain information which identifies the pertinent characteristics of, and relationships between, the elementary streams which constitute each program. Such information may include the language spoken in audio channels, as well as the relationship between video streams when multi-layer video coding is implemented.

Intro. 8 Individual stream operations (PES Packet Layer)

The principal stream-specific operations are:

1) demultiplexing; and

2) synchronizing playback of multiple elementary streams.

Intro. 8.1 Demultiplexing

On encoding, Program Streams are formed by multiplexing elementary streams, and Transport Streams are formed by multiplexing elementary streams, Program Streams, or the contents of other Transport Streams. Elementary streams may include private, reserved, and padding streams in addition to audio and video streams. The streams are temporally subdivided into packets, and the packets are serialized. A PES packet contains coded bytes from one and only one elementary stream.

© ISO/IEC 2000 – All rights reserved

In the Program Stream both fixed and variable packet lengths are allowed subject to constraints as specified in 2.5.1 and 2.5.2. For Transport Streams the packet length is 188 bytes. Both fixed and variable PES packet lengths are allowed, and will be relatively long in most applications.

On decoding, demultiplexing is required to reconstitute elementary streams from the multiplexed Program Stream or Transport Stream. Stream_id codes in Program Stream packet headers, and Packet ID codes in the Transport Stream make this possible.

Intro. 8.2 Synchronization

Synchronization among multiple elementary streams is accomplished with Presentation Time Stamps (PTS) in the Program Stream and Transport streams. Time stamps are generally in units of 90 kHz, but the System Clock Reference (SCR), the Program Clock Reference (PCR) and the optional Elementary Stream Clock Reference (ESCR) have extensions with a resolution of 27 MHz. Decoding of N-elementary streams is synchronized by adjusting the decoding of streams to a common master time base rather than by adjusting the decoding of one stream to match that of another. The master time base may be one of the N-decoders' clocks, the data source's clock, or it may be some external clock.

Each program in a Transport Stream, which may contain multiple programs, may have its own time base. The time bases of different programs within a Transport Stream may be different.

Because PTSs apply to the decoding of individual elementary streams, they reside in the PES packet layer of both the Transport Streams and Program Streams. End-to-end synchronization occurs when encoders save time stamps at capture time, when the time stamps propagate with associated coded data to decoders, and when decoders use those time stamps to schedule presentations.

Synchronization of a decoding system with a channel is achieved through the use of the SCR in the Program Stream and by its analogue, the PCR, in the Transport Stream. The SCR and PCR are time stamps encoding the timing of the bit stream itself, and are derived from the same time base used for the audio and video PTS values from the same program. Since each program may have its own time base, there are separate PCR fields for each program in a Transport Stream containing multiple programs. In some cases it may be possible for programs to share PCR fields. Refer to 2.4.4, Program Specific Information (PSI), for the method of identifying which PCR is associated with a program. A program shall have one and only one PCR time base associated with it.

Intro. 8.3 Relation to compression layer

The PES packet layer is independent of the compression layer in some senses, but not in all. It is independent in the sense that PES packet payloads need not start at compression layer start codes, as defined in Parts 2 and 3 of ISO/IEC 13818. For example, video start codes may occur anywhere within the payload of a PES packet, and start codes may be split by a PES packet header. However, time stamps encoded in PES packet headers apply to presentation times of compression layer constructs (namely, presentation units). In addition, when the elementary stream data conforms to ITU-T Rec. H.262 | ISO/IEC 13818-2 or ISO/IEC 13818-3, the PES_packet_data_bytes shall be byte aligned to the bytes of this Recommendation | International Standard.

Intro. 9 System reference decoder

Part 1 of ISO/IEC 13818 employs a "System Target Decoder" (STD), one for Transport Streams (refer to 2.4.2) referred to as "Transport System Target Decoder" (T-STD) and one for Program Streams (refer to 2.5.2) referred to as "Program System Target Decoder" (P-STD), to provide a formalism for timing and buffering relationships. Because the STD is parameterized in terms of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 fields (for example, buffer sizes) each elementary stream leads to its own parameterization of the STD. Encoders shall produce bit streams that meet the appropriate STD's constraints. Physical decoders may assume that a stream plays properly on its STD. The physical decoder must compensate for ways in which its design differs from that of the STD.

Intro. 10 Applications

The streams defined in this Recommendation | International Standard are intended to be as useful as possible to a wide variety of applications. Application developers should select the most appropriate stream.

Modern data communications networks may be capable of supporting ITU-T Rec. H.222.0 | ISO/IEC 13818-1 video and ISO/IEC 13818 audio. A real time transport protocol is required. The Program Stream may be suitable for transmission on such networks.

 © ISO/IEC 2000 – All rights reserved

The Program Stream is also suitable for multimedia applications on CD-ROM. Software processing of the Program Stream may be appropriate.

The Transport Stream may be more suitable for error-prone environments, such as those used for distributing compressed bit-streams over long distance networks and in broadcast systems.

Many applications require storage and retrieval of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstreams on various Digital Storage Media (DSM). A Digital Storage Media Command and Control (DSM-CC) protocol is specified in Annex B and Part 6 of ISO/IEC 13818 in order to facilitate the control of such media.

INTERNATIONAL STANDARD

ITU-T RECOMMENDATION

INFORMATION TECHNOLOGY – GENERIC CODING OF MOVING PICTURES AND ASSOCIATED AUDIO INFORMATION: SYSTEMS

SECTION 1 – GENERAL

1.1 Scope

This Recommendation | International Standard specifies the system layer of the coding. It was developed principally to support the combination of the video and audio coding methods defined in Parts 2 and 3 of ISO/IEC 13818. The system layer supports five basic functions:

1) the synchronization of multiple compressed streams on decoding;

2) the interleaving of multiple compressed streams into a single stream;

3) the initialization of buffering for decoding start up;

4) continuous buffer management; and

5) time identification.

An ITU-T Rec. H.222.0 | ISO/IEC 13818-1 multiplexed bit stream is either a **Transport Stream** or a **Program Stream**. Both streams are constructed from **PES packets** and packets containing other necessary information. Both stream types support multiplexing of video and audio compressed streams from one program with a common time base. The **Transport Stream** additionally supports the multiplexing of video and audio compressed streams from multiple programs with independent time bases. For almost error-free environments the **Program Stream** is generally more appropriate, supporting software processing of program information. The **Transport Stream** is more suitable for use in environments where errors are likely.

An ITU-T Rec. H.222.0 | ISO/IEC 13818-1 multiplexed bit stream, whether a Transport Stream or a Program Stream, is constructed in two layers: the outermost layer is the system layer, and the innermost is the compression layer. The system layer provides the functions necessary for using one or more compressed data streams in a system. The video and audio parts of this Specification define the compression coding layer for audio and video data. Coding of other types of data is not defined by this Specification, but is supported by the system layer provided that the other types of data adhere to the constraints defined in 2.7.

1.2 Normative references

The following Recommendations and International Standards contain provisions which, through reference in this text, constitute provisions of this Recommendation | International Standard. At the time of publication, the editions indicated were valid. All Recommendations and Standards are subject to revision, and parties to agreements based on this Recommendation | International Standard are encouraged to investigate the possibility of applying the most recent edition of the Recommendations and Standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards. The Telecommunication Standardization Bureau of the ITU maintains a list of currently valid ITU-T Recommendations.

SECTION 2 – TECHNICAL ELEMENTS

2.1 Definitions

For the purposes of this Recommendation | International Standard, the following definitions apply. If specific to a Part, this is parenthetically noted.

2.1.1 access unit (system): A coded representation of a presentation unit. In the case of audio, an access unit is the coded representation of an audio frame.

In the case of video, an access unit includes all the coded data for a picture, and any stuffing that follows it, up to but not including the start of the next access unit. If a picture is not preceded by a group_start_code or a sequence_header_code, the access unit begins with the picture start code. If a picture is preceded by a group_start_code and/or a sequence_header_code, the access unit begins with the first byte of the first of these start codes. If it is the last picture preceding a sequence_end_code in the bitstream, all bytes between the last byte of the coded picture and the sequence_end_code (including the sequence_end_code) belong to the access unit.

2.1.2 bitrate: The rate at which the compressed bit stream is delivered from the channel to the input of a decoder.

2.1.3 byte aligned: A bit in a coded bit stream is byte-aligned if its position is a multiple of 8-bits from the first bit in the stream.

2.1.4 channel: A digital medium that stores or transports an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream.

2.1.5 coded representation: A data element as represented in its encoded form.

2.1.6 compression: Reduction in the number of bits used to represent an item of data.

2.1.7 constant bitrate: Operation where the bitrate is constant from start to finish of the compressed bit stream.

2.1.8 constrained system parameter stream; CSPS (system): A Program Stream for which the constraints defined in 2.7.9 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 apply.

2.1.9 CRC: The Cyclic Redundancy Check to verify the correctness of data.

2.1.10 data element: An item of data as represented before encoding and after decoding.

2.1.11 decoded stream: The decoded reconstruction of a compressed bit stream.

2.1.12 decoder: An embodiment of a decoding process.

2.1.13 decoding (process): The process defined in ITU-T Rec. H.222.0 | ISO/IEC 13818-1 that reads an input coded bit stream and outputs decoded pictures or audio samples.

2.1.14 decoding time-stamp; DTS (system): A field that may be present in a PES packet header that indicates the time that an access unit is decoded in the system target decoder.

2.1.15 digital storage media (DSM): A digital storage or transmission device or system.

2.1.16 DSM-CC: Digital storage media command and control.

2.1.17 entitlement control message (ECM): Entitlement Control Messages are private conditional access information which specify control words and possibly other, typically stream-specific, scrambling and/or control parameters.

2.1.18 entitlement management message (EMM): Entitlement Management Messages are private conditional access information which specify the authorization levels or the services of specific decoders. They may be addressed to single decoders or groups of decoders.

2.1.19 editing: The process by which one or more compressed bit streams are manipulated to produce a new compressed bit stream. Edited bit streams meet the same requirements as streams which are not edited.

2.1.20 elementary stream; ES (system): A generic term for one of the coded video, coded audio or other coded bit streams in PES packets. One elementary stream is carried in a sequence of PES packets with one and only one stream_id.

2.1.21 Elementary Stream Clock Reference; ESCR (system): A time stamp in the PES Stream from which decoders of PES streams may derive timing.

2.1.22 encoder: An embodiment of an encoding process.

2.1.23 encoding (process): A process, not specified in ITU-T Rec. H.222.0 | ISO/IEC 13818-1, that reads a stream of input pictures or audio samples and produces a coded bit stream conforming to ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.24 entropy coding: Variable length lossless coding of the digital representation of a signal to reduce redundancy.

2.1.25 event: An event is defined as a collection of elementary streams with a common time base, an associated start time, and an associated end time.

2.1.26 fast forward playback (video): The process of displaying a sequence, or parts of a sequence, of pictures in display-order faster than real-time.

2.1.27 forbidden: The term "forbidden", when used in the clauses of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defining the coded bit stream, indicates that the value specified shall never be used.

2.1.28 (multiplexed) stream (system): A bit stream composed of 0 or more elementary streams combined in a manner that conforms to ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.29 layer (video and systems): One of the levels in the data hierarchy of the video and system specifications defined in Parts 1 and 2 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.30 pack (system): A pack consists of a pack header followed by zero or more packets. It is a layer in the system coding syntax described in 2.5.3.3 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.31 packet data (system): Contiguous bytes of data from an elementary stream present in a packet.

2.1.32 packet identifier; PID (system): A unique integer value used to identify elementary streams of a program in a single or multi-program Transport Stream as described in 2.4.3 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.33 padding (audio): A method to adjust the average length of an audio frame in time to the duration of the corresponding PCM samples, by conditionally adding a slot to the audio frame.

2.1.34 payload: Payload refers to the bytes which follow the header bytes in a packet. For example, the payload of some Transport Stream packets includes a PES_packet_header and its PES_packet_data_bytes, or pointer_field and PSI sections, or private data; but a PES_packet_payload consists of only PES_packet_data_bytes. The Transport Stream packet header and adaptation fields are not payload.

2.1.35 PES (system): An abbreviation for Packetized Elementary Stream.

2.1.36 PES packet (system): The data structure used to carry elementary stream data. A PES packet consists of a PES packet header followed by a number of contiguous bytes from an elementary data stream. It is a layer in the system coding syntax described in 2.4.3.6 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.37 PES packet header (system): The leading fields in a PES packet up to and not including the PES_packet_data_byte fields, where the stream is not a padding stream. In the case of a padding stream the PES packet header is similarly defined as the leading fields in a PES packet up to and not including padding_byte fields.

2.1.38 PES Stream (system): A PES Stream consists of PES packets, all of whose payloads consist of data from a single elementary stream, and all of which have the same stream_id. Specific semantic constraints apply. Refer to Intro. 4 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.39 presentation time-stamp; PTS (system): A field that may be present in a PES packet header that indicates the time that a presentation unit is presented in the system target decoder.

2.1.40 presentation unit; PU (system): A decoded Audio Access Unit or a decoded picture.

2.1.41 program (system): A program is a collection of program elements. Program elements may be elementary streams. Program elements need not have any defined time base; those that do, have a common time base and are intended for synchronized presentation.

2.1.42 Program Clock Reference; PCR (system): A time stamp in the Transport Stream from which decoder timing is derived.

2.1.43 program element (system): A generic term for one of the elementary streams or other data streams that may be included in a program.

2.1.44 Program Specific Information; PSI (system): PSI consists of normative data which is necessary for the demultiplexing of Transport Streams and the successful regeneration of programs and is described in 2.4.4 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1. An example of privately defined PSI data is the non-mandatory network information table.

2.1.45 random access: The process of beginning to read and decode the coded bit stream at an arbitrary point.

2.1.46 reserved: The term "reserved", when used in the clauses defining the coded bit stream, indicates that the value may be used in the future for ISO defined extensions. Unless otherwise specified within ITU-T Rec. H.222.0 | ISO/IEC 13818-1, all reserved bits shall be set to '1'.

2.1.47 scrambling (system): The alteration of the characteristics of a video, audio or coded data stream in order to prevent unauthorized reception of the information in a clear form. This alteration is a specified process under the control of a conditional access system.

2.1.48 source stream: A single non-multiplexed stream of samples before compression coding.

2.1.49 splicing (system): The concatenation, performed on the system level, of two different elementary streams. The resulting system stream conforms totally to ITU-T Rec. H.222.0 | ISO/IEC 13818-1. The splice may result in discontinuities in timebase, continuity counter, PSI, and decoding.

2.1.50 start codes (system): 32-bit codes embedded in the coded bit stream. They are used for several purposes including identifying some of the layers in the coding syntax. Start codes consist of a 24-bit prefix (0x000001) and an 8-bit stream_id as shown in Table 2-18 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

2.1.51 STD input buffer (system): A first-in first-out buffer at the input of a system target decoder for storage of compressed data from elementary streams before decoding.

2.1.52 still picture: A coded still picture consists of a video sequence containing exactly one coded picture which is intra-coded. This picture has an associated PTS and the presentation time of succeeding pictures, if any, is later than that of the still picture by at least two picture periods.

2.1.53 system header (system): The system header is a data structure defined in 2.5.3.5 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 that carries information summarizing the system characteristics of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Stream.

2.1.54 System Clock Reference; SCR (system): A time stamp in the Program Stream from which decoder timing is derived.

2.1.55 system target decoder; STD (system): A hypothetical reference model of a decoding process used to define the semantics of an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 multiplexed bit stream.

2.1.56 time-stamp (system): A term that indicates the time of a specific action such as the arrival of a byte or the presentation of a Presentation Unit.

2.1.57 Transport Stream packet header (system): The leading fields in a Transport Stream packet, up to and including the continuity_counter field.

2.1.58 variable bitrate: An attribute of Transport Streams or Program Streams wherein the rate of arrival of bytes at the input to a decoder varies with time.

2.2 Symbols and abbreviations

The mathematical operators used to describe this Recommendation | International Standard are similar to those used in the C-programming language. However, integer division with truncation and rounding are specifically defined. The bitwise operators are defined assuming two's-complement representation of integers. Numbering and counting loops generally begin from 0.

2.2.1 Arithmetic operators

+	Addition
−	Subtraction (as a binary operator) or negation (as a unary operator)
++	Increment
−−	Decrement
* or ×	Multiplication
^	Power
/	Integer division with truncation of the result toward 0. For example, 7/4 and −7/−4 are truncated to 1 and −7/4 and 7/−4 are truncated to −1.
//	Integer division with rounding to the nearest integer. Half-integer values are rounded away from 0 unless otherwise specified. For example 3//2 is rounded to 2, and −3//2 is rounded to −2.
DIV	Integer division with truncation of the result towards −∞

%	Modulus operator. Defined only for positive numbers.
Sign( )	$Sign(x) = \begin{cases} 1 & x > 0 \\ 0 & x == 0 \\ -1 & x < 0 \end{cases}$
NINT( )	Nearest integer operator. Returns the nearest integer value to the real-valued argument. Half-integer values are rounded away from 0.
sin	Sine
cos	Cosine
exp	Exponential
√	Square root
$\log_{10}$	Logarithm to base ten
$\log_e$	Logarithm to base e

2.2.2 Logical operators

||	Logical OR
&&	Logical AND
!	Logical NOT

2.2.3 Relational operators

>	Greater than
≥	Greater than or equal to
<	Less than
≤	Less than or equal to
==	Equal to
!=	Not equal to
max [,...,]	The maximum value in the argument list
min [,...,]	The minimum value in the argument list

2.2.4 Bitwise operators

&	AND
|	OR
>>	Shift right with sign extension
<<	Shift left with 0 fill

2.2.5 Assignment

=	Assignment operator

2.2.6 Mnemonics

The following mnemonics are defined to describe the different data types used in the coded bit-stream.

bslbf	Bit string, left bit first, where "left" is the order in which bit strings are written in this Recommendation | International Standard. Bit strings are written as a string of 1s and 0s within single quote marks, e.g. '1000 0001'. Blanks within a bit string are for ease of reading and have no significance.
ch	Channel
gr	Granule of 3 * 32 sub-band samples in audio Layer II, 18 * 32 sub-band samples in audio Layer III.
main_data	The main_data portion of the bit stream contains the scale factors, Huffman encoded data, and ancillary information.

main_data_beg	This gives the location in the bit stream of the beginning of the main_data for the frame. The location is equal to the ending location of the previous frame's main_data plus 1 bit. It is calculated from the main_data_end value of the previous frame.
part2_length	This value contains the number of main_data bits used for scale factors
rpchof	Remainder polynomial coefficients, highest order first
sb	Sub-band
scfsi	Scalefactor selector information
switch_point_l	Number of scalefactor band (long block scalefactor band) from which point on window switching is used
switch_point_s	Number of scalefactor band (short block scalefactor band) from which point on window switching is used
tcimsbf	Two's complement integer, msb (sign) bit first
uimsbf	Unsigned integer, most significant bit first
vlclbf	Variable length code, left bit first, where "left" refers to the order in which the variable length codes are written
window	Number of actual time slot in case of block_type == 2, $0 \leq$ window ≤ 2.

The byte order of multi-byte words is most significant byte first.

2.2.7 Constants

π	3.14159265359
e	2.71828182845

2.3 Method of describing bit stream syntax

The bit streams retrieved by the decoder are described in 2.4.1 and 2.5.1. Each data item in the bit stream is in bold type. It is described by its name, its length in bits, and a mnemonic for its type and order of transmission.

The action caused by a decoded data element in a bit stream depends on the value of that data element and on data elements previously decoded. The decoding of the data elements and definition of the state variables used in their decoding are described in the clauses containing the semantic description of the syntax. The following constructs are used to express the conditions when data elements are present, and are in normal type.

Note this syntax uses the "C"-code convention that a variable or expression evaluating to a non-zero value is equivalent to a condition that is true:

while (condition) {
  data_element
  . . .
}
	If the condition is true, then the group of data elements occurs next in the data stream. This repeats until the condition is not true.

do {
  data_element
  . . .
}
while (condition)
	The data element always occurs at least once. The data element is repeated until the condition is not true.

if (condition) {
  data_element
  . . .
}
	If the condition is true, then the first group of data elements occurs next in the data stream.

else {
  data_element
  . . .
}
	If the condition is not true, then the second group of data elements occurs next in the data stream.

for (i = 0; i < n; i++) {
  data_element
  . . .
}
	The group of data elements occurs n times. Conditional constructs within the group of data elements may depend on the value of the loop control variable i, which is set to zero for the first occurrence, incremented to 1 for the second occurrence, and so forth.

As noted, the group of data elements may contain nested conditional constructs. For compactness, the {} are omitted when only one data element follows:

data_element [] data_element [] is an array of data. The number of data elements is indicated by the context.

data_element [n] data_element [n] is the n+1th element of an array of data.

data_element [m][n] data_element [m][n] is the m+1,n+1th element of a two-dimensional array of data.

data_element [l][m][n] data_element [l][m][n] is the l+1,m+1,n+1th element of a three-dimensional array of data.

data_element [m..n] is the inclusive range of bits between bit m and bit n in the data_element.

While the syntax is expressed in procedural terms, it should not be assumed that either Figure 2-1 or Figure 2-2 implements a satisfactory decoding procedure. In particular, they define a correct and error-free input bitstream. Actual decoders must include a means to look for start codes and sync bytes (Transport Stream) in order to begin decoding correctly, and to identify errors, erasures or insertions while decoding. The methods to identify these situations, and the actions to be taken, are not standardized.

2.4 Transport Stream bitstream requirements

2.4.1 Transport Stream coding structure and parameters

The ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Transport Stream coding layer allows one or more programs to be combined into a single stream. Data from each elementary stream are multiplexed together with information that allows synchronized presentation of the elementary streams within a program.

A Transport Stream consists of one or more programs. Audio and video elementary streams consist of access units.

Elementary Stream data is carried in PES packets. A PES packet consists of a PES packet header followed by packet data. PES packets are inserted into Transport Stream packets. The first byte of each PES packet header is located at the first available payload location of a Transport Stream packet.

The PES packet header begins with a 32-bit start-code that also identifies the stream or stream type to which the packet data belongs. The PES packet header may contain decoding and presentation time stamps (DTS and PTS). The PES packet header also contains other optional fields. The PES packet data field contains a variable number of contiguous bytes from one elementary stream.

Transport Stream packets begin with a 4-byte prefix, which contains a 13-bit Packet ID (PID), defined in Table 2-2. The PID identifies, via the Program Specific Information (PSI) tables, the contents of the data contained in the Transport Stream packet. Transport Stream packets of one PID value carry data of one and only one elementary stream.

The PSI tables are carried in the Transport Stream. There are four PSI tables:

- Program Association Table;
- Program Map Table;
- Conditional Access Table;
- Network Information Table.

These tables contain the necessary and sufficient information to demultiplex and present programs. The Program Map Table, in Table 2-28, specifies, among other information, which PIDs, and therefore which elementary streams are associated to form each program. This table also indicates the PID of the Transport Stream packets which carry the PCR for each program. The Conditional Access Table shall be present if scrambling is employed. The Network Information Table is optional and its contents are not specified by this Recommendation | International Standard.

Transport Stream packets may be null packets. Null packets are intended for padding of Transport Streams. They may be inserted or deleted by re-multiplexing processes and, therefore, the delivery of the payload of null packets to the decoder cannot be assumed.

This Recommendation | International Standard does not specify the coded data which may be used as part of conditional access systems. This Specification does, however, provide mechanisms for program service providers to transport and identify this data for decoder processing, and to reference correctly data which are specified by this Specification. This type of support is provided both through Transport Stream packet structures and in the conditional access table (refer to Table 2-27 of the PSI).

2.4.2 Transport Stream system target decoder

The semantics of the Transport Stream specified in 2.4.3 and the constraints on these semantics specified in 2.7 require exact definitions of byte arrival and decoding events and the times at which these occur. The definitions needed are set out in this Recommendation | International Standard using a hypothetical decoder known as the Transport Stream System Target Decoder (T-STD). Informative Annex D contains further explanation of the T-STD.

The T-STD is a conceptual model used to define these terms precisely and to model the decoding process during the construction or verification of Transport Streams. The T-STD is defined only for this purpose. There are three types of decoders in the T-STD: video, audio, and systems. Figure 2-1 illustrates an example. Neither the architecture of the T-STD nor the timing described precludes uninterrupted, synchronized play-back of Transport Streams from a variety of decoders with different architectures or timing schedules.

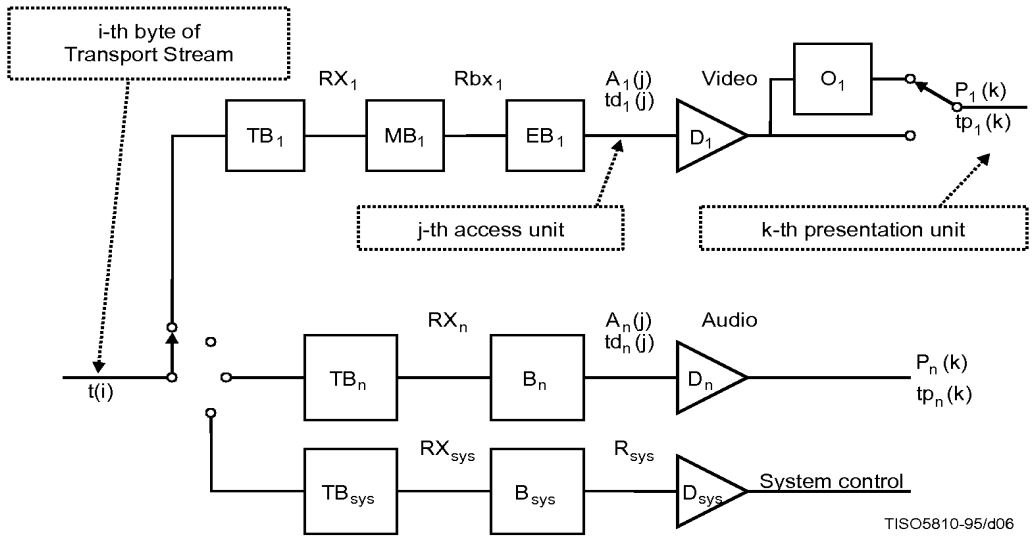

Figure 2-1 – Transport Stream system target decoder notation

The following notation is used to describe the Transport Stream system target decoder and is partially illustrated in Figure 2-1 above.

i, i′, i″ are indices to bytes in the Transport Stream. The first byte has index 0.

j is an index to access units in the elementary streams.

k, k′, k″ are indices to presentation units in the elementary streams.

n is an index to the elementary streams.

p is an index to Transport Stream packets in the Transport Stream.

t(i) indicates the time in seconds at which the i-th byte of the Transport Stream enters the system target decoder. The value t(0) is an arbitrary constant.

PCR(i) is the time encoded in the PCR field measured in units of the period of the 27 MHz system clock where i is the byte index of the final byte of the program_clock_reference_base field.

$A_n(j)$ is the j-th access unit in elementary stream n. $A_n(j)$ is indexed in decoding order.

$td_n(j)$ is the decoding time, measured in seconds, in the system target decoder of the j-th access unit in elementary stream n.

$P_n(k)$ is the k-th presentation unit in elementary stream n. $P_n(k)$ results from decoding $A_n(j)$. $P_n(k)$ is indexed in presentation order.

$tp_n(k)$ is the presentation time, measured in seconds, in the system target decoder of the k-th presentation unit in elementary stream n.

t	is time measured in seconds.
$F_n(t)$	is the fullness, measured in bytes, of the system target decoder input buffer for elementary stream n at time t.
B_n	is the main buffer for elementary stream n. It is present only for audio elementary streams.
BS_n	is the size of buffer, B_n, measured in bytes.
B_{sys}	is the main buffer in the system target decoder for system information for the program that is in the process of being decoded.
BS_{sys}	is the size of B_{sys}, measured in bytes.
MB_n	is the multiplexing buffer, for elementary stream n. It is present only for video elementary streams.
MBS_n	is the size of MB_n, measured in bytes.
EB_n	is the elementary stream buffer for elementary stream n. It is present only for video elementary streams.
EBS_n	is the size of the elementary stream buffer EB_n, measured in bytes.
TB_{sys}	is the transport buffer for system information for the program that is in the process of being decoded.
TBS_{sys}	is the size of TB_{sys}, measured in bytes.
TB_n	is the transport buffer for elementary stream n.
TBS_n	is the size of TB_n, measured in bytes.
D_{sys}	is the decoder for system information in Program Stream n.
D_n	is the decoder for elementary stream n.
O_n	is the re-order buffer for video elementary stream n.
R_{sys}	is the rate at which data are removed from B_{sys}.
Rx_n	is the rate at which data are removed from TB_n.
Rbx_n	is the rate at which PES packet payload data are removed from MB_n when the leak method is used. Defined only for video elementary streams.
$Rbx_n(j)$	is the rate at which PES packet payload data are removed from MB_n when the vbv_delay method is used. Defined only for video elementary streams.
Rx_{sys}	The rate at which data are removed from TB_{sys}.
R_{es}	The video elementary stream rate coded in a sequence header.

2.4.2.1 System clock frequency

Timing information referenced in the T-STD is carried by several data fields defined in this Specification. Refer to 2.4.3.4 and 2.4.3.6. In PCR fields this information is coded as the sampled value of a program's system clock. The PCR fields are carried in the adaptation field of the Transport Stream packets with a PID value equal to the PCR_PID defined in the TS_program_map_section of the program being decoded.

Practical decoders may reconstruct this clock from these values and their respective arrival times. The following are minimum constraints which apply to the program's system clock frequency as represented by the values of the PCR fields when they are received by a decoder.

The value of the system clock frequency is measured in Hz and shall meet the following constraints:

$$27\,000\,000 - 810 \leq \text{system\_clock\_frequency} \leq 27\,000\,000 + 810$$

$$\text{rate of change of system\_clock\_frequency with time} \leq 75 \times 10^{-3}\ \text{Hz/s}$$

NOTE – Sources of coded data should follow a tighter tolerance in order to facilitate compliant operation of consumer recorders and playback equipment.

A program's system_clock_frequency may be more accurate than required. Such improved accuracy may be transmitted to the decoder via the System clock descriptor described in 2.6.20.

Bit rates defined in this Specification are measured in terms of system_clock_frequency. For example, a bit rate of 27 000 000 bits per second in the T-STD would indicate that one byte of data is transferred every eight (8) cycles of the system clock.

The notation "system_clock_frequency" is used in several places in this Specification to refer to the frequency of a clock meeting these requirements. For notational convenience, equations in which PCR, PTS, or DTS appear, lead to values of time which are accurate to some integral multiple of (300×2^{33}/system_clock_frequency) seconds. This is due to the encoding of PCR timing information as 33 bits of 1/300 of the system clock frequency plus 9 bits for the remainder, and encoding as 33 bits of the system clock frequency divided by 300 for PTS and DTS.

2.4.2.2 Input to the Transport Stream system target decoder

Input to the Transport Stream System Target Decoder (T-STD) is a Transport Stream. A Transport Stream may contain multiple programs with independent time bases. However, the T-STD decodes only one program at a time. In the T-STD model all timing indications refer to the time base of that program.

Data from the Transport Stream enters the T-STD at a piecewise constant rate. The time t(i) at which the i-th byte enters the T-STD is defined by decoding the program clock reference (PCR) fields in the input stream, encoded in the Transport Stream packet adaptation field of the program to be decoded and by counting the bytes in the complete Transport Stream between successive PCRs of that program. The PCR field (see equation 2-1) is encoded in two parts: one, in units of the period of 1/300 times the system clock frequency, called program_clock_reference_base (see equation 2-2), and one in units of the system clock frequency called program_clock_reference_extension (see equation 2-3). The values encoded in these are computed by PCR_base(i) (see equation 2-2) and PCR_ext(i) (see equation 2-3) respectively. The value encoded in the PCR field indicates the time t(i), where i is the index of the byte containing the last bit of the program_clock_reference_base field.

Specifically:

$$PCR(i) = PCR\_base(i) \times 300 + PCR\_ext(i) \tag{2-1}$$

where:

$$PCR\_base(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 300) \; \% \; 2^{33} \tag{2-2}$$

$$PCR\_ext(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 1) \; \% \; 300 \tag{2-3}$$

For all other bytes the input arrival time, t(i) shown in equation 2-4 below, is computed from PCR(i″) and the transport rate at which data arrive, where the transport rate is determined as the number of bytes in the Transport Stream between the bytes containing the last bit of two successive program_clock_reference_base fields of the same program divided by the difference between the time values encoded in these same two PCR fields.

$$t(i) = \frac{PCR(i'')}{system\_clock\_frequency} + \frac{i - i''}{transport\_rate\ (i)} \tag{2-4}$$

where:

i is the index of any byte in the Transport Stream for $i'' < i < i'$.

i″ is the index of the byte containing the last bit of the most recent program_clock_reference_base field applicable to the program being decoded.

PCR(i″) is the time encoded in the program clock reference base and extension fields in units of the system clock.

The transport rate is given by

$$transport\_rate(i) = \frac{((i' - i'') \times system\_clock\_frequency)}{PCR(i') - PCR(i'')} \tag{2-5}$$

where

i′ is the index of the byte containing the last bit of the immediately following program_clock_reference_base field applicable to the program being decoded.

NOTE – $i'' < i \leq i'$

In the case of a timebase discontinuity, indicated by the discontinuity_indicator in the transport packet adaptation field, the definition given in equation 2-4 and equation 2-5 for the time of arrival of bytes at the input to the T-STD is not applicable between the last PCR of the old timebase and the first PCR of the new timebase. In this case the time of arrival of these bytes is determined according to equation 2-4 with the modification that the transport rate used is that applicable between the last and next to last PCR of the old timebase.

A tolerance is specified for the PCR values. The PCR tolerance is defined as the maximum inaccuracy allowed in received PCRs. This inaccuracy may be due to imprecision in the PCR values or to PCR modification during re-multiplexing. It does not include errors in packet arrival time due to network jitter or other causes. The PCR tolerance is ± 500 ns.

In the T-STD model, the inaccuracy will be reflected as an inaccuracy in the calculated transport rate using equation 2-5.

Transport Streams with multiple programs and variable rate

Transport Streams may contain multiple programs which have independent time bases. Separate sets of PCRs, as indicated by the respective PCR_PID values, are required for each such independent program, and therefore the PCRs cannot be co-located. The Transport Stream rate is piecewise constant for the program entering the T-STD. Therefore, if the Transport Stream rate is variable it can only vary at the PCRs of the program under consideration. Since the PCRs, and therefore the points in the transport Stream where the rate varies, are not co-located, the rate at which the Transport Stream enters the T-STD would have to differ depending on which program is entering the T-STD. Therefore, it is not possible to construct a consistent T-STD delivery schedule for an entire Transport Stream when that Transport Stream contains multiple programs with independent time bases and the rate of the Transport Stream is variable. It is straightforward, however, to construct constant bit rate Transport Streams with multiple variable rate programs.

2.4.2.3 Buffering

Complete Transport Stream packets containing data from elementary stream n, as indicated by its PID, are passed to the transport buffer for stream n, TB_n. This includes duplicate Transport Stream packets and packets with no payload. Transfer of the i-th byte from the system target decoder input to TB_n is instantaneous, so that the i-th byte enters the buffer for stream n, of size TBS_n, at time t(i).

All bytes that enter the buffer TB_n are removed at the rate Rx_n specified below. Bytes which are part of the PES packet or its contents are delivered to the main buffer B_n for audio elementary streams and system data, and to the multiplexing buffer MB_n for video elementary streams. Other bytes are not, and may be used to control the system. Duplicate Transport Stream packets are not delivered to B_n, MB_n, or B_{sys}.

The buffer TB_n is emptied as follows:

- When there is no data in TB_n, Rx_n is equal to zero.
- Otherwise for video:

$$Rx_n = 1,2 \times R_{max}[\text{profile, level}]$$

where

R_{max}[profile, level] is specified according to the profile and level which can be found in Table 8-13 of ITU-T Rec. H.262 | ISO/IEC 13818-2. This Table specifies the upper bound of the rate of each elementary video stream within a specific profile and level.

Rx_n is equal to $1,2 \times R_{max}$ for ISO/IEC 11172-2 constrained parameter video streams, where R_{max} refers to the maximum bitrate for a Constrained Parameters bitstream in ISO/IEC 11172-2.

For ISO/IEC 13818-7 ADTS audio,

Number of Channels	Rx_n [bit/s]
1-2	2 000 000
3-8	5 529 600
9-12	8 294 400
13-48	33 177 600

Channels: channels that require their own decoder buffer in this elementary stream (i.e. individual channel streams in a single channel element or channel pair element and independently switched coupling channel elements).

For other audio,

$$Rx_n = 2 \times 10^6 \text{ bits per second}$$

For systems data:

$$Rx_n = 1 \times 10^6 \text{ bits per second}$$

Rx_n is measured with respect to the system clock frequency.

Complete Transport Stream packets containing system information, for the program selected for decoding, enter the system transport buffer, TB_{sys}, at the Transport Stream rate. These include Transport Stream packets whose PID values are 0 or 1, and all Transport Stream packets identified via the Program Association Table (see Table 2-25) as having the program_map_PID value for the selected program. Network Information Table (NIT) data as specified by the NIT PID is not transferred to TB_{sys}.

Bytes are removed from TB_{sys} at the rate Rx_{sys} and delivered to B_{sys}. Each byte is transferred instantaneously.

Duplicate Transport Stream packets are not delivered to B_{sys}.

Transport packets which do not enter any TB_n or TB_{sys} are discarded.

The transport buffer size is fixed at 512 bytes.

The elementary stream buffer sizes EBS_1 through EBS_n are defined for video as equal to the vbv_buffer_size as it is carried in the sequence header. Refer to Summary of Constrained Parameters in ISO/IEC 11172-2 and Table 8-14 of ITU-T Rec. H.262 | ISO/IEC 13818-2.

The multiplexing buffer size MBS_1 through MBS_n are defined for video as follows:

For Low and Main level

$$MBS_n = BS_{mux} + BS_{oh} + VBV_{max}[\text{profile, level}] - \text{vbv\_buffer\_size}$$

where BS_{oh}, PES packet overhead buffering is defined as:

$$BS_{oh} = (1/750) \text{ seconds} \times R_{max}[\text{profile, level}]$$

and BS_{mux}, additional multiplex buffering is defined as:

$$BS_{mux} = 0.004 \text{ seconds} \times R_{max}[\text{profile, level}]$$

and where VBV_{max}[profile, level] is defined in Table 8-14 in ITU-T Rec. H.262 | ISO/IEC 13812-2 and R_{max}[profile, level] is defined in Table 8-13 in ITU-T Rec. H.262 | ISO/IEC 13818-2, and vbv buffer size is carried in the sequence header described in 6.2.2 of ITU-T Rec. H.262 | ISO/IEC 13818-2.

For High 1440 and High level

$$MBS_n = BS_{mux} + BS_{oh}$$

where BS_{oh} is defined as:

$$BS_{oh} = (1/750) \text{ seconds} \times R_{max}[\text{profile, level}]$$

and BS_{mux} is defined as:

$$BS_{mux} = 0.004 \text{ seconds} \times R_{max}[\text{profile, level}]$$

and where R_{max}[profile, level] is defined in Table 8-13 in ITU-T Rec. H.262 | ISO/IEC 13818-2.

For Constrained Parameters ISO/IEC 11172-2 bitstreams

$$MBS_n = BS_{mux} + BS_{oh} + vbv\_max - vbv\_buffer\_size$$

where BS_{oh} is defined as:

$$BS_{oh} = (1/750) \text{ seconds} \times R_{max}$$

and BS_{mux} is defined as:

$$BS_{mux} = 0.004 \text{ seconds} \times R_{max}$$

and where R_{max} and vbv_max refer to the maximum bitrate and the maximum vbv_buffer_size for a Constrained Parameters bitstream in ISO/IEC 11172-2 respectively.

A portion BS_{mux} = 4 ms × R_{max}[profile, level] of the MBS_n is allocated for buffering to allow multiplexing. The remainder is available for BS_{oh} and may also be available for initial multiplexing.

NOTE 1 – Buffer occupancy by PES packet overhead is directly bounded in PES streams by the PES-STD which is defined in 2.5.2.4. It is possible, but not necessary, to utilize PES streams to construct Transport Streams.

Buffer BS_n

The main buffer sizes BS_1 through BS_n are defined as follows.

Audio

For ISO/IEC 13818-7 ADTS audio,

Number of Channels	BS_n [bytes]
1-2	3 584
3-8	8 976
9-12	12 804
13-48	51 216

Channels: channels that require their own decoder buffer in this elementary stream (i.e. individual channel streams in a single channel element or channel pair element and independently switched coupling channel elements).

For other audio,

$$BS_n = BS_{mux} + BS_{dec} + BS_{oh} = 3584 \text{ bytes}$$

The size of the access unit decoding buffer BS_{dec}, and the PES packet overhead buffer BS_{oh} are constrained by

$$BS_{dec} + BS_{oh} \leq 2848 \text{ bytes}$$

A portion (736 bytes) of the 3584 byte buffer is allocated for buffering to allow multiplexing. The rest, 2848 bytes, are shared for access unit buffering BS_{dec}, BS_{oh} and additional multiplexing.

Systems

The main buffer B_{sys} for system data is of size BS_{sys} = 1536 bytes.

Video

For video elementary streams, data is transferred from MB_n to EB_n using one of two methods: the leak method or the VBV delay method.

Leak method

The leak method transfers data from MB_n to EB_n using a leak rate R_{bx}. The leak method is used whenever any of the following is true:

- the STD descriptor (refer to 2.6.32) for the elementary stream is not present in the Transport Stream;
- the STD descriptor is present and the leak_valid flag has a value of '1';
- the STD descriptor is present, the leak_valid has a value of '0', and the vbv_delay fields coded in the video stream have the value 0xFFFF; or
- trick mode status is true (refer to 2.4.3.6).

For Low and Main level:

$$Rbx_n = R_{max}[profile, level]$$

For High-1440 and High level:

$$Rbx_n = Min \{1.05 \times R_{es}, R_{max}[profile, level]\}$$

For Constrained Parameters bitstream in ISO/IEC 11172-2:

$$Rbx_n = 1,2 \times R_{max}$$

where R_{max} is the maximum bit rate for a Constrained Parameters bitstream in ISO/IEC 11172-2.

If there is PES packet payload data in MB_n, and buffer EB_n is not full, the PES packet payload is transferred from MB_n to EB_n at a rate equal to R_{bx}. If EB_n is full, data are not removed from MB_n. When a byte of data is transferred from MB_n to EB_n, all PES packet header bytes that are in MB_n and immediately precede that byte, are instantaneously removed and discarded. When there is no PES packet payload data present in MB_n, no data is removed from MB_n. All data that enters MB_n leaves it. All PES packet payload data bytes enter EB_n instantaneously upon leaving MB_n.

Vbv_delay method

The vbv_delay method specifies precisely the time at which each byte of coded video data is transferred from MB_n to EB_n, using the vbv_delay values coded in the video elementary stream. The vbv_delay method is used whenever the STD descriptor (refer to 2.6.32) for this elementary stream is present in the Transport Stream, the leak_valid flag in the descriptor has the value '0', and vbv_delay fields coded in the video stream are not equal to 0xFFFF. If any vbv_delay values in a video sequence are not equal to 0xFFFF, none of the vbv_delay fields in that sequence shall be equal to 0xFFFF (refer to ISO/IEC 11172-2 and ITU-T Rec. H.262 | ISO/IEC 13818-2).

When the vbv_delay method is used, the final byte of the video picture start code for picture j is transferred from MB_n to the EB_n at the time $td_n(j)$ – vbv_delay(j), where $td_n(j)$ is the decoding time of picture j, as defined above, and vbv_delay(j) is the delay time, in seconds, indicated by the vbv_delay field of picture j. The transfer of bytes between the final bytes of successive picture start codes (including the final byte of the second start code), into the buffer EB_n, is at a piecewise constant rate, $R_{bx}(j)$, which is specified for each picture j. Specifically, the rate, $R_{bx}(j)$, of transfer into this buffer is given by:

$$R_{bx}(j) = NB(j) / (vbv\_delay(j) - vbv\_delay(j + 1) + td_n(j + 1) - td_n(j)) \qquad (2\text{-}6)$$

where NB(j) is the number of bytes between the final bytes of the picture start codes (including the final byte of the second start code) of pictures j and j + 1, excluding PES packet header bytes.

NOTE 2 – vbv_delay(j + 1) and $td_n(j + 1)$ may have values that differ from those normally expected for periodic video display if the low_delay flag in the video sequence extension is set to '1'. It may not be possible to determine the correct values by examination of the bit stream.

The $R_{bx}(j)$ derived from equation 2-6 shall be less than or equal to R_{max}[profile, level] for elementary streams of stream type 0x02 (refer to Table 2-29), where R_{max}[profile, level] is defined in ITU-T Rec. H.262 | ISO/IEC 13818-2, and shall be less than or equal to the maximum bit rate allowed for constrained parameter video elementary streams of stream type 0x01, refer to ISO/IEC 11172-2.

When a byte of data is transferred from MB_n to EB_n, all PES packet header bytes that are in MB_n and immediately precede that byte are instantaneously removed and discarded. All data that enters MB_n leaves it. All PES packet payload data bytes enter EB_n instantaneously upon leaving MB_n.

Removal of access units

For each elementary stream buffer EB_n and main buffer B_n all data for the access unit that has been in the buffer longest, $A_n(j)$, and any stuffing bytes that immediately precede it that are present in the buffer at the time $td_n(j)$ are removed instantaneously at time $td_n(j)$. The decoding time $td_n(j)$ is specified in the DTS or PTS fields (refer to 2.4.3.6). Decoding times $td_n(j + 1)$, $td_n(j + 2)$, ... of access units without encoded DTS or PTS fields which directly follow access unit j may be derived from information in the elementary stream. Refer to Annex C of ITU-T Rec. H.262 | ISO/IEC 13818-2, ISO/IEC 13818-3, or ISO/IEC 11172. Also refer to 2.7.5. In the case of audio, all PES packet headers that are stored immediately before the access unit or that are embedded within the data of the access unit are removed simultaneously with the removal of the access unit. As the access unit is removed it is instantaneously decoded to a presentation unit.

System data

In the case of system data, data is removed from the main buffer B_{sys} at a rate of R_{sys} whenever there is at least 1 byte available in buffer B_{sys}.

$$R_{sys} = \max(80\,000\ bits/s,\ transport\_rate(i) \times 8\ bits/byte / 500) \qquad (2\text{-}7)$$

NOTE 3 – The intention of increasing R_{sys} in the case of high transport rates is to allow an increased data rate for the Program Specific Information.

Low delay

When the low_delay flag in the video sequence extension is set to '1' (see 6.2.2.3 of ITU-T Rec. H.262 | ISO/IEC 13818-2) the EB_n buffer may underflow. In this case, when the T-STD elementary stream buffer EB_n is examined at the time specified by $td_n(j)$, the complete data for the access unit may not be present in the buffer EB_n. When this case arises, the buffer shall be re-examined at intervals of two field-periods until the data for the complete access unit is present in the buffer. At this time the entire access unit shall be removed from buffer EB_n instantaneously. Overflow of buffer EB_n shall not occur.

When the low_delay_mode flag is set to '1', EB_n underflow is allowed to occur continuously without limit. The T-STD decoder shall remove access unit data from buffer EB_n at the earliest time consistent with the paragraph above and any DTS or PTS values encoded in the bit stream. Note that the decoder may be unable to re-establish correct decoding and display times as indicated by DTS and PTS until the EB_n buffer underflow situation ceases and a PTS or DTS is found in the bit stream.

Trick mode

When the DSM_trick_mode flag (2.4.3.6) is set to '1' in the PES Packet header of a packet containing the start of a B-type video access unit and the trick_mode_control field is set to '001' (slow motion) or '010' (freeze frame), or '100' (slow reverse) the B-picture access unit is not removed from the video data buffer EB_n until the last time of possibly multiple times that any field of the picture is decoded and presented. Repetition of the presentation of fields and pictures is defined in 2.4.3.8 under slow motion, slow reverse, and field_id_cntrl. The access unit is removed instantaneously from EB_n at the indicated time, which is dependent on the value of rep_cntrl.

When the DSM_trick_mode flag is set to '1' in the PES packet header of a packet containing the first byte of a picture start code, trick_mode status becomes true when that picture start code in the PES packet is removed from buffer EB_n. Trick mode status remains true until a PES packet header is received by the T-STD in which the DSM_trick_mode flag is set to '0' and the first byte of the picture start code after that PES packet header is removed from buffer EB_n. When trick mode status is true, the buffer EB_n may underflow. All other constraints from normal streams are retained when trick mode status is true.

2.4.2.4 Decoding

Elementary streams buffered in B_1 through B_n and EB_1 through EB_n are decoded instantaneously by decoders D_1 through D_n and may be delayed in re-order buffers O_1 through O_n before being presented at the output of the T-STD. Re-order buffers are used only in the case of a video elementary stream when some access units are not carried in presentation order. These access units will need to be re-ordered before presentation. In particular, if $P_n(k)$ is an I-picture or a P-picture carried before one or more B-pictures, then it must be delayed in the re-order buffer, O_n, of the T-STD before being presented. Any picture previously stored in O_n is presented before the current picture can be stored. $P_n(k)$ should be delayed until the next I-picture or P-picture is decoded. While it is stored in the re-order buffer, the subsequent B-pictures are decoded and presented.

The time at which a presentation unit $P_n(k)$ is presented is $tp_n(k)$. For presentation units that do not require re-ordering delay, $tp_n(k)$ is equal to $td_n(j)$ since the access units are decoded instantaneously; this is the case, for example, for B-frames. For presentation units that are delayed, $tp_n(k)$ and $td_n(j)$ differ by the time that $P_n(k)$ is delayed in the re-order buffer, which is a multiple of the nominal picture period. Care should be taken to use adequate re-ordering delay from the beginning of video elementary streams to meet the requirements of the entire stream. For example, a stream which initially has only I- and P-pictures but later includes B-pictures should include re-ordering delay starting at the beginning of the stream.

ITU-T Rec. H.262 | ISO/IEC 13818-2 explains re-ordering of video pictures in greater detail.

2.4.2.5 Presentation

The function of a decoding system is to reconstruct presentation units from compressed data and to present them in a synchronized sequence at the correct presentation times. Although real audio and visual presentation devices generally have finite and different delays and may have additional delays imposed by post-processing or output functions, the system target decoder models these delays as zero.

In the T-STD in Figure 2-1 the display of a video presentation unit (a picture) occurs instantaneously at its presentation time, $tp_n(k)$.

In the T-STD the output of an audio presentation unit starts at its presentation time, $tp_n(k)$, when the decoder instantaneously presents the first sample. Subsequent samples in the presentation unit are presented in sequence at the audio sampling rate.

2.4.2.6 Buffer management

Transport Streams shall be constructed so that conditions defined in this subclause are satisfied. This subclause makes use of the notation defined for the System Target Decoder.

TB_n and TB_{sys} shall not overflow. TB_n and TB_{sys} shall empty at least once every second. B_n shall not overflow nor underflow. B_{sys} shall not overflow.

EB_n shall not underflow except when the low delay flag in the video sequence extension is set to '1' (refer to 6.2.2.3 in ITU-T Rec. H.262 | ISO/IEC 13818-2) or trick_mode status is true.

When the leak method for specifying transfers is in effect, MB_n shall not overflow, and shall empty at least once every second. EB_n shall not overflow.

When the vbv_delay method for specifying transfers is in effect, MB_n shall not overflow nor underflow, and EB_n shall not overflow.

The delay of any data through the System Target Decoder buffers shall be less than or equal to one second except for still picture video data and ISO/IEC 14496 streams. Specifically: $td_n(j) - t(i) \leq 1$ second for all j, and all bytes i in access unit $A_n(j)$.

For still picture video data, the delay is constrained by $td_n(j) - t(i) \leq 60$ seconds for all j, and all bytes i in access unit $A_n(j)$.

For ISO/IEC 14496 streams, the delay is constrained by $td_n(j)-t(i) \leq 10$ second for all j, and all bytes i in access unit $A_n(j)$.

Definition of overflow and underflow

Let $F_n(t)$ be the instantaneous fullness of T-STD buffer B_n.

$F_n(t) = 0$ instantaneously before $t = t(0)$

Overflow does not occur if

$$F_n(t) \leq BS_n$$

for all t and n.

Underflow does not occur if

$$0 \leq F_n(t)$$

for all t and n.

2.4.2.7 T-STD extensions for carriage of ISO/IEC 14496 data

For decoding of ISO/IEC 14496 data carried in a Transport Stream the T-STD model is extended. T-STD parameters for decoding of individual ISO/IEC 14496 elementary streams are defined in subclause 2.11.2, while subclause 2.11.3 defines T-STD extensions and parameters for decoding of ISO/IEC 14496 scenes and associated streams.

2.4.3 Specification of the Transport Stream syntax and semantics

The following syntax describes a stream of bytes. Transport Stream packets shall be 188 bytes long.

2.4.3.1 Transport Stream

See Table 2-1.

Table 2-1 – Transport Stream

Syntax	No. of bits	Mnemonic

MPEG_transport_stream() {
do {
transport_packet()
} while (nextbits() == sync_byte)
}		

2.4.3.2 Transport Stream packet layer

See Table 2-2.

Table 2-2 – Transport packet of this Recommendation | International Standard

Syntax	No. of bits	Mnemonic
transport_packet(){		
sync_byte	**8**	**bslbf**
transport_error_indicator	**1**	**bslbf**
payload_unit_start_indicator	**1**	**bslbf**
transport_priority	**1**	**bslbf**
PID	**13**	**uimsbf**
transport_scrambling_control	**2**	**bslbf**
adaptation_field_control	**2**	**bslbf**
continuity_counter	**4**	**uimsbf**
if(adaptation_field_control == '10' || adaptation_field_control == '11'){		
adaptation_field()		
}		
if(adaptation_field_control == '01' || adaptation_field_control == '11') {		
for (i = 0; i < N; i++){		
data_byte	**8**	**bslbf**
}		
}		
}		

2.4.3.3 Semantic definition of fields in Transport Stream packet layer

sync_byte – The sync_byte is a fixed 8-bit field whose value is '0100 0111' (0x47). Sync_byte emulation in the choice of values for other regularly occurring fields, such as PID, should be avoided.

transport_error_indicator – The transport_error_indicator is a 1-bit flag. When set to '1' it indicates that at least 1 uncorrectable bit error exists in the associated Transport Stream packet. This bit may be set to '1' by entities external to the transport layer. When set to '1' this bit shall not be reset to '0' unless the bit value(s) in error have been corrected.

payload_unit_start_indicator – The payload_unit_start_indicator is a 1-bit flag which has normative meaning for Transport Stream packets that carry PES packets (refer to 2.4.3.6) or PSI data (refer to 2.4.4).

When the payload of the Transport Stream packet contains PES packet data, the payload_unit_start_indicator has the following significance: a '1' indicates that the payload of this Transport Stream packet will commence with the first byte of a PES packet and a '0' indicates no PES packet shall start in this Transport Stream packet. If the payload_unit_start_indicator is set to '1', then one and only one PES packet starts in this Transport Stream packet. This also applies to private streams of stream_type 6 (refer to Table 2-29).

When the payload of the Transport Stream packet contains PSI data, the payload_unit_start_indicator has the following significance: if the Transport Stream packet carries the first byte of a PSI section, the payload_unit_start_indicator value shall be '1', indicating that the first byte of the payload of this Transport Stream packet carries the pointer_field. If the Transport Stream packet does not carry the first byte of a PSI section, the payload_unit_start_indicator value shall be '0', indicating that there is no pointer_field in the payload. Refer to 2.4.4.1 and 2.4.4.2. This also applies to private streams of stream_type 5 (refer to Table 2-29).

For null packets the payload_unit_start_indicator shall be set to '0'.

The meaning of this bit for Transport Stream packets carrying only private data is not defined in this Specification.

transport_priority – The transport_priority is a 1-bit indicator. When set to '1' it indicates that the associated packet is of greater priority than other packets having the same PID which do not have the bit set to '1'. The transport mechanism can use this to prioritize its data within an elementary stream. Depending on the application the transport_priority field may be coded regardless of the PID or within one PID only. This field may be changed by channel specific encoders or decoders.

PID – The PID is a 13-bit field, indicating the type of the data stored in the packet payload. PID value 0x0000 is reserved for the Program Association Table (see Table 2-25). PID value 0x0001 is reserved for the Conditional Access Table (see Table 2-27). PID values 0x0002 – 0x000F are reserved. PID value 0x1FFF is reserved for null packets (see Table 2-3).

Table 2-3 – PID table

Value	Description
0x0000	Program Association Table
0x0001	Conditional Access Table
0x0002	Transport Stream Description Table
0x0003-0x000F	Reserved
0x00010 … 0x1FFE	May be assigned as network_PID, Program_map_PID, elementary_PID, or for other purposes
0x1FFF	Null packet
NOTE – The transport packets with PID values 0x0000, 0x0001, and 0x0010-0x1FFE are allowed to carry a PCR.	

transport_scrambling_control – This 2-bit field indicates the scrambling mode of the Transport Stream packet payload. The Transport Stream packet header, and the adaptation field when present, shall not be scrambled. In the case of a null packet the value of the transport_scrambling_control field shall be set to '00' (see Table 2-4).

Table 2-4 – Scrambling control values

Value	Description
00	Not scrambled
01	User-defined
10	User-defined
11	User-defined

adaptation_field_control – This 2-bit field indicates whether this Transport Stream packet header is followed by an adaptation field and/or payload (see Table 2-5).

Table 2-5 – Adaptation field control values

Value	Description
00	Reserved for future use by ISO/IEC
01	No adaptation_field, payload only
10	Adaptation_field only, no payload
11	Adaptation_field followed by payload

ITU-T Rec. H.222.0 | ISO/IEC 13818-1 decoders shall discard Transport Stream packets with the adaptation_field_control field set to a value of '00'. In the case of a null packet the value of the adaptation_field_control shall be set to '01'.

continuity_counter – The continuity_counter is a 4-bit field incrementing with each Transport Stream packet with the same PID. The continuity_counter wraps around to 0 after its maximum value. The continuity_counter shall not be incremented when the adaptation_field_control of the packet equals '00' or '10'.

In Transport Streams, duplicate packets may be sent as two, and only two, consecutive Transport Stream packets of the same PID. The duplicate packets shall have the same continuity_counter value as the original packet and the adaptation_field_control field shall be equal to '01' or '11'. In duplicate packets each byte of the original packet shall be duplicated, with the exception that in the program clock reference fields, if present, a valid value shall be encoded.

The continuity_counter in a particular Transport Stream packet is continuous when it differs by a positive value of one from the continuity_counter value in the previous Transport Stream packet of the same PID, or when either of the non-incrementing conditions (adaptation_field_control set to '00' or '10', or duplicate packets as described above) are met. The continuity counter may be discontinuous when the discontinuity_indicator is set to '1' (refer to 2.4.3.4). In the case of a null packet the value of the continuity_counter is undefined.

data_byte – Data bytes shall be contiguous bytes of data from the PES packets (refer to 2.4.3.6), PSI sections (refer to 2.4.4), packet stuffing bytes after PSI sections, or private data not in these structures as indicated by the PID. In the case of null packets with PID value 0x1FFF, data_bytes may be assigned any value. The number of data_bytes, N, is specified by 184 minus the number of bytes in the adaptation_field(), as described in 2.4.3.4 below.

2.4.3.4 Adaptation field

See Table 2-6.

2.4.3.5 Semantic definition of fields in adaptation field

adaptation_field_length – The adaptation_field_length is an 8-bit field specifying the number of bytes in the adaptation_field immediately following the adaptation_field_length. The value 0 is for inserting a single stuffing byte in a Transport Stream packet. When the adaptation_field_control value is '11', the value of the adaptation_field_length shall be in the range 0 to 182. When the adaptation_field_control value is '10', the value of the adaptation_field_length shall be 183. For Transport Stream packets carrying PES packets, stuffing is needed when there is insufficient PES packet data to completely fill the Transport Stream packet payload bytes. Stuffing is accomplished by defining an adaptation field longer than the sum of the lengths of the data elements in it, so that the payload bytes remaining after the adaptation field exactly accommodates the available PES packet data. The extra space in the adaptation field is filled with stuffing bytes.

This is the only method of stuffing allowed for Transport Stream packets carrying PES packets. For Transport Stream packets carrying PSI, an alternative stuffing method is described in 2.4.4.

discontinuity_indicator – This is a 1-bit field which when set to '1' indicates that the discontinuity state is true for the current Transport Stream packet. When the discontinuity_indicator is set to '0' or is not present, the discontinuity state is false. The discontinuity indicator is used to indicate two types of discontinuities, system time-base discontinuities and continuity_counter discontinuities.

A system time-base discontinuity is indicated by the use of the discontinuity_indicator in Transport Stream packets of a PID designated as a PCR_PID (refer to 2.4.4.9). When the discontinuity state is true for a Transport Stream packet of a PID designated as a PCR_PID, the next PCR in a Transport Stream packet with that same PID represents a sample of a new system time clock for the associated program. The system time-base discontinuity point is defined to be the instant in time when the first byte of a packet containing a PCR of a new system time-base arrives at the input of the T-STD. The discontinuity_indicator shall be set to '1' in the packet in which the system time-base discontinuity occurs. The discontinuity_indicator bit may also be set to '1' in Transport Stream packets of the same PCR_PID prior to the packet which contains the new system time-base PCR. In this case, once the discontinuity_indicator has been set to '1', it shall continue to be set to '1' in all Transport Stream packets of the same PCR_PID up to and including the Transport Stream packet which contains the first PCR of the new system time-base. After the occurrence of a system time-base discontinuity, no fewer than two PCRs for the new system time-base shall be received before another system time-base discontinuity can occur. Further, except when trick mode status is true, data from no more than two system time-bases shall be present in the set of T-STD buffers for one program at any time.

Prior to the occurrence of a system time-base discontinuity, the first byte of a Transport Stream packet which contains a PTS or DTS which refers to the new system time-base shall not arrive at the input of the T-STD. After the occurrence of a system time-base discontinuity, the first byte of a Transport Stream packet which contains a PTS or DTS which refers to the previous system time-base shall not arrive at the input of the T-STD.

A continuity_counter discontinuity is indicated by the use of the discontinuity_indicator in any Transport Stream packet. When the discontinuity state is true in any Transport Stream packet of a PID not designated as a PCR_PID, the continuity_counter in that packet may be discontinuous with respect to the previous Transport Stream packet of the same PID. When the discontinuity state is true in a Transport Stream packet of a PID that is designated as a PCR_PID, the continuity_counter may only be discontinuous in the packet in which a system time-base discontinuity occurs. A continuity counter discontinuity point occurs when the discontinuity state is true in a Transport Stream packet and the continuity_counter in the same packet is discontinuous with respect to the previous Transport Stream packet of the same PID. A continuity counter discontinuity point shall occur at most one time from the initiation of the discontinuity state until the conclusion of the discontinuity state. Furthermore, for all PIDs that are not designated as PCR_PIDs, when the discontinuity_indicator is set to '1' in a packet of a specific PID, the discontinuity_indicator may be set to '1' in the next Transport Stream packet of that same PID, but shall not be set to '1' in three consecutive Transport Stream packet of that same PID.

For the purpose of this clause, an elementary stream access point is defined as follows:

- Video – The first byte of a video sequence header.
- Audio – The first byte of an audio frame.

After a continuity counter discontinuity in a Transport packet which is designated as containing elementary stream data, the first byte of elementary stream data in a Transport Stream packet of the same PID shall be the first byte of an elementary stream access point or in the case of video, the first byte of an elementary stream access point or a sequence_end_code followed by an access point. Each Transport Stream packet which contains elementary stream data with a PID not designated as a PCR_PID, and in which a continuity counter discontinuity point occurs, and in which a PTS or DTS occurs, shall arrive at the input of the T-STD after the system time-base discontinuity for the associated program occurs. In the case where the discontinuity state is true, if two consecutive Transport Stream packets of the same PID occur which have the same continuity_counter value and have adaptation_field_control values set to '01' or '11', the second packet may be discarded. A Transport Stream shall not be constructed in such a way that discarding such a packet will cause the loss of PES packet payload data or PSI data.

Table 2-6 – Transport Stream adaptation field

}		
}		
}		

After the occurrence of a discontinuity_indicator set to '1' in a Transport Stream packet which contains PSI information, a single discontinuity in the version_number of PSI sections may occur. At the occurrence of such a discontinuity, a version of the TS_program_map_sections of the appropriate program shall be sent with section_length == 13 and the current_next_indicator == 1, such that there are no program_descriptors and no elementary streams described. This shall then be followed by a version of the TS_program_map_section for each affected program with the version_number incremented by one and the current_next_indicator == 1, containing a complete program definition. This indicates a version change in PSI data.

random_access_indicator – The random_access_indicator is a 1-bit field that indicates that the current Transport Stream packet, and possibly subsequent Transport Stream packets with the same PID, contain some information to aid random access at this point. Specifically, when the bit is set to '1', the next PES packet to start in the payload of Transport Stream packets with the current PID shall contain the first byte of a video sequence header if the PES stream type (refer to Table 2-29) is 1 or 2, or shall contain the first byte of an audio frame if the PES stream type is 3 or 4. In addition, in the case of video, a presentation timestamp shall be present in the PES packet containing the first picture following the sequence header. In the case of audio, the presentation timestamp shall be present in the PES packet containing the first byte of the audio frame. In the PCR_PID the random_access_indicator may only be set to '1' in Transport Stream packet containing the PCR fields.

elementary_stream_priority_indicator – The elementary_stream_priority_indicator is a 1-bit field. It indicates, among packets with the same PID, the priority of the elementary stream data carried within the payload of this Transport Stream packet. A '1' indicates that the payload has a higher priority than the payloads of other Transport Stream packets. In the case of video, this field may be set to '1' only if the payload contains one or more bytes from an intra-coded slice. A value of '0' indicates that the payload has the same priority as all other packets which do not have this bit set to '1'.

PCR_flag – The PCR_flag is a 1-bit flag. A value of '1' indicates that the adaptation_field contains a PCR field coded in two parts. A value of '0' indicates that the adaptation field does not contain any PCR field.

OPCR_flag – The OPCR_flag is a 1-bit flag. A value of '1' indicates that the adaptation_field contains an OPCR field coded in two parts. A value of '0' indicates that the adaptation field does not contain any OPCR field.

splicing_point_flag – The splicing_point_flag is a 1-bit flag. When set to '1', it indicates that a splice_countdown field shall be present in the associated adaptation field, specifying the occurrence of a splicing point. A value of '0' indicates that a splice_countdown field is not present in the adaptation field.

transport_private_data_flag – The transport_private_data_flag is a 1-bit flag. A value of '1' indicates that the adaptation field contains one or more private_data bytes. A value of '0' indicates the adaptation field does not contain any private_data bytes.

adaptation_field_extension_flag – The adaptation_field_extension_flag is a 1-bit field which when set to '1' indicates the presence of an adaptation field extension. A value of '0' indicates that an adaptation field extension is not present in the adaptation field.

program_clock_reference_base; program_clock_reference_extension – The program_clock_reference (PCR) is a 42-bit field coded in two parts. The first part, program_clock_reference_base, is a 33-bit field whose value is given by PCR_base(i), as given in equation 2-2. The second part, program_clock_reference_extension, is a 9-bit field whose value is given by PCR_ext(i), as given in equation 2-3. The PCR indicates the intended time of arrival of the byte containing the last bit of the program_clock_reference_base at the input of the system target decoder.

original_program_clock_reference_base; original_program_clock_reference_extension – The optional original program reference (OPCR) is a 42-bit field coded in two parts. These two parts, the base and the extension, are coded identically to the two corresponding parts of the PCR field. The presence of the OPCR is indicated by the OPCR_flag. The OPCR field shall be coded only in Transport Stream packets in which the PCR field is present. OPCRs are permitted in both single program and multiple program Transport Streams.

OPCR assists in the reconstruction of a single program Transport Stream from another Transport Stream. When reconstructing the original single program Transport Stream, the OPCR may be copied to the PCR field. The resulting PCR value is valid only if the original single program Transport Stream is reconstructed exactly in its entirety. This would include at least any PSI and private data packets which were present in the original Transport Stream and would possibly require other private arrangements. It also means that the OPCR must be an identical copy of its associated PCR in the original single program Transport Stream.

The OPCR is expressed as follows:

$$OPCR(i) = OPCR\_base(i) \times 300 + OPCR\_ext(i) \quad (2\text{-}8)$$

where

$$OPCR\_base(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 300) \; \% \; 2^{33} \quad (2\text{-}9)$$

$$OPCR\_ext(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 1) \; \% \; 300 \quad (2\text{-}10)$$

The OPCR field is ignored by the decoder. The OPCR field shall not be modified by any multiplexor or decoder.

splice_countdown – The splice_countdown is an 8-bit field, representing a value which may be positive or negative. A positive value specifies the remaining number of Transport Stream packets, of the same PID, following the associated Transport Stream packet until a splicing point is reached. Duplicate Transport Stream packets and Transport Stream packets which only contain adaptation fields are excluded. The splicing point is located immediately after the last byte of the Transport Stream packet in which the associated splice_countdown field reaches zero. In the Transport Stream packet where the splice_countdown reaches zero, the last data byte of the Transport Stream packet payload shall be the last byte of a coded audio frame or a coded picture. In the case of video, the corresponding access unit may or may not be terminated by a sequence_end_code. Transport Stream packets with the same PID, which follow, may contain data from a different elementary stream of the same type.

