16. A computer program executable in a data processor for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence;

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier, the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

17. A computer program executable in a data processor for controlling bit rate of a video sequence transmission, **characterized** in that the computer program comprises

a program code for obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of a received video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format, wherein the information indicative of the sub-

sequence comprises a scalability layer identifier and a sub-sequence identifier; and

a program code for controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

1ST AUXILIARY REQUEST:

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

2. A method according to claim 1, **characterized** by

forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

3. A method according to claim 1 or 2, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

4. A method according to any preceding claim, **characterized** in that

the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence.

5. A method according to any preceding claim, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

6. A method according to claim 5, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from

a video frame of the scalability layer containing the first sub-sequence, and/or

a video frame of another sub-sequence in the same scalability layer.

7. A method according to claim 6, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least the scalability layer identifier and the sub-sequence identifier.

8. A method according to claim 6 or 7, **characterized** by comprising the step of

coding a first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

9. A method according to claim 6 or 7, **characterized** by comprising the step of

coding a first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

.

10. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence;

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

include the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

11. The video encoder according to claim 10, wherein the video encoder is arranged to

form into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence.

12. The video encoder according to claim 10 or 11, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

13. The video encoder according to any of the claims 10 - 12, **characterized** in that the video encoder is arranged to

encode the second sub-sequence to be removable from the video sequence without affecting decodability of the remaining video sequence.

14. A method for controlling bit rate of a video sequence transmission in a network element of a telecommunications system, **characterized** by

receiving, in the network element, a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence;

controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

15. The method according to claim 14, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

16. A method according to claim 14 or 15, **characterized** by comprising

deducing on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

removing the second sub-sequence.

17. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to

transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to receive a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format;

the element is arranged to obtain information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of the received video sequence; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

18. The element according to claim 17, wherein the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier.

19. The element according to claim 17 or 18, **characterized** in that the element is arranged to

deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and

remove the second sub-sequence.

20. A computer program executable in a data processor for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence;

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI);

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

21. A computer program executable in a data processor for controlling bit rate of a video sequence transmission, **characterized** in that the computer program comprises

a program code for obtaining information indicative of dependencies of sub-sequences from a header field of the video sequence or from a header field of a transfer protocol to be used for transferring the video sequence, or from Supplemental Enhancement Information (SEI) of a received video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video

frame of the first sub-sequence being associated with information indicative of the first sub-sequence and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format; and

a program code for controlling the bit rate of at least one transmission of said video sequence from said network element on the basis of the information indicative of dependencies of sub-sequences in at least one of the following ways:

removing at least one sub-sequence from the video sequence,

adding at least one sub-sequence to the video sequence.

Response to the Summons to attend oral proceedings pursuant to Rule 115(1) EPC
European Patent Application No. 03700321.7 - 2223
Applicant: NOKIA CORPORATION

Dear Sirs,

This letter is in response to the summons to attend oral proceedings, dated 2 June 2010.

We respectfully request that the oral proceedings be suspended and the examination continued in writing on the basis of the main and auxiliary requests filed herewith. To this end we would welcome an opportunity to discuss this application by telephone with the Examiner, if considered necessary.

Please find enclosed three sets of claims, i.e. the main request and the first and second auxiliary request, which are submitted for further consideration for approval of the application.

1. The main request

As the main request, the Applicant files a new set of claims 1 – 25 to replace the claims 1 - 24 presently on file.

1.1. Multiple independent claims (A. 84, R. 43(2) EPC)

The idea underlying the present invention is to encode the dependencies of the sub-sequences within the video sequence by including information of all sub-sequences that have been directly used for predicting the image frames comprised by the sub-sequence in question. This information is usually signalled along the video sequence, preferably separate from the actual image information, so as to enable a streaming server or a corresponding network element to adjust the bit rate of the encoded video sequence by removing or adding sub-sequences, preferably without decoding the encoded video sequence.

Therefore, the inter-related operations are the encoding and the bit rate control rather than the encoding-decoding presented in the claims as filed. Accordingly, the set of amended claims include independent claim pairs for encoding-bit rate control method (claims 1 and 16), encoder-bit rate control element (claims 11 and 20) and encoding-bit rate control computer program (claims 24 and 25). The decoding-related claims have been deleted, as well as the video signal claim.

It is respectfully submitted that the streaming server, as disclosed e.g. in Fig. 1, does not typically carry out encoding operations, but only forwards the multimedia flows received from the editor to the clients, and at the same time, preferably carries out traffic shaping of the multimedia data, as described in paragraph [0028] of the present application.

1.2. Claim amendments

Thus, the new independent claim 1 discloses (amended features underlined, deleted ~~strikethrough~~): a method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames,

and the video frames of the second frame format being predicted from at least one of the other video frames, characterized by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence (*paragr [0034]; e.g. in Fig. 2, I-frame 200 is identified by the sub-sequence number 0*; *paragr. [0031]; Intra layer is assigned an identifier, such as the layer number 0)*; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence (*paragr [0036]; e.g. in Fig. 2, P-frame 204 is identified by the sub-sequence number 0 and its base layer is assigned the layer number 1)*, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence;

wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format (*paragr. [0032]; the sub-sequences of each scalability layer are assigned a unique identifier, paragr. [0031]; each scalability layer is assigned a unique identifier, such as the layer number*).

~~and~~

~~forming into the video sequence information indicating which video frames belong to the second sub-sequence.~~

The dependent claim 2 discloses: forming into the video sequence information indicating which video frames belong to the first sub-sequence and which video frames belong to the second sub-sequence (*paragr [0035 - 41]; e.g. in Fig. 2, together with the sub-sequence numbers and the scalability layer numbers, the consecutive image frame numbers identify the video frames belonging to each sub-sequence; otherwise*

the subject-matter has been shifted in a dependent claim, since the amended independent claim discloses how the sub-sequence information is defined).

The dependent claim 3 discloses: the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier (*paragr. [0032]; the sub-sequences of each scalability layer are assigned a unique identifier, paragr. [0031]; each scalability layer is assigned a unique identifier, such as the layer number; also claim 4 as filed*).

The dependent claim 4 discloses: including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI) (*paragr. [0085], also claim 9 as filed*).

The dependent claim 5 discloses: the second sub-sequence being removable from the video sequence without affecting decodability of the remaining video sequence (*paragr. [0017, 0033]*.

The dependent claim 7 is otherwise similar to the claim 3 as filed, but the possibly unclear definition “higher scalability layer” has been amended as “the scalability layer containing the first sub-sequence”.

The dependent claims 6 and 8 – 10 correspond to the claims 2 and 4 – 6 as filed.

Claims 11 – 15 and 24 define a video encoder and a computer program by features corresponding to claims 1 – 5.

Claim 20 (basis from the claim 13 as filed) discloses: An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least

one terminal device and to control the bit rate of the video sequence transmission, characterized in that

the element is arranged to receive (*paragr. [0028]; multimedia files are transferred to a streaming server*) a video sequence comprising a first sub-sequence, at least part of which has been formed by coding video frames of at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence (*c.f. claim 1 above*), and at least a second sub-sequence, at least part of which has been formed by coding at least video frames of a second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence (*c.f. claim 1 above*), and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format (*c.f. claim 1 above*);

the element is arranged to obtain information indicative of dependencies of sub-sequences in the received video sequence (*paragr. [0020]; the streaming server is capable of deducing the inter-dependencies of the different sub-sequences directly from the identifiers and their inter-dependencies)*; and

the element is arranged to control the bit rate of at least one transmission of said video sequence on the basis of the information indicative of dependencies of sub-sequences (*paragr. [0083]; on the basis of this information, the streaming server decides how many scalability layers and which sub-sequences are transmitted in the video sequence*) in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

The dependent claims 21 and 22 define the features corresponding to claims 13 and 14 (as well as claims 3 and 4).

The dependent claim 23 discloses: the element is arranged to deduce on the basis of the information indicative of the sub-sequence that the second sub-sequence is removable from the video sequence without affecting decodability of the remaining video sequence; and remove the second sub-sequence (*paragr. [0020]; the streaming server is capable of deducing the inter-dependencies of the different sub-sequences directly from the identifiers and their inter-dependencies; paragr. [0017]; independently decodable portions of the video sequence can be easily determined, and the portions can be removed without affecting the decoding of the rest of the image data)*.

Claims 16 – 19 and 25 define a method for controlling bit rate and a computer program by features corresponding to claims 20 – 23.

Thus, all the features of the new claims are disclosed in the application as filed. Hence, none of the amendments violates the Art. 123(2) EPC.

1.3. Novelty (A. 54 EPC)

The claims as filed were objected by Examiner due to lack of novelty in view document D1: Multimedia Signal Processing, 1998 IEEE Second Workshop on 7-9 Dec 1998, S. Wenger, "Temporal scalability using P-pictures for low-latency applications" pp. 559-564. The Examiner also submitted that the well-known MPEG coding resulting in a MPEG sequence comprising I and P frames was novelty-destroying prior art for the claims as filed.

D1 discloses a method for using P-pictures, instead of B-pictures, on the enhancement layers of a scalable video stream. The Examiner has interpreted the different layers as sub-sequences in the meaning of claim 1, the layer being identified by the picture type, and the information of the used reference picture signalled in the bit stream providing information about the dependencies of the sub-sequences (i.e. the layers).

However, D1 does not disclose that the information indicative of the sub-sequence is independent of the frame format. On the contrary, the argumentation of the Examiner is based on the idea that the sub-sequences (i.e. the layers) are identified by their picture types (the base layer by I/P-type and the enhancement layers by P-type).

In the similar manner, the MPEG-coded video sequence comprising I and P frames lacks the feature that the information indicative of the sub-sequence is independent of the frame format.

The same analogy applies to the independent claims 11 and 24 as well.

Regarding the bit rate control in a streaming server-type network element, wherein sub-sequences are removed from or added to an encoded video sequence, D1 is completely silent about such features. D1 only discusses about the increase in the bit rate caused in the encoding phase compared to using B-pictures on enhancement layers.

Thus, the independent claims 1, 11, 16, 20, 24 and 25 are novel in sense of Art. 54(1) EPC.

1.4. Inventive step (A. 56 EPC)

D1 discloses a method for using P-pictures, instead of B-pictures, on the enhancement layers of a scalable video stream. While causing a minor increase in the bit rate, the method enables to minimize latency in the decoding phase compared to using B-pictures on enhancement layers.

However, D1 gives no indication to encoding sub-sequences within scalability layers such that the bit rate of the video sequence could be adjusted in a streaming server-type network element by removing or adding sub-sequences without video sequence decoding being required. On the contrary, D1 emphasizes that scalability can only be achieved by removing

an entire layer (p. 5, last chapter) or if applied e.g. to MPEG coding, the complete video sequence must first be decoded before any adjustment of coding parameters can be done, and thereafter the video sequence must be re-encoded (p. 6, l. 6 – 8). This is evident also in view of the argumentation of the Examiner, where the layers are considered to be equivalent to sub-sequences, but the layers can only be identified their frame format type, i.e. no sub-sequences within scalability layers can be identified.

The characterising features of the amended claim 1 provide the technical effect of including in the video sequence information of independently decodable portions within scalability layers of of the video sequence, which portions can be removed without affecting decodability of the remaining frames of the scalability layer. Thus, the resulting overall technical problem to be solved is to create a coding hierarchy that enables to define such independently decodable portions within scalability layers and to indicate them along the encoded video sequence.

The problem is solved by a method comprising:
A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, characterized by comprising the steps of
forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format, at least one video frame of the first sub-sequence being associated with information indicative of the first sub-sequence; and
forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence being associated with information indicative of the second sub-sequence, and at least one video frame of the second sub-sequence has been

predicted from at least one video frame of the first sub-sequence;
wherein the information indicative of the first sub-sequence and the information indicative of the second sub-sequence are different from each other, and the information indicative of the sub-sequence is independent of the frame format.

Thus, by using such a flexible coding hierarchy it is enabled that, on one hand, the bit rate of a video sequence to be transmitted can be adjusted by removing sub-sequences even within scalability layers without video sequence decoding being required, and, on the other hand, independent decoding of each sub-sequence. This allows the streaming server, for example, to adjust the bit rate advantageously, without video sequence decoding, since the streaming server is capable of deducing the dependencies of the different sub-sequences directly from the identifiers and their dependencies.

D1 would not teach a skilled person to arrive at the claimed invention. On the contrary, D1 teaches that scalability can only be achieved layer-specifically, and D1 is completely silent about independently decodable sub-sequences within layers. Even less D1 gives indication to providing information about such sub-sequences to a steaming element in the network for adjusting the bit rate sub-sequence-specifically.

In the similar manner, a skilled person would not receive any indication for the claimed method from MPEG coding either.

Further, as submitted in D1, if the solution of D1 is applied to MPEG coding, the complete video sequence must first be decoded before any adjustment of coding parameters can be done, and thereafter the video sequence must be re-encoded. Accordingly, even a combination of D1 and D2 would not teach a skilled man to arrive at the claimed solution.

Consequently, the independent claims of the main request involve an inventive step in sense of Art. 56 EPC.

2. First auxiliary request

In comparison to the independent claims of the main request, the independent claims of the 1st auxiliary request include a further definition that including the information indicative of the sub-sequence in a header field of the video sequence or in a header field of a transfer protocol to be used for transferring the video sequence, or as Supplemental Enhancement Information (SEI) (*i.e. the subject-matter of the dependent claim 4 of the main request, paragr. [0085]*).

2.1. Inventive step (A.56 EPC)

The further definition included in the independent claims of the 1st auxiliary request provide the further technical effect that it defines more specifically how the information indicative of sub-sequence is attached to video sequence such that said information can be deduced without decoding the video sequence.

D1 gives no indication such solution. In addition to lacking the teaching towards information indicative of independently decodable sub-sequences within layers, D1 gives no solution for attaching such information. The only piece of information discussed in D1 to be transferred along the video sequence is the information about the used reference pictures, which is signalled in the picture header, i.e. the video sequence must be decoded at least to picture level in order to deduce said information. Thus, a skilled man would not receive any indication from to D1 to arrive at the claimed solution.

Consequently, the solution according to the independent claims of the 1st auxiliary request involves an inventive step.

3. Second auxiliary request

In comparison to the independent claims of the 1st auxiliary request, the independent claims of the 2nd auxiliary request

include a further definition that the information indicative of the sub-sequence comprises a scalability layer identifier and a sub-sequence identifier (*i.e. the subject-matter of the dependent claim 3 of the main and the 1st aux request; paragr. [0031-32])*

3.1. Inventive step (A.56 EPC)

The further definition included in the independent claims of the 1st auxiliary request provide the further technical effect that it defines more specifically the information elements, which can be used to identify independently decodable sub-sequences within scalability layers.

As discussed above, D1 gives no hints to independently decodable sub-sequences within layers, or to providing information about such sub-sequences to a steaming element. Thus, a skilled man would not receive any hints from D1 about the information elements, which can be used to identify independently decodable sub-sequences within scalability layers.

Consequently, the solution according to the independent claims of the 2nd auxiliary request involves an inventive step.

The following persons are announced to participate in the oral proceedings: European patent attorney Timo Pursiainen and patent attorney Eero Palmgren as attorneys familiar with the application, both from Tampereen Patenttitoimisto Oy, and the inventor, Mr. Miska Hannuksela.

With reference to the above request to suspend the oral proceedings, it is naturally in the interest of the Applicant to minimize or preferably avoid the travel costs caused by attending the oral proceedings. Therefore, if it appears to the Examiner that one or more of the submitted claim set would be allowable without a need for the oral proceedings, the Examiner is kindly requested to contact the undersigned (tel. +358-10-

2272 612) or patent attorney Eero Palmgren (tel. +358-10-2272 619) to discuss the matter further.

Yours faithfully,

Timo Pursiainen

1/4-4/4 as published

1 Oral proceedings will take place in accordance with Article 116(1) EPC at the applicants request and because the Examining Division considers it to be expedient.

2 In the official communication of 16.06.2006, objections were raised with respect to multiple independent claims in each category (Rule 43(2) EPC, previous Rule 29(2) EPC), lack of clarity (Article 84 EPC) and lack of novelty (Article 52(1) and 54(1) and (2) EPC).

3 In a letter of 16.10.2006, the applicants provided arguments why the present application meets the requirements of the EPC. The claims were left unamended.

4 Having carefully considered the applicant's arguments, the Examining Division is of the opinion that the present application does not meet the requirements of the EPC and that for the following reasons:

5 Multiple independent claims (Article 84, Rule 43(2) EPC)

The present application contains 8 independent claims, namely claim 1 related to a method for coding, claim 13 related to an element in a streaming system, claim 14 related to a video encoder, claim 15 related to a method for decoding, claim 21 related to a video decoder, claim 22 related to a computer program for coding, claim 23 related to a computer program for decoding and claim 24 related to a video signal.

Under Rule 43(2) EPC, an application may not contain more than one independent claim in a particular category unless the subject-matter claimed falls within one or more of the exceptional situations set out in paragraph (a), (b) or (c) of Rule 43(2) EPC.

The applicant points out that a number of claims are interrelated in that they represent encoder-decoder type inventions, which are an exception to the general rule (Rule 43(2)(a) EPC). The encoder-decoder pairs are:

- claims 1 and 15 (encoding-decoding method);
- claims 14 and 21 (encoder-decoder); and
- claims 22 and 23 (encoding-decoding computer program)

The Examining Division agrees that separate independent claims to an encoder and the corresponding decoder are allowed. However, the encoder-decoder claims in the present case are not strictly interrelated, because the decoders do not reverse the steps of the encoders. In particular, the decoder claims do not refer to dependency data **present in the bit stream**. This also gives rise to a lack of clarity and support by the description (Article 84 EPC), because the dependency information, signalled in the bit stream, is clearly presented as an essential feature in the description (see paras. 0016 and 0033).

Claim 13, which defines an element in a streaming system arranged to control the bit rate of a video sequence transmission, is, in effect, a claim to an encoder. Thus, there are two encoder claims, i.e. claims 13 and 14. The subject-matter of claim 13 is quite different from claim 14. However, both claims relate to the same sub-sequence structure and cannot, therefore, be regarded as alternative solutions to the same problem. Hence, the exception of Rule 43(2)(c) EPC does not apply.

In conclusion, the present set of claims contravenes Rule 43(2) EPC, which is a ground for refusal under Article 97(2) EPC. The Examining Division is bound by the EPC and not by the law of the contracting states or the "general viewpoint of the patenting system". The Examining Division can only adopt a "flexible approach" within the bounds of the EPC.

6 Lack of novelty (Article 52(1) and 54(1) and (2) EPC)

6.1 The present application does not meet the requirements of Article 52(1) EPC because the subject-matter of claims 1, 13-15 and 21-24 is not new within the meaning of Article 54(1) and (2) EPC.

6.2 Claim 1 refers to a method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, comprising forming a first sub-sequence, at least part of

which being coded according to the first format and a second sub-sequence, at least part of which being coded according the the second format, and at least one of the frames of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence, and forming into the video sequence information indicating which video frames belong to the second sub-sequence.

6.3 Thus, claim 1 includes the case where the video sequence is a normal MPEG sequence comprising I and P frames. The I frames represent the first sub-sequence (a single I-frame may form a separate sub-sequence, see para. 0035) and the P-frames the second sub-sequence. The picture-type information present in the picture header indicates the picture type (I or P), and thus implicitly which frames belong to the second sub-sequence. An MPEG sequence may be regarded as scalable in the sense that P-frames, i.e. the second sub-sequence, can be discarded. MPEG coding was indisputably well known at the priority date of the present application. Claim 1 is, therefore, not new within the meaning of Article 54(1) and (2), and the requirements of Article 52(1) are not satisfied.

6.4 Furthermore, claim 1 lacks novelty with respect to D1 (Article 54(1) and (2) EPC).

D1 is a document related to scalable coding using P-pictures (title). The base layer is a sequence of I or P pictures (fig. 2; page 3, line 16) and the enhancement layer consists of P pictures (fig. 2; page 3, line 17). The enhancement layer uses previous pictures of the enhancement layer as well as base layer pictures as reference pictures (fig. 2; page 3, lines 18-19 and fig. 2). Thus, the enhancement layer forms one or several separate sub-sequences (see fig. 2). In addition to the picture type information, which identifies the P-frames and consequently the enhancement layer in the case where the base layer consists of only I pictures), the reference picture used is signalled into the bit stream, thus providing information about the interdependencies of the respective sub-sequences (page 4, lines 6-8).

6.5 The applicant argues in his letter of reply that different temporal layers are not sub-sequences as disclosed in the present application. The Examining Division cannot follow this argument. The wording of claim 1 does not exclude this possibility. Furthermore, according to the description, a scalability layer, or even a single frame, may constitute a sub-sequence (see para. 0034).

The applicant cites the passage "The base layer is the only self-contained representation of the sequence [...]" in D1, page 1, as support for his argument that the temporal layers in D1 are not sub-sequences in the sense

of claim 1. However, the Examiner does not see any difference with respect to the present application. The second sub-sequence in claim 1, which consists of predicted frames, is not self-contained (see also fig. 2 of the present application).

6.6 The applicant also argues that D1 does not disclose information indicating which video frames belong to the second sub-sequence; it just indicates the reference picture. The Examining Division disagrees. The information in D1 constitutes dependency information, identifying the separate layers (sub-sequences). Thus, the bit stream information in D1 indicates, albeit implicitly, which frames belong to the second sub-sequence.

6.7 In conclusion, the applicant's arguments are not convincing. The Examining Division maintains that claim 1 lacks novelty with respect to D1. Also, the claim is so broad that it lacks novelty with respect to a normal MPEG sequence.

6.8 For the same reasons, claims 14, 15 and 21-24 lack novelty (Article 54(1) and (2) EPC). The requirements of Article 52(1) EPC are, therefore, not satisfied.

6.9 Furthermore, D1 discloses video transmission where the bit-rate is controlled by removing scalability layers (sub-sequences) from the bit stream (para. Introduction). The subject-matter of claim 13 is, therefore, not new either (Article 52(1) and 54(1) and (2) EPC).

7 The dependent claims do not appear to contain anything which contributes towards and inventive step.

8 Failure to overcome the above objections may lead to a refusal of the application under Article 97(2) EPC at the end of the oral proceedings.

Summons to attend oral proceedings pursuant to Rule 115(1) EPC

You are hereby summoned to attend oral proceedings arranged in connection with the above-mentioned European patent application.

The matters to be discussed are set out in the communication accompanying this summons (EPO Form 2906).

The oral proceedings, which will not be public, will take place before the Examining Division.

on 17.11.10 at 09.30 hrs at the EPO,
PschorrHöfe, Bayerstr. 34, D-80335 München

No changes to the date of the oral proceedings can be made, except on serious grounds (see OJ EPO 1/2009, 68). If you do not appear as summoned, the oral proceedings may continue without you (R. 115(2) EPC, see also OJ EPO 10/2008, 471).

Your attention is drawn to Rule 4 EPC, regarding the language of the oral proceedings, and to the Special edition No. 3 OJ EPO 2007, L.1., concerning the filing of authorisations for company employees and lawyers acting as representatives before the EPO.

The final date for making written submissions and/or amendments (R. 116 EPC) is 15.10.10.

The actual room number as well as the waiting room numbers will be given to you by the porter in the foyer at the above EPO address.

Parking is available free of charge in the underground car park. However, this applies only in the case of accessing the car park via the entrance "Zollstrasse".

EUROPAN PATENT APPLICATION NO. 03 700 321.7 - 1247
APPLICANT: NOKIA CORPORATION

Dear Sirs

This letter is in response to the official communication dated 16.6.2006.

The Applicant believes that the claims in their current form satisfy the requirements of the patentability in the EPC, and the Applicant submits the following arguments:

Number of independent claims (A. 84, R.29(2) EPC)

Regarding the objection of more than one independent claim in the same category (R.29(2) EPC), the Applicant respectfully disagrees. The independent claims 1, 14 and 22 disclose a method for encoding a video sequence, an encoder and a computer program for encoding. The independent claims 15, 21 and 23, in turn, disclose a method for decoding a video sequence, an decoder and a computer program for decoding. These different aspects of the invention represent an encoder-decoder-type invention concerning a plurality of inter-related products having the same inventive concept, which are allowed according to R. 29(2)(a) EPC. Furthermore, the independent claim 13 discloses an element for controlling the bit rate of the video sequence and the independent claim 24 discloses a video signal encoded according to the method of claim 1. All these different aspects of the invention can be manufactured, delivered and carried out as separate products, entities or actions and in order for the invention to be fully covered, it is essential that a possible infringement against any aspect of the invention can be counteracted. Even though claims 13, 14 and 21 – 24 all define apparatuses, these claim categories are of vital importance for the Applicant in obtaining the full protection for his invention in all designated

EPC contracting states. With this basic viewpoint of the whole patenting system in mind, it is desirable that the Examiner would adopt a flexible approach when evaluating several independent claims in the same category.

Furthermore, from the wording of independent claims 1, 13 - 15 and 21 - 24, it is clear that they all share a unifying inventive (encoding-decoding) concept, whereby the requirement of unity according to Art. 82 EPC is also satisfied and the determination of the extent of the protection is not impeded by any means.

Clarity objections (R. 84 EPC)

The Examiner objects the indeonedent claims, especially claim 1, as being not clear and being inconsistent with various embodiments of the description. The Applicant respectfully disagrees.

Particularly, the Examiner's interpretation of the term "sequence" as implying consecutive frames and not different layers cannot be agreed with. Claim 1 is defined as "a method for coding [...] a scalable, compressed video sequence...". A skilled man readily appreciates that in a scalable video sequence there are typically a plurality of layers, each including their own video sequences. Moreover, in the chap. 0044 it is disclosed: "The sub-sequences of the same layer or of the different layer may be partly or entirely overlapping". Also, the Oxford English dictionary defines a sequence as "a set of related events, movements, or things that follow each other in a particular order"; i.e. by the definition, the frames do not have be consecutive.

A sub-sequence is defined in the application as "consisting of groups of one or more video frames determined for each scalability layer" (chap. 0032, first sentence). The other essential properties of a subsequence are determined in claim 1.

Referring to Figure 2, some examples of sub-sequence can be given: In INTRA layer, frame 200 is an example of "a first sub-sequence" (this sub-sequence only contains 1 frame); In Base layer, frames 204, 206 are an example of "a second sub-sequence" (this sub-sequence contains 2 frames), wherein frame 204 is predicted from a frame of the first sub-sequence (frame 200); In Enh1 layer, frame 208 is also an example of "a second sub-sequence" (this sub-sequence contains only 1 frame); Also in Enh1 layer, frames 210, 212

Received at the EPO on Oct 16, 2006 14:47:01. Page 4 of 7

are also an example of "a second sub-sequence" (this sub-sequence contains 2 frames). This example is further clarified in the corresponding part of by the detailed description of the invention.

Furthermore, the application discloses an identifier that can be used to identify the frames and sub-sequences. An example of such identifier is composed of an image type, a subsequence identifier, and a image number (chap. 0034). Furthermore, in chap. 0057 it is pointed out that "For clarity of illustration, the above description of the embodiment does not comprise layer identifiers, but it is apparent that in order to implement scalability, also the layer identifier must be signalled together with the video sequence, typically as part of the image frame identifiers."

Again, referring to figure 2, frame 200 in the INTRA layer is labeled as (I.0.0), which means this is an I frame, and it belongs to subsequence 0, and within subsequence 0, the image number is 0. Similarly, frames 204 and 206 in the Base layer are labelled as (P.0.0) and (P.0.1) respectively, which means that both are P frames, and both belong to subsequence 0, and the image number within the subsequence 0 is 0 and 1 respectively. Also, the frames 210, 212 in Enh1 layer are labeled as (P.1.0) and (P.1.1) respectively, meaning that both are P frames, and both belong to subsequence 1, and the image number within subsequence 1 is 0 and 1 respectively. Using the above example, the frames 210, 212 forms an example of "a second sub-sequence", wherein at least one video frame (210) has been predicted from at least one video frame (200) of the first subsequence. Thus, it can be concluded that the subject-matter of claim 1 is consistent with figure 2.

Novelty (A. 54 EPC)

Regarding the novelty objection raised by the Examiner in view of the document D1: Multimedia Signal Processing, 1998 IEEE Second Workshop on 7-9 Dec 1998, S. Wenger, "Temporal scalability using P-pictures for low-latency applications" pp. 559-564, it is respectfully submitted that said document does not disclose any sub-seqeunce in the meaning as it is disclosed in the present application.

However, even if the Examiner takes the liberty to interpret the different layers as sub-sequences in the meaning of claim 1, it is still submitted that D1 does not disclose that the video sequence includes information indicating which video frames belong to the second sub-sequence. The mere fact that

Received at the EPO on Oct 16, 2006 14:47:01. Page 5 of 7

information about a reference picture, which can be used as reference for further prediction, is indicated in the video stream does not disclose, which video frames belong to the second sub-sequence; it just tells that there is a reference picture, to which one or more later pictures can refer as a motion prediction basis. This is further underlined by the statement: "The base layer is the only self-contained representation of the sequence [...]" (D1, p. 1) .Thus, the allegation of lack of novelty is groundless and the claims 1, 13 - 15 and 21 – 24 are novel in sense of A.54(1),(2) EPC.

Inventive step (A. 56 EPC)

D1 discloses a method for using P-pictures, instead of B-pictures, on the enhancement layers of a scalable video stream. While causing a minor increase in the bit rate, the method enables to minimize latency in the decoding phase compared to using B-pictures on enhancement layers.

However, the solution of D1 includes technical drawbacks. Adjusting the scalabilty e.g. in a streaming server or a network element becomes difficult, since the complete video sequence must first be decoded before any adjustment of coding parameters can be done, and thereafter the video sequence must be re-encoded (D1, p. 6, l. 6 – 8). This also one of the drawbacks of the prior art mentioned in the present application (chap. 0011). D1 is also completely silent about frame numbering, but since it is commonly known in the prior art to use ascending arithmetical frame numbering, which most probably is used in the solution of D1 as well, although not expressly stated. Such a frame numbering, however, becomes problematic, when inserting a video sequence in the middle of another video sequence or scaling of a video sequence, as is disclosed in the present application (chap. 0013).

Thus, the objective technical problems underlying the present invention are the same as the drawbacks of the prior art mentioned in the present application: carrying out reference picture selection when the prediction includes images temporally succeeding the image to be coded, how to signal differences of significance between INTER-frames, and how to create a frame numbering of video sequence, which allows flexible the insertion of a video sequence in the middle of another video sequence and scaling of a video sequence.

The problem is solved by a method for coding video frames for the purpose of forming a scalable, compressed video sequence, wherein a video signal is formed, which video

Received at the EPO on Oct 16, 2006 14:47:01. Page 6 of 7

signal comprises a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field determining the video frames that belong to the second sub-sequence.

Hence, the idea underlying the present invention is to create a scalable coding hierarchy, wherein, for each sub-sequence, all sub-sequences are determined, upon which the coding of said sub-sequence is dependent. This is achieved by a frame numbering hierarchy, wherein the frame numbering of each sub-sequence includes information on all sub-sequences, which have been used in image frame prediction. This information is signalled along the video sequence, but separately of the image information. This enables a flexible scaling of video sequence, since independently decodable parts of the video sequence can easily be determined.

D1 includes no hints to this kind of solution. D1 does not disclose any independently decodable sub-sequence on enhancement layers, as is disclosed in the present application. D1 does not disclose or even hint that the video sequence could include information indicating which video frames belong to the second sub-sequence, nor does it include any information about how the frame numbering of the video sequence should be carried out.

Therefore, claims 1, 13 - 15 and 21 – 24 involve an inventive step in sense of A.56 EPC.

In view of the amendments and submissions now made, the applicant respectfully submits that the application as a whole is now in order for allowance. If the Examiner is of the opinion that further objections should be raised, then a further written communication is requested. In the event that the Examiner considers any further objections cannot be dealt with in writing, then oral proceedings are requested in precaution under Article 116 EPC.