The payload of the next Transport Stream packet of the same PID (duplicate packets and packets without payload being excluded) shall commence with the first byte of a PES packet. In the case of audio, the PES packet payload shall commence with an access point. In the case of video, the PES packet payload shall commence with an access point, or with a sequence_end_code, followed by an access point. Thus, the previous coded audio frame or coded picture aligns with the packet boundary, or is padded to make this so. Subsequent to the splicing point, the countdown field may also be present. When the splice_countdown is a negative number whose value is minus n (–n), it indicates that the associated Transport Stream packet is the n-th packet following the splicing point (duplicate packets and packets without payload being excluded).

For the purposes of this subclause, an access point is defined as follows:

- Video – The first byte of a video_sequence_header.
- Audio – The first byte of an audio frame.

transport_private_data_length – The transport_private_data_length is an 8-bit field specifying the number of private_data bytes immediately following the transport private_data_length field. The number of private_data bytes shall not be such that private data extends beyond the adaptation field.

private_data_byte – The private_data_byte is an 8-bit field that shall not be specified by ITU-T | ISO/IEC.

adaptation_field_extension_length – The adaptation_field_extension_length is an 8-bit field. It indicates the number of bytes of the extended adaptation field data immediately following this field, including reserved bytes if present.

ltw_flag (legal time window_flag) – This is a 1-bit field which when set to '1' indicates the presence of the ltw_offset field.

piecewise_rate_flag – This is a 1-bit field which when set to '1' indicates the presence of the piecewise_rate field.

seamless_splice_flag – This is a 1-bit flag which when set to '1' indicates that the splice_type and DTS_next_AU fields are present. A value of '0' indicates that neither splice_type nor DTS_next_AU fields are present. This field shall not be set to '1' in Transport Stream packets in which the splicing_point_flag is not set to '1'. Once it is set to '1' in a Transport Stream packet in which the splice_countdown is positive, it shall be set to '1' in all the subsequent Transport Stream packets of the same PID that have the splicing_point_flag set to '1', until the packet in which the splice_countdown reaches zero (including this packet). When this flag is set, if the elementary stream carried in this PID is an audio stream, the splice_type field shall be set to '0000'. If the elementary stream carried in this PID is a video stream, it shall fulfil the constraints indicated by the splice_type value.

ltw_valid_flag (legal time window_valid_flag) – This is a 1-bit field which when set to '1' indicates that the value of the ltw_offset shall be valid. A value of '0' indicates that the value in the ltw_offset field is undefined.

ltw_offset (legal time window offset) – This is a 15-bit field, the value of which is defined only if the ltw_valid flag has a value of '1'. When defined, the legal time window offset is in units of $(300/f_s)$ seconds, where f_s is the system clock frequency of the program that this PID belongs to, and fulfils:

$$\text{offset} = t_1(i) - t(i)$$

$$\text{ltw\_offset} = \text{offset}//1$$

where i is the index of the first byte of this Transport Stream packet, offset is the value encoded in this field, t(i) is the arrival time of byte i in the T-STD, and $t_1(i)$ is the upper bound in time of a time interval called the Legal Time Window which is associated with this Transport Stream packet.

The Legal Time Window has the property that if this Transport Stream is delivered to a T-STD starting at time $t_1(i)$, i.e. at the end of its Legal Time Window, and all other Transport Stream packets of the same program are delivered at the end of their Legal Time Windows, then

- For video – The MB_n buffer for this PID in the T-STD shall contain less than 184 bytes of elementary stream data at the time the first byte of the payload of this Transport Stream packet enters it, and no buffer violations in the T-STD shall occur.
- For audio – The B_n buffer for this PID in the T-STD shall contain less than $BS_{dec} + 1$ bytes of elementary stream data at the time the first byte of this Transport Stream packet enters it, and no buffer violations in the T-STD shall occur.

Depending on factors including the size of the buffer MB_n and the rate of data transfer between MB_n and EB_n, it is possible to determine another time $t_0(i)$, such that if this packet is delivered anywhere in the interval $[t_0(i), t_1(i)]$, no T-STD buffer violations will occur. This time interval is called the Legal Time Window. The value of t_0 is not defined in this Recommendation | International Standard.

The information in this field is intended for devices such as remultiplexers which may need this information in order to reconstruct the state of the buffers MB_n.

piecewise_rate – The meaning of this 22-bit field is only defined when both the ltw_flag and the ltw_valid_flag are set to '1'. When defined, it is a positive integer specifying a hypothetical bitrate R which is used to define the end times of the Legal Time Windows of Transport Stream packets of the same PID that follow this packet but do not include the legal_time_window_offset field.

Assume that the first byte of this Transport Stream packet and the N following Transport Stream packets of the same PID have indices A_i, A_{i+1}, ..., A_{i+N}, respectively, and that the N latter packets do not have a value encoded in the field legal_time_window_offset. Then the values $t_1(A_{i+j})$ shall be determined by:

$$t_1(A_{i+j}) = t_1(A_i) + j \times 188 \times \text{8-bits/byte} / R$$

where j goes from 1 to N.

All packets between this packet and the next packet of the same PID to include a legal_time_window_offset field shall be treated as if they had the value:

$$\text{offset} = t_1(A_i) - t(A_i)$$

corresponding to the value $t_1(.)$ as computed by the formula above encoded in the legal_time_window_offset field. t(j) is the arrival time of byte j in the T-STD.

The meaning of this field is not defined when it is present in a Transport Stream packet with no legal_time_window_offset field.

splice_type – This is a 4-bit field. From the first occurrence of this field onwards, it shall have the same value in all the subsequent Transport Stream packets of the same PID in which it is present, until the packet in which the splice_countdown reaches zero (including this packet). If the elementary stream carried in that PID is an audio stream, this field shall have the value '0000'. If the elementary stream carried in that PID is a video stream, this field indicates the conditions that shall be respected by this elementary stream for splicing purposes. These conditions are defined as a function of profile, level and splice_type in Table 2-7 through Table 2-16.

In these tables, a value for 'splice_decoding_delay' and 'max_splice_rate' means that the following conditions shall be satisfied by the video elementary stream:

1) The last byte of the coded picture ending in the Transport Stream packet in which the splice_countdown reaches zero shall remain in the VBV buffer of the VBV model for an amount of time equal to (splice_decoding_delay $t_{n+1} - t_n$), where for the purpose of this subclause:

   - n is the index of the coded picture ending in the Transport Stream packet in which the splice_countdown reaches zero, i.e. the coded picture referred to above.
   - t_n is defined in C.3.1 of ITU-T Rec. H.262 | ISO/IEC 13818-2.
   - $(t_{n+1} - t_n)$ is defined in C.9 through C.12 of ITU-T Rec. H.262 | ISO/IEC 13818-2.

     NOTE – t_n is the time when coded picture n is removed from the VBV buffer, and $(t_{n+1} - t_n)$ is the duration for which picture n is presented.

2) The VBV buffer of the VBV model shall not overflow if its input is switched at the splicing point to a stream of a constant rate equal to 'max_splice_rate' for an amount of time equal to 'splice_decoding_delay'.

DTS_next_AU (decoding time stamp next access unit) – This is a 33-bit field, coded in three parts. In the case of continuous and periodic decoding through this splicing point it indicates the decoding time of the first access unit following the splicing point. This decoding time is expressed in the time base which is valid in the Transport Stream packet in which the splice_countdown reaches zero. From the first occurrence of this field onwards, it shall have the same value in all the subsequent Transport Stream packets of the same PID in which it is present, until the packet in which the splice_countdown reaches zero (including this packet).

stuffing_byte – This is a fixed 8-bit value equal to '1111 1111' that can be inserted by the encoder. It is discarded by the decoder.

2.4.3.6 PES packet

See Table 2-17.

2.4.3.7 Semantic definition of fields in PES packet

packet_start_code_prefix – The packet_start_code_prefix is a 24-bit code. Together with the stream_id that follows it constitutes a packet start code that identifies the beginning of a packet. The packet_start_code_prefix is the bit string '0000 0000 0000 0000 0000 0001' (0x000001).

stream_id – In Program Streams, the stream_id specifies the type and number of the elementary stream as defined by the stream_id Table 2-18. In Transport Streams, the stream_id may be set to any valid value which correctly describes the elementary stream type as defined in Table 2-18. In Transport Streams, the elementary stream type is specified in the Program Specific Information as specified in 2.4.4.

PES_packet_length – A 16-bit field specifying the number of bytes in the PES packet following the last byte of the field. A value of 0 indicates that the PES packet length is neither specified nor bounded and is allowed only in PES packets whose payload consists of bytes from a video elementary stream contained in Transport Stream packets.

PES_scrambling_control – The 2-bit PES_scrambling_control field indicates the scrambling mode of the PES packet payload. When scrambling is performed at the PES level, the PES packet header, including the optional fields when present, shall not be scrambled (see Table 2-19).

Table 2-18 – Stream_id assignments

stream_id	Note	stream coding
1011 1100	1	program_stream_map
1011 1101	2	private_stream_1
1011 1110		padding_stream
1011 1111	3	private_stream_2
110x xxxx		ISO/IEC 13818-3 or ISO/IEC 11172-3 or ISO/IEC 13818-7 or ISO/IEC 14496-3 audio stream number x xxxx
1110 xxxx		ITU-T Rec. H.262 | ISO/IEC 13818-2 or ISO/IEC 11172-2 or ISO/IEC 14496-2 video stream number xxxx
1111 0000	3	ECM_stream
1111 0001	3	EMM_stream
1111 0010	5	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Annex A or ISO/IEC 13818-6_DSMCC_stream
1111 0011	2	ISO/IEC_13522_stream
1111 0100	6	ITU-T Rec. H.222.1 type A
1111 0101	6	ITU-T Rec. H.222.1 type B
1111 0110	6	ITU-T Rec. H.222.1 type C
1111 0111	6	ITU-T Rec. H.222.1 type D
1111 1000	6	ITU-T Rec. H.222.1 type E
1111 1001	7	ancillary_stream
1111 1010		ISO/IEC14496-1_SL-packetized_stream
1111 1011		ISO/IEC14496-1_FlexMux_stream
1111 1100 … 1111 1110		reserved data stream
1111 1111	4	program_stream_directory

The notation x means that the values '0' or '1' are both permitted and results in the same stream type. The stream number is given by the values taken by the x's.

NOTE 1 – PES packets of type program_stream_map have unique syntax specified in 2.5.4.1.

NOTE 2 – PES packets of type private_stream_1 and ISO/IEC_13552_stream follow the same PES packet syntax as those for ITU-T Rec. H.262 | ISO/IEC 13818-2 video and ISO/IEC 13818-3 audio streams.

NOTE 3 – PES packets of type private_stream_2, ECM_stream and EMM_stream are similar to private_stream_1 except no syntax is specified after PES_packet_length field.

NOTE 4 – PES packets of type program_stream_directory have a unique syntax specified in 2.5.5.

NOTE 5 – PES packets of type DSM-CC_stream have a unique syntax specified in ISO/IEC 13818- 6.

NOTE 6 – This stream_id is associated with stream_type 0x09 in Table 2-29.

NOTE 7 – This stream_id is only used in PES packets, which carry data from a Program Stream or an ISO/IEC 11172-1 System Stream, in a Transport Stream (refer to 2.4.3.7).

Table 2-19 – PES scrambling control values

Value	Description
00	Not scrambled
01	User-defined
10	User-defined
11	User-defined

PES_priority – This is a 1-bit field indicating the priority of the payload in this PES packet. A '1' indicates a higher priority of the payload of the PES packet payload than a PES packet payload with this field set to '0'. A multiplexor can use the PES_priority bit to prioritize its data within an elementary stream. This field shall not be changed by the transport mechanism.

data_alignment_indicator – This is a 1-bit flag. When set to a value of '1' it indicates that the PES packet header is immediately followed by the video start code or audio syncword indicated in the data_stream_alignment_descriptor in 2.6.10 if this descriptor is present. If set to a value of '1' and the descriptor is not present, alignment as indicated in alignment_type '01' in Table 2-47 and Table 2-48 is required. When set to a value of '0' it is not defined whether any such alignment occurs or not.

copyright – This is a 1-bit field. When set to '1' it indicates that the material of the associated PES packet payload is protected by copyright. When set to '0' it is not defined whether the material is protected by copyright. A copyright descriptor described in 2.6.24 is associated with the elementary stream which contains this PES packet and the copyright flag is set to '1' if the descriptor applies to the material contained in this PES packet.

original_or_copy – This is a 1-bit field. When set to '1' the contents of the associated PES packet payload is an original. When set to '0' it indicates that the contents of the associated PES packet payload is a copy.

PTS_DTS_flags – This is a 2-bit field. When the PTS_DTS_flags field is set to '10', the PTS fields shall be present in the PES packet header. When the PTS_DTS_flags field is set to '11', both the PTS fields and DTS fields shall be present in the PES packet header. When the PTS_DTS_flags field is set to '00' no PTS or DTS fields shall be present in the PES packet header. The value '01' is forbidden.

ESCR_flag – A 1-bit flag, which when set to '1' indicates that ESCR base and extension fields are present in the PES packet header. When set to '0' it indicates that no ESCR fields are present.

ES_rate_flag – A 1-bit flag, which when set to '1' indicates that the ES_rate field is present in the PES packet header. When set to '0' it indicates that no ES_rate field is present.

DSM_trick_mode_flag – A 1-bit flag, which when set to '1' it indicates the presence of an 8-bit trick mode field. When set to '0' it indicates that this field is not present.

additional_copy_info_flag – A 1-bit flag, which when set to '1' indicates the presence of the additional_copy_info field. When set to '0' it indicates that this field is not present.

PES_CRC_flag – A 1-bit flag, which when set to '1' indicates that a CRC field is present in the PES packet. When set to '0' it indicates that this field is not present.

PES_extension_flag – A 1-bit flag, which when set to '1' indicates that an extension field exists in this PES packet header. When set to '0' it indicates that this field is not present.

PES_header_data_length – An 8-bit field specifying the total number of bytes occupied by the optional fields and any stuffing bytes contained in this PES packet header. The presence of optional fields is indicated in the byte that precedes the PES_header_data_length field.

marker_bit – A marker_bit is a 1-bit field that has the value '1'.

PTS (presentation time stamp) – Presentation times shall be related to decoding times as follows: The PTS is a 33-bit number coded in three separate fields. It indicates the time of presentation, $tp_n(k)$, in the system target decoder of a presentation unit k of elementary stream n. The value of PTS is specified in units of the period of the system clock frequency divided by 300 (yielding 90 kHz). The presentation time is derived from the PTS according to equation 2-11 below. Refer to 2.7.4 for constraints on the frequency of coding presentation timestamps.

$$PTS(k) = ((system\_clock\_frequency \times tp_n(k)) \; DIV \; 300) \; \% \; 2^{33} \qquad (2\text{-}11)$$

where $tp_n(k)$ is the presentation time of presentation unit $P_n(k)$.

In the case of audio, if a PTS is present in PES packet header it shall refer to the first access unit commencing in the PES packet. An audio access unit commences in a PES packet if the first byte of the audio access unit is present in the PES packet.

In the case of video, if a PTS is present in a PES packet header it shall refer to the access unit containing the first picture start code that commences in this PES packet. A picture start code commences in PES packet if the first byte of the picture start code is present in the PES packet.

For audio presentation units (PUs), video PUs in low_delay sequences, and B-pictures, the presentation time $tp_n(k)$ shall be equal to the decoding time $td_n(k)$.

For I- and P-pictures in non-low_delay sequences and in the case when there is no decoding discontinuity between access units (AUs) k and k', the presentation time $tp_n(k)$ shall be equal to the decoding time $td_n(k')$ of the next transmitted I- or P-picture (refer to 2.7.5). If there is a decoding discontinuity, or the stream ends, the difference between $tp_n(k)$ and $td_n(k)$ shall be the same as if the original stream had continued without a discontinuity and without ending.

NOTE 1 – A low_delay sequence is a video sequence in which the low_delay flag is set (refer to 6.2.2.3 of ITU-T Rec. H.262 | ISO/IEC 13818-2).

If there is filtering in audio, it is assumed by the system model that filtering introduces no delay, hence the sample referred to by PTS at encoding is the same sample referred to by PTS at decoding. In the case of scalable coding refer to 2.7.6.

DTS (decoding time stamp) – The DTS is a 33-bit number coded in three separate fields. It indicates the decoding time, $td_n(j)$, in the system target decoder of an access unit j of elementary stream n. The value of DTS is specified in units of the period of the system clock frequency divided by 300 (yielding 90 kHz). The decoding time derived from the DTS according to equation 2-12 below:

$$DTS(j) = ((system\_clock\_frequency \times td_n(j)) \; DIV \; 300) \; \% \; 2^{33} \tag{2-12}$$

where $td_n(j)$ is the decoding time of access unit $A_n(j)$.

In the case of video, if a DTS is present in a PES packet header it shall refer to the access unit containing the first picture start code that commences in this PES packet. A picture start code commences in PES packet if the first byte of the picture start code is present in the PES packet.

In the case of scalable coding refer to 2.7.6.

ESCR_base; ESCR_extension – The elementary stream clock reference is a 42-bit field coded in two parts. The first part, ESCR_base, is a 33-bit field whose value is given by ESCR_base(i), as given in equation 2-14. The second part, ESCR_ext, is a 9-bit field whose value is given by ESCR_ext(i), as given in equation 2-15. The ESCR field indicates the intended time of arrival of the byte containing the last bit of the ESCR_base at the input of the PES-STD for PES streams (refer to 2.5.2.4).

Specifically:

$$ESCR(i) = ESCR\_base(i) \times 300 + ESCR\_ext(i) \tag{2-13}$$

where

$$ESCR\_base(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 300) \; \% \; 2^{33} \tag{2-14}$$

$$ESCR\_ext(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 1) \; \% \; 300 \tag{2-15}$$

The ESCR and ES_rate field (refer to semantics immediately following) contain timing information relating to the sequence of PES streams. These fields shall satisfy the constraints defined in 2.7.3.

ES_rate (elementary stream rate) – The ES_rate field is a 22-bit unsigned integer specifying the rate at which the system target decoder receives bytes of the PES packet in the case of a PES stream. The ES_rate is valid in the PES packet in which it is included and in subsequent PES packets of the same PES stream until a new ES_rate field is encountered. The value of the ES_rate is measured in units of 50 bytes/second. The value 0 is forbidden. The value of the ES_rate is used to define the time of arrival of bytes at the input of a P-STD for PES streams defined in 2.5.2.4. The value encoded in the ES_rate field may vary from PES_packet to PES_packet.

trick_mode_control – A 3-bit field that indicates which trick mode is applied to the associated video stream. In cases of other types of elementary streams, the meanings of this field and those defined by the following five bits are undefined. For the definition of trick_mode status, refer to the **trick mode** section of 2.4.2.3.

When trick_mode status is false, the number of times N, a picture is output by the decoding process for progressive sequences, is specified for each picture by the repeat_first_field and top_field_first fields in the case of ITU-T Rec. H.262 | ISO/IEC 13818-2 Video, and is specified through the sequence header in the case of ISO/IEC 11172-2 Video.

For interlaced sequences, when trick_mode status is false, the number of times N, a picture is output by the decoding process for progressive sequences, is specified for each picture by the repeat_first_field and progressive_frame fields in the case of ITU-T Rec. H.262 | ISO/IEC 13818-2 Video.

When trick mode status is true, the number of times that a picture shall be displayed depends on the value of N.

When the value of this field changes or trick mode operations cease, any combination of the following may occur:

- discontinuity in the time base;
- decoding discontinuity;
- continuity counter discontinuity.

Table 2-20 – Trick mode control values

Value	Description
'000'	Fast forward
'001'	Slow motion
'010'	Freeze frame
'011'	Fast reverse
'100'	Slow reverse
'101'-'111'	Reserved

In the context of trick mode, the non-normal speed of decoding and presentation may cause the values of certain fields defined in video elementary stream data to be incorrect. Likewise, the semantic constraint on the slice structure may be invalid. The video syntax elements to which this exception applies are:

- bit_rate;
- vbv_delay;
- repeat_first_field;
- v_axis_positive;
- field_sequence;
- subcarrier;
- burst_amplitude;
- subcarrier_phase.

A decoder cannot rely on the values encoded in these fields when in trick mode.

Decoders are not normatively required to decode the trick_mode_control field. However, the following normative requirements shall apply to decoders that do decode the trick_mode_control field.

fast forward – The value '000', in the trick_mode_control field. When this value is present it indicates a fast forward video stream and defines the meaning of the following five bits in the PES packet header. The intra_slice_refresh bit may be set to '1' indicating that there may be missing macroblocks which the decoder may replace with co-sited macroblocks of previously decoded pictures. The field_id field, defined in Table 2-21, indicates which field or fields should be displayed. The frequency_truncation field indicates that a restricted set of coefficients may be included. The meaning of the values of this field are shown in Table 2-22.

slow motion – The value '001', in the trick_mode_control field. When this value is present it indicates a slow motion video stream and defines the meaning of the following five bits in the PES packet header. In the case of progressive sequences, the picture should be displayed N × rep_cntrl times, where N is defined above.

In the case of ISO/IEC 11172-2 Video and ITU-T Rec. H.262 | ISO/IEC 13818-2 Video progressive sequences, the picture should be displayed for N × rep_cntrl picture duration.

In the case of ITU-T Rec. H.262 | ISO/IEC 13818-2 interlaced sequences, the picture should be displayed for N × rep_cntrl field duration. If the picture is a frame picture, the first field to be displayed is the top field if top_field_first is 1, and the bottom field if top_field_first is '0' (refer to ITU-T Rec. H.262 | ISO/IEC 13818-2). This field is displayed for N × rep_cntrl / 2 field duration. The other field of the picture is then displayed for N – N × rep_cntrl / 2 field duration.

freeze frame – The value '010', in the trick_mode_control field. When this value is present it indicates a freeze frame video stream and defines the meaning of the following five bits in the PES packet header. The field_id field, defined in Table 2-21, identifies which field(s) should be displayed. The field_id field refers to the first video access unit that commences in the PES packet which contains the field_id field, unless the PES packet contains zero payload bytes. In the latter case the field_id field refers to the most recent previous video access unit.

fast reverse – The value '011', in the trick_mode_control field. When this value is present it indicates a fast reverse video stream and defines the meaning of the following five bits in the PES packet header. The intra_slice_refresh bit may be set to '1' indicating that there may be missing macroblocks which the decoder may replace with co-sited macroblocks of previously decoded pictures. The field_id field, defined in Table 2-21, indicates which field or fields should be displayed. The frequency_truncation field indicates that a restricted set of coefficients may be included. The meaning of the values of this field are shown in Table 2-22, "Coefficient selection values".

slow reverse – The value '100', in the trick_mode_control field. When this value is present it indicates a slow reverse video stream and defines the meaning of the following five bits in the PES packet header. In the case of ISO/IEC 11172-2 Video and ITU-T Rec. H.262 | ISO/IEC 13818-2 Video progressive sequences, the picture should be displayed for N × rep_cntrl picture duration, where N is defined above.

In the case of ITU-T Rec. H.262 | ISO/IEC 13818-2 interlaced sequences, the picture should be displayed for N × rep_cntrl field duration. If the picture is a frame picture, the first field to be displayed is the bottom field if top_field_first is 1, and the top field if top_field_first is '0' (refer to ITU-T Rec. H.262 | ISO/IEC 13818-2). This field is displayed for N × rep_cntrl / 2 field duration. The other field of the picture is then displayed for N – N × rep_cntrl / 2 field duration.

field_id – A 2-bit field that indicates which field(s) should be displayed. It is coded according to Table 2-21.

Table 2-21 – Field_id field control values

Value	Description
'00'	Display from top field only
'01'	Display from bottom field only
'10'	Display complete frame
'11'	Reserved

intra_slice_refresh – A 1-bit flag, which when set to '1', indicates that there may be missing macroblocks between coded slices of video data in this PES packet. When set to '0' this may not occur. For more information see ITU-T Rec. H.262 | ISO/IEC 13818-2. The decoder may replace missing macroblocks with co-sited macroblocks of previously decoded pictures.

frequency_truncation – A 2-bit field which indicates that a restricted set of coefficients may have been used in coding the video data in this PES packet. The values are defined in Table 2-22.

Table 2-22 – Coefficient selection values

Value	Description
'00'	Only DC coefficients are non-zero
'01'	Only the first three coefficients are non-zero
'10'	Only the first six coefficients are non-zero
'11'	All coefficients may be non-zero

rep_cntrl – A 5-bit field that indicates the number of times each field in an interlaced picture should be displayed, or the number of times that a progressive picture should be displayed. It is a function of the trick_mode_control field and the top_field_first bit in the video sequence header whether the top field or the bottom field should be displayed first in the case of interlaced pictures. The value '0' is forbidden.

additional_copy_info – This 7-bit field contains private data relating to copyright information.

previous_PES_packet_CRC – The previous_PES_packet_CRC is a 16-bit field that contains the CRC value that yields a zero output of the 16 registers in the decoder similar to the one defined in Annex A, but with the polynomial:

$$x^{16} + x^{12} + x^5 + 1$$

after processing the data bytes of the previous PES packet, exclusive of the PES packet header.

NOTE 2 – This CRC is intended for use in network maintenance such as isolating the source of intermittent errors. It is not intended for use by elementary stream decoders. It is calculated only over the data bytes because PES packet header data can be modified during transport.

PES_private_data_flag – A 1-bit flag which when set to '1' indicates that the PES packet header contains private data. When set to a value of '0' it indicates that private data is not present in the PES header.

pack_header_field_flag – A 1-bit flag which when set to '1' indicates that an ISO/IEC 11172-1 pack header or a Program Stream pack header is stored in this PES packet header. If this field is in a PES packet that is contained in a Program Stream, then this field shall be set to '0'. In a Transport Stream, when set to the value '0' it indicates that no pack header is present in the PES header.

program_packet_sequence_counter_flag – A 1-bit flag which when set to '1' indicates that the program_packet_sequence_counter, MPEG1_MPEG2_identifier, and original_stuff_length fields are present in this PES packet. When set to a value of '0' it indicates that these fields are not present in the PES header.

P-STD_buffer_flag – A 1-bit flag which when set to '1' indicates that the P-STD_buffer_scale and P-STD_buffer_size are present in the PES packet header. When set to a value of '0' it indicates that these fields are not present in the PES header.

PES_extension_flag_2 – A 1-bit field which when set to '1' indicates the presence of the PES_extension_field_length field and associated fields. When set to a value of '0' this indicates that the PES_extension_field_length field and any associated fields are not present.

PES_private_data – This is a 16-byte field which contains private data. This data, combined with the fields before and after, shall not emulate the packet_start_code_prefix (0x000001).

pack_field_length – This is an 8-bit field which indicates the length, in bytes, of the pack_header_field().

program_packet_sequence_counter – The program_packet_sequence_counter field is a 7-bit field. It is an optional counter that increments with each successive PES packet from a Program Stream or from an ISO/IEC 11172-1 Stream or the PES packets associated with a single program definition in a Transport Stream, providing functionality similar to a continuity counter (refer to 2.4.3.2). This allows an application to retrieve the original PES packet sequence of a Program Stream or the original packet sequence of the original ISO/IEC 11172-1 stream. The counter will wrap around to 0 after its maximum value. Repetition of PES packets shall not occur. Consequently, no two consecutive PES packets in the program multiplex shall have identical program_packet_sequence_counter values.

MPEG1_MPEG2_identifier – A 1-bit flag which when set to '1' indicates that this PES packet carries information from an ISO/IEC 11172-1 stream. When set to '0' it indicates that this PES packet carries information from a Program Stream.

original_stuff_length – This 6-bit field specifies the number of stuffing bytes used in the original ITU-T Rec. H.222.0 | ISO/IEC 13818-1 PES packet header or in the original ISO/IEC 11172-1 packet header.

P-STD_buffer_scale – The P-STD_buffer_scale is a 1-bit field, the meaning of which is only defined if this PES packet is contained in a Program Stream. It indicates the scaling factor used to interpret the subsequent P-STD_buffer_size field. If the preceding stream_id indicates an audio stream, P-STD_buffer_scale shall have the value '0'. If the preceding stream_id indicates a video stream, P-STD_buffer_scale shall have the value '1'. For all other stream types, the value may be either '1' or '0'.

P-STD_buffer_size – The P-STD_buffer_size is a 13-bit unsigned integer, the meaning of which is only defined if this PES packet is contained in a Program Stream. It defines the size of the input buffer, BS_n, in the P-STD. If P-STD_buffer_scale has the value '0', then the P-STD_buffer_size measures the buffer size in units of 128 bytes. If P-STD_buffer_scale has the value '1', then the P-STD_buffer_size measures the buffer size in units of 1024 bytes. Thus:

$$\text{if } (P\text{-}STD\_buffer\_scale == 0)$$
$$BS_n = \bar{P} - STD\_buffer\_size \times 128 \tag{2-16}$$

else

$$BS_n = P - STD\_buffer\_size \times 1024 \tag{2-17}$$

The encoded value of the P-STD buffer size takes effect immediately when the P-STD_buffer_size field is received by the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 System Target Decoder (refer to 2.7.7).

PES_extension_field_length – This is a 7-bit field which specifies the length, in bytes, of the data following this field in the PES extension field up to and including any reserved bytes.

stuffing_byte – This is a fixed 8-bit value equal to '1111 1111' that can be inserted by the encoder, for example to meet the requirements of the channel. It is discarded by the decoder. No more than 32 stuffing bytes shall be present in one PES packet header.

PES_packet_data_byte – PES_packet_data_bytes shall be contiguous bytes of data from the elementary stream indicated by the packet's stream_id or PID. When the elementary stream data conforms to ITU-T Rec. H.262 | ISO/IEC 13818-2 or ISO/IEC 13818-3, the PES_packet_data_bytes shall be byte aligned to the bytes of this Recommendation | International Standard. The byte-order of the elementary stream shall be preserved. The number of PES_packet_data_bytes, N, is specified by the PES_packet_length field. N shall be equal to the value indicated in the PES_packet_length minus the number of bytes between the last byte of the PES_packet_length field and the first PES_packet_data_byte.

In the case of a private_stream_1, private_stream_2, ECM_stream, or EMM_stream, the contents of the PES_packet_data_byte field are user definable and will not be specified by ITU-T | ISO/IEC in the future.

padding_byte – This is a fixed 8-bit value equal to '1111 1111'. It is discarded by the decoder.

2.4.3.8 Carriage of Program Streams and ISO/IEC 11172-1 Systems streams in the Transport Stream

The Transport Stream contains optional fields to support the carriage of Program Streams and ISO/IEC 11172-1 Systems streams, in a way that allows simple reconstruction of the respective stream at the decoder.

When placing a Program Stream into a Transport Stream, Program Stream PES packets with stream_id values of private_stream_1, ITU-T Rec. H.262 | ISO/IEC 13818-2 or ISO/IEC 11172-2 video, and ISO/IEC 13818-3 or ISO/IEC 11172-3 audio, are carried in Transport Stream packets.

For these PES packets, when reconstructing the Program Stream at the Transport Stream decoder, the PES packet data is copied to the Program Stream being reconstructed.

For Program Streams PES packets with stream_id values of program_stream_map, padding_stream, private_stream_2, ECM, EMM, DSM_CC_stream, or program_stream_directory, all the bytes of the Program Stream PES packet, except for the packet_start_code_prefix, are placed into the data_bytes fields of a new PES packet. The stream_id of this new PES packet has the value of ancillary_stream (refer to Table 2-18). This new PES packet is then carried in Transport Stream packets.

When reconstructing the Program Stream at the Transport Stream decoder, for PES packets with a stream_id value of ancillary_stream_id, packet_start_code_prefix is written to the Program Stream being reconstructed, followed by the data_byte fields from these Transport Stream PES packets.

ISO/IEC 11172-1 streams are carried within Transport Streams by first replacing ISO/IEC 11172-1 packet headers with ITU-T Rec. H.262 | ISO/IEC 13818-2 PES packet headers. ISO/IEC 11172-1 packet header field values are copied to the equivalent ITU-T Rec. H.262 | ISO/IEC 13818-2 PES packet header fields.

The program_packet_sequence_counter field is included within the header of each PES packet carrying data from a Program Stream, or an ISO/IEC 11172-1 System stream. This allows the order of PES packets in the original Program Stream, or packets in the original ISO/IEC 11172-1 System stream, to be reproduced at the decoder.

The pack_header() field of a Program Stream, or an ISO/IEC 11172-1 System stream, is carried in the Transport Stream in the header of the immediately following PES packet.

2.4.4 Program specific information

Program Specific Information (PSI) includes both ITU-T Rec. H.222.0 | ISO/IEC 13818-1 normative data and private data that enable demultiplexing of programs by decoders. Programs are composed of one or more elementary streams, each labelled with a PID. Programs, elementary streams or parts thereof may be scrambled for conditional access. However, Program Specific Information shall not be scrambled.

In Transport Streams, Program Specific Information is classified into five table structures as shown in Table 2-23. While these structures may be thought of as simple tables, they shall be segmented into sections and inserted in Transport Stream packets, some with predetermined PIDs and others with user selectable PIDs.

Table 2-23 – Program specific information

Structure Name	Stream Type	PID number	Description
Program Association Table	ITU-T Rec. H.222.0 | ISO/IEC 13818-1	0x00	Associates Program Number and Program Map Table PID
Program Map Table	ITU-T Rec. H.222.0 | ISO/IEC 13818-1	Assignment indicated in the PAT	Specifies PID values for components of one or more programs
Network Information Table	Private	Assignment indicated in the PAT	Physical network parameters such as FDM frequencies, Transponder Numbers, etc.
Conditional Access Table	ITU-T Rec. H.222.0 | ISO/IEC 13818-1	0x01	Associates one or more (private) EMM streams each with a unique PID value
Transport Stream Description Table	ITU-T Rec. H.222.0 | ISO/IEC 13818-1	0x02	Associates one or more descriptors from Table 2-39 to an entire Transport Stream

ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined PSI tables shall be segmented into one or more sections that are carried within transports packets. A section is a syntactic structure that shall be used for mapping each ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined PSI table into Transport Stream packets.

Along with ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined PSI tables, it is possible to carry private data tables. The means by which private information is carried within Transport Stream packets is not defined by this Specification. It may be structured in the same manner used for carrying of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined PSI tables, such that the syntax for mapping this private data is identical to that used for the mapping of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined PSI tables. For this purpose, a private section is defined. If the private data is carried in Transport Stream packets with the same PID value as Transport Stream packets carrying Program Map Tables, (as identified in the Program Association Table), then the private_section syntax and semantics shall be used. The data carried in the private_data_bytes may be scrambled. However, no other fields of the private_section shall be scrambled. This private_section allows data to be transmitted with a minimum of structure. When this structure is not used, the mapping of private data within Transport Stream packets is not defined by this Recommendation | International Standard.

Sections may be variable in length. The beginning of a section is indicated by a pointer_field in the Transport Stream packet payload. The syntax of this field is specified in Table 2-24.

Adaptation fields may occur in Transport Stream packets carrying PSI sections.

Within a Transport Stream, packet stuffing bytes of value 0xFF may be found in the payload of Transport Stream packets carrying PSI and/or private_sections only after the last byte of a section. In this case all bytes until the end of the Transport Stream packet shall also be stuffing bytes of value 0xFF. These bytes may be discarded by a decoder. In such a case, the payload of the next Transport Stream packet with the same PID value shall begin with a pointer_field of value 0x00 indicating that the next section starts immediately thereafter.

Each Transport Stream shall contain one or more Transport Stream packets with PID value 0x0000. These Transport Stream packets together shall contain a complete Program Association Table, providing a complete list of all programs within the Transport Stream. The most recently transmitted version of the table with the current_next_indicator set to a value of '1' shall always apply to the current data in the Transport Stream. Any changes in the programs carried within the Transport Stream shall be described in an updated version of the Program Association Table carried in Transport Stream packets with PID value 0x0000. These sections shall all use table_id value 0x00. Only sections with this value of table_id are permitted within Transport Stream packets with PID value of 0x0000. For a new version of the PAT to become valid, all sections (as indicated in the last_section_number) with a new version_number and with the current_next_indicator set to '1' must exit B_{sys} defined in the T-STD (refer to 2.4.2). The PAT becomes valid when the last byte of the section needed to complete the table exits B_{sys}.

Whenever one or more elementary streams within a Transport Stream are scrambled, Transport Stream packets with a PID value 0x0001 shall be transmitted containing a complete Conditional Access Table including CA_descriptors associated with the scrambled streams. The transmitted Transport Stream packets will together form one complete version of the conditional access table. The most recently transmitted version of the table with the current_next_indicator set to a value of '1' shall always apply to the current data in the Transport Stream. Any changes in scrambling making the existing table invalid or incomplete shall be described in an updated version of the conditional access table. These sections will all use table_id value 0x01. Only sections with this table_id value are permitted within Transport Stream packets with a PID value of 0x0001. For a new version of the CAT to become valid, all sections (as indicated in the last_section_number) with a new version_number and with the current_next_indicator set to '1' must exit B_{sys}. The CAT becomes valid when the last byte of the section needed to complete the table exits B_{sys}.

Each Transport Stream shall contain one or more Transport Stream packets with PID values which are labelled under the program association table as Transport Stream packets containing TS program map sections. Each program listed in the Program Association Table shall be described in a unique TS_program_map_section. Every program shall be fully defined within the Transport Stream itself. Private data which has an associated elementary_PID field in the appropriate Program Map Table section is part of the program. Other private data may exist in the Transport Stream without being listed in the Program Map Table section. The most recently transmitted version of the TS_program_map_section with the current_next_indicator set to a value of '1' shall always apply to the current data within the Transport Stream. Any changes in the definition of any of the programs carried within the Transport Stream shall be described in an updated version of the corresponding section of the program map table carried in Transport Stream packets with the PID value identified as the program_map_PID for that specific program. All Transport Stream packets which carry a given TS_program_map_section shall have the same PID value. During the continuous existence of a program, including all of its associated events, the program_map_PID shall not change. A program definition shall not span more than one TS_program_map_section. A new version of a TS_program_map_section becomes valid when the last byte of that section with a new version_number and with the current_next_indicator set to '1' exits B_{sys}.

Sections with a table_id value of 0x02 shall contain Program Map Table information. Such sections may be carried in Transport Stream packets with different PID values.

The Network Information Table is optional and its contents are private. If present it is carried within Transport Stream packets that will have the same PID value, called the network_PID. The network_PID value is defined by the user and, when present, shall be found in the Program Association Table under the reserved program_number 0x0000. If the network information table exists, it shall take the form of one or more private_sections.

The maximum number of bytes in a section of a ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined PSI table is 1024 bytes. The maximum number of bytes in a private_section is 4096 bytes.

The Transport Stream Description Table is optional. When present, the Transport Stream Description is carried within Transport Stream packets that have a PID value 0x0002 as specified in Table 2-23 and shall apply to the entire Transport Stream. Sections of the Transport Stream Description shall use a table_id value of 0x03 as specified in Table 2-26 and its contents are restricted to descriptors specified in Table 2-39. The TS_description_section becomes valid when the last byte of the section required to complete the table exits B_{sys}.

There are no restrictions on the occurrence of start codes, sync bytes or other bit patterns in PSI data, whether this Recommendation | International Standard or private.

2.4.4.1 Pointer

The pointer_field syntax is defined in Table 2-24.

Table 2-24 – Program specific information pointer

Syntax	No. of bits	Mnemonic
pointer_field	**8**	**uimsbf**

2.4.4.2 Semantics definition of fields in pointer syntax

pointer_field – This is an 8-bit field whose value shall be the number of bytes, immediately following the pointer_field until the first byte of the first section that is present in the payload of the Transport Stream packet (so a value of 0x00 in the pointer_field indicates that the section starts immediately after the pointer_field). When at least one section begins in a given Transport Stream packet, then the payload_unit_start_indicator (refer to 2.4.3.2) shall be set to 1 and the first byte of the payload of that Transport Stream packet shall contain the pointer. When no section begins in a given Transport Stream packet, then the payload_unit_start_indicator shall be set to 0 and no pointer shall be sent in the payload of that packet.

2.4.4.3 Program association Table

The Program Association Table provides the correspondence between a program_number and the PID value of the Transport Stream packets which carry the program definition. The program_number is the numeric label associated with a program.

The overall table is contained in one or more sections with the following syntax. It may be segmented to occupy multiple sections (see Table 2.25).

Table 2-25 – Program association section

Syntax	No. of bits	Mnemonic
program_association_section() {		
table_id	**8**	**uimsbf**
section_syntax_indicator	**1**	**bslbf**
'0'	**1**	**bslbf**
reserved	**2**	**bslbf**
section_length	**12**	**uimsbf**
transport_stream_id	**16**	**uimsbf**
reserved	**2**	**bslbf**
version_number	**5**	**uimsbf**
current_next_indicator	**1**	**bslbf**
section_number	**8**	**uimsbf**
last_section_number	**8**	**uimsbf**
for (i = 0; i < N; i++) {		
program_number	**16**	**uimsbf**
reserved	**3**	**bslbf**
if (program_number == '0') {		
network_PID	**13**	**uimsbf**
}		
else {		
program_map_PID	**13**	**uimsbf**
}		
}		
CRC_32	**32**	**rpchof**
}		

2.4.4.4 Table_id assignments

The table_id field identifies the contents of a Transport Stream PSI section as shown in Table 2-26.

Table 2-26 – table_id assignment values

Value	description
0x00	program_association_section
0x01	conditional_access_section (CA_section)
0x02	TS_program_map_section
0x03	TS_description_section
0x04	ISO_IEC_14496_scene_description_section
0x05	ISO_IEC_14496_object_descriptor_section
0x06-0x37	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 reserved
0x38-0x3F	Defined in ISO/IEC 13818-6
0x40-0xFE	User private
0xFF	forbidden

2.4.4.5 Semantic definition of fields in program association section

table_id – This is an 8-bit field, which shall be set to 0x00 as shown in Table 2-26.

section_syntax_indicator – The section_syntax_indicator is a 1-bit field which shall be set to '1'.

section_length – This is a 12-bit field, the first two bits of which shall be '00'. The remaining 10 bits specify the number of bytes of the section, starting immediately following the section_length field, and including the CRC. The value in this field shall not exceed 1021 (0x3FD).

transport_stream_id – This is a 16-bit field which serves as a label to identify this Transport Stream from any other multiplex within a network. Its value is defined by the user.

version_number – This 5-bit field is the version number of the whole Program Association Table. The version number shall be incremented by 1 modulo 32 whenever the definition of the Program Association Table changes. When the current_next_indicator is set to '1', then the version_number shall be that of the currently applicable Program Association Table. When the current_next_indicator is set to '0', then the version_number shall be that of the next applicable Program Association Table.

current_next_indicator – A 1-bit indicator, which when set to '1' indicates that the Program Association Table sent is currently applicable. When the bit is set to '0', it indicates that the table sent is not yet applicable and shall be the next table to become valid.

section_number – This 8-bit field gives the number of this section. The section_number of the first section in the Program Association Table shall be 0x00. It shall be incremented by 1 with each additional section in the Program Association Table.

last_section_number – This 8-bit field specifies the number of the last section (that is, the section with the highest section_number) of the complete Program Association Table.

program_number – Program_number is a 16-bit field. It specifies the program to which the program_map_PID is applicable. When set to 0x0000, then the following PID reference shall be the network PID. For all other cases the value of this field is user defined. This field shall not take any single value more than once within one version of the Program Association Table.

NOTE – The program_number may be used as a designation for a broadcast channel, for example.

network_PID – The network_PID is a 13-bit field, which is used only in conjunction with the value of the program_number set to 0x0000, specifies the PID of the Transport Stream packets which shall contain the Network Information Table. The value of the network_PID field is defined by the user, but shall only take values as specified in Table 2-3. The presence of the network_PID is optional.

program_map_PID – The program_map_PID is a 13-bit field specifying the PID of the Transport Stream packets which shall contain the program_map_section applicable for the program as specified by the program_number. No program_number shall have more than one program_map_PID assignment. The value of the program_map_PID is defined by the user, but shall only take values as specified in Table 2-3.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in Annex A after processing the entire program association section.

2.4.4.6 Conditional access Table

The Conditional Access (CA) Table provides the association between one or more CA systems, their EMM streams and any special parameters associated with them. Refer to 2.6.16 for a definition of the descriptor() field in Table 2-27.

The table is contained in one or more sections with the following syntax. It may be segmented to occupy multiple sections.

Table 2-27 – Conditional access section

Syntax	No. of bits	Mnemonic
CA_section() {		
table_id	**8**	**uimsbf**
section_syntax_indicator	**1**	**bslbf**
'0'	**1**	**bslbf**
reserved	**2**	**bslbf**
section_length	**12**	**uimsbf**
reserved	**18**	**bslbf**
version_number	**5**	**uimsbf**
current_next_indicator	**1**	**bslbf**
section_number	**8**	**uimsbf**
last_section_number	**8**	**uimsbf**
for (i = 0; i < N; i++) {		
descriptor()		
}		
CRC_32	**32**	**rpchof**
}		

2.4.4.7 Semantic definition of fields in conditional access section

table_id – This is an 8-bit field, which shall be set to 0x01 as specified in Table 2-26.

section_syntax_indicator – The section_syntax_indicator is a 1-bit field which shall be set to '1'.

section_length – This is a 12-bit field, the first two bits of which shall be '00'. The remaining 10-bits specify the number of bytes of the section starting immediately following the section_length field, and including the CRC. The value in this field shall not exceed 1021 (0x3FD).

version_number – This 5-bit field is the version number of the entire conditional access table. The version number shall be incremented by 1 modulo 32 when a change in the information carried within the CA table occurs. When the current_next_indicator is set to '1', then the version_number shall be that of the currently applicable Conditional Access Table. When the current_next_indicator is set to '0', then the version_number shall be that of the next applicable Conditional Access Table.

current_next_indicator – A 1-bit indicator, which when set to '1' indicates that the Conditional Access Table sent is currently applicable. When the bit is set to '0', it indicates that the Conditional Access Table sent is not yet applicable and shall be the next Conditional Access Table to become valid.

section_number – This 8-bit field gives the number of this section. The section_number of the first section in the Conditional Access Table shall be 0x00. It shall be incremented by 1 with each additional section in the Conditional Access Table.

last_section_number – This 8-bit field specifies the number of the last section (that is, the section with the highest section_number) of the Conditional Access Table.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in Annex A after processing the entire conditional access section.

2.4.4.8 Program Map Table

The Program Map Table provides the mappings between program numbers and the program elements that comprise them. A single instance of such a mapping is referred to as a "program definition". The program map table is the complete collection of all program definitions for a Transport Stream. This table shall be transmitted in packets, the PID values of which are selected by the encoder. More than one PID value may be used, if desired. The table is contained in one or more sections with the following syntax. It may be segmented to occupy multiple sections. In each section, the section number field shall be set to zero. Sections are identified by the program_number field.

Definition for the descriptor() fields may be found in 2.6 (see Table 2-28).

Table 2-28 – Transport Stream program map section

Syntax	No. of bits	Mnemonic
TS_program_map_section() {		
table_id	**8**	**uimsbf**
section_syntax_indicator	**1**	**bslbf**
'0'	**1**	**bslbf**
reserved	**2**	**bslbf**
section_length	**12**	**uimsbf**
program_number	**16**	**uimsbf**
reserved	**2**	**bslbf**
version_number	**5**	**uimsbf**
current_next_indicator	**1**	**bslbf**
section_number	**8**	**uimsbf**
last_section_number	**8**	**uimsbf**
reserved	**3**	**bslbf**
PCR_PID	**13**	**uimsbf**
reserved	**4**	**bslbf**
program_info_length	**12**	**uimsbf**
for (i = 0; i < N; i++) {		
descriptor()		
}		
for (i = 0; i < N1; i++) {		
stream_type	**8**	**uimsbf**
reserved	**3**	**bslbf**
elementary_PID	**13**	**uimsbf**
reserved	**4**	**bslbf**
ES_info_length	**12**	**uimsbf**
for (i = 0; i < N2; i++) {		
descriptor()		
}		
}		
CRC_32	**32**	**rpchof**
}		

2.4.4.9 Semantic definition of fields in Transport Stream program map section

table_id – This is an 8-bit field, which in the case of a TS_program_map_section shall be always set to 0x02 as shown in Table 2-26.

section_syntax_indicator – The section_syntax_indicator is a 1-bit field which shall be set to '1'.

section_length – This is a 12-bit field, the first two bits of which shall be '00'. The remaining 10 bits specify the number of bytes of the section starting immediately following the section_length field, and including the CRC. The value in this field shall not exceed 1021 (0x3FD).

program_number – program_number is a 16-bit field. It specifies the program to which the program_map_PID is applicable. One program definition shall be carried within only one TS_program_map_section. This implies that a program definition is never longer than 1016 (0x3F8). See Informative Annex C for ways to deal with the cases when that length is not sufficient. The program_number may be used as a designation for a broadcast channel, for example. By describing the different program elements belonging to a program, data from different sources (e.g. sequential events) can be concatenated together to form a continuous set of streams using a program_number. For examples of applications refer to Annex C.

version_number – This 5-bit field is the version number of the TS_program_map_section. The version number shall be incremented by 1 modulo 32 when a change in the information carried within the section occurs. Version number refers to the definition of a single program, and therefore to a single section. When the current_next_indicator is set to '1', then the version_number shall be that of the currently applicable TS_program_map_section. When the current_next_indicator is set to '0', then the version_number shall be that of the next applicable TS_program_map_section.

current_next_indicator – A 1-bit field, which when set to '1' indicates that the TS_program_map_section sent is currently applicable. When the bit is set to '0', it indicates that the TS_program_map_section sent is not yet applicable and shall be the next TS_program_map_section to become valid.

section_number – The value of this 8-bit field shall be 0x00.

last_section_number – The value of this 8-bit field shall be 0x00.

PCR_PID – This is a 13-bit field indicating the PID of the Transport Stream packets which shall contain the PCR fields valid for the program specified by program_number. If no PCR is associated with a program definition for private streams, then this field shall take the value of 0x1FFF. Refer to the semantic definition of PCR in 2.4.3.5 and Table 2-3 for restrictions on the choice of PCR_PID value.

program_info_length – This is a 12-bit field, the first two bits of which shall be '00'. The remaining 10 bits specify the number of bytes of the descriptors immediately following the program_info_length field.

stream_type – This is an 8-bit field specifying the type of program element carried within the packets with the PID whose value is specified by the elementary_PID. The values of stream_type are specified in Table 2-29.

NOTE – An ITU-T Rec. H.222.0 | ISO/IEC 13818-1 auxiliary stream is available for data types defined by this Specification, other than audio, video, and DSM CC, such as Program Stream Directory and Program Stream Map.

elementary_PID – This is a 13-bit field specifying the PID of the Transport Stream packets which carry the associated program element.

ES_info_length – This is a 12-bit field, the first two bits of which shall be '00'. The remaining 10 bits specify the number of bytes of the descriptors of the associated program element immediately following the ES_info_length field.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in Annex B after processing the entire Transport Stream program map section.

2.4.4.10 Syntax of the Private section

When private data is sent in Transport Stream packets with a PID value designated as a Program Map Table PID in the Program Association Table the private_section shall be used. The private_section allows data to be transmitted with a minimum of structure while enabling a decoder to parse the stream. The sections may be used in two ways: if the section_syntax_indicator is set to '1', then the whole structure common to all tables shall be used; if the indicator is set to '0', then only the fields 'table_id' through 'private_section_length' shall follow the common structure syntax and semantics and the rest of the private_section may take any form the user determines. Examples of extended use of this syntax are found in Informative Annex C.

Table 2-29 – Stream type assignments

Value	Description
0x00	ITU-T | ISO/IEC Reserved
0x01	ISO/IEC 11172 Video
0x02	ITU-T Rec. H.262 | ISO/IEC 13818-2 Video or ISO/IEC 11172-2 constrained parameter video stream
0x03	ISO/IEC 11172 Audio
0x04	ISO/IEC 13818-3 Audio
0x05	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 private_sections
0x06	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 PES packets containing private data
0x07	ISO/IEC 13522 MHEG
0x08	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Annex A DSM-CC
0x09	ITU-T Rec. H.222.1
0x0A	ISO/IEC 13818-6 type A
0x0B	ISO/IEC 13818-6 type B
0x0C	ISO/IEC 13818-6 type C
0x0D	ISO/IEC 13818-6 type D
0x0E	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 auxiliary
0x0F	ISO/IEC 13818-7 Audio with ADTS transport syntax
0x10	ISO/IEC 14496-2 Visual
0x11	ISO/IEC 14496-3 Audio with the LATM transport syntax as defined in ISO/IEC 14496-3 / AMD 1
0x12	ISO/IEC 14496-1 SL-packetized stream or FlexMux stream carried in PES packets
0x13	ISO/IEC 14496-1 SL-packetized stream or FlexMux stream carried in ISO/IEC14496_sections.
0x14	ISO/IEC 13818-6 Synchronized Download Protocol
0x15-0x7F	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Reserved
0x80-0xFF	User Private

A private table may be made of several private_sections, all with the same table_id (see Table 2-30).

2.4.4.11 Semantic definition of fields in private section

table_id – This 8-bit field, the value of which identifies the Private Table this section belongs to. Only values defined in Table 2-26 as "user private" may be used.

section_syntax_indicator – This is a 1-bit indicator. When set to '1', it indicates that the private section follows the generic section syntax beyond the private_section_length field. When set to '0', it indicates that the private_data_bytes immediately follow the private_section_length field.

private_indicator – This is a 1-bit user definable flag that shall not be specified by ITU-T | ISO/IEC in the future.

private_section_length – A 12-bit field. It specifies the number of remaining bytes in the private section immediately following the private_section_length field up to the end of the private_section. The value in this field shall not exceed 4093 (0xFFD).

Table 2-30 – Private section

Syntax	No. of bits	Mnemonic
private_section() {		
table_id	**8**	**uimsbf**
section_syntax_indicator	**1**	**bslbf**
private_indicator	**1**	**bslbf**
reserved	**2**	**bslbf**
private_section_length	**12**	**uimsbf**
if (section_syntax_indicator == '0') {		
for (i = 0; i < N; i++) {		
private_data_byte	**8**	**bslbf**
}		
}		
else {		
table_id_extension	**16**	**uimsbf**
reserved	**2**	**bslbf**
version_number	**5**	**uimsbf**
current_next_indicator	**1**	**bslbf**
section_number	**8**	**uimsbf**
last_section_number	**8**	**uimsbf**
for (i = 0; i < private_section_length-9; i++) {		
private_data_byte	**8**	**bslbf**
}		
CRC_32	**32**	**rpchof**
}		
}		

private_data_byte – The private_data_byte field is user definable and shall not be specified by ITU-T | ISO/IEC in the future.

table_id_extension – This is a 16-bit field. Its use and value are defined by the user.

version_number – This 5-bit field is the version number of the private_section. The version_number shall be incremented by 1 modulo 32 when a change in the information carried within the private_section occurs. When the current_next_indicator is set to '0', then the version_number shall be that of the next applicable private_section with the same table_id and section_number.

current_next_indicator – A 1-bit field, which when set to '1' indicates that the private_section sent is currently applicable. When the current_next_indicator is set to '1', then the version_number shall be that of the currently applicable private_section. When the bit is set to '0', it indicates that the private_section sent is not yet applicable and shall be the next private_section with the same section_number and table_id to become valid.

section_number – This 8-bit field gives the number of the private_section. The section_number of the first section in a private table shall be 0x00. The section_number shall be incremented by 1 with each additional section in this private table.

last_section_number – This 8-bit field specifies the number of the last section (that is, the section with the highest section_number) of the private table of which this section is a part.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in Annex A after processing the entire private section.

2.4.4.12 Syntax of the Transport Stream section

ITU-T Rec. H.222.0 | ISO/IEC 13818-1 compliant bitstreams may carry the information defined in Table 2-30-1. ITU-T Rec. H.222.0 | ISO/IEC 13818-1 compliant decoders may decode the information defined in this table.

The Transport Stream Description Table is defined to support the carriage of descriptors as found in 2.6 for an entire Transport Stream. The descriptors shall apply to the entire Transport Stream. This table uses a table_id value of 0x03 as specified in Table 2-26 and is carried in Transport Stream packets whose PID value is 0x0002 as specified in Table 2-3.

Table 2-30-1 – The Transport Stream Description Table

Syntax	No. of bits	Mnemonic
TS_description_section() {		
table_id	**8**	**uimsbf**
section_syntax_indicator	**1**	**bslbf**
'0'	**1**	**bslbf**
reserved	**2**	**bslbf**
section_length	**12**	**uimsbf**
reserved	**18**	**bslbf**
version_number	**5**	**uimsbf**
current_next_indicator	**1**	**bslbf**
section_number	**8**	**uimsbf**
last_section_number	**8**	**uimsbf**
for (i = 0; i < N; i++) {		
descriptor()		
}		
CRC_32	**32**	**rpchof**
}		

2.4.4.13 Semantic definition of fields in the Transport Stream section

table_id – This is an 8-bit field, which shall be set to '0x03' as specified in Table 2-26.

section_length – This is a 12-bit field, the first two bits of which shall be '00'. The remaining 10 bits specify the number of bytes of the section, starting immediately following the section_length field, and including the CRC. The value in this field shall not exceed 1021 (0x3FD).

version_number – This 5-bit field is the version number of the whole Transport Stream Description Table. The version number shall be incremented by 1 modulo 32 whenever the definition of the Transport Stream Description Table changes. When the current_next_indicator is set to '1', then the version_number shall be that of the currently applicable Transport Stream Description Table. When the current_next_indicator is set to '0', then the version_number shall be that of the next applicable Transport Stream Description Table.

current_next_indicator – A 1-bit indicator, which, when set to '1', indicates that the Transport Stream Description Table sent is currently applicable. When the bit is set to '0', it indicates that the table sent is not yet applicable and shall be the next table to become valid.

section_number – This 8-bit field gives the number of this section. The section_number of the first section in the Transport Stream Description Table shall be 0x00. It shall be incremented by 1 with each additional section in the Transport Stream Description Table.

last_section_number – This 8-bit field specifies the number of the last section (that is, the section with the highest section_number) of the complete Transport Stream Description Table.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in Annex A after processing the entire Transport Stream Description section.

2.5 Program Stream bitstream requirements

2.5.1 Program Stream coding structure and parameters

The ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Stream coding layer allows one program of one or more elementary streams to be combined into a single stream. Data from each elementary stream are multiplexed together with information that allows synchronized presentation of the elementary streams within the program.

A Program Stream consists of one or more elementary streams from one program multiplexed together. Audio and video elementary streams consist of access units.

Elementary Stream data is carried in PES packets. A PES packet consists of a PES packet header followed by packet data. PES packets are inserted into Program Stream packs.

The PES packet header begins with a 32-bit start-code that also identifies the stream (refer to Table 2-18) to which the packet data belongs. The PES packet header may contain just a Presentation Time Stamp (PTS) or both a presentation timestamp and a Decoding Time Stamp (DTS). The PES packet header also contains other optional fields. The packet data contains a variable number of contiguous bytes from one elementary stream.

In a Program Stream, PES packets are organized in packs. A pack commences with a pack header and is followed by zero or more PES packets. The pack header begins with a 32-bit start-code. The pack header is used to store timing and bitrate information.

The Program Stream begins with a system header that optionally may be repeated. The system header carries a summary of the system parameters defined in the stream.

This Recommendation | International Standard does not specify the coded data which may be used as part of conditional access systems. This Recommendation | International Standard does, however, provide mechanisms for program service providers to transport and identify this data for decoder processing, and to correctly reference data which are here specified.

2.5.2 Program Stream system target decoder

The semantics of the Program Stream and the constraints on these semantics require exact definitions of decoding events and the times at which these events occur. The definitions needed are set out in this Specification using a hypothetical decoder known as the Program Stream system target decoder (P-STD).

The P-STD is a conceptual model used to define these terms precisely and to model the decoding process during the construction of Program Streams. The P-STD is defined only for this purpose. Neither the architecture of the P-STD nor the timing described precludes uninterrupted, synchronized playback of Program Streams from a variety of decoders with different architectures or timing schedules.

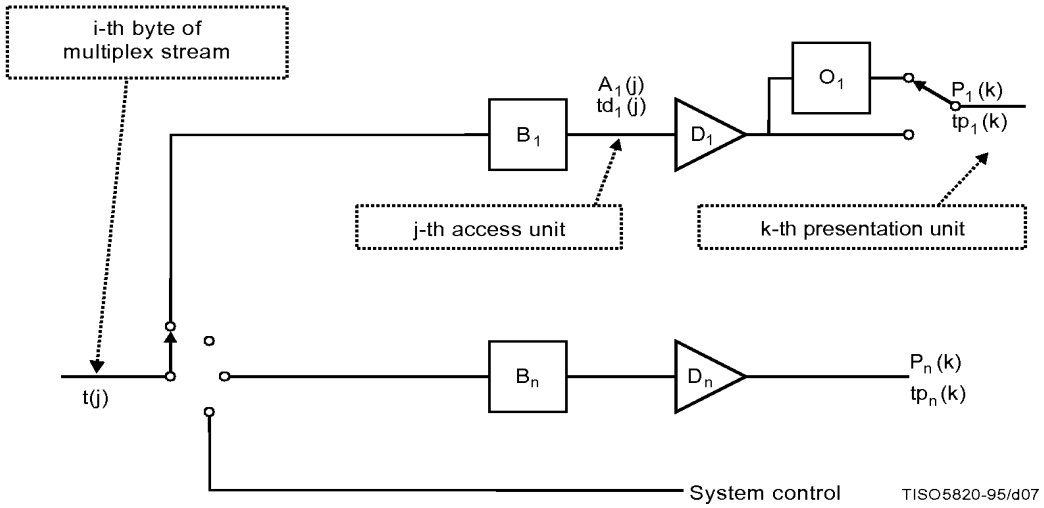

Figure 2-2 – Program Stream system target decoder notation

The following notation is used to describe the Program Stream system target decoder and is partially illustrated in Figure 2-2.

i, i′	are indices to bytes in the Program Stream. The first byte has index 0.
j	is an index to access units in the elementary streams.
k, k′, k″	are indices to presentation units in the elementary streams.
n	is an index to the elementary streams.
t(i)	indicates the time in seconds at which the i-th byte of the Program Stream enters the system target decoder. The value t(0) is an arbitrary constant.
SCR(i)	is the time encoded in the SCR field measured in units of the 27 MHz system clock where i is the byte index of the final byte of the system_clock_reference_base field.
$A_n(j)$	is the j-th access unit in elementary stream n. $A_n(j)$ is indexed in decoding order.
$td_n(j)$	is the decoding time, measured in seconds, in the system target decoder of the j-th access unit in elementary stream n.
$P_n(k)$	is the k-th presentation unit in elementary stream n. $P_n(k)$ is indexed in presentation order.
$tp_n(k)$	is the presentation time, measured in seconds, in the system target decoder of the k-th presentation unit in elementary stream n.

t is time measured in seconds.

$F_n(t)$ is the fullness, measured in bytes, of the system target decoder input buffer for elementary stream n at time t.

B_n the input buffer in the system target decoder for elementary stream n.

BS_n is the size of the system target decoder input buffer, measured in bytes, for elementary stream n.

D_n is the decoder for elementary stream n.

O_n is the reorder buffer for video elementary stream n.

2.5.2.1 System clock frequency

Timing information referenced in P-STD is carried by several data fields defined in this Specification. The fields are defined in 2.5.3.3 and 2.4.3.6. This information is coded as the sampled value of a system clock.

The value of the system clock frequency is measured in Hz and shall meet the following constraints:

– 27 000 000 – 810 <= system_clock_frequency <= 27 000 000 + 810;

– rate of change of system_clock_frequency with time <= 75×10^{-3} Hz/s.

The notation "system_clock_frequency" is used in several places in this Recommendation | International Standard to refer to the frequency of a clock meeting these requirements. For notational convenience, equations in which SCR, PTS, or DTS appear, lead to values of time which are accurate to some integral multiple of (300 ×€2^{33}/system_clock_frequency) seconds. This is due to the encoding of SCR timing information as 33 bits of 1/300 of the system clock frequency plus 9 bits for the remainder, and encoding as 33 bits of the system clock frequency divided by 300 for PTS and DTS.

2.5.2.2 Input to the Program Stream system target decoder

Data from the Program Stream enters the system target decoder. The i-th byte enters at time t(i). The time at which this byte enters the system target decoder can be recovered from the input stream by decoding the input System Clock Reference (SCR) fields and the program_mux_rate field encoded in the pack header. The SCR, as defined in equation 2-18, is coded in two parts: one, in units the period of 1/300 × the system clock frequency, called system_clock_reference_base (see equation 2-19), and one, called system_clock_reference_ext equation (see equation 2-20), in units of the period of the system clock frequency. In the following the values encoded in these fields are denoted by SCR_base(i) and SCR_ext(i). The value encoded in the SCR field indicates time t(i), where i refers to the byte containing the last bit of the system_clock_reference_base field.

Specifically:

$$SCR(i) = SCR\_base(i) \times 300 + SCR\_ext(i) \tag{2-18}$$

where

$$SCR\_base(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 300) \; \% \; 2^{33} \tag{2-19}$$

$$SCR\_ext(i) = ((system\_clock\_frequency \times t(i)) \; DIV \; 1) \; \% \; 300 \tag{2-20}$$

The input arrival time, t(i), as given in equation 2-21, for all other bytes shall be constructed from SCR(i) and the rate at which data arrives, where the arrival rate within each pack is the value represented in the program_mux_rate field in that pack's header.

$$t(i) = \frac{SCR(i')}{system\_clock\_frequency} + \frac{i - i'}{program\_mux\_rate \times 50} \tag{2-21}$$

where

i′ is the index of the byte containing the last bit of the system_clock_reference_base field in the pack header

i is the index of any byte in the pack, including the pack header

SCR(i′)	is the time encoded in the system clock reference base and extension fields in units of the system clock
program_mux_rate	is a field defined in 2.5.3.3.

After delivery of the last byte of a pack there may be a time interval during which no bytes are delivered to the input of the P-STD.

2.5.2.3 Buffering

The PES packet data from elementary stream n is passed to the input buffer for stream n, B_n. Transfer of byte i from the system target decoder input to B_n is instantaneous, so that byte i enters the buffer for stream n, of size BS_n, at time t(i).

Bytes present in the pack header, system headers, Program Stream Maps, Program Stream Directories, or PES packet headers of the Program Stream such as SCR, DTS, PTS, and packet_length fields, are not delivered to any of the buffers, but may be used to control the system.

The input buffer sizes BS_1 through BS_n are given by the P-STD buffer size parameter in the syntax in equation 2-16 and equation 2-17.

At the decoding time, $td_n(j)$, all data for the access unit that has been in the buffer longest, $A_n(j)$, and any stuffing bytes that immediately precede it that are present in the buffer at the time $td_n(j)$, are removed instantaneously at time $td_n(j)$. The decoding time $td_n(j)$ is specified in the DTS or PTS fields. Decoding times $td_n(j + 1)$, $td_n(j + 2)$, ... of access units without encoded DTS or PTS fields which directly follow access unit j may be derived from information in the elementary stream. Refer to Annex C of ITU-T Rec. H.262 | ISO/IEC 13818-2, ISO/IEC 13818-3, ISO/IEC 11172-2 or ISO/IEC 11172-3. Also refer to 2.7.5. As the access unit is removed from the buffer, it is instantaneously decoded to a presentation unit.

The Program Stream shall be constructed and t(i) shall be chosen so that the input buffers of size BS_1 through BS_n neither overflow nor underflow in the program system target decoder. That is:

$$0 \leq F_n(t) \leq BS_n$$

for all t and n

and

$$F_n(t) = 0$$

instantaneously before t = t(0).

$F_n(t)$ is the instantaneous fullness of P-STD buffer B_n.

An exception to this condition is that the P-STD buffer B_n may underflow when the low_delay flag in the video sequence header is set to '1' (refer to 2.4.2.6) or when trick_mode status is true (refer to 2.4.3.8).

For all Program Streams, the delay caused by system target decoder input buffering shall be less than or equal to one second except for still picture video data and ISO/IEC 14496 streams. The input buffering delay is the difference in time between a byte entering the input buffer and when it is decoded.

Specifically: in the case of no still picture video data and no ISO/IEC 14496 stream the delay is constrained by:

$$tdn(j)\text{-}t(i) <= 1\ sec$$

in the case of still picture video data the delay is constrained by:

$$tdn(j)\text{-}t(i) <= 60\ sec$$

in the case of ISO/IEC 14496 streams the delay is constrained by:

$$tdn(j)\text{-}t(i) <= 10\ sec$$

for all bytes contained in access unit j.

For Program Streams, all bytes of each pack shall enter the P-STD before any byte of a subsequent pack.

When the **low_delay** flag in the video sequence extension is set to '1' (refer to 6.2.2.3 of ITU-T Rec. H.262 | ISO/IEC 13818-2) the VBV buffer may underflow. In this case when the P-STD elementary stream buffer B_n is examined at the time specified by $td_n(j)$, the complete data for the access unit may not be present in the buffer B_n. When this case arises, the buffer shall be re-examined at intervals of two field-periods until the data for the complete access unit is present in the buffer. At this time the entire access unit shall be removed from buffer B_n instantaneously.

VBV buffer underflow is allowed to occur continuously without limit. The P-STD decoder shall remove access unit data from buffer B_n at the earliest time consistent with the paragraph above and any DTS or PTS values encoded in the bitstream. The decoder may be unable to re-establish correct decoding and display times as indicated by DTS and PTS until the VBV buffer underflow situation ceases and a PTS or DTS is found in the bitstream.

2.5.2.4 PES streams

It is possible to construct a stream of data as a contiguous stream of PES packets each containing data of the same elementary stream and with the same stream_id. Such a stream is called a PES stream. The PES-STD model for a PES stream is identical to that for the Program Stream, with the exception that the Elementary Stream Clock Reference (ESCR) is used in place of the SCR, and ES_rate in place of program_mux_rate. The demultiplexor sends data to only one elementary stream buffer.

Buffer sizes BS_n in the PES-STD model are defined as follows:

– *For ITU-T Rec. H.262 | ISO/IEC 13818-2 video:*

$$BS_n = VBV_{max}[\text{profile, level}] + BS_{oh}$$

BS_{oh} = (1/750) seconds × R_{max}[profile, level], where VBV_{max}[profile, level] and R_{max}[profile, level] are the maximum VBV size and bit rate per profile, level, and layer as defined in Tables 8-14 and 8-13, respectively, of ITU-T Rec. H.262 | ISO/IEC 13818-2. BS_{oh} is allocated for PES packet header overhead.

– *For ISO/IEC 11172-2 video:*

$$BS_n = VBV_{max} + BS_{oh}$$

BS_{oh} = (1/750) seconds × R_{max}, where R_{max} and vbv_max refer to the maximum bitrate and maximum vbv_buffer_size for a constrained parameter bitstream in ISO/IEC 11172-2 respectively.

– *For ISO/IEC 11172-3 or ISO/IEC 13818-3 audio:*

$$BS_n = 2848 \text{ bytes}$$

2.5.2.5 Decoding and presentation

Decoding and presentation in the Program Stream system target decoder are the same as defined for the Transport Stream system target decoder in 2.4.2.4, and 2.4.2.5 respectively.

2.5.2.6 P-STD extensions for carriage of ISO/IEC 14496 data

For decoding of ISO/IEC 14496 data carried in a Program Stream the P-STD model is extended. For decoding of individual ISO/IEC 14496 elementary streams in the P-STD see clause 2.11.2. Clause 2.11.3 defines P-STD extensions and parameters for decoding of ISO/IEC 14496 scenes and associated streams.

2.5.3 Specification of the Program Stream syntax and semantics

The following syntax describes a stream of bytes.

2.5.3.1 Program Stream

See Table 2-31.

Table 2-31 – Program Stream

Syntax	No. of bits	Mnemonic
MPEG2_program_stream() {		
do {		
pack()		
} while (nextbits() == pack_start_code)		
MPEG_program_end_code	**32**	**bslbf**
}		

2.5.3.2 Semantic definition of fields in Program Stream

MPEG_program_end_code – The MPEG_program_end_code is the bit string '0000 0000 0000 0000 0000 0001 1011 1001' (0x000001B9). It terminates the Program Stream.

2.5.3.3 Pack layer of Program Stream

See Tables 2-32 and 2.33.

Table 2-32 – Program Stream pack

Syntax	No. of bits	Mnemonic
pack() {		
pack_header()		
while (nextbits() == packet_start_code_prefix) {		
PES_packet()		
}		
}		

Table 2-33 – Program Stream pack header

Syntax	No. of bits	Mnemonic
pack_header() {		
pack_start_code	**32**	**bslbf**
'01'	**2**	**bslbf**
system_clock_reference_base [32..30]	**3**	**bslbf**
marker_bit	**1**	**bslbf**
system_clock_reference_base [29..15]	**15**	**bslbf**
marker_bit	**1**	**bslbf**
system_clock_reference_base [14..0]	**15**	**bslbf**
marker_bit	**1**	**bslbf**
system_clock_reference_extension	**9**	**uimsbf**
marker_bit	**1**	**bslbf**
program_mux_rate	**22**	**uimsbf**
marker_bit	**1**	**bslbf**
marker_bit	**1**	**bslbf**
reserved	**5**	**bslbf**
pack_stuffing_length	**3**	**uimsbf**
for (i = 0; i < pack_stuffing_length; i++) {		
stuffing_byte	**8**	**bslbf**
}		
if (nextbits() == system_header_start_code) {		
system_header ()		
}		
}		

2.5.3.4 Semantic definition of fields in program stream pack

pack_start_code – The pack_start_code is the bit string '0000 0000 0000 0000 0000 0001 1011 1010' (0x000001BA). It identifies the beginning of a pack.

system_clock_reference_base; system_clock_reference_extension – The system clock reference (SCR) is a 42-bit field coded in two parts. The first part, system_clock_reference_base, is a 33-bit field whose value is given by SCR_base(i) as given in equation 2-19. The second part, system_clock_reference_extension, is a 9-bit field whose value is given by SCR_ext(i), as given in equation 2-20. The SCR indicates the intended time of arrival of the byte containing the last bit of the system_clock_reference_base at the input of the program target decoder.

The frequency of coding requirements for the SCR field are given in 2.7.1.

marker_bit – A marker_bit is a 1-bit field that has the value '1'.

program_mux_rate – This is a 22-bit integer specifying the rate at which the P-STD receives the Program Stream during the pack in which it is included. The value of program_mux_rate is measured in units of 50 bytes/second. The value 0 is forbidden. The value represented in program_mux_rate is used to define the time of arrival of bytes at the input to the P-STD in 2.5.2. The value encoded in the program_mux_rate field may vary from pack to pack in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program multiplexed stream.

pack_stuffing_length – A 3-bit integer specifying the number of stuffing bytes which follow this field.

stuffing_byte – This is a fixed 8-bit value equal to '1111 1111' that can be inserted by the encoder, for example to meet the requirements of the channel. It is discarded by the decoder. In each pack header no more than 7 stuffing bytes shall be present.

2.5.3.5 System header

See Table 2-34.

Table 2-34 – Program Stream system header

Syntax	No. of bits	Mnemonic
system_header () {		
system_header_start_code	**32**	**bslbf**
header_length	**16**	**uimsbf**
marker_bit	**1**	**bslbf**
rate_bound	**22**	**uimsbf**
marker_bit	**1**	**bslbf**
audio_bound	**6**	**uimsbf**
fixed_flag	**1**	**bslbf**
CSPS_flag	**1**	**bslbf**
system_audio_lock_flag	**1**	**bslbf**
system_video_lock_flag	**1**	**bslbf**
marker_bit	**1**	**bslbf**
video_bound	**5**	**uimsbf**
packet_rate_restriction_flag	**1**	**bslbf**
reserved_bits	**7**	**bslbf**
while (nextbits () == '1') {		
stream_id	**8**	**uimsbf**
'11'	**2**	**bslbf**
P-STD_buffer_bound_scale	**1**	**bslbf**
P-STD_buffer_size_bound	**13**	**uimsbf**
}		
}		

2.5.3.6 Semantic definition of fields in system header

system_header_start_code – The system_header_start_code is the bit string '0000 0000 0000 0000 0000 0001 1011 1011' (0x000001BB). It identifies the beginning of a system header.

header_length – This 16-bit field indicates the length in bytes of the system header following the header_length field. Future extensions of this Specification may extend the system header.

rate_bound – A 22-bit field. The rate_bound is an integer value greater than or equal to the maximum value of the program_mux_rate field coded in any pack of the Program Stream. It may be used by a decoder to assess whether it is capable of decoding the entire stream.

audio_bound – A 6-bit field. The audio_bound is an integer in the inclusive range from 0 to 32 and is set to a value greater than or equal to the maximum number of ISO/IEC 13818-3 and ISO/IEC 11172-3 audio streams in the Program Stream for which the decoding processes are simultaneously active. For the purpose of this subclause, the decoding process of an ISO/IEC 13818-3 or ISO/IEC 11172-3 audio stream is active if the STD buffer is not empty or if a Presentation Unit is being presented in the P-STD model.

fixed_flag – The fixed_flag is a 1-bit flag. When set to '1' fixed bitrate operation is indicated. When set to '0' variable bitrate operation is indicated. During fixed bitrate operation, the value encoded in all system_clock_reference fields in the multiplexed ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream shall adhere to the following linear equation:

$$SCR\_base(i) = ((c1 \times i + c2)\ DIV\ 300)\ \%\ 2^{33} \tag{2-22}$$

$$SCR\_ext(i) = ((c1 \times i + c2)\ DIV\ 300)\ \%\ 300 \tag{2-23}$$

where

c1 is a real-valued constant valid for all i

c2 is a real-valued constant valid for all i

i is the index in the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 multiplexed stream of the byte containing the final bit of any system_clock_reference field in the stream

CSPS_flag – The CSPS_flag is a 1-bit field. If its value is set to '1' the Program Stream meets the constraints defined in 2.7.9.

system_audio_lock_flag – The system_audio_lock_flag is a 1-bit field indicating that there is a specified, constant rational relationship between the audio sampling rate and the system_clock_frequency in the system target decoder. The system_clock_frequency is defined in 2.5.2.1 and the audio sampling rate is specified in ISO/IEC 13818-3. The system_audio_lock_flag may only be set to '1' if, for all presentation units in all audio elementary streams in the Program Stream, the ratio of system_clock_frequency to the actual audio sampling rate, SCASR, is constant and equal to the value indicated in the following table at the nominal sampling rate indicated in the audio stream.

$$SCASR = \frac{system\_clock\_frequency}{audio\_sample\_rate\_in\_the\_P\text{–}STD} \tag{2-24}$$

The notation $\frac{X}{Y}$ denotes real division.

Nominal audio sampling frequency (kHz)	16	32	22,05	44,1	24	48
SCASR	27 000 000 / 16 000	27 000 000 / 32 000	27 000 000 / 22 050	27 000 000 / 44 100	27 000 000 / 24 000	27 000 000 / 48 000

system_video_lock_flag – The system_video_lock_flag is a 1-bit field indicating that there is a specified, constant rational relationship between the video frame rate and the system clock frequency in the system target decoder. Subclause 2.5.2.1 defines system_clock_frequency and the video frame rate is specified in ITU-T Rec. H.262 | ISO/IEC 13818-2. The system_video_lock_flag may only be set to '1' if, for all presentation units in all video elementary streams in the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program, the ratio of system_clock_frequency to the actual video frame rate, SCFR, is constant and equal to the value indicated in the following table at the nominal frame rate indicated in the video stream.

$$SCFR = \frac{system\_clock\_frequency}{frame\_rate\_in\_the\_P\text{–}STD} \tag{2-25}$$

Nominal frame rate (Hz)	23,976	24	25	29,97	30	50	59,94	60
SCFR	1 126 125	1 125 000	1 080 000	900 900	900 000	540 000	450 450	450 000

The values of the ratio SCFR are exact. The actual frame rate differs slightly from the nominal rate in cases where the nominal rate is 23,976, 29,97, or 59,94 frames per second.

video_bound – The video_bound is a 5-bit integer in the inclusive range from 0 to 16 and is set to a value greater than or equal to the maximum number of ITU-T Rec. H.262 | ISO/IEC 13818-2 and ISO/IEC 11172-2 streams in the Program Stream of which the decoding processes are simultaneously active. For the purpose of this subclause, the decoding process of an ITU-T Rec. H.262 | ISO/IEC 13818-2 and ISO/IEC 11172-2 video stream is active if the P-STD buffer is not empty, or if a Presentation Unit is being presented in the P-STD model, or if the reorder buffer is not empty.

packet_rate_restriction_flag – The packet_rate_restriction_flag is a 1-bit flag. If the CSPS flag is set to '1', the packet_rate_restriction_flag indicates which constraint is applicable to the packet rate, as specified in 2.7.9. If the CSPS flag is set to value of '0', then the meaning of the packet_rate_restriction_flag is undefined.

reserved_bits – This 7-bit field is reserved for future use by ISO/IEC. Until otherwise specified by ITU-T | ISO/IEC it shall have the value '111 1111'.

stream_id – The stream_id is an 8-bit field that indicates the coding and elementary stream number of the stream to which the following P-STD_buffer_bound_scale and P-STD_buffer_size_bound fields refer.

If stream_id equals '1011 1000' the P-STD_buffer_bound_scale and P-STD_buffer_size_bound fields following the stream_id refer to all audio streams in the Program Stream.

If stream_id equals '1011 1001' the P-STD_buffer_bound_scale and P-STD_buffer_size_bound fields following the stream_id refer to all video streams in the Program Stream.

If the stream_id takes on any other value it shall be a byte value greater than or equal to '1011 1100' and shall be interpreted as referring to the stream coding and elementary stream number according to Table 2-18.

Each elementary stream present in the Program Stream shall have its P-STD_buffer_bound_scale and P-STD_buffer_size_bound specified exactly once by this mechanism in each system header.

P-STD_buffer_bound_scale – The P-STD_buffer_bound_scale is a 1-bit field that indicates the scaling factor used to interpret the subsequent P-STD_buffer_size_bound field. If the preceding stream_id indicates an audio stream, P-STD_buffer_bound_scale shall have the value '0'. If the preceding stream_id indicates a video stream, P-STD_buffer_bound_scale shall have the value '1'. For all other stream types, the value of the P-STD_buffer_bound_scale may be either '1' or '0'.

P-STD_buffer_size_bound – The P-STD_buffer_size_bound is a 13-bit unsigned integer defining a value greater than or equal to the maximum P-STD input buffer size, BS_n, over all packets for stream n in the Program Stream. If P-STD_buffer_bound_scale has the value '0', then P-STD_buffer_size_bound measures the buffer size bound in units of 128 bytes. If P-STD_buffer_bound_scale has the value '1', then P-STD_buffer_size_bound measures the buffer size bound in units of 1024 bytes. Thus:

$$\text{if (P-STD\_buffer\_bound\_scale} == 0)$$

$$BS_n \leq P - STD\_buffer\_size\_bound \times 128$$

else

$$BS_n \leq P - STD\_buffer\_size\_bound \times 1024$$

2.5.3.7 Packet layer of Program Stream

The packet layer of the Program Stream is defined by the PES packet layer in 2.4.3.6.

2.5.4 Program Stream map

The Program Stream Map (PSM) provides a description of the elementary streams in the Program Stream and their relationship to one another. When carried in a Transport Stream this structure shall not be modified. The PSM is present as a PES packet when the stream_id value is 0xBC (refer to Table 2-18).

NOTE – This syntax differs from the PES packet syntax described in 2.4.3.6.

Definition for the descriptor() fields may be found in 2.6.

2.5.4.1 Syntax of Program Stream map

See Table 2.35.

Table 2-35 – Program Stream map

Syntax	No. of bits	Mnemonic
program_stream_map() {		
packet_start_code_prefix	**24**	**bslbf**
map_stream_id	**8**	**uimsbf**
program_stream_map_length	**16**	**uimsbf**
current_next_indicator	**1**	**bslbf**
reserved	**2**	**bslbf**
program_stream_map_version	**5**	**uimsbf**
reserved	**7**	**bslbf**
marker_bit	**1**	**bslbf**
program_stream_info_length	**16**	**uimsbf**
for (i = 0; i < N; i++) {		
descriptor()		
}		
elementary_stream_map_length	**16**	**uimsbf**
for (i = 0; i < N1; i++) {		
stream_type	**8**	**uimsbf**
elementary_stream_id	**8**	**uimsbf**
elementary_stream_info_length	**16**	**uimsbf**
for (i = 0; i < N2; i++) {		
descriptor()		
}		
}		
CRC_32	**32**	**rpchof**
}		

2.5.4.2 Semantic definition of fields in Program Stream map

packet_start_code_prefix – The packet_start_code_prefix is a 24-bit code. Together with the map_stream_id that follows it constitutes a packet start code that identifies the beginning of a packet. The packet_start_code_prefix is the bit string '0000 0000 0000 0000 0000 0001' (0x000001 in hexadecimal).

map_stream_id – This is an 8-bit field whose value shall be 0xBC.

program_stream_map_length – The program_stream_map_length is a 16-bit field indicating the total number of bytes in the program_stream_map immediately following this field. The maximum value of this field is 1018 (0x3FA).

current_next_indicator – This is a 1-bit field, when set to '1' indicates that the Program Stream Map sent is currently applicable. When the bit is set to '0', it indicates that the Program Stream Map sent is not yet applicable and shall be the next table to become valid.

program_stream_map_version – This 5-bit field is the version number of the whole Program Stream Map. The version number shall be incremented by 1 modulo 32 whenever the definition of the Program Stream Map changes. When the current_next_indicator is set to '1', then the program_stream_map_version shall be that of the currently applicable Program Stream Map. When the current_next_indicator is set to '0', then the program_stream_map_version shall be that of the next applicable Program Stream Map.

program_stream_info_length – The program_stream_info_length is a 16-bit field indicating the total length of the descriptors immediately following this field.

marker_bit – A marker_bit is a 1-bit field that has the value '1'.

elementary_stream_map_length – This is a 16-bit field specifying the total length, in bytes, of all elementary stream information in this program stream map. It includes the stream_type, elementary_stream_id, and elementary_stream_info_length fields.

stream_type – This 8-bit field specifies the type of the stream according to Table 2-29. The stream_type field shall only identify elementary streams contained in PES packets. A value of 0x05 is prohibited.

elementary_stream_id – The elementary_stream_id is an 8-bit field indicating the value of the stream_id field in the PES packet headers of PES packets in which this elementary stream is stored.

elementary_stream_info_length – The elementary_stream_info_length is a 16-bit field indicating the length in bytes of the descriptors immediately following this field.

CRC_32 – This is a 32-bit field that contains the CRC value that gives a zero output of the registers in the decoder defined in Annex A after processing the entire program stream map.

2.5.5 Program Stream directory

The directory for an entire stream is made up of all the directory data carried by Program Stream Directory packets identified with the directory_stream_id. The syntax for program_stream_directory packets is defined in Table 2-36.

NOTE 1 – This syntax differs from the PES packet syntax described in 2.4.3.6.

Directory entries may be required to reference I-pictures in a video stream as defined in ITU-T Rec. H.262 | ISO/IEC 13818-2 and ISO/IEC 11172-2. If an I-picture that is referenced in a directory entry is preceded by a sequence header with no intervening picture headers, the directory entry shall reference the first byte of the sequence header. If an I-picture that is referenced in a directory entry is preceded by a group of pictures header with no intervening picture headers and no immediately preceding sequence header, the directory entry shall reference the first byte of the group of pictures header. Any other picture that a directory entry references shall be referenced by the first byte of the picture header.

NOTE 2 – It is recommended that I-pictures immediately following a sequence header should be referenced in directory structures so that the directory contains an entry at every point where the decoder may be reset completely.

Directory references to audio streams as defined in ISO/IEC 13818-3 and ISO/IEC 11172-3 shall be the syncword of the audio frame.

NOTE 3 – It is recommended that the distance between referenced access units not exceed half a second.

Access units shall be referenced in a program_stream_directory packet in the same order that they appear in the bitstream.

2.5.5.1 Syntax of Program Stream directory packet

See Table 2-36.

2.5.5.2 Semantic definition of fields in Program Stream directory

packet_start_code_prefix – The packet_start_code_prefix is a 24-bit code. Together with the stream_id that follows, it constitutes a packet start code that identifies the beginning of a packet. The packet_start_code_prefix is the bit string '0000 0000 0000 0000 0000 0001' (0x000001 in hexadecimal).

directory_stream_id – This 8-bit field shall have a value '1111 1111' (0xFF).

PES_packet_length – The PES_packet_length is a 16-bit field indicating the total number of bytes in the program_stream_directory immediately following this field (refer to Table 2-18).

number_of_access_units – This 15-bit field is the number of access_units that are referenced in this Directory PES packet.

prev_directory_offset – This 45-bit unsigned integer gives the byte address offset of the first byte of the packet start code of the previous Program Stream Directory packet. This address offset is relative to the first byte of the start code of the packet which contains this previous_directory_offset field. The value '0' indicates that there is no previous Program Stream Directory packet.

next_directory_offset – This 45-bit unsigned integer gives the byte address offset of the first byte of the packet start code of the next Program Stream Directory packet. This address offset is relative to the first byte of the start code of the packet which contains this next_directory_offset field. The value '0' indicates that there is no next Program Stream Directory packet.

packet_stream_id – This 8-bit field is the stream_id of the elementary stream that contains the access unit referenced by this directory entry.

PES_header_position_offset_sign – This 1-bit field is the arithmetic sign for the PES_header_position_offset described immediately following. A value of '0' indicates that the PES_header_position_offset is a positive offset. A value of '1' indicates that the PES_header_position_offset is a negative offset.

PES_header_position_offset – This 44-bit unsigned integer gives the byte offset address of the first byte of the PES packet containing the access unit referenced. The offset address is relative to the first byte of the start-code of the packet containing this PES_header_position_offset field. The value '0' indicates that no access unit is referenced.

reference_offset – This 16-bit field is an unsigned integer indicating the position of the first byte of the referenced access unit, measured in bytes relative to the first byte of the PES packet containing the first byte of the referenced access unit.

Table 2-36 – Program Stream directory packet

Syntax	No. of bits	Mnemonic
directory_PES_packet(){		
packet_start_code_prefix	**24**	**bslbf**
directory_stream_id	**8**	**uimsbf**

marker_bit	**1**	**bslbf**
prev_directory_offset[14..0]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
next_directory_offset[44..30]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
next_directory_offset[29..15]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
next_directory_offset[14..0]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
for (i = 0; i < number_of_access_units; i++) {		
packet_stream_id	**8**	**uimsbf**
PES_header_position_offset_sign	**1**	**tcimsbf**
PES_header_position_offset[43..30]	**14**	**uimsbf**
marker_bit	**1**	**bslbf**
PES_header_position_offset[29..15]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
PES_header_position_offset[14..0]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
reference_offset	**16**	**uimsbf**
marker_bit	**1**	**bslbf**
reserved	**3**	**bslbf**
PTS[32..30]	**3**	**uimsbf**
marker_bit	**1**	**bslbf**
PTS[29..15]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
PTS[14..0]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
bytes_to_read[22..8]	**15**	**uimsbf**
marker_bit	**1**	**bslbf**
bytes_to_read[7..0]	**8**	**uimsbf**
marker_bit	**1**	**bslbf**
intra_coded_indicator	**1**	**bslbf**
coding_parameters_indicator	**2**	**bslbf**
reserved	**4**	**bslbf**
}		
}		

PTS (presentation_time_stamp) – This 33-bit field is the PTS of the access unit that is referenced. The semantics of the coding of the PTS field are as described in 2.4.3.6.

bytes_to_read – This 23-bit unsigned integer is the number of bytes in the Program Stream after the byte indicated by reference_offset that are needed to decode the access unit completely. This value includes any bytes multiplexed at the systems layer including those containing information from other streams.

intra_coded_indicator – This is a 1-bit flag. When set to '1' it indicates that the referenced access unit is not predictively coded. This is independent of other coding parameters that might be needed to decode the access unit. For example, this field shall be coded as '1' for video Intra frames, whereas for 'P' and 'B' frames this bit shall be coded as '0'. For all PES packets containing data which is not from an ITU-T Rec. H.262 | ISO/IEC 13818-2 video stream, this field is undefined (see Table 2-37).

Table 2-37 – Intra_coded indicator

Value	Meaning
0	Not Intra
1	Intra

coding_parameters_indicator – This 2-bit field is used to indicate the location of coding parameters that are needed to decode the access units referenced. For example, this field can be used to determine the location of quantization matrices for video frames.

Table 2-38 – Coding_parameters indicator

Value	Meaning
00	All coding parameters are set to their default values
01	All coding parameters are set in this access unit, at least one of them is not set to a default
10	Some coding parameters are set in this access unit
11	No coding parameters are coded in this access unit

2.6 Program and program element descriptors

Program and program element descriptors are structures which may be used to extend the definitions of programs and program elements. All descriptors have a format which begins with an 8-bit tag value. The tag value is followed by an 8-bit descriptor length and data fields.

2.6.1 Semantic definition of fields in program and program element descriptors

The following semantics apply to the descriptors defined in 2.6.2 through 2.6.34.

descriptor_tag – The descriptor_tag is an 8-bit field which identifies each descriptor.

Table 2-39 provides the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 defined, ITU-T Rec. H.222.0 | ISO/IEC 13818-1 reserved, and user available descriptor tag values. An 'X' in the TS or PS columns indicates the applicability of the descriptor to either the Transport Stream or Program Stream respectively. Note that the meaning of fields in a descriptor may depend on which stream it is used in. Each case is specified in the descriptor semantics below.

descriptor_length – The descriptor_length is an 8-bit field specifying the number of bytes of the descriptor immediately following descriptor_length field.

2.6.2 Video stream descriptor

The video stream descriptor provides basic information which identifies the coding parameters of a video elementary stream as described in ITU-T Rec. H.262 | ISO/IEC 13818-2 or ISO/IEC 11172-2 (see Table 2-40).

Table 2-39 – Program and program element descriptors

descriptor_tag	TS	PS	Identification
0	n/a	n/a	Reserved
1	n/a	n/a	Reserved
2	X	X	video_stream_descriptor
3	X	X	audio_stream_descriptor
4	X	X	hierarchy_descriptor
5	X	X	registration_descriptor
6	X	X	data_stream_alignment_descriptor
7	X	X	target_background_grid_descriptor
8	X	X	Video_window_descriptor
9	X	X	CA_descriptor
10	X	X	ISO_639_language_descriptor

29	X	X	IOD_descriptor
30	X		SL_descriptor
31	X	X	FMC_descriptor
32	X	X	External_ES_ID_descriptor
33	X	X	MuxCode_descriptor
34	X	X	FmxBufferSize_descriptor
35	X		MultiplexBuffer_descriptor
36-63	n/a	n/a	ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Reserved
64-255	n/a	n/a	User Private

Table 2-40 – Video stream descriptor

Syntax	No. of bits	Mnemonic
video_stream_descriptor(){		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
multiple_frame_rate_flag	**1**	**bslbf**
frame_rate_code	**4**	**uimsbf**
MPEG_1_only_flag	**1**	**bslbf**
constrained_parameter_flag	**1**	**bslbf**
still_picture_flag	**1**	**bslbf**
if (MPEG_1_only_flag == '0'){		
profile_and_level_indication	**8**	**uimsbf**
chroma_format	**2**	**uimsbf**
frame_rate_extension_flag	**1**	**bslbf**
reserved	**5**	**bslbf**
}		
}		

2.6.3 Semantic definitions of fields in video stream descriptor

multiple_frame_rate_flag – This 1-bit field when set to '1' indicates that multiple frame rates may be present in the video stream. When set to a value of '0' only a single frame rate is present.

frame_rate_code – This is a 4-bit field as defined in 6.3.3 of ITU-T Rec. H.262 | ISO/IEC 13818-2, except that when the multiple_frame_rate_flag is set to a value of '1' the indication of a particular frame rate also permits certain other frame rates to be present in the video stream, as specified in Table 2-41:

Table 2-41 – Frame rate code

Coded as	Also includes
23,976	
24,0	23,976
25,0	
29,97	23,976
30,0	23,976 24,0 29,97
50,0	25,0
59,94	23,976 29,97
60,0	23,976 24,0 29,97 30,0 59,94

MPEG_1_only_flag – This is a 1-bit field which when set to '1' indicates that the video stream contains only ISO/IEC 11172-2 data. If set to '0' the video stream may contain both ITU-T H.262 | ISO/IEC 13818-2 video data and constrained parameter ISO/IEC 11172-2 video data.

constrained_parameter_flag – This is a 1-bit field which when set to '1' indicates that the video stream shall not contain unconstrained ISO/IEC 11172-2 video data. If this field is set to '0' the video stream may contain both constrained parameters and unconstrained ISO/IEC 11172-2 video streams. If the MPEG_1_only_flag is set to '0', the constrained_parameter_flag shall be set to '1'.

still_picture_flag – This is a 1-bit field, which when set to '1' indicates that the video stream contains only still pictures. If the bit is set to '0' then the video stream may contain either moving or still picture data.

profile_and_level_indication – This bit field is the same manner as the profile_and_level_indication fields in the ITU-T Rec. H.262 | ISO/IEC 13818-2 video stream. The value of this field indicates a profile and level that is equal to or higher than any profile and level in any sequence in the associated video stream. For the purposes of this subclause, an ISO/IEC 11172-2 constrained parameter stream is considered to a be a Main Profile at Low Level stream (MP @ LL).

chroma_format – This 2-bit field is coded in the same manner as the chroma_format fields in the ITU-T Rec. H.262 | ISO/IEC 13818-2 video stream. The value of this field shall be at least equal to or higher than the value of the chroma_format field in any video sequence of the associated video stream. For the purposes of this subclause, an ISO/IEC 11172-2 video stream is considered to have chroma_format field with the value '01', indicating 4:2:0.

frame_rate_extension_flag – This is a 1-bit flag which when set to '1' indicates that either or both the frame_rate_extension_n and the frame_rate_extension_d fields are non-zero in any video sequences of the ITU-T Rec. H.262 | ISO/IEC 13818-2 video stream. For the purposes of this subclause, an ISO/IEC 11172-2 video stream is constrained to have both fields set to zero.

2.6.4 Audio stream descriptor

The audio stream descriptor provides basic information which identifies the coding version of an audio elementary stream as described in ISO/IEC 13818-3 or ISO/IEC 11172-3 (see Table 2-42).

Table 2-42 – Audio stream descriptor

Syntax	No. of bits	Mnemonic
audio_stream_descriptor(){		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
free_format_flag	**1**	**bslbf**
ID	**1**	**bslbf**
layer	**2**	**bslbf**
variable_rate_audio_indicator	**1**	**bslbf**
reserved	**3**	**bslbf**
}		

2.6.5 Semantic definition of fields in audio stream descriptor

free_format_flag – This 1-bit field when set to '1' indicates that the audio stream may contain one or more audio frames with the bitrate_index set to '0000'. If set to '0', then the bitrate_index is not '0000' (refer to 2.4.2.3 of ISO/IEC 13818-3) in any audio frame of the audio stream.

ID – This 1-bit field when set to '1' indicates that the ID field is set to '1' in each audio frame in the audio stream (refer to 2.4.2.3 of ISO/IEC 13818-3).

layer – This 2-bit field is coded in the same manner as the layer field in the ISO/IEC 13818-3 or ISO/IEC 11172-3 audio streams (refer to 2.4.2.3 of ISO/IEC 13818-3). The layer indicated in this field shall be equal to or higher than the highest layer specified in any audio frame of the audio stream.

variable_rate_audio_indicator – This 1-bit flag, when set to '0' indicates that the encoded value of the bit rate field shall not change in consecutive audio frames which are intended to be presented without discontinuity.

2.6.6 Hierarchy descriptor

The hierarchy descriptor provides information to identify the program elements containing components of hierarchically-coded video and audio, and private streams which are multiplexed in multiple streams as described in this Recommendation | International Standard, in ITU-T Rec. H.262 | ISO/IEC 13818-2 and in ISO/IEC 13818-3. (See Table 2-43.)

2.6.7 Semantic definition of fields in hierarchy descriptor

hierarchy_type – The hierarchical relation between the associated hierarchy layer and its hierarchy embedded layer is defined in Table 2-44.

hierarchy_layer_index – The hierarchy_layer_index is a 6-bit field that defines a unique index of the associated program element in a table of coding layer hierarchies. Indices shall be unique within a single program definition.

hierarchy_embedded_layer_index – The hierarchy_embedded_layer_index is a 6-bit field that defines the hierarchy table index of the program element that needs to be accessed before decoding of the elementary stream associated with this hierarchy_descriptor. This field is undefined if the hierarchy_type value is 15 (base layer).

hierarchy_channel – The hierarchy_channel is a 6-bit field that indicates the intended channel number for the associated program element in an ordered set of transmission channels. The most robust transmission channel is defined by the lowest value of this field with respect to the overall transmission hierarchy definition.

NOTE – A given hierarchy_channel may at the same time be assigned to several program elements.

Table 2-43 – Hierarchy descriptor

Syntax	No. of bits	Mnemonic
hierarchy_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
reserved	**4**	**bslbf**
hierarchy_type	**4**	**uimsbf**
reserved	**2**	**bslbf**
hierarchy_layer_index	**6**	**uimsbf**

7	ITU-T Rec. H.262 | ISO/IEC 13818-2 Multi-view Profile
8-14	Reserved
15	Base layer

2.6.8 Registration descriptor

The registration_descriptor provides a method to uniquely and unambiguously identify formats of private data (see Table 2-45).

Table 2-45 – Registration descriptor

Syntax	No. of bits	Identifier
registration_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
format_identifier	**32**	**uimsbf**
for (i = 0; i < N; i++){		
additional_identification_info	**8**	**bslbf**
}		
}		

2.6.9 Semantic definition of fields in registration descriptor

format_identifier – The format_identifier is a 32-bit value obtained from a Registration Authority as designated by ISO/IEC JTC 1/SC 29.

additional_identification_info – The meaning of additional_identification_info bytes, if any, are defined by the assignee of that format_identifier, and once defined they shall not change.

2.6.10 Data stream alignment descriptor

The data stream alignment descriptor describes which type of alignment is present in the associated elementary stream. If the data_alignment_indicator in the PES packet header is set to '1' and the descriptor is present, alignment – as specified in this descriptor – is required (see Table 2-46).

Table 2-46 – Data stream alignment descriptor

Syntax	No. of bits	Mnemonic
data_stream_alignment_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
alignment_type	**8**	**uimsbf**
}		

2.6.11 Semantics of fields in data stream alignment descriptor

alignment_type – Table 2-47 describes the video alignment type when the data_alignment_indicator in the PES packet header has a value of '1'. In each case of alignment_type value the first PES_packet_data_byte following the PES header shall be the first byte of a start code of the type indicated in Table 2-47. At the beginning of a video sequence, the alignment shall occur at the start code of the first sequence header.

NOTE – Specifying alignment type '01' from Table 2-47 does not preclude the alignment from beginning at a GOP or SEQ header.

The definition of access unit for video data is given in 2.1.1.

Table 2-47 – Video stream alignment values

Alignment type	Description
00	Reserved
01	Slice, or video access unit
02	Video access unit
03	GOP, or SEQ
04	SEQ
05-FF	Reserved

Table 2-48 describes the audio alignment type when the data_alignment_indicator in the PES packet header has a value of '1'. In this case the first PES_packet_data_byte following the PES header is the first byte of an audio sync word.

Table 2-48 – Audio stream alignment values

Alignment type	Description
00	Reserved
01	Sync word
02-FF	Reserved

2.6.12 Target background grid descriptor

It is possible to have one or more video streams which, when decoded, are not intended to occupy the full display area (e.g. a monitor). The combination of target_background_grid_descriptor and video_window_descriptors allows the display of these video windows in their desired locations. The target_background_grid_descriptor is used to describe a grid of unit pixels projected on to the display area. The video_window_descriptor is then used to describe, for the associated stream, the location on the grid at which the top left pixel of the display window or display rectangle of the video presentation unit should be displayed. This is represented in Figure 2-3.

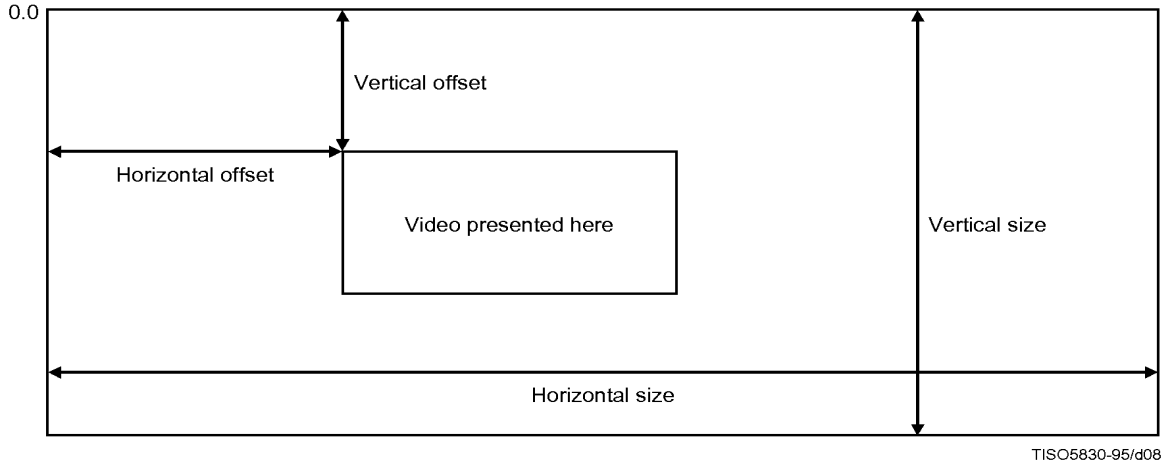

Figure 2-3 – Target background grid descriptor display area

2.6.13 Semantics of fields in target background grid descriptor

horizontal_size – The horizontal size of the target background grid in pixels.

vertical_size – The vertical size of the target background grid in pixels.

aspect_ratio_information – Specifies the sample aspect ratio or display aspect ratio of the target background grid. Aspect_ratio_information is defined in ITU-T Rec. H.262 | ISO/IEC 13818-2 (see Table 2-49).

Table 2-49 – Target background grid descriptor

Syntax	No. of bits	Mnemonic
target_background_grid_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
horizontal_size	**14**	**uimsbf**
vertical_size	**14**	**uimsbf**
aspect_ratio_information	**4**	**uimsbf**
}		

2.6.14 Video window descriptor

The video window descriptor is used to describe the window characteristics of the associated video elementary stream. Its values reference the target background grid descriptor for the same stream. Also see target_background_grid_descriptor in 2.6.12 (see Table 2-50).

Table 2-50 – Video window descriptor

Syntax	No. of bits	Mnemonic
video_window_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
horizontal_offset	**14**	**uimsbf**
vertical_offset	**14**	**uimsbf**
window_priority	**4**	**uimsbf**
}		

2.6.15 Semantic definition of fields in video window descriptor

horizontal_offset – The value indicates the horizontal position of the top left pixel of the current video display window or display rectangle if indicated in the picture display extension on the target background grid for display as defined in the target_background_grid_descriptor. The top left pixel of the video window shall be one of the pixels of the target background grid (refer to Figure 2-3).

vertical_offset – The value indicates the vertical position of the top left pixel of the current video display window or display rectangle if indicated in the picture display extension on the target background grid for display as defined in the target_background_grid_descriptor. The top left pixel of the video window shall be one of the pixels of the target background grid (refer to Figure 2-3).

window_priority – The value indicates how windows overlap. A value of 0 being lowest priority and a value of 15 is the highest priority, i.e. windows with priority 15 are always visible.

2.6.16 Conditional access descriptor

The conditional access descriptor is used to specify both system-wide conditional access management information such as EMMs and elementary stream-specific information such as ECMs. It may be used in both the TS_program_map_section (refer to 2.4.4.8) and the program_stream_map (refer to 2.5.3). If any elementary stream is scrambled, a CA descriptor shall be present for the program containing that elementary stream. If any system-wide conditional access management information exists within a Transport Stream, a CA descriptor shall be present in the conditional access table.

When the CA descriptor is found in the TS_program_map_section (table_id = 0x02), the CA_PID points to packets containing program related access control information, such as ECMs. Its presence as program information indicates applicability to the entire program. In the same case, its presence as extended ES information indicates applicability to the associated program element. Provision is also made for private data.

When the CA descriptor is found in the CA_section (table_id = 0x01), the CA_PID points to packets containing system-wide and/or access control management information, such as EMMs.

The contents of the Transport Stream packets containing conditional access information are privately defined (see Table 2-51).

Table 2-51 – Conditional access descriptor

Syntax	No. of bits	Mnemonic
CA_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
CA_system_ID	**16**	**uimsbf**
reserved	**3**	**bslbf**
CA_PID	**13**	**uimsbf**
for (i = 0; i < N; i++) {		
private_data_byte	**8**	**uimsbf**
}		
}		

2.6.17 Semantic definition of fields in conditional access descriptor

CA_system_ID – This is a 16-bit field indicating the type of CA system applicable for either the associated ECM and/or EMM streams. The coding of this is privately defined and is not specified by ITU-T | ISO/IEC.

CA_PID – This is a 13-bit field indicating the PID of the Transport Stream packets which shall contain either ECM or EMM information for the CA systems as specified with the associated CA_system_ID. The contents (ECM or EMM) of the packets indicated by the CA_PID is determined from the context in which the CA_PID is found, i.e. a TS_program_map_section or the CA table in the Transport Stream, or the stream_id field in the Program Stream.

2.6.18 ISO 639 language descriptor

The language descriptor is used to specify the language of the associated program element (see Table 2-52).

Table 2-52 – ISO 639 language descriptor

Syntax	No. of bits	Mnemonic
ISO_639_language_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
for (i = 0; i < N; i++) {		
ISO_639_language_code	**24**	**bslbf**
audio_type	**8**	**bslbf**
}		
}		

2.6.19 Semantic definition of fields in ISO 639 language descriptor

ISO_639_language_code – Identifies the language or languages used by the associated program element. The ISO_639_language_code contains a 3-character code as specified by ISO 639, Part 2. Each character is coded into 8 bits according to ISO 8859-1 and inserted in order into this 24-bit field. In the case of multilingual audio streams the sequence of ISO_639_language_code fields shall reflect the content of the audio stream.

audio_type – The audio_type is an 8-bit field which specifies the type of stream defined in Table 2-53.

Table 2-53 – Audio type values

Value	Description
0x00	Undefined
0x01	Clean effects
0x02	Hearing impaired
0x03	Visual impaired commentary
0x04-0xFF	Reserved

clean effects – This field indicates that the referenced program element has no language.

hearing impaired – This field indicates that the referenced program element is prepared for the hearing impaired.

visual_impaired_commentary – This field indicates that the referenced program element is prepared for the visually impaired viewer.

2.6.20 System clock descriptor

This descriptor conveys information about the system clock that was used to generate the timestamps.

If an external clock reference was used, the external_clock_reference_indicator may be set to '1'. The decoder optionally may use the same external reference if it is available.

If the system clock is more accurate than the 30 ppm accuracy required, then the accuracy of the clock can be communicated by encoding it in the clock_accuracy fields. The clock frequency accuracy is:

$$\text{clock\_accuracy\_integer} \times 10^{-\text{clock\_accuracy\_exponent}} \text{ ppm} \qquad (2\text{-}26)$$

If clock_accuracy_integer is set to 0, then the system clock accuracy is 30 ppm. When the external_clock_reference_indicator is set to '1', the clock accuracy pertains to the external reference clock (see Table 2-54).

Table 2-54 – System clock descriptor

Syntax	No. of bits	Mnemonic
system_clock_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
external_clock_reference_indicator	**1**	**bslbf**
reserved	**1**	**bslbf**
clock_accuracy_integer	**6**	**uimsbf**
clock_accuracy_exponent	**3**	**uimsbf**
reserved	**5**	**bslbf**
}		

2.6.21 Semantic definition of fields in system clock descriptor

external_clock_reference_indicator – This is a 1-bit indicator. When set to '1', it indicates that the system clock has been derived from an external frequency reference that may be available at the decoder.

clock_accuracy_integer – This is a 6-bit integer. Together with the clock_accuracy_exponent, it gives the fractional frequency accuracy of the system clock in parts per million.

clock_accuracy_exponent – This is a 3-bit integer. Together with the clock_accuracy_integer, it gives the fractional frequency accuracy of the system clock in parts per million.

2.6.22 Multiplex buffer utilization descriptor

The multiplex buffer utilization descriptor provides bounds on the occupancy of the STD multiplex buffer. This information is intended for devices such as remultiplexers, which may use this information to support a desired re-multiplexing strategy (see Table 2-55).

Table 2-55 – Multiplex buffer utilization descriptor

Syntax	No. of bits	Mnemonic
multiplex_buffer_utilization_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
bound_valid_flag	**1**	**bslbf**
LTW_offset_lower_bound	**15**	**uimsbf**
reserved	**1**	**bslbf**
LTW_offset_upper_bound	**14**	**uimsbf**
}		

2.6.23 Semantic definition of fields in multiplex buffer utilization descriptor

bound_valid_flag – A value of '1' indicates that the LTW_offset_lower_bound and the LTW_offset_upper_bound fields are valid.

LTW_offset_lower_bound – This 15-bit field is defined only if the bound_valid flag has a value of '1'. When defined, this field has the units of (27 MHz / 300) clock periods, as defined for the LTW_offset (refer to 2.4.3.4). The LTW_offset_lower_bound represents the lowest value that any LTW_offset field would have, if that field were coded in every packet of the stream or streams referenced by this descriptor. Actual LTW_offset fields may or may not be coded in the bitstream when the multiplex buffer utilization descriptor is present. This bound is valid until the next occurrence of this descriptor.

LTW_offset_upper_bound – This 15-bit field is defined only if the bound_valid has a value of '1'. When defined, this field has the units of (27 MHz / 300) clock periods, as defined for the LTW_offset (refer to 2.4.3.4). The LTW_offset_upper_bound represents the largest value that any LTW_offset field would have, if that field were coded in every packet of the stream or streams referenced by this descriptor. Actual LTW_offset fields may or may not be coded in the bitstream when the multiplex buffer utilization descriptor is present. This bound is valid until the next occurrence of this descriptor.

2.6.24 Copyright descriptor

The copyright_descriptor provides a method to enable audio-visual works identification. This copyright_descriptor applies to programs or program elements within programs (see Table 2-56).

Table 2-56 – Copyright descriptor

Syntax	No. of bits	Identifier
copyright_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
copyright_identifier	**32**	**uimsbf**
for (i = 0; i < N; i++){		
additional_copyright_info	**8**	**bslbf**
}		
}		

2.6.25 Semantic definition of fields in copyright descriptor

copyright_identifier – This field is a 32-bit value obtained from the Registration Authority.

additional_copyright_info – The meaning of additional_copyright_info bytes, if any, are defined by the assignee of that copyright_identifier, and once defined, they shall not change.

2.6.26 Maximum bitrate descriptor

See Table 2-57.

Table 2-57 – Maximum bitrate descriptor

Syntax	No. of bits	Identifier
maximum_bitrate_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
reserved	**2**	**bslbf**
maximum_bitrate	**22**	**uimsbf**
}		

2.6.27 Semantic definition of fields in maximum bitrate descriptor

maximum_bitrate – The maximum bitrate is coded as a 22-bit positive integer in this field. The value indicates an upper bound of the bitrate, including transport overhead, that will be encountered in this program element or program. The value of maximum_bitrate is expressed in units of 50 bytes/second. The maximum_bitrate_descriptor is included in the Program Map Table (PMT). Its presence as extended program information indicates applicability to the entire program. Its presence as ES information indicates applicability to the associated program element.

2.6.28 Private data indicator descriptor

See Table 2-58.

Table 2-58 – Private data indicator descriptor

Syntax	No. of bits	Identifier
private_data_indicator_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
private_data_indicator	**32**	**uimsbf**
}		

2.6.29 Semantic definition of fields in Private data indicator descriptor

private_data_indicator – The value of the private_data_indicator is private and shall not be defined by ITU-T | ISO/IEC.

2.6.30 Smoothing buffer descriptor

This descriptor is optional and conveys information about the size of a smoothing buffer, SB_n, associated with this descriptor, and the associated leak rate out of that buffer, for the program element(s) that it refers to.

In the case of Transport Streams, bytes of Transport Stream packets of the associated program element(s) present in the Transport Stream are input to a buffer SB_n of size given by sb_size, at the time defined by equation 2-4.

In the case of Program Streams, bytes of all PES packets of the associated elementary streams, are input to a buffer SB_n of size given by sb_size, at the time defined by equation 2-21.

When there is data present in this buffer, bytes are removed from this buffer at a rate defined by sb_leak_rate. The buffer, SB_n shall never overflow. During the continuous existence of a program, the value of the elements of the Smoothing Buffer descriptor of the different program element(s) in the program, shall not change.

The meaning of the smoothing buffer_descriptor is only defined when it is included in the PMT or the Program Stream Map.

If, in the case of a Transport Stream, it is present in the ES info in the Program Map Table, all Transport Stream packets of the PID of that program element enter the smoothing buffer.

If, in the case of a Transport Stream, it is present in the program information, the following Transport Stream packets enter the smoothing buffer:

- all Transport Stream packets of all PIDs listed as elementary_PIDs in the extended program information as well as;
- all Transport Stream packets of the PID which is equal to the PMT_PID of this section;
- all Transport Stream packets of the PCR_PID of the program.

All bytes that enter the associated buffer also exit it.

At any given time there shall be at most one descriptor referring to any individual program element and at most one descriptor referring to the program in its entirety.

Table 2-59 – Smoothing buffer descriptor

Syntax	No. of bits	Mnemonic
smoothing_buffer_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
reserved	**2**	**bslbf**
sb_leak_rate	**22**	**uimsbf**
reserved	**2**	**bslbf**
sb_size	**22**	**uimsbf**
}		

2.6.31 Semantic definition of fields in smoothing buffer descriptor

sb_leak_rate – This 22-bit field is coded as a positive integer. Its contents indicate the value of the leak rate out of the SB_n buffer for the associated elementary stream or other data in units of 400 bits/s.

sb_size – This 22-bit field is coded as a positive integer. Its contents indicate the value of the size of the multiplexing buffer smoothing buffer SB_n for the associated elementary stream or other data in units of 1 byte (see Table 2-59).

2.6.32 STD descriptor

This descriptor is optional and applies only to the T-STD model and to video elementary streams, and is used as specified 2.4.2. This descriptor does not apply to Program Streams (see Table 2-60).

Table 2-60 – STD descriptor

Syntax	No. of bits	Mnemonic
STD_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
reserved	**7**	**bslbf**
leak_valid_flag	**1**	**bslbf**
}		

2.6.33 Semantic definition of fields in STD descriptor

leak_valid_flag – The leak_valid_flag is a 1-bit flag. When set to '1', the transfer of data from the buffer MB_n to the buffer EB_n in the T-STD uses the leak method as defined in 2.4.2.3. If this flag has a value equal to '0', and the vbv_delay fields present in the associated video stream do not have the value 0xFFFF, the transfer of data from the buffer MB_n to the buffer EB_n uses the vbv_delay method as defined in 2.4.2.3.

2.6.34 IBP descriptor

This optional descriptor provides information about some characteristics of the sequence of frame types in the video sequence (see Table 2-61).

Table 2-61 – IBP descriptor

Syntax	No. of bits	Mnemonic
ibp_descriptor() {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
closed_gop_flag	**1**	**uimsbf**
identical_gop_flag	**1**	**uimsbf**
max_gop-length	**14**	**uimsbf**
}		

2.6.35 Semantic definition of fields in IBP descriptor

closed_gop_flag – This 1-bit flag when set to '1' indicates that a group of pictures header is encoded before every I-frame and that the closed_gop flag is set to '1' in all group of pictures headers in the video sequence.

identical_gop_flag – This 1-bit flag when set to '1' indicates that the number of P-frames and B-frames between I-frames, and the picture coding types and sequence of picture types between I-pictures is the same throughout the sequence, except possibly for the pictures up to the second I-picture.

max_gop_length – This 14-bit unsigned integer indicates the maximum number of the coded pictures between any two consecutive I-pictures in the sequence. The value of 0 is forbidden.

2.6.36 MPEG-4 video descriptor

For individual ISO/IEC 14496-2 streams directly carried in PES packets, as defined in subclause 2.11.2, the MPEG-4 video descriptor provides basic information for identifying the coding parameters of such visual elementary streams. The MPEG-4 video descriptor does not apply to ISO/IEC 14496-2 streams encapsulated in SL-packets and in FlexMux packets, as defined in subclause 2.11.3.

Syntax	No. of bits	Mnemonic
MPEG-4_video_descriptor ()		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
MPEG-4_visual_profile_and_level	**8**	**uimsbf**
}		

2.6.37 Semantic definition of fields in MPEG-4 video descriptor

MPEG-4_video_profile_and_level – This 8-bit field shall identify the profile and level of the ISO/IEC 14496-2 video stream. This field shall be coded with the same value as the profile_and_level_indication field in the Visual Object Sequence Header in the associated ISO/IEC 14496-2 stream.

2.6.38 MPEG-4 audio descriptor

For individual ISO/IEC 14496-3 streams directly carried in PES packets, as defined in subclause 2.11.2, the MPEG-4 audio descriptor provides basic information for identifying the coding parameters of such audio elementary streams. The MPEG-4 audio descriptor does not apply to ISO/IEC 14496-3 streams encapsulated in SL-packets and in FlexMux packets, as defined in subclause 2.11.3.

Syntax	No. of bits	Mnemonic
MPEG-4_audio_descriptor ()		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
MPEG-4_audio_profile_and_level	**8**	**uimsbf**
}		

2.6.39 Semantic definition of fields in MPEG-4 audio descriptor

MPEG-4_audio_profile_and_level – This 8-bit field shall identify the profile and level of the ISO/IEC 14496-3 audio stream corresponding to the Table 2-62.

2.6.40 IOD descriptor

The IOD descriptor encapsulates the InitialObjectDescriptor structure. An initial object descriptor allows access to a set of ISO/IEC 14496 streams by identifying the ES_ID values of the ISO/IEC 14496-1 scene description and object descriptor streams. Both the scene description stream and the object descriptor stream contain further information about the ISO/IEC 14496 streams that are part of the scene. See Annex R for a description of the content access procedure. The InitialObjectDescriptor is specified in subclause 8.6.3 of ISO/IEC 14496-1.

Within a Transport Stream, the IOD descriptor shall be conveyed in the descriptor loop immediately following the program_info_length field in the Program Map Table. If a Program Stream Map is present in a Program Stream, the IOD descriptor shall be conveyed in the descriptor loop immediately following the program_stream_info_length field in the Program Stream Map. More than one IOD descriptor may be associated to a program.

NOTE – This Specification does not specify how the IOD_label may be used by higher level service information to uniquely select one of the ISO/IEC 14496 presentations identified by multiple IOD descriptors.

Table 2-62 – MPEG-4_audio_profile_and_level assignment values

Value	Description
0x00-0x0F	Reserved
0x10 0x11 0x12 0x13 0x14-0x17	Main profile, level 1 Main profile, level 2 Main profile, level 3 Main profile, level 4 Reserved

0x50-0xFF	Reserved

Syntax	No. of bits	Mnemonic
IOD_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
Scope_of_IOD_label	**8**	**uimsbf**
IOD_label	**8**	**uimsbf**
InitialObjectDescriptor ()	**8**	**uimsbf**
}		

2.6.41 Semantic definition of fields in IOD descriptor

Scope_of_IOD_label – This 8-bit field specifies the scope of the IOD_label field. A value of 0x10 indicates that the IOD_label is unique within the Program Stream or within the specific program in a Transport Stream in which the IOD descriptor is carried. A value of 0x11 indicates that the IOD_label is unique within the Transport Stream in which the IOD descriptor is carried. All other values of the Scope_of_IOD_label field are reserved.

IOD_label – This 8-bit field specifies the label of the IOD descriptor.

InitialObjectDescriptor () – This structure is defined in subclause 8.6.3.1 of ISO/IEC 14496-1.

2.6.42 SL descriptor

The SL descriptor shall be used when a single ISO/IEC 14496-1 SL-packetized stream is encapsulated in PES packets. The SL descriptor associates the ES_ID of this SL-packetized stream to an elementary_PID in case of a Transport Stream or to an elementary_stream_id in case of a Program Stream. Within a Transport Stream, the SL descriptor shall be conveyed for the corresponding elementary stream in the descriptor loop immediately following the ES_info_length field in the Program Map Table. If a Program Stream Map is present in a Program Stream, the SL descriptor shall be conveyed in the descriptor loop immediately following the elementary_stream_info_length field within the Program Stream Map.

NOTE – SL packetized streams may be used in a Program Stream. However, only one stream_id exists for ISO/IEC 14496-1 SL-packetized streams. In order to associate multiple such streams within a Program Stream to an ISO/IEC 14496-1 scene, FlexMux has to be used and signaled appropriately by an FMC descriptor. This limitation does not exist in a Transport Stream where the SL descriptor provides unambiguous mapping between an ISO/IEC 14496-1 ES_ID value and an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 elementary_PID value.

Syntax	No. of bits	Mnemonic
SL_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
ES_ID	**16**	**uimsbf**
}		

2.6.43 Semantic definition of fields in SL descriptor

ES_ID – This 16-bit field shall specify the identifier of an ISO/IEC 14496-1 SL-packetized stream.

2.6.44 FMC descriptor

The FMC descriptor indicates that the ISO/IEC 14496-1 FlexMux tool has been used to multiplex ISO/IEC 14496-1 SL-packetized streams into a FlexMux stream before encapsulation in PES packets or ISO//IEC14496_sections. The FMC descriptor associates FlexMux channels to the ES_ID values of the SL-packetized streams in the FlexMux stream.

An FMC descriptor is required for each program element referenced by an elementary_PID value in a Transport Stream and for each elementary_stream_id in a Program Stream that conveys a FlexMux stream. Within a Transport Stream, the FMC descriptor shall be conveyed for the corresponding elementary stream in the descriptor loop immediately following the ES_info_length field in the Program Map Table. If a Program Stream Map is present in a Program Stream, the FMC descriptor shall be conveyed in the descriptor loop immediately following the elementary_stream_info_length field in the Program Stream Map.

For each SL_packetized stream in a FlexMux stream, the FlexMux channel shall be identified by a single entry in the FMC descriptor.

Syntax	No. of bits	Mnemonic
FMC_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
for (i=0; i<descriptor_length; i += 3) {		
ES_ID	**16**	**uimsbf**
FlexMuxChannel	**8**	**uimsbf**
}		
}		

2.6.45 Semantic definition of fields in FMC descriptor

ES_ID – This 16-bit field specifies the identifier of an ISO/IEC 14496-1 SL-packetized stream.

FlexMuxChannel – This 8-bit field specifies the number of the FlexMux channel used for this SL-packetized stream.

2.6.46 External_ES_ID descriptor

The External_ES_ID descriptor assigns an ES_ID, as defined in ISO/IEC 14496-1, to a program element to which no ES_ID value has been assigned by other means. This ES_ID allows reference to a non-ISO/IEC 14496 component in the scene description or, for example, to associate a non-ISO/IEC 14496 component with an IPMP stream.

Within a Transport stream, the assignment of an ES_ID shall be made by conveying an External_ES_ID descriptor for the corresponding elementary stream in the descriptor loop immediately following the ES_info_length field in the Program Map Table. If a Program Stream Map is present in a Program Stream, the External_ES_ID descriptor shall be conveyed in the descriptor loop immediately following the elementary_stream_info_length field in the Program Stream Map.

Syntax	No. of bits	Mnemonic
External_ES_ID_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
External_ES_ID	**16**	**uimsbf**
}		

2.6.47 Semantic definition of fields in External_ES_ID descriptor

External_ES_ID – This 16-bit field assigns an ES_ID identifier, as defined in ISO/IEC 14496-1, to a component of a program.

2.6.48 Muxcode descriptor

The Muxcode descriptor conveys MuxCodeTableEntry structures as defined in subclause 11.2.4.3 of ISO/IEC 14496-1. MuxCodeTableEntries configure the MuxCode mode of FlexMux.

One or more Muxcode descriptors may be associated to each elementary_PID or elementary_stream_id, respectively, conveying an ISO/IEC 14496-1 FlexMux stream that utilizes the MuxCode mode. Within a Transport stream, the muxcode descriptor shall be conveyed for the corresponding elementary stream in the descriptor loop immediately following the ES_info_length field in the Program Map Table. If a Program Stream Map is present in a Program Stream, the Muxcode descriptor shall be conveyed in the descriptor loop immediately following the elementary_stream_info_length field in the Program Stream Map.

MuxCodeTableEntries may be updated with new versions. In case of such updates, the version_number of each Program Map Table or the program_stream_map_version of each Program Stream Map, respectively, carrying the MuxCode descriptor in their descriptor loop shall be incremented by 1 modulo 32.

Syntax	No. of bits	Mnemonic
Muxcode_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
for (i = 0; i < N; i++) {		
MuxCodeTableEntry ()		
}		
}		

2.6.49 Semantics of fields in Muxcode descriptor

MuxCodeTableEntry () – This structure is defined in subclause 11.2.4.3 of ISO/IEC 14496-1.

2.6.50 FmxBufferSize descriptor

The FmxBufferSize descriptor conveys the size of the FlexMux buffer (FB) for each SL packetized stream multiplexed in a FlexMux stream.

One FmxBufferSize descriptor shall be associated to each elementary_PID or elementary_stream_id, respectively, conveying an ISO/IEC 14496-1 FlexMux stream. Within a Transport stream, the FmxBufferSize descriptor shall be conveyed for the corresponding elementary stream in the descriptor loop immediately following the ES_info_length field in the Program Map Table. If a Program Stream Map is present in a Program Stream, the FmxBufferSize descriptor shall be conveyed in the descriptor loop immediately following the elementary_stream_info_length field within the Program Stream Map.

Syntax	No. of bits	Mnemonic
FmxBufferSize_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
DefaultFlexMuxBufferDescriptor()		
for (i=0; i<descriptor_length; i += 4) {		
FlexMuxBufferDescriptor()		
}		
}		

2.6.51 Semantics of fields in FmxBufferSize descriptor

FlexMuxBufferDescriptor() – This descriptor specifies the FlexMux buffer size for one SL-packetized stream carried within the FlexMux stream. It is defined in subclause 11.2 of ISO/IEC 14496-1.

DefaultFlexMuxBufferDescriptor() – This descriptor specifies the default FlexMux buffer size for this FlexMux stream. It is defined in subclause 11.2 of ISO/IEC 14496-1.

2.6.52 MultiplexBuffer descriptor

The MultiplexBuffer descriptor conveys the size of the multiplex buffer MB_n, as well as the leak rate Rx_n at which data is transferred from transport buffer TB_n into buffer MB_n for a specific ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program element referenced by an elementary_PID value in the Program Map Table.

One MultiplexBuffer descriptor shall be associated to each elementary_PID that contains an ISO/IEC 14496 FlexMux stream or SL-packetized stream, including those containing ISO_IEC_14496_sections. See subclause 2.11.3.9 for the definition of buffers and rates in the T-STD model for decoding of ISO/IEC 14496 content.

The MultiplexBuffer descriptor shall be conveyed in the descriptor loop immediately following the ES_info_length field in the Program Map Table.

Syntax	No. of bits	Mnemonic
MultiplexBuffer_descriptor () {		
descriptor_tag	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
MB_buffer_size	**24**	**uimsbf**
TB_leak_rate	**24**	**uimsbf**
}		

2.6.53 Semantics of fields in MultiplexBuffer descriptor

MB_buffer_size – This 24-bit field shall specify the size in byte of buffer MB_n of the elementary stream n that is associated with this descriptor.

TB_leak_rate – This 24-bit field shall specify in units of 400 bits per second the rate at which data is transferred from transport buffer TB_n to multiplex buffer MB_n for the elementary stream n that is associated with this descriptor.

2.7 Restrictions on the multiplexed stream semantics

2.7.1 Frequency of coding the system clock reference

The Program Stream shall be constructed such that the time interval between the bytes containing the last bit of system_clock_reference_base fields in successive packs shall be less than or equal to 0.7 s. Thus:

$$\left| t(i) - t(i') \right| \leq 0.7 \text{ s}$$

for all i and i′ where i and i′ are the indexes of the bytes containing the last bit of consecutive system_clock_reference_base fields.

2.7.2 Frequency of coding the program clock reference

The Transport Stream shall be constructed such that the time interval between the bytes containing the last bit of program_clock_reference_base fields in successive occurrences of the PCRs in Transport Stream packets of the PCR_PID for each program shall be less than or equal to 0,1 s. Thus:

$$\left| t(i) - t(i') \right| \leq 0.1 \text{ s}$$

for all i and i′ where i and i′ are the indexes of the bytes containing the last bit of consecutive program_clock_reference_base fields in the Transport Stream packets of the PCR_PID for each program.

There shall be at least two (2) PCRs, from the specified PCR_PID within a Transport Stream, between consecutive PCR discontinuities (refer to 2.4.3.4) to facilitate phase locking and extrapolation of byte delivery times.

2.7.3 Frequency of coding the elementary stream clock reference

The Program Stream and Transport Stream shall be constructed such that if the elementary stream clock reference field is coded in any PES packets containing data of a given elementary stream the time interval in the PES_STD between the bytes containing the last bit of successive ESCR_base fields shall be less than or equal to 0,7 s. In PES Streams the ESCR encoding is required with the same interval. Thus:

$$| t(i) - t(i') | \leq 0.7 \text{ s}$$

for all i and i' where i and i' are the indexes of the bytes containing the last bits of consecutive ESCR_base fields.

NOTE – The coding of elementary stream clock reference fields is optional; they need not be coded. However if they are coded, this constraint applies.

2.7.4 Frequency of presentation timestamp coding

The Program Stream and Transport Stream shall be constructed so that the maximum difference between coded presentation timestamps referring to each elementary video or audio stream is 0,7 s. Thus:

$$| tp_n(k) - tp_n(k'') | \leq 0.7 \text{ s}$$

for all n, k, and k″ satisfying:

- $P_n(k)$ and $P_n(k'')$ are presentation units for which presentation timestamps are coded;
- k and k″ are chosen so that there is no presentation unit, $P_n(k')$ with a coded presentation timestamp and with $k < k' < k''$; and
- No decoding discontinuity exists in elementary stream n between $P_n(k)$ and $P_n(k")$.

In the case of still pictures the 0,7 s constraint does not apply.

2.7.5 Conditional coding of timestamps

For each elementary stream of a Program Stream or Transport Stream, a presentation timestamp (PTS) shall be encoded for the first access unit.

A decoding discontinuity exists at the start of an access unit $A_n(j)$ in an elementary stream n if the decoding time $td_n(j)$ of that access unit is greater than the largest value permissible given the specified tolerance on the system_clock_frequency. For video, except when trick mode status is true or when low_delay flag is '1', this is allowed only at the start of a video sequence. If a decoding discontinuity exists in any elementary video or audio stream in the Transport Stream or Program Stream, then a PTS shall be encoded referring to the first access unit after each decoding discontinuity except when trick mode status is true.

When low_delay is '1' a PTS shall be encoded for the first access unit after an EB_n or B_n underflow.

A PTS may only be present in a ITU-T Rec. H.222.0 | ISO/IEC 13818-1 video or audio elementary stream PES packet header if the first byte of a picture start code or the first byte of an audio access unit is contained in the PES packet.

A decoding_timestamp (DTS) shall appear in a PES packet header if and only if the following two conditions are met:

- a PTS is present in the PES packet header;
- the decoding time differs from the presentation time.

2.7.6 Timing constraints for scalable coding

If an audio sequence is coded using an ISO/IEC 13818-3 extension bitstream, corresponding decoding/presentation units in the two layers shall have identical PTS values.

If a video sequence is coded as a SNR enhancement of another sequence, as specified in 7.8 of ITU-T Rec. H.262 | ISO/IEC 13818-2, the set of presentation times for both sequences shall be the same.

If a video sequence is coded as two partitions, as specified in 7.10 of ITU-T Rec. H.262 | ISO/IEC 13818-2, the set of presentation times for both partitions shall be the same.

If a video sequence is coded as a spatial scalable enhancement of another sequence, as specified in 7.7 of ITU-T Rec. H.262 | ISO/IEC 13818-2, the following shall apply:

- If both sequences have the same frame rate, the set of presentation times for both sequences shall be the same.

  NOTE – that this does not imply that the picture coding type is the same in both layers.

- If the sequences have different frame rates, the set of presentation times shall be such that as many presentation times as possible shall be common to both sequences.
- The picture from which the spatial prediction is made shall be one of the following:
  - the coincident or most recently decoded lower layer picture;
  - the coincident or most recently decoded lower layer picture that is an I- or P-picture;
  - the second most recently decoded lower layer picture that is an I- or P-picture, and provided that the lower layer does not have low_delay set to '1'.

If a video sequence is coded as a temporally scalable enhancement of another sequence, as specified in 7.9 of ITU-T Rec. H.262 | ISO/IEC 13818-2, the following lower layer pictures may be used as the reference. Times are relative to presentation times:

- the coincident or most recently presented lower layer picture;
- the next lower layer picture to be presented.