Yours faithfully

Timo Pursiainen, Authorised Representative

RE: EUROPEAN PATENT APPLICATION NO. 03700321.7-1247
in the name of NOKIA CORPORATION
Communication pursuant to Article 96(2) EPC

Dear Sirs,

With reference to the Communication pursuant to Article 96(2) EPC dated 16 June 2006, please be informed that the cited document (*Wenger: Temporal scalability using P-picture for low-latency applications*) was not annexed to the received communication. Therefore, we request that a copy of the document be sent to us as soon as possible.

Yours very truly,

Received at the EPO on Jul 07, 2006 10:09:23. Page 1 of 1

The examination is being carried out on the **following application documents**:

Description, Pages

1-34 as published

Claims, Numbers

1-24 as published

Drawings, Sheets

1/4-4/4 as published

1 The following documents is cited by the examiner (see the Guidelines, C-VI, 8.7). Copies of the documents are annexed to the communication and the numbering will be adhered to in the rest of the procedure:

D1: Wenger: Temporal scalability using P-pictures for low-latency applications, Multimedia Signal Processing, 1998 IEEE Second Workshop on Redondo Beach, CA, USA 7-9 Dec. 1998, Piscataway, NJ, USA,IEEE, US, pages 559-564, XP010318327

2 Claims 1, 13-15, 21-24 have been drafted as separate independent claims. Under Article 84 in combination with Rule 29(2) EPC an application may contain more than one independent claim in a particular category only if the subject matter claimed falls within one or more of the exceptional situations set out in paragraphs (a), (b) or (c) of Rule 29(2) EPC. The applicant is requested to amend the claims to comply with the above provisions.

3 The application does not meet the requirements of Article 84 EPC, because claim 1 is not clear.

Claim 1 lacks clarity as its subject-matter seems to be inconsistent with various embodiments of the description, e.g. that described in fig. 2 and in paras. 0035-0041.

Although claim 1 does not specify that the first and the second sub-sequences belong to the same layer, the term "sequence" implies consecutive frames and not different layers. Hence, according to claim 1, at least a picture in the second subsequence, which thus directly follows the first sub-sequence, is predicted from the first sub-sequence, i.e. "inter GOP prediction". However, according to fig. 2, there is no inter-GOP prediction but rather inter-layer prediction.

The applicant is requested to remove this inconsistency or explain why the subject-matter of claim 1 falls within the embodiment of fig. 2 and in particular explain the term "sub-sequence".

4 The present application does not meet the requirements of Article 52(1) EPC, because the subject-matter of claim 1 is not, as far as it has been understood, new in the sense of Article 54(1) and (2) EPC.

The document D1 discloses the following features of claim 1, as construed in light of the embodiment disclosed in fig. 2 and paras 0035-0041 of the description:

a method for coding video frames for the purpose of forming a scalable, compressed video sequence (title) comprising video frames coded according to at least a first and a second frame format (see fig. 2 and page 3, lines 15-17: The base layer comprises I and P-pictures), the video frames of the first frame format being independent of the other video frames (I), and the video frames of the second frame format being predicted from at least one of the other video frames (P), comprising the steps of forming into the video sequence at least part of a first sub- sequence (fig. 2: the first sub-sequence is the base layer), at least part of which has been formed by coding video frames of the at least first frame format (page 3, lines 15-17: the base layer includes an I-frame); and forming into the video sequence at least a second sub-sequence (fig. 2: the enhancement layer), at least part of which has been formed by coding at least video frames of the second frame format (fig. 2), and at least one video frame of the second sub- sequence has been predicted from at least one video frame of the first sub- sequence (fig. 2: the enhancement layer is predicted from the base layer); and forming into the video sequence information indicating which video frames belong to the second sub-sequence (page 4, lines 6-8: the reference picture

used is signalled in the picture header, thus the frame interdependencies are present in the bit stream).

The subject-matter of claim 1 is therefore not new (Article 54(1) and (2) EPC).

5 The above objections with respect to claim 1 directed to a method of coding apply *mutatis mutandis* to the corresponding independent claims 13-15 and 21-24.

6 The applicant is invited to file new claims which take account of the above objections. The applicant is also requested to explain how any independent claim differs from the method of D1.

7 It is suggested to defer any amendment to the description until an agreement as to an allowable set of claims has been reached.

Communication pursuant to Article 96(2) EPC

The examination of the above-identified application has revealed that it does not meet the requirements of the European Patent Convention for the reasons enclosed herewith. If the deficiencies indicated are not rectified the application may be refused pursuant to Article 97(1) EPC.

You are invited to file your observations and insofar as the deficiencies are such as to be rectifiable, to correct the indicated deficiencies within a period

of 4 months

from the notification of this communication, this period being computed in accordance with Rules 78(2) and 83(2) and (4) EPC.

One set of amendments to the description, claims and drawings is to be filed within the said period on separate sheets (Rule 36(1) EPC).

Failure to comply with this invitation in due time will result in the application being deemed to be withdrawn (Article 96(3) EPC).

GROUPING OF IMAGE FRAMES IN VIDEO CODING

FIELD OF THE INVENTION

[0001] The invention relates to the grouping of multimedia files, particularly video files and particularly in connection with streaming.

BACKGROUND OF THE INVENTION

[0002] The term 'streaming' refers to simultaneous sending and playback of data, typically multimedia data, such as audio and video files, in which the recipient may begin data playback already before all the data to be transmitted has been received. Multimedia data streaming systems comprise a streaming server and terminal devices that the recipients use for setting up a data connection, typically via a telecommunications network, to the streaming server. From the streaming server the recipients retrieve either stored or real-time multimedia data, and the playback of the multimedia data can then begin, most advantageously almost in real-time with the transmission of the data, by means of a streaming application included in the terminal.

[0003] From the point of view of the streaming server, the streaming may be carried out either as normal streaming or as progressive downloading to the terminal. In normal streaming the transmission of the multimedia data and/or the data contents are controlled either by making sure that the bit rate of the transmission substantially corresponds to the playback rate of the terminal device, or, if the telecommunications network used in the transmission causes a bottleneck in data transfer, by making sure that the bit rate of the transmission substantially corresponds to the bandwidth available in the telecommunications network. In progressive downloading the transmission of the multimedia data and/or the data contents do not necessarily have to be interfered with at all, but the multimedia files are transmitted as such to the recipient, typically by using transfer protocol flow control. The terminals then receive, store and reproduce an exact copy of the data transmitted from the server, which copy can then be later reproduced again on the terminal without needing to start a streaming again via the telecommunications network. The multimedia files stored in the terminal are, however, typically very large and their transfer to the terminal is time-consuming, and they require a significant amount of memory capacity, which is why normal streaming is often preferred.

[0004] The video files in multimedia files comprise a great number of still image frames, which are displayed rapidly in succession (of typically 15

to 30 frames per s) to create an impression of a moving image. The image frames typically comprise a number of stationary background objects, determined by image information which remains substantially unchanged, and few moving objects, determined by image information that changes to some extent. The information comprised by consecutively displayed image frames is typically largely similar, i.e. successive image frames comprise a considerable amount of redundancy. The redundancy appearing in video files can be divided into spatial, temporal and spectral redundancy. Spatial redundancy refers to the mutual correlation of adjacent image pixels, temporal redundancy refers to the changes taking place in specific image objects in subsequent frames, and spectral redundancy to the correlation of different colour components within an image frame.

[0005] To reduce the amount of data in video files, the image data can be compressed into a smaller form by reducing the amount of redundant information in the image frames. In addition, while encoding, most of the currently used video encoders downgrade image quality in image frame sections that are less important in the video information. Further, many video coding methods allow redundancy in a bit stream coded from image data to be reduced by efficient, lossless coding of compression parameters known as VLC (Variable Length Coding).

[0006] In addition, many video coding methods make use of the above-described temporal redundancy of successive image frames. In that case a method known as motion-compensated temporal prediction is used, i.e. the contents of some (typically most) of the image frames in a video sequence are predicted from other frames in the sequence by tracking changes in specific objects or areas in successive image frames. A video sequence always comprises some compressed image frames the image information of which has not been determined using motion-compensated temporal prediction. Such frames are called INTRA-frames, or I-frames. Correspondingly, motion-compensated video sequence image frames predicted from previous image frames are called INTER-frames, or P-frames (Predicted). The image information of P-frames is determined using one I-frame and possibly one or more previously coded P-frames. If a frame is lost, frames dependent on it can no longer be correctly decoded.

[0007] An I-frame typically initiates a video sequence defined as a Group of Pictures (GOP), the P-frames of which can only be determined on the

basis of the I-frame and the previous P-frames of the GOP in question. The next I-frame begins a new group of pictures GOP, the image information comprised by which cannot thus be determined on the basis of the frames of the previous GOP. In other words, groups of pictures GOP are not temporally overlapping, and each group of picture can be decoded separately. In addition, many video compression methods employ bi-directionally predicted B-frames (Bi-directional), which are set between two anchor frames (I- and P-frames, or two P-frames) within a group of pictures GOP, the image information of a B-frame being predicted from both the previous anchor frame and the one succeeding the B-frame. B-frames therefore provide image information of higher quality than P-frames, but typically they are not used as anchor frames, and therefore their removal from the video sequence does not degrade the quality of subsequent images. However, nothing prevents B-frames from being used as anchor frames as well, only in that case they cannot be removed from the video sequence without deteriorating the quality of the frames dependent on them.

[0008] Each video frame can be divided into what are known as macroblocks that comprise the colour components (such as Y, U, V) of all pixels of a rectangular image area. More specifically, a macroblock consists of at least one block per colour component, the blocks each comprising colour values (such as Y, U or V) of one colour level in the image area concerned. The spatial resolution of the blocks may differ from that of the macroblocks, for example U- and V-components may be displayed using only half of the resolution of a Y-component. Macroblocks can be further grouped into slices, for example, which are groups of macroblocks that are typically selected in the scanning order of the image. Temporal prediction is typically carried out in video coding methods block- or macroblock-specifically, instead of image-frame-specifically.

[0009] To allow for flexible streaming of video files, many video coding systems employ scalable coding in which some elements or element groups of a video sequence can be removed without affecting the reconstruction of other parts of the video sequence. Scalability is typically implemented by grouping the image frames into a number of hierarchical layers. The image frames coded into the image frames of the base layer substantially comprise only the ones that are compulsory for the decoding of the video information at the receiving end. The base layer of each group of

pictures GOP thus comprises one I-frame and a necessary number of P-frames. One or more enhancement layers can be determined below the base layer, each one of the layers improving the quality of the video coding in comparison with an upper layer. The enhancement layers thus comprise P- or B-frames predicted on the basis of motion-compensation from one or more upper layer images. The frames are typically numbered according to an arithmetical series.

[0010] In streaming, transmission bit rate must be controllable either on the basis of the bandwidth to be used or the maximum decoding or bit rate value of the recipient. Bit rate can be controlled either at the streaming server or in some element of the telecommunications network, such as an Internet router or a base station of a mobile communications network. The simplest means for the streaming server to control the bit rate is to leave out B-frames having a high information content from the transmission. Further, the streaming server may determine the number of scalability layers to be transmitted in a video stream, and thus the number of the scalability layers can be changed always when a new group of pictures GOP begins. It is also possible to use different video sequence coding methods. Correspondingly, also other P-frames of the enhancement layers, in addition to the B-frames, can be removed from the bit stream in a telecommunications network element.

[0011] The above arrangement involves a number of problems. Many coding methods, such as the coding according to the ITU-T (International Telecommunications Union, Telecommunications Standardization Sector) standard H.263, are familiar with a procedure called reference picture selection. In reference picture selection at least a part of a P-image has been predicted from at least one other image than the one immediately preceding the P-image in the time domain. The selected reference image is signalled in a coded bit stream or in bit stream header fields image-, image-segment- (such as a slice or a group of macroblocks), macroblock-, or block-specifically. The reference picture selection can be generalized such that the prediction can also be made from images temporally succeeding the image to be coded. Further, the reference picture selection can be generalized to cover all temporally predicted frame types, including B-frames. Since it is possible to also select at least one image preceding an I-image that begins a group of pictures GOP as the reference image, a group of pictures employing reference picture selection cannot necessarily be decoded independently. In

addition, the adjusting of scalability or coding method in the streaming server or a network element becomes difficult, because the video sequence must be decoded, parsed and buffered for a long period of time to allow any dependencies between different image groups to be detected.

[0012] Another problem in the prior art coding methods is that there is no useful method of signalling differences of significance between INTER-frames. For example, when a plural number of P-frames are to be predicted successively, the first P-frames are usually the most significant ones for the reconstruction because there are more image frames that are dependent on the first P-frame than on subsequent P-frames. However, known coding methods fail to provide a simple method for signalling such differences in significance.

[0013] A further problem relates to the insertion of a video sequence in the middle of another video sequence, which has typically led to discontinuity in image numbering. The numbering of video sequence images is typically used for detecting the loss of image frames. However, if a separate video sequence, such as a commercial, is inserted into a video sequence, the separate video sequence is typically provided with separate image numbering, which is not in line with the ascending image numbering of the original video sequence. The receiving terminal may therefore interpret the deviating image numbering as a signal of lost image frames and start unnecessary actions to reconstruct the image frames suspected as lost or to request a re-transmission thereof. A similar problem is encountered when scaling a video sequence: for example, if a plural number of successive frames is removed, the receiving terminal may unnecessarily interpret these removals as protocol errors.

BRIEF DESCRIPTION OF THE INVENTION

[0014] It is therefore an object of the invention to provide a method and equipment implementing the method that allow the disadvantages caused by the above problems to be reduced. The objects of the invention are achieved by a method, video encoder, video decoder, streaming system element and computer programs that are chacterized by what is stated in the independent claims.

[0015] The preferred embodiments of the invention are disclosed in the dependent claims.

[0016] The invention is based on the idea of coding a scalable, compressed video sequence that comprises video frames coded on the basis of at least a first and a second frame format, the video frames conforming to the first frame format being independent of other video frames, i.e. they are typically I-frames, and the video frames according to the second frame format being frames predicted from at least one other video frame, for example P-frames. A video sequence comprises a first sub-sequence formed therein, at least part of the sub-sequence being formed by coding video frames (I-frames) of the at least first frame format (I-frames), and at least a second sub-sequence, at least part of which is formed by coding video frames of the at least second frame format (e.g. P-frames), at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. In addition, identifying data of the video frames comprised by the at least second sub-sequence are determined into the video sequence in question.

[0017] Consequently, an essential aspect of the present invention is to determine the sub-sequences each sub-sequence is dependent on, i.e. a sub-sequence will comprise information of all sub-sequences that have been directly used for predicting the image frames comprised by the sub-sequence in question. This information is signalled in the bit stream of the video sequence, preferably separate from the actual image information, whereby the image data comprised by the video sequence can preferably be scaled, because independently decodable portions of the video sequence can be easily determined, and the portions can be removed without affecting the decoding of the rest of the image data.

[0018] According to a preferred embodiment of the invention, a scalable coding hierarchy is formed for the video sequences, according to which hierarchy a first scalability layer of the video sequence is coded in such a way that it comprises at least video frames of the first frame format, i.e. I-frames, and the lower scalability layers of the video sequence are coded such that they comprise at least video frames of the second frame format, i.e. P- and/or B-frames, grouped into sub-sequences in which at least one video frame is predicted either from a video frame of an upper scalability layer or from another video frame of the same sub-sequence. The number of the scalability layers is not restricted.

[0019] According to a preferred embodiment of the invention, a unique identifier combining the scalability layer number, sub-sequence identifier and image number is determined for each video frame. The identifier can be included into a header field of the video sequence, or into a header field according to the transfer protocol to be used for the video sequence transfer.

[0020] An advantage of the procedure of the invention is that it provides a flexible coding hierarchy that enables, on one hand, the scaling of the bit rate of a video sequence to be transmitted without video sequence decoding being required, and, on the other hand, independent decoding of each sub-sequence. This allows the streaming server, for example, to adjust the bit rate advantageously, without video sequence decoding, parsing and buffering, because the streaming server is capable of deducing the inter-dependencies of the different sub-sequences directly from the identifiers and their inter-dependencies. Further, the streaming server may, when necessary, carry out sub-sequence-specific adjusting of the scalability or the coding employed, because the inter-dependencies of the different frames are known. A further advantage is that the coding hierarchy and the image numbering of the invention allow a separate video sequence to the easily inserted into another video sequence.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] In the following, the invention will be described in connection with the preferred embodiments and with reference to the accompanying drawings, in which

Figure 1 illustrates a common multimedia data streaming system in which the scalable coding hierarchy of the invention can be applied;

Figure 2 illustrates a scalable coding hierarchy of a preferred embodiment of the invention;

Figures 3a and 3b illustrate embodiments of the invention for adjusting scalability;

Figures 4a, 4b and 4c illustrate embodiments of the invention for adjusting image numbering;

Figures 5a, 5b and 5c illustrate embodiments of the invention for using B-frames in a scalable coding hierarchy;

Figures 6a, 6b and 6c illustrate scalable coding hierarchies of preferred embodiments of the invention in connection with reference picture selection; and

Figure 7 illustrates an arrangement according to a preferred embodiment of the invention for coding scene transition.

DETAILED DESCRIPTION OF THE INVENTION

[0022] In the following, a general-purpose multimedia data streaming system is disclosed, the basic principles of which can be applied in connection with any telecommunications system. Although the invention is described here with a particular reference to a streaming system, in which multimedia data is transmitted most preferably through a telecommunications network employing a packet-switched data protocol, such as an IP network, the invention can equally well be implemented in circuit-switched networks, such as fixed telephone networks PSTN/ISDN (Public Switched Telephone Network/Integrated Services Digital Network) or in mobile communications networks PLMN (Public Land Mobile Network). Further, the invention can be applied in the streaming of multimedia files in the form of both normal streaming and progressive downloading, and for implementing video calls, for example.

[0023] It is also to be noted that although the invention is described here with a particular reference to streaming systems and the invention can also be advantageously applied in them, the invention is not restricted to streaming systems alone, but can be applied in any video reproduction system, irrespective of how a video file that is to be decoded is downloaded and where it is downloaded from. The invention can therefore be applied for example in the playback of a video file to be downloaded from a DVD disc or from some other computer memory carrier, for example in connection with varying processing capacity available for video playback. In particular, the invention can be applied to different video codings of low bit rate that are typically used in telecommunications systems subject to bandwidth restrictions. One example is the system defined in the ITU-T standard H.263 and the one that is being defined in H.26L (possibly later to become H.264). In connection with these, the invention can be applied to mobile stations, for example, in which case the video playback can be made to adjust both to changing transfer capacity or channel quality and to the processor power currently available, when the

mobile station is used also for executing other applications than video playback.

[0024] It is further to be noted that, for the sake of clarity, the invention will be described below by giving an account of image frame coding and temporal predicting on image frame level. However, in practice coding and temporal predicting typically take place on block or macroblock level, as described above.

[0025] With reference to Figure 1, a typical multimedia streaming system will be described, which is a preferred system for applying the procedure of the invention.

[0026] A multimedia data streaming system typically comprises one or more multimedia sources 100, such as a video camera and a microphone, or video image or computer graphic files stored in a memory carrier. Raw data obtained from the different multimedia sources 100 is combined into a multimedia file in an encoder 102, which can also be referred to as an editing unit. The raw data arriving from the one or more multimedia sources 100 is first captured using capturing means 104 included in the encoder 102, which capturing means can be typically implemented as different interface cards, driver software, or application software controlling the function of a card. For example, video data may be captured using a video capture card and the associated software. The output of the capturing means 104 is typically either an uncompressed or slightly compressed data flow, for example uncompressed video frames of the YUV 4:2:0 format or motion-JPEG image format, when a video capture card is concerned.

[0027] An editor 106 links different media flows together to synchronize video and audio flows to be reproduced simultaneously as desired. The editor 106 may also edit each media flow, such as a video flow, by halving the frame rate or by reducing spatial resolution, for example. The separate, although synchronized, media flows are compressed in a compressor 108, where each media flow is separately compressed using a compressor suitable for the media flow. For example, video frames of the YUV 4:2:0 format may be compressed using the low bit rate video coding according to the ITU-T recommendation H.263 or H.26L. The separate, synchronized and compressed media flows are typically interleaved in a multiplexer 110, the output obtained from the encoder 102 being a single, uniform bit flow that comprises data of a plural number of media flows and that may be referred to

as a multimedia file. It is to be noted that the forming of a multimedia file does not necessarily require the multiplexing of a plural number of media flows into a single file, but the streaming server may interleave the media flows just before transmitting them.

[0028] The multimedia files are transferred to a streaming server 112, which is thus capable of carrying out the streaming either as a real-time streaming or in the form of progressive downloading. In progressive downloading the multimedia files are first stored in the memory of the server 112 from where they may be retrieved for transmission as need arises. In real-time streaming the editor 102 transmits a continuous media flow of multimedia files to the streaming server 112, and the server 112 forwards the flow directly to a client 114. The streaming server 112 carries out traffic shaping of the multimedia data as regards the bandwidth available or the maximum decoding and playback rate of the client 114, the streaming server being able to adjust the bit rate of the media flow for example by leaving out B-frames from the transmission or by adjusting the number of the scalability layers. Further, the streaming server 112 may modify the header fields of a multiplexed media flow to reduce their size and encapsulate the multimedia data into data packets that are suitable for transmission in the telecommunications network employed. The client 114 may typically adjust, at least to some extent, the operation of the server 112 by using a suitable control protocol. The client 114 is capable of controlling the server 112 at least in such a way that a desired multimedia file can be selected for transmission to the client, in addition to which the client is typically capable of stopping and interrupting the transmission of a multimedia file.

[0029] When the client 114 is receiving a multimedia file, the file is first supplied to a demultiplexer 116, which separates the media flows comprised by the multimedia file. The separate, compressed media flows are then supplied to a decompressor 118 where each separate media flow is decompressed by a decompressor suitable for each particular media flow. The decompressed and reconstructed media flows are supplied to a playback unit 120 where the media flows are rendered at a correct pace according to their synchronization data and supplied to presentation means 124 for reproduction. The actual presentation means 124 may comprise for example a computer or mobile station display, and loudspeaker means. The client 114 also typically comprises a control unit 122 that the end user can typically control through a

user interface and that controls both the operation of the server, through the above-described control protocol, and the operation of the playback unit 120, on the basis of the instructions given by the end user.

[0030] It is to be noted that the transfer of multimedia files from the streaming server 112 to the client 114 takes place through a telecommunications network, the transfer path typically comprising a plural number of telecommunications network elements. It is therefore possible that there is at least some network element that can carry out traffic shaping of multimedia data with regard to the available bandwidth or the maximum decoding and playback rate of the client 114 at least partly in the same way as described above in connection with the streaming server.

[0031] Scalable coding will be described below with reference to a preferred embodiment of the invention and an example illustrated in Figure 2. Figure 2 shows part of a compressed video sequence having a first frame 200, which is an INTRA frame, or I-frame, and thus an independently determined video frame the image information of which is determined without using motion-compensated temporal prediction. The I-frame 200 is placed on a first scalability layer, which may be referred to as an INTRA layer. Each scalability layer is assigned a unique identifier, such as the layer number. The INTRA layer may therefore be given the number 0, for example, or some other alphanumeric identifier, for example a letter, or a combination of a letter and a number.

[0032] Correspondingly, sub-sequences consisting of groups of one or more video frames are determined for each scalability layer, at least one of the images in a group (typically the first or the last one) being temporally predicted at least from a video frame of another sub-sequence of typically either a higher or the same scalability layer, the rest of the video frames being temporally predicted either from only the video frames of the same sub-sequence, or possibly also from one or more video frames of said second sub-sequence. A sub-sequence may be decoded independently, irrespective of other sub-sequences, except said second sub-sequence. The sub-sequences of each scalability layer are assigned a unique identifier using for example consecutive numbering starting with number 0 given for the first sub-sequence of a scalability layer. Since the I-frame 200 is determined independently and can also be decoded independently upon reception, irrespective of other image frames, it also forms in a way a separate sub-sequence.

[0033] An essential aspect of the present invention is therefore to determine each sub-sequence in terms of those sub-sequences the sub-sequence is dependent on. In other words, a sub-sequence comprises information about all the sub-sequences that have been directly used for predicting the image frames of the sub-sequence in question. This information is signalled in a video sequence bit stream, preferably separate from the actual image information, and therefore the image data of the video sequence can be preferably adjusted because it is easy to determine video sequence portions that are to be independently decoded and can be removed without affecting the decoding of the rest of the image data.

[0034] Next, within each sub-sequence, the video frames of the sub-sequence are given image numbers, using for example consecutive numbering that starts with the number 0 given to the first video frame of the sub-sequence. Since the I-frame 200 also forms a separate sub-sequence, its image number is 0. In Figure 2, the I-frame 200 shows the type (I), sub-sequence identifier and image number (0.0) of the frame.

[0035] Figure 2 further shows a next I-frame 202 of the INTRA layer, the frame thus being also an independently determined video frame that has been determined without using motion-compensated temporal prediction. The temporal transmission frequency of I-frames depends on many factors relating to video coding, image information contents and the bandwidth to be used, and, depending on the application or application environment, the I-frames are transmitted in a video sequence at intervals of 0.5 to 10 seconds, for example. Since the I-frame 202 can be independently decoded, it also forms a separate sub-sequence. Since this is the second sub-sequence in the INTRA-layer, the consecutive numbering of the sub-sequence identifier of the I-frame 202 is 1. Further, since the I-frame 202 also forms a separate sub-sequence, i.e. it is the only video frame in the sub-sequence, its image number is 0. The I-frame 202 can thus be designated with identifier (I.1.0.) Correspondingly, the identifier of the next I-frame on the INTRA layer is (I.2.0.), etc. As a result, only independently determined I-frames in which the image information is not determined using motion-compensated temporal prediction are coded into the first scalability layer, i.e. the INTRA layer. The sub-sequences can also be determined using other kind of numbering or other identifiers, provided that the sub-sequences can be distinguished from one another.

[0036] The next scalability layer, which has a layer number 1, for example, and which may be referred to as the base layer, comprises coded, motion-compensated INTER or P-frames typically predicted only from previous image frames, i.e. in this case from the I-frames of an upper INTRA layer. The image information of the first P-frame 204 of the base layer shown in Figure 2 is determined using the I-frame 200 of the INTRA layer. A P-frame 204 begins the first sub-sequence of the base layer and therefore the sub-sequence identifier of the P-frame 204 is 0. Further, since the P-frame 204 is the first image frame of the first sub-sequence of the base layer, the image number of the P-frame 204 is 0. The P-frame 204 can thus be identified with (P.0.0).

[0037] The temporally succeeding P-frame 206 of the base layer is predicted from the previous P-frame 204. The P-frames 204 and 206 thus belong to the same sub-sequence, whereby the P-frame 206 also receives the sub-sequence identifier 0. Since the P-frame 206 is the second image frame in the sub-sequence 0, the image number of the P-frame 206 is 1, and the P-frame 206 can be identified with (P.0.1).

[0038] The scalability layer succeeding the base layer and having the layer number 2, is called the first enhancement layer. This layer comprises coded, motion-compensated P-frames predicted only from previous image frames, in this case either from I-frames of the INTRA layer or P-frames of the base layer. Figure 2 shows a first image frame 208 and a second image frame 210 of the first enhancement layer, which are both predicted only from the first image frame 200 of the INTRA layer. The P-frame 208 begins the first sub-sequence of the first enhancement layer, the sub-sequence identifier of the P-frame 208 thus being 0. Further, since the P-frame 208 is the first and only image frame in said sub-sequence, the P-frame 208 receives the image number 0. The P-frame 208 can thus be identified with (P.0.0.).

[0039] Since the second image frame 210 is also predicted only from the first image frame 200 of the INTRA layer, the P-frame 210 begins the second sub-sequence of the first enhancement layer and the sub-sequence identifier of the P-frame 210 is therefore 1. Since the P-frame 210 is the first image frame in the sub-sequence, the image number of the P-frame 210 is 0. The P-frame can thus be identified with (P.1.0.). The temporally succeeding P-frame 212 of the first enhancement layer is predicted from the previous P-frame 210. The P-frames 210 and 212 thus belong to the same sub-sequence, and therefore the P-frame also receives the sub-sequence identifier 1. The P-

frame 212 is the second image frame in the sub-sequence 1, and therefore the P-frame 212 receives the image number 1 and can be identified with (P.1.1).

[0040] The temporally fourth image frame 214 of the first enhancement layer is predicted from the first image frame 204 of the base layer. The P-frame 214 thus begins a third sub-sequence of the first enhancement layer and therefore the P-frame 214 receives the sub-sequence identifier 2. Further, since the P-frame 214 is the first and only image frame in the sub-sequence, the image number of the P-frame 214 is 0. The P-frame 208 can therefore be identified with (P.2.0).

[0041] Also the temporally fifth image frame 216 of the first enhancement layer is predicted only from the first image frame 204 of the base layer, and therefore the P-frame 216 begins the fourth sub-sequence of the first enhancement layer, the sub-sequence identifier of the P-frame 216 being 3. In addition, since the P-frame 216 is the first one in the sub-sequence in question, the image number of the P-frame 216 is 0. The P-frame 216 can therefore be identified with (P.3.0). The temporally following P-frame 218 of the first enhancement layer is predicted from the previous P-frame 216. The P-frames 216 and 218 thus belong to the same sub-sequence and thus the sub-sequence identifier of the P-frame 218 is also 3. Since the P-frame 218 is the second image frame in sub-sequence 3, the image number of the P-frame 218 is 1 and the identifier of the P-frame 218 is (P.3.1).

[0042] For simplicity and clarity of illustration the above disclosure only relates to I- and P-frames. However, a person skilled in the art will find it apparent that the scalable video coding of the invention can also be implemented using other known image frame types, such as the above described B-frames and at least SI-frames, SP-frames and MH-frames. SI-frames correspond to I-frames, but together with an SP-frame they allow an identical image to be reconstructed. An SP-frame, in turn, is a P-frame subjected to a particular coding that allows an identical image to be reconstructed together with an SI-frame or another SP-frame. SP-frames are typically placed into video sequence points, where an access point or a scanning point is desired, or where the changing of the coding parameters of the video stream should be possible. The frames can also be used for error correction and for increasing error tolerance. SP-frames are otherwise similar to ordinary P-frames predicted from previous frames, except that they are defined so that they can be replaced by another video frame of the SP- or SI-

type, the result of the decoding of the new frame being identical with the decoding result of the original SP-frame that was in the video stream. In other words, a new SP-frame that is used for replacing the SP-frame that was in the video stream is predicted from another sequence or video stream and yet the reconstructed frame has identical contents. SP-frames are described for example in the Applicant's earlier application PCT/FI02/00004.

[0043] Similarly as B-frames, macroblocks of MH (Multi Hypothesis) frames, based on motion-compensated prediction, are predicted from two other frames, which are not, however, necessarily located next to an MH-frame. More precisely, the predicted macroblocks are computed as an average of two macroblocks of two other frames. Instead of two frames, MH-frame macroblocks can naturally be also predicted from one other frame. Reference images may change according to macroblock, in other words, all macroblocks in one and the same image are not necessarily predicted using the same frames.

[0044] A sub-sequence thus covers a specific period of time in a video sequence. The sub-sequences of the same layer or of different layers may be partly or entirely overlapping. If there are temporally overlapping image frames on the same layer, the frames are interpreted as alternative presentations of the same image content and therefore any mode of image presentation can be used. On the other hand, if there are temporally overlapping image frames on different layers, they form different presentations of the same image content, and therefore presentations differ in image quality, i.e. the quality of image is better on a lower layer.

[0045] The above disclosure referring to Figure 2 illustrates a scalable coding arrangement and a hierarchical structure and numbering of image frames according to a preferred embodiment of the invention. In this embodiment the INTRA-layer only comprises I-frames and the base layer can only be decoded using the information received from the INTRA-layer. Correspondingly, the decoding of the first enhancement layer typically requires information from both the base layer and the INTRA-layer.

[0046] The number of the scalability layers is not restricted to three, as above, but any number of enhancement layers that is considered necessary for producing sufficient scalability may be used. Consequently, the layer number of the second enhancement layer is four, that of the third enhancement layer is five, etc. Since some of the image frames in the above

example are given the same identifier (e.g. the identifier of both image frames 204 and 208 is (P.0.0)), by including the layer number in the identifier each image frame can be uniquely identified and, at the same time, the dependencies of each image frame on other image frames is preferably determined. Each image frame is thus uniquely identified, the identifier of image frame 204, for example, being (P.1.0.0), or simply (1.0.0) and, correspondingly, that of image frame 208 being (P.2.0.0), or (2.0.0).