2.7.7 Frequency of coding P-STD_buffer_size in PES packet headers

In a Program Stream, the P-STD_buffer_scale and P-STD_buffer_size fields shall occur in the first PES packet of each elementary stream and again whenever the value changes. They may also occur in any other PES packet.

2.7.8 Coding of system header in the Program Stream

In a Program Stream, the system header may be present in any pack, immediately following the pack header. The system header shall be present in the first pack of an Program Stream. The values encoded in all the system headers in the Program Stream shall be identical.

2.7.9 Constrained system parameter Program Stream

A Program Stream is a "Constrained System Parameters Stream" (CSPS) if it conforms to the bounds specified in this subclause. Program Streams are not limited to the bounds specified by the CSPS. A CSPS may be identified by means of the CSPS_flag defined in the system header in 2.5.3.5. The CSPS is a subset of all possible Program Streams.

Packet Rate

In the CSPS, the maximum rate at which packets shall arrive at the input to the P-STD is 300 packets per second if the value encoded in the rate_bound field (refer to 2.5.3.6) is less than or equal to 4 500 000 bits/s if the packet_rate_restriction_flag is set to '1', and less than or equal to 2 000 000 bits/s if the packet_rate_restriction_flag is set to '0'. For higher bit rates the CSPS packet rate is bounded by a linear relation to the value encoded in the rate_bound field.

Specifically, for all packs p in the Program Stream when the packet_rate_restriction_flag (refer to 2.5.3.5) is set to a value of '1',

$$NP \leq \left(t(i') - t(i')\right) \times 300 \times \max\left[1, \frac{R_{\max}}{4.5 \times 10^6}\right] \tag{2-27}$$

and if the packet_rate_restriction_flag is set to a value of '0'

$$NP \leq \left(t(i') - t(i')\right) \times 300 \times \max\left[1, \frac{R_{\max}}{2.5 \times 10^6}\right] \tag{2-28}$$

where

$$R_{max} = 8 \times 50 \times rate\_bound \quad \text{bit/s} \tag{2-29}$$

NP is the number of packet_start_code_prefixes and system_header_start_codes between adjacent pack_start_codes or between the last pack_start_code and the MPEG_program_end_code as defined in Table 2-31 and semantics in 2.5.3.2.

t(i) is the time, measured in seconds, encoded in the SCR of pack p.

t(i′) is the time, measured in seconds, encoded in the SCR for pack p + 1, immediately following pack p, or in the case of the final pack in the Program Stream, the time of arrival of the byte containing the last bit of the MPEG_program_end_code.

Decoder Buffer Size

In the case of a CSPS the maximum size of each input buffer in the system target decoder is bounded. Different bounds apply for video elementary streams and audio elementary streams.

In the case of a video elementary stream in a CSPS, the following applies:

BS_n has a size which is equal to the sum of the size of the video buffer verifier (vbv) as specified in ITU-T Rec. H.262 | ISO/IEC 13818-2 and an additional amount of buffering BS_{add}. BS_{add} is specified as:

$$BS_{add} \leq MAX\left[6 \times 1024, R_{vmax} \times 0{,}001\right] \text{ bytes}$$

where R_{vmax} is the maximum video bit rate of the video elementary stream.

In the case of an audio elementary stream in a CSPS, the following applies:

$$BS_n \leq 4096 \text{ bytes}$$

In the case of ISO/IEC 13818-7 ADTS audio elementary stream in a CSPS the following applies to support 8 channels:

$$BS_n \leq 8976 \text{ bytes}$$

2.7.10 Transport Stream

Sample rate locking in Transport Streams

In the Transport Stream there shall be a specified constant rational relationship between the audio sampling rate and the system clock frequency in the system target decoder, and likewise a specified rational relationship between the video frame rate and the system clock frequency. The system_clock_frequency is defined in 2.4.2. The video frame rate is specified in ITU-T Rec. H.262 | ISO/IEC 13818-2 or in ISO/IEC 11172-2. The audio sampling rate is specified in ISO/IEC 13818-3 or in ISO/IEC 11172-3. For all presentation units in all audio elementary streams in the Transport Stream, the ratio of system_clock_frequency to the actual audio sampling rate, SCASR, is constant and equal to the value indicated in the following table at the nominal sampling rate indicated in the audio stream.

$$SCASR = \frac{system\_clock\_frequency}{audio\_sample\_rate\_in\_the\_T\text{-}STD} \tag{2-30}$$

The notation $\frac{X}{Y}$ denotes real division.

Nominal audio sampling frequency (kHz)	16	32	22,05	44,1	24	48
SCASR	27 000 000 / 16 000	27 000 000 / 32 000	27 000 000 / 22 050	27 000 000 / 44 100	27 000 000 / 24 000	27 000 000 / 48 000

For all presentation units in all video elementary streams in the Transport Stream, the ratio of system_clock_frequency to the actual video frame rate, SCFR, is constant and equal to the value indicated in the following table at the nominal frame rate indicated in the video stream.

$$SCFR = \frac{system\_clock\_frequency}{frame\_rate\_in\_the\_T\text{-}STD} \tag{2-31}$$

Nominal frame rate (Hz)	23.976	24	25	29.97	30	50	59.94	60
SCFR	1 126 125	1 125 000	1 080 000	900 900	900 000	540 000	450 450	450 000

The values of the SCFR are exact. The actual frame rate differs slightly from the nominal rate in cases where the nominal rate is 23.976, 29.97, or 59.94 frames per second.

2.8 Compatibility with ISO/IEC 11172

The Program Stream of this Recommendation | International Standard is defined to be forward compatible with ISO/IEC 11172-1. Decoders of the Program Stream as defined in this Recommendation | International Standard shall also support decoding of ISO/IEC 11172-1.

2.9 Registration of copyright identifiers

2.9.1 General

Parts 1, 2 and 3 of ISO/IEC 13818 provide support for the management of audiovisual works copyrighting. In ITU-T Rec. H.222.0 | ISO/IEC 13818-1 this is by means of a copyright descriptor, while ITU-T Rec. H.262 | ISO/IEC 13818-2 and ISO/IEC 13818-3 contain fields for identifying copyright holders through syntax fields in the elementary stream syntax. This Recommendation | International Standard presents the method of obtaining and registering copyright identifiers in ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

ITU-T Rec. H.222.0 | ISO/IEC 13818-1 specifies a unique 32-bit copyright_identifier which is a work type code identifier (such as ISBN, ISSN, ISRC, etc.) carried in the copyright descriptor. The copyright_identifier enables identification of a wide number of Copyright Registration Authorities. Each Copyright Registration Authority may specify a syntax and semantic for identifying the audiovisual works or other copyrighted works within that particular copyright organization through appropriate use of the variable length additional_copyright_info field which contains the copyright number.

In the following subclause and Annexes L, M and N, the benefits and responsibilities of all parties to the registration of copyright_identifier are outlined.

2.9.2 Implementation of a Registration Authority (RA)

ISO/IEC JTC 1 shall call for nominations for an international organization which will serve as the Registration Authority for the **copyright_identifier** as defined in 2.6.24 of ITU-T Rec. H.222.0 | ISO/IEC 13818-1. The selected organization shall serve as the Registration Authority. The so-named Registration Authority shall execute its duties in compliance with Annex H/JTC 1 Directives. The registered copyright_identifier is hereafter referred to as the Registered Identifier (RID).

Upon selection of the Registration Authority, JTC 1 shall require the creation of a Registration Management Group (RMG) which will review appeals filed by organizations whose request for a RID to be used in conjunction with ITU-T Rec. H.222.0 | ISO/IEC 13818-1 has been denied by the Registration Authority.

Annexes L, M and N provide information on the procedure for registering a unique copyright identifier.

2.10 Registration of private data format

The registration descriptor of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 is provided by this text in order to enable users of this Specification to unambiguously carry data when its format is not recognized by this Specification. This provision will permit this Specification to carry all types of data while providing for a method of unambiguous identification of the characteristics of the underlying private data.

2.10.1 General

In the following subclause and Annexes O and P, the benefits and responsibilities of all parties to the registration of private data format are outlined.

2.10.2 Implementation of a Registration Authority (RA)

ISO/IEC JTC 1/SC 29 shall call for nominations from member bodies of ISO or National Committees of IEC which will serve as the Registration Authority for the **format_identifier** as defined in 2.6.8 and 2.6.9. The selected organization shall serve as the Registration Authority. The so-named Registration Authority shall execute its duties in compliance with Annex H/JTC 1 Directives. The registered private data format_identifier is hereafter referred to as the Registered Identifier (RID).

Upon selection of the Registration Authority, JTC 1 shall require the creation of a Registration Management Group (RMG) which will review appeals filed by organizations whose request for an RID to be used in conjunction with this Specification has been denied by the Registration Authority.

Annexes O and P provide information on the procedures for registering a unique format identifier.

2.11 Carriage of ISO/IEC 14496 data

2.11.1 Introduction

An ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream may carry individual ISO/IEC 14496-2 and 14496-3 elementary streams as well as ISO/IEC 14496-1 audiovisual scenes with its associated streams. Typically, the ISO/IEC 14496 streams will be elements of an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program, as defined by the PMT in a Transport Stream and the PSM in a Program Stream.

For the carriage of ISO/IEC 14496 data in Transport Streams and Program Streams distinction is made between individual elementary streams and an ISO/IEC 14496-1 audiovisual scene with its associated streams.

For carriage of individual ISO/IEC 14496-2 and 14496-3 elementary streams only system tools from ITU-T Rec. H.222.0 | ISO/IEC 13818-1 are used, as defined in subclause 2.11.2;

For carriage of an audiovisual ISO/IEC 14496-1 scene and associated ISO/IEC 14496 elementary streams, contained in ISO/IEC 14496-1 SL_packetized streams or FlexMux streams, tools from both ITU-T Rec. H.222.0 | ISO/IEC 13818-1 and from ISO/IEC 14496-1 are used, as defined in subclause 2.11.3.

2.11.2 Carriage of individual ISO/IEC 14496-2 and 14496-3 Elementary Streams in PES packets

2.11.2.1 Introduction

Individual ISO/IEC 14496-2 and 14496-3 elementary streams may be carried in PES packets as PES_packet_data_bytes. For PES packetization no specific data alignment constraints apply. For synchronisation PTSs and, when appropriate, DTSs are encoded in the header of the PES packet that carries the ISO/IEC 14496 elementary stream data; for PTS and DTS encoding the same constraints apply as for ISO/IEC 13818 elementary streams. See Table 2-63 for an overview of how to carry individual ISO/IEC 14496 streams within an ISO/IEC ITU-T Rec. H.222.0 | 13818-1 stream.

Table 2-63 – Carriage of individual ISO/IEC 14496 streams in ITU-T Rec. H.222.0 | ISO/IEC 13818-1

ISO/IEC 14496-2 visual	Carriage in PES packets	Stream_type = 0x10	Stream_id = '1110 xxxx'
ISO/IEC 14496-3 audio	Carriage in PES packets	Stream_type = 0x11	Stream_id = '110x xxxx'

If a PTS or DTS is present in the PES packet header it shall refer to the visual object that follows either the first VOP start code or the first still texture object startcode that commences in the PES packet. Each ISO/IEC 14496-2 video stream carried by ITU-T Rec. H.222.0 | ISO/IEC 13818-1 shall contain the information required to decode the ISO/IEC 14496-2 video stream; consequently the stream shall contain Visual Object Sequence Headers, Visual Object Headers and Video Object Layer Headers.

In case of an ISO/IEC 14496-3 elementary stream, before PES packetization the elementary stream data shall be first encapsulated in the LATM transport syntax defined in ISO/IEC 14496-3 / AMD 1. If a PTS is present in the PES packet header it shall refer to the first audio frame that follows the first syncword that commences in the payload of the PES packet.

Carriage of individual ISO/IEC 14496 elementary streams in PES packets shall be identified by appropriate stream_id and stream_type values, indicating the use of ISO/IEC 14496-2 Visual or 14496-3 Audio. In addition, such carriage shall be signaled by the MPEG-4_video descriptor or MPEG-4_audio descriptor, respectively. These descriptors shall be conveyed in the descriptor loop for the respective elementary stream entry in the Program Map Table in case of a Transport Stream or in the Program Stream Map, when present, in case of a Program Stream. ITU-T Rec. H.222.0 | ISO/IEC 13818-1 does not specify presentation of ISO/IEC 14496 elementary streams in the context of a program.

2.11.2.2 STD extensions for individual ISO/IEC 14496 elementary streams

The T-STD model includes a transport buffer TB_n and a multiplex buffer B_n prior to decoding of each individual ISO/IEC 14496 elementary stream n. Note that in the T-STD the single multiplex buffer B_n is also applied for ISO/IEC 14496-2 video, as indicated in Figure 2-4, instead of the approach with two buffers MB_n and EB_n used for ISO/IEC 13818-2 video in the T-STD. For buffers TB_n and B_n and the rate Rx_n between TB_n and B_n the following constraints apply.

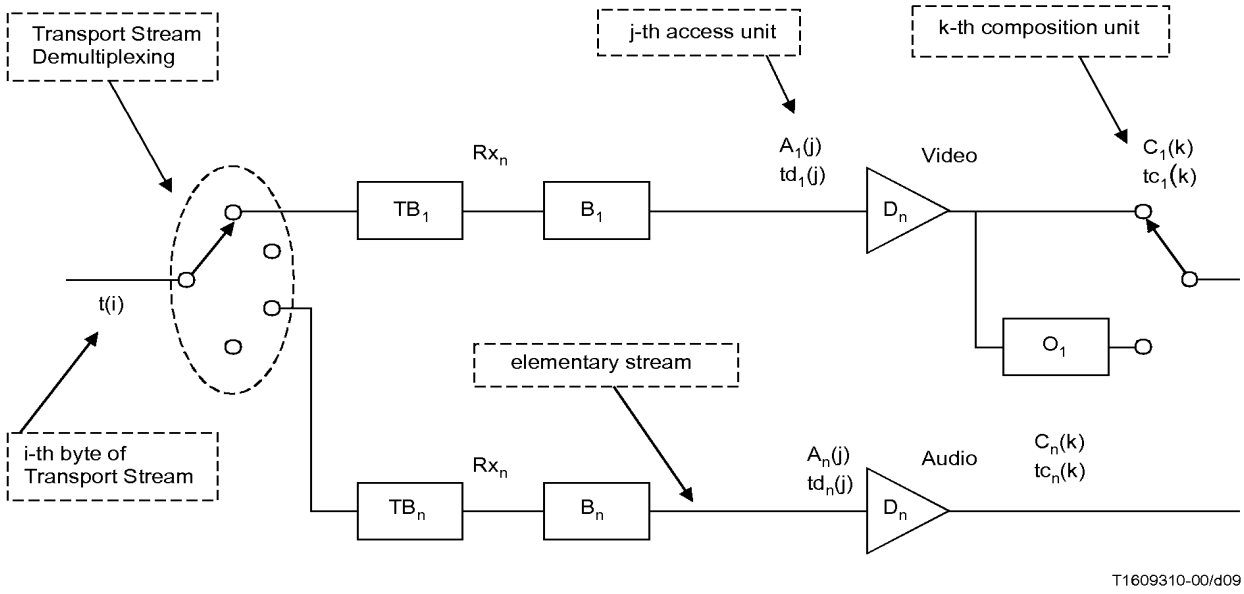

Figure 2-4 – T-STD model extensions for individual ISO/IEC 14496 elementary streams

In case of carriage of an ISO/IEC 14496-2 stream:

Size BS_n of Buffer B_n:

$$BS_n = BS_{mux} + BS_{oh} + VBV_{max}[profile,level]$$

where:

BS_{oh}, packet overhead buffering, is defined as:

$BS_{oh} = (1/750)$ seconds $\times \max\{R_{max}[profile,level], 2\ 000\ 000$ bit/second$\}$

and

BS_{mux}, additional multiplex buffering, is defined as:

$BS_{mux} = 0.004$ seconds $\times$ max{R_{max}[profile,level], 2 000 000 bit/second}

Rate Rx_n:

$$Rx_n = 1.2 \times R_{max}[profile,level]$$

Where

VBV_{max}[profile,level] and R_{max}[profile,level] are defined in ISO/IEC 14496-2 for each profile and level. For profiles and levels for which no VBV_{max} value is specified, the size of B_n and the rate Rx_n are user defined.

In case of carriage of an ISO/IEC 14496-3 stream:

Size BS_n of Buffer B_n for ISO/IEC 14496-3 AAC audio as defined in this Specification,

$$\text{else } BS_n = BS_{mux} + BS_{dec} + BS_{oh} = 3584 \text{ bytes}$$

In this case the size of the access unit decoding buffer BS_{dec}, and the PES packet overhead buffer BS_{oh} are constrained by:

$$BS_{dec} + BS_{oh} \leq 2848 \text{ bytes}$$

A portion (736 bytes) of the 3584 byte buffer is allocated for buffering to allow multiplexing. The rest, 2848 bytes, are shared for access unit buffering BS_{dec}, BS_{oh} and additional multiplexing.

Rate Rx_n for ISO/IEC 14496-3 AAC audio as defined in this Specification,

$$\text{else } Rx_n = 2\ 000\ 000 \text{ bit/sec}$$

The P-STD model includes a multiplex buffer B_n prior to decoding of each individual ISO/IEC 14496 elementary stream n. The size BS_n of buffer B_n in the P-STD is defined by the P-STD_buffer_size field in the PES packet header.

2.11.3 Carriage of audiovisual ISO/IEC 14496-1 scenes and associated ISO/IEC 14496 streams

2.11.3.1 Introduction

This clause describes the encapsulation and signaling when an audiovisual scene represented by ISO/IEC 14496 data is carried in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Stream or Transport Stream. ISO/IEC 14496 content consists of the initial object descriptor and a variable number of streams such as object descriptor streams, scene description streams (carrying either BIFS-Command or BIFS-Anim access units), IPMP streams, OCI streams and audio-visual streams. Each of the ISO/IEC 14496 streams shall be contained in an SL-packetized stream and may optionally be multiplexed into a FlexMux stream, both defined in ISO/IEC 14496-1. For carriage in ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Stream or Transport Stream, these SL-packetized streams and FlexMux streams shall contain encoded Object Clock Reference (OCR) and FlexMux Clock Reference (FCR) fields as specified in 2.11.3.4 and in 2.11.3.5, respectively. The SL-packetized streams or FlexMux streams are then encapsulated either in PES packets or in ISO_IEC_14496_sections prior to Transport Stream packetization and multiplexing or Program Stream multiplexing. ISO_IEC_14496_sections are built on the long format of H.222.0 | ISO/IEC 13818-1 sections.

2.11.3.2 Assignment of ES_ID values

An ISO/IEC 14496-1 scene carried over an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream may associate a number of ISO/IEC 14496, ISO/IEC 13818 and other streams by the use of the ES_ID parameter. The scene and the associated streams may be carried over the same ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream, but a scene may also reference streams carried elsewhere, for example over an IP network. How to identify such other means is not defined in this Specification.

ISO/IEC 14496-1 defines name scoping rules for identifiers. These rules allow the same ES_ID value to be used for two different streams within ISO/IEC 14496 content. When one or multiple ISO/IEC 14496-1 scenes are carried in a ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program, duplicate ES_ID values shall not occur within the program such that each ISO/IEC 14496 SL-packetized stream or ISO/IEC 14496-1 Flexmux channel has a unique ES_ID value in the program.

2.11.3.3 Timing of ISO/IEC 14496 scenes and associated streams

When carried over an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream, the object time base of each ISO/IEC 14496 stream shall be locked to the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 STC, that is:

$$\text{If } X(t) = f_{stc}(t) / f_{object}(t),$$

then the value of X(t) shall be constant at any time t.

Where

$f_{stc}(t)$ denotes the intended frequency of the STC at time t, i.e. 27 000 000 Hz

$f_{object}(t)$ denotes the frequency of the object time base at time t

The object time base of ISO/IEC 14496 streams carried over an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream is conveyed as follows:

- The object time base of an SL-packetized stream carried in PES packets without the use of the FlexMux shall be conveyed by coded OCRs in the SL packet header of that stream. See subclause 2.11.3.4.
- The object time base of SL-packetized streams carried in PES packets within a FlexMux stream shall be conveyed by FCRs in that FlexMux stream. See subclause 2.11.3.5. Consequently, all ISO/IEC 14496 streams contained within the same FlexMux stream share the same object time base.
- The object time base of an SL-packetized stream carried in sections shall be conveyed by another ISO/IEC 14496 stream within the Transport Stream or Program Stream as indicated by the OCR_ES_ID field in the ES descriptor for that stream.

The following constraints shall apply for encoding of OCRs and FCRs in SL-packetized streams and FlexMux streams carried over an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream:

- The OCRs and FCRs in each SL-packetized stream and each FlexMux stream associated to the same scene shall have the same resolution.
- The resolution of OCRs and FCRs for a scene, f_{cr}, shall have a value smaller than or equal to 90 000 Hz.
- The ratio $(f_{stc}(t) / 300) / f_{cr}$, shall be an integer value larger than or equal to one. Consequently the resolution of the OCR and FCR syntax elements may only take values such as 90 000 Hz, 45 000 Hz, 30 000 Hz, 22 500 Hz, 18 000 Hz, etc.

Within the above constraints and the ISO/IEC 14496-1 constraint that the resolution f_{cr} shall represent an integer number of cycles per second, f_{cr} can be selected as appropriate for the scene.

The ISO/IEC 14496 time stamps coded in the SL packet header shall refer to instants of the object time base of the stream carried in the SL packet. The resolution of each such time stamp shall be of a factor 2^k smaller than the resolution of the OCRs or FCRs associated to the stream, with k a positive integer larger than or equal to zero. To achieve the same wrap around, the length of the time stamp fields, TimeStampLength, shall be k bit smaller than the length of the OCR or FCR field, OCRLength and FCRLength, respectively. Hence for each stream the following conditions shall apply for encoding of time stamps:

- TimeStampResolution = (OCRResolution or FCRResolution respectively) / 2^k, with k a positive integer larger than or equal to zero. ISO/IEC 14496-1 requires TimeStampResolution to represent an integer number of cycles per second.
- TimeStampLength = OCRLength or FCRLength respectively – k.

The relationship between a value of the STC and the corresponding value of the object time base of a stream is established by associating PTS fields in PES packet headers with the OCR or FCR in SL packet headers and FlexMux Stream packets, respectively, as specified in subclauses 2.11.3.6 and 2.11.3.7.

2.11.3.4 Delivery timing of SL-packetized streams

To carry ISO/IEC 14496 content in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream, ISO/IEC 14496-1 SL-packetized streams are used. In each SL-packetized stream carried in a PES packet without the use of FlexMux, the objectClockReference field shall be encoded as follows:

1) An objectClockReference (OCR) field shall be present in the first SL packet header of a SL-packetized stream.

2) The SL-packetized stream shall be constructed such that the time interval between the bytes containing the last bit of successive OCR fields shall be less than or equal to 0,7 second. Thus:

$$| t(i'') - t(i') | <= 0,7 \text{ s}$$

for all i' and i'' where i' and i'' are the indexes of the bytes containing the last bit of consecutive OCR fields in the FlexMux stream.

If an objectClockReference is encoded in an SL packet header, also the instantBitrate field shall be coded.

2.11.3.5 Delivery timing of FlexMux streams

Next to SL-packetized streams also the ISO/IEC 14496-1 FlexMux tool may be used to carry ISO/IEC 14496 content in ITU-T Rec. H.222.0 | ISO/IEC 13818-1 streams. The payload of FlexMux packets shall consist of SL packets as specified in ISO/IEC 14496-1. In each FlexMux stream carried in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream the fmxClockReference field shall be encoded as follows:

1) An fmxClockReference (FCR) field shall be present in the first FlexMux packet of a FlexMux stream.

2) The FlexMux stream shall be constructed such that the time interval between the bytes containing the last bit of successive FCR fields shall be less than or equal to 0,7 second. Thus:

$$| t(i'') - t(i') | <= 0,7 \text{ s}$$

for all i' and i'' where i' and i'' are the indexes of the bytes containing the last bit of consecutive FCR fields in the FlexMux stream.

3) All ISO/IEC 14496 time stamps within the SL-packetized streams carried within a FlexMux stream shall refer to instants of the object time base conveyed by the FCR fields in the FlexMux stream. The SL-packetized streams carried in FlexMux packets need not carry OCR fields. If OCR fields are present, they may be ignored.

2.11.3.6 Carriage of SL-packetized streams in PES packets

A single ISO/IEC 14496-1 SL-packetized stream may be mapped into a single PES stream. One and only one SL packet from an SL-packetized stream shall constitute the payload of one PES packet. PES packets that carry an SL-packetized stream shall be identified by stream_id = 0xFA in the PES packet header.

When an OCR field is coded in the SL packet header, a PTS shall be encoded in the header of the PES packet that carries such SL packet header. This PTS shall be encoded with the 33 bit value of the 90 kHz portion of the STC that corresponds to the value of the object time base at the instant in time indicated by the OCR.

The ES_ID associated to the SL-packetized stream shall be signaled by an SL descriptor as specified in 2.6.46.

2.11.3.7 Carriage of FlexMux streams in PES packets

PES packets with a payload consisting of FlexMux packets shall be identified by stream_id = 0xFB in the PES packet header. An integer number of FlexMux packets shall constitute the payload of one PES packet, i.e., the payload of a PES packet carrying a FlexMux stream shall start with a FlexMux packet header and shall end with the last byte of a FlexMux packet.

If an fmxClockReference (FCR) field is encoded in one of the FlexMux packets contained in a PES packet, then a PTS shall be encoded in the header of the PES packet that contains such FlexMux packet. This PTS shall be encoded with the 33 bit value of the 90 kHz portion of the STC that corresponds to the value of the object time base of the FlexMux stream at the instant in time indicated by the FCR. In case multiple FlexMux packets with an encoded FCR field are contained in a PES packet, the PTS shall correspond to the time indicated by the FCR in the first such FlexMux packet encountered in the payload of the PES packet.

The ES_IDs associated to each SL-packetized stream conveyed in the FlexMux stream shall be signaled by an FMC descriptor as specified in 2.6.38.

2.11.3.8 Carriage of SL packets and FlexMux packets in sections

For transport of ISO/IEC 14496 content in sections, ISO_IEC_14496_sections are defined. Only SL-packetized object descriptor streams and scene description streams shall use ISO_IEC_14496_sections. A single ISO_IEC_14496_section shall contain either an entire SL packet of an SL-packetized stream or an integer number of FlexMux packets each carrying an SL packet of the same ISO/IEC 14496-1 elementary stream.

Table 2-64 shows the syntax of ISO_IEC_14496_sections defined to convey ISO/IEC 14496-1 elementary streams, qualified by the table_id as either object descriptor or scene description stream data. Object descriptor stream data consists of an Object Descriptor Table that comprises a number of object descriptors. The Object Descriptor Table may be transmitted in multiple ISO_IEC_14496_sections. Scene description data consists of a Scene Description Table that may comprise a number of BIFS commands. The Scene Description Table may be transmitted in multiple ISO_IEC_14496_sections. It is not required that a complete table be received in order to process its payload. However, the payload of sections shall be processed in the correct order, as indicated by the value of the section_number field in the ISO_IEC_14496_section header bytes.

Table 2-64 – Section syntax for transport of ISO/IEC14496 streams

Syntax	No. of bits	Mnemonic
ISO_IEC_14496_section() {		
table_id	**8**	**uimsbf**
section_syntax_indicator	**1**	**bslbf**
private_indicator	**1**	**bslbf**
reserved	**2**	**bslbf**
ISO_IEC_14496_section_length	**12**	**uimsbf**
table_id_extension	**16**	**uimsbf**
reserved	**2**	**bslbf**
version_number	**5**	**uimsbf**
current_next_indicator	**1**	**bslbf**
section_number	**8**	**uimsbf**
last_section_number	**8**	**uimsbf**
if (PMT_has_SL_descriptor(current_PID)) {		
SL_Packet()		
}		
else if (PMT_has_FMC_descriptor(current_PID)) {		
for (i=1; i<N; i++)		
FlexMuxPacket()		
}		
else {		
for (i=1; i<N; i++)		
reserved	**8**	**bslbf**
}		
CRC_32	**32**	**rpchof**
}		

table_id – This 8-bit field shall be set to '0x04' or '0x05' in case of an ISO_IEC_14496_section. A value of '0x04' indicates an ISO_IEC_14496_scene_description_section that carries an ISO/IEC 14496-1 scene description stream. A value of '0x05' indicates an ISO_IEC_14496_object_descriptor_section that carries an ISO/IEC 14496-1 object descriptor stream.

section_syntax_indicator – This 1-bit field shall be set to '1'.

private_indicator – This 1-bit field shall not be specified by this Specification.

ISO_IEC_14496_section_length – This 12-bit field shall specify the number of remaining bytes in the section immediately following the ISO_IEC_14496_section_length field up to the end of the ISO_IEC_14496_section. The value of this field shall not exceed 4093 (0xFFD).

table_id_extension – This 16-bit field shall not be specified by this Specification; its use and value are define by the user.

version_number – This 5-bit field shall represent the version number of the Object Descriptor Table or Scene Description Table respectively. The version number shall be incremented by 1 modulo 32 with each new version of the table. Version control is at the discretion of the application.

current_next_indicator – This 1-bit field shall be set to 1.

section_number – This 8-bit field shall represent the number of the ISO_IEC_14496_section. The section_number field of the first ISO_IEC_14496_section of the Object Descriptor Table or the Scene Description Table shall have a value equal to 0x00. The value of section_number shall be incremented by 1 with each additional section in the table.

last_section_number – This 8-bit field shall specify the number of the last section of the Object Descriptor Table or Scene Description Table of which this section is a part.

PMT_has_SL_descriptor(current_PID) – a pseudo function that shall be true if an SL descriptor is contained in the descriptor loop in the Program Map Table for the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program element that conveys this ISO_IEC_14496_section.

SL_Packet() – a sync layer packet as specified in subclause 10.2.2 of ISO/IEC 14496-1.

PMT_has_FMC_descriptor(current_PID) – a pseudo function that shall be true if an FMC descriptor is contained in the descriptor loop in the Program Map Table for the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program element that conveys this ISO_IEC_14496_section.

FlexMuxPacket() – a FlexMux packet as specified in subclause 11.2.4 of ISO/IEC 14496-1.

CRC_32 – This 32-bit field shall contain the CRC value that gives a zero output of the registers in the decoder defined in Annex A of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 after processing the entire ISO_IEC_14496_section.

2.11.3.9 T-STD extensions

2.11.3.9.1 T-STD Model for 14496 content

Figure 2-5 shows extensions of the Transport System Target Decoder for delivery of ISO/IEC 14496 program elements encapsulated in ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Transport Streams.

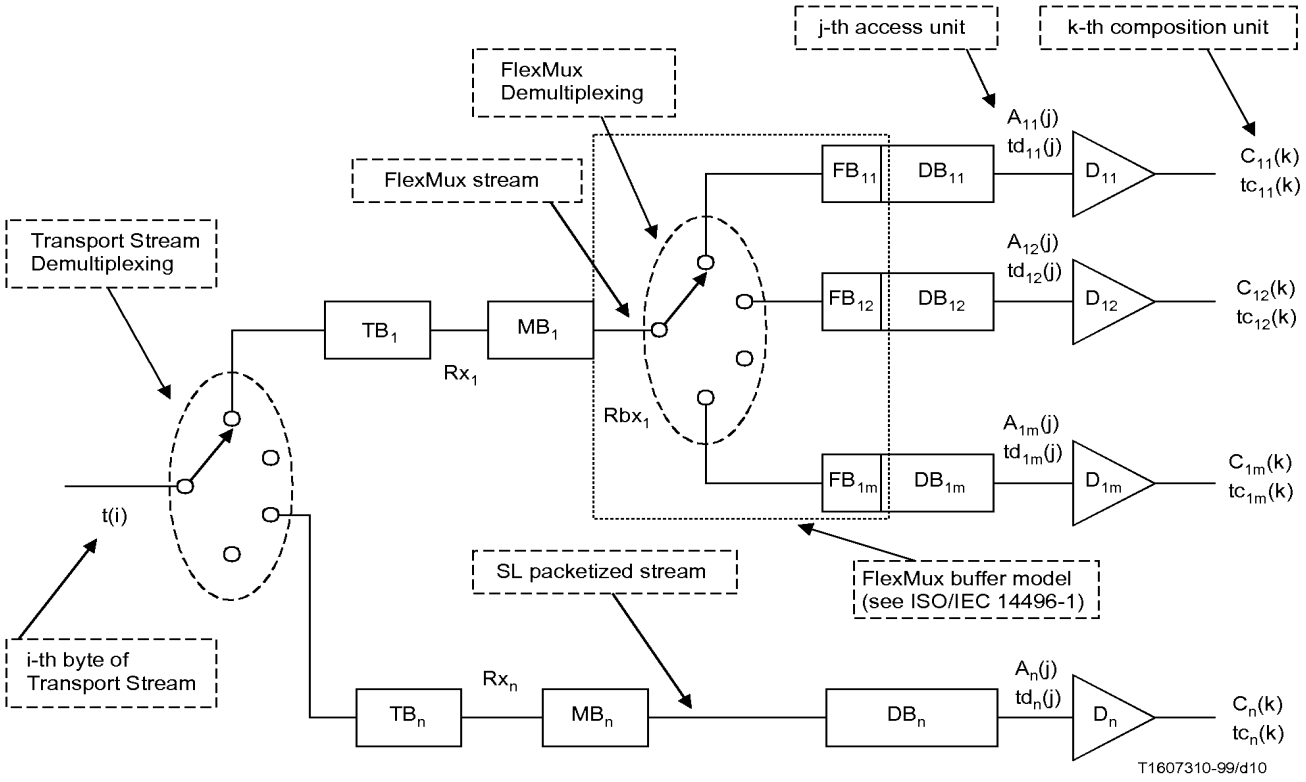

Figure 2-5 – T-STD model for ISO/IEC 14496 content

The following notation is used in Figure 2-5 and its description:

TB_n is the transport buffer.

MB_n is the multiplex buffer for FlexMux stream n or for SL-packetized stream n.

FB_{np} is the FlexMux buffer for the elementary stream in FlexMux channel p of FlexMux stream n.

DB_{np} is the decoder buffer for the elementary stream in FlexMux channel p of FlexMux stream n.

DB_n is the decoder buffer for elementary stream n.

D_{np} is the decoder for the elementary stream in FlexMux channel p of FlexMux stream n.

D_n is the decoder for elementary stream n.

Rx_n is the rate at which data are removed from TB_n.

Rbx_n is the rate at which data are removed from MB_n.

$A_{np}(j)$ is the jth access unit in elementary stream in FlexMux channel p of FlexMux stream n. $A_{np}(j)$ is indexed in decoding order.

$A_n(j)$ is the jth access unit in elementary stream n. $A_n(j)$ is indexed in decoding order.

$Td_{np}(j)$ is the decoding time, measured in seconds, in the system target decoder of the jth access unit in elementary stream in FlexMux channel p of FlexMux stream n.

$Td_n(j)$ is the decoding time, measured in seconds, in the system target decoder of the jth access unit in elementary stream n.

$C_{np}(k)$ is the kth composition unit in elementary stream in FlexMux channel p of FlexMux stream n. $C_{np}(k)$ results from decoding $A_{np}(j)$. $C_{np}(k)$ is indexed in composition order.

$C_n(k)$ is the kth composition unit in elementary stream n. $C_n(k)$ results from decoding $A_n(j)$. $C_n(k)$ is indexed in composition order.

$tc_{np}(k)$ is the composition time, measured in seconds, in the system target decoder of the kth composition unit in elementary stream in FlexMux channel p of FlexMux stream n.

$tc_n(k)$ is the composition time, measured in seconds, in the system target decoder of the kth composition unit in elementary stream n.

t(i) indicates the time in seconds at which the ith byte of the Transport Stream enters the system target decoder.

2.11.3.9.2 Processing of FlexMux streams

Complete Transport Stream packets containing data from FlexMux stream n are passed to the transport buffer for FlexMux stream n, TB_n. The size of TB_n is fixed at 512 bytes. All bytes that enter TB_n are removed from TB_n at a rate Rx_n, specified by the TB_leak_rate field in the MultiplexBuffer descriptor associated with FlexMux stream n. When there is no data in buffer TB_n, rate Rx_n is equal to zero. Duplicate Transport Stream packets are not delivered to MB_n.

In case of carriage in PES packets, the PES packet header and payload data bytes are delivered to buffer MB_n; all other bytes leaving TB_n do not enter MB_n, and may be used to control the system. In case of carriage in ISO_IEC_14496_sections, the section header, payload and CRC32 data bytes are delivered to buffer MB_n; all other bytes do not enter MB_n and may be used to control the system. In either case, the size of MB_n shall be specified by the MB_buffer_size field in the MultiplexBuffer descriptor.

The FlexMux Stream packet bytes in buffer MB_n are all delivered to their associated FlexMux buffer at the rate specified by the field fmxRate encoded in the FlexMux stream and in compliance with the FlexMux buffer model defined in subclause 11.2.9 of ISO/IEC 14496-1. Only FlexMux packet payload data bytes in FlexMux channel p of FlexMux stream n enter buffer FB_{np}. FlexMux packet header bytes in FlexMux channel p of FlexMux stream n are discarded and may be used to control the system. The rate specified by the fmxRate field shall be applicable for all FlexMux packets in the stream immediately following the FlexMux Clock Reference channel packet up to the next encountered FlexMux Clock Reference channel packet. When there is no FlexMux stream data present in MB_n, no data is removed from MB_n. Bytes from the PES packet header or from the ISO_IEC_14496_section header that immediately precede a FlexMux header are instantaneously removed and discarded and may be used to control the system. Bytes from the ISO_IEC_14496_section CRC32 fields that immediately follow the last FlexMux Stream packet in the section payload are removed instantaneously and discarded and may be used to verify the integrity of the data. Bytes from the FlexMux Clock Reference channel are instantaneously removed and discarded and may be used to lock the ISO/IEC 14496 object time base to the STC. When there is no PES packet or section payload data bytes, respectively present in MB_n, no data is removed from MB_n. All data that enters MB_n leaves it. All PES packet payload bytes of stream n enter the FlexMux demultiplexer instantaneously upon leaving MB_n.

2.11.3.9.3 Definition of FlexMux Buffer, FB_{np}

For each channel p of a FlexMux stream n, the size of FlexMux buffer FB_{np} is defined using the FmxBufferSize descriptor. FlexMux packet payload bytes are transferred from buffer FB_{np} to decoder buffer DB_{np} in compliance with the FlexMux buffer model defined in subclause 11.2.9 of ISO/IEC 14496-1. Only SL packet payload bytes in FlexMux channel p of FlexMux stream n enter buffer DB_{np}. The SL packet header bytes in FlexMux channel p of FlexMux stream n are discarded and may be used to control the system.

2.11.3.9.4 Processing of SL-packetized streams

Complete Transport Stream packets containing data from SL-packetized stream n are passed to the transport buffer for SL-packetized stream n, TB_n. All bytes that enter TB_n are removed at a rate Rx_n, specified by the TB_leak_rate field in the MultiplexBuffer descriptor. When there is no data in buffer TB_n, rate Rx_n is equal to zero. Duplicate Transport Stream packets are not delivered to MB_n.

In case of carriage in PES packets, the PES packet header and payload data bytes are delivered to buffer MB_n; all other bytes leaving TB_n do not enter MB_n, and may be used to control the system. In case of carriage in ISO_IEC_14496_sections, the section header, payload and CRC32 data bytes are delivered to buffer MB_n; all other bytes do not enter MB_n and may be used to control the system. In either case the size of MB_n is specified by the MB_buffer_size field in the MultiplexBuffer descriptor.

The SL-packetized stream bytes in buffer MB_n are all delivered to the decoder buffer DB_n at the rate specified by the field instantBitRate encoded in the SL-packetized stream and in compliance with the System Decoder Model defined in subclause 7.4 of ISO/IEC 14496-1. The rate specified by the instantBitRate field shall be applicable for all data bytes in the SL-packetized stream immediately following the instantBitRate field in the SL packet header up to the next encountered instantBitRate field. If there are no SL-packetized stream bytes in MB_n, no bytes are removed from MB_n. Bytes from the PES packet header or from the ISO_IEC_14496_section header that immediately precede a SL packet header are instantaneously removed and discarded and may be used to control the system. Bytes from the ISO_IEC_14496_section CRC32 fields that immediately follow the last SL packet payload byte in the section are removed instantaneously and discarded and may be used to verify the integrity of the data. When there are no PES packet or section payload data bytes, respectively present in MB_n, no data is removed from MB_n. All data that enters MB_n leaves it. All PES packet payload bytes of stream n enter buffer DB_n instantaneously upon leaving MB_n, with the exception of the SL packet headers. Bytes from the SL packet headers do not enter DB_n and may be used to control the system. The size of decoder buffer DB_n is given by the bufferSizeDB of the DecoderConfigDescriptor defined in ISO/IEC 14496-1.

2.11.3.9.5 Buffer management

Transport streams shall be constructed so that conditions defined in this subclause are satisfied.

TB_n shall not overflow and shall be empty at least once every second. MB_n shall not overflow. FB_{np} shall not overflow. DB_{np} and DB_n shall neither underflow nor overflow. Underflow of DB_{np} occurs when one or more bytes of an access unit are not present in DB_{np} at the decoding time associated with this access unit. Underflow of DB_n occurs when one or more bytes of an access unit are not present in DB_n at the decoding time associated with this access unit.

2.11.3.10 Carriage within a Transport Stream

2.11.3.10.1 Overview

A Transport Stream may contain one or more programs, each described by a Program Map Table. ISO/IEC 14496 content can be conveyed in addition to the already defined stream types for such a program. Elements of the ISO/IEC 14496 content may be conveyed in one or more ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program elements referenced by a unique PID value within a Transport Stream. As a special case, it is possible that a program within a Transport Stream consists only of ISO/IEC 14496 program elements. ISO/IEC 14496 content associated to a program and carried in the Transport Stream shall be referenced in the Program Map Table of that program. An initial object descriptor shall be used to define an ISO/IEC 14496-1 scene; the use of this descriptor is specified in subclause 2.11.3.10.2.

Carriage of ISO/IEC 14496 content in a PID is signaled by a stream_type value of 0x12 or 0x13 in the Program Map Table in association with that PID value. A value of 0x12 indicates carriage in PES packets. The stream_id field in the PES packet header signals whether the PES packet contains a single SL packet or a number of FlexMux packets. A stream_type value of 0x13 in the Program Map Table indicates that the program element carries an object descriptor

stream or a BIFS-Command stream contained in sections. In this case the table_id in the section header indicates whether an object descriptor stream is carried in the sections or a BIFS-Command stream. See also table 2-65. The section contains either a single SL packet or a number of FlexMux packets, as indicated by the presence of an SL descriptor or a FMC descriptor respectively in the descriptor loop of the Program Map Table for the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 program element that carries the sections. When ISO/IEC 14496 content is carried, the SL descriptor and the FMC descriptor shall specify the ES_ID for each encapsulated ISO/IEC 14496 stream. When the assignment of ES_ID values changes, the Program Map Table shall be updated and the version_number of the PMT shall be incremented by 1 modulo 32. An example of a content access procedure for ISO/IEC 14496 program components within a Transport Stream is given in Annex R Carriage of ISO/IEC 14496 scenes in ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

Table 2-65 – ISO/IEC defined options for carriage of an ISO/IEC 14496 scene and associated streams in ITU-T Rec. H.222.0 | ISO/IEC 13818-1

ISO/IEC 14496-1 object descriptor streams	Encapsulation in SL packets	Carriage in PES packets	Stream_type = 0x12	Stream_id = '1111 1010'
		Carriage in ISO_IEC_ 14496_sections	Stream_type = 0x13	Table_id = 0x05
	Encapsulation in SL packets followed by Multiplex into FlexMux packets	Carriage in PES packets	Stream_type = 0x12	Stream_id = '1111 1011'
		Carriage in ISO_IEC_ 14496_sections	Stream_type = 0x13	Table_id = 0x05
ISO/IEC 14496-1 scene description streams	Encapsulation in SL packets	Carriage in PES packets	Stream_type = 0x12	Stream_id = '1111 1010'
		Carriage in ISO_IEC_ 14496_sections	Stream_type = 0x13	Table_id = 0x04
	Encapsulation in SL packets followed by Multiplex into FlexMux packets	Carriage in PES packets	Stream_type = 0x12	Stream_id = '1111 1011'
		Carriage in ISO_IEC_ 14496_sections	Stream_type = 0x13	Table_id = 0x04
All other ISO/IEC 14496 streams	Encapsulation in SL packets	Carriage in PES packets	Stream_type = 0x12	Stream_id = '1111 1010'
	Encapsulation in SL packets followed by Multiplex into FlexMux packets	Carriage in PES packets	Stream_type = 0x12	Stream_id = '1111 1011'

2.11.3.10.2 Initial Object Descriptor

In case of carriage of an ISO/IEC 14496-1 scene, the ISO/IEC 14496-1 initial object descriptor serves as the initial access point to all associated streams. The initial object descriptor shall be conveyed in the IOD descriptor located in the descriptor loop immediately following the program_info_length field in the Program Map Table of the program to which the scene is associated. It contains ES_Descriptors identifying the scene description and object descriptor streams that form part of this program. It may also contain ES_Descriptors identifying one or more associated IPMP or OCI streams. Identification of streams is done by means of ES_IDs as specified in clause 8 of ISO/IEC 14496-1.

2.11.3.11 P-STD Model for 14496 content

Figure 2-6 shows the STD model when ISO/IEC 14496 systems data are carried in a Program Stream.

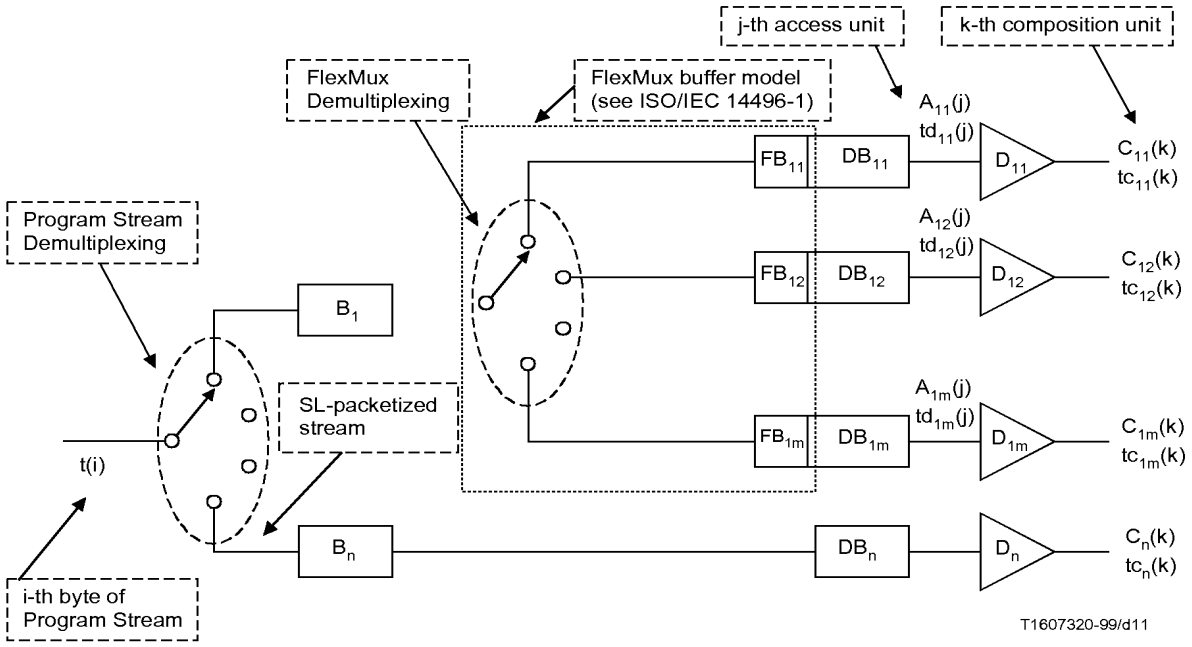

Figure 2-6 – P-STD model for ISO/IEC 14496 Systems stream

The following notation is used in Figure 2-6 and its description :

B_n is the input buffer for FlexMux stream n or for SL-packetized stream n.

FB_{np} is the FlexMux buffer for the elementary stream in FlexMux channel p of FlexMux stream n.

DB_{np} is the decoder buffer for the elementary stream in FlexMux channel p of FlexMux stream n.

DB_n is the decoder buffer for elementary stream n.

D_{np} is the decoder for elementary stream in FlexMux channel p of FlexMux stream n.

D_n is the decoder for elementary stream n.

$A_{np}(j)$ is the jth access unit in elementary stream in FlexMux channel p of FlexMux stream n. $A_{np}(j)$ is indexed in decoding order.

$A_n(j)$ is the jth access unit in elementary stream n. An(j) is indexed in decoding order.

$Td_{np}(j)$ is the decoding time, measured in seconds, in the system target decoder of the jth access unit in elementary stream in FlexMux channel p of FlexMux stream n.

$Td_n(j)$ is the decoding time, measured in seconds, in the system target decoder of the jth access unit in elementary stream n.

$C_{np}(k)$ is the kth composition unit in elementary stream in FlexMux channel p of FlexMux stream n. $C_{np}(k)$ results from decoding $A_{np}(j)$. $C_{np}(k)$ is indexed in composition order.

$C_n(k)$ is the kth composition unit in elementary stream n. $C_n(k)$ results from decoding $A_n(j)$. $C_n(k)$ is indexed in composition order.

$tc_{np}(k)$ is the composition time, measured in seconds, in the system target decoder of the kth composition unit in elementary stream in FlexMux channel p of FlexMux stream n.

$tc_n(k)$ is the composition time, measured in seconds, in the system target decoder of the kth composition unit in elementary stream n.

t(i) indicates the time in seconds at which the ith byte of the Program Stream enters the system target decoder.

2.11.3.11.1 Processing of FlexMux streams

At the input of the STD each byte in the payload of PES packets carrying a FlexMux stream n is transferred instantaneously to buffer B_n. The i-th byte enters B_n at time t(i). PES packet header bytes do not enter buffer B_n and may be used to control the system. The size of B_n is specified by the P-STD_buffer_size field in the header of the PES packet that carries stream n.

The FlexMux stream packet bytes in buffer B_n are all delivered to their associated FlexMux buffer at the rate specified by the field fmxRate encoded in the FlexMux stream and in compliance with the FlexMux buffer model defined in clause 11.2.9 of ISO/IEC 14496-1. Only FlexMux packet payload data bytes in FlexMux channel p of FlexMux stream n enter buffer FB_{np}. FlexMux packet header bytes in FlexMux channel p of FlexMux stream n are discarded and may be used to control the system. The rate specified by the fmxRate field shall be applicable for all FlexMux packets in the stream up to the next encountered FlexMux Clock Reference channel packet. Bytes from the FlexMux Clock Reference channel are instantaneously removed and discarded and may be used to lock the ISO/IEC 14496 object time base to the STC. When there is no PES packet payload data present in B_n, no data is removed from B_n. All data that enters B_n leaves it. All PES packet payload bytes of stream n enter the FlexMux demultiplexer instantaneously upon leaving B_n.

2.11.3.11.2 Definition of FlexMux Buffer, FB_{np}

For each channel p of a FlexMux stream n, the size of FlexMux buffer FB_{np} is defined using the FmxBufferSize descriptor if a Program Stream Map is present in the Program Stream. FlexMux packet payload bytes are transferred from buffer FB_{np} to decoder buffer DB_{np} in compliance with the FlexMux buffer model defined in subclause 11.2.9 of ISO/IEC 14496-1. Only SL packet payload bytes in FlexMux channel p of FlexMux stream n enter buffer DB_{np}. The SL packet header bytes in FlexMux channel p of FlexMux stream n are discarded and may be used to control the system

2.11.3.11.3 Processing of SL-packetized streams

At the input of the STD each byte in the payload of PES packets carrying an SL-packetized stream n is transferred instantaneously to buffer B_n. The i-th byte enters B_n at time t(i). PES packet header bytes do not enter buffer B_n and may be used to control the system. The size of B_n is specified by the P-STD_buffer_size field in the header of the PES packet that carries stream n. The SL-packetized stream bytes in buffer B_n are delivered to the decoder buffer DB_n at the rate specified by the field instantBitRate encoded in the SL-packetized stream and in compliance with the System Decoder Model defined in subclause 7.4 of ISO/IEC 14496-1. The rate specified by the instantBitRate field shall be applicable for all data bytes in the SL-packetized stream up to the next encountered instantBitRate field. When there is no PES packet payload data present in B_n, no data is removed from B_n. All data that enters B_n leaves it. All bytes of stream n enter buffer DB_n instantaneously upon leaving B_n, with the exception of the SL packet headers. Bytes from the SL packet headers do not enter DB_n and may be used to control the system. The size of decoder buffer DB_n is given by the bufferSizeDB of the DecoderConfigDescriptor defined in ISO/IEC 14496-1.

2.11.3.11.4 Buffer management

Program Streams shall be constructed so that B_n does not overflow. FB_{np} shall not overflow. DB_{np} and DB_n shall neither underflow nor overflow. Underflow of DB_{np} occurs when one or more bytes of an access unit are not present in DB_{np} at the decoding time associated with this access unit. Underflow of DB_n occurs when one or more bytes of an access unit are not present in DB_n at the decoding time associated with this access unit.

2.11.3.12 Carriage within a Program Stream

2.11.3.12.1 Overview

A Program Stream contains only one program. ISO/IEC 14496 data can be conveyed in addition to the already defined stream types for such a program. As a special case, it is also possible that a Program Stream carries only ISO/IEC 14496 data. If a Program Stream Map is present, ISO/IEC 14496 content carried in the Program Stream shall be referenced as follows. Carriage of ISO/IEC 14496-1 scenes and associated ISO/IEC 14496 streams in SL and FlexMux packets is indicated by the appropriate stream_id and by an initial object descriptor; the use of this descriptor is specified in subclause 2.11.3.12.2. For each carried ISO/IEC 14496 stream the SL descriptor and the FMC descriptor shall specify the ES_ID. When the assignment of ES_ID values changes, the Program Stream Map, if present, shall be updated and the program_stream_map_version shall be incremented by 1 modulo 32. Note that in a Program Stream the ISO/IEC 14496 content may also be referenced by private means.

For an example of a content access procedure for ISO/IEC 14496 program components within a Program Stream, see Annex R.

2.11.3.12.2 Initial Object Descriptor

In case of carriage of an ISO/IEC 14496-1 scene, the ISO/IEC 14496 initial object descriptor serves as the initial access point to all associated streams. If a Program Stream Map is present in the Program Stream, the initial object descriptor shall be conveyed in the IOD descriptor that is located in the descriptor loop immediately following the program_stream_info_length field. It contains ES_Descriptors identifying the scene description and object descriptor streams of the scene that form part of this program. It may also contain ES_Descriptors identifying one or more associated IPMP or OCI streams. Identification of streams is done by means of ES_IDs as specified in clause 8 of ISO/IEC 14496-1. In a Program Stream, the initial object descriptor may also be conveyed by private means.

Annex A

CRC Decoder Model

(This annex forms an integral part of this Recommendation | International Standard)

A.0 CRC decoder model

The 32-bit CRC Decoder Model is specified in Figure A.1.

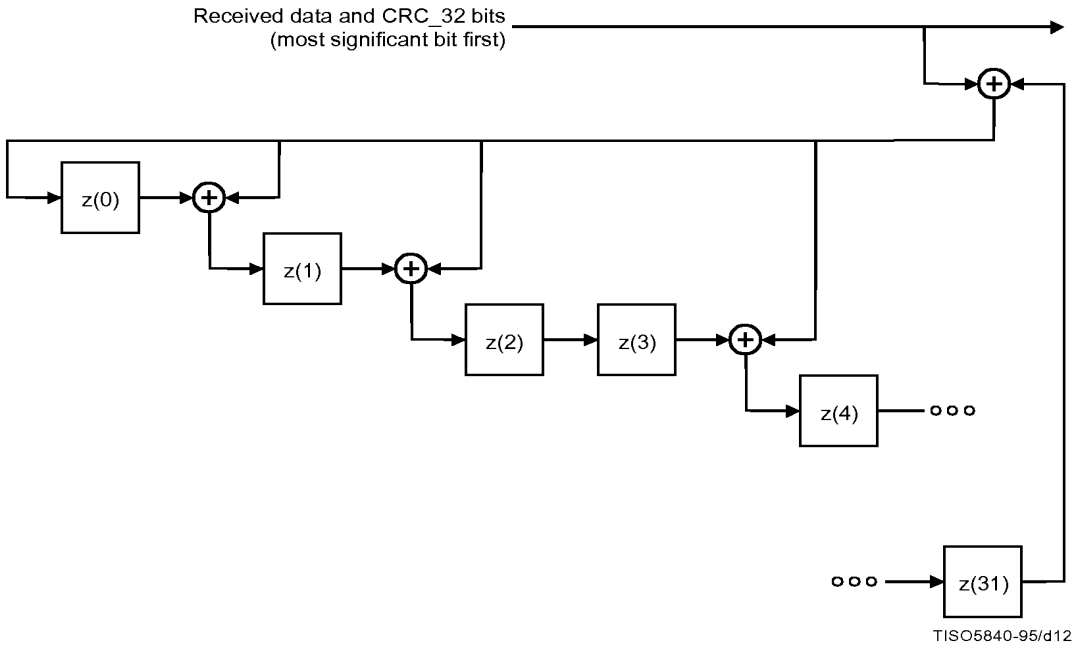

Figure A.1 – 32-bit CRC decoder model

The 32-bit CRC Decoder operates at bit level and consists of 14 adders '+' and 32 delay elements z(i). The input of the CRC decoder is added to the output of z(31), and the result is provided to the input z(0) and to one of the inputs of each remaining adder. The other input of each remaining adder is the output of z(i), while the output of each remaining adder is connected to the input of z(i + 1), with i = 0, 1, 3, 4, 6, 7 , 9, 10, 11, 15, 21, 22, and 25. Refer to Figure A.1 above.

This is the CRC calculated with the polynomial:

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \qquad \text{(A-1)}$$

Bytes are received at the input of the CRC decoder. Each byte is shifted into the CRC decoder one bit at a time, with the left most bit (msb) first. For example, if the input is byte 0x01 the seven '0's enter the CRC decoder first, followed by the one '1'. Before the CRC processing of the data of a section the output of each delay element z(i) is set to its initial value '1'. After this initialization, each byte of the section is provided to the input of the CRC decoder, including the four CRC_32 bytes. After shifting the last bit of the last CRC_32 byte into the decoder, i.e. into z(0) after the addition with the output of z(31), the output of all delay elements z(i) is read. In the case where there are no errors, each of the outputs of z(i) shall be zero. At the CRC encoder the CRC_32 field is encoded with a value such that this is ensured.

Annex B

Digital Storage Medium Command and Control (DSM-CC)

(This annex does not form an integral part of this Recommendation | International Standard)

B.0 Introduction

The DSM CC protocol is a specific application protocol intended to provide the basic control functions and operations specific to managing an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream on digital storage media. This DSM CC is a low-level protocol above network/OS layers and below application layers.

The DSM-CC shall be transparent in the following sense:

- it is independent of the DSM used;
- it is independent of whether the DSM is located at a local or remote site;
- it is independent of the network protocol with which the DSM-CC is interfaced;
- it is independent of the various operating systems on which the DSM is operated.

B.0.1 Purpose

Many applications of ITU-T Rec. H.222.0 | ISO/IEC 13818-1 DSM Control Commands require access to an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream stored on a variety of digital storage media at a local or remote site. Different DSM have their own specific control commands and thus, a user would need to know different sets of specific DSM control commands in order to access ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstreams from different DSM. This brings many difficulties to the interface design of an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 or ISO 11172-1 application system. To overcome this difficulty, a set of common DSM control commands, which is independent of the specific DSM used, is suggested in this annex. This annex is informative only. ISO/IEC 13818-6 defines DSM-CC extension with a broader scope.

B.0.2 Future applications

Beyond the immediate applications supported by the current DSM control commands, future applications based on extensions of DSM command control could include the following:

Video on demand

Video programs are provided as requested by a customer through various communication channels. The customer could select a video program from a list of programs available from a video server. Such applications could be used by hotels, cable TV, educational institutions, hospitals, etc.

Interactive video services

In these applications, the user provides frequent feedback controlling the manipulation of stored video and audio. These services can include video based games, user controlled video tours, electronic shopping, etc.

Video networks

Various applications may wish to exchange stored audio and video data through some type of computer network. Users could route AV information through the video network to their terminals. Electronic publishing and multimedia applications are examples of this kind of application.

B.0.3 Benefits

Specifying the DSM control commands independent of the DSM, end-users can perform ITU-T Rec. H.222.0 | ISO/IEC 13818-1 decoding without having to fully understand the detailed operation of the specific DSM used.

The DSM control commands are codes to give end users the assurance that the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstreams can be played and stored with the same semantics, independent of the DSM and user interface. They are fundamental commands for the control of DSM operation.

B.0.4 Basic functions

B.0.4.1 Stream selection

The DSM-CC provides the means to select an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream upon which to perform the succeeding operations. Such operations include creation of a new bitstream. Parameters of this function include:

- index of the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream (the mapping between this index and a name meaningful to an application is outside the scope of the current DSM-CC)
- mode (retrieval/storage)

B.0.4.2 Retrieval

The DSM CC provides the means to:

- play an identified ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream;
- play from a given presentation time;
- set the playback speed (normal or fast);
- set the playback duration (until a specified presentation time, the end of the bitstream in forward play or the beginning in reverse play or the issuance of a stop command);
- set the direction (forward or reverse);
- pause;
- resume;
- change the access point in the bitstream;
- stop.

B.0.4.3 Storage

The DSM-CC provides the means to:

- cause storage of a valid bitstream for a specified duration;
- cause storage to stop.

DSM-CC provides a useful but limited subset of functionality that may be required in DSM based ITU-T Rec. H.222.0 | ISO/IEC 13818-1 applications. It is fully expected that significant additional capabilities will be added through subsequent extensions.

B.1 General elements

B.1.1 Scope

The scope of this work consists of the development of a Recommendation | International Standard to specify a useful set of commands for control of digital storage media on which an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream is stored. The commands can perform remote control of a digital storage media in a general way independently of the specific DSM and apply to any ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream stored on a DSM.

B.1.2 Overview of the DSM-CC application

The current DSM-CC syntax and semantics cover the single user to DSM application. The user's system is capable of retrieving an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream and is also (optionally) capable of generating an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream. The control channel over which the DSM commands and acknowledgements are sent is shown in Figure B.1 as an out of band channel. This can also be accomplished by inserting the DSM-CC commands and acknowledgements into the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstreams if an out of band channel is not available.

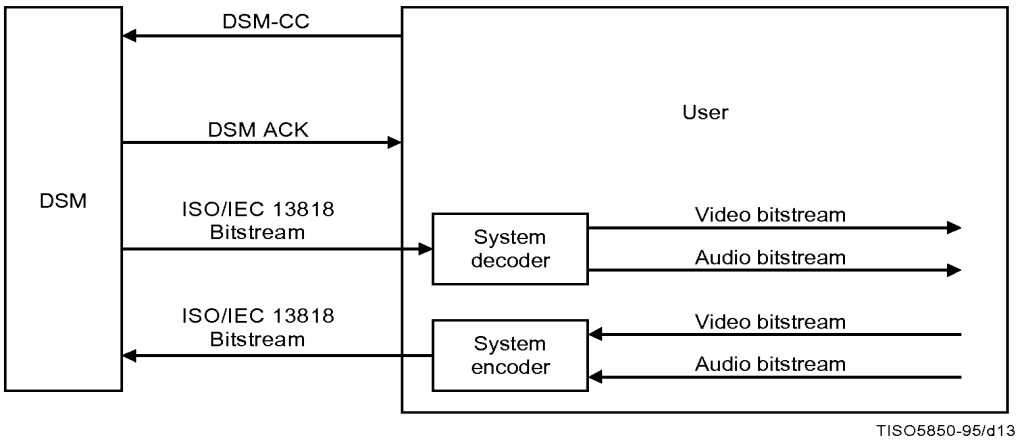

Figure B.1 – Configuration of DSM-CC application

B.1.3 The transmission of DSM-CC commands and acknowledgements

The DSM-CC is encoded into a DSM-CC bitstream according to the syntax and semantics defined in B.2.2 through B.2.9. The DSM-CC bitstream can be transmitted both as a stand-alone bitstream and in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Systems bitstream.

When the DSM-CC bitstream is transmitted in stand alone mode, its relationship to the Systems bitstream and the decoding process is illustrated in Figure B.2. In this case, the DSM-CC bitstream is not embedded in the Systems bitstream. This transmission mode can be used in the applications when the DSM is connected directly with the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 decoder. It can also be used in the applications where the DSM-CC bitstream could be controlled and transmitted by other types of network multiplexors.

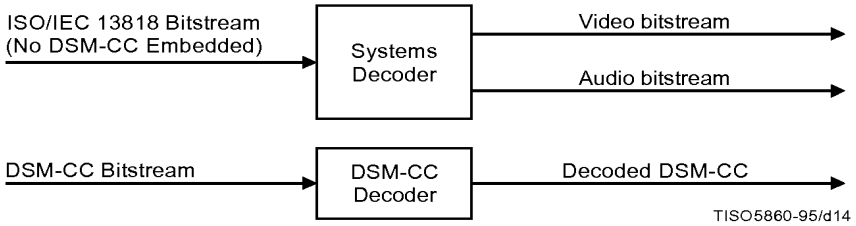

Figure B.2 – DSM-CC bitstream decoded as a standalone bitstream

For some applications, it is desirable to transmit the DSM-CC in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 systems bitstream so that some features of the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 systems bitstream could be applied to the DSM-CC bitstream as well. In this case, the DSM-CC bitstream is embedded in the systems bitstream by the systems multiplexor.

The DSM-CC bitstream is encoded by the systems encoder in the following process. First, the DSM-CC bitstream is packetized into a packetized elementary stream (PES) according to the syntax described in 2.4.3.6. The PES packet is then multiplexed into either a Program Stream (PS) or a Transport Stream (TS) according to the requirement of the transmission media. The decoding procedures are the inverse of the encoding procedures and are illustrated in the block diagram of the Systems decoder depicted in Figure B.3.

In Figure B.3, the output of the Systems decoder is a video bitstream, audio bitstream and/or DSM-CC bitstream. The DSM-CC bitstream is identified by the stream_id, value '1111 0010' as defined by the stream_id Table 2-18. Once the DSM-CC bitstream is identified, it follows the rules as specified by T-STD or P-STD.

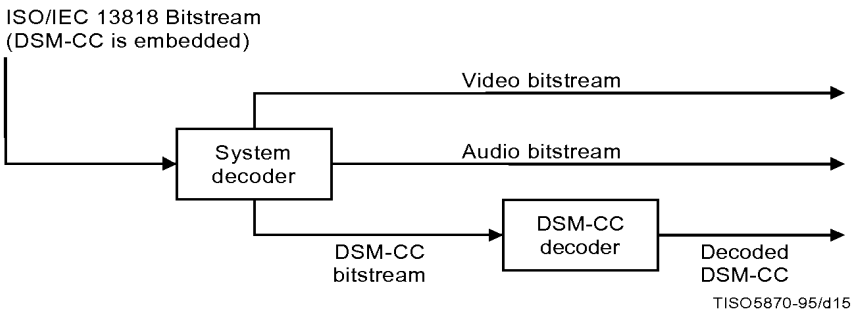

Figure B.3 – DSM-CC bitstream decoded as part of the system bitstream

B.2 Technical elements

B.2.1 Definitions

For the purposes of this Recommendation | International Standard, the following definitions apply:

B.2.1.1 DSM-CC: Digital Storage Media Command and Control Commands that are specified by Rec. H.222.0 | ISO/IEC 13818-1 for the control of digital storage media at a local or remote site containing an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream.

B.2.1.2 DSM ACK: The acknowledgement from the DSM-CC command receiver to the command initiator.

B.2.1.3 MPEG bitstream: An ISO/IEC 11172-1 Systems stream, ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Stream or ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Transport stream.

B.2.1.4 DSM-CC server: A system, either local or remote, used to store and/or retrieve an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream.

B.2.1.5 point of random access: A point in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream with the property that for at least one elementary stream within the bitstream, the next access unit, 'N', completely contained in the bitstream can be decoded without reference to previous access units, and for every elementary stream in the bitstream all access units with the same or later presentation times are completely contained subsequently in the bitstream and can be completely decoded by a system target decoder without access to information prior to the point of random access. The bitstream as stored on the DSM may have certain points of random access; the output of the DSM may include additional points of random access manufactured by the DSM's own manipulation of the stored material (e.g. storing quantization matrices so that a sequence header can be generated whenever necessary). A point of random access has an associated PTS, namely the actual or implied PTS of access unit 'N'.

B.2.1.6 current operational PTS value: The actual or implied PTS associated with the last point of random access preceding the last access unit provided from the DSM from the currently selected ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream. If no access unit has been provided from this ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream, the DSM is incapable of providing random access into the current bitstream, then the current operational PTS value is the first point of random access in the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream.

B.2.1.7 DSM-CC bitstream: A sequence of bits satisfying the syntax of B.2.2.

B.2.2 Specification of DSM-CC syntax

- Every DSM control command shall commence with a start_code, as specified in Table B.1.
- Every DSM control command shall have a packet_length to specify the number of byte in a DSM-CC packet.
- When the DSM-CC bitstream is transmitted as a PES packet as defined in 2.4.3.6, the fields up to the packet_length field are identical to those specified in 2.4.3.6. In other words, if the DSM-CC packet is encapsulated in a PES packet, the PES packet start code is the only start code at the beginning of the packet.

- The actual control command or acknowledgement shall follow the last byte of the packet_length field.
- An acknowledgement stream shall be provided by the DSM control bitstream receiver after the requested operation is started or is completed, depending on the command received.
- At all times the DSM is responsible for providing a normative ITU-T Rec. H.222.0 | ISO/IEC 13818-1 stream. This may include manipulating the trick mode bits defined in 2.4.3.6.

Table B.1 – DSM-CC syntax

Syntax	No. of bits	Mnemonic
DSM_CC() {		
packet_start_code_prefix	**24**	**bslbf**
stream_id	**8**	**uimsbf**
packet_length	**16**	**uimsbf**
command_id	**8**	**uimsbf**
If (command_id == '01') {		
control()		
} else if (command_id == '02') {		
ack()		
}		
}		

B.2.3 Semantics of fields in specification of DSM-CC syntax

packet_start_code_prefix – This is a 24-bit code. Together with the stream_id that follows it constitutes a DSM-CC packet start code that identifies the beginning of a DSM-CC packet bitstream. The packet_start_code_prefix is the bit string '0000 0000 0000 0000 0000 0001' (0x000001).

stream_id – This 8-bit field specifies the bitstream type and shall have a value '1111 0010' for the DSM-CC bitstream. Refer to Table 2-19.

packet_length – This 16-bit field specifies the number of bytes in the DSM-CC packet immediately following the last byte of this field.

command_id – This 8-bit unsigned integer identifies the bitstream is a control command or an acknowledgement stream. The values are defined in Table B.2.

Table B.2 – Command_id assigned values

Value	**Command_id**
0x00	Forbidden
0x01	Control
0x02	Ack
0x03-0xFF	Reserved

B.2.4 Control layer

Constraints on setting flags in DSM-CC control

- At most one of the flags for select, playback and storage shall be set to '1' for each DSM control command. If none of these bits are set, then this command shall be ignored.
- At most one of pause_mode, resume_mode, stop_mode, play_flag, and jump_flag shall be set for each retrieval command. If none of these bits are set, then this command shall be ignored.
- At most one of record_flag and stop_mode shall be selected for each storage command. If none of these bits are set, then this command shall be ignored.

See Table B.3.

Table B.3 – DSM-CC control

Syntax	No. of bits	Mnemonic
control() {		
select_flag	**1**	**bslbf**
retrieval_flag	**1**	**bslbf**
storage_flag	**1**	**bslbf**
reserved	**12**	**bslbf**
marker_bit	**1**	**bslbf**
If (select_flag == '1') {		
bitstream_id [31..17]	**15**	**bslbf**
marker_bit	**1**	**bslbf**
bitstream_id [16..2]	**15**	**bslbf**
marker_bit	**1**	**bslbf**
bitstream_id [1..0]	**2**	**bslbf**
select_mode	**5**	**bslbf**
marker_bit	**1**	**bslbf**
}		
if (retrieve_flag == '1') {		
jump_flag	**1**	**bslbf**
play_flag	**1**	**bslbf**
pause_mode	**1**	**bslbf**
resume_mode	**1**	**bslbf**
stop_mode	**1**	**bslbf**
reserved	**10**	**bslbf**
marker_bit	**1**	**bslbf**
if (jump_flag == '1') {		
reserved	**7**	**bslbf**
direction_indicator	**1**	**bslbf**
time_code()		
}		
if (play_flag == '1'){		
speed_mode	**1**	**bslbf**
direction_indicator	**1**	**bslbf**
reserved	**6**	**bslbf**
time_code()		
}		
}		
if (storage_flag == '1') {		
reserved	**6**	**bslbf**
record_flag	**1**	**bslbf**
stop_mode	**1**	**bslbf**
if (record_flag == '1') {		
time_code()		
}		
}		
}		

B.2.5 Semantics of fields in control layer

marker_bit – This is a 1-bit marker that is always set to '1' to avoid start code emulation.

reserved_bits – This 12-bit field is reserved for future use by this Recommendation | International Standard for DSM control commands. Until otherwise specified by ITU-T | ISO/IEC it shall have the value '0000 0000 0000'.

select_flag – This 1-bit flag when set to '1' specifies a bitstream selection operation. When it is set to '0' no bitstream selection operation shall occur.

retrieval_flag – This 1-bit flag when set to '1' specifies that a specific retrieval (playback) action will occur. The operation starts from the current operational PTS value.

storage_flag – This 1-bit flag when set to '1' specifies that a storage operation is to be executed.

bitstream_ID – This 32-bit field is coded in three parts. The parts are combined to form an unsigned integer specifying which ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream is to be selected. It is the DSM server's responsibility to map the names of the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstreams stored on its DSM uniquely to a series of numbers which could be represented by the bitstream_ID.

select_mode – This 5-bit unsigned integer specifies which mode of bitstream operation is requested. Table B.4 specifies the defined modes.

Table B.4 – Select mode assigned values

Code	Mode
0x00	Forbidden
0x01	Storage
0x02	Retrieval
0x03-0x1F	Reserved

jump_flag – This 1-bit flag when set to '1' specifies a jump in the playback pointer to a new access unit. The new PTS is specified by a relative time_code with respect to the current operational PTS value. This function is only valid when the current ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream is in the "stop" mode.

play_flag – This 1-bit flag when set to '1' specifies to play a bitstream for a certain time period. The speed, direction, and play duration are additional parameters in the bit stream. The play starts from the current operational PTS value.

pause_mode – This is a one-bit code specifying to pause the playback action and keep the playback pointer at the current operational PTS value.

resume_mode – This is a one-bit code specifying to continue the playback action from the current operational PTS value. Resume only has meaning if the current bitstream is in the "pause" state, and the bitstream will be set to the forward play state at normal speed.

stop_mode – This is a one-bit code specifying to stop a bitstream transmission.

direction_indicator – This is a one-bit code to indicate the playback direction. If this bit is set to '1', it stands for a forward play. Otherwise it stands for a backward play.

speed_mode – This is a 1-bit code to specify the speed scale. If this bit is set to '1', it specifies that the speed is normal play. If this bit is set to '0', it specifies that the speed is fast play (i.e. fast forward or fast reverse).

record_flag – This is one-bit flag to specify the request of recording the bitstream from an end user to a DSM for a specified duration or until the reception of a stop command, whichever comes first.

B.2.6 Acknowledgement layer

Constraints on setting flags in DSM-CC control

Only one of the acks bits specified below can be set to '1' for each DSM ack bitstream (see Table B.5).

Table B.5 – DSM-CC Acknowledgement

Syntax	No. of bits	Mnemonic
ack() {		
select_ack	**1**	**bslbf**
retrieval_ack	**1**	**bslbf**
storage_ack	**1**	**bslbf**
error_ack	**1**	**bslbf**
reserved	**10**	**bslbf**
marker_bit	**1**	**bslbf**
cmd_status	**1**	**bslbf**
If (cmd_status == '1' &&		
(retrieval_ack == '1' || storage_ack == '1')) {		
time_code()		
}		
}		

B.2.7 Semantics of fields in Acknowledgement layer

select_ack – This 1-bit field when it is set to '1' indicates that the ack() command is to acknowledge a select command.

retrieval_ack – This 1-bit field when set to '1' indicates that the ack() command is to acknowledge a retrieval command.

storage_ack – This 1-bit field when set to '1' indicates that the ack() command is to acknowledge a storage command.

error_ack – This 1-bit field when set to '1' indicates a DSM error. The defined errors are EOF (end of file on forward play or start of file on reverse play) on a stream being retrieved and Disk Full on a stream being stored. If this bit is set to '1', cmd_status is undefined. The current bitstream is still selected.

cmd_status – This 1-bit flag set to '1' indicates that the command is accepted. When set to '0' it indicates the command is rejected. The semantics vary according to the command received as follows:

- If select_ack is set and cmd_status is set to '1', it specifies that the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream is selected and the server is ready to provide the selected mode of operation. The current operational PTS value is set to the first point of random access of the newly selected ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream. If cmd_status is set to '0', the operation has failed and no bitstream is selected.

- If retrieval_ack is set and cmd_status is set to '1', it specifies that the retrieval operation is initiated for all retrieval commands. The position of the current operational PTS pointer is reported by the succeeding time_code.

- For the play_flag command with infinite_time_flag != '1', a second acknowledgement will be sent. This will acknowledge that the play operation has ended by reaching the duration defined by the play_flag command.

- If the cmd_status is set to '0' in a retrieval acknowledgement, the operation has failed. Possible reasons for this failure include an invalid bitstream_ID, jumping beyond the end of a file, or a function not supported such as reverse play in standard speed.

- If storage_ack is set, it specifies that the storage operation is being started for the record_flag command or is completed by the stop_mode command. The PTS of the last complete access unit stored is reported by the succeeding time_code.

- If the recording operation is ended by reaching the duration defined by the storage_flag command, another acknowledgement shall be sent and the current operational PTS value after the recording shall be reported.

- If the cmd_status is set to '0' in a storage acknowledgement, the operation has failed. Possible reasons for this failure include an invalid bitstream_ID, or the inability of the DSM to store data.

B.2.8 Time code

Constraints on time code

- A forward operation of specified duration given by a time_code terminates after the actual or implied PTS of an access unit is observed such that PTS minus the current operational PTS value at the start of the operation modulo 2^{33} exceeds the duration.
- A backward operation of specified duration given by a time_code terminates after the actual or implied PTS of an access unit is observed such that current operational PTS value at the start of the operation minus that PTS modulo 2^{33} exceeds the duration.
- For all the commands in the control() layer, the time_code is specified as a relative duration with respect to the current operational PTS value.
- For all the commands in the ack() layer, the time_code is specified by the current operational PTS value.

See Table B.6.

Table B.6 – Time code

Syntax	No. of bits	Mnemonic
time_code() {		
reserved	**7**	**bslbf**
infinite_time_flag	**1**	**bslbf**
if (infinite_time_flag == '0') {		
reserved	**4**	**bslbf**
PTS [32..30]	**3**	**bslbf**
marker	**1**	**bslbf**
PTS [29..15]	**15**	**bslbf**
marker_bit	**1**	**bslbf**
PTS [14..0]	**15**	**bslbf**
marker_bit	**1**	**bslbf**
}		
}		

B.2.9 Semantics of fields in time code

infinite_time_flag – This 1-bit flag when set to '1' indicates an infinite time period. This flag is set to '1' in applications where a time period for a specific operation could not be defined in advance.

PTS [32..0] – The presentation timestamp of the access unit of the bitstream. Depending upon the function, this can be an absolute value or a relative time delay in cycles of the 90 kHz system clock.

Annex C

Program Specific Information

(This annex does not form an integral part of this Recommendation | International Standard)

C.0 Explanation of Program Specific Information in Transport Streams

Subclause 2.4.4 contains the normative syntax, semantics and text concerning Program Specific Information. In all cases, compliance with the constraints of 2.4.4 is required. This annex provides explanatory information on how to use the PSI functions, and considers examples of how it may be used in practice.

C.1 Introduction

This Recommendation | International Standard provides a method for describing the contents of Transport Stream packets for the purpose of the demultiplexing and presentation of programs. The coding specification accommodates this function through the Program Specific Information (PSI). This annex discusses the use of PSI.

The PSI may be thought of as belonging to four tables:

1) Program Association Table (PAT);
2) TS Program Map Table (PMT);
3) Network Information Table (NIT);
4) Conditional Access Table (CAT).

The contents of the PAT, PMT and CAT are specified in this Recommendation | International Standard. The NIT is a private table, but the PID value of the Transport Stream packets which carry it is specified in the PAT. It must however, follow the section structure defined in this Recommendation | International Standard.

C.2 Functional Mechanism

The tables listed above are conceptual in that they need never be regenerated in a specified form within a decoder. While these structures may be thought of as simple tables, they may be partitioned before they are sent in Transport Stream packets. The syntax supports this operation by allowing the tables to be partitioned into sections and by providing a normative mapping method into Transport Stream packet payloads. A method is also provided to carry private data in a similar format. This is advantageous as the same basic processing in the decoder can then be used for both the PSI data and the private data helping to keep cost down. For advice on the optimum placing of PSI in the Transport Stream, see Annex D.

Each section is uniquely identified by the combination of the following elements:

i) **table_id**

The 8-bit table_id identifies to which table the section belongs.

- Sections with table_id 0x00 belong to the Program Association Table.
- Sections with table_id 0x01 belong to the Conditional Access Table.
- Sections with table_id 0x02 belong to the TS Program Map Table.

Other values of the table_id can be allocated by the user for private purposes.

It is possible to set up filters looking at the table_id field to identify whether a new section belongs to a table of interest or not.

ii) **table_id_extension**

This 16-bit field exists in the long version of a section. In the Program Association Table it is used to identify the transport_stream_id of the stream – effectively a user-defined label which allows one Transport Stream to be distinguished from another within a network or across networks. In the Conditional Access Table this field currently has no meaning and is therefore marked as "reserved" meaning that it shall be coded as 0xFFFF, but that a meaning may be defined by ITU-T | ISO/IEC in a subsequent revision of this Recommendation | International Standard. In a TS Program Map section the field contains the program_number, and thereby identifies the program to which the data in the section refers. The table_id_extension can also be used as a filter point in certain cases.

iii) **section_number**

The section_number field allows the sections of a particular table to be reassembled in their original order by the decoder. There is no obligation within this Recommendation | International Standard that sections must be transmitted in numerical order, but this is recommended, unless it is desired to transmit some sections of the table more frequently than others, e.g. due to random access considerations.

iv) **version_number**

When the characteristics of the Transport Stream described in the PSI change, (e.g. extra programs added, different composition of elementary streams for a given program), then new PSI data has to be sent with the updated information as the most recently transmitted version of the sections marked as "current" must always be valid. Decoders need to be able to identify whether the most recently received section is identical with the section they have already processed/stored (in which case the section can be discarded), or whether it is different, and may therefore signify a configuration change. This is achieved by sending a section with the same table_id, table_id_extension, and section_number as the previous section containing the relevant data, but with the next value version_number.

v) **current_next_indicator**

It is important to know at what point in the bitstream the PSI is valid. Each section can therefore be numbered as valid "now" (current), or as valid in the immediate future (next). This allows the transmission of a future configuration in advance of the change, giving the decoder the opportunity to prepare for the change. There is however no obligation to transmit the next version of a section in advance, but if it is transmitted, then it shall be the next correct version of that section.

C.3 The Mapping of Sections into Transport Stream Packets

Sections are mapped directly into Transport Stream packets, that is to say without a prior mapping into PES packets. Sections do not have to start at the beginning of Transport Stream packets, (although they may), because the start of the first section in the payload of a Transport Stream packet is pointed to by the pointer_field. The presence of the pointer_field is signalled by the payload_unit_start_indicator being set to a value of '1' in PSI packets. (In non-PSI packets, the indicator signals that a PES packet starts in the Transport Stream packet). The pointer_field points to the start of the first section in the Transport Stream packet. There is never more than one pointer_field in a Transport Stream packet, as the start of any other section can be identified by counting the length of the first and any subsequent sections, since no gaps between sections within a Transport Stream packet are allowed by the syntax.

It is important to note that within Transport Stream packets of any single PID value, one section must be finished before the next one is allowed to be started, or else it is not possible to identify to which section header the data belongs. If a section finishes before the end of a Transport Stream packet, but it is not convenient to open another section, a stuffing mechanism is provided to fill up the space. Stuffing is performed by filling each remaining byte of the packet with the value 0xFF. Consequently the table_id value 0xFF is forbidden, or else this would be confused with stuffing. Once a 0xFF byte has occurred at the end of a section, then the rest of the Transport Stream packet must be stuffed with 0xFF bytes, allowing a decoder to discard the rest of the Transport Stream packet. Stuffing can also be performed using the normal adaptation_field mechanism.

C.4 Repetition Rates and Random Access

In systems where random access is a consideration, it is recommended to re-transmit PSI sections several times, even when changes do not occur in the configuration, as in the general case, a decoder needs the PSI data to identify the contents of the Transport Stream, to be able to start decoding. This Recommendation | International Standard does not place any requirements on the repetition or occurrence rate of PSI sections. Clearly though, repeating sections frequently helps random access applications, whilst causing an increase in the amount of bitrate used by PSI data. If program mappings are static or quasi-static, they may be stored in the decoder to allow faster access to the data than having to wait for it to be re-transmitted. The trade-off between the amount of storage required and the desired impact on channel acquisition time may be made by the decoder manufacturer.

C.5 What is a Program?

The concept of a program has a precise definition within this Recommendation | International Standard [refer to 2.1.42 program (system)]. For a Transport Stream the time base is defined by the PCR. This effectively creates a virtual channel within the Transport Stream.

Note that this is not the same definition as is commonly used in broadcasting, where a "program" is a collection of elementary streams not only with a common timebase, but also with a common start and end time. A series of "broadcaster programs" (referred to in this annex as events) can be transmitted sequentially in a Transport Stream using the same program_number to create a "broadcasting conventional" TV-channel (sometimes called a service).

Event descriptions could be transmitted in private_sections().

A program is denoted by a program_number which has significance only within a Transport Stream. The program_number is a 16-bit unsigned integer and thus permits 65535 unique programs to exist within a Transport Stream (program_number 0 is reserved for identification of the NIT). Where several Transport Streams are available to the decoder (e.g. in a cable network), in order to successfully demultiplex a program, the decoder must be notified of both the transport_stream_id (to find the right multiplex) and the program_number of the service (to find the right program within the multiplex).

The Transport Stream mapping may be accomplished via the optional Network Information Table. Note that the Network Information Table may be stored in decoder non-volatile memory to reduce channel acquisition time. In this case, it needs to be transmitted only often enough to support timely decoder initialization set-up operations. The contents of the NIT are private, but shall take at least the minimum section structure.

C.6 Allocation of program_number

It may not be convenient in all cases to group together all the program element which share a common clock reference as one program. It is conceivable to have a multi-service Transport Stream with only one set of PCRs, common to all. In general, though, a broadcaster may prefer to logically split up the Transport Stream into several programs, where the PCR_PID (location of the clock reference) is always the same. This method of splitting the program elements into pseudo-independent programs can have several uses. Two examples follow:

i) *multilingual transmissions into separate markets*

One video stream may be accompanied by several audio streams in different languages. It is advisable to include an example of the ISO_639_language_descriptor associated with each audio stream to enable the selection of the correct program and audio. It is reasonable to have several program definitions with different program_numbers, where all the programs reference the same video stream and PCR_PID, but have different audio PIDs. It is, however, also reasonable and possible to list the video stream and all the audio streams as one program, where this does not exceed the section size limit of 1024 bytes.

ii) *Very large program definitions*

There is a maximum limit on the length of a section of 1024 bytes (including section header and CRC_32). This means that no single program definition may exceed this length. For the great majority of cases, even with each program element having several descriptors, this size is adequate. However, one may envisage cases in very high bitrate systems, which could exceed this limit. It is then in general possible to identify methods of splitting the references of the streams, so that they do not all have to be listed together. Some program elements could be referenced under more than one program, and some under only one or the other, but not both.

C.7 Usage of PSI in a Typical System

A communications system, especially in broadcast applications, may consist of many individual Transport Streams. Each one of the four PSI data structures may appear in each and every Transport Stream in a system. There must always be a complete version of the program association table listing all programs within the Transport Stream and a complete TS program map table, containing complete program definitions for all programs within the Transport Stream. If any streams are scrambled, then there must also be a conditional access table present listing the relevant Entitlement Management Messages (EMM) streams. The presence of a NIT is fully optional.

The PSI tables are mapped into Transport Stream packets via the section structure described above. Each section has a table_id field in its header, allowing sections from PSI tables and private data in private_sections to be mixed in Transport Stream packets of the same PID value or even in the same Transport Stream packet. Note, however, that within packets of the same PID, a complete section must be transmitted before the next section can be started. This is only possible for packets labelled as containing TS Program Map Table section or NIT packets however, since private sections may not be mapped into PAT or CAT packets.

It is required that all PAT sections be mapped into Transport Stream packets with PID = 0x0000 and all CA sections be mapped into packets with PID = 0x0001. PMT sections may be mapped into packets of user-selected PID value, listed as the PMT_PID for each program in the Program Association Table. Likewise, the PID for the NIT-bearing Transport Stream packets is user-selected, but must be pointed to by the entry "program_number == 0x00" in the PAT, if the NIT exists.

The contents of any CA parameter streams are entirely private, but EMMs and ECMs must also be sent in Transport Stream packets to be compliant with this Recommendation | International Standard.

Private data tables may be sent using the private_section() syntax. Such tables could be used for example in a broadcasting environment to describe a service, an upcoming event, broadcast schedules and related information.

C.8 The Relationships of PSI Structures

Figure C.1 shows an example of the relationship between the four PSI structures and the Transport Stream. Other examples are possible, but the figure shows the primary connections.

In the following subclauses, each PSI table is described.

C.8.1 Program Association Table

Every Transport Stream must contain a complete valid Program Association Table. The Program Association Table gives the correspondence between a program_number and the PID of the Transport Stream packets that carry the definition of that program (the PMT_PID). The PAT may be partitioned into up to 255 sections before it is mapped into Transport Stream packets. Each section carries a part of the overall PAT. This partitioning may be desirable to minimize data loss in error conditions. That is, packet loss or bit errors may be localized to smaller sections of the PAT, thus allowing other sections to still be received and correctly decoded. If all PAT information is put into one section, an error causing a changed bit in the table_id, for example, would cause the loss of the entire PAT. However, this is still permitted as long as the section does not extend beyond the 1024-byte maximum length limit.

Program 0 (zero) is reserved and is used to specify the Network PID. This is a pointer to the Transport Stream packets which carry the Network Information Table.

The Program Association Table is always transmitted without encryption.

C.8.2 Program Map Table

The Program Map Table provides the mapping between a program number and the program elements that comprise it. This table is present in Transport Stream packets having one or more privately-selected PID values. These Transport Stream packets may contain other private structures as defined by the table_id field. It is possible to have TS PMT sections referring to different programs carried in Transport Stream packets having a common PID value.

This Recommendation | International Standard requires a minimum of program identification: program number, PCR PID, stream types and program elements PIDs. Additional information for either programs or elementary streams may be conveyed by use of the descriptor() construct. Refer to C.8.6.

Private data may also be sent in Transport Stream packets denoted as carrying TS program map table sections. This is accomplished by the use of the private_section(). In a private_section() the application decides whether version_number and current_next_indicator represent the values of these fields for a single section or whether they are applicable to many sections as parts of a larger private table.

NOTE 1 – Transport stream packets containing the Program Map Table are transmitted unencrypted.

NOTE 2 – It is possible to transmit information on events in private descriptors carried within the TS_program_map_section()s.

C.8.3 Conditional Access Table

The Conditional Access (CA) Table gives the association between one or more CA systems, their EMM streams and any special parameters associated with them.

NOTE – The (private) contents of the Transport Stream packets containing EMM and CA parameters if present will, in general, be encrypted (scrambled).

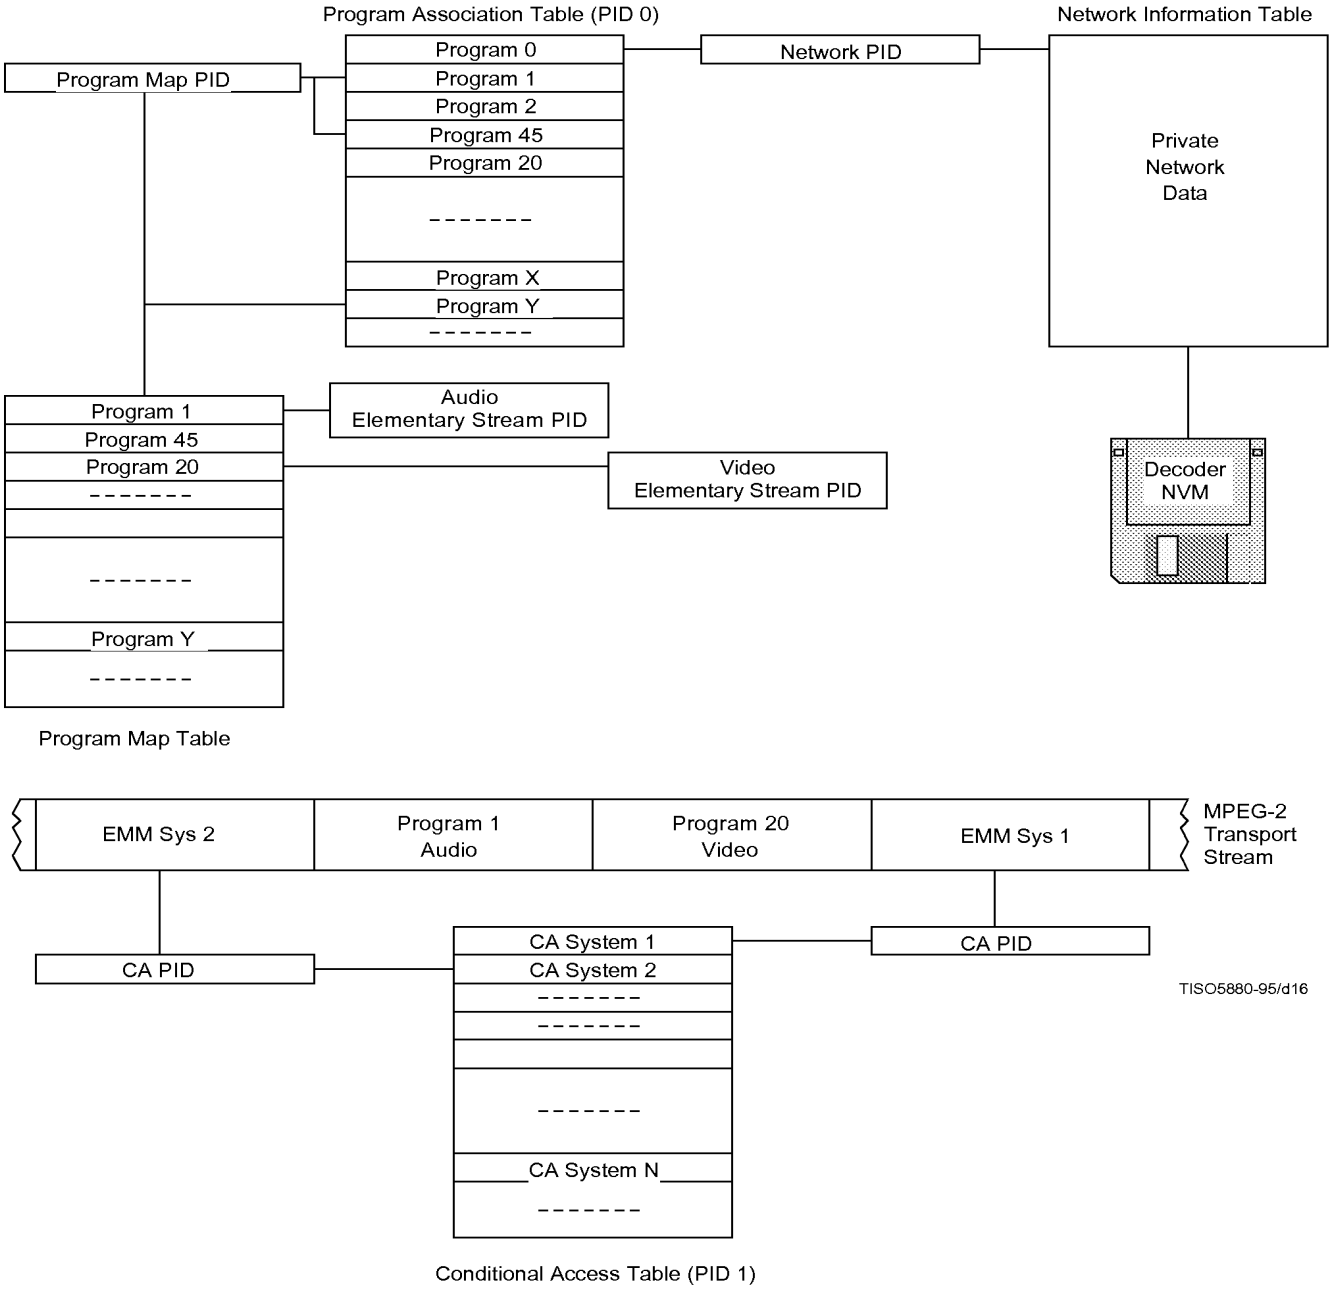

Figure C.1 – Program and network mapping relationships

C.8.4 Network Information Table

The contents of the NIT are private and not specified by this Recommendation | International Standard. In general, it will contain mappings of user-selected services with transport_stream_ids, channel frequencies, satellite transponder numbers, modulation characteristics, etc.

C.8.5 Private_section()

Private_sections() can occur in two basic forms, the short version (where only the fields up to and including section_length are included) or the long version (where all the fields up to and including last_section_number are present, and after the private data bytes the CRC_32 field is present).

Private_section()s can occur in PIDs which are labelled as PMT_PIDs or in Transport Stream packets with other PID values which contain exclusively private_sections(), including the PID allocated to the NIT. If the Transport Stream packets of the PID carrying the private_section()s are identified as a PID carrying private_sections (stream_type assignment value 0x05), then only private_sections may occur in Transport Stream packets of that PID value. The sections may be either of the short or long type.

C.8.6 Descriptors

There are several normative descriptors defined in this Recommendation | International Standard. Many more private descriptors may also be defined. All descriptors have a common format: {tag, length, data}. Any privately defined descriptors must adhere to this format. The data portion of these private descriptors are privately defined.

One descriptor (the CA_descriptor()), is used to indicate the location (PID value of transport packets) of ECM data associated with program elements when it is found in a TS PMT section. When found in a CA section it refers to EMMs.

In order to extend the number of private_descriptors available, the following mechanism could be used: A private descriptor_tag could be privately defined to be constructed as a composite descriptor. This entails privately defining a further sub_descriptor as the first field of the private data bytes of the private descriptor. The described structure is as indicated in Tables C.1 and C.2.

Table C.1 – Composite_descriptor

Syntax	No. of bits	Mnemonic
Composite_descriptor(){		
descriptor_tag(privately defined)	**8**	**uimsbf**
descriptor_length	**8**	**uimsbf**
for (i = 0; i < N; i++){		
sub_descriptor()		
}		
}		

Table C.2 – Sub-descriptor

Syntax	No. of bits	Mnemonic
sub_descriptor() {		
sub_descriptor_tag	**8**	**uimsbf**
sub_descriptor_length	**8**	**uimsbf**
for (i = 0; i < N; i++) {		
private_data_byte	**8**	**uimsbf**
}		
}		

C.9 Bandwidth Utilization and Signal Acquisition Time

Any implementation of an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bitstream must make reasonable bandwidth demands for PSI information and, in applications where random access is a consideration, should promote fast signal acquisition. This subclause analyses this issue and gives some broadcast application examples.

The packet-based nature of the Transport Stream allows for the interspersing of PSI information with fine granularity in the multiplexed data. This provides significant flexibility in the construction and transmission of PSI.

Signal acquisition time in a real decoder is dependent on many factors, including: FDM tuning slew time, demultiplexing time, sequence headers, I-frame occurrence rate and scrambling key retrieval and processing.

This subclause examines both the bitrate and signal acquisition time impacts of the PSI syntax subclauses 2.4.4.4 and 2.4.4.9. It is assumed that the Conditional Access Table does not need to be received dynamically at every program change. This assumption is also made of the private EMM streams. This is because these streams do not contain the quickly-varying ECM components used for program element scrambling (encryption).

Also, in the discussion below, the time to acquire and process ECMs has been neglected.

Tables C.3 and C.4 provide bandwidth usage values for a range of Transport Stream conditions. One axis of the table is the number of programs contained in a single Transport Stream. The other axis is the frequency with which the PSI information is transmitted in the Transport Stream.

This frequency will be a key determinant of the component of signal acquisition time due to PSI structures.

Both bandwidth usage tables assume that only the minimum program mapping information is provided. This means that the PID values and stream types are provided with no additional descriptors. All programs in the example are composed of two elementary streams. Program associations are 2 bytes long, while the minimal program map is 26 bytes long. There is additional overhead associated with version numbers, section lengths, etc. This will be on the order of 1-3% of the total PSI bitrate usage in sections of moderate to maximum length (a few hundred bytes to 1024 bytes) and will thus be ignored here.

The above assumptions allow forty-six (46) program associations to map into one Program Association Table Transport Stream packet (if no adaptation field is present). Similarly, seven (7) TS_program_map_sections fit into a single Transport Stream packet. It may be noted that to facilitate easy "drop/add" it is possible to transmit only one (1) TS_program_map_section per PMT_PID. This may cause an undesirable increase in PSI bitrate usage, however.

Table C.3 – Program association table bandwidth usage (bit/s)

Number of Programs Per Transport Stream

		1	5	10	32	128
Frequency of PA Table Information (s^{-1})	1	1504	1504	1504	1504	4512
	10	15040	15040	15040	15040	45120
	25	37600	37600	37600	37600	112800
	50	75200	75200	75200	75200	225600
	100	150400	150400	150400	150400	451200
NOTE – Since 46 **program_association_sections** fit into one transport packet, the numbers in the table do not change until the last column.						

Table C.4 – Program map table bandwidth usage (bit/s)

Number of Programs Per Transport Stream

		1	5	10	32	128
Frequency of PM Table Information (s^{-1})	1	1504	1504	3008	7520	28576
	10	15040	15040	30080	75200	285760
	25	37600	37600	75200	188000	714400
	50	75200	75200	150400	376000	1428800
	100	150400	150400	300800	601600	2857600

Using a frequency of 25 Hz for the two PSI Tables, yields a worst case contribution to the signal acquisition time of approximately 80 ms. This would only occur when the required PAT data was "just missed" and then, once the PAT was acquired and decoded, the required PMT data was also "just missed". This doubling of the worst case acquisition time is one disadvantage of the extra level of indirection introduced by the PAT structure. This effect could be reduced by co-ordinated transmission of related PAT and PMT packets. Presumably, the advantage that this approach offers for "drop/add" re-multiplexing operations is compensatory.

With the 25 Hz PSI frequency, the following examples may be constructed (all examples leave ample allowance for various datalink, FEC, CA and routing overheads):

6 MHz CATV channel

- five 5.2-Mbit/s programs: 26.5 Mbit/s (includes transport overhead)
- total PSI bandwidth: 5.2 kbit/s
- CA bandwidth: 500 kbit/s

  total ITU-T Rec. H.222.0 | ISO/IEC 13818-1 transport bandwidth: 27.1 Mbit/s
- PSI Overhead: 0.28 %

OC-3 fiber channel (155 Mbit/s)

- 32 3.9-Mbit/s programs: 127.5 Mbit/s (includes transport overhead)
- total PSI bandwidth: 225.6 kbit/s
- CA bandwidth: 500 kbit/s

  total ITU-T Rec. H.222.0 | ISO/IEC 13818-1 transport bandwidth: 128.2 Mbit/s
- PSI Overhead: 0.18 %

C-band satellite transponder

- 128 256-kbit/s audio programs: 33.5 Mbit/s (includes transport overhead)
- total PSI bandwidth: 826.4 kbit/s
- CA bandwidth: 500 kbit/s

  total ITU-T Rec. H.222.0 | ISO/IEC 13818-1 transport bandwidth: 34.7 Mbit/s
- PSI Overhead: 2.4 % (actually would be lower if only one PID used per program)

As expected, the percent overhead increases for lower-rate services since many more services are possible per Transport Stream. However, the overhead is not excessive in all cases. Higher transmission rates (than 25 Hz) for the PSI data may be used to decrease the impact on channel acquisition time with only modest bitrate demand increases.

Annex D

Systems Timing Model and Application Implications of this Recommendation | International Standard

(This annex does not form an integral part of this Recommendation | International Standard)

D.0 Introduction

The ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Systems specification includes a specific timing model for the sampling, encoding, encoder buffering, transmission, reception, decoder buffering, decoding, and presentation of digital audio and video in combination. This model is embodied directly in the specification of the syntax and semantic requirements of compliant ITU-T Rec. H.222.0 | ISO/IEC 13818-1 data streams. Given that a decoding system receives a compliant bit stream that is delivered correctly in accordance with the timing model it is straightforward to implement the decoder such that it produces as output high quality audio and video which are properly synchronized. There is no normative requirement, however, that decoders be implemented in such a way as to provide such high quality presentation output. In applications where the data are not delivered to the decoder with correct timing, it may be possible to produce the desired presentation output, however such capabilities are not in general guaranteed. This informative annex describes the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Systems timing model in detail, and gives some suggestions for implementing decoder systems to suit some typical applications.

D.0.1 Timing Model

ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Systems embodies a timing model in which all digitized pictures and audio samples that enter the encoder are presented exactly once each, after a constant end to end delay, at the output of the decoder. As such, the sample rates, i.e. the video frame rate and the audio sample rate, are precisely the same at the decoder as they are at the encoder. This timing model is diagrammed in Figure D.1:

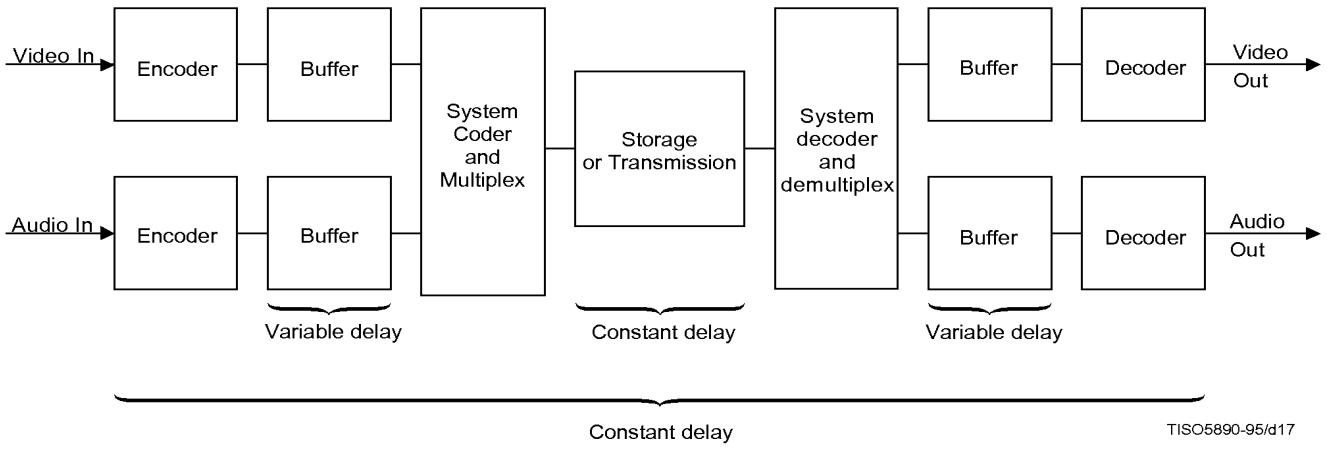

Figure D.1 – Constant delay model

As indicated in Figure D.1, the delay from the input to the encoder to the output or presentation from the decoder is constant in this model[1)], while the delay through each of the encoder and decoder buffers is variable. Not only is the delay through each of these buffers variable within the path of one elementary stream, the individual buffer delays in the video and audio paths differ as well. Therefore the relative location of coded bits representing audio or video in the combined stream does not indicate synchronization information. The relative location of coded audio and video is constrained only by the System Target Decoder (STD) model such that the decoder buffers must behave properly; therefore coded audio and video that represent sound and pictures that are to be presented simultaneously may be separated in time within the coded bit stream by as much as one second, which is the maximum decoder buffer delay that is allowed in the STD model.

1) Constant delay as indicated for the entire system is required for correct synchronizaton, however some deviations are possible. Network delay is discussed as being constant. Slight deviations may be tolerated, and network adaptation may allow greater variations of network delay. Both of these are discussed later.

The audio and video sample rates at the encoder are significantly different from one another, and may or may not have an exact and fixed relationship to one another, depending on whether the combined stream is a Program Stream or a Transport Stream, and on whether the System_audio_locked and System_video_locked flags are set in the Program Stream. The duration of a block of audio samples (an audio presentation unit) is generally not the same as the duration of a video picture.

There is a single, common system clock in the encoder, and this clock is used to create timestamps that indicate the correct presentation and decoding timing of audio and video, as well as to create timestamps that indicate the instantaneous values of the system clock itself at sampled intervals. The timestamps that indicate the presentation time of audio and video are called Presentation Time Stamps (PTS). Those that indicate the decoding time are called Decoding Timestamps (DTS), and those that indicate the value of the system clock are called the System Clock Reference (SCR) in Program Streams and the Program Clock Reference (PCR) in Transport Streams. It is the presence of this common system clock in the encoder, the timestamps that are created from it, and the recreation of the clock in the decoder and the correct use of the timestamps that provide the facility to synchronize properly the operation of the decoder.

Encoder implementations may not follow this model exactly, however the data stream which results from the actual encoder, storage system, network, and one or more multiplexor must follow the model precisely. (Delivery of the data may deviate somewhat, depending on the application). Therefore in this annex, the term "encoder system clock" is used to mean either the actual common system clock as described in this model or the equivalent function, however it may be implemented.

Since the end-to-end delay through the entire system is constant, the audio and video presentations are precisely synchronized. The construction of System bit streams is constrained such that when they are decoded by a decoder that follows this model with the appropriately sized decoder buffers, those buffers are guaranteed never to overflow nor underflow, with specific exceptions allowing intentional underflow.

In order for the decoder system to incur the precise amount of delay that causes the entire end-to-end delay to be constant, it is necessary for the decoder to have a system clock whose frequency of operation and absolute instantaneous value match those of the encoder. The information necessary to convey the encoder's system clock is encoded in the SCR or PCR; this function is explained below.

Decoders which are implemented in accordance with this timing model such that they present audio samples and video pictures exactly once (with specific intentionally coded exceptions), at a constant rate, and such that decoder buffers behave as in the model, are referred to in this annex as precisely timed decoders, or those that produce precisely timed output. Decoder implementations are not required by this International Standard to present audio and video in accordance with this model; it is possible to construct decoders that do not have constant delay, or equivalently do not present each picture or audio sample exactly once. In such implementations, however, the synchronization between presented audio and video may not be precise, and the behaviour of the decoder buffers may not follow the reference decoder model. It is important to avoid overflow at the decoder buffers, as overflow causes a loss of data that may have significant effects on the resulting decoding process. This annex covers primarily the operation of such precisely timed decoders and some of the options that are available in implementing these decoders.

D.0.2 Audio and Video Presentation Synchronization

Within the coding of this Recommendation | International Standard Systems data are timestamps concerning the presentation and decoding of video pictures and blocks of audio samples. The pictures and blocks are called "Presentation Units", abbreviated PU. The sets of coded bits which represent the PUs and which are included within the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 bit stream are called "Access Units", abbreviated AU. An audio access unit is abbreviated AAU, and a video access unit is abbreviated VAU. In ISO/IEC 13818-3 audio the term "audio frame" has the same meaning as AAU or APU (audio presentation unit) depending on the context. A video presentation unit (VPU) is a picture, and a VAU is a coded picture.

Some, but not necessarily all, AAUs and VAUs have associated with them PTSs. A PTS indicates the time that the PU which results from decoding the AU which is associated with the PTS should be presented to the user. The audio PTSs and video PTSs are both samples from a common time clock, which is referred to as the System Time Clock or STC. With the correct values of audio and video PTSs included in the data stream, and with the presentation of the audio and video PUs occurring at the time indicated by the appropriate PTSs in terms of the common STC, precise synchronization of the presented audio and video is achieved at the decoding system. While the STC is not part of the normative content of this Recommendation | International Standard, and the equivalent information is conveyed in this Recommendation | International Standard via such terms as the system_clock_frequency, the STC is an important and convenient element for explaining the timing model, and it is generally practical to implement encoders and decoders which include an STC in some form.

PTSs are required for the conveyance of accurate relative timing between audio and video, since the audio and video PUs generally have significantly different and essentially unrelated duration. For example, audio PUs of 1152 samples each at a sample rate of 44 100 samples per second have a duration of approximately 26,12 ms, and video PUs at a frame rate of 29,97 Hz have a duration of approximately 33,76 ms. In general the temporal boundaries of APUs and VPUs rarely, if ever, coincide. Separate PTSs for audio and video provide the information that indicates the precise temporal relation of audio and video PUs without requiring any specific relationship between the duration and interval of audio and video PUs.

The values of the PTS fields are defined in terms of the System Target Decoder or STD, which is a fundamental normative constraint on all System bit streams. The STD is a mathematical model of an idealized decoder which specifies precisely the movement of all bits into and out of the decoder's buffers, and the basic semantic constraint imposed on the bit stream is that the buffers within the STD must never overflow nor underflow, with specific exceptions provided for underflow in special cases. In the STD model the virtual decoder is always exactly synchronized with the data source, and audio and video decoding and presentation are exactly synchronized. While exact and consistent, the STD is somewhat simplified with respect to physical implementations of decoders in order to clarify its specification and to facilitate its broad application to a variety of decoder implementations. In particular, in the STD model each of the operations performed on the bit stream in the decoder is performed instantaneously, with the obvious exception of the time that bits spend in the decoder buffers. In a real decoder system the individual audio and video decoders do not perform instantaneously, and their delays must be taken into account in the design of the implementation. For example, if video pictures are decoded in exactly one picture presentation interval 1/P, where P is the frame rate, and compressed video data are arriving at the decoder at bit rate R, the completion of removing bits associated with each picture is delayed from the time indicated in the PTS and DTS fields by 1/P, and the video decoder buffer must be larger than that specified in the STD model by R/P. The video presentation is likewise delayed with respect to the STD, and the PTS should be handled accordingly. Since the video is delayed, the audio decoding and presentation should be delayed by a similar amount in order to provide correct synchronization. Delaying decoding and presentation of audio and video in a decoder may be implemented for example by adding a constant to the PTS values when they are used within the decoder.

Another difference between the STD and precise practical decoder implementation is that in the STD model the explicit assumption is made that the final audio and video output is presented to the user instantaneously and without further delay. This may not be the case in practice, particularly with cathode-ray tube displays, and this additional delay should also be taken into account in the design. Encoders are required to encode audio and video such that the correct synchronization is achieved when the data is decoded with the STD. Delays in the input and sampling of audio and video, such as video camera optical charge integration, must be taken into account in the encoder.

In the STD model proper synchronization is assumed and the timestamps and buffer behaviour are tested against this assumption as a condition of bit stream validity. Of course in a physical decoder precise synchronization is not automatically the case, particularly upon start-up and in the presence of timing jitter. Precise decoder timing is a goal to be targeted by decoder designs. Inaccuracy in decoder timing affects the behaviour of the decoder buffers. These topics are covered in more detail in later subclauses of this annex.

The STD includes Decoding Time Stamps (DTS) as well as PTS fields. The DTS refers to the time that an AU is to be extracted from the decoder buffer and decoded in the STD model. Since the audio and video elementary stream decoders are instantaneous in the STD, the decoding time and presentation time are identical in most cases; the only exception occurs with video pictures which have undergone re-ordering within the coded bit stream, i.e. I- and P-pictures in the case of non-low-delay video sequences. In cases where re-ordering exists, a temporary delay buffer in the video decoder is used to store the appropriate decoded I- or P-picture until it should be presented. In all cases where the decoding and presentation times are identical in the STD, i.e. all AAUs, B-picture VAUs, and I- and P-picture VAUs within low-delay video sequences, the DTS is not coded, as it would have the same value as the PTS. Where the values differ, both are coded if either is coded. For all AUs where only the PTS is coded, this field may be interpreted as being both the PTS and the DTS.

Since PTS and DTS values are not required for every AAU and VAU, the decoder may choose to interpolate values which are not coded. PTS values are required with intervals not exceeding 700 ms in each elementary audio and video stream. These time intervals are measured in presentation time, that is, in the same context as the values of the fields, not in terms of the times that the fields are transmitted and received. In cases of data streams where the system, video and audio clocks are locked, as defined in the normative part of this Recommendation | International Standard, each AU following one for which a DTS or PTS is explicitly coded has an effective decoding time of the sum of that for the previous AU plus a fixed and specified difference in value of the STC. For example, in video coded at 29,97 Hz each picture has a difference in time of 3003 cycles of the 90 kHz portion of the STC from the previous picture when the video and system clocks are locked. The same time relationship exists for decoding successive AUs, although re-ordering delay in the decoder affects the relationship between decoder AUs and presented PUs. When the data stream is coded such that the video or audio clock is not locked to the system clock the time difference between decoding successive AUs may be estimated using the same values as indicated above; however these time differences are not exact due to the fact that relationships between the frame rate, audio sample rate, and system clock frequency were not exact at the encoder.

Note that the PTS and DTS fields do not, by themselves, indicate the correct fullness of the decoder buffers at start up nor at any other time, and equivalently, they do not indicate the amount of time delay that should elapse upon receiving the initial bits of a data stream before decoding should start. This information is retrieved by combining the functions of the PTS and DTS fields and correct clock recovery, which is covered below. In the STD model, and therefore in decoders which are modelled after it, the decoder buffer behaviour is determined completely by the SCR (or PCR) values, the times that they are received, and the PTS and DTS values, assuming that data is delivered in accordance with the timing model. This information specifies the time that coded data spends in the decoder buffers. The amount of data that is in the coded data buffers is not explicitly specified, and this information is not necessary, since the timing is fully specified. Note also that the fullness of the data buffers may vary considerably with time in a fashion that is not predictable by the decoder, except through the proper use of the timestamps.

In order for the audio and video PTSs to refer correctly to a common STC, a correctly timed common clock must be made available within the decoder system. This is subject of the next subclause.

D.0.3 System Time Clock recovery in the decoder

Within the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Systems data stream there are, in addition to the PTS and DTS fields, clock reference timestamps. These references are samples of the system time clock, which are applicable both to a decoder and to an encoder. They have a resolution of one part in 27 000 000 per second, and occur at intervals up to 100 ms in Transport Streams, or up to 700 ms in Program Streams. As such, they can be utilized to implement clock reconstruction control loops in decoders with sufficient accuracy for all identified applications.

In the Program Stream, the clock reference field is called the System Clock Reference or SCR. In the Transport Stream, the clock reference field is called the Program Clock Reference or PCR. In general the SCR and PCR definitions may be considered to be equivalent, although there are distinctions. The remainder of this subclause uses the term SCR for clarity; the same statements apply to the PCR except where otherwise noted. The PCR in Transport Streams provides the clock reference for one program, where a program is a set of elementary streams that have a common time base and are intended for synchronized decoding and presentation. There may be multiple programs in one Transport Stream, and each may have an independent time base and a separate set of PCRs.

The SCR field indicates the correct value of the STC when the SCR is received at the decoder. Since the SCR occupies more than one byte of data, and System data streams are defined as streams of bytes, the SCR is defined to arrive at the decoder when the last byte of the system_clock_reference_base field is received at the decoder. Alternatively the SCR can be interpreted as the time that the SCR field should arrive at the decoder, assuming that the STC is already known to be correct. Which interpretation is used depends on the structure of the application system. In applications where the data source can be controlled by the decoder, such as a locally attached DSM, it is possible for the decoder to have an autonomous STC frequency, and so the STC need not be recovered. In many important applications, however, this assumption cannot be made correctly. For example, consider the case where a data stream is delivered simultaneously to multiple decoders. If each decoder has its own autonomous STC with its own independent clock frequency, the SCRs cannot be assured to arrive at the correct time at all decoders; one decoder will in general require the SCRs sooner than the source is delivering them, while another requires them later. This difference cannot be made up with a finite size data buffer over an unbounded length of time of data reception. Therefore the following addresses primarily the case where the STC must slave its timing to the received SCRs (or PCRs).

In a correctly constructed and delivered ITU-T Rec. H.222.0 | ISO/IEC 13818-1 data stream, each SCR arrives at the decoder at precisely the time indicated by the value of that SCR. In this context, "time" means correct value of the STC. In concept, this STC value is the same value that the encoder's STC had when the SCR was stored or transmitted. However, the encoding may have been performed not in real time or the data stream may have been modified since it was originally encoded, and in general the encoder or data source may be implemented in a variety of ways such that the encoder's STC may be a theoretical quantity.

If the decoder's clock frequency matches exactly that of the encoder, then the decoding and presentation of video and audio will automatically have the same rate as those at the encoder, and the end-to-end delay will be constant. With matched encoder and decoder clock frequencies, any correct SCR value can be used to set the instantaneous value of the decoder's STC, and from that time on the decoder's STC will match that of the encoder without the need for further adjustment. This condition remains true until there is a discontinuity of timing, such as the end of a Program Stream or the presence of a discontinuity indicator in a Transport Stream.

In practice a decoder's free-running system clock frequency will not match the encoder's system clock frequency which is sampled and indicated in the SCR values. The decoder's STC can be made to slave its timing to the encoder using the received SCRs. The prototypical method of slaving the decoder's clock to the received data stream is via a phase-locked loop (PLL). Variations of a basic PLL, or other methods, may be appropriate, depending on the specific application requirements.

A straight-forward PLL which recovers the STC in a decoder is diagrammed and described here.

Figure D.2 shows a classic PLL, except that the reference and feedback terms are numbers (STC and SCR or PCR values) instead of signal events such as edges.

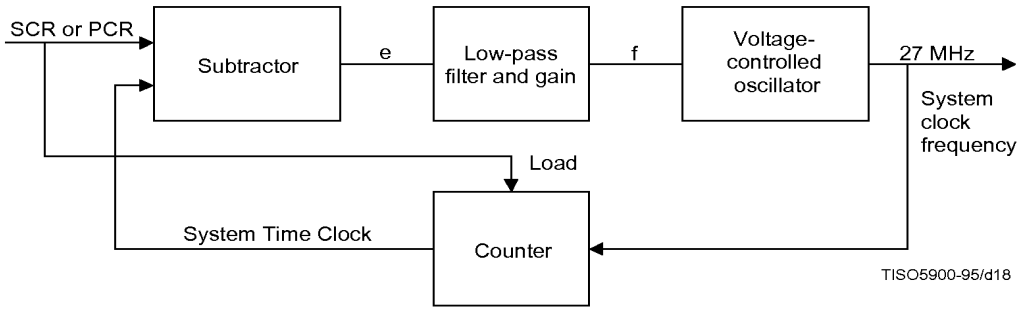

Figure D.2 – STC recovery using PLL

Upon initial acquisition of a new time base, i.e. a new program, the STC is set to the current value encoded in the SCRs. Typically the first SCR is loaded directly into the STC counter, and the PLL is subsequently operated as a closed loop. Variations on this method may be appropriate, i.e. if the values of the SCRs are suspect due to jitter or errors.

The closed-loop action of the PLL is as follows. At the moment that each SCR (or PCR) arrives at the decoder, that value is compared with the current value of the STC. The difference is a number, which has one part in units of 90 kHz and one part in terms of 300 times this frequency, i.e. 27 MHz. The difference value is linearized to be in a single number space, typically units of 27 MHz, and is called "**e**", the error term in the loop. The sequence of **e** terms is input to the low-pass filter and gain stage, which are designed according to the requirements of the application. The output of this stage is a control signal "**f**" which controls the instantaneous frequency of the Voltage Controlled Oscillator (VCO). The output of the VCO is an oscillator signal with a nominal frequency of 27 MHz; this signal is used as the system clock frequency within the decoder. The 27 MHz clock is input to a counter which produces the current STC values, which consist of both a 27 MHz extension, produced by dividing by 300, and a 90 kHz base value which is derived by counting the 90 kHz results in a 33-bit counter. The 33 bit, 90 kHz portion of the STC output is used as needed for comparison with PTS and DTS values. The complete STC is also the feedback input to the subtractor.

The bounded maximum interval between successive SCRs (700 ms) or PCRs (100 ms) allows the design and construction of PLLs which are known to be stable. The bandwidth of the PLLs has an upper bound imposed by this interval. As shown below, in many applications the PLL required has a very low bandwidth, and so this bound typically does not impose a significant limitation on the decoder design and performance.

If the free-running or initial frequency of the VCO is close enough to the correct, encoder's system clock frequency, the decoder may be able to operate satisfactorily as soon as the STC is initialized correctly, before the PLL has reached a defined locked state. For a given decoder STC frequency which differs by a bounded amount from the frequency encoded in the SCRs and which is within the absolute frequency bounds required by the decoder application, the effect of the mis-match between the encoder's and the decoder's STC frequencies if there were not PLL is the gradual and unavoidable increase or decrease of the fullness of the decoder's buffers, such that overflow or underflow would occur eventually with any finite size of decoder buffers. Therefore the amount of time allowable before the decoder's STC frequency is locked to that of the encoder is determined by the allowable amount of additional decoder buffer size and delay.

If the SCRs are received by the decoder with values and timing that reflect instantaneously correct samples of a constant frequency STC in the encoder, then the error term **e** converges to an essentially constant value after the loop has reached the locked state. This condition of correct SCR values is synonymous with either constant-delay storage and transmission of the data from the encoder to the decoder, or if this delay is not constant, the effective equivalent of constant delay storage and transmission with the SCR values having been corrected to reflect the variations in delay. With the values of **e** converging to a constant, variations in the instantaneous VCO frequency become essentially zero after the loop is locked; the VCO is said to have very little jitter or frequency slew. While the loop is in the process of locking, the rate of change of the VCO frequency, the frequency slew rate, can be controlled strictly by the design of the low pass filter and gain stage. In general the VCO slew rate can be designed to meet application requirements, subject to constraints of decoder buffer size and delay.

D.0.4 SCR and PCR Jitter

If a network or a Transport Stream re-multiplexor varies the delay in delivering the data stream from the encoder or storage system to the decoder, such variations tend to cause a difference between the values of the SCRs (or PCRs) and the values that they should have when they are actually received. This is referred to as SCR or PCR jitter. For example, if the delay in delivering one SCR is greater than the delay experienced by other similar fields in the same program, that SCR is late. Similarly, if the delay is less than for other clock reference fields in the program, the field is early.

Timing jitter at the input to a decoder is reflected in the combination of the values of the SCRs and the times when they are received. Assuming a clock recovery structure as illustrated in Figure D.2, any such timing jitter will be reflected in the values of the error term **e**; and non-zero values of **e** induce variations in the values of **f**, resulting in variations in the frequency of the 27 MHz system clock. Variations in the frequency of the recovered clock may or may not be acceptable within decoder systems, depending on the specific application requirements. For example, in precisely timed decoders that produce composite video output, the recovered clock frequency is typically used to generate the composite video sample clock and the chroma sub-carrier; the applicable specifications for sub-carrier frequency stability may permit only very slow adjustment of the system clock frequency. In applications where a significant amount of SCR or PCR jitter is present at the decoder input and there are tight constraints on the frequency slew rate of the STC, the constraints of reasonable additional decoder buffer size and delay may not allow proper operation.

The presence of SCR or PCR jitter may be caused for example by network transmission which incorporates packet or cell multiplexing or variable delay of packets through the network, as may be caused by queuing delays or by variable network access time in shared-media systems.

Multiplexing or re-multiplexing of Transport or Program Streams changes the order and relative temporal location of data packets and therefore also of SCRs or PCRs. The change in temporal location of SCRs causes the value of previously correct SCRs to become incorrect, since in general the time at which they are delivered via a constant delay network is not correctly represented by their values. Similarly, a Program Stream or Transport Stream with correct SCRs or PCRs may be delivered over a network which imposes a variable delay on the data stream, without correcting the SCR or PCR values. The effect is once again SCR or PCR jitter, with attendant effects on the decoder design and performance. The worst case amount of jitter which is imposed by a network on the SCRs or PCRs received at a decoder depends on a number of factors which are beyond the scope of this Recommendation | International Standard, including the depth of queues implemented in each of the network switches and the total number of network switches or re-multiplexing operations which operate in cascade on the data stream.

In the case of a Transport Stream, correction of PCRs is necessary in a re-multiplex operation, creating a new Transport Stream from one or more Transport Streams. This correction is accomplished by adding a correction term to the PCR; this term can be computed as:

$$\Delta PCR = del_{act} - del_{const}$$

where del_{act} is the actual delay experienced by the PCR, and del_{const} is a constant which is used for all PCRs of that program. The value which should be used for del_{const} will depend on the strategy used by the original encoder/multiplexor. This strategy could be, for instance, to schedule packets as early as possible, in order to allow later transmission links to delay them. In Table D.1, three different multiplex strategies are shown together with the appropriate value for del_{const}.

Table D.1 – Re-multiplexing strategy

Strategy	del_{const}
Early	del_{min}
Late	del_{max}
Middle	del_{avg}

When designing a system, private agreements may be needed as to what strategy should be used by the encoder/multiplexors, since this will have an effect on the ability to perform any additional re-multiplexing.

The amount of multiplex jitter allowed is not normatively bounded in this Recommendation | International Standard. However, 4 ms is intended to be the maximum amount of jitter in a well behaved system.

In systems which include re-multiplexors special care might be necessary to ensure that the information in the Transport Stream is consistent. In particular, this applies to PSI and to discontinuity points. Changes in PSI tables might need to be inserted into a Transport Stream in such a way that subsequent re-multiplexor steps never move them so far that information becomes incorrect. For instance, a new version of PMT section in some cases should not be sent within 4 ms of the data affected by the change.

Similarly, it may be necessary for an encoder/mux to avoid inserting PTS or DTS in a ±4 ms window around a discontinuity point.

D.0.5 Clock Recovery in the Presence of Network Jitter

In applications in which there is any significant amount of jitter present in the received clock reference timestamps, there are several choices available for decoder designs; how the decoder is designed depends in large part on the requirements for the decoder's output signal characteristics as well as the characteristics of the input data and jitter.

Decoders in various applications may have differing requirements for the accuracy and stability of the recovered system clock, and the degree of this stability and accuracy that is required may be considered to fall along a single axis. One extreme of this axis may be considered to be those applications where the reconstructed system clock is used directly to synthesize a chroma sub-carrier for use in composite video. This requirement generally exists where the presented video is of the precisely timed type, as described above, such that each coded picture is presented exactly once, and where the output is composite video in compliance with the applicable specifications. In that case the chroma sub-carrier, the pixel clock, and the frame rate all have exactly specified ratios, and all of these have a defined relationship to the system clock. The composite video sub-carrier must have at least sufficient accuracy and stability that any normal television receiver's chroma sub-carrier PLL can lock to the sub-carrier, and the chroma signals which are demodulated using the recovered sub-carrier do not show visible chrominance phase artifacts. The requirement in some applications is to use the system clock to generate a sub-carrier that is in full compliance with the NTSC, PAL, or SECAM specifications, which are typically even more stringent than those imposed by typical television receivers. For example, the SMPTE specification for NTSC requires a sub-carrier accuracy of 3 ppm, with a maximum short term jitter of 1 ns per horizontal line time and a maximum long term drift of 0,1 Hz per second.

In applications where the recovered system clock is not used to generate a chroma sub-carrier, it may still be used to generate a pixel clock for video and it may be used to generate a sample clock for audio. These clocks have their own stability requirements that depend on the assumptions made about the receiving display monitor and on the acceptable amount of audio frequency drift, or "wow and flutter", at the decoder's output.

In applications where each picture and each audio sample are not presented exactly once, i.e. picture and audio sample "slipping" is allowed, the system clock may have relatively loose accuracy and stability requirements. This type of decoder may not have precise audio-video presentation synchronization, and the resulting audio and video presentation may not have the same quality as for precisely timed decoders.

The choice of requirements for the accuracy and stability of the recovered system clock is application dependent. The following focuses on the most stringent requirement which is identified above, i.e. where the system clock is to be used to generate a chroma sub-carrier.

D.0.6 System clock used for chroma sub-carrier generation

The decoder design requirements can be determined from the requirements on the resulting sub-carrier and the maximum amount of network jitter that must be accepted. Similarly, if the system clock performance requirements and the decoder design's capabilities are known, the tolerable maximum network jitter can be determined. While it is beyond the scope of this Recommendation | International Standard to state such requirements, the numbers which are needed to specify the design are identified in order to clarify the statement of the problem and to illustrate a representative design approach.

With a clock recovery PLL circuit as illustrated in Figure D.2, the recovered system clock must meet the requirements of a worst case frequency deviation from the nominal, measured in units of ppm (parts per million), and a worst case frequency slew rate, measured in ppm/s (ppm per second). The peak-to-peak uncorrected network timing jitter has a value that may be specified in milliseconds. In such a PLL the network timing jitter appears as the error term **e** in the diagram, and since the PLL acts as a low-pass filter on jitter at its input, the worst case effect on the 27 MHz output frequency occurs when there is a maximum amplitude step function of PCR timing at the input. The value **e** then has a maximum amplitude equal to the peak-to-peak jitter, which is represented numerically as the jitter times 2**33 in the base portion of the SCR or PCR encoding. The maximum rate of change of the output of the low pass filter (LPF), **f**, with this maximum value of **e** at its input, directly determines the maximum frequency slew rate of the 27 MHz output. For any given maximum value of **e** and maximum rate of change of **f** a LPF can be specified. However, as the gain or cut-off frequency of the LPF is reduced, the time required for the PLL to lock to the frequency represented by the SCRs or PCRs is increased. Implementation of PLLs with very long time constants can be achieved through the use of digital LPF techniques, and possibly analogue filter techniques. With digital LPF implementations, when the frequency term **f** is the input to an analogue VCO, **f** is quantized by a digital to analogue converter, whose step size should be considered when calculating the maximum slew rate of the output frequency.

In order to ensure that **e** converges to a value that approaches zero, the open loop gain of the PLL must be very high, such as might be implemented in an integrator function in the low-pass filter in the PLL.

With a given accuracy requirement, it may be reasonable to construct the PLL such that the initial operating frequency of the PLL meets the accuracy requirement. In this case the initial 27 MHz frequency before the PLL is locked is sufficiently accurate to meet the stated output frequency requirement. If it were not for the fact that the decoder's buffers would eventually overflow or underflow, this initial system clock frequency would be sufficient for long term operation. However, from the time the decoder begins to receive and decode data until the system clock is locked to the time and clock frequency that is represented by the received SCRs or PCRs, data is arriving at the buffers at a different rate than it is being extracted, or equivalently the decoder is extracting access units at times that differ from those of the System Target Decoder (STD) model. The decoder buffers will continue to become more or less full than those of the STD according to the trajectory of recovered system clock frequency with respect to the encoder's clock frequency. Depending on the relative initial VCO frequency and encoder system clock frequency, decoder buffer fullness is either increasing or decreasing. Assuming this relationship is not known, the decoder needs additional data buffering to allow for either case. The decoder should be constructed to delay all decoding operations by an amount of time that is at least equal to the amount of time that is represented by the additional buffering that is allocated for the case of the initial VCO frequency being greater than the encoder's clock frequency, in order to prevent buffer underflow. If the initial VCO frequency is not sufficiently accurate to meet the stated accuracy requirements, then the PLL must reach the locked state before decoding may begin, and there is a different set of considerations regarding the PLL behaviour during this time and the amount of additional buffering and static delay which is appropriate.

A step function in the input timing jitter which produces a step function in the error term **e** of the PLL in Figure D.2 must produce an output frequency term **f** such that when it is multiplied by the VCO gain the maximum rate of change is less than the specified frequency slew rate. The gain of the VCO is stated in terms of the amount of the change in output frequency with respect to a change in control input. An additional constraint on the LPF in the PLL is that the static value of **e** when the loop is locked must be bounded in order to bound the amount of additional buffering and static decoding delay that must be implemented. This term is minimized when the LPF has very high DC gain.

Clock recovery circuits which differ somewhat from that shown in Figure D.2 may be practical. For example, it may be possible to implement a control loop with a Numerically Controlled Oscillator (NCO) instead of a VCO, wherein the NCO uses a fixed frequency oscillator and clock cycles are inserted or deleted from normally periodic events at the output in order to adjust the decoding and presentation timing. There may be some difficulties with this type of approach when used with composite video, as there is a tendency to cause either problematic phase shifts of the sub-carrier or jitter in the horizontal or vertical scan timing. One possible approach is to adjust the period of horizontal scans at the start of vertical blanking, while maintaining the phase of the chroma sub-carrier.