[0047] According to a preferred embodiment of the invention, the number of a reference image frame is determined according to a specific, predetermined alpha-numeric series, for example as an integer between 0 and 255. When the parameter value achieves the maximum value N (e.g. 255) in the series concerned, the determining of the parameter value starts from the beginning, i.e. from the minimum value of the series (e.g. 0). An image frame is thus uniquely identified within a specific sub-sequence up to the point where the same image number is used again. The sub-sequence identifier can also be determined according to a specific, predetermined arithmetic series. When the value of the sub-sequence identifier achieves the maximum value N of the series, the determining of the identifier starts again from the beginning of the arithmetic series. However, a sub-sequence cannot be assigned an identifier that is still in use (within the same layer). The series in use may also be determined in another way than arithmetically. One alternative is to assign random sub-sequence identifiers, taking into account that an assigned identifier is not used again.

[0048] A problem in the numbering of image frames arises when browsing of a video file is to be started in the middle of a video sequence. Such situations occur for example when the user wishes to browse a locally stored video file backward or forward or to browse a streaming file at a particular point; when the user initiates the playback of a streaming file from a random point; or when a video file that is to be reproduced is detected to contain an error that interrupts the playback or requires the playback to be resumed from a point following the error. When the browsing of a video file is resumed from a random point after previous browsing, discontinuity typically occurs in the image numbering and the decoder typically interprets this as unintentional loss of image frames and unnecessarily tries to reconstruct the image frames suspected as lost.

[0049] According to a preferred embodiment of the invention, this can be avoided in the decoder by defining an initiation image in an independently decodable Group of Pictures GOP that is activated at a random point of the video file and by setting the number of the initiation image at zero. This independently decodable image group can thus be a sub-sequence of an INTRA-layer, for example, in which case an I-frame is used as the initiation image, or, if scaling originating from the base layer is employed, the independently decodable image group is a sub-sequence of the base layer, in which case the first image frame of the sub-sequence, typically an I-frame, is used as the initiation image. Consequently, when activated at a random point, the decoder preferably sets the identifier of the first image frame, preferably an I-frame, of the independently decodable sub-sequence at zero. Since the sub-sequence to be decoded may also comprise other image frames whose identifier is zero (for example when the above described alpha-numeric series starts from the beginning), the beginning of the sub-sequence, i.e. its first image frame, can be indicated to the decoder for example by a separate flag added to the header field of a slice of the image frame. This allows the decoder to interpret the image numbers correctly and to find the correct image frame that initiates the sub-sequence among the video sequence image frames.

[0050] The above numbering system provides only one example of how the unique image frame identification of the invention can be carried out so that interdependencies between the image frames are indicated at the same time. However, video coding methods in which the method of the invention can be applied, such as video coding methods according to the ITU-T standards H.263 and H.26L, employ code tables, which in turn use variable length codes. When variable length codes are used for coding layer numbers, for example, a lower code word index, i.e. a smaller layer number, signifies a shorter code word. In practice the scalable coding of the invention will be used in most cases in such a way that the base layer will consist significantly more image frames than the INTRA-layer. This justifies the use of a lower index, i.e. a smaller layer number, on the base layer than on the INTRA-layer, because the amount of coded video data is thereby advantageously reduced. Consequently, the INTRA-layer is preferably assigned layer number 1 and the base layer is given layer number 0. Alternatively, the code can be formed by using fewer bits for coding the base layer number than the INTRA-layer

number, in which case the actual layer number value is not relevant in view of the length of the code created.

[0051] Further, according to a second preferred embodiment of the invention, when the number of the scalability layers is to be kept low, the first scalability layer in particular can be coded to comprise both the INTRA-layer and the base layer. From the point of view of coding hierarchy, the simplest way to conceive this is to leave out the INTRA-layer altogether and to provide the base layer with coded frames consisting of both independently defined I-frames, the image information of which has not been determined using motion-compensated temporal prediction, and image frames predicted from previous frames, which image frames in this case are motion-compensated P-frames predicted from the I-frames of the same layer. The layer number value 0 can thus still be used for the base layer and, if enhancement layers are coded into the video sequence, the first enhancement layer is assigned layer number 1. This is illustrated in the following, with reference to Figures 3a and 3b.

[0052] Figure 3a shows a non-scalable video sequence structure, in which all image frames are placed on the same scalability layer, i.e. the base layer. The video sequence comprises a first image frame 300 which is an I-frame (I.0.0) and which thus initiates a first sub-sequence. The image frame 300 is used for predicting a second image frame 302 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 304 of the sub-sequence, i.e. a P-frame (P.0.2), which is in turn used for predicting the next image frame 306, i.e. a P-frame (P.0.3). The video sequence is then provided with an I-frame (I.1.0) coded therein, i.e. an I-frame 308, which thus initiates a second sub-sequence in the video sequence. This kind of non-scalable coding can be used for example when the application employed does not allow scalable coding to be used, or there is no need for it. In a circuit-switched videophone application, for example, channel bandwidth remains constant and the video sequence is coded in real-time and therefore there is typically no need for scalable coding.

[0053] Figure 3b, in turn, illustrates an example of how scalability can be added, when necessary, to a combined INTRA- and base layer. Here, too, the video sequence base layer comprises a first image frame 310 which is again an I-frame (I.0.0) and which initiates a first sub-sequence of the base layer. The image frame 310 is used for predicting a second image frame 312 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a

third image frame 314 of the sub-sequence, i.e. a P-frame (P.0.2). The first enhancement layer, however, is also coded into this video sequence and it comprises a first sub-sequence, the first and only image frame 316 of which is a P-frame (P.0.0), which is predicted from the first image frame 310 of the base layer. The first image frame 318 of a second sub-sequence of the enhancement layer is, in turn, predicted from the second image frame 312 of the base layer, and therefore the identifier of this P-frame is (P.1.0). The next image frame 320 of the enhancement layer is again predicted from the previous image frame 318 of the same layer and, therefore, it belongs to the same sub-sequence, its identifier thus being (P.1.1).

[0054] In this embodiment of the invention the sub-sequences of the base layer can be decoded independently, although a base layer sub-sequence may be dependent on another base layer sub-sequence. The decoding of the base layer sub-sequences requires information from the base layer and/or from the second sub-sequence of the first enhancement layer, the decoding of the sub-sequences of the second enhancement layer requires information from the first enhancement layer and/or from the second sub-sequence of the second enhancement layer, etc. According to an embodiment, I-frames are not restricted to the base layer alone, but lower enhancement layers may also comprise I-frames.

[0055] The basic idea behind the above embodiments is that a sub-sequence comprises information about all the sub-sequences it is dependent on, i.e. about all sub-sequences that have been used for predicting at least one of the image frames of the sub-sequence in question. However, according to an embodiment it is also possible that a sub-sequence comprises information about all sub-sequences that are dependent on the sub-sequence in question, in other words, about all the sub-sequences in which at least one image frame has been predicted using at least one image frame of the sub-sequence in question. Since in the latter case the dependencies are typically determined temporally forward, image frame buffers can be advantageously utilized in the coding in a manner to be described later.

[0056] In all the above embodiments the numbering of the image frames is sub-sequence-specific, i.e. a new sub-sequence always starts the numbering from the beginning. The identification of an individual image frame thus requires the layer number, sub-sequence identifier, and image frame number to be determined. According to a preferred embodiment of the

invention, the image frames can be independently numbered using consecutive numbering in which successive reference image frames in the coding order are indicated with numbers incremented by one. As regards layer numbers and sub-sequence identifiers, the above-described numbering procedure can be used. This allows each image frame to be uniquely identified, when necessary, without using the layer number and sub-sequence identifier.

[0057] This is illustrated with the example shown in Figure 4a in which the base layer comprises a temporally first I-frame 400 (I.0.0). This frame is used for predicting a first image frame 402 of the first enhancement layer, i.e. (P.0.1), which is then used for predicting a second image frame 404 (P.0.2) belonging to the same sub-sequence (with sub-sequence identifier 0), which is used for predicting a third image frame 406 (P.0.3) of the same sub-sequence, which is used for predicting a fourth image frame 408 (P.0.4) and, finally, the fourth frame for predicting a fifth image frame 410 (P.0.5). The temporally next video sequence image frame 412 is located on the base layer, where it is in the same sub-sequence as the I-frame 400, although temporally it is only the seventh coded image frame. Therefore its identifier is (P.0.6). The seventh frame is then used for predicting a first image frame 414 (P.1.7) of the second sub-sequence of the first enhancement layer, which is then used for predicting a second image frame 416 (P.1.8) belonging to the same sub-sequence (with sub-sequence identifier 1), which is in turn used for predicting a third image frame 418 (P.1.9), the third for predicting a fourth image frame 420 (P.1.10) and, finally, the fourth for predicting a fifth image frame 422 (P.1.11) of the same sub-sequence. Again, the temporally next video sequence image frame 424 is located on the base layer, where it is in the same sub-sequence as the I-frame 400 and the P-frame 412, although temporally it is only the thirteenth coded image frame and therefore its identifier is (P.0.12). For clarity of illustration, the above description of the embodiment does not comprise layer identifiers, but it is apparent that in order to implement scalability, also the layer identifier must be signalled together with the video sequence, typically as part of the image frame identifiers.

[0058] Figures 4b and 4c show alternative embodiments for grouping the image frames of the video sequence shown in Figure 4a. The image frames in Figure 4b are numbered according to sub-sequence, i.e. a new sub-sequence always starts the numbering from the beginning (from

zero). Figure 4c, in turn, employs image frame numbering which corresponds otherwise to that used in Figure 4a, except that the P-frames of the base layer are replaced by SP-frame pairs to allow for identical reconstruction of image information.

[0059] As stated above, the procedure of the invention can also be implemented using B-frames. One example of this is illustrated in Figures 5a, 5b and 5c. Figure 5a shows a video sequence in the time domain, the sequence comprising P-frames P1, P4 and P7, with B-frames placed between them, the interdependencies of the B-frames with regard to temporal predicting being shown with arrows. Figure 5b shows a preferred grouping of video sequence image frames in which the interdependencies shown in Figure 5a are indicated. Figure 5b illustrates sub-sequence-specific image frame numbering in which a new sub-sequence always starts the numbering of the image frames from the beginning (from zero). Figure 5c, in turn, illustrates image frame numbering, which is otherwise consecutive except that a P-frame following a B-frame always receives the same image number as the B-frame.

[0060] The above examples illustrate different alternatives of how scalability of video sequence coding can be adjusted by using the method of the invention. From the point of view of the terminal device reproducing the video sequence, the more scalability layers are available, or the more scalability layers it is capable of decoding, the better the image quality. In other words, increase in the amount of image information and in the bit rate used for transferring the information improves the temporal or spatial resolution or the spatial quality of the image data. Correspondingly, a higher number of scalability layers also sets considerably higher demands on the processing capacity of the terminal device performing decoding.

[0061] In addition, the above examples illustrate the advantage gained by using sub-sequences. With image frame identifiers, the dependencies of each image frame from other image frames in the sub-sequence are indicated in an unambiguous manner. A sub-sequence thus forms an independent whole that can be left out of a video sequence, when necessary, without affecting the decoding of subsequent image frames of the video sequence. In that case, only the image frames of the sub-sequence in question and of those sub-sequences on the same and/or lower scalability layers dependent on it are not decoded.

[0062] The image frame identifier data transmitted together with the video sequence are preferably included in the video sequence header fields or in the header fields of the transfer protocol to be used for transferring the video sequence. In other words, the identifier data of predicted image frames are not included in the image data of the coded video sequence, but always into the header fields, whereby the dependencies of the image frames can be detected without decoding the images of the actual video sequence. The identifier data of the image frames can be stored for example in the buffer memory of the streaming server as the video sequence is being coded for transmission. In addition, the sub-sequences can be independently decoded on each scalability layer, because the image frames of a sub-sequence are not dependent on other sub-sequences of the same scalability layer.

[0063] According to an embodiment of the invention, the image frames comprised by a sub-sequence may thus depend also on other sub-sequences of the same scalability layer. This dependency must then be signalled for example to the streaming server carrying out traffic shaping, because interdependent sub-sequences located on the same layer cannot be separately removed from a video sequence to be transmitted. A preferred way to carry out the signalling is to include it in the image frame identifiers to be transmitted, for example by listing the layer-sub-sequence pairs the sub-sequence in question depends on. This also provides a preferred way of indicating dependency from another sub-sequence of the same scalability layer.

[0064] The above examples illustrate a situation where image frames are temporally predicted from previous image frames. In some coding methods, however, the reference picture selection has been further extended to also include the predicting of the image information of image frames from temporally succeeding image frames. Reference picture selection offers most diversified means for creating different temporally scalable image frame structures and allows the error sensitivity of the video sequence to be reduced. One of the coding techniques based on reference picture selection is INTRA-frame postponement. The INTRA-frame is not placed into its temporally "correct" position in the video sequence, but its position is temporally postponed. The video sequence image frames that are between the "correct" position of the INTRA-frame and its actual position are predicted temporally backward from the INTRA-frame in question. This naturally requires that image

frames that are not coded be buffered for a sufficiently long period of time so that all image frames that are to be displayed can be coded and arranged into their order of presentation. INTRA-frame transfer and the associated determining of sub-sequences in accordance with the invention are illustrated in the following with reference to Figure 6.

[0065] Figure 6a shows a video sequence part in which the INTRA-frame comprises a single I-frame 600, which is temporally transferred to the position shown in Figure 6, although the "correct" position of the I-frame in the video sequence would have been at the first image frame. The video sequence image frames between the "correct" position and the real position 600 are thus temporally predicted backward from the I-frame 600. This is illustrated by a sub-sequence coded into the first enhancement layer and having a first temporally backward predicted image frame 602, which is a P-frame (P.0.0). This P-frame is used for predicting a temporally previous image frame 604, i.e. a P-frame (P.0.1), which is used in turn for predicting an image frame 606, i.e. a P-frame (P.0.2), and, finally, an image frame 608, i.e. a P-frame (P.0.3), which is at the temporal position that would have been the temporally "correct" position of the I-frame 600 in the video sequence. Correspondingly, the I-frame 600 on the base layer is used for a temporally forward prediction of a sub-sequence comprising four P-frames 610, 612, 614 and 616, i.e. P-frames (P.0.0), (P.0.1), (P.0.2) and (P.0.3).

[0066] The fact that in this example backward predicted image frames are placed on a lower layer than forward predicted image layers indicates that for purposes of illustration, backward predicted image frames are in this coding example considered subjectively less valuable than forward predicted image frames. Naturally the sub-sequences could both be placed on the same layer, in which case they would be considered equal, or a backward predicted sub-sequence could be on the upper layer, in which case it would be considered subjectively more valuable.

[0067] Figures 6b and 6c show some alternatives for coding a video sequence according to Figure 6a. In Figure 6b both forward and backward predicted sub-sequences are placed on the base layer, the I-frame being only located on the INTRA-layer. The forward predicted sub-sequence on this layer is thus the second sub-sequence and its sub-sequence identifier is 1. In Figure 6c, in turn, an I-frame and a forward predicted sub-sequence based on it are

located on the base layer, while a backward predicted sub-sequence is located on the first enhancement layer.

[0068] Moreover, according to a preferred embodiment of the invention, the above-described scalability can be utilized for coding what is known as a scene transition into a video sequence. Video material, such as news reports, music videos and movie trailers, often comprise rapid cuts between separate image material scenes. Sometimes the cuts are abrupt, but often a procedure known as scene transition is used in which transfer from one scene to another takes place by dimming, wiping, mosaic dissolving or scrolling the image frames of a previous scene, and, correspondingly, by presenting those of a later scene. From the point of view of coding efficiency, the video coding of a scene transition is often most problematic, because the image frames appearing during the scene transition comprise information on the image frames of both the terminating and the initiating scene.

[0069] A typical scene transition, fading, is carried out by gradually reducing the intensity or luminance of the image frames of a first scene to zero, while gradually increasing the intensity of the image frames of a second scene to its maximum value. This scene transition is referred to as cross-faded scene transition.

[0070] Generally speaking, a computer-made image can be thought of as consisting of layers, or image objects. Each image object can be defined with reference to at least three information types: the structure of the image object, its shape and transparency, and the layering order (depth) in relation to the background of the image and to other image objects. Shape and transparency are often determined using what is known as an alpha plane, which measures opacity and the value of which is usually determined separately for each image object, possibly excluding the background, which is usually determined as non-transparent. The alpha plane value of a non-transparent image object, such as the background, can thus be set at 1.0, whereas the alpha plane value of a fully transparent image object is 0.0. The values in between define the intensity of the visibility of a specific image object in a picture in proportion to the background and to other, at least partly overlapping image objects that have a higher depth value than the image object in question.

[0071] The superimposition of image objects in layers according to their shape, transparency and depth position is referred to as scene

composition. In practice the procedure is based on the use of weighted averages. First, the image object that is closest to the background, i.e. deepest according to its depth position, is placed onto the background and a combined image is formed of the two. The pixel values of the combined image are formed as an average weighted by the alpha plane values of the background image and the image object in question. The alpha plane value of the combined image is then set at 1.0, after which it serves as a background image for the next image object. The process continues until all image objects are attached to the image.

[0072] In the following, a procedure according to a preferred embodiment of the invention will be described in which video sequence scalability layers are combined with the above described image objects of image frames and their information types to provide a scene transition with scalable video coding that also has good compression efficiency.

[0073] This embodiment of the invention is illustrated in the following by way of example and in a simplified manner by using cross-faded scene transition, on one hand, and abrupt scene transition, on the other hand, as examples. The image frames to be displayed during a scene transition are typically formed of two superimposed image frames, a first image frame comprising a first image scene and a second image frame a second scene. One of the image frames serves as the background image, whereas the other, which is referred to as a foreground image, is placed on top of the background image. The opacity of the background image, i.e. its non-transparency value, is constant, in other words, its pixel-specific alpha plane values are not adjusted.

[0074] In this embodiment of the invention, the background and foreground images are both defined according to scalability layer. This is illustrated in Figure 7, which shows an example of how image frames of two different scenes can be placed on scalability layers during a scene transition of the invention. Figure 7 shows a first image frame 700 of a first (terminating) scene positioned on the base layer. The image frame 700 may be either an I-frame containing image information that has not been determined using motion-compensated temporal predicting, or it may be a P-frame that is a motion-compensated image frame predicted from previous image frames. The coding of a second (initiating) scene starts during the temporally following image frame and, according to the invention, the image frames of the scene are also placed on the base layer. Remaining image frames 702, 704 of the

second (terminating) scene are then placed on the first enhancement layer. These image frames are typically P-frames.

[0075] In this embodiment, the image frames of the second (initiating) scene are thus placed on the base layer, at least for the duration of the scene transition. The first image frame 706 of the scene is typically an I-frame, and it is used for temporally predicting the succeeding image frames of the scene. Consequently, the succeeding image frames of the second scene are temporally predicted frames, typically P-frames, such as frames 708 and 710 shown in Figure 7.

[0076] According to a preferred embodiment of the invention, this placing of image frames on scalability layers can be used for implementing a cross-faded scene transition by determining the image layer that is on the base layer always as a background image of maximum opacity (100%), or non-transparency value. During a scene transition, image frames located on enhancement layers are placed onto the background image and their opacity is adjusted for example by means of suitable filters such that the frames gradually change from non-transparent to transparent.

[0077] In the video sequence of Figure 7, there are no image frames on the lower scalability layers during the first base layer image frame 700. For this time instant, the first image frame 700 is only coded into the video sequence.

[0078] The next image frame 706 of the base layer initiates a new (second) scene, during which the image frame 706 is provided with depth positioning that places it as the background image, and its opacity value is set to the maximum. Temporally simultaneously with the image frame 706 of the base layer, there is an image frame 702 of a terminating (first) scene on the first enhancement layer. To allow a cross-faded scene transition to be produced, the transparency of the frame 702 must be increased. The example of Figure 7 assumes that the opacity of the image frame 702 is set at 67% and, in addition, the image frame 702 is provided with depth positioning that determines it as a foreground image. For this time instant, an image combining the image frames 706 and 702 is coded into the video sequence, image 706 being visible as a weaker image on the background and image 702 as a stronger image at the front, because its opacity value is essentially high (67%).

[0079] During the temporally following image frame, there is a second image frame 708 of the second scene on the base layer, the frame

being thus correspondingly provided with depth positioning determining it as a background image, and its opacity value is set to the maximum. The first enhancement layer further comprises the last image frame 704 of a temporally simultaneously terminating (first) scene, the opacity value of the frame being set at 33% and, in addition, the image frame 704 being provided with depth positioning that determines it as a foreground image as well. Consequently, for this time instant, an image combined of the image frames 708 and 704 is coded into the video sequence, the image 708 being displayed as a stronger image on the background and the image 704 as a weaker image on the foreground, because the opacity value of the image 704 is no longer more than 33%.

[0080] During the temporally following image frame, the base layer comprises a third image frame 710 of the second scene. Since the first scene has terminated, only the image frame 710 is coded into the video sequence, and the displaying of the second scene continues from the frame 710.

[0081] The above disclosure describes, by way of example, the positioning of image frames according to the invention on scalability layers to implement cross-faded scene transition in a manner that is advantageous from the point of view of coding efficiency. However, it is possible that when a video sequence is being transmitted or decoded, a situation arises in which the bit rate of the video sequence must be adjusted according to the maximum value of the bandwidth and/or terminal device decoding rate available for data transfer. This kind of bit rate control causes problems when the scene transition is to be implemented using prior art video coding methods.

[0082] A preferred embodiment of the present invention now allows one or more scalability layers, or independently decodable sub-sequences included in them, to be removed from a video sequence, whereby the bit rate of the video sequence can be decreased and yet, at the same time, the video sequence can be decoded without reducing image frequency. In the image frame positioning according to Figure 7, this can be implemented by removing the first enhancement layer from the video sequence. The video sequence is thus only used for displaying the image frames 700, 706, 708 and 710 of the base layer. In other words, a direct transition from the first (terminating) scene to the second (initiating) scene takes place in the form of an abrupt scene transition, i.e. directly from the image frame 700 of the first scene into the I-image frame 706 that initiates the second scene. The transition is thus not a

cross-faded scene transition but an abrupt scene transition. Nevertheless, the scene transition can be carried out in an advantageous manner without affecting the quality of the video sequence image, and the viewer usually does not experience an abrupt scene transition carried out instead of a cross-faded scene transition in any way disturbing or faulty. On the contrary, since the prior art implementation does not allow scalability layers to be removed, scene transition would often require image frequency to be reduced, which the viewer would find jerky and disturbing.

[0083] The invention thus provides a preferred means for carrying out multimedia data traffic shaping in a streaming server comprising information about the different sub-sequences of a video sequence: their average bit rate, location in relation to the entire video sequence, duration and their interdependencies regarding the layers. The streaming server also determines the maximum value of the bandwidth available for the data transfer and/or the decoding rate of the terminal device. On the basis of this information, the streaming server decides how many scalability layers and which sub-sequences are transmitted in the video sequence. Bit rate control can thus be carried out, when necessary, by making first a rough adjustment of the number of the scalability layers, after which finer sub-sequence-specific adjustment can be easily carried out. At its simplest, bit rate control means making sub-sequence-specific decisions on whether a particular sub-sequence will be added to a video sequence or removed from it. In case of removal it is advisable to remove entire sub-sequences from a video sequence, because the removal of separate images may cause errors in other images of the same sub-sequence. For the same reason, all sub-sequences of a lower enhancement layer should be left out if they are dependent on the removed sub-sequence of a higher layer. If there are interdependent sub-sequences on one and the same scalability layer, sub-sequences dependent on an earlier sub-sequence must be removed if the earlier sub-sequence is removed.

[0084] If the image frame identifier data are added to a video sequence that is to be transmitted, traffic shaping can also be carried out in a telecommunications network element to be used for the transfer of the video sequence, for example in an Internet router, in different gateways, or at a base station or base station controller of a mobile communications network. For the network element to be able to maintain and process the sub-sequence information, it must have extra memory and processing capacity. For this

reason traffic shaping that is to be carried out in the network is perhaps most probably executed using simple processing methods, such as the DiffServ, i.e. differentiated services, a procedure that is supported by some IP-based networks. In the DiffServ method, each IP data packet is assigned a priority, whereby data packets of a higher priority are relayed faster and more reliably to the recipient than packets of a lower priority. This is advantageously applied to the scalability of the invention by determining not only scalability-layer-specific, but also sub-sequence-specific priorities, which enables a highly advanced prioritization.

[0085] There are many alternatives for adding image frame identifier data to a video sequence that is to be transmitted. In addition, it is also possible not to include any identifier data into the video sequence, in which case traffic shaping is only carried out at the streaming server. The identifier data can be included in the header fields of a video sequence, or in the header fields of the transfer protocol to be used, such as RTP (Real Time Protocol). In the latter case traffic shaping can be carried out also at one of the network elements of the transfer path. In addition, the receiving terminal device can control the decoding.

[0086] If the encoder or decoder supports reference picture selection, video sequence coding requires that decoded image frames be buffered before the coding so as to allow the relationships between different image frames to be temporally predicted from one or more other image frames. Image frame buffering can be arranged at least in two different ways, either as sliding windowing or as adaptive buffer memory control. In sliding windowing, M image frames that were coded last are used as a buffer. The frames in the buffer memory are in a decoded and reconstructed form, which allows them to be used as reference images in the coding. As the coding proceeds, the image frame buffering functions on the basis of the FIFO principle (First-In-First-Out). Images that are not used as reference images, such as conventional B-images, do not need to be stored in the buffer. Alternatively, the buffering can also be implemented as adaptive buffer memory control, in which case the image buffering is not restricted to the FIFO principle, but image frames that are not needed can be removed from the buffer in the middle of the process, or, correspondingly, some image frames can be stored in the buffer for a longer period of time, if they are needed as reference images for later image frames. A known reference picture selection is implemented by indexing image

frames that are in the buffer memory into a specific order, the image indices being then used to refer to an image in connection with motion-compensation, for example. This indexing method generally provides better compression efficiency compared to using image numbers, for example, for referring to a specific image when motion-compensation reference images are to be signalled.

[0087] The above reference image indexing method is sensitive to transfer errors, because the buffers of the sender's encoder and the recipient's decoder must contain mutually corresponding reconstructed images in identical order to ensure that the encoder and decoder both form the same indexing order. If the image frames are indexed in different order in the buffers of the encoder and the decoder, an incorrect reference image may be used in the decoder. To prevent this, it is essential that the decoder can be controlled to take into account image frames and sub-sequences that the encoder has intentionally removed from the video sequence. In that case the image frame numbering may comprise gaps, which the decoder typically interprets as errors and tries to reconstruct the image frames interpreted as lost. For this reason, it is essential that the encoder is capable to inform the decoder that the discontinuities in the image numbering of the transmitted image frames are intentional.

[0088] In response to this, and provided that sliding windowing is used for buffering the image frames, the decoder enters into the buffer memory a number of image frames, the contents of which may be fully random, corresponding to the missing image numbers. These random image frames are then designated by an identifier "invalid" to indicate that the frames in question do not belong to the actual video sequence, but are only filler frames entered for purposes of buffer memory management. A filler frame can naturally be implemented using only memory indicators, i.e. no data is preferably entered into the buffer memory, but memory management is used merely to store a reference to a generic "invalid" frame. The entering of the image frames of the actual video sequence continues from the correct image frame number after the number of filler frames indicated by the missing image numbers has been entered into the buffer, which allows the buffer memories of the encoder and the decoder to be kept preferably in synchronism. If during decoding a reference to an image number is detected which is then found to indicate a filler frame located in the buffer, error correction actions are initiated

in the decoder to reconstruct the actual reference image, for example by asking the encoder to re-transmit the reference image in question.

[0089] Further, the procedure of the invention allows separate buffer memories to be used on the different scalability layers, or, correspondingly, sub-sequence-specifically. Each scalability layer may thus have a separate buffer memory that is conceptually separate and functions on the basis of the sliding window principle. Similarly, each sub-sequence may also be provided with a conceptually separate buffer memory that also functions on the basis of the sliding window principle. This means that the buffer memory is always emptied when a sub-sequence terminates. Separate buffer memories can be used in a preferred manner for reducing the need for signalling in certain situations in which ordinary sliding window buffering would be inadequate and actively adaptive buffer memory management would need to be used instead.

[0090] The above disclosure describes a procedure for coding video frames for the purpose of producing a scalable, compressed video sequence. The actual procedure is carried out in a video encoder, such as the compressor 108 of Figure 1, which may be any known video encoder. For example a video encoder according to the ITU-T recommendation H.263 or H.26L may be used, the video encoder being arranged to form, in accordance with the invention, a first sub-sequence into a video sequence, at least part of the sub-sequence being formed by coding I-frames; to form at least a second sub-sequence into the video sequence, at least part of the sub -sequence being formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence being predicted from at least one video frame of the first sub-sequence; and to determine into the video sequence the identification data of at least the video frames of the second sub-sequence.

[0091] According to the procedure of the invention, each sub-sequence of a particular scalability layer is preferably independently decodable, naturally taking into account dependencies from higher scalability layers and possibly other sub-sequences of the same scalability layer. A scalably compressed video sequence such as the one described above can thus be decoded by decoding a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding at least I-frames, and by decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least

P- or B-frames, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence, and by determining the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence, and by reconstructing at least part of the video sequence on the basis of the sub-sequence dependencies.

[0092] The actual decoding takes places in the video decoder, such as the decompressor 118 of Figure 1, which may be any known video decoder. For example, a low bit rate video decoder according to the ITU-T recommendation H.263 or H.26L may be used, which in this invention is arranged to decode a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding I-frames; to decode at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. The video decoder is arranged to determine the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence and to reconstruct at least part of the video sequence on the basis of the dependencies of the sub-sequences.

[0093] An essential aspect in the operation of the streaming system of the invention is that the encoder and decoder are positioned at least so that the encoder is operationally connected to the streaming server and the decoder is operationally connected to the receiving terminal device. However, the different elements of the streaming system, terminal devices in particular, may include functionalities that allow two-way transfer of multimedia files, i.e. transmission and reception. The encoder and decoder can thus be implemented in the form of what it known as a video codec integrating both encoder and decoder functionalities.

[0094] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder, and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the

invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

[0095] Another alternative is to implement the invention as a video signal comprising a scalably compressed video sequence which in turn comprises video frames coded according to at least a first and a second frame format, the video frames according to the first frame format being independent of other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames. According to the invention, the video signal in question comprises at least a first sub-sequence, at least part of which has been formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format; and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field that determines video frames belonging to the second sub-sequence.

[0096] It is apparent to a person skilled in the art that as technology advances the basic idea of the invention can be implemented in various ways. The invention and its embodiments are therefore not restricted to the above examples, but they may vary within the scope of the claims.

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence, the compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising:

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence.

2. A method according to claim 1, **characterized** by comprising:

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

3. A method according to claim 2, **characterized** by comprising:

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

a video frame of a higher scalability layer,

an image frame of the second sub-sequence of the same scalability layer.

4. A method according to claim 3, **characterized** by comprising:

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. A method according to claim 3 or 4, **characterized** by comprising:

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. A method according to claim 3 or 4, **characterized** by comprising:

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. A method according to claim 3, **characterized** by comprising:

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. A method according to claim 3, **characterized** by comprising:

determining a unique identifier for each video frame on the basis of the image number.

9. A method according to claim 7 or 8, **characterized** by comprising:

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. A method according to any one of the preceding claims, **characterized** in that

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

11. A method according to any one of the preceding claims, **characterized** by comprising:

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

12. A method according to any one of the preceding claims, **characterized** by comprising:

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

13. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

14. A video encoder for forming a scalable, compressed video sequence, the compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

15. A method for decoding a scalably compressed video sequence, the compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame

format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising:

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

16. A method according to claim 15, wherein video frames are entered into a gliding buffer memory in connection with decoding, **characterized** by comprising:

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

17. A method according to claim 16, **characterized** by comprising:

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

18. A method according to any one of claims 15 to 17, **characterized** by comprising:

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

19. A method according to any one of claims 15 to 18, **characterized** by comprising:

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

20. A video decoder for decoding a scalably compressed video sequence, the compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which has been formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

21. A computer program for coding video frames so as to form a scalable, compressed video sequence, the compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

22. A computer program for decoding a scalably compressed video sequence, the video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

23. A video signal comprising a scalably compressed video sequence, the video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video signal comprises

a first sub-sequence, at least part of which has been formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at

least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

(57) ABSTRACT

A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format. The video frames of the first frame format are independent of the other video frames, and the video frames of the second frame format are predicted from at least one of the other video frames. The video sequence is provided with a first sub-sequence determined therein, at least part of the first sub-sequence having been formed by coding at least video frames of the first frame format; and with at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. Identifier data of at least the video frames comprised by the second sub-sequence is determined into the video sequence.

NOTIFICATION OF EUROPEAN PUBLICATION NUMBER AND INFORMATION ON THE APPLICATION OF ARTICLE 67(3) EPC

The provisional protection under Article 67(1) and (2) EPC in the individual Contracting States becomes effective only when the conditions referred to in Article 67(3) EPC have been fulfilled (for further details, see information brochure of the European Patent Office "National Law relating to the EPC" and additional information in the Official Journal of the European Patent Office).

Pursuant to Article 158(1) EPC the publication under Article 21 PCT of an international application for which the European Patent Office is a designated Office takes the place of the publication of a European patent application.

The bibliographic data of the above-mentioned Euro-PCT application will be published on 24.11.04 in Section I.1 of the European Patent Bulletin.
The European publication number is 1479245.

In all future communications to the European Patent Office, please quote the application number plus Directorate number.

Communication pursuant to Rules 109 and 110 EPC

(1) Amendment of application documents, especially the claims (Rule 109 EPC)

The above mentioned international (Euro-PCT) application has entered the European phase, or can do so, once the necessary conditions are fulfilled.

Under Articles 28, 41 PCT, Rules 52, 78 PCT and Rule 86(2) to (4) EPC, the applicant may amend the application documents after receiving the international search report.

Whether or not he has already done so, he now has a further opportunity to file amended claims or other application documents within a non-extendable time limit of ONE MONTH after notification of the present communication (Rule 109 EPC).

The claims applicable on expiry of the above time limit, i.e. those filed on entry into the European phase or in response to the present communication, will form the basis for the calculation of any claims fee to be paid (see page 2) and for any supplementary search to be carried out under Article 157(2) EPC (Rule 109 EPC).

--2/

(2) Claims fees under Rule 110 EPC

If the application documents on which the European grant procedure is to be based comprise more than ten claims, a claims fee shall be payable for the eleventh and each subsequent claim within the period provided for in Rule 107(1) EPC.

☑ Based on the application documents currently on file, all necessary claims fees have already been paid (or the documents do not comprise more than 10 claims).

☐ All necessary fees will be/have been debited automatically according to the automatic debit order.

☐ The claims fee due for the claims ..... to ..... were not paid within the above-mentioned period.

Any non-paid claims fee, either based on the current set of claims or on any amended claims to be filed pursuant to Rule 109 EPC (see page 1), may still be validly paid within a non-extendable period of grace of **ONE MONTH** after notification of this communication.

If a payment is made for only some of the claims, it must be indicated for which claims it is intended. If a claims fee is not paid in due time, the claim concerned is deemed to be abandoned (Rule 110(4) EPC).

If claims fees have already been paid, but on expiry of the above-mentioned time limit there is a new set of claims containing fewer fee-incurring claims than previously, the claims fees in excess of those due under Rule 110(2), 2nd sentence, EPC will be refunded (Rule 110(3) EPC).

You are reminded that any supplementary search under Article 157(2) EPC will relate only to the last set of claims applicable on expiry of the above time limit AND will be confined to those fee-incurring claims for which fees have been paid in due time.

The fee for the eleventh and each subsequent claim is EUR 40,00.

Nokia Corporation et al.

1. This written opinion is the first (first, etc.) drawn by this International Preliminary Examining Authority.
2. This opinion contains indications relating to the following items:

   I ☒ Basis of the report

   II ☐ Priority

   III ☐ Non-establishment of opinion with regard to novelty, inventive step and industrial applicability

   IV ☐ Lack of unity of invention

   V ☒ Reasoned statement under Rule 66.2(a)(ii) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

   VI ☐ Certain documents cited

   VII ☐ Certain defects in the international application

   VIII ☐ Certain observations on the international application

3. The applicant is hereby **invited to reply** to this opinion.

   When? See the time limit indicated above. The applicant may, before the expiration of that time limit, request this Authority to grant an extension, see Rule 66.2(d).

   How? By submitting a written reply, accompanied, where appropriate, by amendments, according to Rule 66.3. For the form and the language of the amendments, see Rules 66.8 and 66.9.

   Also For an additional opportunity to submit amendments, see Rule 66.4. For the examiner's obligation to consider amendments and/or arguments, see Rule 66.4*bis*. For an informal communication with the examiner, see Rule 66.6.

   If no reply is filed, the international preliminary examination report will be established on the basis of this opinion.

4. The final date by which the international preliminary examination report must be established according to Rule 69.2 is: 23-05-2004

WRITTEN OPINION

International application No.
PCT/FI03/00053

I. Basis of the opinion

1. With regard to the **elements** of the international application:*

☒ the international application as originally filed

☐ the description:
pages _____, as originally filed
pages _____, filed with the demand
pages _____, filed with the letter of _____

☐ the claims:
pages _____, as originally filed
pages _____, as amended (together with any statement) under article 19
pages _____, filed with the demand
pages _____, filed with the letter of _____

☐ the drawings:
pages _____, as originally filed
pages _____, filed with the demand
pages _____, filed with the letter of _____

☐ the sequence listing part of the description:
pages _____, as originally filed
pages _____, filed with the demand
pages _____, filed with the letter of _____

2. With regard to the **language**, all the elements marked above were available or furnished to this Authority in the language in which the international application was filed, unless otherwise indicated under this item.
These elements were available or furnished to this Authority in the following language _____ which is:

☐ the language of a translation furnished for the purposes of international search (under Rule 23.1(b)).

☐ the language of publication of the international application (under Rule 48.3(b)).

☐ the language of the translation furnished for the purposes of international preliminary examination (under Rules 55.2 and/or 55.3).

3. With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, the written opinion was drawn on the basis of the sequence listing:

☐ contained in the international application in printed form.

☐ filed together with the international application in computer readable form.

☐ furnished subsequently to this Authority in written form.

☐ furnished subsequently to this Authority in computer readable form.

☐ The statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.

☐ The statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished.

4. ☐ The amendments have resulted in the cancellation of:

☐ the description, pages _____

☐ the claims, Nos. _____

☐ the drawings, sheet/fig _____

5. ☐ This opinion has been drawn as if (some of) the amendments had not been made, since they have been considered to go beyond the disclosure as filed, as indicated in the Supplemental Box (Rule 70.2 (c)).

* *Replacement sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this opinion as "originally filed".*

V. Reasoned statement under Rule 66.2(a)(ii) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

1. Statement

Novelty (N)	Claims	1-24	YES
	Claims		NO
Inventive step (IS)	Claims		YES
	Claims	1-24	NO
Industrial applicability (IA)	Claims	1-24	YES
	Claims		NO

2. Citations and explanations

Documents cited in the International Search Report:

D1: WO 0147283 A1
D2: US 6337881 B1
D3: EP 1005232 A2
D4: US 5774593 A
D5: US 6307886 B1

D1 is considered to the most relevant document.

D1 discloses a system for determining whether simulcast coding or temporal/spatial scalability coding should be used to encode video for clients with a specific communication link. The part which concerns the spatial and temporal scalability coding is considered to be the most relevant part of D1, because the invention according to the application concerns this kind of coding technique.

The invention according to the application concerns a method for coding video frames. The aim of the invention is to code the video frames into a scalable a compressed video sequence. The scalability feature can be utilized when streaming a video sequence to multiple clients, where clients have different amount of bandwidth or processing power. The method, according to the claimed invention, includes a way of dividing a video sequence into sub-sequences, where each sub-sequence can be decoded independently. In the video sequence there is also an indication included which shows which frames belong to a certain sub-sequence. According to the application, the above mentioned indication facilitates inclusion of extra material, e.g. a commercial clip, into the video sequence.

.../...

Supplemental Box
(To be used when the space in any of the preceding boxes is not sufficient)

Continuation of: Box V

Referring to claim 1, 13-15, 21-24:

Claim 1 reveals a method for coding video frames into a scalable and compressed video sequence. The claim also includes that the video sequence comprise two frame formats (which are later in the claims identified as I- and P-frames). Claim 1 further describes that into the video sequence two sub-sequences are formed, where at least one video frame of the second sub-sequence has been predicted from at least on video frame from the first sub-sequence. Information indicating which video frame belongs to the second sub-sequence is formed into the video sequence.

In D1 (see figure 2 and page 13, row 21, to page 14, row 5) temporal scalability is illustrated and described. As can be seen from figure 2, the layers comprise I-, P- and B-frames. From the figure it can also be seen that the video sequence is composed of several sub-sequences.

The invention according to claim 1 differs by mentioning a way of including, into the video stream, an indication of which video frame belongs to the second sub-sequence. Although the above difference is not explicitly mentioned in D1, it is considered to be an obvious measure for a person skilled, facing the previous described problem, to include, in the video stream, some kind of information that indicates which frames belong to a certain sub-sequence.
Therefore, the invention according to claim 1 is not considered to involve an inventive step.

The independent claims 13-15, 21-24 are based on the same idea that is presented in D1. Although the above claims represent different categories (e.g. a decoder, a computer program), the argumentation regarding claim 1 is considered to be valid for claims 13-15 and 21-24 as well. Therefore, the invention of claims 13-15 and 21-24 is not considered to involve an inventive step.

Referring to claims 2-12, 16-20:

All the additional features described in the above mentioned claims are either known from the prior art documents cited in the International Search Report or generally known in the technical field of video processing/compression. Therefore, the invention according to claims 2-12, 16-20 is not considered to involve an inventive step.

February 6, 2004

INTERNATIONAL PATENT APPLICATION No. PCT/FI03/00053
Applicant: Nokia Corporation
Our Ref: 2011658PC/Pg/art

Dear Mr. Lakic,

In response to the Written Opinion, dated 11.12.2003, regarding the PCT application mentioned above, the Applicant considers the originally filed claims to involve both novelty and an inventive step. The Applicant submits the following arguments:

Novelty

The Examiner has not raised any objections regarding the novelty of the originally filed claims.

Inventive Step

The Examiner has cited one document, WO01/47283, which, according to the Examiner, teaches a skilled man such that the present would become obvious for him.

WO01/47283 discloses a method for coding a scalable multilayer video sequence, wherein the layers include a base layer and one or more enhancements layers. By adjusting the number of the layers, the frame rate, resolution and the quality of the video sequence can be affected, whereby the available bandwidth can be the decisive criterium. Furthermore, WO01/47283 discloses how I-, P- and B-frames are positioned on different layers forming several group of pictures (GOPs). There is no dependencies between the group of pictures, but only inside each group of pictures.

Thus, WO01/47283 discloses a method, which is stated as prior art for the present application (chap. 0009 – 0010). Therefore, also the drawbacks of the prior art mentioned in the present application are included in the solution according to WO01/47283: carrying out reference picture selection when the prediction includes images temporally succeeding the image to be coded, how to signal differences of significance between INTER-frames, and how to create a frame numbering of video

sequence, which allows flexible the insertion of a video sequence in the middle of another video sequence and scaling of a video sequence.

The problem is solved by a method for coding video frames for the purpose of forming a scalable, compressed video sequence, wherein a video signal is formed, which video signal comprises a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field determining the video frames that belong to the second sub-sequence.

Hence, the idea underlying the present invention is to create a scalable coding hierarchy, wherein, for each sub-sequence, all sub-sequences are determined, upon which the coding of said sub-sequence is dependent. This is achieved by a frame numbering hierarchy, wherein the frame numbering of each sub-sequence includes information on all sub-sequences, which have been used in image frame prediction. This information is signalled along the video sequence, but separately of the image information. This enables a flexible scaling of video sequence, since independently decodable parts of the video sequence can easily be determined.

WO01/47283 would not give a man skilled in the art any hints for such a solution. First of all, in WO01/47283 there can be no dependencies between the group of pictures; therefore the group of pictures is not a sub-sequence as it is determined in the present application. Secondly, WO01/47283 does not include any information how the frame numbering of the video sequence should be carried out. It is commonly known in the prior art to use ascending arithmetical frame numbering, which most probably is used in the solution of WO01/47283 as well, although not expressly stated. Such a frame numbering, however, cannot be used to solve problems underlying the present invention.

Therefore is respectfully noted that the invention according to the independent claims 1, 13 - 15 and 21 - 24 is considered both novel and inventive.

Yours faithfully

KOLSTER OY AB

Eero Palmgren

To the European Patent Office

Entry into the European phase (EPO as designated or elected Office)

European application number	EP03700321.7
PCT application number	PCT/FI2003/00053
PCT publication number	WO03063505
Applicant's or representative's reference	2011658

1. Applicant

Particulars of the applicant(s) are contained in the international publication or were recorded by the International Bureau subsequent to the international publication. ☑

Changes which have not yet been recorded by the International Bureau are set out here: ☐

Address for correspondence

2. Representative 1

This is the representative who will be listed in the Register of European Patents and to whom notifications will be made

Name Kaukonen, Mr Juha

Address of place of business

Kolster Oy Ab
(Iso Roobertinkatu 23) P.O.Box 148
FIN-00121 Helsinki
Finland

Telephone +358-9-618 821

Fax +358-9-602 244

e-mail epline@kolster.fi

Any additional representative(s) is/are listed here: ☐

3. Authorisation

An individual authorisation is attached. ☐

A general authorisation has been registered under No: ☐

A general authorisation has been filed, but not yet registered. ☐

The authorisation filed with the EPO as PCT receiving Office expressly includes the European phase. ☐

4. Request for examination

Examination of the application under Art. 94 EPC is hereby requested. The examination fee is being (has been, will be) paid. ☑

Request for examination in an admissible non-EPO language: ☑

Täten pyydetään hakemuksen tutkimista artiklan 94 mukaisesti.

5. Copies

One or more additional sets of copies of the documents cited in the supplementary European search report are hereby requested. ☐

Number of additional sets of copies

6. Documents intended for proceedings before the EPO

6.1 Proceedings before the EPO as designated Office (PCT I) are to be based on the following documents:

the application documents published by the International Bureau (with all claims, description and drawings), where applicable with amended claims under Art. 19 PCT ☑

unless replaced by the amendments attached. ☐

Where necessary, clarifications should be attached as 'Other Documents'

6.2 Proceedings before the EPO as elected Office (PCT II) are to be based on the following documents:

the documents on which the international preliminary examination report is based, including any annexes ☑

unless replaced by the amendments attached. ☐

Where necessary, clarifications should be attached as 'Other Documents'

If the EPO as International Preliminary Examining Authority has been supplied with test reports, these may be used as the basis of proceedings before the EPO. ☑

7. Translations

Translations in one of the official languages of the EPO (English, French, German) are attached as crossed below:

* *In proceedings before the EPO as designated or elected Office (PCT I + II):*

Translation of the international application (description, claims, any text in the drawings) as originally filed, of the abstract as published and of any indication under Rule 13bis.3 and 13bis.4 PCT regarding biological material ☐

Translation of priority application(s) ☐

It is hereby declared that the international application as originally filed is a complete translation of the previous application (Rule 38(5) EPC) ☐

* *In addition, in proceedings before the EPO as designated Office (PCT I):*

Translation of amended claims and any statement under Art. 19 PCT, if the claims as amended are to form the basis for the proceedings before the EPO (see Section 6). ☐

* *In addition, in proceedings before the EPO as elected office (PCT II):*

Translation of annexes to the international preliminary examination report ☐

8. Biological material

The invention relates to and/or uses biological material deposited under Rule 28 EPC. ☐

The particulars referred to in Rule 28(1)(c) EPC (if not yet known, the depository institution and the identification reference(s) [number, symbols, etc.] of the depositor) are given in the international publication or in the translation submitted under Section 7 on: ☐

page(s) / line(s)

A copy of the receipt(s) of deposit issued by the depositary institution

is attached ☐

will be filed at a later date ☐

A waiver of the right to an undertaking from the requester pursuant to Rule 28(3) EPC is attached. ☐

9. Nucleotide and amino acid sequences

The items required under Rules 5.2 and 13ter PCT and Rule 111(3) EPC have already been furnished to the EPO. ☐

The sequence listing as part of the description is attached in PDF format. ☐

The sequence listing does not include matter that goes beyond the content of the application as filed. ☐

In addition, the sequence listing data is attached in computer-readable form in accordance with WIPO Standard 25. ☐

The sequence listing data in computer-readable form in accordance with WIPO Standard 25 is identical to the sequence listing in PDF format. ☐

10. Designation fees

10.1 It is currently intended to pay seven times the amount of the designation fee. The designation fees for all the EPC contracting states designated in the international application are thereby deemed to have been paid (Art. 2 No. 3 RFees). ☑

AT BE BG CH&LI CY CZ DE DK EE ES FI FR GB GR HU IE IT LU MC NL PT SE SI SK TR

10.2 The declaration in No. 10.1 does not apply. Instead, it is currently intended to pay fewer than seven designation fees for the following EPC contracting states designated in the international application: ☐

It is requested that no communications under Rule 108(3) EPC be issued in respect of any contracting states not indicated.

10.3 If an automatic debit order has been issued (Section 12), the EPO is authorised, on expiry of the basic period under Rule 107(1)(d) EPC, to debit seven times the amount of the designation fee. If states are indicated in No. 10.2, the EPO will debit designation fees for those states only, unless instructed otherwise before the basic period expires. ☑

11. Extension of the European patent

This application is also considered as being a request for extension to all the non-contracting states to the EPC designated in the international application with which "extension agreements" were in force on the date of filing the international application. However, the extension only takes effect if the prescribed extension fee is paid. ☑

It is currently intended to pay the extension fee for the following states:

12. Debit from deposit account ☑

Currency: EUR

The European Patent Office is hereby authorised to debit from the following deposit account any fees and costs indicated on the fees page.

Deposit account number: 28150002
Account holder: Kolster Oy Ab

13. Reimbursements (if any) should be made to the following EPO deposit account: ☑

Number and account holder: 28150002, Kolster Oy Ab

14. Fees

		Factor applied	Fee schedule	Amount to be paid
14-1	002 Search fee	0	690.00	0.00
14-2	005 Designation fee	7	75.00	525.00
14-3	006 Examination fee	1 (80%)	1 430.00	1 144.00
14-4	015 Claims fee	14	40.00	560.00
14-5	020 Basic national fee for an international application	1	90.00	90.00
	Total:		**EUR**	**2 319.00**

15. Annotations

15-1. Note (for EPO) (EP Phase)

Change of inventor's address (Virkkala, Mr. Antero; 26.7.2004)
Current address for inventor: Miska Hannuksela, Lakotie 15, FI-36110 Ruutana

16. Signature(s) of applicant(s) or representative

Place: **Helsinki**
Date: **29 July 2004**
Signed by: **Subject: FI, Kolster Oy AB, Antero Virkkala**
Issuer: DE, D-Trust GmbH, D-Trust for EPO 2.0

Entry into the European phase before the European Patent Office

These notes describe the procedural steps required for entry into the European phase before the European Patent Office (EPO). You are advised to read them carefully: failure to take the necessary action in time can lead to your application being deemed withdrawn.

1. The above-mentioned international patent application has been given European application No. **03700321.7**.

2. Applicants **without** a residence or their principal place of business in an EPC contracting state may themselves initiate European processing of their international applications, provided they do so before expiry of the 31st month from the priority date (see also point 6 below).

   During the European phase before the EPO as designated or elected Office, however, such applicants must be represented by a professional representative (Arts. 133(2) and 134(1), (7) EPC).

   Procedural acts performed after expiry of the 31st month by a professional representative who acted during the international phase but is not authorised to act before the EPO have no legal effect and therefore lead to loss of rights.

   Please note that a professional representative authorised to act before the EPO and who acted for the applicant during the international phase does not automatically become the representative for the European phase. Applicants are therefore strongly advised to appoint in good time any representative they wish to initiate the European phase for them; otherwise, the EPO has to send all communications direct to the applicant.

3. Applicants **with** a residence or their principal place of business in an EPC contracting state are not obliged to appoint, for the European phase before the EPO as designated or elected Office, a professional representative authorised to act before the EPO.
   However, in view of the complexity of the procedure it is recommended that they do so.

4. Applicants and professional representatives are also strongly advised to initiate the European phase using EPO Form 1200 (available free of charge from the EPO). This however is not compulsory.

5. **To enter the European phase before the EPO**, the following acts must be performed.
(N.B.: Failure validly to do so will entail loss of rights or other adverse legal consequences.)

5.1 If the EPO is acting as **designated** or **elected** Office (Arts. 22(1)(3) and 39(1) PCT respectively), applicants must, within 31 months from the date of filing or (where applicable) the earliest priority date:

a) Supply a translation of the international application into an EPO official language, if the International Bureau did not publish the application in such a language (Art. 22(1) PCT and Rule 107(1)(a) EPC).
If the translation is not filed in time, the international application is deemed withdrawn before the EPO (Rule 108(1) EPC).
This loss of rights is deemed not to have occurred if the translation is then filed within a two-month grace period as from notification of an EPO communication, provided a surcharge is paid at the same time (Rule 108(3) EPC).

b) Pay the national basic fee (EUR 125,00) and, where a supplementary European search report has to be drawn up, the search fee (EUR 690,00 ; Rule 107(1)(c) and (e) EPC).

c) If the time limit under Article 79(2) EPC expires before the 31-month time limit, pay the designation fee (EUR 75,00) for each contracting state designated (Rule 107(1)(d) EPC).

d) If the time limit under Article 94(2) EPC expires before the 31-month time limit, file the written request for examination **and** pay the examination fee (EUR 1430,00 ; Rule 107(1)(f) EPC).

e) Pay the third-year renewal fee (EUR 380,00) if it falls due before expiry of the 31-month time limit (Rule 107(1)(g) EPC).

If the fees under (b) to (d) above are not paid in time, or the written request for examination is not filed in time, the international application is deemed withdrawn before the EPO, or the contracting-state designation(s) in question is (are) deemed withdrawn (Rule 108(1) and (2) EPC). However, the fees may still be validly paid within a two-month grace period as from notification of an EPO communication, provided the necessary surcharges are paid at the same time (Rule 108(3) EPC). For the renewal fee under (e) above, the grace period is **six** months from the fee's due date (Article 86(2) EPC).

5.2 If the application documents on which the European grant procedure is to be based comprise more then ten claims, a claims fee is payable within the 31-month time limit under Rule 107(1) EPC for the eleventh and each subsequent claim (Rule 110(1) EPC). The fee can however still be paid within a one-month grace period as from notification of an EPO communication pointing out the failure to pay (Rule 110(2) EPC).

6. If the applicant had a representative during the application's international phase, the present notes will be sent to the representative, asking him to inform the applicant accordingly.

All subsequent communications will be sent to the applicant, or - if the EPO is informed of his appointment in time - to the applicant's European representative.

7. For more details about time limits and procedural acts before the EPO as designated and elected Office, see the EPO brochure

1. This report is the international preliminary examination report, established by this International Preliminary Examining Authority under Article 35 and transmitted to the applicant according to Article 36.
2. This REPORT consists of a total of 4 sheets, including this cover sheet.
3. This report is also accompanied by ANNEXES, comprising:
   a. ☐ *(sent to the applicant and to the International Bureau)* a total of _____ sheets, as follows:
      ☐ sheets of the description, claims and/or drawings which have been amended and are the basis of this report and/or sheets containing rectifications authorized by this Authority (see Rule 70.16 and Section 607 of the Administrative Instructions).
      ☐ sheets which supersede earlier sheets, but which this Authority considers contain an amendment that goes beyond the disclosure in the international application as filed, as indicated in item 4 of Box No. I and the Supplemental Box.
   b. ☐ *(sent to the International Bureau only)* a total of (indicate type and number of electronic carrier(s))
      _____, containing a sequence listing and/or tables related thereto, in computer readable form only, as indicated in the Supplemental Box Relating to Sequence Listing (see Section 802 of the Administrative Instructions).
4. This report contains indications relating to the following items:
   - ☒ Box No. I Basis of the report
   - ☐ Box No. II Priority
   - ☐ Box No. III Non-establishment of opinion with regard to novelty, inventive step and industrial applicability
   - ☐ Box No. IV Lack of unity of invention
   - ☒ Box No. V Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement
   - ☐ Box No. VI Certain documents cited
   - ☐ Box No. VII Certain defects in the international application
   - ☐ Box No. VIII Certain observations on the international application

INTERNATIONAL PRELIMINARY REPORT ON PATENTABILITY

International application No.
PCT/FI 2003/000053

Box No. I Basis of the report

1. With regard to the **language**, this report is based on the international application in the language in which it was filed, unless otherwise indicated under this item.

☐ This report is based on a translation from the original language into the following language _____, which is the language of a translation furnished for the purposes of:

☐ international search (under Rules 12.3 and 23.1(b))
☐ publication of the international application (under Rule 12.4)
☐ international preliminary examination (under Rules 55.2 and/or 55.3)

2. With regard to the **elements** of the international application, this report is based on *(replacement sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to this report):*

☒ the international application as originally filed/furnished

☐ the description:

pages _____ as originally filed/furnished
pages* _____ received by this Authority on _____
pages* _____ received by this Authority on _____

☐ the claims:

pages _____ as originally filed/furnished
pages* _____ as amended (together with any statement) under Article 19
pages* _____ received by this Authority on _____
pages* _____ received by this Authority on _____

☐ the drawings:

pages _____ as originally filed/furnished
pages* _____ received by this Authority on _____
pages* _____ received by this Authority on _____

☐ a sequence listing and/or any related table(s) – see Supplemental Box Relating to Sequence Listing.

3. ☐ The amendments have resulted in the cancellation of:

☐ the description, pages _____
☐ the claims, Nos. _____
☐ the drawings, sheets/figs _____
☐ the sequence listing *(specify)*: _____
☐ any table(s) related to the sequence listing *(specify)*: _____

4. ☐ This report has been established as if (some of) the amendments annexed to this report and listed below had not been made, since they have been considered to go beyond the disclosure as filed, as indicated in the Supplemental Box (Rule 70.2(c)).

☐ the description, pages _____
☐ the claims, Nos. _____
☐ the drawings, sheets/figs _____
☐ the sequence listing *(specify)*: _____
☐ any table(s) related to the sequence listing *(specify)*: _____

* *If item 4 applies, some or all of those sheets may be marked "superseded."*

INTERNATIONAL PRELIMINARY REPORT ON PATENTABILITY

International application No.
PCT/FI 2003/000053

Box No. V **Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement**

1. Statement

Novelty (N)	Claims	1-24	YES
	Claims		NO
Inventive step (IS)	Claims	1-24	YES
	Claims		NO
Industrial applicability (IA)	Claims	1-24	YES
	Claims		NO

2. Citations and explanations (Rule 70.7)

Documents cited in the International Search Report:

D1: WO 0147283 A1
D2: US 6337881 B1
D3: EP 1005232 A2
D4: US 5774593 A
D5: US 6307886 B1

D1 is considered to the most relevant document. D2-D5 only disclose the general state of the art, and are not considered being of particular relevance.

D1 discloses a system for determining whether simulcast coding or temporal/spatial scalability coding should be used to encode video for clients with a specific communication link. The part which concerns the spatial and temporal scalability coding is considered to be the most relevant part of D1.

The invention according to the application concerns a method for coding video frames. The aim of the invention is to code the video frames into a scalable and compressed video sequence. The scalability feature can be utilized when streaming a video sequence to multiple clients, where clients have different amount of bandwidth or processing power. The method, according to the claimed invention, includes a way of dividing a video sequence into sub-sequences, where each sub-sequence can be decoded independently. In the video sequence there is also an indication included which shows which frames belong to a certain sub-sequence. According to the application, the above mentioned indication facilitates inclusion of extra material, e.g. a commercial clip, into the video sequence.

.../...

Copied from 32032 on 25-07-2004

Supplemental Box

In case the space in any of the preceding boxes is not sufficient.
Continuation of: Box V

Referring to claim 1-24:

Claim 1-24 reveals a method for coding video frames into a scalable and compressed video sequence. The claims also includes that the video sequence comprise two frame formats (I- and P-frames). Claim 1-24 further describes that into the video sequence, two sub-sequences are formed, where at least one video frame of the second sub-sequence has been predicted from at least on video frame from the first sub-sequence. Information indicating which video frame belongs to the second sub-sequence is formed into the video sequence.

In D1 (see figure 2 and page 13, row 21, to page 14, row 5) temporal scalability is illustrated and described. As can be seen from figure 2, the layers comprise I-, P- and B-frames. From the figure it can also be seen that the video sequence is composed of several GOP:s (Group of Pictures).

The invention according to claims 1-24 differs from D1 in the way the scalable coding hierarchy is structured. The multilayer sequence presented in D1 only defines dependencies within each GOP and no dependencies are defined between the GOP:s, therefore the GOP:s mentioned in D1 do not correspond to the sub-sequences according to the applied invention. The sub-sequences defined in claims 1-24 however, are independently decodable because the frame numbering of each sub-sequence includes information on all sub-sequences that has been used in the image frame prediction. A person skilled in the art with aid of the information in D1 would not be able to arrive at the solution according to claims 1-24, because there are no hints of how to modify the coding hierarchy defined in D1 in order to achieve dependencies between the GOP:s. Also, no suggestions or hints are given in D1 on how the frame numbering of the video sequence is carried out.

In view of the aforementioned, the invention according to claims 1-24 is novel, is considered to involve an inventive step and has industrial applicability.

(54) **Title:** GROUPING OF IMAGE FRAMES IN VIDEO CODING

(57) **Abstract:** A method for coding video frames for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format. The video frames of the first frame format are independent video frames, and the video frames of the second frame format are predicted from at least one of the other video frames. The video sequence has a first sub-sequence determined therein, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format; and with at least a second sub-sequence, at least part of which is formed by coding video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. Frame identifier data of the second sub-sequence is determined into the video sequence.

GROUPING OF IMAGE FRAMES IN VIDEO CODING

FIELD OF THE INVENTION

[0001] The invention relates to the grouping of multimedia files, particularly video files and particularly in connection with streaming.

BACKGROUND OF THE INVENTION

[0002] The term 'streaming' refers to simultaneous sending and playback of data, typically multimedia data, such as audio and video files, in which the recipient may begin data playback already before all the data to be transmitted has been received. Multimedia data streaming systems comprise a streaming server and terminal devices that the recipients use for setting up a data connection, typically via a telecommunications network, to the streaming server. From the streaming server the recipients retrieve either stored or real-time multimedia data, and the playback of the multimedia data can then begin, most advantageously almost in real-time with the transmission of the data, by means of a streaming application included in the terminal.

[0003] From the point of view of the streaming server, the streaming may be carried out either as normal streaming or as progressive downloading to the terminal. In normal streaming the transmission of the multimedia data and/or the data contents are controlled either by making sure that the bit rate of the transmission substantially corresponds to the playback rate of the terminal device, or, if the telecommunications network used in the transmission causes a bottleneck in data transfer, by making sure that the bit rate of the transmission substantially corresponds to the bandwidth available in the telecommunications network. In progressive downloading the transmission of the multimedia data and/or the data contents do not necessarily have to be interfered with at all, but the multimedia files are transmitted as such to the recipient, typically by using transfer protocol flow control. The terminals then receive, store and reproduce an exact copy of the data transmitted from the server, which copy can then be later reproduced again on the terminal without needing to start a streaming again via the telecommunications network. The multimedia files stored in the terminal are, however, typically very large and their transfer to the terminal is time-consuming, and they require a significant amount of storage memory capacity, which is why a normal streaming is often preferred.