In summary, depending on the values specified for the requirements, it may or may not be practical to construct a decoder which reconstructs the system clock with sufficient accuracy and stability, while maintaining desired decoder buffer sizes and added decoding delay.

D.0.7 Component video and audio reconstruction

If component video is produced at the decoder output, the requirements for timing accuracy and stability are generally less stringent than is the case for composite video. Typically the frequency tolerance is that which the display deflection circuitry can accept, and the stability tolerance is determined by the need to avoid visible image displacement on the display.

The same principles as illustrated above apply, however the specific requirements are generally easier to meet.

Audio sample rate reconstruction again follows the same principles, however the stability requirement is determined by the amount of acceptable long and short term sample rate variation. Using a PLL approach as illustrated in the previous subclause, short term deviation can be made to be very small, and longer term frequency variation is manifested as variation in perceived pitch. Again, once specified bounds on this variation are set specific design requirements can be determined.

D.0.8 Frame Slipping

In some applications where precise decoder timing is not required, the decoder's system time clock may not adjust its operating frequency to match the frequency represented by received SCRs (or PCRs); it may have a free-running 27 MHz clock instead, while still slaving the decoder's STC to the received data. In this case the STC value must be updated as needed to match the received SCRs. Updating the STC upon receipt of SCRs causes discontinuities in the STC value. The magnitude of these discontinuities depends upon the difference between the decoder's 27 MHz frequency and the encoder's 27 MHz, i.e. that which is represented by the received SCRs, and upon the time interval between successive received SCRs or PCRs. Since the decoder's 27 MHz system clock frequency is not locked to that of

the received data, it cannot be used to generate the video or audio sample clocks while maintaining the precise timing assumptions of presenting each video and audio presentation unit exactly once and of maintaining the same picture and audio presentation rate at the decoder and the encoder, with precise audio and video synchronization. There are multiple possibilities for implementing decoding and presentation systems using this structure.

In one type of implementation, the pictures and audio samples are decoded at the time indicated by the decoder's STC, while they are presented at slightly different times, according to the locally produced sample clocks. Depending on the relationships of the decoder's sample clocks to the encoder's system clock, pictures and audio samples may on occasion be presented more than one each or not at all; this is referred to as "frame slipping" or "sample slipping", in the case of audio. There may be perceptible artifacts introduced by this mechanism. The audio-video synchronization will in general not be precise, due to the units of time over which pictures, and perhaps audio presentation units, are repeated or deleted. Depending on the specific implementation, additional buffering in the decoder is generally needed for coded data or decoded presentation data. Decoding may be performed immediately before presentation, and not quite at the time indicated in the decoder's STC, or decoded presentation units may be stored for delayed and possibly repeated presentation. If decoding is performed at the time of presentation, a mechanism is required to support deleting the presentation of pictures and audio samples without causing problems in the decoding of predictively coded data.

D.0.9 Smoothing of network jitter

In some applications it may be possible to introduce a mechanism between a network and a decoder in order to reduce the degree of jitter which is introduced by a network. Whether such an approach is feasible depends on the type of streams received and the amount and type of jitter which is expected.

Both the Transport Stream and the Program Stream indicate within their syntax the rate at which the stream is intended to be input to a decoder. These indicated rates are not precise, and cannot be used to reconstruct data stream timing exactly. They may, however, be useful as part of a smoothing mechanism.

For example, a Transport Stream may be received from a network such that the data is delivered in bursts. It is possible to buffer the received data and to transmit data from the buffer to the decoder at an approximately constant rate such that the buffer remains approximately one-half full.

However, a variable rate stream should not be delivered at constant rate, and with variable rate streams the smoothing buffer should not always be one-half full. A constant average delay through the buffer requires a buffer fullness that varies with the data rate. The rate that data should be extracted from the buffer and input to the decoder can be approximated using the rate information present in the data stream. In Transport Streams the intended rate is determined by the values of the PCR fields and the number of Transport Stream bytes between them. In Program Streams the intended rate is explicitly specified as the Program_mux_rate, although as specified in this Recommendation | International Standard the rate may drop to zero at SCR locations, i.e. if the SCR arrives before the time expected when the data is delivered at the indicated rate.

In the case of variable rate streams, the correct fullness of the smoothing buffer varies with time, and may not be determined exactly from the rate information. In an alternative approach, the SCRs or PCRs may be used to measure the time when data enter the buffer and to control the time when data leave the buffer. A control loop can be designed to provide constant average delay through the buffer. It may be observed that such a design is similar to the control loop illustrated in Figure D.2. The performance obtainable from inserting such a smoothing mechanism before a decoder can also be achieved by cascading multiple clock recovery PLLs. The rejection of jitter from the received timing will benefit from the combined low pass filter effect of the cascaded PLLs.

Annex E

Data Transmission Applications

(This annex does not form an integral part of this Recommendation | International Standard)

E.0 General considerations

- ITU-T Rec. H.222.0 | ISO/IEC 13818-1 transport multiplex will be used to transmit data as well as video and audio.
- Data elementary streams are not continuous as may appear video and audio streams in broadcast applications.
- While it is already possible to identify the beginning of a PES packet, it is not always possible to identify the end of a PES packet by the beginning of the next PES packet, because it is possible for one or more Transport packet carrying PES packets to be lost.

E.1 Suggestion

A suitable solution is to transmit the following PES packet just after an associated PES packet. A PES packet without payload may be sent when there are no further PES packets to send.

Table E.1 is an example of such a PES packet.

Table E.1 – PES packet header example

PES packet header fields	Values
packet_start_code_prefix	0x000001
stream_id	assigned
PES_packet_length	0x0003
'10'	'10'
PES_scrambling_control	'00'
PES_priority	'0'
data_alignment_indicator	'0'
copyright	'0'
original_or_copy	'0'
PTS_DTS_flags	'00'
ESCR_flag	'0'
ES_rate_flag	'0'
DSM_trick_mode_flag	'0'
additonal_copy_info_flag	'0'
PES_CRC_flag	'0'
PES_extension_flag	'0'
PES_header_data_length	0x00

Annex F

Graphics of Syntax for this Recommendation | International Standard

(This annex does not form an integral part of this Recommendation | International Standard)

F.0 Introduction

This annex is an informative annex presenting graphically the Transport Stream and Program Stream syntax. This annex in no way replaces any normative clause(s).

In order to produce clear drawings, not all fields have been fully described or represented. Reserved fields may be omitted or indicated by areas with no detail. Fields length are indicated in bits.

Annex G

General Information

(This annex does not form an integral part of this Recommendation | International Standard)

G.0 General Information

G.0.1 Sync Byte Emulation

In the choice of PID values it is recommended that the periodic emulation of sync bytes be avoided. Such emulation may potentially occur within the PID field or as a combination of the PID field and adjacent flag settings. It is recommended that emulation of the sync byte be permitted to occur in the same position of the packet header for a maximum of 4-consecutive transport packets.

G.0.2 Skipped picture status and decoding process

Assume that the sequence being displayed contains only I- and P-frames. Denote the next picture to be decoded by picture_next, and the picture currently being displayed by picture_current. Because of the fact that the video encoder may skip pictures, it is possible that not all of the bits of picture_next are present in the STD buffers EB_n or B_n when the time arrives to remove those bits for instantaneous decoding and display. When this case arises, no bits are removed from the buffer and picture_current is displayed again. When the next picture display time arrives, if the remainder of the bits corresponding to picture_next are now in buffer EB_n or B_n, all the bits of picture_next are removed and picture_next is displayed. If all the bits of picture_next are not in the buffer EB_n or B_n, the above process of re-displaying picture_current is repeated. This process is repeated until picture_next can be displayed. Note that if a PTS preceded picture_next in the bitstream, it will be incorrect by some multiple of the picture display interval, which itself may depend on some parameters, and must be ignored.

Whenever the skipped picture situation described above occurs, the encoder is required to insert a PTS before the picture to be decoded after picture_next. This allows the decoder to immediately verify that it has correctly displayed the received picture sequence.

G.0.3 Selection of PID Values

Applications are encouraged to use low numbered PID values (avoiding reserved values as specified in Table 2-4) and group values together as much as possible.

G.0.4 PES start_code emulation

Three consecutive bytes having the value of a packet_start_code_prefix (0x000001), which when concatenated with a fourth byte, may emulate the four bytes of a PES_packet_header at a unintended place in the stream.

Such, so called, start code emulation is not possible in video elementary streams. It is possible in audio and data elementary streams. It is also possible at the boundary of a PES_packet_header and a PES_packet payload, even if the PES_packet payload is video.

Annex H

Private Data

(This annex does not form an integral part of this Recommendation | International Standard)

H.0 Private Data

Private data is any user data which is not coded according to a standard specified by ITU-T | ISO/IEC and referred to in this Specification. The contents of this data is not and shall not be specified within this Recommendation | International Standard in the future. The STD defined in this Specification does not cover private data other than the demultiplex process. A private party may define each STD for private streams.

Private data may be carried in the following locations within the ITU-T Rec. H.222.0 | ISO/IEC 13818-1 syntax.

1) *Transport Stream packet Table 2-2*

   The data bytes of the transport_packet() syntax may contain private data. Private data carried in this format is referred to as user private within the stream_type Table 2-29. It is permitted for Transport Stream packets containing private data to also include adaptation_field()s.

2) *Transport Stream Adaptation Field Table 2-6*

   The presence of any optional private_data_bytes in the adaptation_field() is signalled by the transport_private_data_flag. The number of the private_data_bytes is inherently restricted by the semantic of the adaptation_field_length field, where the value of the adaptation_field_length shall not exceed 183 bytes.

3) *PES packet Table 2-17*

   There are two possibilities for carrying private data within PES packets. The first possibility is within the PES_packet_header, within the optional 16 bytes of PES_private_data. The presence of this field is signalled by the PES_private_data_flag. The presence of the PES_private_data_flag is signalled by the PES_extension_flag. If present, these bytes, when considered with the adjacent fields, shall not emulate the packet_start_code_prefix.

   The second possibility is within the PES_packet_data_byte field. This may be referred to as private data within PES packets under the stream_type Table 2-29. This category of private data can be split in two: private_stream_1 refers to private data within PES packets which follow the PES_packet() syntax such that all fields up to and including, but not limited to, PES_header_data_length are present. private_stream_2 refers to private data within PES packets where only the first three fields shall be present followed by the PES_packet_data_bytes containing private data.

   Note that PES packets exist within both Program Streams and Transport Streams therefore private_stream_1 and private_stream_2 exist within both Program Streams and Transport Streams.

4) *Descriptors*

   Descriptors exist within Program Streams and Transport Streams. A range of private descriptors may be defined by the user. These descriptors shall commence with descriptor_tag and descriptor_length fields. For private descriptors, the value of descriptor_tag may take the values 64-55 as identified in Table 2-39. These descriptors may be placed within a program_stream_map() Table 2-29, a CA_section() Table 2-27, a TS_program_map_section(), Table 2-28 and in any private section(), Table 2-30.

   Specifically private_data_bytes also appear in the CA_descriptor().

5) *Private Section*

   The private_section Table 2-30 provides a further means to carry private data also in two forms. This type of elementary stream may be identified under stream_type Table 2-29 as private_data in PSI sections. One type of private_section() includes only the first five defined fields, and is followed by private data. For this structure the section_syntax_indicator shall be set to a value of '0'. For the other type, the section_syntax_indicator shall be set to a value of '1' and the full syntax up to and including last_section_number shall be present, followed by private_data_bytes and ending with the CRC_32.

Annex I

Systems conformance and real-time interface

(This annex does not form an integral part of this Recommendation | International Standard)

I.0 Systems conformance and real-time interface

Conformance for ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Streams and Transport Streams is specified in terms of the normative specifications in this Recommendation | International Standard. These specifications include, among other requirements, a System Target Decoder (T-STD and P-STD) which specifies the behaviour of an idealized decoder when the stream is the input to such a decoder. This model, and the associated verification, do not include information concerning the real-time delivery performance of the stream, except for the accuracy of the system clock frequency which is represented by the Transport Stream and the Program Stream. All Transport Streams and Program Streams must comply with this Recommendation | International Standard.

In addition, there is a real-time interface specification for input of Transport Streams and Program Streams to a decoder. This Recommendation | International Standard allows standardization of the interface between MPEG decoders and adapters to networks, channels, or storage media. The timing effects of channels, and the inability of practical adapters to eliminate completely these effects, causes deviations from the idealized byte delivery schedule to occur. While it is not necessary for all MPEG decoders to implement this interface, implementations which include the interface shall adhere to the specifications. This Recommendation | International Standard covers the real-time delivery behaviour of Transport Streams and Program streams to decoders, such that the coded data buffers in decoders are guaranteed not to overflow nor underflow, and decoders are guaranteed to be able to perform clock recovery with the performance required by their applications.

The MPEG real-time interface specifies the maximum allowable amount of deviation from the idealized byte delivery schedule which is indicated by the Program Clock Reference (PCR) and System Clock Reference (SCR) fields encoded in the stream.

Annex J

Interfacing Jitter-Inducing Networks to MPEG-2 Decoders

(This annex does not form an integral part of this Recommendation | International Standard)

J.0 Introduction

In this annex the expression system stream will be used to refer to both ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Transport Streams and ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Streams. When the term STD is used, it is understood to mean the P-STD (Program System Target Decoder) for Program Streams and the T-STD (Transport System Target Decoder) for Transport Streams.

The intended byte delivery schedule of a system stream can be deduced by analyzing the stream. A system stream is compliant if it can be decoded by the STD, which is a mathematical model of an idealized decoder. If a compliant system stream is transmitted over a jitter-inducing network, the true byte delivery schedule may differ significantly from the intended byte delivery schedule. In such cases it may not be possible to decode the system stream on such an idealized decoder, because jitter may cause buffer overflows or underflows and may make it difficult to recover the time base. An important example of such a jitter-inducing network is ATM.

The purpose of this annex is to provide guidance and insight to entities concerned with sending system streams over jitter-inducing networks. Network specific compliance models for transporting system streams are likely to be developed for several types of networks, including ATM. The STD plus a real-time interface definition can play an integral role in defining such models. A framework for developing network compliance models is presented in J.2.

Three examples of network encoding to enable the building of jitter-smoothing network adapters are discussed in J.3. In the first example a constant bitrate system stream is assumed and a FIFO is used for jitter smoothing. In the second example the network adaptation layer includes timestamps to facilitate jitter smoothing. In the final example a common network clock is assumed to be available end-to-end, and is exploited to achieve jitter smoothing.

J.4 presents two examples of decoder implementations in which network-induced jitter can be accommodated. In the first example, a jitter-smoothing network adapter is inserted between a network's output and an MPEG-2 decoder. The MPEG-2 decoder is assumed to conform to a real-time MPEG-2 interface specification. This interface requires an MPEG-2 decoder with more jitter tolerance than the idealized decoder of the STD. The network adapter processes the incoming jittered bitstream and outputs a system stream whose true byte delivery schedule conforms to the real-time specification. Example one is discussed in J.4.1. For some applications the network adapter approach will be too costly because it requires two stages of processing. Therefore, in the second example the dejittering and MPEG-2 decoding functions are integrated. The intermediate processing of the jitter-removal device is bypassed, so only a single stage of clock recovery is required. Decoders that perform integrated dejittering and decoding are referred to in this annex as integrated network-specific decoders, or simply integrated decoders. Integrated decoders are discussed in J.4.2.

In order to build either network adapters or integrated decoders a maximum value for the peak-to-peak network jitter must be assumed. In order to promote interoperability, a peak-to-peak jitter bound must be specified for each relevant network type.

J.1 Network compliance models

One way to model the transmission of a system stream across a jitter-inducing network is shown in Figure J.1.

The system stream is input to a network-specific encoding device that converts the system stream into a network specific format. Information to assist in jitter removal at the network output may be part of this format. The network decoder comprises a network-specific decoder and an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 decoder. The ITU-T Rec. H.222.0 | ISO/IEC 13818-1 decoder is assumed to conform to a real-time interface specification, and could have the same architecture as the STD with appropriate buffers made larger to provide more jitter tolerance. The network-specific decoder removes the non- ITU-T Rec. H.222.0 | ISO/IEC 13818-1 data added by the network-specific encoder and dejitters the network's output. The output of the network-specific decoder is a system stream that conforms to the real-time specification.

A network target decoder (NTD) can be defined based on the above architecture. A compliant network bitstream would be one that was able to be decoded by the NTD. A network decoder would be compliant provided it could decode any network bitstream able to be decoded by the NTD. A real network decoder might or might not have the architecture of the NTD.

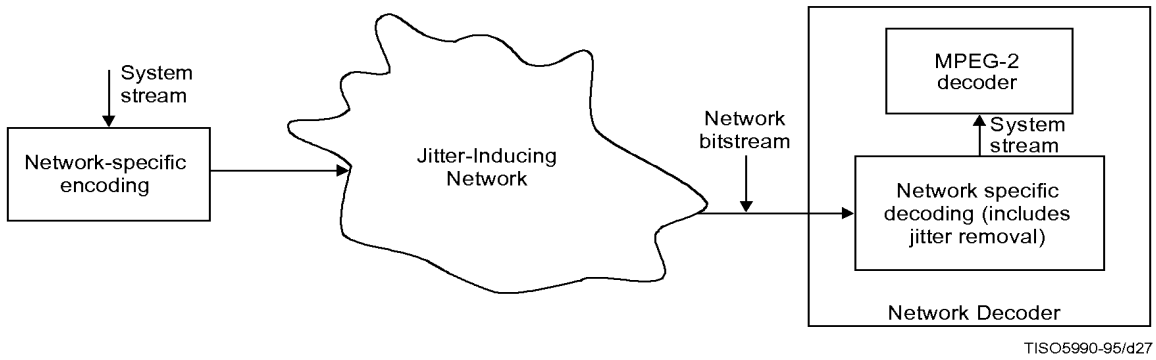

Figure J.1 – Sending system streams over a jitter-inducing network

J.2 Network specification for jitter smoothing

In the case of constant bit rate system streams, jitter smoothing can be accomplished with a FIFO. Additional data that provides specific support for dejittering is not required in the network adaptation layer. After the bytes added by the network encoding are removed, the system stream data is placed in a FIFO. A PLL keeps the buffer approximately half full by adjusting the output rate in response to changes in buffer fullness. In this example the amount of jitter-smoothing achieved will depend on the size of the FIFO and the characteristics of the PLL.

Figure J.2 illustrates a second way to accomplish jitter smoothing. In this example timestamp support from a network adaptation layer is assumed. Using this technique, both constant bit rate and variable bit rate system streams can be dejittered.

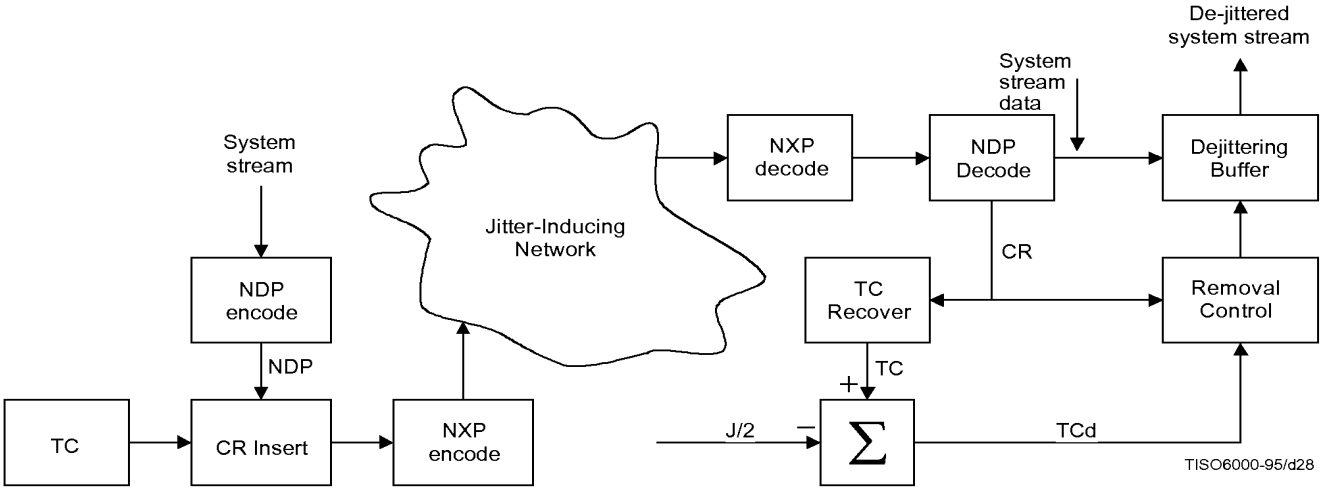

Figure J.2 – Jitter-smoothing using network-layer timestamps

Assume the network adapter is designed to compensate for a peak-to-peak jitter of J seconds. The intended byte delivery schedule is reconstructed using Clock Reference (CRs) samples taken from a Time Clock (TC). The CRs and the TC are analogous to PCRs and the STC. The Network Data Packet (NDP) encode converts each system stream packet into a Network Data Packet (NDP). The network data packets contain a field for carrying CR values, and the current value of the TC is inserted into this field as the NDP leaves the NDP encoder. The Network Transport Packetization (NXP) function encapsulates the NDPs into network transport packets. After transmission across the network, the CRs are extracted by the NDP decoder as the NDPs enter the NDP decoder. The CRs are used to reconstruct the TC, for example by using a PLL. The first MPEG-2 packet is removed from the dejittering buffer when the delayed TC (TCd) is equal to the first MPEG-2 packet's CR. Subsequent MPEG-2 packets are removed when their CR values equal the value of the TCd.

Ignoring implementation details such as the speed of the TC clock recovery loop and the spectral purity of the TC, the size of the dejittering buffer depends only on the maximum peak-to-peak jitter to be smoothed and the largest transport rate that occurs in the system stream. The dejittering buffer size, B_{dj}, is given by

$$B_{dj} = JR_{max}$$

where R_{max} is the maximum data rate of the system stream in bits per second. When packets traversing the network experience the nominal delay, the buffer is half full. When they experience a delay of J/2 seconds, the buffer is empty, and when they experience a delay (advance) of –J/2 seconds the buffer is full.

As a final example, in some cases a common network clock will be available end-to-end, and it may be feasible to lock the system clock frequency to the common clock. The network adapter can smooth jitter with a FIFO. The adapter uses PCRs or SCRs to reconstruct the original byte delivery schedule.

J.3 Example decoder implementations

J.3.1 Network adapter followed by an MPEG-2 decoder

In this implementation a network adapter conforming to the network compliance specification is connected to an MPEG-2 decoder conforming to the real-time interface specification.

J.3.2 Integrated decoder

The example presented in J.4.1 requires two stages of processing. The first stage is necessary to dejitter the network's output. The second stage, recovering the STC by processing PCRs or SCRs, is required for STD decoding. The example presented in this subclause is a decoder that integrates the dejittering and decoding functions in a single system. The STC clock is recovered directly using the jittered PCR or SCR values. For presenting this example, an MPEG-2 transport stream will be assumed.

Figure J.3 illustrates the operation of the integrated decoder. The stream of network packets input to the decoder is assumed to be the same as the one shown in Figure J.2.

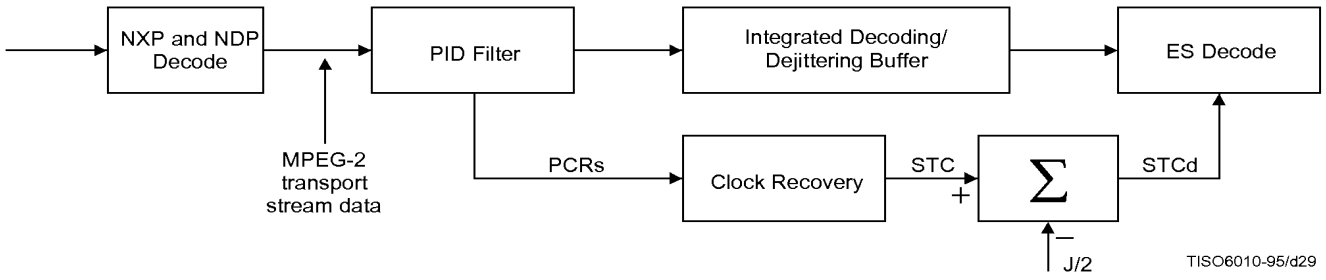

Figure J.3 – Integrated dejittering and MPEG-2 decoding

The incoming network packets are reassembled into MPEG-2 transport stream data by the NXP and NDP decode functions. The jittered ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Transport Stream packets are then filtered to extract packets with the desired PID. For the case illustrated, the PID being decoded is also carrying the PCRs. The PCR values are sent to a PLL to recover the STC. Entire packets for the selected PID are placed in the integrated buffer. A positive value of J/2 s is subtracted from the STC to obtain the delayed STC, STCd. Again, J is the peak-to-peak jitter the network-savvy decoder can accommodate. The delay is introduced to guarantee that all the data required for an access unit has arrived in the buffer when the PTS/DTS of the access unit equals the current value of the STCd.

Ignoring implementation details such as the speed of the STC clock recovery loop and the spectral purity of the STC:

$$\begin{aligned} B_{size} &= B_{dec} + B_{mux} + B_{OH} + 512 + B_j \\ &= B_n + 512 + B_j \end{aligned}$$

where $B_j = R_{max} J$ and R_{max} the maximum rate at which data is input to the PID filter. Depending on the implementation, the integrated memory could be broken into two components as in the transport STD.

Annex K

Splicing Transport Streams

(This annex does not form an integral part of this Recommendation | International Standard)

K.0 Introduction

For the purposes of this annex, the term 'splicing' refers to the concatenation performed on the Transport level of two different elementary streams, the resulting Transport Stream conforming totally to this Recommendation | International Standard. The two elementary streams may have been generated at different locations and/or at different times, and were not necessarily intended to be spliced together when they were generated. In the following we will call the 'old' stream a continuous elementary stream (video or audio), which has been superseded by another stream (the 'new' one) from a certain point on. This point is called the splice. It is the boundary between data belonging to the 'old' stream and data belonging to the 'new' one.

A splice can be seamless or non-seamless:

- A seamless splice is a splice inducing no decoding discontinuity (refer to 2.7.6). This means that the decoding time of the first access unit of the 'new' stream is consistent with respect to the decoding time of the access unit of the 'old' stream preceding the splice, i.e. it is equal to the one that the next access unit would have had if the 'old' stream had continued. In the following, we will call this decoding time the 'seamless decoding time'.
- A non-seamless splice is a splice which results in a decoding discontinuity, i.e. the decoding time of the first access unit of the 'new' stream is greater than the seamless decoding time.

  NOTE – A decoding time lower than the seamless decoding time is forbidden.

Splicing is allowed to be performed at any transport stream packet boundary, since the resulting stream is legal. But in a general case, if nothing is known about the location of PES packet starts and access unit starts, this constraint imposes that not only the Transport layer is parsed, but also the PES layer and the Elementary Stream layer, and may in some cases, make some processing on the payload of Transport Stream packets necessary. If such complex operations are wished to be avoided, splicing should be performed at locations where the Transport Stream has favourable properties, these properties being indicated by the presence of a splicing point.

The presence of a splicing point is indicated by the splice_flag and splice_countdown fields (refer to 2.4.3.4 for the semantics of these fields). In the following, the Transport Stream packet in which the splice_countdown field value reaches zero will be called 'splicing packet'. The splicing point is located immediately after the last byte of the splicing packet.

K.1 The different types of splicing point

A splicing point can be either an ordinary splicing point or a seamless splicing point.

K.1.1 Ordinary splicing points

If the seamless_splice_flag field is not present, or if its value is zero, the splicing point is ordinary. The presence of an ordinary splicing point only signals alignment properties of the Elementary Stream: the splicing packet ends on the last byte of an Access Unit, and the payload of the next Transport Stream packet of the same PID will start with the header of a PES packet, the payload of which will start with an Elementary Stream Access Point (or with a sequence_end_code() immediately followed by an Elementary Stream Access Point, in the case of video). These properties allow 'Cut and Paste' operations to be performed easily on the Transport level, while respecting syntactical constraints and ensuring bit stream consistency. However, it does not provide any information concerning timing or buffer properties. As a consequence, with such splicing points, seamless splicing can only be done with the help of private arrangements, or by analyzing the payload of the Transport Stream Packets and tracking buffer status and timestamp values.

K.1.2 Seamless splicing points

If the seamless_splice_flag field is present and its value is one, information is given by the splicing point, indicating some properties of the 'old' stream. This information is not aimed at decoders. Its primary goal is to facilitate seamless splicing. Such a splicing point is called a seamless splicing point. The available information is:

- The seamless decoding time, which is encoded as a DTS value in the DTS_next_AU field. This DTS value is expressed in the time base which is valid in the splicing packet.
- In the case of a video elementary stream, the constraints that have been applied to the 'old' stream when it was generated, aiming at facilitating seamless splicing. These conditions are given by the value of the splice_type field, in the table corresponding to the profile and level of the video stream.

Note that a seamless splicing point can be used as an ordinary splicing point, by discarding this additional information. This information may also be used if judged helpful to perform non-seamless splicing, or for purposes other than splicing.

K.2 Decoder behaviour on splices

K.2.1 On non-seamless splices

As described above, a non-seamless splice is a splice which results in a decoding discontinuity.

It shall be noted that with such a splice, the constraints related to the decoding discontinuity (see 2.7.6) shall be fulfilled. In particular:

- a PTS shall be encoded for the first access unit of the 'new' stream (except during trick mode operation or when low_delay = '1');
- the decoding time derived from this PTS (or from the associated DTS) shall not be earlier than the seamless decoding time;
- in the case of a video elementary stream, if the splicing packet does not end on a sequence_end_code(), the 'new' stream shall begin with a sequence_end_code() immediately followed by a sequence_header().

In theory, since they introduce decoding discontinuities, such splices result in a non-continuous presentation of presentation units (i.e. a variable length dead time between the display of two consecutive pictures, or between two consecutive audio frames). In practice, the result will depend on how the decoder is implemented, especially in video. With some video decoders, the freezing of one or more pictures may be the preferred solution. See Part 4 of ISO/IEC 13818.

K.2.2 On seamless splices

The aim of having no decoding discontinuity is to allow having no presentation discontinuity. In the case of audio, this can always be ensured. But it has to be noted that in the case of video, presentation continuity is in theory not possible in cases 1) and 2) below:

1) The 'old' stream ends on the end of a low-delay sequence, and the 'new' stream begins with the start of a non-low-delay sequence.
2) The 'new' stream ends on the end of a non-low-delay sequence, and the 'new' stream begins with the start of a low-delay sequence.

The effects induced by such situations is implementation dependent. For instance, in case 1, a picture may have to be presented during two frame periods, and in case 2, a picture may have to be skipped. However, it is technically possible that some implementations support such situations without any undesirable effect.

In addition, referring to 6.1.1.6 of ITU-T Rec. H.262 | ISO/IEC 13818-2, a sequence_end_code() shall be present before the first sequence_header() of the 'new' stream, if at least one sequence parameter (i.e. a parameter defined in the sequence header or in a sequence header extension) has a different value in both streams, with the only exception of those defining the quantization matrix. As an example, if the bit rate field has not the same value in the 'new' stream as in the 'old' one, a sequence_end_code() shall be present. Thus, if the splicing packet does not end on a sequence_end_code, the 'new' stream shall begin with a sequence_end_code followed by a sequence_header.

According to the previous paragraph, a sequence_end_code will be mandatory in most splices, even seamless ones. It has to be noted that ITU-T Rec. H.262 | ISO/IEC 13818-2 specifies the decoding process of video sequences (i.e. data comprised between a sequence_header() and a sequence_end_code()), and nothing is specified about how to handle a sequence change. Thus, for the behaviour of the decoders when such splices are encountered, refer to Part 4 of ISO/IEC 13818.

K.2.3 Buffer Overflow

Even if both elementary streams obey the T-STD model before being spliced, it is not necessarily ensured that the STD buffers do not overflow with the spliced stream in the time interval during which bits of both streams are in these buffers.

In the case of constant bit rate video, if no particular conditions have been applied to the 'old' stream, and if no particular precautions have been taken during splicing, this overflow is possible in the case where the video bit rate of the 'new' stream is greater than the video bit rate of the 'old' one. Indeed, it is certainly true that the buffers MB_n and EB_n of the T-STD do not overflow if bits are delivered to the T-STD at the 'old' rate. But if the delivery rate is switched to a higher value at the input of TB_n before 'old' bits are completely removed from the T-STD, the fullness of the STD buffers will become higher than if the 'old' stream had continued without splicing, and may cause overflow of EB_n and/or MB_n. In the case of variable bit rate video, the same problem can occur if the delivery rate of the 'new' stream is higher than the one for which provision was made during the creation of the 'old' stream. Such a situation is forbidden.

However, it is possible for the encoder generating the 'old' stream to add conditions in the VBV buffer management in the neighborhood of splicing points, so that provision is made for any 'new' video bit rate lower than a chosen value. For instance, in the case of a seamless splicing point, such additional conditions can be indicated by a 'splice_type' value to which entries correspond in Table 2-7 through Table 2-16 for 'splice_decoding_delay' and 'max_splice_rate'. In that case, if the video bit rate of the 'new' stream is lower than 'max_splice_rate', it is ensured that the spliced stream will not lead to overflow during the time interval during which bits of both streams are in the T-STD buffer.

In the case where no such constraints have been applied, this problem can be avoided by introducing a dead time in the delivery of bits between the 'old' stream and the 'new' one, in order to let the T-STD buffers get sufficiently empty before the bits of the 'new' stream are delivered. If we call t_{in} the time at which the last byte of the last access unit of the 'old' stream enters the STD, and t_{out} the time at which it exits the STD, it is sufficient to ensure that no more bits enter the T-TD the time interval $[t_{in}, t_{out}]$ with the spliced stream than if the 'old' stream had continued without splicing. As an example, in the case where the 'old' stream has a constant bit rate R_{old}, and the 'new' one a constant bit rate R_{new}, it is sufficient to introduce a dead time T_d satisfying the following relations to avoid this risk of overflow:

$$T_d \geq 0 \text{ and } T_d \geq (t_{out} - t_{in}) \times (1 - R_{old}/R_{new})$$

Annex L

Registration procedure (see 2.9)

(This annex does not form an integral part of this Recommendation | International Standard)

L.1 Procedure for the request of a Registered Identifier (RID)

Requesters of a RID shall apply to the Registration Authority. Registration forms shall be available from the Registration Authority. Information which the requester shall provide is given in L.3. Companies and organizations are eligible to apply.

L.2 Responsibilities of the Registration Authority

The primary responsibilities of the Registration Authority administrating the registration of copyright_identifiers is outlined in this subclause; certain other responsibilities may be found in the JTC 1 Directives. The Registration Authority shall:

a) implement a registration procedure for application for a unique RID in accordance with Annex H/JTC 1 Directives;

b) receive and process the applications for allocation of the work type code identifier from Copyright Registration Authority;

c) ascertain which applications received are in accordance with this registration procedure, and to inform the requester within 30 days of receipt of the application of their assigned RID;

d) inform application providers whose request is denied in writing within 30 days of receipt of the application, and also inform the requesting party of the appeals process;

e) maintain an accurate register of the allocated RID. Revisions to the contact information and technical specifications shall be accepted and maintained by the Registration Authority;

f) make the contents of this register available upon request to any interested party;

g) maintain a database of RID request forms, granted and denied. Parties seeking technical information on the format of private data which has a copyright_identifier shall have access to such information which is part of the database maintained by the Registration Authority;

h) report its activities to JTC 1, the ITTF and the JTC 1/SC 29 Secretariat, or their respective assignees, annually on a schedule mutually agreed upon.

L.2.1 Contact information of the Registration Authority

Organization Name:

Address:

Telephone:

Fax:

L.3 Responsibilities of parties requesting an RID

The party requesting an RID for the purpose of copyright identification shall:

a) apply using the form and procedures supplied by the Registration Authority;

b) provide contact information describing how a complete description of the copyright organization can be obtained on a non-discriminatory basis;

c) include technical details of the syntax and semantics of the data format used to describe the audiovisual works or other copyrighted works within the **additional_copyright_info** field. Once registered, the syntax used for the additional copyright information shall not change;

d) agree to institute the intended use of the granted copyright_identifier within a reasonable time-frame;

e) maintain a permanent record of the application form and the notification received from the Registration Authority of each granted copyright_identifier.

L.4 Appeal procedure for denied applications

The Registration Management Group is formed to have jurisdiction over appeals relating to a denied request for an RID. The RMG shall have a membership who are nominated by P and L members of the ISO technical body responsible for this Recommendation | International Standard. It shall have a convenor and secretariat nominated from its members. The Registration Authority is entitled to nominate one non-voting observing member.

The responsibilities of the RMG shall be:

a) to review and act on all appeals within a reasonable time-frame;

b) to inform, in writing, organizations which make an appeal for reconsideration of its petition of the RMG's disposition of the matter;

c) to review the annual report of the Registration Authority summary of activities;

d) to supply ISO member bodies with information concerning the scope of operation of the Registration Authority.

Annex M

Registration application form (see 2.9)

(This annex does not form an integral part of this Recommendation | International Standard)

M.1 Contact information of organization requesting a Registered Identifier (RID)

Organization Name:

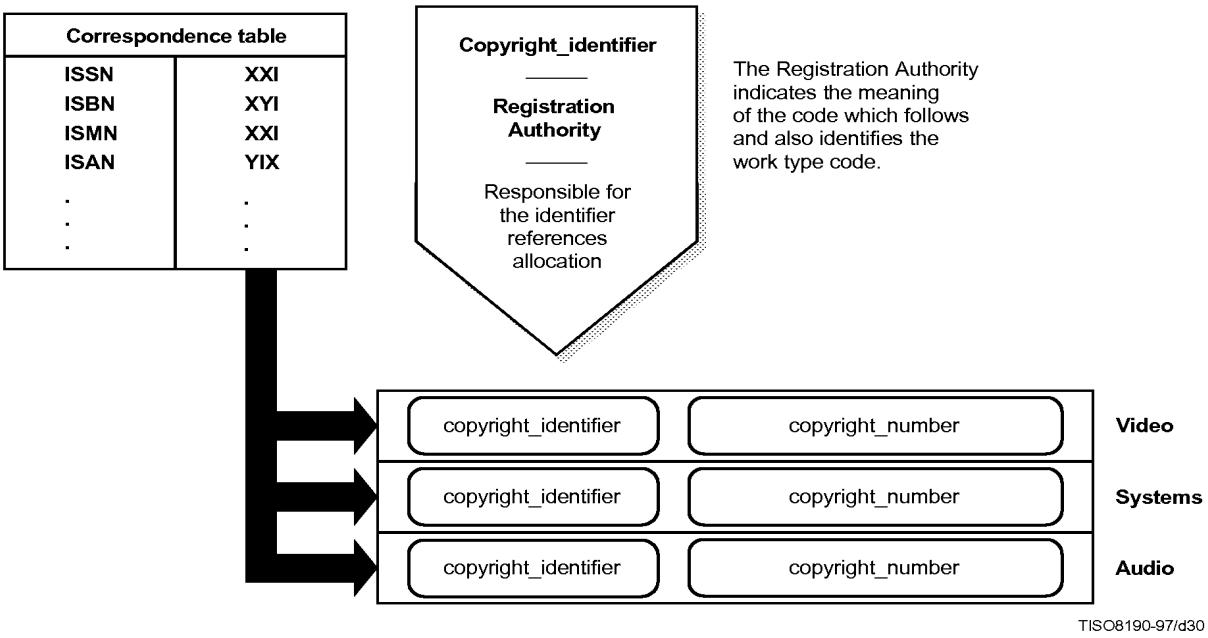
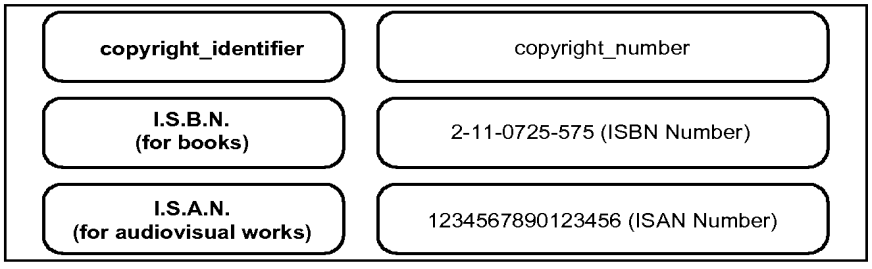
M.5 For official use only of the Registration Authority

Registration rejected: _____ Reason for rejection of the application: Registration granted: _____ Registration value: _____



Attachment 1 – Attachment of technical details of the registered data format.

Attachment 2 – Attachment of notification of appeal procedure for rejected applications.



Annex N

(This annex does not form an integral part of this Recommendation | International Standard)

Registration Authority
Diagram of administration structure (see 2.9)

Examples

All the copyright_identifiers are registered by the Registration Authority, uniquely for copyright_numbers standardized by ISO. Each organization which allocates copyright_numbers, requests a specific copyright_identifier from the Registration Authority, e.g. Staatsbibliothek Preussischer Kulturbesitz, designated by ISO to manage I.S.B.N., asks for a specific copyright_identifier from the R.A. for book numbering.

Annex O

Registration procedure (see 2.10)

(This annex does not form an integral part of this Recommendation | International Standard)

O.1 Procedure for the request of an RID

Requesters of an RID shall apply to the Registration Authority. Registration forms shall be available from the Registration Authority. The requester shall provide the information specified in O.4. Companies and organizations are eligible to apply.

O.2 Responsibilities of the Registration Authority

The primary responsibilities of the Registration Authority administrating the registration of private data format_identifiers is outlined in this annex; certain other responsibilities may be found in the JTC 1 Directives. The Registration Authority shall:

a) implement a registration procedure for application for a unique RID in accordance with the JTC 1 Directives;

b) receive and process the applications for allocation of an identifier from application providers;

c) ascertain which applications received are in accordance with this registration procedure, and to inform the requester within 30 days of receipt of the application of their assigned RID;

d) inform application providers whose request is denied in writing within 30 days of receipt of the application, and to consider resubmission of the application in a timely manner;

e) maintain an accurate register of the allocated identifiers. Revisions to format specifications shall be accepted and maintained by the Registration Authority;

f) make the contents of this register available upon request to National Bodies of JTC 1 that are members of ISO or IEC, to liaison organizations of ISO or IEC and to any interested party;

g) maintain a database of RID request forms, granted and denied. Parties seeking technical information on the format of private data which has an RID shall have access to such information which is part of the database maintained by the Registration Authority;

h) report its activities to JTC 1, the ITTF, and the SC 29 Secretariat, or their respective designees, annually;

i) accommodate the use of existing RIDs whenever possible.

O.3 Contact information for the Registration Authority

O.4 Responsibilities of parties requesting an RID

The party requesting a format_identifier shall:

a) apply, using the form and procedures supplied by the Registration Authority;

b) include a description of the purpose of the registered bit stream, and the required technical details as specified in the application form;

c) provide contact information describing how a complete description can be obtained on a non-discriminatory basis;

d) agree to institute the intended use of the granted RID within a reasonable time-frame;

e) to maintain a permanent record of the application form and the notification received from the Registration Authority of a granted RID.

O.5 Appeal procedure for denied applications

The Registration Management Group is formed to have jurisdiction over appeals to denied requests for an RID. The RMG shall have a membership who is nominated by P- and L-members of the ISO technical committee responsible for this Specification. It shall have a convenor and secretariat nominated from its members. The Registration Authority is entitled to nominate one non-voting observing member.

The responsibilities of the RMG shall be:

a) to review and act on all appeals within a reasonable time-frame;

b) to inform, in writing, organizations which make an appeal for reconsideration of its petition of the RMG's disposition of the matter;

c) to review the annual report of the Registration Authorities summary of activities;

d) to supply member bodies of ISO and National Committees of IEC with information concerning the scope of operation of the Registration Authority.

Annex Q

T-STD and P-STD buffer models for ISO/IEC 13818-7 ADTS

(This annex does not form an integral part of this Recommendation | International Standard)

Q.1 Introduction

The Transport Stream system target decoder model for audio streams is defined in subclause 2.4.2. In this annex, the buffer model for ISO/IEC 13818-7 ADTS is described.

ISO/IEC 13818-7 ADTS audio streams can be recognized in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 multiplex through the presence of stream_id=0x110yyyyy ('y' = "don't care") and stream_type=0x0F as defined in Tables 2-18 and 2-19.

Q.2 Leak Rate from Transport Buffer

For audio except ISO/IEC 13818-7 ADTS, the leak rate from Transport Buffer is 2 Mbit/s. This rate is, however, lower than the maximum rate of ISO/IEC 13818-7 ADTS. Therefore, the leak rate for ISO/IEC 13818-7 ADTS streams is set to a different value from ISO/IEC 11172-3 and ISO/IEC 13818-3 audio streams.

ISO/IEC 13818-7 ADTS elementary stream consists of one or more channels. The maximum rate of each channel is 576 kbit/s where the sampling frequency is 96 kHz. Therefore, the leak rate for ISO/IEC 13818-7 ADTS is calculated as following equation.

$$Rx_n = 1.2 \times R_{max} \times N \text{ bits per second}$$

where:

R_{max} is a constant 576 kbit/s as defined in subclause 3.2.2 of ISO/IEC 13818-7. It is an upper bound of the bit rate per channel of AAC ADTS stream corresponding to the maximum value of sampling frequency (i.e., Fs = 96 kHz).

And where:

N is the number of audio channels that require their own decoder buffer in this elementary stream (i.e. individual channel streams in a single channel element or channel pair element and independently switched coupling channel elements).

Q.3 Buffer Size

For audio except ISO/IEC 13818-7 ADTS, the main buffer size is 3584 bytes. This size is, however, smaller than the maximum decoder input buffer size of ISO/IEC 13818-7 ADTS. Therefore, the main buffer size for the ISO/IEC 13818-7 ADTS stream is set to a different value from ISO/IEC 11172-3 and ISO/IEC 13818-3 audio streams.

The main buffer size for ISO/IEC 13818-7 ADTS is calculated as following.

$$BS_n = BS_{mux} + BS_{dec} + BS_{oh}$$

Where BS_{oh}, PES packet overhead buffering is defined as:

$$BS_{oh} = 528 \text{ bytes}$$

and BS_{mux}, additional multiplexing buffering is defined as:

$$BS_{mux} = 0.004 \text{ seconds} \times R_{max} \times N$$

and BS_{dec}, access unit buffering is defined as

$$BS_{dec} = 6144 \text{ bits} \times N$$

where

R_{max} is a constant 576 kbit/s as defined in subclause 3.2.2 of ISO/IEC 13818-7. It is an upper bound of the bit rate per channel of AAC ADTS stream corresponding to the maximum value of sampling frequency (i.e., Fs = 96 kHz).

And where

N is the number of audio channels that require their own decoder buffer in this elementary stream (i.e. individual channel streams in a single channel element or channel pair element and independently switched coupling channel elements).

Q.3.1 TBS_n: same as other audio

In term of the smoothing buffer, there is no difference in TB_n between ISO/IEC 13818-7 ADTS and other audio streams. Consequently, it is not necessary to change TBS_n, which is size of TB_n.

Q.3.2 BS_{mux}: different from other audio

BS_{mux}, additional multiplexing buffering, shall be changed to accept up to 4 msec of delay jitter. This is similar to the approach taken for other streams in ITU-T Rec. H.222.0 | ISO/IEC 13818-1.

Q.3.3 BS_{dec}: different from other audio

BS_{dec}, access unit buffering is based on the decoder input buffer size of the elementary stream. As defined in subclause 3.2.2 of ISO/IEC 13818-7, total decoder input buffer size is 6144 bit multiplied by the number of channels which require their each decoder input buffer.

Q.3.4 BS_{oh}: different from other audio

BS_{oh} is corresponding to the PES packet header overhead.

In subclause 2.4.2.6,

> *The delay of any data through the System Target Decoders buffers shall be less than or equal to one second except for still picture video data.*

Besides, in subclause 2.7.4,

> *The program Stream and Transport Stream shall be constructed so that the maximum difference between coded presentation time stamp referring to each elementary video or audio stream is 0.7 seconds.*

BS_{oh} shall be set to the appropriate size corresponding to the PES packet header overhead when AAC stream is packetized with the above rules. The maximum size of PES packet header is 264 bytes. Therefore, BS_{oh} = 528 bytes, i.e. the twice the maximum size of PES packet header, assures that at least two PES packet headers can enter the main buffer regardless of the size of PES packet header. It means that PES packet header with PTS can be inserted at less than 0.7 seconds intervals even when the data of one second will be in the main buffer.

Example: sampling frequency is 48 kHz

The size of PES packet header without any optional fields except PTS is 18 bytes. The number of Access Units of one second is about 47. When the data of one second is in the main buffer (i.e. the worst case), PES packet header overhead can fit the BS_{oh} with packetizing more than or equal to two Access Units into one packet.

number_of_AU = 48 kHz/1024 = 46,875 per second

(number_of_AU/2) × 18[byte] = 421,875 bytes < BS_{oh}

More frequent PES packet headers can fit BS_{oh}, if the delay of any data through the main buffer is shorter than one second.

Q.4 Conclusion

The decoder buffer model should cover the maximum size of buffer, however AAC can handle up to 48 channels and very high bitrate. Therefore the 3 levels of number of channels, 2, 8 and 48, are used to define the leak rate and the main buffer size. In a case of 2, the same leak rate and main buffer size as the conventional values are used to keep the compatibility. In other cases (8 and 48), the proposed formulas are applied.

T-STD leak rate for ISO/IEC 13818-7 ADTS audio,

Number of Channels	Rx_n [bit/s]
1-2	2 000 000
3-8	5 529 600
9-12	8 294 400
13-48	33 177 600

Channels: channels that require their own decoder buffer in this elementary stream (i.e. individual channel streams in a single channel element or channel pair element and independently switched coupling channel elements).

T-STD main buffer size or ISO/IEC 13818-7 ADTS audio,

Number of Channels	BSn [bytes]
1-2	3 584
3-8	8 976
9-12	12 804
13-48	51 216

Channels: channels that require their own decoder buffer in this elementary stream (i.e. individual channel streams in a single channel element or channel pair element and independently switched coupling channel elements).

For Program stream, the above main buffer size should be set in the P-STD_buffer_scale and P-STD_buffer_size as follows.

Number of Channels	P-STD_buffer_scale	P-STD_buffer_size
1-2	0	28
3-8	0	71
9-48	0	401

Annex R

Carriage of ISO/IEC 14496 scenes in ITU-T Rec. H.222.0 | ISO/IEC 13818-1

(This annex does not form an integral part of this Recommendation | International Standard)

R.1 Content access procedure for ISO/IEC 14496 program components within a Program Stream

The following provides a reference receiver acquisition procedure for accessing ISO/IEC 14496 program elements in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Program Stream. Here, it is assumed that the Program Stream includes a Program Stream Map (conveyed in a PES packet having stream_id equal to 0xBC):

- Acquire the Program Stream Map.
- Identify the IOD descriptor in the first descriptor loop.
- Identify the ES_IDs of the object descriptor, scene description and other streams described within the initial object descriptor.
- Acquire the SL descriptor and FMC descriptor in the second descriptor loop for elementary_stream_ids 0xFA and 0xFB, as applicable.
- Generate from these descriptors a stream map table between ES_IDs and associated elementary_stream_id plus FlexMux channel, if applicable.
- Locate the object descriptor stream using its ES_ID and the stream map table.
- Locate other streams described in the initial object descriptor using their ES_ID and the stream map table.
- Continuously monitor the object descriptor stream and identify ES_IDs of additional streams.
- Locate the additional streams using their ES_ID and the stream map table.

Figure R.1 gives an example of ISO/IEC 14496 content in a Program Stream, consisting of object descriptor stream, scene description stream (BIFS-Command), BIFS-Anim stream and IPMP stream. All ISO/IEC 14496 streams are multiplexed in a single FlexMux stream.

R.2 Content access procedure for ISO/IEC 14496 program components within a Transport Stream

The following provides a reference receiver acquisition procedure for accessing ISO/IEC 14496 program elements in an ITU-T Rec. H.222.0 | ISO/IEC 13818-1 Transport Stream:

- Acquire the Program Map Table for the desired program.
- Identify the IOD descriptor in the first descriptor loop.
- Identify the ES_IDs of the object descriptor, scene description and other streams described within the initial object descriptor.
- Acquire the set of all SL descriptors and FMC descriptors present in the second descriptor loop for any of the elementary_PIDs.
- Generate from these descriptors a stream map table between ES_IDs and associated elementary_PID plus FlexMux channel, if applicable.
- Locate the object descriptor stream using its ES_ID and the stream map table.
- Locate other streams described in the initial object descriptor using their ES_ID and the stream map table.
- Continuously monitor the object descriptor stream and identify ES_IDs of additional streams.
- Locate the additional streams using their ES_ID and the stream map table.

Figure R.2 gives an example of ISO/IEC 14496 program elements in a Transport Stream, consisting of object descriptor stream, scene description stream (BIFS-Command), BIFS-Anim and IPMP elementary streams. BIFS-Command and OD stream are conveyed by means of ISO_IEC_14496_sections, while BIFS-Anim and IPMP elementary streams are conveyed in PES packets referenced by two distinct elementary_PID values, without the use of the ISO/IEC 14496-1 FlexMux tool.

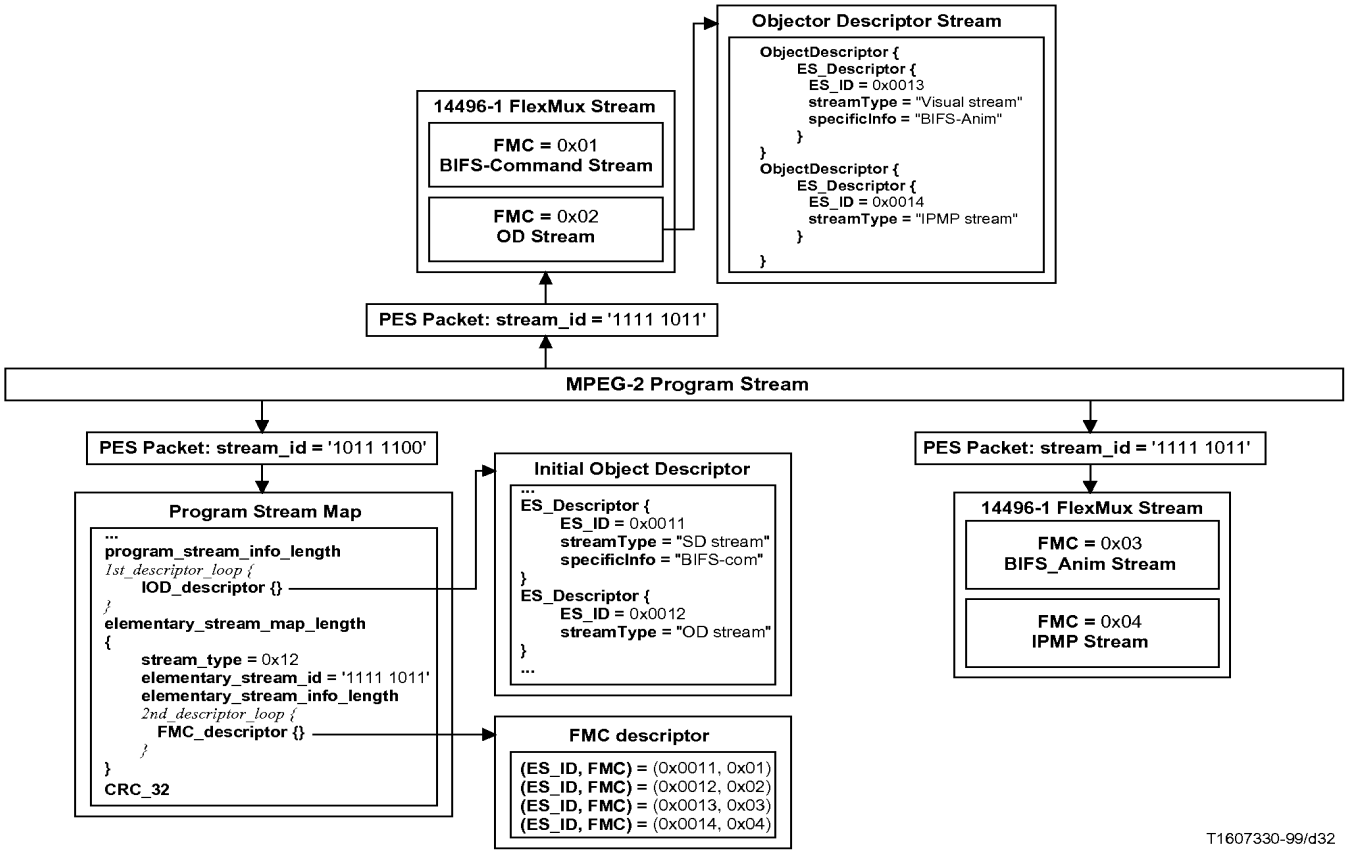

Figure R.1 – Example of ISO/IEC 14496 content in a Program Stream

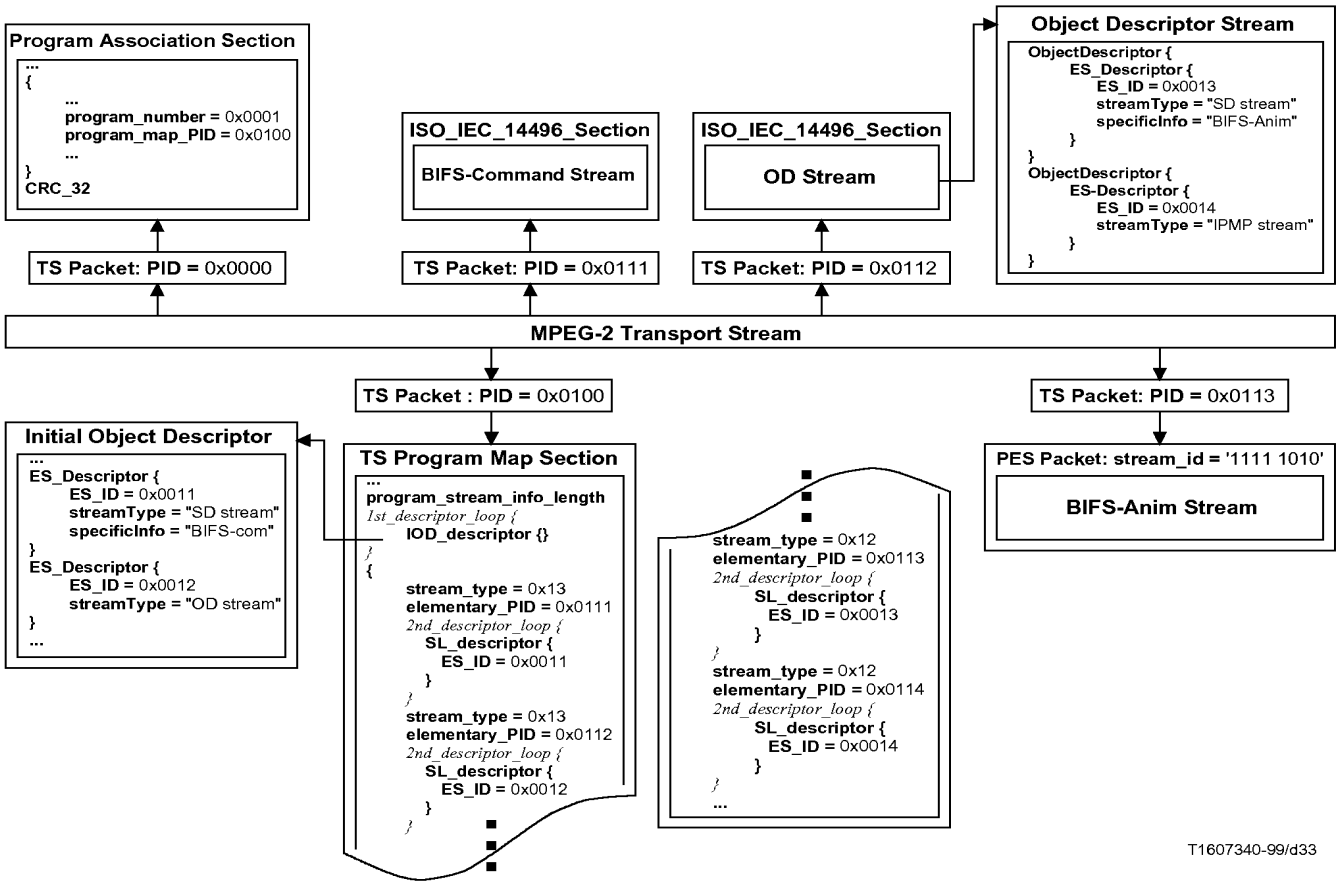

Figure R.2 – Example of ISO/IEC 14496 content in a Transport Stream

Annex S

Patents

(This annex is only applicable to ISO/IEC 13818-1)

Patent List

The user's attention is called to the possibility that - for some of the processes specified in this Recommendation | International Standard conformance with this Recommendation | International Standard may require use of an invention covered by patent rights.

By publication of this part of Recommendation | International Standard, no position is taken with respect to the validity of this claim or of any patent rights in connection therewith. However, each company listed in this annex has undertaken to file with the Information Technology Task Force (ITTF) a statement of willingness to grant a license under such rights that they hold on reasonable and non-discriminatory terms and conditions to applicants desiring to obtain such a license.

Information regarding such patents can be obtained from the following organizations.

The table summarizes the formal patent statements received and indicates the parts of the standard to which the statement applies. Three "N"s in a row corresponding to a company means that the statement from the company did not mention any part. The list includes all organizations that have submitted informal patent statements. However, if no "X" is present, no formal patent statement has yet been received from that organization.

1. Способ кодирования видеопоследовательности, содержащей независимую последовательность кадров изображения, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что содержит этап, на котором кодируют в видеопоследовательность указание по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения упомянутой независимой последовательности, при этом упомянутый по меньшей мере один опорный кадр изображения включают в данную последовательность.

2. Способ по п. 1, отличающийся тем, что кодируют упомянутое указание в видеопоследовательность в качестве отдельного флага, включаемого в заголовок среза.

3. Способ по п.1, отличающийся тем, что кодируют значения идентификаторов для кадров изображения согласно схеме нумерации,

переустанавливают значение идентификатора для указанного первого кадра изображения независимой последовательности.

4. Способ по п.1, отличающийся тем, что кодируют в видеопоследовательность значение идентификатора для независимой последовательности.

5. Видеокодер для кодирования видеопоследовательности, содержащей независимую последовательность кадров изображения, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в

порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что выполнен с возможностью кодирования в видеопоследовательность указания по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения упомянутой независимой последовательности, при этом упомянутый по меньшей мере один опорный кадр изображения включается в данную последовательность.

6. Видеокодер по п. 5, отличающийся тем, что выполнен с возможностью кодирования упомянутого указания в видеопоследовательность в качестве отдельного флага, включаемого в заголовок среза.

7. Видеокодер по п. 5, отличающийся тем, что выполнен с возможностью кодирования значений идентификаторов для кадров изображения согласно схеме нумерации, переустановки значения идентификатора для указанного первого кадра изображения независимой последовательности.

8. Видеокодер по п. 5, отличающийся тем, что выполнен с возможностью кодирования в видеопоследовательность значения идентификатора для независимой последовательности.

9. Машиночитаемый носитель, на котором хранится исполняемый в устройстве обработки данных компьютерный программный код, предназначенный для кодирования видеопоследовательности, содержащей независимую последовательность кадров изображения, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что компьютерный программный код содержит компьютерный программный код для кодирования в видеопоследовательность указания по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения упомянутой независимой последовательности, при этом упомянутый по меньшей мере один опорный кадр изображения включается в данную последовательность.

10. Способ декодирования сжатой видеопоследовательности, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что содержит этапы, на которых декодируют из видеопоследовательности указание по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения независимой последовательности, причем данная последовательность включает в себя упомянутый по меньшей мере один опорный кадр изображения, начинают декодирование видеопоследовательности с упомянутого первого кадра изображения упомянутой независимой последовательности, при этом видеопоследовательность декодируется без прогнозирования на основе какого-либо кадра изображения, декодированного до упомянутого первого кадра изображения.

11. Способ по п. 10, отличающийся тем, что упомянутое указание является отдельным флагом, включенным в заголовок среза.

12. Способ по п. 10 или 11, отличающийся тем, что декодируют значения идентификаторов для кадров изображения согласно схеме нумерации, переустанавливают значение идентификатора для указанного первого кадра изображения независимой последовательности.

13. Видеодекодер для декодирования сжатой видеопоследовательности, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что выполнен с возможностью декодировать из видеопоследовательности указание по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения независимой последовательности, причем данная последовательность включает в себя упомянутый по меньшей мере один опорный кадр изображения, начинать декодирование видеопоследовательности с

упомянутого первого кадра изображения упомянутой независимой последовательности, при этом видеопоследовательность декодируется без прогнозирования на основе какого-либо кадра изображения, декодированного до упомянутого первого кадра изображения.

14. Машиночитаемый носитель, на котором хранится исполняемый в устройстве обработки данных компьютерный программный код, предназначенный для декодирования сжатой видеопоследовательности, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что компьютерный программный код содержит компьютерный программный код для того, чтобы декодировать из видеопоследовательности указание по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения независимой последовательности, причем данная последовательность включает в себя упомянутый по меньшей мере один опорный кадр изображения, компьютерный программный код для того, чтобы начинать декодирование видеопоследовательности с упомянутого первого кадра изображения упомянутой независимой последовательности, при этом видеопоследовательность декодируется без прогнозирования на основе какого-либо кадра изображения, декодированного до упомянутого первого кадра изображения.

15. Видеосигнал, содержащий сжатую видеопоследовательность, включающую в себя независимую последовательность кадров изображения, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения, отличающийся тем, что содержит указание по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения упомянутой независимой

последовательности, при этом упомянутый по меньшей мере один опорный кадр изображения включен в данную последовательность.

16. Видеосигнал по п. 15, отличающийся тем, что содержит значение идентификатора для упомянутой независимой последовательности.

(54) ГРУППИРОВАНИЕ КАДРОВ ИЗОБРАЖЕНИЯ НА ВИДЕО КОДИРОВАНИИ

Реферат

(57) Изобретение относится к области видеокодирования, и в частности, к группированию видео файлов с использованием потоковой передачи. Техническим результатом является обеспечение высокого качества восстановленного изображения. Техническим результат достигается тем, что способ кодирования видеопоследовательности, содержащей независимую последовательность кадров изображения, при этом по меньшей мере один опорный кадр изображения является прогнозируемым на основе по меньшей мере одного предыдущего кадра изображения, который предшествует в порядке декодирования предыдущему опорному кадру изображения. В видеопоследовательность кодируется указание по меньшей мере одного кадра изображения, который является первым, в порядке декодирования, кадром изображения упомянутой независимой последовательности, при этом упомянутый по меньшей мере один опорный кадр изображения включается в данную последовательность. На стадии декодирования из видеопоследовательности декодируется указание по меньшей мере одного кадра изображения, и декодирование видеопоследовательности начинается с упомянутого первого кадра изображения упомянутой независимой последовательности, при этом видеопоследовательность декодируется без прогнозирования на основе какого-либо кадра изображения, декодированного до упомянутого первого кадра изображения. 7 н.п., 9 з.п. ф-лы, 14 ил.

(54) СПОСОБ АНАЛИЗА ВЕКТОРОВ ДВИЖЕНИЯ ДЕТАЛЕЙ В ДИНАМИЧЕСКИХ ИЗОБРАЖЕНИЯХ

(57) Реферат:

Изобретение относится к видеоинформационной технике и может найти применение при разработке цифровых кодирующих устройств для видеотелефонии, видеоконференцсвязи, телевизионного цифрового вещания стандартной и высокой четкости. Технический результат заключается в сокращении количества вычислительных операций, увеличении зоны поиска векторов движения деталей в динамических изображениях и, вследствие этого, повышении качества воспроизведения быстро перемещающихся деталей. Технический результат достигается за счет того, что в способе анализа векторов движения деталей в динамических изображениях все множество пикселов каждого из макроблоков изображения разбивается на участки, в каждом из которых выбирается только один пиксел таким образом, что уровни всей совокупности выбранных пикселов характеризуют изменение рельефа сигнала яркости макроблока текущего кадра, и затем контрольная сумма, являющаяся суммой норм попиксельной разности уровней в текущем и опорном кадрах, вычисляется лишь по выбранным упомянутым пикселам. 1 з.п. ф-лы, 8 ил., 4 табл.