[0004] The video files in multimedia files comprise a great number of still image frames, which are displayed rapidly in succession (of typically 15 to 30 frames per s) to create an impression of a moving image. The image frames typically comprise a number of stationary background objects, determined by image information which remains substantially unchanged, and few moving objects, determined by image information that changes to some extent. The information comprised by consecutively displayed image frames is typically largely similar, i.e. successive image frames comprise a considerable amount of redundancy. The redundancy appearing in video files can be divided into spatial, temporal and spectral redundancy. Spatial redundancy refers to the mutual correlation of adjacent image pixels, temporal redundancy refers to the changes taking place in specific image objects in subsequent frames, and spectral redundancy to the correlation of different colour components within an image frame.

[0005] To reduce the amount of data in video files, the image data can be compressed into a smaller form by reducing the amount of redundant information in the image frames. In addition, while encoding, most of the currently used video encoders downgrade image quality in image frame sections that are less important in the video information. Further, many video coding methods allow redundancy in a bit stream coded from image data to be reduced by efficient, lossless coding of compression parameters known as VLC (Variable Length Coding).

[0006] In addition, many video coding methods make use of the above-described temporal redundancy of successive image frames. In that case a method known as motion-compensated temporal prediction is used, i.e. the contents of some (typically most) of the image frames in a video sequence are predicted from other frames in the sequence by tracking changes in specific objects or areas in successive image frames. A video sequence always comprises some compressed image frames the image information of which has not been determined using motion-compensated temporal prediction. Such frames are called INTRA-frames, or I-frames. Correspondingly, motion-compensated video sequence image frames predicted from previous image frames, are called INTER-frames, or P-frames (Predicted). The image information of P-frames is determined using one I-frame and possibly one or more previously coded P-frames. If a frame is lost, frames dependent on it can no longer be correctly decoded.

[0007] An I-frame typically initiates a video sequence defined as a Group of Pictures (GOP), the P-frames of which can only be determined on the basis of the I-frame and the previous P-frames of the GOP in question. The next I-frame begins a new group of pictures GOP, the image information comprised by which cannot thus be determined on the basis of the frames of the previous GOP. In other words, groups of pictures are not temporally overlapping, and each group of picture can be decoded separately. In addition, many video compression methods employ bi-directionally predicted B-frames (Bi-directional), which are set between two anchor frames (I- and P-frames, or two P-frames) within a group of pictures GOP, the image information of a B-frame being predicted from both the previous anchor frame and the one succeeding the B-frame. B-frames therefore provide image information of higher quality than P-frames, but typically they are not used as anchor frames, and therefore their removal from the video sequence does not degrade the quality of subsequent images. However, nothing prevents B-frames from being used as anchor frames as well, only in that case they cannot be removed from the video sequence without deteriorating the quality of the frames dependent on them.

[0008] Each video frame may be divided into what are known as macroblocks that comprise the colour components (such as Y, U, V) of all pixels of a rectangular image area. More specifically, a macroblock consists of at least one block per colour component, the blocks each comprising colour values (such as Y, U or V) of one colour level in the image area concerned. The spatial resolution of the blocks may differ from that of the macroblocks, for example U- and V-components may be displayed using only half of the resolution of Y-component. Macroblocks can be further grouped into slices, for example, which are groups of macroblocks that are typically selected in the scanning order of the image. Temporal prediction is typically carried out in video coding methods block- or macroblock-specifically, instead of image-frame-specifically.

[0009] To allow for flexible streaming of video files, many video coding systems employ scalable coding in which some elements or element groups of a video sequence can be removed without affecting the reconstruction of other parts of the video sequence. Scalability is typically implemented by grouping the image frames into a number of hierarchical layers. The image frames coded into the image frames of the base layer

substantially comprise only the ones that are compulsory for the decoding of the video information at the receiving end. The base layer of each group of pictures GOP thus comprises one I-frame and a necessary number of P-frames. One or more enhancement layers can be determined below the base layer, each one of the layers improving the quality of the video coding in comparison with an upper layer. The enhancement layers thus comprise P- or B-frames predicted on the basis of motion-compensation from one or more upper layer images. The frames are typically numbered according to an arithmetical series.

[0010] In streaming, transmission bit rate must be controllable either on the basis of the bandwidth to be used or the maximum decoding or bit rate value of the recipient. Bit rate can be controlled either at the streaming server or in some element of the telecommunications network, such as an Internet router or a base station of a mobile communications network. The simplest means for the streaming server to control the bit rate is to leave out B-frames having a high information content from the transmission. Further, the streaming server may determine the number of scalability layers to be transmitted in a video stream, and thus the number of the scalability layers can be changed always when a new group of pictures GOP begins. It is also possible to use different video sequence coding methods. Correspondingly, B-frames, as well as other P-frames of the enhancement layers, can be removed from the bit stream in a telecommunications network element.

[0011] The above arrangement involves a number of drawbacks. Many coding methods, such as the coding according to the ITU-T (International Telecommunications Union, Telecommunications Standardization Sector) standard H.263, are familiar with a procedure called reference picture selection. In reference picture selection at least a part of a P-image has been predicted from at least one other image than the one immediately preceding the P-image in the time domain. The selected reference image is signalled in a coded bit stream or in bit stream header fields image-, image-segment- (such as a slice or a group of macroblocks), macroblock-, or block-specifically. The reference picture selection can be generalized such that the prediction can also be made from images temporally succeeding the image to be coded. Further, the reference picture selection can be generalized to cover all temporally predicted frame types, including B-frames. Since it is possible to also select at least one image preceding an I-image that begins a

group of pictures GOP as the reference image, a group of pictures employing reference picture selection cannot necessarily be decoded independently. In addition, the adjusting of scalability or coding method in the streaming server or a network element becomes difficult, because the video sequence must be decoded, parsed and buffered for a long period of time to allow any dependencies between different image groups to be detected.

[0012] Another problem in the prior art coding methods is that there is no useful method of signalling differences of significance between INTER-frames. For example, when a plural number of P-frames are to be predicted successively, the first P-frames are usually the most significant ones for the reconstruction because there are more image frames that are dependent on the first P-frame than on subsequent P-frames. However, known coding methods fail to provide a simple method for signalling such differences in significance.

[0013] A further problem relates to the insertion of a video sequence in the middle of another video sequence, which has typically led to discontinuity in image numbering. The numbering of video sequence images is typically used for detecting the loss of image frames. However, if a separate video sequence, such as a commercial, is inserted into a video sequence, the separate video sequence is typically provided with separate image numbering, which is not in line with the ascending image numbering of the original video sequence. The receiving terminal may therefore interpret the deviating image numbering as a signal of lost image frames and start unnecessary actions to reconstruct the image frames suspected as lost or to request a re-transmission thereof. A similar problem is encountered when scaling a video sequence: for example, if a plural number of successive frames is removed, the receiving terminal may unnecessarily interpret these removals as protocol errors.

BRIEF DESCRIPTION OF THE INVENTION

[0014] It is therefore an object of the invention to provide a method and equipment implementing the method that allow the disadvantages caused by the above problems to be reduced. The objects of the invention are achieved by a method, video encoder, video decoder, streaming system element and computer programs that are chacterized by what is stated in the independent claims.

[0015] The preferred embodiments of the invention are disclosed in the dependent claims.

[0016] The invention is based on the idea of coding a scalable, compressed video sequence that comprises video frames coded on the basis of at least a first and a second frame format, the video frames conforming to the first frame format being independent of other video frames, i.e. they are typically I-frames, and the video frames according to the second frame format being frames predicted from at least one other video frame, for example P-frames. A video sequence comprises a first sub-sequence formed therein, at least part of the sub-sequence being formed by coding video frames (I-frames) of the at least first frame format (I-frames), and at least a second sub-sequence, at least part of which is formed by coding video frames of the at least second frame format (e.g. P-frames), at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. In addition, identifying data of the video frames comprised by the at least second sub-sequence are determined into the video sequence in question.

[0017] Consequently, an essential aspect of the present invention is to determine the sub-sequences each sub-sequence is dependent on, i.e. a sub-sequence will comprise information of all sub-sequences that have been directly used for predicting the image frames comprised by the sub-sequence in question. This information is signalled in the bit stream of the video sequence, preferably separate from the actual image information, whereby the image data comprised by the video sequence can preferably be scaled, because independently decodable portions of the video sequence can be easily determined, and the portions can be removed without affecting the decoding of the rest of the image data.

[0018] According to a preferred embodiment of the invention, a scalable coding hierarchy is formed for the video sequences, according to which hierarchy a first scalability layer of the video sequence is coded in such a way that it comprises at least video frames of the first frame format, i.e. I-frames, and the lower scalability layers of the video sequence are coded such that they comprise at least video frames of the second frame format, i.e. P- and/or B-frames, grouped into sub-sequences in which at least one video frame is predicted either from a video frame of an upper scalability layer or

from another video frame of the same sub-sequence. The number of the scalability layers is not restricted.

[0019] According to a preferred embodiment of the invention, a unique identifier combining the scalability layer number, sub-sequence identifier and image number is determined for each video frame. The identifier can be included into a header field of the video sequence, or into a header field according to the transfer protocol to be used for the video sequence transfer.

[0020] An advantage of the procedure of the invention is that it provides a flexible coding hierarchy that enables, on one hand, the scaling of the bit rate of a video sequence to be transmitted without video sequence decoding being required, and, on the other hand, independent decoding of each sub-sequence. This allows the streaming server, for example, to adjust the bit rate advantageously, without video sequence decoding, parsing and buffering, because the streaming server is capable of deducing the inter-dependencies of the different sub-sequences directly from the identifiers and their inter-dependencies. Further, the streaming server may, when necessary, carry out sub-sequence-specific adjusting of the scalability or the coding employed, because the inter-dependencies of the different frames are known. A further advantage is that the coding hierarchy and the image numbering of the invention allow a separate video sequence to the easily inserted into another video sequence.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] In the following, the invention will be described in connection with the preferred embodiments and with reference to the accompanying drawings, in which

Figure 1 illustrates a common multimedia data streaming system in which the scalable coding hierarchy of the invention can be applied;

Figure 2 illustrates a scalable coding hierarchy of a preferred embodiment of the invention;

Figures 3a and 3b illustrate embodiments of the invention for adjusting scalability;

Figures 4a, 4b and 4c illustrate embodiments of the invention for adjusting image numbering;

Figures 5a, 5b and 5c illustrate embodiments of the invention for using B-frames in a scalable coding hierarchy;

Figures 6a, 6b and 6c illustrate scalable coding hierarchies of preferred embodiments of the invention in connection with reference picture selection; and

Figure 7 illustrates an arrangement according to a preferred embodiment of the invention for coding scene transition.

DETAILED DESCRIPTION OF THE INVENTION

[0022] In the following, a general-purpose multimedia data streaming system is disclosed, the basic principles of which can be applied in connection with any telecommunications system. Although the invention is described here with a particular reference to a streaming system, in which the multimedia data is transmitted most preferably through a telecommunications network employing a packet-switched data protocol, such as an IP network, the invention can equally well be implemented in circuit-switched networks, such as fixed telephone networks PSTN/ISDN (Public Switched Telephone Network/Integrated Services Digital Network) or in mobile communications networks PLMN (Public Land Mobile Network). Further, the invention can be applied in the streaming of multimedia files in the form of both normal streaming and progressive downloading, and for implementing video calls, for example.

[0023] It is also to be noted that although the invention is described here with a particular reference to streaming systems and the invention can also be advantageously applied in them, the invention is not restricted to streaming systems alone, but can be applied in any video reproduction system, irrespective of how a video file that is to be decoded is downloaded and where it is downloaded from. The invention can therefore be applied for example in the playback of a video file to be downloaded from a DVD disc or from some other computer memory carrier, for example in connection with varying processing capacity available for video playback. In particular, the invention can be applied to different video codings of low bit rate that are typically used in telecommunications systems subject to bandwidth restrictions. One example is the system defined in the ITU-T standard H.263 and the one that is being defined in H.26L (possibly later to become H.264). In connection with these, the invention can be applied to mobile stations, for example, in which case the

video playback can be made to adjust both to changing transfer capacity or channel quality and to the processor power currently available, when the mobile station is used also for executing other applications than video playback.

[0024] It is further to be noted that, for the sake of clarity, the invention will be described below by giving an account of image frame coding and temporal predicting on image frame level. However, in practice coding and temporal predicting typically take place on block or macroblock level, as described above.

[0025] With reference to Figure 1, a typical multimedia streaming system will be described, which is a preferred system for applying the procedure of the invention.

[0026] A multimedia data streaming system typically comprises one or more multimedia sources 100, such as a video camera and a microphone, or video image or computer graphic files stored in a memory carrier. Raw data obtained from the different multimedia sources 100 is combined into a multimedia file in an encoder 102, which can also be referred to as an editing unit. The raw data arriving from the one or more multimedia sources 100 is first captured using capturing means 104 included in the encoder 102, which capturing means can be typically implemented as different interface cards, driver software, or application software controlling the function of a card. For example, video data may be captured using a video capture card and the associated software. The output of the capturing means 104 is typically either an uncompressed or slightly compressed data flow, for example uncompressed video frames of the YUV 4:2:0 format or motion-JPEG image format, when a video capture card is concerned.

[0027] An editor 106 links different media flows together to synchronize video and audio flows to be reproduced simultaneously as desired. The editor 106 may also edit each media flow, such as a video flow, by halving the frame rate or by reducing spatial resolution, for example. The separate, although synchronized, media flows are compressed in a compressor 108, where each media flow is separately compressed using a compressor suitable for the media flow. For example, video frames of the YUV 4:2:0 format may be compressed using the low bit rate video coding according to the ITU-T recommendation H.263 or H.26L. The separate, synchronized and compressed media flows are typically interleaved in a multiplexer 110, the

output obtained from the encoder 102 being a single, uniform bit flow that comprises data of a plural number of media flows and that may be referred to as a multimedia file. It is to be noted that the forming of a multimedia file does not necessarily require the multiplexing of a plural number of media flows into a single file, but the streaming server may interleave the media flows just before transmitting them.

[0028] The multimedia files are transferred to a streaming server 112, which is thus capable of carrying out the streaming either as real-time streaming or in the form of progressive downloading. In progressive downloading the multimedia files are first stored in the memory of the server 112 from where they may be retrieved for transmission as need arises. In real-time streaming the editor 102 transmits a continuous media flow of multimedia files to the streaming server 112, and the server 112 forwards the flow directly to a client 114. As a further option, real-time streaming may also be carried out such that the multimedia files are stored in a storage that is accessible from the server 112, from where real-time streaming can be driven and a continuous media flow of multimedia files is started as need arises. In such case, the editor 102 does not necessarily control the streaming by any means. The streaming server 112 carries out traffic shaping of the multimedia data as regards the bandwidth available or the maximum decoding and playback rate of the client 114, the streaming server being able to adjust the bit rate of the media flow for example by leaving out B-frames from the transmission or by adjusting the number of the scalability layers. Further, the streaming server 112 may modify the header fields of a multiplexed media flow to reduce their size and encapsulate the multimedia data into data packets that are suitable for transmission in the telecommunications network employed. The client 114 may typically adjust, at least to some extent, the operation of the server 112 by using a suitable control protocol. The client 114 is capable of controlling the server 112 at least in such a way that a desired multimedia file can be selected for transmission to the client, in addition to which the client is typically capable of stopping and interrupting the transmission of a multimedia file.

[0029] When the client 114 is receiving a multimedia file, the file is first supplied to a demultiplexer 116, which separates the media flows comprised by the multimedia file. The separate, compressed media flows are then supplied to a decompressor 118 where each separate media flow is decompressed by a decompressor suitable for each particular media flow. The

decompressed and reconstructed media flows are supplied to a playback unit 120 where the media flows are rendered at a correct pace according to their synchronization data and supplied to presentation means 124. The actual presentation means 124 may comprise for example a computer or mobile station display, and loudspeaker means. The client 114 also typically comprises a control unit 122 that the end user can typically control through a user interface and that controls both the operation of the server, through the above-described control protocol, and the operation of the playback unit 120, on the basis of the instructions given by the end user.

[0030] It is to be noted that the transfer of multimedia files from the streaming server 112 to the client 114 takes place through a telecommunications network, the transfer path typically comprising a plural number of telecommunications network elements. It is therefore possible that there is at least some network element that can carry out traffic shaping of multimedia data with regard to the available bandwidth or the maximum decoding and playback rate of the client 114 at least partly in the same way as described above in connection with the streaming server.

[0031] Scalable coding will be described below with reference to a preferred embodiment of the invention and an example illustrated in Figure 2. Figure 2 shows part of a compressed video sequence having a first frame 200, which is an INTRA frame, or I-frame, and thus an independently determined video frame the image information of which is determined without using motion-compensated temporal prediction. The I-frame 200 is placed on a first scalability layer, which may be referred to as an INTRA layer. Each scalability layer is assigned a unique identifier, such as the layer number. The INTRA layer may therefore be given the number 0, for example, or some other alphanumeric identifier, for example a letter, or a combination of a letter and a number.

[0032] Correspondingly, sub-sequences consisting of groups of one or more video frames are determined for each scalability layer, at least one of the images in a group (typically the first or the last one) being temporally predicted at least from a video frame of another, sub-sequence of typically either a higher or the same scalability layer, the rest of the video frames being temporally predicted either from only the video frames of the same sub-sequence, or possibly also from one or more video frames of said second sub-sequence. A sub-sequence may de decoded independently, irrespective of

other sub-sequences, except said second sub-sequence. The sub-sequences of each scalability layer are assigned a unique identifier using for example consecutive numbering starting with number 0 given for the first sub-sequence of a scalability layer. Since the I-frame 200 is determined independently and can also be decoded independently upon reception, irrespective of other image frames, it also forms in a way a separate sub-sequence.

[0033] An essential aspect of the present invention is therefore to determine each sub-sequence in terms of those sub-sequences the sub-sequence is dependent on. In other words, a sub-sequence comprises information about all the sub-sequences that have been directly used for predicting the image frames of the sub-sequence in question. This information is signalled in a video sequence bit stream, preferably separate from the actual image information, and therefore the image data of the video sequence can be preferably adjusted because it is easy to determine video sequence portions that are to be independently decoded and can be removed without affecting the decoding of the rest of the image data.

[0034] Next, within each sub-sequence, the video frames of the sub-sequence are given image numbers, using for example consecutive numbering that starts with the number 0 given to the first video frame of the sub-sequence. Since the I-frame 200 also forms a separate sub-sequence, its image number is 0. In Figure 2, the I-frame 200 shows the type (I), sub-sequence identifier and image number (0.0) of the frame.

[0035] Figure 2 further shows a next I-frame 202 of the INTRA layer, the frame thus being also an independently determined video frame that has been determined without using motion-compensated temporal prediction. The temporal transmission frequency of I-frames depends on many factors relating to video coding, image information contents and the bandwidth to be used, and, depending on the application or application environment, I-frames are transmitted in a video sequence at intervals of 0.5 to 10 seconds, for example. Since the I-frame 202 can be independently decoded, it also forms a separate sub-sequence. Since this is the second sub-sequence in the INTRA-layer, the consecutive numbering of the sub-sequence identifier of the I-frame 202 is 1. Further, since the I-frame 202 also forms a separate sub-sequence, i.e. it is the only video frame in the sub-sequence, its image number is 0. The I-frame 202 can thus be designated with identifier (I.1.0.) Correspondingly, the identifier of the next I-frame on the INTRA layer is (I.2.0.), etc. As a result, only

independently determined I-frames in which the image information is not determined using motion-compensated temporal prediction are coded into the first scalability layer, i.e. the INTRA layer. The sub-sequences can also be determined using other kind of numbering or other identifiers, provided that the sub-sequences can be distinguished from one another.

[0036] The next scalability layer, which has a layer number 1, for example, and which may be referred to as the base layer, comprises coded, motion-compensated INTER or P-frames typically predicted only from previous image frames, i.e. in this case from the I-frames of an upper INTRA layer. The image information of the first P-frame 204 of the base layer shown in Figure 2 is determined using the I-frame 200 of the INTRA layer. A P-frame 204 begins the first sub-sequence of the base layer, and therefore the sub-sequence identifier of the P-frame 204 is 0. Further, since the P-frame 204 is the first image frame of the first sub-sequence of the base layer, the image number of the P-frame 204 is 0. The P-frame 204 can thus be identified with (P.0.0).

[0037] The temporally succeeding P-frame 206 of the base layer is predicted from the previous P-frame 204. The P-frames 204 and 206 thus belong to the same sub-sequence, whereby the P-frame 206 also receives the sub-sequence identifier 0. Since the P-frame 206 is the second image frame in the sub-sequence 0, the image number of the P-frame 206 is 1, and the P-frame 206 can be identified with (P.0.1).

[0038] The scalability layer succeeding the base layer and having the layer number 2, is called enhancement layer 1. This layer comprises coded, motion-compensated P-frames predicted only from previous image frames, in this case either from I-frames of the INTRA layer or P-frames of the base layer. Figure 2 shows a first image frame 208 and a second image frame 210 of enhancement layer 1, which are both predicted only from the first image frame 200 of the INTRA layer. The P-frame 208 begins the first sub-sequence of enhancement layer 1, the sub-sequence identifier of the P-frame thus being 0. Further, since the P-frame 208 is the first and only image frame in said sub-sequence, the P-frame 208 receives the image number 0. The P-frame 208 can thus be identified with (P.0.0.).

[0039] Since the second image frame 210 is also predicted only from the first image frame 200 of the INTRA layer, the P-frame 210 begins the second sub-sequence of enhancement layer 1 and the sub-sequence identifier of the P-frame 210 is therefore 1. Since the P-frame 210 is the first image

frame in the sub-sequence, the image number of the P-frame 210 is 0. The P-frame can thus be identified with (P.1.0.). The temporally succeeding P-frame 212 of enhancement layer 1 is predicted from the previous P-frame 210. The P-frames 210 and 212 thus belong to the same sub-sequence, and therefore the P-frame also receives the sub-sequence identifier 1. The P-frame 212 is the second image frame in the sub-sequence 1, and therefore the P-frame receives the image number 1 and can be identified with (P.1.1).

[0040] The temporally fourth image frame 214 of enhancement layer 1 is predicted from the first image frame 204 of the base layer. The P-frame 214 thus begins a third sub-sequence of enhancement layer 1 and therefore the P-frame 214 receives the sub-sequence identifier 2. Further, since the P-frame 214 is the first and only image frame in the sub-sequence, the image number of the P-frame 214 is 0. The P-frame 208 can therefore be identified with (P.2.0).

[0041] Also the temporally fifth image frame 216 of enhancement layer 1 is predicted only from the first image frame 204 of the base layer, the P-frame 216 thus beginning the fourth sub-sequence of enhancement layer 1, and the sub-sequence identifier of the P-frame 216 is 3. In addition, since the P-frame 216 is the first one in the sub-sequence in question, the image number of the P-frame 216 is 0. The P-frame 216 can therefore be identified with (P.3.0). The temporally following P-frame 218 of enhancement layer 1 is predicted from the previous P-frame 216. The P-frames 216 and 218 thus belong to the same sub-sequence, and the sub-sequence identifier of the P-frame 218 is also 3. Since the P-frame 218 is the second image frame in the sub-sequence 3, the image number of the P-frame 218 is 1 and the identifier of the P-frame 218 is (P.3.1).

[0042] For simplicity and clarity of illustration the above disclosure only relates to I- and P-frames. However, a person skilled in the art will find it apparent that the scalable video coding of the invention can also be implemented using other known image frame types, such as the above described B-frames and at least SI-frames, SP-frames and MH-frames. SI-frames correspond to I-frames, but together with an SP-frame they allow an identical image to be reconstructed. An SP-frame, in turn, is a P-frame subjected to a particular coding that allows an identical image to be reconstructed together with an SI-frame or another SP-frame. SP-frames are typically placed into a video sequence into points where an access point or a

scanning point is desired, or where the changing of the coding parameters of the video stream should be possible. The frames can also be used for error correction and for increasing error tolerance. SP-frames are otherwise similar to ordinary P-frames predicted from previous frames, except that they are defined so that they can be replaced by another video frame of the SP- or SI-type, the result of the decoding of the new frame being identical with the decoding result of the original SP-frame that was in the video stream. In other words, a new SP-frame that is used for replacing the one that was in the video stream is predicted from another sequence or video stream and yet the reconstructed frame has identical contents. SP-frames are described for example in the Applicant's earlier application PCT/FI02/00004.

[0043] Similarly as B-frames, macroblocks of MH (Multi Hypothesis) frames, based on motion-compensated prediction, are predicted from two other frames, which are not, however, necessarily located next to an MH-frame. More precisely, the predicted macroblocks are computed as an average of two macroblocks of two other frames. Instead of two frames, MH-frame macroblocks can naturally be also predicted from one other frame. Reference images may change according to macroblock, in other words, all macroblocks in one and the same image are not necessarily predicted using the same frames.

[0044] A sub-sequence thus covers a specific period of time in a video sequence. The sub-sequences of the same layer or of different layers may be partly or entirely overlapping. If there are temporally overlapping image frames on the same layer, the frames are interpreted as alternative presentations of the same image content and therefore any mode of image presentation can be used. On the other hand, if there are temporally overlapping image frames on different layers, they form different presentations of the same image content, and therefore presentations differ in image quality, i.e. the quality of image is better on a lower layer.

[0045] The above disclosure referring to Figure 2 illustrates a scalable coding arrangement and a hierarchical structure and numbering of image frames according to a preferred embodiment of the invention. In this embodiment the INTRA-layer only comprises I-frames and the base layer can only be decoded using the information received from the INTRA-layer. Correspondingly, the decoding of enhancement layer 1 typically requires information from both the base layer and the INTRA-layer.

[0046] The number of the scalability layers is not restricted to three, as above, but any number of enhancement layers that is considered necessary for producing sufficient scalability may be used. Consequently, the layer number of enhancement layer 2 is four, that of enhancement layer 3 is five, etc. Since some of the image frames in the above example are given the same identifier (e.g. the identifier of both image frames 204 and 208 is (P.0.0)), by including the layer number in the identifier each image frame can be uniquely identified and, at the same time, the dependencies of each image frame on other image frames is preferably determined. Each image frame is thus uniquely identified, the identifier of image frame 204, for example, being (P.1.0.0), or simply (1.0.0) and, correspondingly, that of image 208 being (P.2.0.0), or (2.0.0).

[0047] According to a preferred embodiment of the invention, the number of a reference image frame is determined according to a specific, predetermined alpha-numeric series, for example as an integer between 0 and 255. When the parameter value achieves the maximum value N (e.g. 255) in the series concerned, the determining of the parameter value starts from the beginning, i.e. from the minimum value of the series (e.g. 0). An image frame is thus uniquely identified within a specific sub-sequence up to the point where the same image number is used again. The sub-sequence identifier can also be determined according to a specific, predetermined arithmetic series. When the value of the sub-sequence identifier achieves the maximum value N of the series, the determining of the identifier starts again from the beginning of the series. However, a sub-sequence cannot be assigned an identifier that is still in use (within the same layer). The series in use may also be determined in another way than arithmetically. One alternative is to assign random sub-sequence identifiers, taking into account that an assigned identifier is not be used again.

[0048] A problem in the numbering of image frames arises when the user wishes to start browsing a video file in the middle of a video sequence. Such situations occur for example when the user wishes to browse a locally stored video file backward or forward or to browse a streaming file at a particular point; when the user initiates the playback of a streaming file from a random point; or when a video file that is to be reproduced is detected to contain an error that interrupts the playback or requires the playback to be resumed from a point following the error. When the browsing of a video file is

resumed from a random point after previous browsing, discontinuity typically occurs in the image numbering. The decoder typically interprets this as unintentional loss of image frames and unnecessarily tries to reconstruct the image frames suspected as lost.

[0049] According to a preferred embodiment of the invention, this can be avoided in the decoder by defining an initiation image in an independently decodable Group of Pictures GOP that is activated at the random point of the video file, and the number of the initiation image is set at zero. This independently decodable image group can thus be a sub-sequence of an INTRA-layer, for example, in which case an I-frame is used as the initiation image, or, if scaling originating from the base layer is employed, the independently decodable image group is a sub-sequence of the base layer, in which case the first image frame of the sub-sequence, typically an I-frame, is usually used as the initiation image. Consequently, when activated at a random point, the decoder preferably sets the identifier of the first image frame, preferably an I-frame, of the independently decodable sub-sequence at zero. Since the sub-sequence to be decoded may also comprise other image frames whose identifier is zero (for example when the above described alpha-numeric series starts from the beginning), the beginning of the sub-sequence, i.e. its first image frame, can be indicated to the decoder for example by a separate flag added to the header field of a slice of the image frame. This allows the decoder to interpret the image numbers correctly and to find the correct image frame that initiates the sub-sequence from the video sequence image frames.

[0050] The above numbering system provides only one example of how the unique image frame identification of the invention can be carried out so that interdependencies between the image frames are indicated at the same time. However, video coding methods in which the method of the invention can be applied, such as video coding methods according to the ITU-T standards H.263 and H.26L, employ code tables, which in turn use variable length codes. When variable length codes are used for coding layer numbers, for example, a lower code word index, i.e. a smaller layer number, signifies a shorter code word. In practice the scalable coding of the invention will be used in most cases in such a way that the base layer will consist significantly more image frames than the INTRA-layer. This justifies the use of a lower index, i.e. a smaller layer number, on the base layer than on the INTRA-layer, because

the amount of coded video data is thereby advantageously reduced. Consequently, the INTRA-layer is preferably assigned layer number 1 and the base layer is given layer number 0. Alternatively, the code can be formed by using fewer bits for coding the base layer number than the INTRA-layer number, in which case the actual layer number value is not relevant in view of the length of the code created.

[0051] Further, according to a second preferred embodiment of the invention, when the number of the scalability layers is to be kept low, the first scalability layer in particular can be coded to comprise both the INTRA-layer and the base layer. From the point of view of coding hierarchy, the simplest way to conceive this is to leave out the INTRA-layer altogether, and to provide the base layer with coded frames consisting of both independently defined I-frames, the image information of which has not been determined using motion-compensated temporal prediction, and image frames predicted from previous frames, which image frames in this case are motion-compensated P-frames predicted from the I-frames of the same layer. The layer number 0 can thus still be used for the base layer and, if enhancement layers are coded into the video sequence, enhancement layer 1 is assigned layer number 1. This is illustrated in the following, with reference to Figures 3a and 3b.

[0052] Figure 3a shows a non-scalable video sequence structure, in which all image frames are placed on the same scalability layer, i.e. the base layer. The video sequence comprises a first image frame 300 which is an I-frame (I.0.0) and which thus initiates a first sub-sequence. The image frame 300 is used for predicting a second image frame 302 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 304 of the sub-sequence, i.e. a P-frame (P.0.2), which is in turn used for predicting the next image frame 306, i.e. a P-frame (P.0.3). The video sequence is then provided with an I-frame (I.1.0) coded therein, i.e. an I-frame 308, which thus initiates a second sub-sequence in the video sequence. This kind of non-scalable coding can be used for example when the application employed does not allow scalable coding to be used, or there is no need for it. In a circuit-switched videophone application, for example, channel bandwidth remains constant and the video sequence is coded in real-time, and therefore there is typically no need for scalable coding.

[0053] Figure 3b, in turn, illustrates an example of how scalability can be added, when necessary, to a combined INTRA- and base layer. Here,

too, the video sequence base layer comprises a first image frame 310 which is an I-frame (I.0.0) and which initiates a first sub-sequence of the base layer. The image frame 310 is used for predicting a second image frame 312 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 314 of the sub-sequence, i.e. a P-frame (P.0.2). Enhancement layer 1, however, is also coded into this video sequence and it comprises a first sub-sequence, the first and only image frame 316 of which is a P-frame (P.0.0), which is predicted from the first image frame 310 of the base layer. The first image frame 318 of a second sub-sequence of the enhancement layer is, in turn, predicted from the second image frame 312 of the base layer, and therefore the identifier of this P-frame is (P.1.0). The next image frame 320 of the enhancement layer is again predicted from the previous image frame 318 of the same layer and, therefore, it belongs to the same sub-sequence, its identifier thus being (P.1.1).

[0054] In this embodiment of the invention the sub-sequences of the base layer can be decoded independently, although a base layer sub-sequence may be dependent on another base layer sub-sequence. The decoding of the base layer sub-sequences requires information from the base layer and/or from the second sub-sequence of enhancement layer 1, the decoding of the sub-sequences of enhancement layer 2 requires information from enhancement layer 1 and/or from the second sub-sequence of enhancement layer 2, etc. According to an embodiment, I-frames are not restricted to the base layer alone, but lower enhancement layers may also comprise I-frames.

[0055] The basic idea behind the above embodiments is that a sub-sequence comprises information about all the sub-sequences it is dependent on, i.e. about all sub-sequences that have been used for predicting at least one of the image frames of the sub-sequence in question. However, according to an embodiment it is also possible that a sub-sequence comprises information about all sub-sequences that are dependent on the sub-sequence in question, in other words, about all the sub-sequences in which at least one image frame has been predicted using at least one image frame of the sub-sequence in question. Since in the latter case the dependencies are typically determined temporally forward, image frame buffers can be advantageously utilized in the coding in a manner to be described later.

[0056] In all the above embodiments the numbering of the image frames is sub-sequence-specific, i.e. a new sub-sequence always starts the numbering from the beginning. The identification of an individual image frame thus requires the layer number, sub-sequence identifier and image frame number to be determined. According to a preferred embodiment of the invention, the image frames can be independently numbered using consecutive numbering in which successive reference image frames in the coding order are indicated with numbers incremented by one. As regards layer numbers and sub-sequence identifiers, the above-described numbering procedure can be used. This allows each image frame to be uniquely identified, when necessary, without using the layer number and sub-sequence identifier.

[0057] This is illustrated with the example shown in Figure 4a in which the base layer comprises a temporally first I-frame 400 (I.0.0). This frame is used for predicting a first image frame 402 of enhancement layer 1, i.e. (P.0.1), which is then used for predicting a second image frame 404 belonging to the same sub-sequence (with sub-sequence identifier 0), i.e. (P.0.2), which is used for predicting a third image frame 406 of the same sub-sequence, i.e. (P.0.3), which is used for predicting a fourth image frame 408 (P.0.4) and, finally, the fourth frame for predicting a fifth image frame 410 (P.0.5). The temporally next video sequence image frame 412 is located on the base layer, where it is in the same sub-sequence as the I-frame 400, although temporally it is only the seventh coded image frame, and therefore its identifier is (P.0.6). The seventh frame is then used for predicting a first image frame 414 of the second sub-sequence of enhancement layer 1, i.e. (P.1.7), which is then used for predicting a second image frame 416 belonging to the same sub-sequence (with sub-sequence identifier 1), i.e. (P.1.8), which in turn used for predicting a third image frame 418 (P.1.9), the third for predicting a fourth image frame 420 (P.1.10) and, finally, the fourth for predicting a fifth image frame 422 (P.1.11) of the same sub-sequence. Again, the temporally next video sequence image frame 424 is located on the base layer, where it is in the same sub-sequence as the I-frame 400 and the P-frame 412, although temporally it is only the thirteenth coded image frame and therefore its identifier is (P.0.12). For clarity of illustration, the above description of the embodiment does not comprise layer identifiers, but it is apparent that in order

to implement scalability, also the layer identifier must be signalled together with the video sequence, typically as part of the image frame identifiers.

[0058] Figures 4b and 4c show alternative embodiments for grouping the image frames of the video sequence shown in Figure 4a. The image frames in Figure 4b are numbered according to sub-sequence, i.e. a new sub-sequence always starts the numbering from the beginning (from zero). Figure 4c, in turn, employs image frame numbering which corresponds otherwise to that used in Figure 4a, except that the P-frames of the base layer are replaced by SP-frame pairs to allow for identical reconstruction of image information.

[0059] As stated above, the procedure of the invention can also be implemented using B-frames. One example of this is illustrated in Figures 5a, 5b and 5c. Figure 5a shows a video sequence in the time domain, the sequence comprising P-frames P1, P4 and P7, with B-frames placed between them, the interdependencies of the B-frames with regard to temporal predicting being shown with arrows. Figure 5b shows a preferred grouping of video sequence image frames in which the interdependencies shown in Figure 5a are indicated. Figure 5b illustrates sub-sequence-specific image frame numbering in which a new sub-sequence always starts the numbering of the image frames from zero. Figure 5c, in turn, illustrates image frame numbering, which is consecutive in the order of temporal prediction, wherein the following reference frame always receives the next image number as the previously encoded reference frame. The image frame (B1.8) (and (B2.10)) does not serve as a reference prediction frame to any other frame, therefore it does not affect the image frame numbering.

[0060] The above examples illustrate different alternatives of how scalability of video sequence coding can be adjusted by using the method of the invention. From the point of view of the terminal device reproducing the video sequence, the more scalability layers are available, or the more scalability layers it is capable of decoding, the better the image quality. In other words, increase in the amount of image information and in the bit rate used for transferring the information improves the temporal or spatial resolution, or the spatial quality of the image data. Correspondingly, a higher number of scalability layers also sets considerably higher demands on the processing capacity of the terminal device performing decoding.

[0061] In addition, the above examples illustrate the advantage gained by using sub-sequences. With image frame identifiers, the dependencies of each image frame from other image frames in the sub-sequence are indicated in an unambiguous manner. A sub-sequence thus forms an independent whole that can be left out of a video sequence, when necessary, without affecting the decoding of subsequent image frames of the video sequence. In that case, only the image frames of the sub-sequence in question and of those sub-sequences on the same and/or lower scalability layers dependent on it are not decoded.

[0062] The image frame identifier data transmitted together with the video sequence are preferably included in the video sequence header fields or in the header fields of the transfer protocol to be used for transferring the video sequence. In other words, the identifier data of predicted image frames are not included in the image data of the coded video sequence, but always into the header fields, whereby the dependencies of the image frames can be detected without decoding the images of the actual video sequence. The identifier data of the image frames can be stored for example in the buffer memory of the streaming server as the video sequence is being coded for transmission. In addition, the sub-sequences can be independently decoded on each scalability layer, because the image frames of a sub-sequence are not dependent on other sub-sequences of the same scalability layer.

[0063] According to an embodiment of the invention, the image frames comprised by a sub-sequence may thus depend also on other sub-sequences of the same scalability layer. This dependency must then be signalled for example to the streaming server carrying out traffic shaping, because interdependent sub-sequences located on the same layer cannot be separately removed from a video sequence to be transmitted. A preferred way to carry out the signalling is to include it in the image frame identifiers to be transmitted, for example by listing the layer-sub-sequence pairs the sub-sequence in question depends on. This also provides a preferred way of indicating dependency from another sub-sequence of the same scalability layer.

[0064] The above examples illustrate a situation where image frames are temporally predicted from previous image frames. In some coding methods, however, the reference picture selection has been further extended to also include the predicting of the image information of image frames from

temporally succeeding image frames. Reference picture selection offers most diversified means for creating different temporally scalable image frame structures and allows the error sensitivity of the video sequence to be reduced. One of the coding techniques based on reference picture selection is INTRA-frame postponement. The INTRA-frame is not placed into its temporally "correct" position in the video sequence, but its position is temporally postponed. The video sequence image frames that are between the "correct" position of the INTRA-frame and its actual position are predicted temporally backward from the INTRA-frame in question. This naturally requires that uncoded image frames be buffered for a sufficiently long period of time so that all image frames that are to be displayed can be coded and arranged into their order of presentation. INTRA-frame transfer and the associated determining of sub-sequences in accordance with the invention are illustrated in the following with reference to Figure 6.

[0065] Figure 6a shows a video sequence part in which the INTRA-frame comprises a single I-frame 600, which is temporally transferred to the position shown in Figure 6, although the "correct" position of the I-frame in the video sequence would have been at the first image frame. The video sequence image frames between the "correct" position and the real position 600 are thus temporally predicted backward from the I-frame 600. This is illustrated by a sub-sequence coded into enhancement layer 1 and having a first temporally backward predicted image frame 602, which is a P-frame (P.0.0). This frame is used for temporally predicting a previous image frame 604, i.e. a P-frame (P.0.1), which is used in turn for predicting an image frame 606, i.e. a P-frame (P.0.2), and, finally, the frame 606 for predicting an image frame 608, i.e. a P-frame (P.0.3), which is at the position that would have been the "correct" position of the I-frame 600 in the video sequence. Correspondingly, the I-frame 600 on the base layer is used for temporally forward prediction of a sub-sequence comprising four P-frames 610, 612, 614 and 616, i.e. P-frames (P.0.0), (P.0.1), (P.0.2) and (P.0.3).

[0066] The fact that in this example backward predicted image frames are placed on a lower layer than forward predicted image layers indicates that for purposes of illustration, backward predicted image frames are in this coding example considered subjectively less valuable than forward predicted image frames. Naturally the sub-sequences could both be placed on the same layer, in which case they would be considered equal, or a backward

predicted sub-sequence could be on the upper layer, in which case it would be considered subjectively more valuable.

[0067] Figures 6b and 6c show some alternatives for coding a video sequence according to Figure 6a. In Figure 6b both forward and backward predicted sub-sequences are placed on the base layer, the I-frame being only located on the INTRA-layer. The forward predicted sub-sequence on this layer is thus the second sub-sequence and its sub-sequence identifier is 1. In Figure 6c, in turn, an I-frame and a forward predicted sub-sequence based on it are located on the base layer, while a backward predicted sub-sequence is located on enhancement layer 1.

[0068] Moreover, according to a preferred embodiment of the invention, the above-described scalability can be utilized for coding what is known as a scene transition into a video sequence. Video material, such as news reports, music videos and movie trailers, often comprise rapid cuts between separate image material scenes. Sometimes the cuts are abrupt, but often a procedure known as scene transition is used in which transfer from one scene to another takes place by dimming, wiping, mosaic dissolving or scrolling the image frames of a previous scene, and, correspondingly, by presenting those of a later scene. From the point of view of coding efficiency, the video coding of a scene transition is often most problematic, because the image frames appearing during the scene transition comprise information on the image frames of both the terminating and the initiating scene.

[0069] A typical scene transition, fading, is carried out by gradually reducing the intensity or luminance of the image frames of a first scene to zero, while gradually increasing the intensity of the image frames of a second scene to its maximum value. This scene transition is referred to as cross-faded scene transition.

[0070] Generally speaking, a computer-made image can be thought of as consisting of layers, or image objects. Each object can be defined with reference to at least three information types: the structure of the image object, its shape and transparency, and the layering order (depth) in relation to the background of the image and to other image objects. Shape and transparency are often determined using what is known as an alpha plane, which measures opacity and the value of which is usually determined separately for each image object, possibly excluding the background, which is usually determined as non-transparent. The alpha plane value of a non-transparent image object, such as

the background, can thus be set at 1.0, whereas the alpha plane value of a fully transparent image object is 0.0. The values in between define the intensity of the visibility of a specific image object in a picture in proportion to the background and to other, at least partly overlapping, image objects that have a higher depth value than the image object in question.

[0071] The superimposition of image objects in layers according to their shape, transparency and depth position is referred to as scene composition. In practice the procedure is based on the use of weighted averages. First, the image object that is closest to the background, i.e. deepest according to its depth position, is placed onto the background and a combined image is formed of the two. The pixel values of the combined image are formed as an average weighted by the alpha plane values of the background image and the image object in question. The alpha plane value of the combined image is then set at 1.0, after which it serves as a background image for the next image object. The process continues until all image objects are attached to the image.

[0072] In the following, a procedure according to a preferred embodiment of the invention will be described in which video sequence scalability layers are combined with the above described image objects of image frames and their information types to provide a scene transition with scalable video coding that also has good compression efficiency.

[0073] This embodiment of the invention is illustrated in the following by way of example and in a simplified manner by using cross-faded scene transition, on one hand, and abrupt scene transition, on the other hand, as examples. The image frames to be displayed during a scene transition are typically formed of two superimposed image frames, a first image frame comprising a first image scene and a second image frame a second scene. One of the image frames serves as the background image and other, which is referred to as a foreground image, is placed on top of the background image. The opacity of the background image, i.e. its non-transparency value, is constant. In other words, its pixel-specific alpha plane values are not adjusted.

[0074] In this embodiment of the invention, the background and foreground images are both defined according to scalability layer. This is illustrated in Figure 7, which shows an example of how image frames of two different scenes can be placed on scalability layers during a scene transition of the invention. Figure 7 shows a first image frame 700 of a first (terminating)

scene positioned on the base layer. The image frame 700 may be either an I-frame containing image information that has not been determined using motion-compensated temporal predicting, or it may be a P-frame that is a motion-compensated image frame predicted from previous image frames. The coding of a second (initiating) scene starts during the temporally following image frame and, according to the invention, the image frames of the scene are also placed on the base layer. Remaining image frames 702, 704 of the second (terminating) scene are then placed on enhancement layer 1. These image frames are typically P-frames.

[0075] In this embodiment, the image frames of the second (initiating) scene are thus placed on the base layer, at least for the duration of the scene transition. The first image frame 706 of the scene is typically an I-frame, and it is used for temporally predicting the succeeding image frames of the scene. Consequently, the succeeding image frames of the second scene are temporally predicted frames, typically P-frames, such as frames 708 and 710 shown in Figure 7.

[0076] According to a preferred embodiment of the invention, this placing of image frames on scalability layers can be used for implementing a cross-faded scene transition by determining the image layer that is on the base layer always as a background image of maximum opacity (100%), or non-transparency value. During a scene transition, image frames located on enhancement layers are placed onto the background image and their opacity is adjusted for example by means of suitable filters such that the frames gradually change from non-transparent to transparent.

[0077] In the video sequence of Figure 7, there are no image frames on the lower scalability layers during the first base layer image frame 700. For this time instant, the first image frame 700 is only coded into the video sequence.

[0078] The next image frame 706 of the base layer initiates a new (second) scene, during which the image frame 706 is provided with depth positioning that places it as the background image, and its opacity value is set to the maximum. Temporally simultaneously with the image frame 706 of the base layer, there is an image frame 702 of a terminating (first) scene on enhancement layer 1. To allow a cross-faded scene transition to be produced, the transparency of the frame 702 must be increased. The example of Figure 7 assumes that the opacity of the image frame 702 is set at 67% and, in addition,

the image frame 702 is provided with depth positioning that determines it as a foreground image. For this time instant, an image combining the image frames 706 and 702 is coded into the video sequence, image 706 being visible as a weaker image on the background and image 702 as a stronger image at the front, because its opacity value is essentially high (67%).

[0079] During the temporally following image frame, there is a second image frame 708 of the second scene on the base layer, the frame 708 being thus correspondingly provided with depth positioning determining it as a background image, and its opacity value is set to the maximum. Enhancement layer 1 further comprises the last image frame 704 of a temporally simultaneously terminating (first) scene, the opacity value of the frame being set at 33% and, in addition, the image frame 704 being provided with depth positioning that determines it as a foreground image as well. Consequently, for this time instant, an image combined of the image frames 708 and 704 is coded into the video sequence, the image 708 being displayed as a stronger image on the background and the image 704 as a weaker image on the foreground, because the opacity value of the image 704 is no longer more than 33%.

[0080] During the temporally following image frame, the base layer comprises a third image frame 710 of the second scene. Since the first scene has terminated, only the image frame 710 is coded into the video sequence, and the displaying of the second scene continues from the frame 710.

[0081] The above disclosure describes, by way of example, the positioning of image frames according to the invention on scalability layers to implement cross-faded scene transition in a manner that is advantageous from the point of view of coding efficiency. However, it is possible that when a video sequence is being transmitted or decoded, a situation arises in which the bit rate of the video sequence must be adjusted according to the maximum value of the bandwidth and/or terminal device decoding rate available for data transfer. This kind of bit rate control causes problems when the scene transition is to be implemented using prior art video coding methods.

[0082] A preferred embodiment of the present invention now allows one or more scalability layers, or independently decodable sub-sequences included in them, to be removed from a video sequence, whereby the bit rate of the video sequence can be decreased and yet, at the same time, the video sequence can be decoded without reducing image frequency. In the image

frame positioning according to Figure 7, this can be implemented by removing enhancement layer 1 from the video sequence. The video sequence is thus only used for displaying the image frames 700, 706, 708 and 710 of the base layer. In other words, a direct transition from the first (terminating) scene to the second (initiating) scene takes place in the form of an abrupt scene transition, i.e. directly from the image frame 700 of the first scene into the I-image frame 706 that initiates the second scene. The transition is thus not a cross-faded scene transition but an abrupt scene transition. Nevertheless, the scene transition can be carried out in an advantageous manner without affecting the quality of the video sequence image, and the viewer usually does not experience an abrupt scene transition carried out instead of a cross-faded scene transition in any way disturbing or faulty. On the contrary, since the prior art implementation does not allow scalability layers to be removed, scene transition would often require image frequency to be reduced, which the viewer would find jerky and disturbing.

[0083] The invention thus provides a preferred means for carrying out multimedia data traffic shaping in a streaming server comprising information about the different sub-sequences of a video sequence: their average bit rate, location in relation to the entire video sequence, duration and their interdependencies regarding the layers. The streaming server also determines the maximum value of the bandwidth available for the data transfer and/or the decoding rate of the terminal device. On the basis of this information, the streaming server decides how many scalability layers and which sub-sequences are transmitted in the video sequence. Bit rate control can thus be carried out, when necessary, by making first a rough adjustment of the number of the scalability layers, after which finer sub-sequence-specific adjustment can be easily carried out. At its simplest, bit rate control means making sub-sequence-specific decisions on whether a particular sub-sequence will be added to a video sequence or removed from it. In case of removal it is advisable to remove entire sub-sequences from a video sequence, because the removal of separate images may cause errors in other images of the same sub-sequence. For the same reason, all sub-sequences of a lower enhancement layer should be left out if they are dependent on the removed sub-sequence of a higher layer. If there are interdependent sub-sequences on one and the same scalability layer, sub-sequences dependent on an earlier sub-sequence must be removed if the earlier sub-sequence is removed.

[0084] If the image frame identifier data are added to a video sequence that is to be transmitted, traffic shaping can also be carried out in a telecommunications network element to be used for the transfer of the video sequence, for example in an Internet router, in different gateways, or at a base station or base station controller of a mobile communications network. For the network element to be able to maintain and process the sub-sequence information, it must have extra memory and processing capacity. For this reason traffic shaping that is to be carried out in the network is perhaps most probably executed using simple processing methods, such as the DiffServ, i.e. differentiated services, procedure that is supported by some IP-based networks. In the DiffServ method, each IP data packet is assigned a priority, whereby data packets of a higher priority are relayed faster and more reliably to the recipient than packets of a lower priority. This is advantageously applied to the scalability of the invention by determining not only scalability-layer-specific, but also sub-sequence-specific priorities, which enables a highly advanced priorisation.

[0085] There are many alternatives for adding image frame identifier data to a video sequence that is to be transmitted. In addition, it is also possible not to include any identifier data into the video sequence, in which case traffic shaping is only carried out at the streaming server. The identifier data can be included in the header fields of a video sequence, or in the header fields of the transfer protocol to be used, such as RTP (Real Time Protocol). According to a preferred embodiment, the identifier data can be transferred using a Supplemental Enhancement Information (SEI) mechanism. SEI provides a data delivery mechanism that is transferred synchronously with the video data content, thus assisting in the decoding and displaying of the video sequence. The SEI mechanism, particularly when used for transferring layer and sub-sequence information, is disclosed more in detail in the ITU-T standard document ITU-T Rec. H.264 (ISO/IEC 14496 – 10:2002), Annex D. In the cases, wherein a separate transfer protocol or mechanism is used for identifier data transfer, traffic shaping can be carried out also at one of the network elements of the transfer path. In addition, the receiving terminal device can control the decoding.

[0086] If the encoder or decoder supports reference picture selection, video sequence coding requires that decoded image frames be buffered before the coding so as to allow the relationships between different

image frames to be temporally predicted from one or more other image frames. Image frame buffering can be arranged at least in two different ways, either as sliding windowing or as adaptive buffer memory control. In sliding windowing, M image frames that were coded last are used as a buffer. The frames in the buffer memory are in a decoded and reconstructed form, which allows them to be used as reference images in the coding. As the coding proceeds, the image frame buffering functions on the basis of the FIFO principle (First-In-First-Out). Images that are not used as reference images, such as conventional B-images, do not need to be stored in the buffer. Alternatively, the buffering can be also be implemented as adaptive buffer memory control, in which case the image buffering is not restricted to the FIFO principle, but image frames that are not needed can be removed from the buffer in the middle of the process, or, correspondingly, some image frames can be stored in the buffer for a longer period of time, if they are needed as reference images for later image frames. A known reference picture selection is implemented by indexing image frames that are in the buffer memory into a specific order, the image indices being then used to refer to an image in connection with motion-compensation, for example. This indexing method generally provides better compression efficiency compared to using image numbers, for example, for referring to a specific image when motion-compensation reference images are to be signalled.

[0087] The above reference image indexing method is sensitive to transfer errors, because the buffers of the sender's encoder and the recipient's decoder must contain mutually corresponding reconstructed images in identical order to ensure that the encoder and decoder both form the same indexing order. If the image frames are indexed in different order in the buffers of the encoder and the decoder, an incorrect reference image may be used in the decoder. To prevent this, it is essential that the decoder can be controlled to take into account image frames and sub-sequences that the encoder has intentionally removed from the video sequence. In that case the image frame numbering may comprise gaps, which the decoder typically interprets as errors and tries to reconstruct the image frames interpreted as lost. For this reason, it is essential that the encoder is capable to inform the decoder that the discontinuities in the image numbering of the transmitted image frames are intentional.

[0088] In response to this, and provided that sliding windowing is used for buffering the image frames, the decoder enters into the buffer memory a number of image frames, the contents of which may be fully random, corresponding to the missing image numbers. These random image frames are then designated by an identifier "invalid" to indicate that the frames in question do not belong to the actual video sequence, but are only filler frames entered for purposes of buffer memory management. A filler frame can naturally be implemented using only memory indicators, i.e. no data is preferably entered into the buffer memory, but memory management is used merely to store a reference to a generic "invalid" frame. The entering of the image frames of the actual video sequence continues from the correct image frame number after the number of filler frames indicated by the missing image numbers has been entered into the buffer, which allows the buffer memories of the encoder and the decoder to be kept preferably in synchronism. If during decoding a reference to an image number is detected which is then found to indicate a filler frame located in the buffer, error correction actions are initiated in the decoder to reconstruct the actual reference image, for example by asking the encoder to re-transmit the reference image in question.

[0089] Further, the procedure of the invention allows separate buffer memories to be used on the different scalability layers, or, correspondingly, sub-sequence-specifically. Each scalability layer may thus have a separate buffer memory that is conceptually separate and functions on the basis of the sliding window principle. Similarly, each sub-sequence may also be provided with a conceptually separate buffer memory that also functions on the basis of the sliding window principle. This means that the buffer memory is always emptied when a sub-sequence terminates. Separate buffer memories can be used in a preferred manner for reducing the need for signalling in certain situations in which ordinary sliding window buffering would be inadequate and actively adaptive buffer memory management would need to be used instead.

[0090] The H.26L standard defines a picture order count as a picture position in output order. The decoding process specified in the H.26L standard uses picture order counts to determine default index orderings for reference pictures in B slices, to represent picture order differences between frames and fields for vector scaling in motion vector prediction and for implicit mode weighted prediction in B slices, and to determine when successive slices

in decoding order belong to different pictures. The picture order count is coded and transmitted for each picture.

[0091] In one embodiment of the invention, the decoder uses the picture order count to conclude that pictures are temporally overlapping, i.e., pictures that have an equal picture order count are temporally overlapping. Preferably, the decoder outputs only the picture on the highest received layer. In the absence of layer information, the decoder concludes that the latest temporally overlapping picture in decoding order resides on highest received layer.

[0092] The above disclosure describes a procedure for coding video frames for the purpose of producing a scalable, compressed video sequence. The actual procedure is carried out in a video encoder, such as the compressor 108 of Figure 1, which may be any known video encoder. For example a video encoder according to the ITU-T recommendation H.263 or H.26L may be used, the video encoder being arranged to form, in accordance with the invention, a first sub-sequence into a video sequence, at least part of the sub-sequence being formed by coding I-frames; to form at least a second sub-sequence into the video sequence, at least part of the sub-sequence being formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence being predicted from at least one video frame of the first sub-sequence; and to determine into the video sequence the identification data of at least the video frames of the second sub-sequence.

[0093] According to the procedure of the invention, each sub-sequence of a particular scalability layer is preferably independently decodable, naturally taking into account dependencies from higher scalability layers and possibly other sub-sequences of the same scalability layer. A scalably compressed video sequence such as the one described above can thus be decoded by decoding a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding at least I-frames, and by decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence, and by determining the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence, and by

reconstructing at least part of the video sequence on the basis of the sub-sequence dependencies.

[0094] The actual decoding takes places in the video decoder, such as the decompressor 118 of Figure 1, which may be any known video decoder. For example, a low bit rate video decoder according to the ITU-T recommendation H.263 or H.26L may be used, which in this invention is arranged to decode a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding I-frames; to decode at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. The video decoder is arranged to determine the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence and to reconstruct at least part of the video sequence on the basis of the dependencies of the sub-sequences.

[0095] An essential aspect in the operation of the streaming system of the invention is that the encoder and decoder are positioned at least so that the encoder is operationally connected to the streaming server and the decoder is operationally connected to the receiving terminal device. However, the different elements of the streaming system, terminal devices in particular, may include functionalities that allow two-way transfer of multimedia files, i.e. transmission and reception. The encoder and decoder can thus be implemented in the form of what it known as a video codec integrating both encoder and decoder functionalities.

[0096] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

[0097] Another alternative is to implement the invention as a video signal comprising a scalably compressed video sequence which in turn comprises video frames coded according to at least a first and a second frame format, the video frames according to the first frame format being independent of other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames. According to the invention, the video signal in question comprises at least a first sub-sequence, at least part of which has been formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format; and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field that determines video frames belonging to the second sub-sequence.

[0098] It is apparent to a person skilled in the art that as technology advances the basic idea of the invention can be implemented in various ways. The invention and its embodiments are therefore not restricted to the above examples, but they may vary within the scope of the claims.

CLAIMS

1. A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

forming into the video sequence at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and

forming into the video sequence at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence; and

forming into the video sequence information indicating which video frames belong to the second sub-sequence.

2. A method according to claim 1, **characterized** by comprising the steps of

determining into the video sequence the interdependency between at least the video frames of the second sub-sequence and at least one video frame of the first sub-sequence.

3. A method according to claim 2, **characterized** by comprising the steps of

coding the video sequence into a plural number of scalability layers; and

determining the dependency of the video frames of the second sub-sequence such that at least one video frame of the second sub-sequence is predicted from a group comprising

a video frame of a higher scalability layer,

a video frame of another sub-sequence in the same scalability layer.

4. A method according to claim 3, **characterized** by comprising the step of

determining the dependencies of the video frames of the second sub-sequence on the basis of at least a scalability layer identifier and a sub-sequence identifier.

5. A method according to claim 3 or 4, **characterized** by comprising the step of

coding the first scalability layer of the video sequence to comprise video frames according to one frame format, each one of the frames forming a separate sub-sequence.

6. A method according to claim 3 or 4, **characterized** by comprising the step of

coding the first scalability layer of the video sequence to comprise video frames according to both the first and the second frame format.

7. A method according to claim 3, **characterized** by comprising the step of

determining a unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number.

8. A method according to claim 3, **characterized** by comprising the step of

determining a unique identifier for each video frame on the basis of the image number.

9. A method according to claim 7 or 8, **characterized** by comprising the step of

adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence.

10. A method according to any one of the preceding claims, **characterized** in that

the video frames of the first frame format are I-frames and the video frames of the second frame format are temporally forward and/or backward predicted P-frames, which have been predicted using at least one reference image.

11. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the sub-sequences in such a way that at least some of the sub-sequence frames are temporally at least partly overlapping.

12. A method according to any one of the preceding claims, **characterized** by comprising the step of

coding the video frames in such a way that the temporal predicting taking place between the video frames is block- or macroblock-specific.

13. An element in a streaming system, such as a streaming server or a network element in a telecommunications system, which is arranged to transmit compressed video sequences to at least one terminal device and to control the bit rate of the video sequence transmission, **characterized** in that

the element is arranged to control the bit rate of a video sequence transmission in which a first sub-sequence of the video sequence comprises video frames of at least a first frame format and at least a second sub-sequence comprises video frames of at least a second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

the bit rate control being arranged to be carried out in at least one of the following ways:

at least one sub-sequence is removed from the video sequence,

at least one sub-sequence is added to the video sequence.

14. A video encoder for forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video encoder is arranged to

form into the video sequence a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format; and to

form into the video sequence at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and to

form into the video sequence information indicating which video frames belong the second sub-sequence.

15. A method for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the

other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** by comprising the steps of

decoding a first sub-sequence of the video sequence, at least part of the first sub-sequence being formed by coding at least video frames of the first frame format;

decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence being formed by coding at least video frames of the second frame format, at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determining dependency data relating at least to the video frames comprised by the second sub-sequence of the video sequence; and

reconstructing at least part of the video sequence on the basis of the dependencies of the sub-sequences.

16. A method according to claim 15, wherein video frames are entered into a sliding buffer memory in connection with decoding, **characterized** by comprising the steps of

decoding from the video sequence an indication informing that the discontinuities in the numbering of the images of the image frames in the video sequence are intentional;

configuring, in response to the indication, the buffer memory to comprise a number of image frames corresponding to the missing image numbers; and

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to comprise the number of image frames corresponding to the missing image numbers.

17. A method according to claim 16, **characterized** by comprising the step of

entering into the buffer memory a number of filler frames corresponding to the missing image numbers.

18. A method according to any one of claims 15 to 17, **characterized** by comprising the step of

decoding the video sequence by removing at least one independently decodable sub-sequence from the video sequence.

19. A method according to any one claims 15 to 18, **characterized** by comprising the steps of

initiating the decoding from a random point in the video sequence;

determining an independently decodable sub-sequence that is next after the random point, and

setting the value of the image number of the first video frame in the sub-sequence at zero.

20. A method according to any one claims 15 to 19, **characterized** by comprising the steps of

identifying at least partly temporally overlapping sub-sequence frames from the video sequence based on the picture order count information, and

outputting from the decoder the last image frame in the decoding order, said frame being selected from a group of said at least partly temporally overlapping image frames.

21. A video decoder for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the video decoder is arranged to

decode a first sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the first frame format;

decode at least a second sub-sequence of the video sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence;

determine the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

reconstruct at least part of the video sequence on the basis of the dependency of the sub-sequences.

22. A computer program for coding video frames so as to form a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the

other video frames, **characterized** in that the computer program comprises

a program code for forming a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for forming at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining data into the video sequence to determine which video frames belong to the second sub-sequence.

23. A computer program for decoding a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames, **characterized** in that the computer program comprises

a program code for decoding a first sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the first frame format; and

a program code for decoding at least a second sub-sequence of the video sequence, at least part of the sub-sequence being formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

a program code for determining the dependency data of at least the video frames comprised by the second sub-sequence of the video sequence; and

a program code for reconstructing at least part of the video sequence on the basis of the dependency of the sub-sequences.

24. A video signal comprising a scalably compressed video sequence comprising video frames coded according to at least a first and a second frame format, the video frames of the first frame format being independent of the other video frames, and the video frames of the second

frame format being predicted from at least one of the other video frames, **characterized** in that the video signal comprises

a first sub-sequence, at least part of which is formed by coding at least video frames of the first frame format;

at least a second sub-sequence, at least part of which is formed by coding at least video frames of the second frame format, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and

at least one data field determining the video frames that belong to the second sub-sequence.

1. INTRODUCTION

The enhanced GOP concept introduced in JVT-B042 was adopted to the JVT coding standard in the second JVT meeting. The enhanced GOP concept organizes pictures in layers and sub-sequences. A sub-sequence represents a number of inter-dependent pictures that can be disposed without affecting the decoding of any other sub-sequence in less enhanced layers. The enhanced GOP concept was proposed for unequal error protection and rate shaping purposes in streaming servers. Consequently, the concept required support only in the file storage format. JVT-B042 included the changes regarding the interim file format in the working draft. No changes in the JVT syntax were seen necessary at that time.