(54) METHOD FOR ANALYSIS OF MOVEMENT VECTORS OF ELEMENTS IN DYNAMIC IMAGES

(57) Abstract:

FIELD: video presentation devices, in particular, digital encoders for video telephones, conference calls, standard and high-definition TV systems. SUBSTANCE: method involves splitting complete set of pixels of each large image block into regions in which only one pixel is chosen so that levels of complete set of chosen pixels define alteration of shape of brightness signal of large image block of current frame. Then check sum which is defined as sum of norms of by-pixel difference in levels in current and reference frames is calculated using data from only chosen pixels. EFFECT: decreased amount of calculations, increased region for search of movement vectors of elements, improved quality of representation of fast moving elements. 2 cl, 13 dwg, 4 tbl

Изобретение относится к видеоинформационной технике и может найти применение при разработке цифровых кодирующих устройств для видеотелефонии, видеоконференцсвязи, телевизионного цифрового вещания стандартной и высокой четкости.

Известно множество способов анализа векторов движения деталей в динамических изображениях.

Наиболее простым и точным является способ поиска векторов движения макроблоков на основе полного перебора [1, с. 89-91]. Для поиска вектора движения $\vec{V} = (V_x, V_y)$ рассматривается норма разницы сигналов яркости двух макроблоков в текущем и опорном кадрах SAD со сдвигом на вектор движения:

$$SAD = \sum_{x,y=1,16} |F(x,y,t) - F(x-V_x, y-V_y, t-1)| \quad (1)$$

Под опорным подразумевается кадр, относительно которого осуществляется поиск векторов движения макроблоков текущего кадра. Иногда в качестве суммы норм принимают величину

$$SAD = \sum_{x,y=1,16} [F(x,y,t) - F(x-V_x, y-V_y, t-1)]^2 \quad (1.1)$$

Здесь F - значение яркости, (x, y) - пространственные координаты точки в кадре, t - временной индекс кадра, суммирование производится по всем точкам макроблока. Значение $\vec{V}$, для которого норма SAD имеет наименьшее значение, принимается за искомый вектор. Вектора движения ищутся методом полного перебора в некоторой ограниченной окрестности: $\min < V_x, V_y < \max$. Предполагая, что размер этой окрестности равен $\pm N$ по координатам x и y, получим для числа операций, необходимых для определения вектора движения одного макроблока, величину порядка $3 \cdot 256 (2N+1)^2$. На один пиксел макроблока количество операций составляет $3 \cdot (2N+1)^2$, что уже при N = 15 (значения векторов движения в пределах ± 15 точек) составляет значительную величину более 10^3 операций / пиксел.

Этот способ обычно используется в качестве эталонного для оценки качества других способов анализа векторов движения деталей в динамических изображениях.

Недостатком этого способа является требуемое большое количество вычислительных операций и в связи с этим низкое быстродействие.

Для уменьшения количества операций были предложены различные способы и методы, основанные на ограничении возможного числа кандидатов на вектора движения, в частности логарифмический и иерархический методы поиска векторов движения [1, с.92-96]. При логарифмическом поиске вектора движения поиск осуществляется в небольшой окрестности с шагом изменения значения вектора движения в 2 пиксела до тех пор, пока не будет найден локальный минимум SAD, после чего значение вектора движения уточняется с шагом в один пиксел в окрестности этого минимума. В 3-х шаговом способе поиск ведется первоначально по всей окрестности с шагом в 4 пиксела, затем вокруг найденного минимума с шагом в 2 пиксела, и, наконец, с шагом в один пиксел. В иерархическом способе первоначально проводится поиск векторов движения для специальным образом передискретизированного изображения, обладающего более грубым разрешением, потом значения найденных векторов движения уточняются при переходе к следующему уровню более высокого разрешения.

Недостатками этих ускоренных способов анализа являются существенные ошибки анализа движений деталей в динамических изображениях вследствие достаточно сложной зависимости SAD от V, которая практически всегда не является гладкой функцией. Функция $SAD(\vec{V})$ может иметь несколько экстремумов, что усложняет применение и значительно снижает эффективность данных методов.

Наиболее близким по технической сущности к заявляемому техническому решению является наиболее простой и точный способ [1] анализа векторов движения деталей в динамических изображениях, включающий преобразование последовательности кадров изображений в цифровую форму, запоминание дискретных отсчетов яркости текущего и соседнего по времени кадров, разбиение текущего кадра на макроблоки и поиск вектора движения каждого из макроблоков текущего кадра относительно опорного кадра посредством минимизации по рассматриваемому множеству векторов движения контрольной суммы данного макроблока, являющейся суммой норм попиксельной разности уровней в текущем и опорном кадрах.

Как уже было сказано, недостатком этого способа является требуемое большое количество вычислительных операций и в связи с этим низкое быстродействие. Этот недостаток не позволяет реально обеспечить большие зоны анализа движения, что приводит к снижению качества воспроизведения быстродвижущихся деталей в динамических изображениях.

В основу изобретения положена задача за счет сокращения объема вычислительных операций повысить быстродействие кодирующих устройств и производить анализ движения деталей динамических изображений в больших областях, сократив при этом объем сжатой информации и повысив качество воспроизведения быстродвижущихся деталей.

Эта задача решена посредством способа анализа векторов движения деталей в динамических изображениях, включающего преобразование последовательности кадров изображений в цифровую форму, запоминание дискретных отсчетов яркости текущего и опорного кадров, разбиение текущего кадра на макроблоки и поиск вектора движения каждого из макроблоков текущего кадра относительно опорного кадра посредством минимизации по рассматриваемому множеству векторов движения контрольной суммы данного макроблока, являющейся суммой норм попиксельной разности уровней в текущем и опорных кадрах. Согласно изобретению, все

RU 2137194 C1

RU 2137194 C1

множество пикселов рассматриваемого макроблока разбивают на участки, в каждом из которых определенным образом выбирают только один пиксел, и упомянутую контрольную сумму вычисляют лишь по выбранным упомянутым пикселам, при этом упомянутые пикселы в каждом из участков выбирают таким образом, что их уровни в смежных участках наиболее отличаются друг от друга.

Было бы целесообразно при использовании описанного выше способа анализа векторов движения деталей в динамических изображениях дополнительно для каждого текущего рассматриваемого значения вектора движения вычисление контрольной суммы по выбранным упомянутым пикселам производить в порядке убывания отклонения значения сигнала в каждом пикселе от среднего значения по всей совокупности упомянутых пикселов и прерыванием дальнейшего вычисления контрольной суммы в случае, когда она превышает значение минимальной контрольной суммы, найденной среди всех уже рассмотренных векторов движения.

На фиг. 1 изображен один из возможных вариантов устройства для реализации способа анализа векторов движения деталей в динамических изображениях; на фиг. 2 - 8 - диаграммы, поясняющие его работу.

Устройство, изображенное на фиг. 1, содержит подключенные к входу 1 параллельно блок синхронизации 2 и последовательно соединенные аналого-цифровой преобразователь 3, схему выделения 4 сигнала яркости, последовательно соединенные блок памяти 5 текущего кадра и блок памяти 6 опорного кадра, подключенные к выходам блока памяти текущего кадра последовательно соединенные блок памяти 7 текущего макроблока, блок преобразования 8 в порядковую статистику уровней пикселов макроблока и вычислитель 9 положений и уровней характерных пикселов макроблока, первые выходы которого соединены с блоком памяти 10 уровней выбранных пикселов, а вторые входы - через сумматор 11 к входам управления блока памяти опорного кадра 6, выходы которого через блок памяти 12 уровней пикселов сравнения подключены к первым входам блока 13 попиксельного вычитания уровней характерных пикселов текущего и опорного кадров, вторые входы которого подключены к вторым выходам блока памяти 10, а выходы - к блоку суммирования 14 модулей, выходы которого параллельно подключены к блоку сравнения сумм 15 и блоку вычисления 16 минимальной суммы и текущих векторов движения, вторые входы блока сравнения сумм 15 подключены к выходам блока 16, а выходы - непосредственно ко входам управления блока 14 и через счетчик перемещений 17 к второму входу сумматора 11, вторые выходы блока 16 подключены через блок памяти 18 векторов движения к выходам устройства 19, вторые выходы блока 18 соединены параллельно с дополнительными входами блока 16 и счетчика 17, выходы блока синхронизации 2 соединены с входами управления блоков 3 и 4, а также через блок управления 20 - с входами синхронизации работы блоков 5-18 устройства.

Сущность предполагаемого способа состоит в следующем.

Цель проводимых над сигналами динамического изображения преобразований состоит в резком сокращении объема вычислительных операций при увеличении зоны поиска векторов движения деталей в динамических изображениях, что позволяет существенно повысить быстродействие кодирующих устройств и производить анализ движения деталей динамических изображений в больших областях, сократив при этом объем сжатой информации и повысив качество воспроизведения быстродвижущихся деталей.

Изложение предлагаемого способа иллюстрируется на примере анализа вектора движения одного из макроблоков динамического изображения, приведенного на фиг. 2: фиг. 2а - текущий кадр, фиг. 2б - опорный кадр. На фиг. 3а приведена в увеличенном масштабе часть изображения текущего кадра в увеличенном масштабе с обведенным макроблоком, вектор движения которого определяется в зоне опорного кадра, изображенной на фиг. 3б. Макроблок имеет размер 16•16 пикселов, зона поиска движения - 64•64 пиксела. На фиг. 3б обозначено положение смещенного макроблока в опорном кадре.

В случае использования стандартного метода поиска вектора движения в указанной зоне поиска требуется использование вычислительной мощности в $3 \cdot 49^2 = 7203$ операций на каждый пиксел макроблока. Рельеф сигнала яркости макроблока изображен на фиг. 4а, а на фиг. 4б приведены цифровые значения пикселов этого макроблока.

В соответствии с предлагаемым способом макроблок разбивается на несколько участков, например на девять, как показано на фиг. 4б. В каждом из этих участков выбирается лишь один пиксел.

Один из вариантов выбора может быть связан с использованием порядковых статистик. В этом случае все значения пикселов $F_1 \ldots F_{256}$ располагаются в порядке возрастания уровней, как показано в таблице на фиг. 5. В этой таблице наряду со значениями уровней пикселов $F_{(1)} \le F_{(2)} \le \ldots F_{(255)} \le F_{(246)}$ приведена принадлежность их к соответствующим выбранным девяти участкам.

Для того, чтобы на точность оценки векторов движения в меньшей степени влияло наличие помех в сигнале яркости, в качестве первых двух пикселов принимаются пикселы, уровни в которых соответствуют следующему за минимальным и предшествующий максимальному (в данном случае - пиксел с уровнем $F_{(2)}$= 24, расположенный на 5-м участке макроблока и пиксел с уровнем $F_{(255)}$=236, расположенный на 7-м участке макроблока). Если эти пикселы оказываются расположенными в одном участке, то положение одного, например $F_{(2)}$, - фиксируется, и пикселы $F_{(254)}$, $F_{(253)}$ ... перебираются, пока участок окажется не тем, в котором располагается пиксел с уровнем $F_{(2)}$.

Пикселы в других участках выбираются отступая от $F_{(2)}$ в сторону увеличения индекса

RU 2137194 C1

RU 2137194 C1

и от $F_{(255)}$ в сторону уменьшения индекса, например, на равное количество пикселов $\frac{256}{9} \approx 28$. Следовательно, выбранными пикселами должны быть $F_{(30)}$=87, расположенный на 4-м участке и $F_{(227)}$=178, расположенный на 6-м участке.

Аналогично следующими пикселами выбираются $F_{(59)}$=112, расположенный на 9-ом участке, и $F_{(198)}$=164, расположенный на 1-м участке.

Далее выбираются пиксел с уровнем $F_{(88)}$=124, расположенный на 8-м участке, и пиксел с уровнем $F_{(169)}$=151, расположенный на 5-м участке. Учитывая, что на 5-м участке пиксел уже был выбран ранее ($F_{(2)}$), выбор осуществляется из двух пикселов $F_{(170)}$ и $F_{(168)}$ в данном случае с равными уровнями. Из них выбирается пиксел $F_{(170)}$, расположенный на 3-м участке.

И, наконец, в качестве претендента на выбранное значение пиксела можно указать $F_{(117)}$= 132. Но этот пиксел оказался также расположенным на 6-м участке и по этой причине подбирается пиксел с тем же уровнем $F_{(118)}$, расположенный на 2-м участке.

Таким образом,

на 1-м участке выбран пиксел с уровнем 164;

на 2-м участке выбран пиксел с уровнем 132;

на 3-м участке выбран пиксел с уровнем 151;

на 4-м участке выбран пиксел с уровнем 87;

на 5-м участке выбран пиксел с уровнем 24;

на 6-м участке выбран пиксел с уровнем 178;

на 7-м участке выбран пиксел с уровнем 236;

на 8-м участке выбран пиксел с уровнем 124;

на 9-м участке выбран пиксел с уровнем 112.

Для реализации этого метода подбора пикселов требуется использование примерно $\log_2 256 = 8$ вычислительных операций на каждый пиксел макроблока.

Возможен более простой метод выбора характерных пикселов в каждом из участков макроблока, например, путем чередования максимальных и минимальных значений уровней в смежных участках. Предположим, на заштрихованных на фиг. 4б участках выбираются пикселы с минимальными значениями уровней, а на остальных - с максимальными значениями уровней. Тогда

на 1-м участке будет выбран пиксел с уровнем 81;

на 2-м участке будет выбран пиксел с уровнем 196;

на 3-м участке будет выбран пиксел с уровнем 84;

на 4-м участке будет выбран пиксел с уровнем 221;

на 5-м участке будет выбран пиксел с уровнем 24;

на 6-м участке будет выбран пиксел с уровнем 237;

на 7-м участке будет выбран пиксел с уровнем 61;

на 8-м участке будет выбран пиксел с уровнем 188;

на 9-м участке будет выбран пиксел с уровнем 94.

Этот более простой метод подбора пикселов требует использования лишь одной вычислительной операции на пиксел.

Для поиска вектора движения $\vec{V} = (V_x, V_y)$ в предлагаемом способе рассматривается норма разницы сигналов яркости выбранных точек двух макроблоков в текущем и опорном кадрах SAD1 со сдвигом на вектор движения:

$$SAD1 = \sum_{\substack{(x,y)-\text{координаты выбранных точек в соответствующих участках макроблока}} |F(x,y,t)-F(x-V_x,y-V_y,t-1)| \quad (2)$$

Очевидно, что скорость анализа движения при использовании предлагаемого способа увеличивается в N/M раз, где N - число пикселов в макроблоке, M - количество участков, на которое поделен макроблок. В данном случае скорость анализа увеличивается в 256/9=28,44 раз.

Дополнительно скорость анализа движения макроблоков увеличивается в соответствии с п. 2 настоящего изобретения за счет определенного подбора вычисления контрольной суммы SAD 1.

В этом случае вычисляется среднее значение яркости выбранных пикселов макроблока

$$F_{ср} = \frac{1}{M} \sum_{\substack{(x,y)-\text{координаты выбранных точек в соответствующих участках макроблока}} F(x,y,t) \quad (3)$$

Затем вычисляются модули разностей $X(x,y) = |F(x,y,t)-F_{ср}|$,

где (x, y) - координаты выбранных точек в соответствующих участках макроблока, и контрольная сумма (2) вычисляется последовательно по координатам (x, y), для которых величины X(x, y) располагаются в убывающей последовательности.

В случае, если текущий выбранный вектор $\vec{V} = (V_x, V_y)$ не соответствует истинному вектору движения, для которого контрольная сумма минимальна, рассчитываемая контрольная сумма статистически достаточно быстро возрастает и в этом случае обычно не требуется производить вычисления по всем выбранным точкам макроблока. При этом в среднем по кадру скорость анализа движения макроблоков дополнительно возрастает в два раза.

Эффективность предлагаемого способа анализа движения иллюстрируется на фиг. 6-8.

На фиг. 6 приведены изображения разности текущего и опорного кадров после компенсации движения (а) и векторов движения (б), рассчитанных стандартным методом с использованием всех 256 пикселов макроблока.

На фиг. 7 приведены изображения разности текущего и опорного кадров после компенсации движения (а) и векторов

RU 2137194 C1

RU 2137194 C1

движения (б), рассчитанных предлагаемым способом с использованием лишь 9 пикселов макроблока.

На фиг. 8 приведены значения результирующей контрольной суммы до и после проведения анализа векторов движения; цифрой 1 обозначена кривая, характеризующая контрольную сумму до проведения анализа движения (без компенсации движения), цифрой 2 - кривая, характеризующая контрольную сумму при стандартном медленном анализе движения макроблоков с использованием 256 пикселов; цифрой 3 - кривая, характеризующая контрольную сумму при предложенном быстром способе анализа движения макроблоков с использованием лишь 9 пикселов.

Из визуального сравнения диаграмм фиг.6б и 7б видно, что анализ движения макроблоков с использованием стандартного и предлагаемого способов практически во всех областях кадра, насыщенных резко изменяющимся рельефом, осуществляется одинаково. Отличия возникают лишь в областях с малым изменением рельефа. Это подтверждается фиг. 8, на которой видно, что различие контрольных сумм оказывается малым (менее 10%).

Испытания различных динамических изображений показывают, что при увеличении числа выбранных участков, скажем, с 9 до 16 различие контрольных сумм с использованием стандартного и предлагаемого способа практически отсутствует.

Устройство для реализации предложенного способа работает следующим образом.

Предположим, на вход 1 устройства поступает аналоговый сигнал изображения, например полный цветовой телевизионный сигнал стандартных систем SECAM, PAL или NTSC. Со входа этот сигнал подается параллельно на блок синхронизации 2, выделяющий соответствующие сигналы и обеспечивающий формирование импульсов дискретизации, и на аналого-цифровой преобразователь АЦП 2, в котором дискретные отсчеты сигнала преобразуются в цифровой код, поступающий на схему выделения сигнала яркости 4, устраняющую цветовые поднесущие из полного цветового телевизионного сигнала. Выделение сигнала яркости необходимо, поскольку в соответствии со стандартами MPEG анализ движения деталей изображения осуществляется только при использовании яркостной компоненты изображения. Синхронизация работы схемы 4 осуществляется также дискретизирующими импульсами, поступающими с блока синхронизации 2.

Цифровой поток сигнала яркости со схемы 4 последовательно поступает на блок памяти 5 текущего кадра и блок памяти 6 опорного (предыдущего) кадра, в которых запоминаются дискретные отсчеты сигналов яркости текущего кадра, анализ движения макроблоков которого осуществляется относительно соответствующих структур опорного кадра.

Выходы блока 5 соединены со входами блока памяти макроблока 7, анализ движения которого производится. В этом блоке запоминаются значения рельефа сигнала яркости макроблока 16 •16 пикселов. После вычисления вектора движения 1-го макроблока, соответствующего левому верхнему углу изображения, в память этого блока вводится рельеф сигнала яркости следующего за ним макроблока. Отсчет номера макроблока осуществляется обычно слева направо и сверху вниз.

После запоминания уровней яркости всех пикселов макроблока они в блоке 8 преобразуются в порядковую статистику.

Обычно такое преобразование производится с использованием быстрого алгоритма, требующего для N чисел $N\log_2 N$ операций. При построении порядковой статистики одновременно фиксируются координаты пикселов, которым соответствует каждое их значение.

По значениям порядковой статистики в соответствии с упомянутым выше способом с помощью вычислителя положений и уровней 9 выбираются расположенные в выбранных участках по одному пикселу, по значениям, например, номеров порядковых статистик, приблизительно равноудаленных друг от друга. Принцип расчета поясняется для выбранного макроблока фиг.4а с помощью таблиц на фиг. 4б и 5. Рассчитанные выбранные пикселы соответствуют координатам, приведенным в табл. 1.

В случае использования описанного выше второго варианта выбора точек их координаты будут иными (см. табл. 2)

Таким образом, в вычислителе 9 выделяются значения уровней яркости выбранных пикселов и их координаты x и y.

В этом же блоке осуществляется преобразование выбранных пикселов в последовательность по мере убывания отклонений значений уровней пикселов от их среднего значения, для этой цели в первом варианте вычисляется среднее значение уровней

$F_{ср}$ =(164+132+151+87+24+178+236+124+112)/9 ≈ 134, а затем модули

$X(i) = X(x,y) = |F(x,y,t)-F_{ср}|$:

X(1) = 30; X(2) = 2; X(3) = 17; X(4)= 47; X(5)= 110;

X(6) = 44; X(7) = 102; X(8) = 10; X(9) = 22.

При этом выбранные пикселы представляются и запоминаются в вычислителе 9 в последовательности уменьшения модулей разностей (см. табл. 3).

При выборе пикселов по второму варианту среднее значение яркости будет равно:

$F_{ср}$ =(81+196+84+221+24+237+61+188+94)/9≈132.

Модули разностей при этом равны:

X(1)=51; X(2)=64; X(3)=48; X(4)=91; X(5)=108;

X(6) = 105; X(7) = 71; X(8) = 56; X(9) = 38, и выбранные пикселы представляются и запоминаются в вычислителе 9 в последовательности (см. табл. 4).

Далее уровни сигналов яркости в рассчитанной пиксельной последовательности запоминаются в блоке памяти 10, а их координаты (x, y) - через сумматор 11 поступают на вход управления блока памяти опорного кадра 6, обеспечивая запись в блоке 12 памяти уровней пикселов сравнения уровней пикселов с координатами

RU 2137194 C1

RU 2137194 C1

$(x-V_{OX}-V_{x,y}-V_{OY}-V_Y)$,

где (V_{OX}, V_{OY})- координаты начального вектора смещения, которые определяются, например, из результатов оценки движения соответствующих макроблоков в предыдущем кадре или из иных соображений,

(V_X, V_Y) - координаты текущего вектора смещения макроблока, при изменении которых производится анализ контрольной суммы разностей модулей уровней выбранных пикселов в макроблоке и пикселов в опорном кадре.

С блоков памяти 10 и 12 в указанной выше последовательности значения соответствующих уровней пикселов поступают на блок попиксельного высчитания 13 и с его выхода - на блок суммирования модулей 14. Блоки 13 и 14 совместно реализуют операцию, определяемую соотношением (2).

Последовательно вычисляемая в блоке 14 сумма поступает параллельно на блок сравнения сумм 15 и блок вычисления 16 минимальной суммы и соответствующих ей векторов движения. Первоначально при переходе от одного макроблока к другому в блоке 16 запоминается рассчитанный ранее начальный вектор движения (V_{OX}, V_{OY}), а сумма устанавливается нереально большой величиной.

При вычислении суммы для начального вектора движения эта сумма запоминается в блоке 16 и становится опорной для последующих расчетов. Если эта сумма при первом же расчете оказывается ниже некоторой установленной малой величины, то считается, что вектор движения найден. В противном случае по окончании расчета суммы при нулевом векторе (V_X, V_Y) блок сравнения 15 выдает команду на изменение координат вектора движения в счетчик перемещений 17 и обнуление результатов суммирования в блок 14. Обычно для обеспечения эффективного анализа вектора движения перемещение текущего вектора движения осуществляется от точки (V_{OX}, V_{OY}) по расходящейся спирали в пределах заданной зоны анализа.

В счетчике 17 формируется вектор $(-V_{OX} - V_X, - V_{OY} - V_Y)$, который затем суммируется в схеме 11 с текущими значениями координат выбранных характерных пикселов макроблока. Полученные координаты определяют запись уровней яркости соответствующих пикселов из блока 6 в блок 12, и процесс анализа вектора движения продолжается до тех пор, пока не найден будет истинный вектор движения макроблока (когда минимальная сумма, вычисляемая блоком 16, не станет меньше некоторой установленной минимальной величины), либо пока не будет проанализирована вся заданная зона анализа. Последний случай означает, что подобного макроблока в опорном кадре не существует.

Ускорение процесса анализа движения в соответствии с п. 2 настоящего изобретения определяется непрерывным сравнением текущей суммы и минимальной суммы в блоке 15. Если текущая сумма (до окончания процесса суммирования по всем выбранным пикселам) превышает ранее найденную минимальную сумму, то процесс суммирования прекращается и счетчик 17 перемещений изменяет координаты текущего вектора движения макроблока.

Результаты вычисления векторов движения, определяемые в блоке 16, запоминаются блоком памяти 18 векторов движения из которого результаты расчетов векторов движения, например в предыдущих кадрах (V_{OX}, V_{OY}), используются блоками 16 и 17 в качестве исходных векторов. С блока 18 координаты векторов движения подаются на цифровые выхода устройства 19.

Выполнение операций различных блоков устройства в описанной выше последовательности задается блоком управления, синхронизируемым импульсами с выхода блока синхронизации.

Формула изобретения:

1. Способ анализа векторов движения деталей в динамических изображениях, включающий преобразование последовательности кадров изображений в цифровую форму, запоминание дискретных отсчетов яркости текущего и опорного кадров, разбиение текущего кадра на макроблоки и поиск вектора движения каждого из макроблоков текущего кадра относительно опорного кадра посредством минимизации по рассматриваемому множеству векторов движения контрольной суммы данного макроблока, являющейся суммой норм попиксельной разности уровней в текущем и опорных кадрах, отличающийся тем, что все множество пикселов рассматриваемого макроблока разбивают на участки, в каждом из которых определенным образом выбирают только один пиксел, и упомянутую контрольную сумму вычисляют лишь по выбранным упомянутым пикселам, при этом упомянутые пикселы в каждом из участков выбирают таким образом, что их уровни в смежных участках наиболее отличаются друг от друга.

2. Способ анализа векторов движения по п. 1, отличающийся тем, что для каждого текущего рассматриваемого значения вектора движения вычисление контрольной суммы по выбранным упомянутым пикселам производят в порядке убывания отклонения значения сигнала в каждом пикселе от среднего значения по всей совокупности упомянутых пикселов и прерывают дальнейшее вычисление контрольной суммы в случае, когда она превышает значение минимальной контрольной суммы, найденной среди всех уже рассмотренных векторов движения.

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *25 January 2006*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-16* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *1-16* is/are rejected.

7)☐ Claim(s) _____ is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *25 January 2006* is/are: a)☐ accepted or b)☒ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☒ Certified copies of the priority documents have been received in Application No. 10/306942.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

Continuation of Attachment(s) 3). Information Disclosure Statement(s) (PTO/SB/08), Paper No(s)/Mail Date :6/19/2006, 8/18/2006, 11/24/2006, 10/22/2007, 6/16/2008, 3/12/2009, 4/20/2009, 2/08/2010, 2/18/2010, 3/30/2010.

DETAILED ACTION

Claim Objections

1. Claims 1-4, 5-8, and 10-12 are objected to because of the following informalities:

Claim 1, line 4 recites “the previous reference image frame”; there is a lack of antecedent basis for this limitation.

Claims 5, line 4 recites “the previous reference image frame”; there is a lack of antecedent basis for this limitation.

Claim 10, line 3 recites “the previous reference image frame”; there is a lack of antecedent basis for this limitation.

Appropriate correction is required.

Drawings

2. The drawings are objected to because Figure 1 does not have sufficiently descriptive labels. Blank boxes in drawings should be labeled descriptively unless it is a well-known component. For example, the blank box, "100" should be labeled as "Multimedia Source". Corrected drawing sheets in compliance with 37 CFR 1.121(d) are required in reply to the Office action to avoid abandonment of the application. Any amended replacement drawing sheet should include all of the figures appearing on the immediate prior version of the sheet, even if only one figure is being amended. The figure or figure number of an amended drawing should not be labeled as “amended.” If a drawing figure is to be canceled, the appropriate figure must be removed from the

replacement sheet, and where necessary, the remaining figures must be renumbered and appropriate changes made to the brief description of the several views of the drawings for consistency. Additional replacement sheets may be necessary to show the renumbering of the remaining figures. Each drawing sheet submitted after the filing date of an application must be labeled in the top margin as either "Replacement Sheet" or "New Sheet" pursuant to 37 CFR 1.121(d). If the changes are not accepted by the examiner, the applicant will be notified and informed of any required corrective action in the next Office action. The objection to the drawings will not be held in abeyance.

Claim Rejections - 35 USC § 101

3. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

Claims 5-8 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "video encoder" is non-structural per se and because the specification discloses a "software" embodiment (page 5, paragraph 0014 and page 33, paragraph 0097). Therefore, a reasonable interpretation in light of the specification leads to the conclusion that the claim video encoder as pure software (further confirm in claim 9 that computer program code for encoding a compressed video sequence, claim 9, line 7), which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claim 13 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "video decoder" is non-structural per se and because the specification discloses a "software" embodiment (page 5, paragraph 0014 and page 33, paragraph 0097). Therefore, a broadest reasonable interpretation in light of the specification leads to the conclusion that the claim video decoder as pure software (further confirm in claim 9 that computer program code for decoding from the video sequence, claim 14, line 7), which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claim 9 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claim is drawn to a "computer program product stored in a computer readable medium". The specification does not define the computer readable medium, therefore, it includes transitory and non-transitory computer readable medium. The broadest reasonable interpretation of the claim in light of the specification concludes that the claim as a whole covers a transitory signal, which does not fall within the definition of a process, machine, manufacture, or composition of matter (In re Nuijten). Therefore, claim 9 does not fall within a statutory category (the rejection can be overcome by specifying the computer readable medium as "non-transitory computer readable medium").

Claim 14 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine,

manufacture or composition of matter. The claim is drawn to a "computer program product stored in a computer readable medium". The specification does not define the computer readable medium, therefore, it includes transitory and non-transitory computer readable medium. The broadest reasonable interpretation of the claim in light of the specification concludes that the claim as a whole covers a transitory signal, which does not fall within the definition of a process, machine, manufacture, or composition of matter (In re Nuijten). Therefore, claim 9 does not fall within a statutory category (the rejection can be overcome by specifying the computer readable medium as "non-transitory computer readable medium").

Claim 15-16 are directed to a "video signal"; a signal is not limited to that which falls within a statutory category of invention because it is not limit to a process, machine, manufacture, or a composition of matter. Instead, it includes a form of energy. Energy does not fall with in a statutory category since it is clearly not a series of steps or acts to constitute a process, not a mechanical device or combination of mechanical device to constitute a machine, not a tangible physical article or object which is some form of matter to be a product and constitute a manufacture, and not a composite of two or more substances to constitute a composite of matter.

Claim Rejections - 35 USC § 112

4. The following is a quotation of the first paragraph of 35 U.S.C. 112:

> The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

Claims 5-8 are rejected under 112, 1st paragraph as being a single component (video encoder) claim, i.e., where a single component (video encoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Claim 13 is rejected under 112, 1st paragraph as being a single component (video decoder) claim, i.e., where a single component (video decoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Double Patenting

5. The nonstatutory double patenting rejection is based on a judicially created doctrine grounded in public policy (a policy reflected in the statute) so as to prevent the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees. A nonstatutory obviousness-type double patenting rejection is appropriate where the conflicting claims are not identical, but at least one examined application claim is not patentably distinct from the reference claim(s) because the examined application claim is either anticipated by, or would have been obvious over, the reference claim(s). See, e.g., *In re Berg*, 140 F.3d 1428, 46 USPQ2d 1226 (Fed. Cir. 1998); *In re Goodman*, 11 F.3d 1046, 29 USPQ2d 2010 (Fed. Cir. 1993); *In re Longi*, 759 F.2d 887, 225 USPQ 645 (Fed. Cir. 1985); *In re Van Ornum*, 686 F.2d 937, 214 USPQ 761 (CCPA 1982); *In re Vogel*, 422

F.2d 438, 164 USPQ 619 (CCPA 1970); and *In re Thorington*, 418 F.2d 528, 163 USPQ 644 (CCPA 1969).

A timely filed terminal disclaimer in compliance with 37 CFR 1.321(c) or 1.321(d) may be used to overcome an actual or provisional rejection based on a nonstatutory double patenting ground provided the conflicting application or patent either is shown to be commonly owned with this application, or claims an invention made as a result of activities undertaken within the scope of a joint research agreement.

Effective January 1, 1994, a registered attorney or agent of record may sign a terminal disclaimer. A terminal disclaimer signed by the assignee must fully comply with 37 CFR 3.73(b).

6. Claims 1-2, and 4 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 9 of copending Application No. 10/306942 in view of Kim et al. (US 2003/0063806 A1, hereinafter Kim).

Claim	Instant application	Claim	Co-pending application 10/306942
1	A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the	9	Claim 1 A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, **the video frames of the first frame format being independent of the**

	method comprising: encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence.		**other video frames**, and **the video frames of the second frame format being predicted from at least one of the other video frames**, the method comprising encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and **at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence**; and encoding, at the
2	A method according to claim 1, further comprising: encoding the indication into the video sequence as a separate flag included in the header of a slice.		
4	A method according to claim 1, further comprising: encoding into the video sequence an identifier value for the independent sequence.		

			encoder, into the video sequence information indicating which video frames belong to the second sub-sequence. Claim 3 A method according to claim 2, further comprising coding the video sequence into a plural number of scalability layers; and determining the dependency of the video frames of the second sub-sequence **such that at least one video frame of the second sub-sequence is predicted from a group comprising a video frame of a higher scalability layer, a video frame of another sub-sequence in the same scalability layer**. Claim 7 A method according to claim 3, further comprising **determining a**

			unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number. Claim 9 A method according to claim 7, further comprising **adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence**.

This is a provisional obviousness-type double patenting rejection.

(1) Regarding claim 1:

The co-pending application discloses a method for encoding a video sequence comprising an independent sequence of image frames (video sequence comprising video frame coded according to at least a first and second fame format), wherein at least one reference image frame (second sub-sequence) is predictable from at least one previous image frame that is earlier than a previous reference image frame in decoding order (at least one video frame of the second sub-sequence has been

predicted from at least one video frame of the first sub-sequence or a video frame of another sub-sequence in the same scalability layer), the method comprising:

encoding into the video sequence an indication (identifier) of at least one image frame (determined a unique identifier for each video frame), which is the first image frame, in decoding order, of the independent sequence (since **each** frame has an identifier added to the header field of the video sequence, therefore, it included the first image frame), said at least one reference image frame being included in the sequence (the video sequence includes at least a second sub-sequence, therefore, the claimed at least one reference image frame is included in the video sequence).

Claim 9 of the instant application does not explicitly disclose at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order.

However, Kim discloses an independent video sequence in figure 7 that at least one reference image frame P frame 708) is predictable from at least one previous image frame (I frame 704) that is earlier than a previous reference image frame in decoding order (P frame 706).

It is desirable to have at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order because it reduces latency when decoding the video sequence. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Kim in the method of the co-pending application to reduce latency when decoding the video sequence.

(2) Regarding claim 2 (the examiner interprets "a slice" as the video sequence as claim in claim 1):

The copending application discloses:

encoding the indication into the video sequence as a separate flag included in the header of a slice (adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence, the examiner interprets the adding process as the encoding process as claim).

(3) Regarding claim 4:

The co-pending application discloses:

encoding into the video sequence an identifier value for the independent sequence (determining a unique identifier for each video frame and adding the identifier to the header field of the video sequence, the examiner interpret adding the unique identifier to the header as encoding the identifier into the video sequence).

7. Claim 3 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 9 of copending Application No. 10/306942 in view of Kim et al. (US 2003/0063806 A1, hereinafter Kim) as apply to claim 1 and further in view of Kawashima et al. (US 4,390,966).

Copending application and Kim discloses all subject matter as discussed in claim 1 and copending application further discloses the encoding identifier values for image frames according to a numbering scheme (layer number, sub-sequence identifier and

image number), but fail to disclose resetting the identifier value for the indicated first image frame of an independent sequence.

However, Kawashima discloses a controller that setting or resetting flags as desired according to user instruction (column 6, lines 37-40).

It is desirable to reset the identifier value for the indicated first image frame of an independent sequence because since the video sequence is independent of other sequences, it would simplify the identifier value and reset the identifier value. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the resetting step as taught by Kawashima in the method of copending application and Kim to simplify the identifier value of the video sequence.

Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456)

Claim Rejections - 35 USC § 102

8. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

9. Claims 1 and 5 are rejected under 35 U.S.C. 102(e) as being anticipated by Kim et al. (US 2003/0063806 A1, hereinafter Kim).

Kim discloses a method and encoder (encoder discloses in figure 1B and 1C) for encoding a video sequence comprising an independent sequence of image frames (independent sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame (a video coding apparatus is provided to receive an indication that a first frame is to be intracoded, paragraph 0018, the examiner interprets the first intracoded frame as the claimed indication), which is the first image frame (the first frame is intracoded), in decoding order, of the independent sequence (independent sequence as shown in figure 7), said at least one reference image frame being included in the sequence (the P frame 708 is included in the sequence).

Claim Rejections - 35 USC § 103

10. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

11. Claims 1, 2, 4, 6, 8, 10, 11, 13, and 15-16 are rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456).

(1) Regarding claim 1:

Kim discloses a method and encoder (encoder discloses in figure 1B and 1C) for encoding a video sequence comprising an independent sequence of image frames (independent sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

encoding into the video sequence at least one image frame (a video coding apparatus is provided to receive an indication that a first frame is to be intracoded, paragraph 0018, the examiner interprets the first intracoded frame as the claimed indication), which is the first image frame (the first frame is intracoded), in decoding order, of the independent sequence (independent sequence as shown in figure 7), said at least one reference image frame being included in the sequence (the P frame 708 is included in the sequence).

Kim fails to explicitly disclose an indication of the first I frame.

However, Ueda discloses an encoded video sequence that comprises a fixed parameter identifier in the header of an input video code that indicates the type of picture from the picture header (I frame, column 10, lines 38-42).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

(2) Regarding claims 2 and 6:

Kim discloses all subject matter as discussed in claims 1 and 5 but fail to disclose encoding the indication into the video sequence as a separate flag included in the header of a slice.

However, Ueda discloses an encoded video sequence that comprises a fixed parameter identifier in the header of an input video code that indicates the type of picture from the picture header (column 10, lines 38-42).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

(3) Regarding claims 4 and 8:

Ueda further discloses encoding into the video sequence an identifier value for the independent sequence (an identifier of six bytes indicative of type of picture, column 7, lines 60-64 and column 10, lines 38-42).

(4) Regarding claims 10 and 13:

Kim discloses a method and decoder for decoding a compressed video sequence (sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising

decoding the first two frames of a sequence that yield the exact frame rate, the first two frame as I frame of figure 7 (paragraph 0071) which is the first image frame (I frame 702 in figure 7 is the first frame of the sequence), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (P frame 708 is included in the sequence) and starting the decoding of the video sequence from said first image frame of the independent sequence (as shown in figure 7, the first I frame 702 and the second I frame 704 is for generating the P frame 706-

712, therefore, the decoding processing is start from I frame 702), whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (as shown in figure 7, the sequence is independent and I frame 702 is the first frame of the sequence and no other frame prior to frame 702 is required).

Kim does not explicitly disclose decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence.

However, Ueda discloses a method that determines from an identifier in the header and determine if the frame is an I frame (step 111 and 112 of figure 12, column 14, lines 31-35).

It is desirable to decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence because it improves the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the decoding method of Kim to improve the reproduction speed of the encoded video sequence.

(5) Regarding claim 11:

Ueda further discloses wherein the indication is a separate flag in the header of a slice (an identifier of six bytes indicative of type of picture, column 7, lines 60-64 and column 10, lines 38-42).

(6) Regarding claim 15:

Kim discloses a signal comprising a compressed video sequence including an independent sequence of image frames (sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

at least one image frame (the first frame is an intracoded frame), which is the first image frame, in decoding order, of the independent sequence (the first I frame 702 is the first frame of the sequence as shown in figure 7), said at least one reference image frame being included in the sequence (P frame 708 is included in the sequence as shown in figure 7).

Kim fails to explicitly disclose an indication of the first I frame.

However, Ueda discloses an encoded video sequence that comprises a fixed parameter identifier in the header of an input video code that indicates the type of picture from the picture header (I frame, column 10, lines 38-42).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

(7) Regarding claim 16:

Ueda further discloses encoding into the video sequence an identifier value for the independent sequence (an identifier of six bytes indicative of type of picture, column 7, lines 60-64 and column 10, lines 38-42).

12. Claims 3 and 7 are rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456) and Kawashima et al. (US 4,390,966).

Kim discloses all subject matter as discussed in claims 1 and 5 except (a) encoding identifier values for image frames according to a numbering scheme, and (b) resetting the identifier value for the indicated first image frame of an independent sequence.

With respect to (a), Ueda discloses a fixed parameter identifier of six bits in the header of an input video code that indicates the type of picture from the picture header (column 7, lines 60-64 and column 10, lines 38-42, the examiner interprets the bits as a representation of numbering scheme in binary).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is

obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

With respect to (b), Kawashima discloses a controller that setting or resetting flags as desired according to user instruction (column 6, lines 37-40).

It is desirable to reset the identifier value for the indicated first image frame of an independent sequence because since the video sequence is independent of other sequences, it would simplify the identifier value and reset the identifier value. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the resetting step as taught by Kawashima in the method of copending application and Kim to simplify the identifier value of the video sequence.

13. Claims 9 and 14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Langberg et al. (US 5,852,630).

(1) Regarding claim 9:

Kim discloses a method and encoder (encoder discloses in figure 1B and 1C) for encoding a video sequence comprising an independent sequence of image frames

(independent sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame (a video coding apparatus is provided to receive an indication that a first frame is to be intracoded, paragraph 0018, the examiner interprets the first intracoded frame as the claimed indication), which is the first image frame (the first frame is intracoded), in decoding order, of the independent sequence (independent sequence as shown in figure 7), said at least one reference image frame being included in the sequence (the P frame 708 is included in the sequence).

Kim fails to disclose implementing the encoder by a computer program product, stored on a computer readable medium and executable in a data processing unit.

However, Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Kim would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability,

and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg to implement the method and encoder of Kim in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 14:

Kim discloses a method and decoder for decoding a compressed video sequence (sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising

decoding the first two frames of a sequence that yield the exact frame rate, the first two frame as I frame of figure 7 (paragraph 0071) which is the first image frame (I frame 702 in figure 7 is the first frame of the sequence), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (P frame 708 is included in the sequence) and starting the decoding of the video sequence from said first image frame of the independent sequence (as shown in figure 7, the first I frame 702 and the second I frame 704 is for generating the P frame 706-712, therefore, the decoding processing is start from I frame 702), whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (as shown in figure 7, the sequence is independent and I frame 702 is the first frame of the sequence and no other frame prior to frame 702 is required).

Kim does not explicitly disclose (a) decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence, and (b) implementing the method by a computer program product, stored on a computer readable medium and executable in a data processing unit.

With respect to (a), Ueda discloses a method that determines from an identifier in the header and determine if the frame is a I frame (step 111 and 112 of figure 12, column 14, lines 31-35).

It is desirable to decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence because it improves the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the decoding method of Kim to improve the reproduction speed of the encoded video sequence.

With respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Kim would have been implemented in a software. The implemented

software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg to implement the method and encoder of Kim and Ueda in order to reduce cost and improve the adaptability and flexibility of the communication system.

14. Claim 12 is rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456) as applied to claim 10 and further in vie of Kawashima et al. (US 4,390,966).

Kim and Ueda disclose all subject matter as discussed in claim 10, and Ueda further discloses a fixed parameter identifier of six bits in the header of an input video code that indicates the type of picture from the picture header (column 7, lines 60-64 and column 10, lines 38-42, the examiner interprets the bits as a representation of numbering scheme in binary).

Kim and Ueda fail to disclose resetting the identifier value for the indicated first image frame of an independent sequence.

However, Kawashima discloses a controller that setting or resetting flags as desired according to user instruction (column 6, lines 37-40).

It is desirable to reset the identifier value for the indicated first image frame of an independent sequence because since the video sequence is independent of other sequences, it would simplify the identifier value and reset the identifier value. Therefore, it would have been obvious to one of ordinary skill in the art at the time of

invention to employ the resetting step as taught by Kawashima in the method of copending application and Kim to simplify the identifier value of the video sequence.

Conclusion

15. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

Cuccia (US 202/0051621 A1) discloses an instant replay on digital video optimized using non MPEG frame tag.

Hannuksela et al. (US 2001/0040700 A1) discloses a video coding.

Apostolopoulos (US 7,103,669 B2) discloses a video communication method and system employing multiple state encoding and path diversity.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. §1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office Action on the merits but before the mailing date of a final Office Action under 37 C.F.R. §1.113 or a Notice of Allowance under 37 C.F.R. §1.311. Please charge Deposit Account 50-3581 (TPO.004.C1) the amount of $180.00 under 37 C.F.R. §1.17(p) for consideration of the item.

In accordance with 37 C.F.R. §1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that the reference is "prior art" within the meaning of 35 U.S.C. §§102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. §1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed June 17, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1-25 remain pending in the application. Claims 1-3, 5-12, 14-20, and 22-25 have been amended. No claims have been added, and claims 26-31 have been canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 8.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising:

decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames;

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to [[a]]the at least one discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. (Currently amended) A method according to claim 1, wherein said indication informs that the at least one discontinuity in the numbering of the image frames in the video sequence [[are]]is intentional.

3. (Currently amended) A method according to claim 1, further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

4. (Original) A method according to claim 1, wherein the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. (Currently amended) A method according to claim 1, further comprising

continuing the entering of the image frames comprised by the compressed video sequence ~~in question~~ into the buffer memory from [[the]]a correct image frame number after the buffer memory has been configured to provide the number of image frames

corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

6. (Currently amended) A method according to claim 1, further comprising

entering into the buffer memory a number of filler frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

7. (Currently amended) A method according to claim 6, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the ~~actual~~compressed video sequence.

8. (Currently amended) A method according to claim 1, wherein

~~the step of~~ configuring the buffer memory to provide a number of image frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. (Currently amended) A method according to claim 3, further comprising

detecting an error in the compressed video sequence on [[the]]a basis of a reference in the decoding process to an image frame corresponding to [[a]]the at least one discontinuity in the numbering of image frames.

10. (Currently amended) A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being ~~arranged~~configured to

decode from the decompressed video sequence an indication related to at least one discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to [[a]]the at least one discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. (Currently amended) A video decoder according to claim 10, wherein

said indication informs that ~~discontinuities~~the at least one discontinuity in the numbering of the image frames in the video sequence [[are]]is intentional.

12. (Currently amended) A video decoder according to claim 10, wherein the video decoder is further ~~arranged~~configured to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

13. (Original) A video decoder according to claim 10, wherein

the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. (Currently amended) A video decoder according to claim 10, wherein the video decoder is further ~~arranged~~configured to

continue the entering of the image frames comprised by the compressed video sequence ~~in question~~ into the buffer memory from [[the]]a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

15. (Currently amended) A video decoder according to claim 10, wherein the video decoder is further ~~arranged~~configured to

enter into the buffer memory a number of filler frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

16. (Currently amended) A video decoder according to claim 15, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the ~~actual~~compressed video sequence.

17. (Currently amended) A video decoder according to claim 10, wherein the video decoder is further ~~arranged~~configured to

configure the buffer memory to provide a number of image frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, the computer program product comprising:

a computer program code for decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to [[a]]the at least one discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. (Currently amended) A computer program product according to claim 18, wherein said indication informs that ~~discontinuities~~the at least one discontinuity in the numbering of the image frames in the video sequence [[are]]is intentional.

20. (Currently amended) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

21. (Original) A computer program product according to claim 18, the computer program product further comprising

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. (Currently amended) A computer program product according to claim 18, the computer program product further comprising

a computer program code for continuing the entering of the image frames comprised by the compressed video sequence ~~in question~~ into the buffer memory from [[the]]a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

23. (Currently amended) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for entering into the buffer memory a number of filler frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames.

24. (Currently amended) A computer program product according to claim 23, the computer program product further comprising:

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the ~~actual~~compressed video sequence.

25. (Currently amended) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the ~~discontinuities~~at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

26-31. (Canceled)

REMARKS/ARGUMENTS

Applicant appreciates the indication of allowability for claims 7-9. In view of the amendments and remarks herein, these claims are believed to be allowable in their pending format; therefore, Applicant declines the opportunity to rewrite these claims at this time.

The rejections presented in the Office action dated June 17, 2010 (hereinafter Office action) have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Claims 26-31 have been canceled, without prejudice, rendering the respective objections to, and rejections of, these claims moot. Applicant accordingly requests that the respective objections to, and rejections of, each of these claims be withdrawn.

With respect to the objection to claims 1, 5, 9, 10, 14, 18, 22, and 24, each of these claims has been amended to provide antecedent basis for the identified terms. In addition, further dependent claims have been amended to provide consistency with the changes to these claims. Applicant accordingly requests that the objection be removed.

With respect to the objection to Fig. 1, Applicant respectfully traverses. In contrast to the assertion that the figure includes "blank boxes", each of the boxes of Fig. 1 is labeled with a reference numeral in accordance with MPEP § 608.02. Moreover, no requirement has been cited for the request to label the boxes with text. Since Fig. 1 complies with the drawing requirements, and in an effort to maintain consistency with the parent application, Applicant requests that the objection be removed.

With respect to the § 101 rejection of claims 10-17, Applicant respectfully traverses. The Office action incorrectly asserts that the claimed video decoder is "pure software". While the specification refers to embodiments involving computer readable media storing program code (*e.g.*, claim 18), the claimed video decoder is a device constituting statutory subject matter. The term "decoder" is well-known in the art to refer to a device or circuit. Notably, the specification illustrates structural components of the decoder (*e.g.*, demultiplexer 116 and decompressor 118), and independent claim 10 recites that the video decoder is connected to a buffer memory. Paragraph [0095] teaches examples of a decoder

including a low bit rate video decoder as described in the ITU-T recommendation H.263 or H.26L. Moreover, paragraph [0096] describes positioning of the decoder that would not be possible if it was "pure software". Contrary to the assertion, the claimed video decoder is a device constituting statutory subject matter. Applicant accordingly requests that the rejection be withdrawn.

With respect to the § 101 rejection of claims 18-25, the claims have been amended to indicate that the claimed computer readable medium is non-transitory in accordance with the Examiner's suggestion. Applicant notes that non-transitory computer readable media comprise all computer readable media, with the sole exception being a transitory, propagating signal. Since an interpretation of the claims is now limited to statutory subject matter, Applicant submits that the rejection has been overcome and accordingly requests that the rejection be withdrawn.

With respect to the provisional rejections of claims 1-6, 10-15, and 18-23 under the judicially-created doctrine of obviousness-type double patenting over co-pending and commonly-owned patent application no. 10/306,942 (hereinafter "the '942 application"), Applicant will consider filing a Terminal Disclaimer once the instant application is in condition for allowance or the '942 application issues as a patent. However, Applicant respectfully asserts that, in view of the amendments to the claims and arguments made above, the Examiner is compelled to withdraw the rejections of the claims. Once withdrawn, the only rejection remaining in the instant application would be the provisional obviousness-type double patenting rejection. In view of MPEP § 804 I(B), Applicant respectfully requests that the provisional obviousness-type double patenting rejection be withdrawn and that the instant application be permitted to issue as a patent.

It should also be noted that Applicant does not acquiesce to the Examiner's statements or conclusions concerning what would have been obvious to one of ordinary skill in the art, obvious design choices, inherent, common knowledge at the time of Applicant's invention, officially noticed facts, and the like. Applicant reserves the right to address in detail the Examiner's characterizations, conclusions, and rejections in future prosecution.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C1) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111
If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371
If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office
If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed June 23, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1, 3-13, 15-24, 26, and 27, remain pending in the application. Claims 1, 3, 15, 22, and 23 have been amended. No claims have been added, and claim 2 has been canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 10.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of [[the]]other video frames, and the video frames of the second frame format being predicted from at least one ~~of the~~ other video ~~frames~~frame, the method comprising

encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence;

determining a dependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence; and

encoding~~, at the encoder,~~ said dependency into the video sequence ~~information indicating which video frames belong to the second sub-sequence~~.

2. (Canceled)

3. (Currently amended) A method according to claim [[2]]1, further comprising

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

- a video frame of a higher scalability layer,

- a video frame of another sub-sequence in the same scalability layer.

4. (Original) A method according to claim 3, further comprising

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. (Original) A method according to claim 3, further comprising

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. (Original) A method according to claim 3, further comprising

determining a unique identifier for each video frame on the basis of the image number.

9. (Original) A method according to claim 7, further comprising

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. (Original) A method according to claim 7, further comprising

adding the identifier to the Supplemental Enhancement Information (SEI) data structure to be transmitted synchronously with the video sequence.

11. (Original) A method according to claim 1, wherein

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

12. (Original) A method according to claim 1, further comprising

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

13. (Original) A method according to claim 1, further comprising

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

14. (Canceled)

15. (Currently amended) A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of [[the]]other video frames, and the video frames of the second frame format being predicted from at least one ~~of the~~ other video ~~frames~~frame, wherein the video encoder is ~~arranged~~configured to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; ~~and to~~

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine a dependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence; and [[to]]

[[form]]encode said dependency into the video sequence ~~information indicating which video frames belong the second sub-sequence~~.

16. (Previously presented) A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

decoding, at a decoder, a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding, at the decoder, at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining, at the decoder, dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing, at the decoder, at least part of the video sequence on the basis of the dependencies of the sub-sequences.

17. (Original) A method according to claim 16, wherein video frames are entered into a sliding buffer memory in connection with decoding, further comprising

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

18. (Original) A method according to claim 17, further comprising

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

19. (Original) A method according to claim 16, further comprising

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

20. (Original) A method according to claim 16, further comprising

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

21. (Original) A method according to claim 16, further comprising

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

22. (Currently amended) A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the video decoder is ~~arranged~~configured to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. (Currently amended) A computer program product, stored on a computer readable medium and executable in a data processing device, for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; [[and]]

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

a program code for determining a dependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence; and

a program code for ~~determining data~~encoding said dependency into the video sequence ~~to determine which video frames belong to the second sub-sequence~~.

24. (Previously presented) A computer program product, stored on a computer readable medium and executable in a data processing device, for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, wherein the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

25. (Canceled)

26. (Previously presented) A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising

encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format;

encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

encoding, at the encoder, into the video sequence information indicating which video frames belong to the second sub-sequence, wherein subsequence information is different from picture type information.

27. (Previously presented) A method according to claim 26, wherein

a removal of the second subsequence from the bitstream does not prevent decoding of the bitstream correctly.

REMARKS/ARGUMENTS

The rejections presented in the Office action dated June 23, 2010 (hereinafter Office action) have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Applicant appreciates the indication of allowability for claims 17, 18, and 21 but respectfully declines the opportunity to amend such claims at this time in view of the remarks below.

With respect to the § 112, first paragraph, rejection of claims 2-10, Applicant respectfully traverses. The original specification describes indicating interdependencies in at least paragraphs [0050] and [0059]. It is noted that the subject matter of a claim need not be described literally in the Specification (*i.e.*, using the same terms or *in haec verba*) and an applicant is not limited to the nomenclature used in the application as filed. MPEP §§ 608.01(o) and 2163.01. However, the term "interdependency" has been changed to "dependency" in the claims. Support for these changes may be found in the original specification, for example, at paragraph [0033] and in independent claims 16, 22, and 24; therefore, the changes do not introduce new matter. In view of at least the changes to the objected-to term, the rejection is believed to be overcome. Applicant accordingly requests that the rejection be withdrawn.

Applicant respectfully traverses the § 102(b) rejection based upon U.S. Patent No. 6,363,208 to Nitta *et al.* (hereinafter "Nitta") because Nitta was not patented or described in a printed publication in this or a foreign country more than one year prior to the filing date of the instant application for patent in the United States. The present application was filed in the United States on November 29, 2002. Since Nitta was patented on March 26, 2002, less than a year prior to the filing of the instant application in the United States, § 102(b) is not an appropriate statutory basis for rejection. Applicant accordingly requests that the rejection be withdrawn.

Without acquiescing to characterizations of the asserted art, Applicant's claimed subject matter, or to the applications of the asserted art or combinations thereof to Applicant's claimed subject matter, independent claims 1, 15, and 23 have been amended to

include the limitations of dependent claim 2. Since these limitations were present in original claim 2, the amendments do not introduce new matter. Independent claims 16, 22, 24, and 26 already include subject matter of original claim 2. Since the Office action does not assert that Nitta teaches the limitations of claim 2 (claim 2 is not rejected in view of Nitta), each of the claims is believed to be patentable over Nitta. In addition, the cited portion of Nitta (Col. 1, lines 44-56) merely teaches that the group of pictures includes an intra-frame coding picture (I picture), a P picture, and a B picture without any discussion of determining dependency between frames of a second sub-sequence and at least one video frame of a first sub-sequence and encoding the dependency into the video sequence, as now claimed in each of the independent claims. Without correspondence to each of the claimed limitations, a § 102 rejection based on Nitta would be improper. Applicant accordingly requests that the rejection be withdrawn.

Dependent claims 11-13, 19-20, and 27 depend from independent claims 1, 16, and 26, respectively, and also stand rejected as being anticipated by Nitta. While Applicant does not acquiesce with the particular rejections to these dependent claims, including any assertions concerning inherency, these rejections are moot in view of the remarks made above in connection with the independent claims. These dependent claims include all of the limitations of independent claims 1, 16, and 26 and any intervening claims, and recite additional features which further distinguish these claims from the cited reference. Therefore, the rejection of dependent claims 11-13, 19-20, and 27 is improper and should be withdrawn.

Authorization is given to charge Deposit Account No. 50-3581 (TAPA.004PA) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed May 25, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1, 2, 4-6, 8-11, 13, and 14 remain pending in the application. Claims 1, 5, 6, 8-10, 13, and 14 have been amended. No claims have been added, and claims 3, 7, 12, 15, and 16 have been canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 6.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

encoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of an independent sequence.

2. (Original) A method according to claim 1, further comprising:

encoding the indication into the video sequence as a separate flag included in the header of a slice.

3. (Canceled)

4. (Original) A method according to claim 1, further comprising:

encoding into the video sequence an identifier value for the independent sequence.

5. (Currently amended) A video encoder for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the video encoder being ~~arranged~~configured to:

encode into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

encode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of an independent sequence.

6. (Currently amended) A video encoder according to claim 5, wherein the video encoder is ~~arranged~~configured to

encode the indication into the video sequence as a separate flag included in the header of a slice.

7. (Canceled)

8. (Currently amended) A video encoder according to claim 5, wherein the video encoder is ~~arranged~~configured to

encode into the video sequence an identifier value for the independent sequence.

9. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame [[that]]and wherein the at least one reference frame is earlier than the at least one previous ~~reference~~ image frame in decoding order, the computer program product comprising:

a computer program code for encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

a computer code for encoding identifier values for image frames according to a numbering scheme; and

a computer code for resetting the identifier value for the indicated first image frame of an independent sequence.

10. (Currently amended) A method for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame [[that]]and wherein the at least one reference frame is earlier than the at least one previous ~~reference~~ image frame in decoding order, the method comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; [[and]]

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

decoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of an independent sequence.

11. (Original) A method according to claim 10, wherein the indication is a separate flag included in the header of a slice.

12. (Canceled)

13. (Currently amended) A video decoder for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the video decoder being ~~arranged~~configured to:

decode from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; [[and]]

start the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; and

decode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of an independent sequence.

14. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the computer program product comprising:

a computer program code for decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; [[and]]

a computer program code for starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

a computer program code for decoding identifier values for image frames according to a numbering scheme; and

a computer program code for resetting the identifier value for the indicated first image frame of an independent sequence.

15-16. (Canceled)

REMARKS/ARGUMENTS

The rejections presented in the Office action dated May 25, 2010 (hereinafter Office Action), have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Claims 3, 7, 12, 15, and 16 have been canceled, without prejudice, rendering the respective rejections of these claims moot. Applicant accordingly requests that the rejections of each of these claims be withdrawn.

With respect to the objection to claims 1, 2, 4, 5, 6, 8, 10, and 11, the term "the previous reference image frame" in independent claims 1, 5, and 10 has been amended to read "the previous image frame" in order to provide antecedent basis for the term. Applicant accordingly requests that the objection be removed.

With respect to the objection to Fig. 1, Applicant respectfully traverses. In contrast to the assertion that the figure includes "blank boxes", each of the boxes of Fig. 1 is labeled with a reference numeral in accordance with MPEP § 608.02. Moreover, no requirement has been cited for the request to label the boxes with text. Since Fig. 1 complies with the drawing requirements, and in an effort to maintain consistency with the parent application, Applicant requests that the objection be removed.

With respect to the § 101 rejection of claims 5-8 and 13, Applicant respectfully traverses. The Office action incorrectly asserts that the claimed encoder and decoder are "pure software". While the specification refers to embodiments involving computer readable media storing program code (*e.g.*, claims 9 and 14), the claimed encoder and decoder are devices constituting statutory subject matter. The terms "encoder" and "decoder" are well-known in the art to refer to a device or circuit. Notably, the specification illustrates structural components of the encoder (*e.g.*, compressor 108 and multiplexer 110) and decoder (*e.g.*, demultiplexer 116 and decompressor 118). Paragraph [0095] teaches examples of a decoder including a low bit rate video decoder as described in the ITU-T recommendation H.263 or H.26L. Moreover, paragraph [0096] describes positioning of the encoder and decoder that would not be possible if they were "pure

software". Contrary to the assertion, the claimed encoder and decoder are devices constituting statutory subject matter. Applicant accordingly requests that the rejection be withdrawn.

With respect to the § 101 rejection of claims 9 and 14, the claims have been amended to indicate that the claimed computer readable media are non-transitory in accordance with the Examiner's suggestion. Applicant notes that non-transitory computer readable media comprise all computer readable media, with the sole exception being a transitory, propagating signal. Since an interpretation of the claims is now limited to statutory subject matter, Applicant submits that the rejection has been overcome and accordingly requests that the rejection be withdrawn.

Applicant respectfully traverses the § 112, first paragraph, rejection of claims 5, 6, 8, and 13 because the claims are not "single means" claims. First, none of these claims uses a "means recitation" or "means plus function" language. While a claim dependent upon a recited property could result in a fact situation similar to that discussed in the cited *Hyatt* decision when the claim covers every conceivable structure for achieving the stated property, such is not the case for claims 5, 6, 8, and 13. In contrast the claims are limited to the structures of an encoder (claims 5, 6, and 8) and of a decoder (claim 13), which are well-accepted and understood terms in the art, for achieving the stated properties of the respective claims. Therefore, the claims are not unduly broad and are enabled by the specification. Applicant accordingly requests that the rejection be withdrawn.

Applicant respectfully traverses the § 102(e) rejection of claim 1 in view of U.S. Publication No. 2003/0063806 by Kim *et al*. (hereinafter "Kim") because the Office action acknowledges that Kim fails to teach or suggest each of the claimed limitations. In the § 103(a) rejection of claim 1 at page fifteen, the Office action states that "Kim fails to explicitly disclose an indication of the first I frame". Since Kim admittedly fails to correspond to each of the limitations of at least claim 1, the § 102(e) rejection is improper. Applicant accordingly requests that the rejection be withdrawn.

In an effort to facilitate prosecution and without acquiescing to characterizations of the asserted art, Applicant's claimed subject matter, or to the applications of the asserted art

or combinations thereof to Applicant's claimed subject matter, the independent claims have been amended to include the respective limitations of dependent claims 3, 7, and 12; therefore, these changes do not introduce new matter. Since the Office action acknowledges that Kim and U.S. Patent No. 6,094,456 to Ueda fail to teach or suggest each of the limitations of dependent claims 3, 7, and 12, each of the rejections based on these references is overcome. Each of the claims is further believed to be patentable over the asserted references for the reasons set forth below.

In rejecting dependent claims 3, 7, and 12, the Office action relies upon the teachings of U.S. Patent No. 4,390,966 to Kawashima *et al.* (hereinafter "Kawashima") as teaching the claimed resetting of the identifier value for the indicated first image frame of an independent sequence; however, this reliance is misplaced. Kawashima merely teaches that a sequence controller system is capable of setting and resetting flags according to predetermined user instructions. Kawashima's flags fail to at least correspond to the claimed identifier value since Kawashima is silent with respect to the flags being associated with an image frame of a coded video sequence. Also, Kawashima's flags are toggle flags for use in a multi CPU environment where each controller can run sequentially stored code in a parallel environment. There is no correspondence to the claimed resetting of an encoded identifier value for a first image frame of a video sequence. Without correspondence to each of the claimed limitations, the § 103(a) rejections of the subject matter of dependent claims 3, 7, and 12 is improper. Applicant accordingly requests that the rejections be withdrawn.

Further, the asserted modification of the combination of Kim and Ueda with the teachings of Kawashima is improper since the asserted modification is illogical and the teachings of Kawashima are not analogous to the field of Applicant's endeavor. First, the Office action asserts that it would be desirable to reset the identifier value since the video sequence is independent because it would simplify the identifier value and reset the identifier value. No explanation or evidence has been provided to indicate that resetting Kawashima's flags would simplify a value. Moreover, it is illogical to assert that it is

desirable to reset an identifier value because it would reset the identifier value. Thus, the proposed modification to the combination of Kim and Ueda is illogical and unsupported.

Second, the teachings of Kawashima are nonanalogous art as they are directed to very different technology than the field of video coding. In contrast, Kawashima is directed to the field of multi-core processing. Since Kawashima is in a field different than Applicant's endeavor, to be considered reasonably pertinent, Kawashima would need to address a problem addressed by the application at issue (MPEP § 2141.01(a)). However, the Office action fails to assert or identify any such relationship. Kawashima, directed to very different technology and failing to address video coding, would not have logically commended itself to an inventor of the instant application. Thus, Kawashima is nonanalogous art and fails to support the § 103(a) rejections. Applicant respectfully maintains the request that the § 103(a) rejections based upon Kawashima be withdrawn.

It should also be noted that Applicant does not acquiesce to the Examiner's statements or conclusions concerning what would have been obvious to one of ordinary skill in the art, obvious design choices, common knowledge at the time of Applicant's invention, officially noticed facts, and the like. Applicant reserves the right to address in detail the Examiner's characterizations, conclusions, and rejections in future prosecution.

With respect to the provisional rejections of claims 1-4 under the judicially-created doctrine of obviousness-type double patenting over co-pending and commonly-owned patent application no. 10/306,942 (hereinafter "the '942 application"), Applicant will consider filing a Terminal Disclaimer once the instant application is in condition for allowance or the '942 application issues as a patent. However, Applicant respectfully asserts that, in view of the amendments to the claims and arguments made above, the Examiner is compelled to withdraw the rejections of the claims. Once withdrawn, the only rejection remaining in the instant application would be the provisional obviousness-type double patenting rejection. In view of MPEP § 804 I(B), Applicant respectfully requests that the provisional obviousness-type double patenting rejection be withdrawn and that the instant application be permitted to issue as a patent.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C2) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311. Please charge Deposit Account 50-3581 (TPO.004.C1) the amount of $180.00 under 37 C.F.R. § 1.17(p) for consideration of the items.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

Abstract of **JP 11275576 (A)**

PROBLEM TO BE SOLVED: To detect aptitude of random independent reproduction processing in a short time with respect to compressed image data through the analysis of an identification flag in the case of analysis processing of a header imparted to the compressed image data · corresponding to a moving image. SOLUTION: In the image transmission method, compressed image data Dv obtained by applying compression coding processing to digital image data corresponding to a moving image are transmitted, and in this case, an identification flag Hfd denoting whether or not the compressed image data Dv are proper to random independent reproduction onto an optional screen is sent next to a synchronizing signal Hsd placed at a head of a header Hv.

Abstract of **JP 4348690 (A)**

PURPOSE:To prevent mis-recognition as cell abort when a sequence number of cell between frames is discontinuous due to the frame edit of the cell in a picture data storage section. CONSTITUTION:After each cell with a sequence number added thereto in the ascending order is stored in a picture data storage section 2, when a storage control section 3 edits each cell in the unit of frames and the sequence numbers between frames outputted one after another are discontinuous, an identification cell multiplex section 4 is activated to multiplex the identification cell between the frames. As a result, an abort discrimination section 7 recognizes the identification cell to prevent the abort of a cell in the sequence number missing part from being mis-recognized regardless of the discontinuous sequence numbers.