JVT-C080 proposed a couple of applications that could utilize transmission of enhanced GOP information. However, the JVT did not consider these applications as important enough to justify the inclusion of the enhanced GOP feature in the syntax and semantics of the NAL units. Since the Fairfax meeting, we found a couple of other use cases where the transmitted enhanced GOP information would be beneficial. We present these use cases in this contribution.

The contribution is organized as follows: Section 2 summarizes the use cases for signaling of layers and sub-sequences within the coded data stream. Section 3 presents the proposed changes relative to the JVT CD. Section 4 presents one of the uses, namely the Multimedia Messaging Service.

Proposed agenda category: improvements & enhancements

Keywords for agenda allocation: high-level syntax and semantics

2. USE CASES FOR ENHANCED GOP SIGNALING

We have identified the following applications for signaling of layers and sub-sequences within the coded data stream:

- Identification of coded data in out-of-decoding-order transmission and recovery of decoding order from transmission order. The out-of-decoding-order transmission can be used to smooth out bit-rate and delay variations, and to have more time for

retransmissions of subjectively most important data in streaming systems. See JVT-D093 for details.

- Identification of random access, splicing, and editing operations. See JVT-D097 for details.
- Signaling the reference frames of sync pictures as explained in JVT-D101.
- Signaling of bit-rate-scalable bit-streams when transmitting a file from an encoder to a streaming server. This can be utilized in the Multimedia Messaging Service (MMS) of mobile networks, for example. See section 4 for details.
- Computational scalability in decoders. As explained in JVT-C080, sometimes there is no file or stream suitable for decoder's computational capabilities available, while a very demanding stream or file has to be used. In multitasking systems the processing power is shared between multiple processes, and therefore the performance of the video decoder may fluctuate depending on the number and complexity of other tasks executed simultaneously.
- A video communication gateway may sometimes have to tune the bit-rate of a coded video stream. The abilities of bit-rate control methods for coded data are limited. Thus, it is advantageous to carry enhanced GOP information in systems where bit-rate control of coded video is desired. Gateways may decide to forward only certain layers or they may decide to discard one sub-sequence to drop the bit-rate.

3. PROPOSED CHANGES IN THE JVT CD

3.1 Definitions

The following definitions are to be inserted to section 3 of the JVT standard:

3.QQ sub-sequence layer: A sub-sequence layer contains a subset of the pictures in a coded data stream. A sub-sequence layer is characterized by an average bit-rate and an average frame rate. Sub-sequence layers can be ordered hierarchically based on their dependency on each other, i.e., layer 0 is independently decodable, pictures in layer 1 may be predicted from layer 0, pictures in layer 2 may be predicted from layers 0 and 1, etc. The subjective quality increases along with the number of decoded layers. A layer having a larger layer number is a higher layer than a layer having a smaller layer number.

3.QQ sub-sequence: A set of pictures that cover a certain period of time within the sequence. The presentation times of pictures in different sub-sequences can overlap partly or entirely. A picture shall reside in one layer and in one sub-sequence only. A sub-sequence shall not depend on any other sub-sequence in the same or in a higher sub-sequence layer. A sub-sequence in layer 0 can be decoded independently of any other sub-sequences and previous long-term reference pictures.

3.2 Parameter Set

The following parameter is added to the parameter set:

num_layers	0	e(v)

num_layers 0 indicates that no layer number or sub-sequence identifier is present in slice headers. Value 1 indicates that no layer number is present in slice headers but sub-sequence identifiers are included in slice headers. Values greater than 2 indicate that the layer number field is present in slice headers.

3.3 Picture-Layer Data

The following parameters are added to the picture layer. If there will be no picture layer in the JVT standard, the parameters may either reside in the slice header or in the parameter set.

if (num_layers > 1)		
layer_num	3	e(v)
if (num_layers > 0)		
subsequence_id	3	e(v)

layer_num indicates the sub-sequence layer number of the picture.

subsequence_id identifies the sub-sequence within a layer. Consecutive sub-sequences in transmission order shall have a different subsequence_id from each other.

3.4 Supplemental Enhancement Information

The characteristics of layers and sub-sequences as well as dependency information of sub-sequences may be used in sub-sequence-based editing operations. We think that Supplemental Enhancement Information is a correct transport mechanism for this type of information. The presented notation is not aligned to the notation of the JVT CD due to lack of time, but a straightforward conversion can be easily done later.

Layer Information

```
while (more_data_in_SEI_payload()) {
   unsigned int(32) avgBitRate;
   unsigned int(32) avgFrameRate;
}
```

The structure above is repeated until the size of the SEI payload is reached. The first instance of the structure signals the data for layer 0. The second instance of the structure signals the data for layer 1 and so on.

avgBitRate gives the average bit-rate in bits/second of the layer. All NAL units of the layer are taken into account in the calculation. Value zero means an undefined bit-rate.

avgFrameRate gives the average frame rate in frames/(256 seconds) of the layer. Value zero means an undefined frame rate.

The values are in effect from the point they are transmitted until an update of the values is transmitted.

Sub-Sequence Information

```
{
   uvlc layerNumber;
   uvlc subSequenceIdentifer;
   uvlc pictureNumber;
```

```
   uvlc parameterSetAddress;
   unsigned int(64) ssDuration;
   unsigned int(32) avgBitRate;
   unsigned int(32) avgFrameRate;
   uvlc numReferencedSubSequences;
   for (i = 0; i < numReferencedSubSequences; i++) {
      uvlc layerNumber;
      uvlc subSequenceIdentifier;
}
```

One structure as above exists per one SEI message.

layerNumber and subSequenceIdentifier identify the sub-sequence.

pictureNumber identifies the first picture of the sub-sequence.

ssDuration indicates the duration of the sub-sequence. ssDuration equal to zero indicates an undefined duration. The clock frequency for ssDuration is fetched from the parameter set indicated by parameterSetAddress.

avgBitRate gives the average bit-rate in bits/second of the sub-sequence. All NALPs of the sub-sequence are taken into account in the calculation. Value zero means an undefined bit-rate.

avgFrameRate gives the average frame rate in frames/(256 seconds) of the sub-sequence within the segment. Value zero means an undefined frame rate.

numReferencedSubSequences gives the number of directly referenced sub-sequences. The following loop lists the referenced sub-sequences, i.e., layerNumber and subSequenceIdentifier within the loop identify a sub-sequence that is used as a motion compensation reference for the current sub-sequence.

3.5 Decoder Process

Normative decoding process for some of the applications has been proposed in JVT-D093, JVT-D097, and JVT-D101. For the other presented applications, the decoder process is non-normative. The following text may be inserted to a non-normative part of the JVT standard:

The decoder may decide not to decode a certain layer having layer number n. In such a case, the decoder shall not decode any slice having a layer number greater than n and any slice in other sub-sequence that has a same layer number.

The decoder may decide not to decode a certain sub-sequence lies in layer n and have sub-sequence identifier m. In practice, the decoder shall not decode any slice having a layer number equal to n and a sub-sequence identifier equal to m. Once the decoder has received a Sub-Sequence Information SEI message concerning a sub-sequence in layer n and having the sub-sequence identifier m but starting from a different picture number than the discarded sub-sequence, the decoder should stop discarding slices having layer number n and sub-sequence identifier m.

3.6 Other Syntax Design Alternatives

It could be argued that layer numbers and sub-sequence identifiers could be conveyed in SEI messages. However, because some of the identified use cases require normative decoder process related to sub-sequence identifiers and because standard-compliant decoders may not support SEI messages, the SEI mechanism is not suitable.

Sub-sequences can but do not have to be organized into layers. Layers help to signal long-term characteristics of sub-sequence series. They also help signaling sub-sequence dependencies, as a sub-sequence can only depend on sub-sequences in lower layers. However, there is nothing that would mandate the use of layer numbers in slice headers, and therefore the layer number could be signaled as a part of an appropriate SEI message.

4. MULTIMEDIA MESSAGING SERVICE

This section presents the Multimedia Messaging Service (MMS), discusses video coding requirements for the service, and justifies why the enhanced GOP concept suits MMS.

4.1 Overview

The Multimedia Messaging Service (MMS) can be considered a continuation of the famous Short Message Service (SMS) of GSM mobile networks.

A simplified flow of operations in an MMS transaction is as follows: A user creates a message. For example, he can shoot a video clip with his mobile camera phone. After creating the message, he selects a receiver and sends the message. In practice, an audio-video message is stored according to the 3GPP flavor of the ISO media file format (.3GP) and uploaded to an MMS server using a reliable transport protocol. Then, depending on the capabilities of the receiver terminal, user preferences, and the capabilities of MMS network elements, the message is either downloaded or streamed to the receiving terminal.

MMS works in both 2G (GSM and its evolutions) and 3G mobile networks. Consequently, MMS streaming may take place through different types of mobile networks, such as GPRS or UMTS, which are further characterized by a variety of characteristics in the radio access network. Notice also that the downlink network characteristics are unknown when the message is being created. Moreover, the characteristics of the mobile network may change in a function of the location of the terminal and the number of terminals in a cell among other things. Consequently, the network throughput may be highly varying. In order to stream in real-time through a variable bit-rate connection, the MMS server should be able to adjust the media bit-rate easily.

It is expected that a majority of multimedia messages will be created in hand-held terminals. Generally, at least the following aspects of hand-held terminals limit the possibilities when creating multimedia messages:

- Processing power is limited compared to desktop computers.
- The amount of data and program memory is limited compared to desktop computers.
- Screen size is small compared to desktop computers.
- User interaction is typically limited to a relatively small keyboard.

4.2 JVT Video Coding for MMS

We believe that the JVT codec has good chances to become a mandatory video codec in a future evolution of MMS. Thus, it would be beneficial if the JVT codec provide tools that make it more suitable for MMS (compared to previous video coding standards, for example).

Due to the presented characteristics of MMS, we consider the following as key features of a video encoder:

- One-pass causal or nearly causal encoding in order to avoid storage of uncompressed frames in a device having limited storage space. (Herein, “causal” refers to encoding of a frame immediately after it is captured.)
- The encoder should output bit-rate-scalable files allowing the MMS server to shape the stream for different network conditions. The dynamic range of scalability should be large. We expect that a practical range of bit-rates is from 10 to 64 kbps in the short run and the range is likely to become broader in the long run.
- Fast encoding.
- Efficient compression.

One of the few bit-rate-scalability tools included in the JVT syntax is the possibility to discard non-stored frames. Conventional B frames provide efficient means for bit-rate-scalable coding, but their relevance decreases in low frame rates (used in very low bit rates expected in MMS), i.e., their compression efficiency drops in low frame rates. Conventional B frames require storage of uncompressed frames, their encoding requires more processing power and more memory than encoding of I and P frames, and the dynamic range of achievable bit-rates is limited, typically up to 50 % bit-rate reduction from the total bit-rate is achievable (in 25-30 Hz frame rates). Thus, we feel that other means for bit-rate-scalability would be desirable.

Encoders can achieve larger dynamics in bit-rate-scalability and use less memory than with conventional B frames when coding streams similar to the one depicted in Figure 1. “SP 6” (and “SP 12”) boxes indicate identical representations of frame 6 (and 12 respectively) based on different reference frames. A streaming server decides which coded SP frame is transmitted based on the temporal resolution of the previously transmitted section of the bitstream. The encoder may switch to a lower or higher temporal resolution after such an SP frame. The compression efficiency of these kinds of coding schemes is nearly as good as in a non-scalable coding scheme as shown in VCEG-M73.

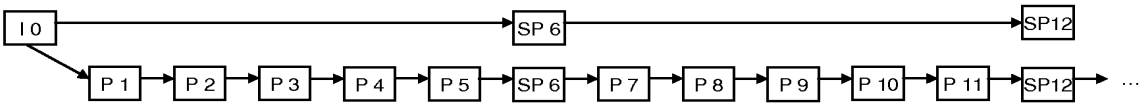

Figure 1. Temporal scalability for rate shaping.

It was shown in JVT-B042 that the enhanced GOP concept is optimal for signaling the dependencies of coding scenarios such as the one shown in Figure 1. As audio-video files are uploaded using the ISO media file format, the enhanced GOP concept should be ideally conveyed as metadata in the file format. Thus, in order to ensure the support of enhanced GOP concept in MMS, we propose adding the enhanced GOP signaling possibility into the JVT syntax.

JVT Patent Disclosure Form

International Telecommunication Union
Telecommunication Standardization Sector

International Organization for Standardization

International Electrotechnical Commission

Joint Video Coding Experts Group - *Patent Disclosure Form*

(Typically one per contribution and one per Standard | Recommendation)

Please send to:
JVT Rapporteur Gary Sullivan, Microsoft Corp., One Microsoft Way, Bldg. 9, Redmond WA 98052-6399, USA
Email (preferred): Gary.Sullivan@itu.int Fax: +1 425 706 7329 (+1 425 70MSFAX)

This form provides the ITU-T | ISO/IEC Joint Video Coding Experts Group (JVT) with information about the patent status of techniques used in or proposed for incorporation in a Recommendation | Standard. JVT requires that all technical contributions be accompanied with this form. *Anyone* with knowledge of any patent affecting the use of JVT work, of their own or of any other entity ("third parties"), is strongly encouraged to submit this form as well.

This information will be maintained in a "living list" by JVT during the progress of their work, on a best effort basis. If a given technical proposal is not incorporated in a Recommendation | Standard, the relevant patent information will be removed from the "living list". The intent is that the JVT experts should know in advance of any patent issues with particular proposals or techniques, so that these may be addressed well before final approval.

This is not a binding legal document; it is provided to JVT for information only, on a best effort, good faith basis. Please submit corrected or updated forms if your knowledge or situation changes.

This form is *not* a substitute for the *ITU ISO IEC Patent Statement and Licensing Declaration*, which should be submitted by Patent Holders to the ITU TSB Director and ISO Secretary General before final approval.

Submitting Organization or Person:	
Organization name	**Nokia Corporation**
Mailing address	
Country	
Contact person	
Telephone	
Fax	
Email	
Place and date of submission	
**Relevant Recommendation	Standard and, if applicable, Contribution:**	
Name (ex: "JVT")	**JVT**
Title	**Signaling of Enhanced GOPs**
Contribution number	**JVT-D098**

(Form continues on next page)

Disclosure information – Submitting Organization/Person (choose one box)

☐ 2.0 The submitter is not aware of having any granted, pending, or planned patents associated with the technical content of the Recommendation | Standard or Contribution.

or,

The submitter (Patent Holder) has granted, pending, or planned patents associated with the technical content of the Recommendation | Standard or Contribution. In which case,

☐ 2.1 The Patent Holder is prepared to grant – on the basis of reciprocity for the above Recommendation | Standard – a free license to an unrestricted number of applicants on a worldwide, non-discriminatory basis to manufacture, use and/or sell implementations of the above Recommendation | Standard.

☐ 2.2 The Patent Holder is prepared to grant – on the basis of reciprocity for the above Recommendation | Standard – a license to an unrestricted number of applicants on a worldwide, non-discriminatory basis and on reasonable terms and conditions to manufacture, use and/ or sell implementations of the above Recommendation | Standard.

Such negotiations are left to the parties concerned and are performed outside the ITU | ISO/IEC.

☒ 2.2.1 The same as box 2.2 above, but in addition the Patent Holder is prepared to grant a "royalty-free" license to anyone on condition that all other patent holders do the same.

☐ 2.3 The Patent Holder is unwilling to grant licenses according to the provisions of either 2.1, 2.2, or 2.2.1 above. In this case, the following information must be provided as part of this declaration:

- patent registration/application number;
- an indication of which portions of the Recommendation | Standard are affected.
- a description of the patent claims covering the Recommendation | Standard;

*In the case of any box **other than 2.0** above, please provide the following:*

Patent number(s)/status _____

Inventor(s)/Assignee(s) _____

Relevance to JVT _____

Any other remarks: _____

(please provide attachments if more space is needed)

(form continues on next page)

Third party patent information – fill in based on your best knowledge of relevant patents granted, pending, or planned by other people or by organizations other than your own.

Disclosure information – Third Party Patents (choose one box)

☒ 3.1 The submitter is not aware of any granted, pending, or planned patents *held by third parties* associated with the technical content of the Recommendation | Standard or Contribution.

☐ 3.2 The submitter believes third parties may have granted, pending, or planned patents associated with the technical content of the Recommendation | Standard or Contribution.

For box 3.2, please provide as much information as is known (provide attachments if more space needed) - JVT will attempt to contact third parties to obtain more information:

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)(1)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311.

The items listed on the enclosed Form 1449 were first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of the information disclosure statement. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449. However, if fees are deemed necessary, authorization is given to charge Deposit Account 50-3581 (TPO.004.C1) for consideration of the information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), a copy of the non-U.S. patent/application documents listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that the reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,
HOLLINGSWORTH & FUNK, LLC
8500 Normandale Lake Blvd., Suite 320

TERMINAL DISCLAIMER INFORMAL CHECKLIST

APPL. S.N.: 11/338,996	**DATE:**
EXAMINER:	**ART UNIT:**
PARALEGAL: /FELICIA ROBERTS/	**MAIL ROOM DATE:**
NUMBER OF TD(s) FILED: 1	

INSTRUCTIONS: The paralegal has reviewed the submitted TD with the results as set forth below.
If you agree, please use the appropriate form paragraphs identified by this informal memo in your next Office action to notify applicant about the TD. If you disagree, please contact a QAS.

THIS CHECKLIST IS AN INFORMAL, INTERNAL CHECKLIST ONLY. IT MUST NOT BE MAILED TO APPLICANT. IT WILL BE SOFT SCANNED AND NOT VIEWABLE TO THE PUBLIC.

☐ The TD is PROPER and has been accepted and recorded. (See FP 14.23.)

☒ The TD is NOT PROPER and has not been accepted for the reason(s) checked below. (See FP 14.24.)

☐ The disclaimer fee under 37 CFR 1.20(d) in the amount of $ has not been submitted, nor is there any pre authorization in the application to charge to a deposit account. (See FP 14.24 and 14.26.07.)

☐ The LIE has not processed fee for TD (the Paralegal should ask LIE to process the fee).

☐ The TD does not satisfy 37 CFR 1.32(b) (3) in that the person who signed the TD has not stated either: (a) the extent of his/her ownership interest, or (b) the extent of the business/organization entity's ownership interest on whose behalf the person signed. (See FPs 14.26 and 14.26.01.)

☐ The TD lacks the – enforceable only during the period of common ownership – clause needed to overcome a double patenting 37 CFR 1.321(c). (See FP 14.27.01).

☐ The TD lacks 37 CFR 1.321(d) statement for joint research agreement under 35 U.S.C. 103(c) (2) & (3). It doesn't include the waiver and enforceability provisions of 37 CFR 1.321(d). (See FP 14.27.011.)

☐ TD is directed to a particular claim(s); this is not acceptable, since the disclaimer must be of a terminal portion of the entire patent to be granted, MPEP 1490. (See FPs 14.26 and 14.26.02).

☒ The person who signed the terminal disclaimer:

- ☐ failed to state his/her capacity to sign for the business/organization entity. (See FP 14.28.)
- ☐ is not recognized as an officer of the assignee. (See FP 14.29.)
- ☒ does not have power of attorney, and thus, is not of record. (See FP 14.29.01.)

(Note: PoA can be given to a customer number, wherein all practitioners listed under the customer number have PoA. If PoA is established by a list of practitioners, the list may not comprise more than 10 practitioners. A representative of the assignee, who is not of record, cannot sign the TD unless it is established that the representative is a party authorized to act on behalf of the assignee.)

☐ The TD is not supported by evidence of chain of title to the assignee signing the TD due to a failure to submit either: (a) documentary evidence of a chain of title from the original inventor(s) to the assignee and a statement affirming that the documentary evidence was, or concurrently is being, submitted for recordation; or (b) the reel and frame number(s) where such documentary evidence is recorded in the Office. 37 CFR 3.73(b). (See FPs 14.30 and 14.34)

NOTE: This documentary evidence or the specifying of the reel and frame number may be found in the TD or in a separate paper submitted by applicant.)

☐ The TD is not supported by adequate evidence of chain of title to the assignee signing the TD, because the person who signed the submission under 37 CFR 3.73(b):

☐ has failed to state his/her capacity to sign for the business entity. (See FPs 14.30.02 and 14.16.02

☐ is not recognized as an officer of the assignee. (See FP 14.30.02 and 14.16.03)

(Note: On the submission under 37 CFR 3.73(b), the signature of an attorney or agent registered to practice before the Office is not sufficient, unless the attorney or agent is authorized to act on behalf of the assignee.)

☐ The TD is not signed (See FPs 14.26 and 14.26.03)

☐ The serial number of the application (or the number of the patent) which forms the basis for the double patenting is not identified (i.e., missing or incorrect) in the TD. (See FP 14.32)

☐ The serial number of the application being examined (or the number of the patent under reexam or reissue) is not identified or incorrect. (See FPs 14.26 and 14.26.04 or 14.26.05)

☐ The TD is not signed by all owners. See FPs 14.26 and 14.26.06.

☐ The period disclaimed is incorrect or not specified. (See FPs 14.24, 14.27.02 or 14.27.03)

☐ Other

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action dated February 18, 2011, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1-25 remain pending in the application. Claims 1, 2, 10, 11, 18, and 19 have been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 8.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising:

decoding from the compressed video sequence an indication related to ~~at least one~~an intentional discontinuity of numbering of the image frames;

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to [[the]]at least one discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. (Currently amended) A method according to claim 1, wherein ~~said indication informs that~~ the at least one discontinuity in the numbering of the image frames in the video sequence is intentional.

3. (Previously presented) A method according to claim 1, further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

4. (Original) A method according to claim 1, wherein the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. (Previously presented) A method according to claim 1, further comprising

continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

6. (Previously presented) A method according to claim 1, further comprising

entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

7. (Previously presented) A method according to claim 6, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

8. (Previously presented) A method according to claim 1, wherein

configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. (Previously presented) A method according to claim 3, further comprising

detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image frame corresponding to the at least one discontinuity in the numbering of image frames.

10. (Currently amended) A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the compressed video sequence an indication related to ~~at least one~~an intentional discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to [[the]]at least one discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. (Currently amended) A video decoder according to claim 10, wherein

~~said indication informs that~~ the at least one discontinuity in the numbering of the image frames in the video sequence is intentional.

12. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

13. (Original) A video decoder according to claim 10, wherein

the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

continue the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

15. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

enter into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

16. (Previously presented) A video decoder according to claim 15, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

17. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

configure the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, the computer program product comprising:

a computer program code for decoding from the compressed video sequence an indication related to ~~at least one~~an intentional discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to [[the]]at least one discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. (Currently amended) A computer program product according to claim 18, wherein ~~said indication informs that~~ the at least one discontinuity in the numbering of the image frames in the video sequence is intentional.

20. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

21. (Original) A computer program product according to claim 18, the computer program product further comprising

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. (Previously presented) A computer program product according to claim 18, the computer program product further comprising

a computer program code for continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

23. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

24. (Previously presented) A computer program product according to claim 23, the computer program product further comprising:

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the compressed video sequence.

25. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

26-31. (Canceled)

REMARKS/ARGUMENTS

The reference to "Transitional After Final Practice" on page two of the Office action appears to be in error. Applicant notes that this application does not meet the timing requirements for Rule 1.129(a) and no such fee was paid. Applicant requests that these comments be withheld from further actions or that an explanation be provided.

The rejections presented in the Office action dated February 18, 2011 (hereinafter "Office action") have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

With particular respect to claims 3, 5-7, 9, 10, 12, 14-16, 18, and 20-25, Applicant notes that the claims are not included in any statement of rejection. MPEP § 707.07(d) indicates that where a claim is refused the word "reject" must be used and the statutory basis for any ground of rejection should be designated by an express reference in the opening sentence of each ground of rejection. While it appears that these claims were intended to be rejected on the same grounds as respective claims 1 and 18, these claims are believed to be allowable for the reasons set forth below in connection with claims 1 and 18. If this was not the Examiner's intention, Applicant requests clarification, an opportunity to respond, and that any future rejections comply with MPEP § 707.07(d).

Applicant appreciates the indication of allowability for claims 2, 11, and 19.

Consistent with the indication of allowable subject matter on page fourteen of the Office action, independent claims 1, 10, and 18 have been amended to include elements indicated as being directed to allowable subject matter in respective claims 2, 11, and 19. Therefore these changes do not introduce new matter. Each of the independent claims recites that an indication related to an intentional discontinuity of numbering in the image frames is decoded from the compressed video sequence. This is not recited with respect to the buffer memory configuration since the buffer memory is configured to take into account both intentional discontinuities and errors in the compressed video sequence. U.S. Patent No. 7,103,669 to Apostolopoulos (hereinafter "Apostolopoulos") fails to teach or suggest each of the now-claimed elements of the independent claims since Apostolopoulos discusses only discontinuities of numbering caused by errors. In view of these changes and the indication of

allowable subject matter, each of claims 1-25 is believed to be patentable over the asserted references.

Thus, based upon the Examiner's acknowledgement that elements now included in each of the pending claims are not found in Apostolopoulos, either alone or as modified, each of the prior art rejections would be improper. Applicant accordingly requests that each of the § 102(e) and § 103(a) rejections be withdrawn.

To the extent that the current response does not respond to any characterization in the Office action of the asserted art or of the claimed subject matter, or to any application in the Office action of the asserted art to any claimed subject matter, it is stated for the record that any such lack of response should not be interpreted as an acquiescence to such characterizations or applications. A detailed discussion of each of the Office action's characterizations, or any other assertions or statements beyond that provided above is unnecessary in view of the present response. The right to address in detail any such assertions or statements in the future is reserved.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C1) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the Examiner is invited to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

Filed:	January 25, 2006	Docket No.:	TPO.004.C1
Title:	GROUPING OF IMAGE FRAMES IN VIDEO CODING		

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311. Please charge Deposit Account 50-3581 (TPO.004.C1) the amount of $180.00 under 37 C.F.R. § 1.17(p) for consideration of the items.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *02 February 2011*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1,2,4-6,8-11,13 and 14* is/are pending in the application.

DETAILED ACTION

Transitional After Final Practice

1. Since this application is eligible for the transitional procedure of 37 CFR 1.129(a), and the fee set forth in 37 CFR 1.17(r) has been timely paid, the finality of the previous Office action is hereby withdrawn pursuant to 37 CFR 1.129(a). Applicant's first submission after final filed on 12/3/2011 has been entered.

Response to Arguments

2. Applicant's arguments, see page 8-9, filed on 12/3/2011, with respect to the rejections of claims 5-8 and 13 under 35 U.S.C. § 101 and claims 5-8 and 13 under 35 U.S.C. § 112, 1st paragraph have been fully considered and are persuasive. Therefore, the rejection has been withdrawn.

Claim Rejections - 35 USC § 112

3. The following is a quotation of the second paragraph of 35 U.S.C. 112:

> The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

4. Claims 1-2, 4-6, 8-11, 13-14 are rejected under 35 U.S.C. 112, second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention.

Independent claims 1, 5, 9-10, 13-14 all recite in the preamble a limitation "at least one reference image frame is predictable from at least one previous image frame,

and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order". As the limitation states, the reference image frame is predictable from a previous image frame, therefore, it is essential for the previous image frame to be decoded before it can use to predict the reference image frame. It is unclear when the reference image frame is decoded earlier than the previous image frame, it would not be predict from the previous image frame since the reference image frame is earlier in decoding order. As stated in the abstract of the instant application, "In the decoding phase, the indication of at least one image frame is decoded from the video sequence, and the decoding of the video sequence is started from **said first image frame of the independent sequence**, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame"; that is the first I frame of the sequence is always being decode first. Therefore, it is unclear what "at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order" means.

Independent claims 9-10, 13-14 all recite in the preamble a limitation "resetting the identifier value for the indicated first image frame of the independent sequence"; as disclose in paragraph 0018 of the publication of the instant application (2006/0120451 A1), the resetting step of the identifier value for the indicated first picture of an independent sequence is performed in the encoder, however, claims 9-11, 13-14 are

directed to a decoding, it is unclear how the decoder reset the identifier value of the indicated first image frame of the independent sequence.

Claim Rejections - 35 USC § 103

5. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

6. Claims 1 and 10 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 1:

(claim 1 is rejected without the consideration of the limitation in the preamble because of the 112 rejection as explained in above)

Apostolopoulos discloses an encoder comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame (encoded I1 frame as shown in figure 4), in decoding order, of the independent sequence (decoding of the P frames are depending on the I1 frame), said at least one reference image frame being included in the sequence (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

encoding identifier values for the image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65; the numbering scheme of odd 1,3,5….15 and even 2,4,6…).

Apostolopoulos fails to explicitly disclose resetting the identifier value for the indicated first image frame of the independent sequence.

However, each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

(2) Regarding claim 10:

(claim 10 is rejected without the consideration of the limitation in the preamble because of the 112 rejection as explained in above, the examiner interprets the resetting of the identifier values are reset in the encoder)

Apostolopoulos discloses a method for decoding comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame (the decoder decode the even frames and odd frames sequence, column 8, lines 40-49 as disclose in figure 4, the first frame is identified as an I1 frame for prediction of the following frames, column 9, lines 60-65), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (all the other P frames are depend on the I1 frame, therefore, no prediction is need from any image frame prior to I1, column 9, lines 60-65);

decoding identifier values for image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65).

Apostolopoulos fails to explicitly disclose resetting the identifier value for the indicated first image frame of the independent sequence.

However, each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

7. Claims 2 and 11 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) as applied to claims 1 and 10 above, and further in view of Yagasaki et al. (US 5,786,858).

Apostolopoulos discloses all subject matter as discussed in claim 10 except wherein the indication is a separate flag included in the header of a slice.

However, Yagasaki discloses putting a flag for indicating an intra-frame coded block in the slice header (column 10, line 65 – column 11, line 2).

It is desirable to have the indication is a separate flag included in the header of a slice because it prevents a decoding process of the entire bit stream for extraction of the flag (column 11, lines 1-2). Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Yagasaki in the decoder of Apostolopoulos to simplify the extraction process of the identifier.

8. Claims 5, 9, and 13-14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) as applied to claim 10 above, and further in view of Langberg et al. (US 5,852,630).

(1) Regarding claims 5 and 9:

Apostolopoulos discloses an encoder comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame (encoded I1 frame as shown in figure 4), in decoding order, of the independent sequence (decoding of the P frames are depending on the I1 frame), said at least one reference image frame being included in the sequence (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

encoding identifier values for the image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65; the numbering scheme of odd 1,3,5….15 and even 2,4,6…).

Apostolopoulos fails to explicitly disclose (a) resetting the identifier value for the indicated first image frame of the independent sequence; and (b) a computer program

product stored on a non-transitory computer readable medium and executable in a data processing device for implementing the method.

With respect to (a), each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

With respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system (processor) or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg et al. for implementing the decoding method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the encoder.

(2) Regarding claim 13 and 14:

Apostolopoulos discloses a method for decoding comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame (the decoder decode the even frames and odd frames sequence, column 8, lines 40-49 as disclose in figure 4, the first frame is identified as an I1 frame for prediction of the following frames, column 9, lines 60-65), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (all the other P frames are depend on the I1 frame, therefore, no prediction is need from any image frame prior to I1, column 9, lines 60-65);

decoding identifier values for image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65).

Apostolopoulos fails to explicitly disclose (a) resetting the identifier value for the indicated first image frame of the independent sequence; and (b) the decoder comprising at least one processor and at leas tone memory including computer program code to perform the method.

With respect to (a), each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to

represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

with respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system (processor) or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg et al. for implementing the decoding method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the decoder.

9. Claim 2 is rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) as applied to claim 10 above, and further in view of Yagasaki et al. (US 5,786,858).

Apostolopoulos discloses all subject matter as discussed in claim 10 except wherein the indication is a separate flag included in the header of a slice.

However, Yagasaki discloses putting a flag for indicating an intra-frame coded block in the slice header (column 10, line 65 – column 11, line 2).

It is desirable to have the indication is a separate flag included in the header of a slice because it prevents a decoding process of the entire bit stream for extraction of the flag (column 11, lines 1-2). Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Yagasaki in the decoder of Apostolopoulos to simplify the extraction process of the identifier.

10. Claim 6 is rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) in view of Langberg et al. (US 5,852,630) as applied to claim 5 above, and further in view of Yagasaki et al. (US 5,786,858).