(54)【発明の名称】　画像蓄積伝送装置

(57)【要約】
【目的】　この発明は、画像データ蓄積部におけるセルのフレーム編集によりフレーム間のセルのシーケンス番号が非連続になった場合に、セルの廃棄と誤認するのを防ぐことを特徴とする。
【構成】　昇順にシーケンス番号が符された各セルを画像データ蓄積部２に蓄積した後、蓄積制御部３によって各セルをフレーム編集した際、前後して出力されるフレーム間のシーケンス番号が非連続になった時、識別セル多重化部４を稼働し、フレーム間に識別セルを多重化する。この結果、廃棄判定部７では識別セルを認識することで、シーケンス番号の非連続線にも拘らず、シーケンス番号欠落部分のセルの廃棄を誤認することがない。

1

【特許請求の範囲】

【請求項1】　個々に昇順のシーケンス番号が符されたセル単位の符号化画像データを伝送路を介して蓄積部へ蓄積した後、必要に応じてフレーム編集を施して復号化部へ出力する画像蓄積伝送装置において、上記蓄積部に蓄積画像データをフレーム編集する蓄積制御部と、フレーム編集によりシーケンス番号が非連続になったフレームの前に識別セルを多重する識別セル多重化部と、前記識別セル読み取りによりセルの廃棄を判定する廃棄判定部とを備えたことを特徴とする画像蓄積伝送装置。

【発明の詳細な説明】

【０００１】

【産業上の利用分野】この発明は、伝送されてきた符号化画像データを一旦蓄積した後、復号化部へ伝送する画像蓄積伝送装置に関するものである。

【０００２】

【従来の技術】以下に、本発明に関する従来技術の説明をする。図３は、テレビジョン学会誌、Ｖｏｌ．４３，Ｎｏ１０（１９８９）ｐｐ．１０７２～１０７８“周期的フレーム内符号化を用いた蓄積メディア用動画象符号化方式”および同Ｖｏｌ．４３，Ｎｏ１０（１９８９）ｐｐ．１１０６～１１１１“フレーム間符号化方式を用いた記録系動画再生システムの検討”の文中から予測した従来の画像蓄積再生装置の構成を示すものであるが、ここで３は蓄積媒体８の制御を行う蓄積制御部、９は蓄積媒体のクロックから復号クロックへ乗せ換えるための速度変換バッファ、７は符号化された画像データを可変長復号化し、さらに逆量子化を行い、モニタへ表示するための復号化部である。

【０００３】図４は、Ｂ－ＩＳＤＮの伝送方式の一種であるＡＴＭ（Ａｓｙｎｃｈｒｏｎｏｕｓ　Ｔｒａｎｓｆｅｒ　Ｍｏｄｅ：非同期転送モード）網を用いた画像伝送装置の受信部の構成を表したものであり、１は伝送路（ＡＴＭ）、５は廃棄判定部、６は伝送路でのデータの揺らぎ等を吸収するための受信バッファ、７は符号化された画像データを可変長復号し、さらに逆量子化を行い、モニタへ表示するための復号化部、１０は音声多重化されたセルの分解、合成を行うセル分解・合成部である。図５は上記ＡＴＭ網での伝送概念の一例を表したものである。各セルは昇順にシーケンス番号が符下れて蓄積媒体８に蓄積された後、蓄積制御部３によって、所定数のセル単位毎にフレーム編集される。

【０００４】次に従来技術の詳細動作について説明する。まず、従来の画像蓄積再生装置は図３のように構成されるが、ここで蓄積媒体８にはあらかじめフレーム間符号化された一定量のデータが蓄積されている。ここでは蓄積メディアとして例えば画像フレームの編集、コマ送り等ができるように、ここでの画像データは一定の周期でフレーム内符号化されている（例えば３０フレーム周期でフレーム内符号化をしていればフレーム内のみを

2

蓄積媒体から読み出せば、コマ送りとなる）。次に蓄積制御部３で蓄積媒体８からデータを読み出す制御を行う。読み出されたデータは速度変換バッファ９にてクロックの乗せ変えが行われ、復号部７で可変長復号化、逆量子化、データフォーマット変換等が行われ、モニタに出力される。

【０００５】また、従来のＡＴＭ網を用いた画像伝送装置は図４のように構成されているが、ここでＡＴＭの伝送路１から入って来た画像画像セル化データはセル分解・合成部１０で音声／映像の分解網での制御情報などが分解される。次にＡＴＭは網が輻輳した場合、優先度の低いセルが廃棄されるため、廃棄判定部５にてセルの廃棄があったかどうかを判定する。これはセル１つ１つに対して付加されているシーケンス番号の連続性を見て判定する。廃棄判定部５から出力されたデータは受信バッファ６に格納される。ここでは伝送路１でのデータ揺らぎに対する許容、また伝送クロックから復号クロックに乗せ換える機能も司る。復号化部７では可変長符号化されて伝送されて来たデータを逆に可変長復号化し、逆量子化、データフォーマットの変換等を行い、モニタに出力する。

【０００６】

【発明が解決しようとする課題】従来のＡＴＭ網用の画像伝送装置で、図３のように蓄積メディアを搭載した場合、以下のような問題点が生じる。即ち、蓄積媒体で蓄積された画像データをフレーム編集（コマ送り、逆再生等）して読み出した時、セルの順番が伝送路より入って来た時と異なってしまう。伝送路で廃棄が起こったかどうかは、先にも述べたが、セル１つ１つに対してヘッダとして付加されているシーケンス番号が連続しているかどうかで判定するので蓄積媒体でセルの順番を加工してしまうと、廃棄と誤認してしまうという問題があった。

【０００７】この発明は上記のような問題点を解決するためになされたもので、蓄積部での編集で変わってしまったシーケンス番号の連続を認識し、廃棄との区別を行い、正しい廃棄処理の行える画像蓄積伝送装置を得ることを目的とする。

【０００８】

【課題を解決するための手段】この発明に係る画像蓄積伝送装置は、個々に昇順のシーケンス番号が符されたセル単位の符号化画像データを伝送路を介して蓄積部へ蓄積した後、必要に応じてフレーム編集を施して復号化部へ出力する画像蓄積伝送装置において、上記蓄積部に蓄積画像データをフレーム編集する蓄積制御部と、フレーム編集によりシーケンス番号が非連続になったフレームの前に識別セルを多重する識別セル多重化部と、前記識別セル読み取りによりセルの廃棄を判定する廃棄判定部とを備えたものである。

【０００９】

【作用】この発明における識別セル多重化部は、制御部

Page 1759 of 2504

3

でフレーム編集シーケンス番号が非連続になったという情報（タイミング等）を受けてフレーム編集したフレームの前に識別セルを多重し、後段の廃棄判定部で編集かどうかを判断するものである。

【0010】

【実施例】以下、この発明の一実施例を図について説明する。図1において、1は網が輻輳した場合に、セルが廃棄される可能性のある伝送方式の網（例えばATM）（伝送路）、2は伝送路1より送られて来た画像データを一定量蓄積するための画像データ蓄積部、3は画像データ蓄積部2でのデータの書き込みと読み出しを制御する蓄積制御部、4は画像データ蓄積部2でフレーム編集等を行った場合に廃棄と区別するために識別セルを付加するための識別セル多重化部、5は伝送路でセルの廃棄があったかどうかを判定する廃棄判定部、6は伝送クロックから復号クロックへ乗せ換えるための受信バッファ、7は符号化された画像データを復号化しモニタへ表示するための復号化部である。

【0011】次に、この発明の一実施例について作用、動作を説明する。まず図1で、伝送路1から送られてきた画像データは、一旦画像データ蓄積部2で蓄積される。ここでの蓄積容量は画像フレームを複数フレーム蓄積できる容量を持っているものとする。この画像データ蓄積部2へデータを書き込む制御、および読み出す制御、また画像データ蓄積部2内でフレーム編集等を制御するのが蓄積制御部3であり、蓄積制御部3でフレーム編集した場合にそのフレームおよびタイミングを認識しているので、その情報を識別セル多重化部7に送る。画像データ蓄積部2から読み出されたデータ（セル）は識別セル多重化部4に入力される。ここでは、画像データ蓄積部2でフレーム編集を行わない場合、データはそのまま通過する。画像データ蓄積部2でフレーム編集を行った場合に各フレーム間のセルのシーケンス番号が非連続になった時は、蓄積制御部3で編集をしたタイミングで識別セルを多重化する。これは図2と図4に1例を表しており、それぞれの図について説明する。

【0012】まず図4であるが、これは通常のセルの並びであり、セル内の番号はパケットごと付いているシーケンス番号である。図4ではフレームごとに第1フレームから第3フレームまでを表示してあるが、ここでは編集を行って、第1フレームと第3フレームを接続した場合を述べる。図2は編集した場合のセルの並びである。第2フレームを削除してしまったために、第1フレームと第2フレームのシーケンス番号が連続でなくなっている。このため識別セルを多重しないと第2フレームは廃棄されたものとして扱われてしまう。識別セル多重化部7に手上記の処理を施した後、廃棄判定部4で廃棄されているかの判定を行い、速度変換バッファ5で伝送クロックから復号クロックに乗せ換える。そして復号部6で画像データの各種復号を行い、画像を表示するためのフォーマットに変換して出力する。

4

【0013】

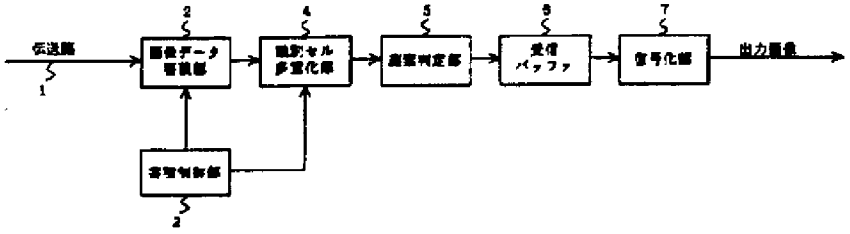
【発明の効果】以上のように、この発明によれば蓄積部でのデータ編集を行った場合にセルのシーケンス番号が非連続になった時、フレーム編集を行ったフレームの前に識別セルを多重するように構成したので、セル廃棄または編集によるシーケンス番号の非連続を容易に区別でき、正しい廃棄処理が行われるという効果がある。

【図面の簡単な説明】

【図1】この発明の一実施例による画像蓄積伝送装置の構成図である。

【図2】この発明の一実施例によるセルフォーマットを示す図である。

【図3】従来の画像蓄積伝送装置の構成図である。



【図4】ATM用画像伝送装置の構成図である。

【図5】ATMのセルフォーマットを示す図である。

NOTICE OF REASONS FOR REJECTION

(TRANSLATION)

Patent Application No.:	2006-120297
Drafting Date:	August 11, 2010
Patent Office Examiner:	Akiyo Sakamoto 2954 5C00
Attorney for Patent Applicant:	Atsushi Aoki (and four others)
Applicable Provisions:	Article 29, paragraph 1; Article 29, paragraph 2; Article 36

It is deemed that the present application should be rejected for the following reasons. An argument, if any, should be submitted within 3 months from the mailing date of this notice.

REASONS

a. The inventions described in the following claims of this application are inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 1, item 3 of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)

Claims: 1, 5, 9, 10, 13, and 14
Reference: 1
Remarks:

It is not deemed that there are any differences between the inventions according to claims 1, 5, 9, 10, 13, and 14 and the invention described in Reference 1 (refer to Reason b).

b. The inventions described in the following claims of this application are deemed ones which could easily have been made, prior to the filing of the patent application, by a person with ordinary skill in the art to which the inventions pertain, on the basis of the inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 2, of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)

Claims: 1, 2, 4 to 6, 8 to 11, 13, and 14
References: 1 and 2

Remarks:

Reference 1 describes that an independently reproducible flag is included in a frame header (specifically, refer to paragraphs [0112] to [0113]).

With respect to claims 2, 6, and 11, Reference 2 describes that the additional information of the frame layer is included in the header of the slice layer.

Therefore, it is deemed that including an indication identifying the image frame initially encoded in an independently decodable sequence in the header of a slice as in the present invention could have easily been conceived of by a person skilled in the art by applying the invention described in Reference 2 to the aforementioned flag of the invention described in Reference 1 to include the aforementioned flag in the header of the slice layer.

c. The description of the claims of this application does not satisfy the requirements prescribed in Article 36, paragraph 6, item 2 of the Patent Law on the following points.

Notes

There are two Japanese expressions corresponding to the "first image frame" described in claim 3, but whether or not both mean the same frame is unclear from the descriptions.

The same is true for the Japanese descriptions corresponding to "first" in other claims.

If an amendment is made, it should be noted that no new matter can be added. In an amendment, the reasons that the amendments meet the requirements prescribed in the Patent Law should be stated identifying the relevant descriptions of the original specification on which the amendments rest.

If another reason for rejection is found, a further notice of reasons for rejection will be issued.

Mailing Date: August 24, 2010

NOTICE OF REASONS FOR REJECTION

Patent Application No.:	2006-120296
Drafting Date:	August 17, 2010
Patent Office Examiner:	Akiyo Sakamoto 2954 5C00
Attorney for Patent Applicant:	Atsushi Aoki (and four others)
Applicable Provisions:	Article 29, paragraph 2; Article 36

It is deemed that the present application should be rejected for the following reasons. An argument, if any, should be submitted within 3 months from the mailing date of this notice.

REASONS

a. The inventions described in the following claims of this application are deemed ones which could easily have been made, prior to the filing of the patent application, by a person with ordinary skill in the art to which the inventions pertain, on the basis of the inventions described in the following publications distributed or the inventions made available to the public through electronic telecommunications lines in Japan or a foreign country prior to the filing of the patent application and, therefore, are unpatentable under the provisions of Article 29, paragraph 2, of the Patent Law.

NOTE (For the numbers of the cited references, see the List of Cited References)

Claim: 26
Reference: 1
Remarks:

Reference 1 describes that when the discontinuity of the sequence number of the cells occurs between frames as a result of frame editing, the identification cells are multiplexed before the frame at which the sequence number of the cells is discontinuous, in order to distinguish the discontinuity from a discontinuity which is caused by discarding of the cells in a transmission path (specifically, refer to paragraphs [0006] to [0009]).

In the invention described in Reference 1, the discontinuity of the sequence numbers is caused by a change in the sequence of the frames as a result of frame editing, thus, it is considered that the aforementioned identification cells mean a change of the sequence of the frames by the editing.

The technology for adding a frame number to each frame is known. When the editing in the invention described in Reference 1 is performed for the image data to which the frame number is added, then, the frame number becomes discontinuous due to a change of the sequence of the frames, thus, the discontinuity of the frame number is represented by the aforementioned identification cell.

Therefore, it is deemed that informing that a discontinuity in the numbering of the image frames is intentional as in the invention of the present application,

could have easily been conceived of by a person skilled in the art based on the invention described in Reference 1 and the aforementioned known technology.

b. The description of the claims of this application does not satisfy the requirements prescribed in Article 36, paragraph 6, item 2 of the Patent Law on the following points.

Notes

(1) The Japanese description corresponding to "the video sequence in question" is described in claims 14 and 22, but from the description of "the...in question", what is indicated by the description of "the" is unclear.

(2) "a computer program comprising steps to be executed by a computer...step of (omitted)..., step of...(omitted)...." is described in claim 18, but from the description of "to be executed by a computer...step of (omitted)...", whether or not the computer program causes a computer to execute each step is unclear(refer to Part VII, Chapter 1, 1.1.1(2)(b) of Examination Guidelines for Patent and Utility Model).

Note that, the above reason is overcome if the description of "a computer program comprising steps to be executed by a computer, the steps including the step of decoding a compressed video sequence, a step of...(omitted)...." is amended to, for example, "a computer program for causing a computer to execute a step of decoding a compressed video sequence, a step of...(omitted)....".

(3) Claims 22 to 25 describe "...comprises code for...", but

claim 18 upon which claims 22 to 25 are dependent upon uses not the term "code", but uses the term "step", thus, claims 22 to 25 which describe "comprises code" contradict the description of claim 18 and are unclear.

Note that, the above reason is overcome if the term "code" of claims 22 to 25 is replaced with, for example, "a step".

Further, if an amendment is made, it should be noted that no new matter can be added and in an argument, the reasons that the amendments meet the requirements of the Patent Law should be stated, identifying the relevant descriptions of the original specification on which the amendments are based.

<Claims for which no reasons for rejection have been found>

No reasons for rejection have been found at present for the inventions according to claims 1 to 13. If another reason for rejection is found, a further notice of reasons for rejection will be issued.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. §1.97(c)(1) and 37 C.F.R. §1.97 (e)(1)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted after the mailing date of the first Office Action on the merits but before the mailing date of a final Office Action under 37 C.F.R. §1.113 or a Notice of Allowance under 37 C.F.R. §1.311.

The items listed on the enclosed Form 1449 were first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of the information disclosure statement. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449. However, if fees are deemed necessary, authorization is given to charge Deposit Account 50-3581 (TPO.004.C1) for consideration of the information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE *3* MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *10 September 2010*.

2a)☒ This action is **FINAL**. 2b)☐ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-25* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

DETAILED ACTION

Response to Arguments

1. Applicant's arguments, see page 8, filed 9/10/2010, with respect to claim objection to claims 1, 5, 9, 10, 14, 18, 22, and 24 and objection to figure 1 have been fully considered and are persuasive. The objection of claims 1, 5, 9, 10, 14, 18, 22, and 24 and objection to figure 1 have been withdrawn.

2. Applicant's arguments, see page 8, filed 9/10/2010, with respect to 35 U.S.C. 101 rejection to claims 18-25 have been fully considered and are persuasive. The 35 U.S.C. 101 rejection to claims 18-25 has been withdrawn.

3. Applicant's arguments filed 9/10/2010 with respect to the 35 U.S.C. 101 rejection of claims 10-17 have been fully considered but they are not persuasive.

Applicant's argument:

The claimed video decoder is a device constituting statutory subject matter. The term "decoder" is well known in the art to refer to a device or circuit. Notably, the specification illustrates structural component of the decoder, and independent claim 10 recites that the video decoder is connected to a buffer memory. Paragraph 006 describes positioning of the decoder that would not be possible if it was "pure software".

Examiner's response:

Page 33, paragraph 0097 of the specification of the instant application clearly disclose that the decoder can be implemented by software, hardware, or a combination of hardware and software:

"**[0097] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two.**"

Base on the specification and the fact that the claimed decoder is non-structural per se, the claimed video decoder covers hardware, software, and a combination of hardware and software embodiment. In light of the specification, a broadest reasonable interpretation of the claimed video decoder can be interpreted as software per se. Therefore, the 35 U.S.C. 101 rejection of claims 10-17 are maintained.

4. Applicant's arguments filed 9/10/2010 with respect to the obviousness-type double patenting rejection of claims 1-6, 10-15, and 18-23 over co-pending and commonly owned patent application 10/306,942, the applicant states that the applicant will consider filing a terminal disclaimer once the instant application is in condition for allowance or the application 10/306942 application issues as a patent.

According to the record of the application 10/306,942, the application has been allow on 10/7/2010; therefore, the examiner maintain the double patenting rejection on

claims 1-6, 10-15, and 18-23. The applicant can file a terminal disclaimer to overcome the double patenting rejection on claims1-6, 10-15, and 18-23.

Claim Objections

5. Claim 10-17 are objected to because of the following informalities:

Line 4 recites “decode from the decompressed video sequence”; there is a lack of antecedent basis for “the decompressed video sequence”. The examiner suggests changing to “decode from the **compressed** video sequence".

Appropriate correction is required.

Claim Rejections - 35 USC § 101

6. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

Claims 10-17 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed “video decoder” is non-structural per se and because the specification discloses a “software” embodiment (page 6, paragraph 0015 and page 33, paragraph 0097). Therefore, a reasonable interpretation in light of the specification leads to the conclusion that the claim video decoder covers a software embodiment, which does not fall within the definition of a process, machine, manufacture or composition of matter.

Double Patenting

7. The nonstatutory double patenting rejection is based on a judicially created doctrine grounded in public policy (a policy reflected in the statute) so as to prevent the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees. A nonstatutory obviousness-type double patenting rejection is appropriate where the conflicting claims are not identical, but at least one examined application claim is not patentably distinct from the reference claim(s) because the examined application claim is either anticipated by, or would have been obvious over, the reference claim(s). See, e.g., *In re Berg*, 140 F.3d 1428, 46 USPQ2d 1226 (Fed. Cir. 1998); *In re Goodman*, 11 F.3d 1046, 29 USPQ2d 2010 (Fed. Cir. 1993); *In re Longi*, 759 F.2d 887, 225 USPQ 645 (Fed. Cir. 1985); *In re Van Ornum*, 686 F.2d 937, 214 USPQ 761 (CCPA 1982); *In re Vogel*, 422 F.2d 438, 164 USPQ 619 (CCPA 1970); and *In re Thorington*, 418 F.2d 528, 163 USPQ 644 (CCPA 1969).

A timely filed terminal disclaimer in compliance with 37 CFR 1.321(c) or 1.321(d) may be used to overcome an actual or provisional rejection based on a nonstatutory double patenting ground provided the conflicting application or patent either is shown to be commonly owned with this application, or claims an invention made as a result of activities undertaken within the scope of a joint research agreement.

Effective January 1, 1994, a registered attorney or agent of record may sign a terminal disclaimer. A terminal disclaimer signed by the assignee must fully comply with 37 CFR 3.73(b).

1. Claims 1-5 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim	Instant application	Claim	Co-pending application 10/306942

1	A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising: decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames; configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames; and using the image frames in the buffer memory in the decoding process.	17	(including limitation of claim 16) Claim 16 A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, the method comprising: decoding, at a decoder, a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format; decoding, at the decoder, at least a second sub-sequence of the

10	A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being configured to decode from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames; configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames; and use the image frames in the buffer memory in the decoding process.		video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; determining, at the decoder, dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and reconstructing, at the decoder, at least part of the video sequence on the basis of the dependencies of the sub-sequences. Claim 17 A method according to claim 16, **wherein video frames are entered into a sliding buffer**

			memory in connection with decoding, further comprising: **decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional**; **configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers**; and continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to

			the missing image numbers.

(1) Regarding claim 1:

Claim 17 of the copending application discloses decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; and configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames (the bold and underlined part in the above table).

The co-pending application does not explicitly disclose using the image frame in the buffer memory in the decoding process.

However, claim 17 also discloses wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

(2) Regarding claim 2:

Claim 17 further disclose wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

(3) Regarding claim 3:

The co-pending application does not explicitly discloses using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

However, claim 17 discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

As the video frames are enter into a sliding buffer memory in connection with decoding, it is obvious that the comprise number of image frames corresponding to the missing image number are used in the decoding process in place of the missing frame number to provide a benefit of performing decoding with a continuous sequence number.

(4) Regarding claim 4:

Claim 17 further disclose the number of image frames in the buffer memory are used in sliding window buffering of image frame (wherein video frames are entered into a sliding buffer memory in connection with decoding).

(5) Regarding claim 5:

Clam 17 further discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames (continuing the entering of the image frames comprised by the video sequence in

question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, claim 17).

2. Claim 6 is provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 18 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim 17 discloses all subject matter as discussed in above and claim 18 of the co-pending application depends on claim 17 and further disclose entering onto the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames (entering into the buffer memory a number of filler frames corresponding to the missing image number, claim 18).

3. Claims 10-14 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending Application No. 10/306942.

(1) Regarding claim 10:

Claim 17 of the copending application discloses decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; and configuring, in response to the indication, the buffer memory to provide a

number of image frames corresponding to a discontinuity in the numbering of the image frames (the bold and underlined part in the above table).

The co-pending application does not explicitly disclose (a) using the image frame in the buffer memory in the decoding process; and (b) the decoding method is performed by a decoder.

With respect to (a), claim 17 also discloses wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

With respect to (b), since the claim is non-structural per se, and claim 17 discloses the decoding steps, it is inherently that the decoding method is performed by a decoder.

(2) Regarding claim 11:

Claim 17 further disclose wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

(3) Regarding claim 12:

The co-pending application does not explicitly discloses using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

However, claim 17 discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

As the video frames are enter into a sliding buffer memory in connection with decoding, it is obvious that the comprise number of image frames corresponding to the missing image number are used in the decoding process in place of the missing frame number to provide a benefit of performing decoding with a continuous sequence number.

(4) Regarding claim 13:

Claim 17 further disclose the number of image frames in the buffer memory are used in sliding window buffering of image frame (wherein video frames are entered into a sliding buffer memory in connection with decoding).

(5) Regarding claim 14:

Clam 17 further discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames (continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, claim 17).

4. Claim 15 is provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 18 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim 17 of the co-pending application discloses all subject matter as discussed in above and claim 18 of the co-pending application depends on claim 17 and further disclose entering onto the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames (entering into the buffer memory a number of filler frames corresponding to the missing image number, claim 18, since the claim is non-structural per se, and claim 17 discloses the decoding steps, it is inherently that the decoding method is performed by a decoder).

5. Claims 18-22 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 17 of copending Application No. 10/306942 in view of Langberg et al. (US 5,852,630, hereinafter Langberg).

(1) Regarding claim 18:

Claim 17 of the copending application discloses decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames; and configuring, in response to the indication, the buffer memory to provide a

number of image frames corresponding to a discontinuity in the numbering of the image frames (the bold and underlined part in the above table).

The co-pending application does not explicitly disclose (a) using the image frame in the buffer memory in the decoding process; and (b) the decoding method is perform by a computer program product stored on a computer readable medium and having program code to perform the method.

With respect to (a), claim 17 also discloses wherein video frames are entered into a sliding buffer memory in connection with decoding (preamble of claim 17).

Therefore, it is obvious that the image frame in the buffer memory in the decoding process for the benefit of performing decoding with a continuous frame sequence number.

With respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of claim 17 of the co-pending application would have been implemented in software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software in as taught by Langberg to implement the method of the co-

pending application in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 19:

Claim 17 further disclose wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional (the discontinuity in the numbering of the images of the image frames in the video sequence are intentional, claim 17).

(3) Regarding claim 20:

The co-pending application does not explicitly discloses using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

However, claim 17 discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

As the video frames are enter into a sliding buffer memory in connection with decoding, it is obvious that the comprise number of image frames corresponding to the missing image number are used in the decoding process in place of the missing frame number to provide a benefit of performing decoding with a continuous sequence number.

(4) Regarding claim 21:

Claim 17 further disclose the number of image frames in the buffer memory are used in sliding window buffering of image frame (wherein video frames are entered into a sliding buffer memory in connection with decoding).

(5) Regarding claim 22:

Clam 17 further discloses continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames (continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers, claim 17).

6. Claim 23 is provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 18 of copending Application No. 10/306942.

This is a provisional obviousness-type double patenting rejection.

Claim 17 and Langberg discloses all subject matter as discussed in above and Claim 18 of the co-pending application depends on claim 17 and disclose entering onto the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames (entering into the buffer memory a number of filler frames corresponding to the missing image number, claim 18, since the claim is non-

structural per se, and claim 17 discloses the decoding steps, it is inherently that the decoding method is performed by a decoder).

Allowable Subject Matter

Claims 7-8, 16-17, and 24-25 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Conclusion

7. **THIS ACTION IS MADE FINAL.** Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the mailing date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083.

The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

TERMINAL DISCLAIMER TO OBVIATE A PROVISIONAL DOUBLE PATENTING REJECTION OVER A PENDING "REFERENCE" APPLICATION	Docket Number (Optional) TPO.004.C1

In re Application of: Hannuksela

Application No.: 11/338,996

Filed: January 25, 2006

For: Grouping of Image Frames in Video Coding

The owner*, Nokia Corporation, of 100 percent interest in the instant application hereby disclaims, except as provided below, the terminal part of the statutory term of any patent granted on the instant application which would extend beyond the expiration date of the full statutory term of any patent granted on pending **reference** Application Number 10/306,942, filed on November 29, 2002, as such term is defined in 35 U.S.C. 154 and 173, and as the term of any patent granted on said **reference** application may be shortened by any terminal disclaimer filed prior to the grant of any patent on the pending **reference** application. The owner hereby agrees that any patent so granted on the instant application shall be enforceable only for and during such period that it and any patent granted on the **reference** application are commonly owned. This agreement runs with any patent granted on the instant application and is binding upon the grantee, its successors or assigns.

In making the above disclaimer, the owner does not disclaim the terminal part of any patent granted on the instant application that would extend to the expiration date of the full statutory term as defined in 35 U.S.C. 154 and 173 of any patent granted on said **reference** application, "as the term of any patent granted on said **reference** application may be shortened by any terminal disclaimer filed prior to the grant of any patent on the pending **reference** application," in the event that: any such patent: granted on the pending **reference** application: expires for failure to pay a maintenance fee, is held unenforceable, is found invalid by a court of competent jurisdiction, is statutorily disclaimed in whole or terminally disclaimed under 37 CFR 1.321, has all claims canceled by a reexamination certificate, is reissued, or is in any manner terminated prior to the expiration of its full statutory term as shortened by any terminal disclaimer filed prior to its grant.

Check either box 1 or 2 below, if appropriate.

1. ☐ For submissions on behalf of a business/organization (e.g., corporation, partnership, university, government agency, etc.), the undersigned is empowered to act on behalf of the business/organization.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

2. ☑ The undersigned is an attorney or agent of record. Reg. No. 57,125

/Erin Nichols Matkaiti/ — Signature
January 31, 2011 — Date

Erin Nichols Matkaiti — Typed or printed name

952-232-6907 — Telephone Number

☑ Terminal disclaimer fee under 37 CFR 1.20(d) is included.

WARNING: Information on this form may become public. Credit card information should not be included on this form. Provide credit card information and authorization on PTO-2038.

*Statement under 37 CFR 3.73(b) is required if terminal disclaimer is signed by the assignee (owner).
Form PTO/SB/96 may be used for making this statement. See MPEP § 324.

This collection of information is required by 37 CFR 1.321. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.11 and 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

Privacy Act Statement

The **Privacy Act of 1974 (P.L. 93-579)** requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (*i.e.*, GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.116

Mail Stop AF
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action dated December 9, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.116.

Claims 1-25 remain pending in the application. Claim 10 has been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE SPECIFICATION begin on page 2.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 3 of this paper.

REMARKS/ARGUMENTS begin on page 9.

AMENDMENTS TO THE SPECIFICATION

Please amend the paragraph at page 33, lines 6-16, as indicated below.

[0097] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by ~~means of software, by~~ hardware solutions[[,]] or as a combination of ~~the two~~hardware and software. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

AMENDMENTS TO THE CLAIMS

Applicant respectfully requests that the amendments presented below be entered and that this listing of claims replace all prior versions of claims in the application.

1. (Previously presented) A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising:

decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames;

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. (Previously presented) A method according to claim 1, wherein said indication informs that the at least one discontinuity in the numbering of the image frames in the video sequence is intentional.

3. (Previously presented) A method according to claim 1, further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

4. (Original) A method according to claim 1, wherein the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. (Previously presented) A method according to claim 1, further comprising

continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer

memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

6. (Previously presented) A method according to claim 1, further comprising

entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

7. (Previously presented) A method according to claim 6, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

8. (Previously presented) A method according to claim 1, wherein

configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. (Previously presented) A method according to claim 3, further comprising

detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image frame corresponding to the at least one discontinuity in the numbering of image frames.

10. (Currently amended) A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the ~~decompressed~~compressed video sequence an indication related to at least one discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. (Previously presented) A video decoder according to claim 10, wherein

said indication informs that the at least one discontinuity in the numbering of the image frames in the video sequence is intentional.

12. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

13. (Original) A video decoder according to claim 10, wherein

the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

continue the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

15. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

enter into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

16. (Previously presented) A video decoder according to claim 15, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

17. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

configure the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. (Previously presented) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, the computer program product comprising:

a computer program code for decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. (Previously presented) A computer program product according to claim 18, wherein said indication informs that the at least one discontinuity in the numbering of the image frames in the video sequence is intentional.

20. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

21. (Original) A computer program product according to claim 18, the computer program product further comprising

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. (Previously presented) A computer program product according to claim 18, the computer program product further comprising

a computer program code for continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

23. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

24. (Previously presented) A computer program product according to claim 23, the computer program product further comprising:

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the compressed video sequence.

25. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

26-31. (Canceled)

REMARKS/ARGUMENTS

The rejections presented in the Office action dated December 9, 2010 (hereinafter Office action) have been considered, and reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Applicant appreciates the indication of allowability for claims 7, 8, 16, 17, 24, and 25.

With respect to the objection to claims 10-17, claim 10 has been amended to correct the typographical error in accordance with the Examiner's suggestion. Since this change is believed to overcome the objection, Applicant requests that the objection be removed.

With respect to the § 101 rejection of claims 10-17, Applicant respectfully maintains that the claimed decoder is directed to statutory subject matter. While the specification refers to embodiments involving computer readable media storing program code (*e.g.*, claim 18), the claimed video decoder is a device constituting statutory subject matter. The cited portion at page 6, paragraph [0015] makes no mention of a software only embodiment. The term "decoder" is well-known in the art to refer to a device or circuit. Notably, the specification illustrates structural components of the decoder (*e.g.*, demultiplexer 116 and decompressor 118), and independent claim 10 recites that the video decoder is connected to a buffer memory. Paragraph [0095] teaches examples of a decoder including a low bit rate video decoder as described in the ITU-T recommendation H.263 or H.26L. Moreover, paragraph [0096] describes positioning of the decoder that would not be possible if it was only software. However, paragraph [0097] has been amended to remove an interpretation of the claimed decoder as being software only. Since the claimed decoder is directed to statutory subject matter, Applicant requests that the rejection be withdrawn.

With respect to the provisional double patenting rejections, each of which is based on co-pending application serial number 10/306,942, Applicant submits the attached Terminal Disclaimer. Applicant accordingly requests that each of the provisional non-statutory double patenting rejections be withdrawn.

In view of the above, Applicant believes each of the pending claims is in condition for allowance and requests that the application be allowed.

It should also be noted that Applicant does not acquiesce to the Examiner's statements or conclusions concerning what would have been obvious to one of ordinary skill in the art, obvious design choices, inherent, common knowledge at the time of Applicant's invention, officially noticed facts, and the like. Applicant reserves the right to address in detail the Examiner's characterizations, conclusions, and rejections in future prosecution.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C1) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

Please find below and/or attached an Office communication concerning this application or proceeding.

The time period for reply, if any, is set in the attached communication.

Notice of the Office communication was sent electronically on above-indicated "Notification Date" to the following e-mail address(es):

tdotter@hfiplaw.com
roswood@hfiplaw.com

Office Action Summary	Application No.	Applicant(s)	
	11/338,996	HANNUKSELA, MISKA	
	Examiner	Art Unit	
	SIU M. LEE	2611	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE *3* MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *31 January 2011*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-25* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *1,3-10,12-18 and 20-25* is/are rejected.

7)☒ Claim(s) *2,11 and 19* is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *25 January 2006* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☒ Certified copies of the priority documents have been received in Application No. _____.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

DETAILED ACTION

Transitional After Final Practice

1. Since this application is eligible for the transitional procedure of 37 CFR 1.129(a), and the fee set forth in 37 CFR 1.17(r) has been timely paid, the finality of the previous Office action is hereby withdrawn pursuant to 37 CFR 1.129(a). Applicant's first submission after final filed on 1/31/2011 has been entered.

Response to Arguments

2. Applicant's arguments, see page 9-10, filed 1/31/2011, with respect to Double Patenting rejection of claims 1-6, 10-15, 18-23 and 35 U.S.C. 101 rejection of claims 10-17 have been fully considered and are persuasive. The Double Patenting rejection of claims 1-6, 10-15, 18-23 and 35 U.S.C. 101 rejection of claims 10-17 have been withdrawn. However, upon further consideration, a new ground(s) of rejection is made in view of Apostolopoulos (US 7,103,669 B2).

Claim Rejections - 35 USC § 102

3. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States

only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

4. Claims 1 are rejected under 35 U.S.C. 102(e) as being anticipated by Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 1:

Apostolopoulos disclose a method for decoding a compressed video sequence (odd number sequence ort even number sequence), wherein image frames are entered into a buffer memory in connection with the decoding (decode 322 in figure 5 enter the decoded frame into the frame memory including the previous decoded frames as shown in figure 5), the method comprising:

decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frame (the packet is decoded in step 914 and a determination is made whether an error has been detected, when an error is detected, state recovery is performed by employing previous and future frames of correctly decoded frames, column 7, lines 9-37; the examiner interprets the claimed discontinuity of numbering as the detected error that one of the frame (for example P5 as discussed in column 10, lines 52-63) is unable to be retrieved due to packet loss);

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the art least one discontinuity in the numbering of the image frames (the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, full frame versions of P2, P4, and P6 through P14, as well we P1 and P3 in the buffer memory are use in the decoding process).

(2) Regarding claim 10:

Apostolopoulos discloses a video decoder (multiple state video decoding 128 in figure 1 comprises decode block 320 and 322 as shown in figure 5) for decoding a compressed video sequence, the video decoder being connected to a buffer memory (frame memory as shown in figure 5) wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frames (the packet is decoded in step 914 and a determination is made whether an error has been detected, when an error is detected, state recovery is performed by employing previous and future frames of correctly decoded frames, column 7, lines 9-37; the examiner interprets the claimed discontinuity of numbering as the detected error that one of the frame (for example P5 as discussed in column 10, lines 52-63) is unable to be retrieved due to packet loss);

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the

image frames (the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18); and

use the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, full frame versions of P2, P4, and P6 through P14, as well we P1 and P3 in the buffer memory are use in the decoding process).

(3) Regarding claims 3 and 12:

Apostolopoulos further disclose using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets “do not exist at a decoder due to the at least one discontinuity in the numbering of the image frame" as due to the error occur in the transmission of the encoded odd frame and prevent the decode block from properly reconstructing P_5, therefore there is a discontinuity in the numbering of image frame, column 9, lines 66-67).

(4) Regarding claim 9:

Apostolopoulos further disclose detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image frame corresponding to the at least one discontinuity in the numbering of image frames (the error occur in the transmission of the encoded odd frame and prevent the decode block from properly reconstructing P_5, therefore there is a discontinuity in the numbering of image frame, column 9, lines 66-67).

(5) Regarding claims 5 and 14:

Apostolopoulos further disclose continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (the receiver 332 includes a state recovery 526 for recovering the lost P-frame P5 of the stream 354 using the information provided by the stream 356, the recovery of P5 enables the decode block 322 to continue with its prediction loop by correctly updating its state information and reconstruct p7 to P13, column 10, lines 55-60; as the frames are correctly decode by the decoder, frames are enter into the frame memory as a previous decoded frames as shown in figure 5).

(6) Regarding claims 6 and 15:

Apostolopoulos further discloses entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly

decoded frame, column 11, lines 48-49; the examiner interprets the correctly decode frame that replace the lost frame as the claimed “filler frame”).

(7) Regarding claims 7 and 16:

Apostolopoulos further discloses wherein said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; therefore an odd frame can be replace by an even frame, wherein the even frame number (identifier) indicates that the filler frame do not belong to the odd frame sequence).

Claim Rejections - 35 USC § 103

5. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

6. Claim 18 is rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) in view of Langberg (US 5,852,630).

(1) Regarding claim 18:

Apostolopoulos disclose a method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding (decode 322 in figure 5 enter the decoded frame into the frame memory including the previous decoded frames as shown in figure 5), the method comprising:

decoding from the compressed video sequence an indication related to at least one discontinuity of numbering of the image frame (the packet is decoded in step 914 and a determination is made whether an error has been detected, when an error is detected, state recovery is performed by employing previous and future frames of correctly decoded frames, column 7, lines 9-37; the examiner interprets the claimed discontinuity of numbering as the detected error that one of the frame (for example P5 as discussed in column 10, lines 52-63) is unable to be retrieved due to packet loss);

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the art least one discontinuity in the numbering of the image frames (the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, full frame versions of P2, P4, and P6 through P14, as well we P1 and P3 in the buffer memory are use in the decoding process).

Apostolopoulos discloses all of the subject matter as described above except for the method is perform by a computer program product, stored on a non-transitory computer readable medium and executable in a data processing device.

However, Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg for implementing the method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 20:

Apostolopoulos further disclose using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets “do not exist at a decoder due to the at least one discontinuity in the numbering of the image frame" as due to the error occur in the transmission of the encoded odd frame and prevent the decode block from properly reconstructing P_5,

therefore there is a discontinuity in the numbering of image frame, column 9, lines 66-67).

(3) Regarding claim 21:

Apostolopoulos disclose all subject matter as discussed in claim 1 but fails to explicitly disclose wherein the number of image frames in the buffer memory are used in sliding widow buffering of image frames.

However, as shown in figure 5, decoded frame as input into the frame memory as previous decode frames, these frames are used for recovery of a lost frame (recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstructed full frame versions of P2, P4, P6 through P14 as well as P1 and P3, column 11, lines 14-18), therefore, the frame memory have to store the decoded frame P2 to P14 in the frame memory on the even frame number sequence and obviously, the frame memory have to store the decoded frame P1 to P13 in the frame memory on the odd frame number sequence, therefore, the examiner interprets the frame memory are used in sliding window buffering of the decode image frame.

It is desirable to have the number of image frames in the buffer memory are used in sliding widow buffering of image frames because the buffer of image frame is need for recovering of a full frame version of a lost frame and provide the benefit of increase the image quality of the recovered video sequence.

(4) Regarding claim 22:

Apostolopoulos further disclose continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (the receiver 332 includes a state recovery 526 for recovering the lost P-frame P5 of the stream 354 using the information provided by the stream 356, the recovery of P5 enables the decode block 322 to continue with its prediction loop by correctly updating its state information and reconstruct p7 to P13, column 10, lines 55-60; as the frames are correctly decode by the decoder, frames are enter into the frame memory as a previous decoded frames as shown in figure 5).

(5) Regarding claim 23:

Apostolopoulos further discloses entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets the correctly decode frame that replace the lost frame as the claimed “filler frame”).

(6) Regarding claim 24:

Apostolopoulos further discloses wherein said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; therefore an odd frame can be replace by an even

frame, wherein the even frame number (identifier) indicates that the filler frame do not belong to the odd frame sequence).

(7) Regarding claim 25:

Apostolopoulos further discloses wherein configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by frame number, whereby no data is entered into the buffer memory (past and future frames with respect to the lost frame P5 to recover frame P5, column 10, lines 60-63, as the past and future frames are identified by frame number and when the decoder cannot decode P5, the decode block 322 cannot reconstruct P5 to P13, therefore, no data is entered into the buffer memory (frame memory that store previous decoded frames)).

Apostolopoulos fails to disclose using memory indications for reconstruction of a lost frame.

However, as shown in figure 5, the correctly decoded frames are storage in the frame memory as previous decoded frames. Therefore, it would have been obvious to one of ordinary skill in the art to modify the invention Apostolopoulos to use memory indication (location) for locating future frames in the even frame number sequence and past frame in the odd frame number sequence for reconstruction of the lose frame since using the frame number and memory location are interchangeable to one of ordinary skill in the art.

7. Claims 4, 8, 13, and 17 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 4 and13:

Apostolopoulos disclose all subject matter as discussed in claim 1 but fails to explicitly disclose wherein the number of image frames in the buffer memory are used in sliding widow buffering of image frames.

However, as shown in figure 5, decoded frame as input into the frame memory as previous decode frames, these frames are used for recovery of a lost frame (recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstructed full frame versions of P2, P4, P6 through P14 as well as P1 and P3, column 11, lines 14-18), therefore, the frame memory have to store the decoded frame P2 to P14 in the frame memory on the even frame number sequence and obviously, the frame memory have to store the decoded frame P1 to P13 in the frame memory on the odd frame number sequence, therefore, the examiner interprets the frame memory are used in sliding window buffering of the decode image frame.

It is desirable to have the number of image frames in the buffer memory are used in sliding widow buffering of image frames because the buffer of image frame is need for recovering of a full frame version of a lost frame and provide the benefit of increase the image quality of the recovered video sequence.

(2) Regarding claims 8 and 17:

Apostolopoulos further discloses wherein configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by frame number, whereby no data is entered into the buffer memory (past and future frames with respect to the lost frame P5 to recover frame P5, column 10, lines 60-63, as the past and future frames are identified by frame number and when the decoder cannot decode P5, the decode block 322 cannot reconstruct P5 to P13, therefore, no data is entered into the buffer memory (frame memory that store previous decoded frames)).

Apostolopoulos fails to disclose using memory indications for reconstruction of a lost frame.

However, as shown in figure 5, the correctly decoded frames are storage in the frame memory as previous decoded frames. Therefore, it would have been obvious to one of ordinary skill in the art to modify the invention Apostolopoulos to use memory indication (location) for locating future frames in the even frame number sequence and past frame in the odd frame number sequence for reconstruction of the lose frame since using the frame number and memory location are interchangeable to one of ordinary skill in the art.

Allowable Subject Matter

8. Claims 2, 11, and 19 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Subject: Private PAIR Correspondence Notification for Customer Number 10888

Feb 18, 2011 06:01:49 AM

Dear PAIR Customer:

Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437
UNITED STATES

The following USPTO patent application(s) associated with your Customer Number, 10888 , have new outgoing correspondence. This correspondence is now available for viewing in Private PAIR.

The official date of notification of the outgoing correspondence will be indicated on the form PTOL-90 accompanying the correspondence.

Disclaimer:
The list of documents shown below is provided as a courtesy and is not part of the official file wrapper. The content of the images shown in PAIR is the official record.

Application	Document	Mailroom Date	Attorney Docket No.
11338996	CTNF	02/18/2011	TPO.004.C1

All requests

1/4-4/4	as published

Claims, Numbers

Main Request

1-25	filed in electronic form on	13-10-2010

Auxiliary Request 1

1-21	filed in electronic form on	13-10-2010

Auxiliary Request 2

1-17	filed in electronic form on	13-10-2010

1 The applicant is summoned to attend oral proceedings before the Examining Division in accordance with Article 116(1) and Rule 115 EPC. The points to be discussed are the following:

2 *Added subject-matter*

2.1 *Main request*

Claim 1 has been amended to include *inter alia* the following features:

a. the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other; and

b. the information indicative of the sub-sequence is independent of the frame format.

a. Firstly, it is not clear what it means that the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are *different* from each other. If the two pieces of information indicate different things, they are inherently different. Secondly, there is no direct and unambiguous basis in the application as filed for this language. On the contrary, in paragraph [0033], it appears that the different sub-sequences and their associated information depend on each other.

b. It is unclear what is meant by the information indicative of the sub-sequence being *independent* of the frame format, especially since the formation of the sub-sequences depends on the frame format. Furthermore, there is no direct and unambiguous basis in the application as filed for this feature.

As basis for the amendment, the applicant refers to paragraphs [0032] *"the sub-sequences of each scalability layer are assigned a unique identifier"* and [0031] *"each scalability layer is assigned a unique identifier such as a layer number"*. The Examining Division does not consider this to be a clear and unequivocal basis for the present wording of claim 1.

For these reasons, claim 1 contravenes article 123(2) EPC and is, therefore, not allowable. The same applies for claims 11, 16, 20, 24 and 25 which are not allowable either.

2.2 *1st auxiliary request*

Claims 1, 10, 14, 17, 20 and 21 of the 1st auxiliary request contravene, for the same reasons, Article 123(2) EPC and are, therefore, not allowable.

2.3 *2nd auxiliary request*

Claims 1, 9, 12, 16 and 17 of the 2nd auxiliary request contravene, for the same reasons, Article 123(2) EPC and are, therefore, not allowable.

3 *Priority*

The present application claims priority from FI20020127 (P1) filed on 23.01.2002 and from US10/206942 (P2) filed on 29.11.2002.

The feature of including the information indicative of the sub-sequence as Supplemental Enhancement Information is not disclosed in P1. The effective date of this subject-matter is, therefore, the filing date of P2, i.e. **29.11.2002** (Article 87(1) and 89 EPC).

4 *Prior art*

As a consequence, the following documents are prior art under Article 54(2) EPC for the following claims:

D2 HANNUKSELA: "Enhanced Concept of GOP", ITU STUDY GROUP 16 - VIDEO CODING EXPERTS GROUP - ISO/IEC MPEG & ITU-T VCEG(ISO/IEC JTC1/SC29/WG11 AND ITU-T SG16 Q6), XX, XX, no. JVT-B042r1, 1 February 2002 (2002-02-01), XP030005042,

D3 HANNUKSELA: "Signaling of Enhanced GOPs", ITU STUDY GROUP 16 - VIDEO CODING EXPERTS GROUP - ISO/IEC MPEG & ITU-T VCEG(ISO/IEC JTC1/SC29/WG11 AND ITU-T SG16 Q6), XX, XX, no. JVT-D098, 26 July 2002 (2002-07-26), XP030005372,

Main request: claims 4, 14, 18, 22

1st auxiliary request: claims 1, 10, 14, 17, 20, 21

2nd auxiliary request: 1, 9, 12, 14, 16, 17

Copies of the documents are annexed to this communication.

5 *Novelty*

D3 is a document by the present inventor and discloses the organization of pictures in layers and sub-sequences (page 2, s. 3.1), wherein a sub-sequence represents a number of inter-dependent pictures that can be disposed without affecting the decoding of any other sub-sequence in less enhanced layers (page 1, s. 1). The information indicative of the layers and sub-sequences is signalled in the Supplemental Enhancement Information (SEI) message (page 3, s. 3.4).

The subject-matter of the following claims, therefore, lack novelty over D3 in the sense of Article 54(1) and (2) EPC, contrary to Article 52(1) EPC.

Main request: claims 4, 14, 18, 22

1st auxiliary request: claims 1, 10, 14, 17, 20, 21

2nd auxiliary request: 1, 9, 12, 14, 16, 17

6 *Inventive step*

If the applicant files amended claims which overcome the objections in point 2 *supra*, novelty and inventive step (Article 52(1), 54 and 56 EPC) will be discussed with respect to D1 and, where applicable, D2 and D3. The applicant should be prepared to indicate the basis in the priority document P1 for the subject-matter of the amended claims.

D1 discloses temporally scalable video coding (fig. 2; page 3, lines 15-27). The base layer (fig. 2, e.g. base 10fps) forms a first sub-sequence comprising I and P pictures and the enhancement layer (e.g. Enh 30fps) one or several further sub-sequences comprising P-pictures. Information indicative of the picture dependencies and, consequently of the respective sub-sequences, is signalled in the picture header (page 4, lines 2-6). Furthermore, as an alternative, D1 suggests to include each temporal layer (sub-sequence) in a separate transport stream (page 5, last paragraph). Information indicative of the respective sub-sequences would therefore be present at the transport layer.

It appears that any difference with respect to D1 would lie in the particular syntax for indicating the respective sub-sequences. This is in the Examining Division's opinion merely a matter of design. In principle, a coding choice or concept can be indicated at any appropriate level of the bitstream. The person skilled in the art is well aware of the trade-off between flexibility and the amount of overhead and will choose the appropriate syntax depending on the circumstances, including the intended application and compatibility issues with various standards. Therefore, it is not at present apparent which part of the application could serve as a basis for a new, allowable claim.

7 *Clarity*

Claims 1, 9, 12, 14, and 16 of the second auxiliary request include the feature that the information indicative of the sub-sequence comprises a *"scalability layer identifier"* and a *"sub-sequence identifier"*. The scalability layers are not defined in said claims and it is unclear how they differ from the sub-sequences (see point 6 above with reference to D1: a sub-sequence can be a temporal scalability layer; see also the description, paragraphs [0017] and [0032]: the second sub-sequence is removable without affecting decodability of the

remaining video sequence, which is, in fact, the definition of a scalability layer). Claims 1, 9, 12, 14 and 16 of the second auxiliary request, therefore, lack clarity, contrary to Article 84 EPC.

Preparation for oral proceedings - Instructions to Support Service

Oral proceedings are to be held in connection with the above patent application

1. The matters to be discussed are set out in the annex (Form 2906)

2. Dispatch the summons using Form 2008/2310 and Form 2906 for the parties to attend on:

Day 26.05.2011 Time 09:00

ROOMS

Room booked

ORAL 01, 02, 03 and 05 coded

10.09.11 EK
Date Initials

2.1 Parties' submissions in preparation for the oral proceedings, if any, should be made no later than

1 month(s)

before the date of the oral proceedings
(transfer to Form 2008.1 / 2310.1)

2.2 Encode ORAL(04)

coded 10.09.11 EK
Date Initials

2.3 Dispatch Form 2008.7 / 2310.7 to division

10.09.11 EK
Date Initials

3. ☐ Arrange for the following special equipment to be provided in the conference room:

Date Initials

Summons to attend oral proceedings pursuant to Rule 115(1) EPC

You are hereby summoned to attend oral proceedings arranged in connection with the above-mentioned European patent application.

The matters to be discussed are set out in the communication accompanying this summons (EPO Form 2906).

The oral proceedings, which will not be public, will take place before the Examining Division.

on 26.05.11 at 09.00 hrs at the EPO,
PschorrHöfe, Bayerstr. 34, D-80335 München

No changes to the date of the oral proceedings can be made, except on serious grounds (see OJ EPO 1/2009, 68). If you do not appear as summoned, the oral proceedings may continue without you (R. 115(2) EPC, see also OJ EPO 10/2008, 471).

Your attention is drawn to Rule 4 EPC, regarding the language of the oral proceedings, and to the Special edition No. 3 OJ EPO 2007, L.1., concerning the filing of authorisations for company employees and lawyers acting as representatives before the EPO.

The final date for making written submissions and/or amendments (R. 116 EPC) is 26.04.11.

The actual room number as well as the waiting room numbers will be given to you by the porter in the foyer at the above EPO address.

Parking is available free of charge in the underground car park. However, this applies only in the case of accessing the car park via the entrance "Zollstrasse".

BRIEF COMMUNICATION

Oral Proceedings on 17.11.10

Subject: ☒ Your letter of 13.10.2010

Communication:
- ☒ The summons to attend oral proceedings on 17.11.10 has been cancelled.
- ☒ The procedure will be continued in writing.
- ☐ The date fixed for oral proceedings is maintained.
- ☐ A new date will be set later.
- ☐

Please take note.

For the Examining Division

Europäisches Patentamt • European Patent Office • Office européen des brevets

European patent application No. 03700321.7

II. To the Formalities Officer

1. ☐ The date / time fixed for oral proceedings is maintained.

   ☐ (if necessary) The reasons are indicated on enclosed EPO Form 2906/2906O, which is to be dispatched to the party with EPO Form 2008A/2310A.

2. ☐ At the instigation of the division the oral proceedings cannot take place on the arranged date for the reasons indicated on enclosed EPO Form 2906, which is to be dispatched to the party with EPO Form 2008A/2310A.

   Date _____ Director (see Internal Instructions IE-III, 1.2) _____

3. ☒ The summons to attend oral proceedings on 17.11.10 should be cancelled.

   3.1 ☒ The proceedings will be continued in writing.

   3.2 A new date will be set later.

   3.3 ☐ A new date/time is set as follows:

   date ..... at ..... hrs.
   Parties' written submissions and amendments in preparation for the oral proceedings, if any, should be made not later than

   ..... month(s) before the date of the oral proceedings.

4. ☐ The request for the oral proceedings to be held as a videoconference

   4.1 ☐ is allowed.

   4.2 ☐ is rejected for the reasons indicated on enclosed EPO Form 2906, which is to be dispatched to the party with EPO Form 2008A.

5. ☐ The application is deemed to be withdrawn. The oral proceedings are cancelled.

1ST AUXILIARY REQUEST:

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

2. A method according to claim 1, **characterized** by

forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

3. A method according to claim 1 or 2, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

4. A method according to any preceding claim, **characterized** in that

the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence.

25. A method according to any preceding claim ~~1~~, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

~~3~~6. A method according to claim 25, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from ~~a group comprising~~

a video frame of ~~a higher~~the scalability layer containing the first sub-sequence, and/or

a video frame of another sub-sequence in the same scalability layer.

~~4~~7. A method according to claim ~~3~~6, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least ~~a~~the scalability layer identifier and ~~a~~the sub-sequence identifier.

~~5~~8. A method according to claim ~~3~~6 or 47, **characterized** by comprising the step of

coding ~~the~~a first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

~~6~~9. A method according to claim ~~3~~6 or 47, **characterized** by comprising the step of

coding ~~the~~a first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

~~7. A method according to claim 3, characterized by comprising the step of~~

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. A method according to claim 3, **characterized** by comprising the step of

determining a unique identifier for each video frame on the basis of the image number.

9. A method according to claim 7 or 8, **characterized** by comprising the step of

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. A method according to any one of the preceding claims, **characterized** in that

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

11. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

12. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

13. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

~~the bit rate control being arranged to be carried out in at least one of the following ways:~~

~~at least one sub-sequence is removed from the video sequence,~~

~~at least one sub-sequence is added to the video sequence.~~

~~11~~10. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; ~~and to~~

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

include the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format. ~~and to~~

11. The video encoder according to claim 10, wherein the video encoder is arranged to

form into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

12. The video encoder according to claim 10 or 11, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

13. The video encoder according to any of the claims 10 - 12, **characterized** in that the video encoder is arranged to

encode the second sub-sequence to be removable from the video sequence without affecting decodability of the remaining video sequence.

14. A method for controlling bit rate of a video sequence transmission in a network element of a telecommunications system, **characterized** by

receiving, in the network element, a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence;

controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

15. The method according to claim 14, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

16. A method according to claim 14 or 15, **characterized** by comprising

deducing on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

removing the second sub-sequence.

17. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to receive a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

the element is arranged to obtain information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

18. The element according to claim 17, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

19. The element according to claim 17 or 18, **characterized** in that the element is arranged to

deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

remove the second sub-sequence.

~~15. A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of~~

~~decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;~~

~~decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;~~

~~determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and~~

~~reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.~~

~~16. A method according to claim 15, wherein video frames are entered into a sliding buffer memory in connection with decoding, **characterized** by comprising the steps of~~

~~decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;~~

~~configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and~~

~~continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame~~

number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

17. A method according to claim 16, **characterized** by comprising the step of

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

18. A method according to any one of claims 15 to 17, **characterized** by comprising the step of

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

19. A method according to any one claims 15 to 18, **characterized** by comprising the steps of

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

20. A method according to any one claims 15 to 19, **characterized** by comprising the steps of

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

21. A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format,

~~and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;~~

~~determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and~~

~~reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.~~

~~22~~20. A computer program executable in a data processor for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **c h a r a c t e r i z e d** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; ~~and~~

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format. ~~and~~

~~a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.~~

21. A computer program executable in a data processor for controlling bit rate of a video sequence transmission, **characterized** in that the computer program comprises

a program code for obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of a received video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format; and

a program code for controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

~~23. A computer program for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises~~

~~a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and~~

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

24. A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, characterized in that the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

2ND AUXILIARY REQUEST:

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier, the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

2. A method according to claim 1, **characterized** by

forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

3. A method according to claim 1 or 2, wherein

the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence.

24. A method according to any preceding claim 1, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

35. A method according to claim 24, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from ~~a group comprising~~

a video frame of ~~a higher~~the scalability layer containing the first sub-sequence, and/or

a video frame of another sub-sequence in the same scalability layer.

46. A method according to claim 35, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least ~~a~~ the scalability layer identifier and ~~a~~ the sub-sequence identifier.

57. A method according to claim ~~3~~ 5 or 46, **characterized** by comprising the step of

coding ~~the~~ a first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

68. A method according to claim ~~3~~ 5 or 46, **characterized** by comprising the step of

coding ~~the~~ a first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

~~7. A method according to claim 3, characterized by comprising the step of~~

~~determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.~~

~~8. A method according to claim 3, characterized by comprising the step of~~

determining a unique identifier for each video frame on the basis of the image number.

9. A method according to claim 7 or 8, **characterized** by comprising the step of

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. A method according to any one of the preceding claims, **characterized** in that

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

11. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

12. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

13. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

~~149~~. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **c h a r a c t e r i z e d** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; ~~and to~~

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

include the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier, the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format. ~~and to~~

10. The video encoder according to claim 9, wherein the video encoder is arranged to

form into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

11. The video encoder according to claim 10 or 11, wherein the video encoder is arranged to

encode the second sub-sequence to be removable from the video sequence without affecting decodability of the remaining video sequence.

12. A method for controlling bit rate of a video sequence transmission in a network element of a telecommunications system, **characterized** by

receiving, in the network element, a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence, the information indicative of the sub-sequence comprising a scalability layer identifier and a sub-sequence identifier;

controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

13. The method according to claim 12, **characterized** by comprising

deducing on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

removing the second sub-sequence.

14. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to

control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to receive a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

the element is arranged to obtain information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence, the information indicative of the sub-sequence comprising a scalability layer identifier and a sub-sequence identifier; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

15. The element according to claim 14, **characterized** in that the element is arranged to

deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

remove the second sub-sequence.

~~15. A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from~~

at least one of the other video frames, characterized by comprising the steps of

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

16. A method according to claim 15, wherein video frames are entered into a sliding buffer memory in connection with decoding, characterized by comprising the steps of

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

17. A method according to claim 16, characterized by comprising the step of

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

18. A method according to any one of claims 15 to 17, characterized by comprising the step of

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

~~19. A method according to any one claims 15 to 18, characterized by comprising the steps of~~

~~initiating the decoding from a random point in the video sequence;~~

~~determining an independently decodable sub-sequence that is next after the random point, and~~

~~setting the value of the image number of the first video frame in the sub-sequence at zero.~~

~~20. A method according to any one claims 15 to 19, characterized by comprising the steps of~~

~~identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and~~

~~outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.~~

~~21. A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, characterized in that the video decoder is arranged to~~

~~decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;~~

~~decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;~~

~~determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and~~

~~reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.~~

~~22~~16. A computer program executable in a data processor for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being

predicted from at least one of the other video frames, **c h a r a c t e r i z e d** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; ~~and~~

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier, the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format. ~~and~~

~~a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.~~

17. A computer program executable in a data processor for controlling bit rate of a video sequence transmission, **c h a r a c t e r i z e d** in that the computer program comprises

a program code for obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of a received video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of

which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier; and

a program code for controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

~~23. A computer program for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, characterized in that the computer program comprises~~

~~a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and~~

~~a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and~~

~~a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and~~

~~a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.~~

24. A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, characterized in that the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

MAIN REQUEST:

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; ~~and~~

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

2. A method according to claim 1, **characterized** by

forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

3. A method according to claim 1 or 2, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

4. A method according to any preceding claim, **characterized** by comprising the step of

including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used

for transferring the video sequence, or as Supplemental Enhancement Information (SEI).

5. A method according to any preceding claim, **characterized** in that

the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence.

~~2~~6. A method according to any preceding claim ~~1~~, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

~~3~~7. A method according to claim ~~2~~6, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from ~~a group comprising~~

a video frame of ~~a higher~~the scalability layer containing the first sub-sequence, and/or

a video frame of another sub-sequence in the same scalability layer.

~~4~~8. A method according to claim ~~3~~7, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least ~~a~~the scalability layer identifier and ~~a~~the sub-sequence identifier.

~~5~~9. A method according to claim ~~3~~7 or ~~4~~8, **characterized** by comprising the step of

coding ~~the~~a first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

~~6~~10. A method according to claim ~~3~~7 or ~~4~~8, **characterized** by comprising the step of

coding ~~the~~a first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. A method according to claim 3, **characterized** by comprising the step of

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. A method according to claim 3, **characterized** by comprising the step of

determining a unique identifier for each video frame on the basis of the image number.

9. A method according to claim 7 or 8, **characterized** by comprising the step of

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. A method according to any one of the preceding claims, **characterized** in that

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

11. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

12. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

13. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least

~~one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;~~

~~the bit rate control being arranged to be carried out in at least one of the following ways:~~

~~at least one sub-sequence is removed from the video sequence,~~

~~at least one sub-sequence is added to the video sequence.~~

~~14~~11. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **c h a r a c t e r i z e d** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format. ~~and to~~

12. The video encoder according to claim 11, wherein the video encoder is arranged to

form into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

13. The video encoder according to claim 11 or 12, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

14. The video encoder according to any of the claims 11 - 13, wherein the video encoder is arranged to

include the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI).

15. The video encoder according to any of the claims 11 - 14, **characterized** in that the video encoder is arranged to

encode the second sub-sequence to be removable from the video sequence without affecting decodability of the remaining video sequence.

16. A method for controlling bit rate of a video sequence transmission in a network element of a telecommunications system, **characterized** by

receiving, in the network element, a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

obtaining information indicative of dependencies of sub-sequences in the received video sequence;

controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

17. The method according to claim 16, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

18. A method according to claim 16 or 17, **characterized** by comprising

obtaining the information indicative of the sub-sequence from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI).

19. A method according to any of the claims 16 - 18, **characterized** by comprising

deducing on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

removing the second sub-sequence.

20. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to receive a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

the element is arranged to obtain information indicative of dependencies of sub-sequences in the received video sequence; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

21. The element according to claim 20, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

22. The element according to claim 20 or 21, **characterized** in that the element is arranged to

obtain the information indicative of the sub-sequence from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI).

23. The element according to any of the claims 20 - 22, **characterized** in that the element is arranged to

deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

remove the second sub-sequence.

~~15. A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of~~

~~decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;~~

~~decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;~~

~~determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and~~

~~reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.~~

~~16. A method according to claim 15, wherein video frames are entered into a sliding buffer memory in connection with decoding, **characterized** by comprising the steps of~~

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

17. A method according to claim 16, **characterized** by comprising the step of

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

18. A method according to any one of claims 15 to 17, **characterized** by comprising the step of

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

19. A method according to any one claims 15 to 18, **characterized** by comprising the steps of

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

20. A method according to any one claims 15 to 19, **characterized** by comprising the steps of

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

21. A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the

~~other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video decoder is arranged to~~

~~decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;~~

~~decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;~~

~~determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and~~

~~reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.~~

~~22~~24. A computer program executable in a data processor for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format, ~~and~~

~~a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.~~

25. A computer program executable in a data processor for controlling bit rate of a video sequence transmission, **characterized** in that the computer program comprises

a program code for obtaining information indicative of dependencies of sub-sequences in a received video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format; and

a program code for controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

~~23. A computer program for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises~~

~~a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and~~

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

24. A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, characterized in that the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

MAIN REQUEST:

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence;

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

2. A method according to claim 1, **characterized** by

forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

3. A method according to claim 1 or 2, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

4. A method according to any preceding claim, **characterized** by comprising the step of

including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used

for transferring the video sequence, or as Supplemental Enhancement Information (SEI).

5. A method according to any preceding claim, **characterized** in that

the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence.

6. A method according to any preceding claim, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

7. A method according to claim 6, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from

a video frame of the scalability layer containing the first sub-sequence, and/or

a video frame of another sub-sequence in the same scalability layer.

8. A method according to claim 7, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least the scalability layer identifier and the sub-sequence identifier.

9. A method according to claim 7 or 8, **characterized** by comprising the step of

coding a first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

10. A method according to claim 7 or 8, **characterized** by comprising the step of

coding a first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

.

11. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

12. The video encoder according to claim 11, wherein the video encoder is arranged to

form into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

13. The video encoder according to claim 11 or 12, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

14. The video encoder according to any of the claims 11 - 13, wherein the video encoder is arranged to

include the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI).

15. The video encoder according to any of the claims 11 - 14, **characterized** in that the video encoder is arranged to

encode the second sub-sequence to be removable from the video sequence without affecting decodability of the remaining video sequence.

16. A method for controlling bit rate of a video sequence transmission in a network element of a telecommunications system, **characterized** by

receiving, in the network element, a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

obtaining information indicative of dependencies of sub-sequences in the received video sequence;

controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

17. The method according to claim 16, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

18. A method according to claim 16 or 17, **characterized** by comprising

obtaining the information indicative of the sub-sequence from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI).

19. A method according to any of the claims 16 - 18, **characterized** by comprising

deducing on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

removing the second sub-sequence.

20. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to receive a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

the element is arranged to obtain information indicative of dependencies of sub-sequences in the received video sequence; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

21. The element according to claim 20, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

22. The element according to claim 20 or 21, **characterized** in that the element is arranged to

obtain the information indicative of the sub-sequence from a header field of the video sequence or from a header field of a transfer protocol to be

used for transferring the video sequence, or from Supplemental Enhancement Information (SEI).

23. The element according to any of the claims 20 - 22, **characterized** in that the element is arranged to

deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

remove the second sub-sequence.

24. A computer program executable in a data processor for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

25. A computer program executable in a data processor for controlling bit rate of a video sequence transmission, **characterized** in that the computer program comprises

a program code for obtaining information indicative of dependencies of sub-sequences in a received video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at

least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format; and

a program code for controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

2ND AUXILIARY REQUEST:

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier, the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

2. A method according to claim 1, **characterized** by

forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

3. A method according to claim 1 or 2, wherein

the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence.

4. A method according to any preceding claim, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

5. A method according to claim 4, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from

a video frame of the scalability layer containing the first sub-sequence, and/or

a video frame of another sub-sequence in the same scalability layer.

6. A method according to claim 5, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least the scalability layer identifier and the sub-sequence identifier.

7. A method according to claim 5 or 6, **characterized** by comprising the step of

coding a first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

8. A method according to claim 5 or 6, **characterized** by comprising the step of

coding a first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

9. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence;

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

include the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier, the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

10. The video encoder according to claim 9, wherein the video encoder is arranged to

form into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

11. The video encoder according to claim 10 or 11, wherein the video encoder is arranged to

encode the second sub-sequence to be removable from the video sequence without affecting decodability of the remaining video sequence.

12. A method for controlling bit rate of a video sequence transmission in a network element of a telecommunications system, **characterized** by

receiving, in the network element, a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been

formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence, the information indicative of the sub-sequence comprising a scalability layer identifier and a sub-sequence identifier;

controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

13. The method according to claim 12, **characterized** by comprising

deducing on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

removing the second sub-sequence.

14. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to receive a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one

video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

the element is arranged to obtain information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence, the information indicative of the sub-sequence comprising a scalability layer identifier and a sub-sequence identifier; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

15. The element according to claim 14, **characterized** in that the element is arranged to

deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and remove the second sub-sequence.