Apostolopoulos and Langberg discloses all subject matter as discussed in claim 5 except wherein the indication is a separate flag included in the header of a slice.

However, Yagasaki discloses putting a flag for indicating an intra-frame coded block in the slice header (column 10, line 65 – column 11, line 2).

It is desirable to have the indication is a separate flag included in the header of a slice because it prevents a decoding process of the entire bit stream for extraction of the flag (column 11, lines 1-2). Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Yagasaki in the decoder of Apostolopoulos and Langberg to simplify the extraction process of the identifier.

Conclusion

11. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

Hasebe et al. (US 6,483,875 B1) discloses a picture signal processing apparatus.

Shinoda (US 5,680,322) discloses a method and apparatus for dynamic image data transmission.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE *3* MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *17 May 2011*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-25* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

DETAILED ACTION

Response to Arguments

1. Applicant's arguments with respect to claims 1-25 have been considered but are moot in view of the new ground(s) of rejection based on new interpretation of Apostolopoulos (US 7,103,669 B2).

Claim Objections

2. Claims 2, 11, and 19 are objected to under 37 CFR 1.75(c), as being of improper dependent form for failing to further limit the subject matter of previous claims 1, 10, and 18 respectively. Applicant is required to cancel the claims, or amend the claims to place the claims in proper dependent form, or rewrite the claims in independent form.

Claim Rejections - 35 USC § 102

3. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

4. Claims 1-3, 5-7, 9-12, 14-16 are rejected under 35 U.S.C. 102(e) as being anticipated by Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 1:

Apostolopoulos disclose a method for decoding a compressed video sequence (odd number sequence ort even number sequence), wherein image frames are entered into a buffer memory in connection with the decoding (decode 322 in figure 5 enter the decoded frame into the frame memory including the previous decoded frames as shown in figure 5), the method comprising:

decoding from the compressed video sequence an indication (detected error that one of the frame (for example P5 as discussed in column 10, lines 52-63) is unable to be retrieved due to packet loss) related to an intentional discontinuity of numbering of the image frame (the packet is decoded in step 914 and a determination is made whether an error has been detected, when an error is detected, state recovery is performed by employing previous and future frames of correctly decoded frames, column 7, lines 9-37; the examiner interprets the detected error is related to the intentional discontinuity (frames in subsequence of the even frames that is missing from the subsequence of the odd frames) since the error rate is reconstruct by interpolation or estimation based on the odd frame);

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the art least one discontinuity in the numbering of the image frames (the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, full frame versions of P2, P4, and P6 through P14, as well we P1 and P3 in the buffer memory are use in the decoding process).

(2) Regarding claim 10:

Apostolopoulos discloses a video decoder (multiple state video decoding 128 in figure 1 comprises decode block 320 and 322 as shown in figure 5) for decoding a compressed video sequence, the video decoder being connected to a buffer memory (frame memory as shown in figure 5) wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the compressed video sequence an indication (detected error that one of the frame (for example P5 as discussed in column 10, lines 52-63) is unable to be retrieved due to packet loss) related to an intentional discontinuity of numbering of the image frames (the packet is decoded in step 914 and a determination is made whether an error has been detected, when an error is detected, state recovery is performed by employing previous and future frames of correctly decoded frames, column 7, lines 9-37; the examiner interprets the detected error is related to the intentional discontinuity (frames in subsequence of the even frames that is missing from the subsequence of the odd frames)

since the error rate is reconstruct by interpolation or estimation based on the odd frame); and

use the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, full frame versions of P2, P4, and P6 through P14, as well we P1 and P3 in the buffer memory are use in the decoding process).

(3) Regarding claims 3 and 12:

Apostolopoulos further disclose using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets “do not exist at a decoder due to the at least one discontinuity in the numbering of the image frame" as due to the error occur in the transmission of the encoded odd frame and prevent the decode block from properly reconstructing P_5, therefore there is a discontinuity in the numbering of image frame, column 9, lines 66-67).

(4) Regarding claim 9:

Apostolopoulos further disclose detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image

frame corresponding to the at least one discontinuity in the numbering of image frames (the error occur in the transmission of the encoded odd frame and prevent the decode block from properly reconstructing P_5, therefore there is a discontinuity in the numbering of image frame, column 9, lines 66-67).

(5) Regarding claims 5 and 14:

Apostolopoulos further disclose continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (the receiver 332 includes a state recovery 526 for recovering the lost P-frame P5 of the stream 354 using the information provided by the stream 356, the recovery of P5 enables the decode block 322 to continue with its prediction loop by correctly updating its state information and reconstruct p7 to P13, column 10, lines 55-60; as the frames are correctly decode by the decoder, frames are enter into the frame memory as a previous decoded frames as shown in figure 5).

(6) Regarding claims 6 and 15:

Apostolopoulos further discloses entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets the correctly decode frame that replace the lost frame as the claimed “filler frame”).

(7) Regarding claims 7 and 16:

Apostolopoulos further discloses wherein said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; therefore an odd frame can be replace by an even frame, wherein the even frame number (identifier) indicates that the filler frame do not belong to the odd frame sequence).

(8) Regarding claim 2 and 11:

Apostolopoulos further discloses the at least one discontinuity in the numbering of the image frames in the video sequence is intentional (the discontinuity in the odd frame sequence (even frame is missing) is intentional for the purpose of path diversity, therefore, it is intentional, abstract).

Claim Rejections - 35 USC § 103

5. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

6. Claims 18-25 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) in view of Langberg (US 5,852,630).

(1) Regarding claim 18:

Apostolopoulos disclose a method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding (decode 322 in figure 5 enter the decoded frame into the frame memory including the previous decoded frames as shown in figure 5), the method comprising:

decoding from the compressed video sequence an indication (detected error that one of the frame (for example P5 as discussed in column 10, lines 52-63) is unable to be retrieved due to packet loss) related to an intentional discontinuity of numbering of the image frame (the packet is decoded in step 914 and a determination is made whether an error has been detected, when an error is detected, state recovery is performed by employing previous and future frames of correctly decoded frames, column 7, lines 9-37; the examiner interprets the detected error is related to the intentional discontinuity (frames in subsequence of the even frames that is missing from the subsequence of the odd frames) since the error rate is reconstruct by interpolation or estimation based on the odd frame); and

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the art least one discontinuity in the numbering of the image frames (the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, full frame versions of P2, P4, and P6 through P14, as well we P1 and P3 in the buffer memory are use in the decoding process).

Apostolopoulos discloses all of the subject matter as described above except for the method is perform by a computer program product, stored on a non-transitory computer readable medium and executable in a data processing device.

However, Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg for

implementing the method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 20:

Apostolopoulos further disclose using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets “do not exist at a decoder due to the at least one discontinuity in the numbering of the image frame" as due to the error occur in the transmission of the encoded odd frame and prevent the decode block from properly reconstructing P_5, therefore there is a discontinuity in the numbering of image frame, column 9, lines 66-67).

(3) Regarding claim 21:

Apostolopoulos disclose all subject matter as discussed in claim 1 but fails to explicitly disclose wherein the number of image frames in the buffer memory is used in sliding widow buffering of image frames.

However, as shown in figure 5, decoded frame as input into the frame memory as previous decode frames, these frames are used for recovery of a lost frame (recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstructed full frame versions of P2, P4, P6 through P14 as well as P1 and P3, column 11, lines 14-18), therefore, the frame memory have to store the decoded frame P2 to P14 in the frame memory on the even frame number sequence and obviously, the frame

memory have to store the decoded frame P1 to P13 in the frame memory on the odd frame number sequence, therefore, the examiner interprets the frame memory are used in sliding window buffering of the decode image frame.

It is desirable to have the number of image frames in the buffer memory are used in sliding widow buffering of image frames because the buffer of image frame is need for recovering of a full frame version of a lost frame and provide the benefit of increase the image quality of the recovered video sequence.

(4) Regarding claim 22:

Apostolopoulos further disclose continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (the receiver 332 includes a state recovery 526 for recovering the lost P-frame P5 of the stream 354 using the information provided by the stream 356, the recovery of P5 enables the decode block 322 to continue with its prediction loop by correctly updating its state information and reconstruct p7 to P13, column 10, lines 55-60; as the frames are correctly decode by the decoder, frames are enter into the frame memory as a previous decoded frames as shown in figure 5; the number of image frames corresponding to the at least one discontinuity are the correctly decoded even frames).

(5) Regarding claim 23:

Apostolopoulos further discloses entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; the examiner interprets the correctly decode frame that replace the lost frame as the claimed "filler frame").

(6) Regarding claim 24:

Apostolopoulos further discloses wherein said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence (the lost frame may be estimated by replacing it by another correctly decoded frame, column 11, lines 48-49; therefore an odd frame can be replace by an even frame, wherein the even frame number (identifier) indicates that the filler frame do not belong to the odd frame sequence).

(7) Regarding claim 25:

Apostolopoulos further discloses wherein configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by frame number, whereby no data is entered into the buffer memory (past and future frames with respect to the lost frame P5 to recover frame P5, column 10, lines 60-63, as the past and future frames are identified by frame number and when the decoder cannot decode P5, the decode block 322 cannot reconstruct P5 to P13, therefore, no data is entered into the buffer memory (frame memory that store previous decoded frames)).

Apostolopoulos fails to disclose using memory indications for reconstruction of a lost frame.

However, as shown in figure 5, the correctly decoded frames are storage in the frame memory as previous decoded frames. Therefore, it would have been obvious to one of ordinary skill in the art to modify the invention Apostolopoulos to use memory indication (location) for locating future frames in the even frame number sequence and past frame in the odd frame number sequence for reconstruction of the lose frame since using the frame number and memory location are interchangeable to one of ordinary skill in the art.

(8) Regarding claim 19:

Apostolopoulos further discloses the at least one discontinuity in the numbering of the image frames in the video sequence is intentional (the discontinuity in the odd frame sequence (even frame is missing) is intentional for the purpose of path diversity, therefore, it is intentional, abstract).

7. Claims 4, 8, 13, and 17 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 4 and 13:

Apostolopoulos disclose all subject matter as discussed in claim 1 but fails to explicitly disclose wherein the number of image frames in the buffer memory is used in sliding widow buffering of image frames.

However, as shown in figure 5, decoded frame as input into the frame memory as previous decode frames, these frames are used for recovery of a lost

frame (recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstructed full frame versions of P2, P4, P6 through P14 as well as P1 and P3, column 11, lines 14-18), therefore, the frame memory have to store the decoded frame P2 to P14 in the frame memory on the even frame number sequence and obviously, the frame memory have to store the decoded frame P1 to P13 in the frame memory on the odd frame number sequence, therefore, the examiner interprets the frame memory are used in sliding window buffering of the decode image frame.

It is desirable to have the number of image frames in the buffer memory are used in sliding widow buffering of image frames because the buffer of image frame is need for recovering of a full frame version of a lost frame and provide the benefit of increase the image quality of the recovered video sequence.

(2) Regarding claims 8 and 17:

Apostolopoulos further discloses wherein configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by frame number, whereby no data is entered into the buffer memory (past and future frames with respect to the lost frame P5 to recover frame P5, column 10, lines 60-63, as the past and future frames are identified by frame number and when the decoder cannot decode P5, the decode block 322 cannot reconstruct P5 to P13, therefore, no data is entered into the buffer memory (frame memory that store previous decoded frames)).

Apostolopoulos fails to disclose using memory indications for reconstruction of a lost frame.

However, as shown in figure 5, the correctly decoded frames are storage in the frame memory as previous decoded frames. Therefore, it would have been obvious to one of ordinary skill in the art to modify the invention Apostolopoulos to use memory indication (location) for locating future frames in the even frame number sequence and past frame in the odd frame number sequence for reconstruction of the lose frame since using the frame number and memory location are interchangeable to one of ordinary skill in the art.

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 6:15-3:45 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

Subject: Private PAIR Correspondence Notification for Customer Number 10888

Aug 09, 2011 05:22:55 AM

Dear PAIR Customer:

Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437
UNITED STATES

The following USPTO patent application(s) associated with your Customer Number, 10888 , have new outgoing correspondence. This correspondence is now available for viewing in Private PAIR.

The official date of notification of the outgoing correspondence will be indicated on the form PTOL-90 accompanying the correspondence.

Disclaimer:
The list of documents shown below is provided as a courtesy and is not part of the official file wrapper. The content of the images shown in PAIR is the official record.

DATE MAILED: 08/18/2011

APPLICATION NO.	FILING DATE	FIRST NAMED INVENTOR	ATTORNEY DOCKET NO.	CONFIRMATION NO.
11/338,934	01/25/2006	Miska Hannuksela	TPO.004.C2	6610

TITLE OF INVENTION: GROUPING OF IMAGE FRAMES IN VIDEO CODING

APPLN. TYPE	SMALL ENTITY	ISSUE FEE DUE	PUBLICATION FEE DUE	PREV. PAID ISSUE FEE	TOTAL FEE(S) DUE	DATE DUE
nonprovisional	NO	$1510	$300	$0	$1810	11/18/2011

THE APPLICATION IDENTIFIED ABOVE HAS BEEN EXAMINED AND IS ALLOWED FOR ISSUANCE AS A PATENT. PROSECUTION ON THE MERITS IS CLOSED. THIS NOTICE OF ALLOWANCE IS NOT A GRANT OF PATENT RIGHTS. THIS APPLICATION IS SUBJECT TO WITHDRAWAL FROM ISSUE AT THE INITIATIVE OF THE OFFICE OR UPON PETITION BY THE APPLICANT. SEE 37 CFR 1.313 AND MPEP 1308.

THE ISSUE FEE AND PUBLICATION FEE (IF REQUIRED) MUST BE PAID WITHIN THREE MONTHS FROM THE MAILING DATE OF THIS NOTICE OR THIS APPLICATION SHALL BE REGARDED AS ABANDONED. THIS STATUTORY PERIOD CANNOT BE EXTENDED. SEE 35 U.S.C. 151. THE ISSUE FEE DUE INDICATED ABOVE DOES NOT REFLECT A CREDIT FOR ANY PREVIOUSLY PAID ISSUE FEE IN THIS APPLICATION. IF AN ISSUE FEE HAS PREVIOUSLY BEEN PAID IN THIS APPLICATION (AS SHOWN ABOVE), THE RETURN OF PART B OF THIS FORM WILL BE CONSIDERED A REQUEST TO REAPPLY THE PREVIOUSLY PAID ISSUE FEE TOWARD THE ISSUE FEE NOW DUE.

HOW TO REPLY TO THIS NOTICE:

I. Review the SMALL ENTITY status shown above.

If the SMALL ENTITY is shown as YES, verify your current SMALL ENTITY status:

A. If the status is the same, pay the TOTAL FEE(S) DUE shown above.

B. If the status above is to be removed, check box 5b on Part B - Fee(s) Transmittal and pay the PUBLICATION FEE (if required) and twice the amount of the ISSUE FEE shown above, or

If the SMALL ENTITY is shown as NO:

A. Pay TOTAL FEE(S) DUE shown above, or

B. If applicant claimed SMALL ENTITY status before, or is now claiming SMALL ENTITY status, check box 5a on Part B - Fee(s) Transmittal and pay the PUBLICATION FEE (if required) and 1/2 the ISSUE FEE shown above.

II. PART B - FEE(S) TRANSMITTAL, or its equivalent, must be completed and returned to the United States Patent and Trademark Office (USPTO) with your ISSUE FEE and PUBLICATION FEE (if required). If you are charging the fee(s) to your deposit account, section "4b" of Part B - Fee(s) Transmittal should be completed and an extra copy of the form should be submitted. If an equivalent of Part B is filed, a request to reapply a previously paid issue fee must be clearly made, and delays in processing may occur due to the difficulty in recognizing the paper as an equivalent of Part B.

III. All communications regarding this application must give the application number. Please direct all communications prior to issuance to Mail Stop ISSUE FEE unless advised to the contrary.

IMPORTANT REMINDER: Utility patents issuing on applications filed on or after Dec. 12, 1980 may require payment of maintenance fees. It is patentee's responsibility to ensure timely payment of maintenance fees when due.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), to: Mail **Mail Stop ISSUE FEE**
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450
or Fax (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence including the Patent, advance orders and notification of maintenance fees will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications.

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

10888 7590 08/18/2011
Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

Certificate of Mailing or Transmission
I hereby certify that this Fee(s) Transmittal is being deposited with the United States Postal Service with sufficient postage for first class mail in an envelope addressed to the Mail Stop ISSUE FEE address above, or being facsimile transmitted to the USPTO (571) 273-2885, on the date indicated below.

1. Change of correspondence address or indication of "Fee Address" (37 CFR 1.363).
- ❑ Change of correspondence address (or Change of Correspondence Address form PTO/SB/122) attached.
- ❑ "Fee Address" indication (or "Fee Address" Indication form PTO/SB/47; Rev 03-02 or more recent) attached. **Use of a Customer Number is required.**

2. For printing on the patent front page, list
(1) the names of up to 3 registered patent attorneys or agents OR, alternatively,
(2) the name of a single firm (having as a member a registered attorney or agent) and the names of up to 2 registered patent attorneys or agents. If no name is listed, no name will be printed.
1 _____
2 _____
3 _____

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)

PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document has been filed for recordation as set forth in 37 CFR 3.11. Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE (B) RESIDENCE: (CITY and STATE OR COUNTRY)

Please check the appropriate assignee category or categories (will not be printed on the patent) : ❑ Individual ❑ Corporation or other private group entity ❑ Government

4a. The following fee(s) are submitted:
- ❑ Issue Fee
- ❑ Publication Fee (No small entity discount permitted)
- ❑ Advance Order - # of Copies _____

4b. Payment of Fee(s): **(Please first reapply any previously paid issue fee shown above)**
- ❑ A check is enclosed.
- ❑ Payment by credit card. Form PTO-2038 is attached.
- ❑ The Director is hereby authorized to charge the required fee(s), any deficiency, or credit any overpayment, to Deposit Account Number _____ (enclose an extra copy of this form).

5. **Change in Entity Status** (from status indicated above)
- ❑ a. Applicant claims SMALL ENTITY status. See 37 CFR 1.27.
- ❑ b. Applicant is no longer claiming SMALL ENTITY status. See 37 CFR 1.27(g)(2).

NOTE: The Issue Fee and Publication Fee (if required) will not be accepted from anyone other than the applicant; a registered attorney or agent; or the assignee or other party in interest as shown by the records of the United States Patent and Trademark Office.

Authorized Signature _____ Date _____

Typed or printed name _____ Registration No. _____

This collection of information is required by 37 CFR 1.311. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, Virginia 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450.

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

DATE MAILED: 08/18/2011

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b)
(application filed on or after May 29, 2000)

The Patent Term Adjustment to date is 1107 day(s). If the issue fee is paid on the date that is three months after the mailing date of this notice and the patent issues on the Tuesday before the date that is 28 weeks (six and a half months) after the mailing date of this notice, the Patent Term Adjustment will be 1107 day(s).

If a Continued Prosecution Application (CPA) was filed in the above-identified application, the filing date that determines Patent Term Adjustment is the filing date of the most recent CPA.

Applicant will be able to obtain more detailed information by accessing the Patent Application Information Retrieval (PAIR) WEB site (http://pair.uspto.gov).

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Customer Service Center of the Office of Patent Publication at 1-(888)-786-0101 or (571)-272-4200.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

	9. ☐ Other _____.

DETAILED ACTION

Allowable Subject Matter

1. Claims 1-2, 4-6, 8-11, and 13-14 are allowed.

2. The following is an examiner's statement of reasons for allowance:

(1) Regarding claims 1-2, 4-6, and 8-9:

The present invention describes a method, encoder and a computer program product for encoding a video sequence comprising an independent sequence of image frames, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence, the method comprising encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence; encoding identifier values for the image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of the independent sequence. The closest prior art, Apostolopoulos (US 7,103,669 B2) discloses a similar method but fails to disclose encoding identifier values for the image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of the independent sequence. This distinct feature has been added to the independent claims 1, 5, and 9, thus rendering claims 1-2, 4-6, and 8-9 allowable.

(2) Regarding claims 10-11, 13-14:

The present invention describes a method, decoder, and a computer program product for decoding a compressed video sequence, comprising decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence; starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; decoding identifier values for image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of the independent sequence. The closest prior art, Apostolopoulos (US 7,103,669 B2) discloses a similar method but fails to disclose starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; decoding identifier values for image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of the independent sequence. This distinct feature has been added to independent claims 10, 13 and 14, thus rendering claims 10-11 and 13-14 allowable.

Any comments considered necessary by applicant must be submitted no later than the payment of the issue fee and, to avoid processing delays, should preferably

accompany the issue fee. Such submissions should be clearly labeled “Comments on Statement of Reasons for Allowance.”

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 6:15-3:45 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner’s supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed March 4, 2011, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1, 2, 4-6, 8-11, 13, and 14 remain pending in the application. Claims 1, 5, 9, 10, 13, and 14 have been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 7.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for encoding a video sequence comprising an independent sequence of image frames, wherein ~~at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order~~all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence, the method comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence~~, said at least one reference image frame being included in the sequence~~;

encoding identifier values for the image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of the independent sequence.

2. (Original) A method according to claim 1, further comprising:

encoding the indication into the video sequence as a separate flag included in the header of a slice.

3. (Canceled)

4. (Original) A method according to claim 1, further comprising:

encoding into the video sequence an identifier value for the independent sequence.

5. (Currently amended) A video encoder comprising at least one processor and at least one memory including computer program code, the at least one memory and the computer program code configured to, with the at least one processor, cause the video encoder to

encode a video sequence comprising an independent sequence of image frames, wherein ~~at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order~~all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence by causing the video encoder to at least:

encode into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence~~, said at least one reference image frame being included in the sequence~~;

encode identifier values for the image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of the independent sequence.

6. (Previously presented) A video encoder according to claim 5, wherein the video encoder is configured to

encode the indication into the video sequence as a separate flag included in the header of a slice.

7. (Canceled)

8. (Previously presented) A video encoder according to claim 5, wherein the video encoder is configured to

encode into the video sequence an identifier value for the independent sequence.

9. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for encoding a video sequence comprising an independent sequence of image frames, wherein ~~at least one reference image frame is predictable from at least one previous image frame and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order~~all

motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence, the computer program product comprising:

a computer program code for encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence~~, said at least one reference image frame being included in the sequence~~;

a computer code for encoding identifier values for the image frames according to a numbering scheme; and

a computer code for resetting the identifier value for the indicated first image frame of the independent sequence.

10. (Currently amended) A method for decoding a compressed video sequence, ~~wherein at least one reference image frame is predictable from at least one previous image frame and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order,~~ the method comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, [[said]]wherein all motion-compensated temporal prediction references of the independent sequence ~~including the at least one reference~~refer only to image ~~frame~~frames within said independent sequence;

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

decoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of the independent sequence.

11. (Original) A method according to claim 10, wherein the indication is a separate flag included in the header of a slice.

12. (Canceled)

13. (Currently amended) A video decoder comprising at least one processor and at least one memory including computer program code, the at least one memory and the computer program code configured to, with the at least one processor, cause the video decoder to decode a compressed video sequence, ~~wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order~~ by causing the video decoder to at least:

decode from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, [[said]]wherein all motion-compensated temporal prediction references of the independent sequence ~~including the at least one reference~~refer only to image ~~frame~~frames within said independent sequence;

start the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; and

decode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of the independent sequence.

14. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, ~~wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order,~~ the computer program product comprising:

a computer program code for decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, [[said]]wherein all motion-compensated temporal prediction references of the

independent sequence ~~including the at least one reference~~refer only to image ~~frame~~frames within said independent sequence;

a computer program code for starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

a computer program code for decoding identifier values for image frames according to a numbering scheme; and

a computer program code for resetting the identifier value for the indicated first image frame of the independent sequence.

15-16. (Canceled)

REMARKS/ARGUMENTS

The reference to "Transitional After Final Practice" on page two of the Office action appears to be in error. Applicant notes that this application does not meet the timing requirements for Rule 1.129(a) and no such fee was paid. Applicant requests that these comments be withheld from further actions or that an explanation be provided.

The rejections presented in the Office action dated March 4, 2011 (hereinafter "Office action") have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

With respect to the § 112, second paragraph, rejection of the independent claims, each of the independent claims has been amended to remove the objected-to language. The language has been rewritten to characterize that "all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence". Since these changes merely re-characterize the original claim language, the changes do not introduce new matter. With particular respect to claims 9, 10, 13, and 14, Applicant notes that the identified language directed to "resetting" is located in the bodies, not the preambles, of these claims. In contrast to the assertion, claim 9 is directed to encoding. Moreover, discussion of these elements in the decoder may be found in the original specification, for example, at paragraph [0057] (using the numbering of U.S. Publication No. 2006/0120451). In view of the above, the claims particularly point out and distinctly claim the intended subject matter, and Applicant requests that the rejection be withdrawn.

Applicant respectfully traverses each of the §103(a) rejections based primarily upon the teachings of U.S. Patent No. 7,103,669 to Apostolopoulos (hereinafter "Apostolopoulos") because Apostolopoulos does not teach or suggest each of the claimed elements. For example, Apostolopoulos does not teach or suggest at least encoding into the video sequence, or decoding, an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, as claimed in each of the independent claims. Notably, Apostolopoulos does not discuss browsing a video file from a

random point and the discontinuities typically occurring in the image numbering due to such random access.

The present invention is directed to signaling to a decoder which video frame is to be decoded first as part of an independently decodable sequence of image frames, especially if there is another I-frame in the middle of the independently decodable sequence. This is discussed in paragraphs [0012-0013, 0056] (using the numbering of U.S. Publication No. 2006/0120451). Paragraph [0057] describes that there is encoded an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence (GOP), wherein all motion-compensated temporal prediction references of the independent sequence refer only to image frames within said independent sequence, identifier values for the image frames are encoded according to a numbering scheme, and the identifier value for the indicated first image frame of the independent sequence is reset at zero.

In contrast, Apostolopoulos does not disclose or address such issues. In Apostolopoulos, a video stream is divided in two video streams, even frames encoded in a first stream and odd frame encoded in a second stream. The two streams are transmitted via separate transmission paths, decoded at reception and then combined into a complete video stream. Apostolopoulos addresses when a video file that is to be reproduced is detected to contain an error that interrupts the playback or requires the playback to be resumed from a point following the error. However, to solve this problem, Apostolopoulos suggests that if a frame is missing at the decoder, the decoding of that particular video stream is halted until the next I-frame of the video stream is received (Col. 9, line 60 – Col. 10, line 8). Thus, there is no indication, as claimed. Rather, if such an indication were included in the video stream, the decoder would immediately know where to start the decoding.

In addition, the Examiner acknowledges that Apostolopoulos does not disclose "resetting the identifier value for the indicated first image frame of the independent sequence". The assertion that such resetting would be obvious for a skilled person when aiming to prevent using an extra bit to represent higher frame numbers, is entirely unsupported. Moreover, the purpose of resetting the identifier value is not to reduce the

amount of data to be transmitted to the decoder, but to (in combination with the indication) allow the decoder to interpret the image numbers correctly and to find the correct image frame that initiates the sub-sequence from the video sequence image frames (previously cited paragraph [0057]). Without a presentation of correspondence to each of the claimed elements, each of the § 103(a) rejections is improper.

By similar reasoning, the dependent claims are also not obvious in view of the asserted references, whether each reference is considered alone or the references are considered in combination. Applicant respectfully requests withdrawal of the rejections of claims 1, 2, 4-6, 8-11, 13, and 14 and submits that all claims are in condition for allowance.

To the extent that the current response does not respond to any characterization in the Office action of the asserted art or of the claimed subject matter, or to any application in the Office action of the asserted art to any claimed subject matter, it is stated for the record that any such lack of response should not be interpreted as an acquiescence to such characterizations or applications. A detailed discussion of each of the Examiner's characterizations, or any other assertions or statements beyond that provided above is unnecessary in view of the present response. The right to address in detail any such assertions or statements in the future is reserved.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C2) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the Examiner is invited to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311. Please charge Deposit Account 50-3581 (TPO.004.C2) the amount of $180.00 under 37 C.F.R. § 1.17(p) for consideration of the items.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)(1)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311.

The items listed on the enclosed Form 1449 were first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of the information disclosure statement. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449. However, if fees are deemed necessary, authorization is given to charge Deposit Account 50-3581 (TPO.004.C2) for consideration of the information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), a copy of the non-U.S. patent/application documents listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that the reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.116

Mail Stop AF
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed December 3, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.116.

Claims 1, 2, 4-6, 8-11, 13, and 14 remain pending in the application. Claims 1, 5, 9, 10, 13, and 14 have been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE SPECIFICATION begin on page 2.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 3 of this paper.

REMARKS/ARGUMENTS begin on page 8.

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *02 February 2011*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1,2,4-6,8-11,13 and 14* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *1,2,4-6,8-11,13 and 14* is/are rejected.

7)☐ Claim(s) _____ is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *1/25/2006* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

DETAILED ACTION

Transitional After Final Practice

1. Since this application is eligible for the transitional procedure of 37 CFR 1.129(a), and the fee set forth in 37 CFR 1.17(r) has been timely paid, the finality of the previous Office action is hereby withdrawn pursuant to 37 CFR 1.129(a). Applicant's first submission after final filed on 12/3/2011 has been entered.

Response to Arguments

2. Applicant's arguments, see page 8-9, filed on 12/3/2011, with respect to the rejections of claims 5-8 and 13 under 35 U.S.C. § 101 and claims 5-8 and 13 under 35 U.S.C. § 112, 1st paragraph have been fully considered and are persuasive. Therefore, the rejection has been withdrawn.

Claim Rejections - 35 USC § 112

3. The following is a quotation of the second paragraph of 35 U.S.C. 112:

> The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

4. Claims 1-2, 4-6, 8-11, 13-14 are rejected under 35 U.S.C. 112, second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention.

Independent claims 1, 5, 9-10, 13-14 all recite in the preamble a limitation "at least one reference image frame is predictable from at least one previous image frame,

and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order". As the limitation states, the reference image frame is predictable from a previous image frame, therefore, it is essential for the previous image frame to be decoded before it can use to predict the reference image frame. It is unclear when the reference image frame is decoded earlier than the previous image frame, it would not be predict from the previous image frame since the reference image frame is earlier in decoding order. As stated in the abstract of the instant application, "In the decoding phase, the indication of at least one image frame is decoded from the video sequence, and the decoding of the video sequence is started from **said first image frame of the independent sequence**, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame"; that is the first I frame of the sequence is always being decode first. Therefore, it is unclear what "at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order" means.

Independent claims 9-10, 13-14 all recite in the preamble a limitation "resetting the identifier value for the indicated first image frame of the independent sequence"; as disclose in paragraph 0018 of the publication of the instant application (2006/0120451 A1), the resetting step of the identifier value for the indicated first picture of an independent sequence is performed in the encoder, however, claims 9-11, 13-14 are

directed to a decoding, it is unclear how the decoder reset the identifier value of the indicated first image frame of the independent sequence.

Claim Rejections - 35 USC § 103

5. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

6. Claims 1 and 10 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 1:

(claim 1 is rejected without the consideration of the limitation in the preamble because of the 112 rejection as explained in above)

Apostolopoulos discloses an encoder comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame (encoded I1 frame as shown in figure 4), in decoding order, of the independent sequence (decoding of the P frames are depending on the I1 frame), said at least one reference image frame being included in the sequence (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

encoding identifier values for the image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65; the numbering scheme of odd 1,3,5….15 and even 2,4,6…).

Apostolopoulos fails to explicitly disclose resetting the identifier value for the indicated first image frame of the independent sequence.

However, each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

(2) Regarding claim 10:

(claim 10 is rejected without the consideration of the limitation in the preamble because of the 112 rejection as explained in above, the examiner interprets the resetting of the identifier values are reset in the encoder)

Apostolopoulos discloses a method for decoding comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame (the decoder decode the even frames and odd frames sequence, column 8, lines 40-49 as disclose in figure 4, the first frame is identified as an I1 frame for prediction of the following frames, column 9, lines 60-65), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (all the other P frames are depend on the I1 frame, therefore, no prediction is need from any image frame prior to I1, column 9, lines 60-65);

decoding identifier values for image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65).

Apostolopoulos fails to explicitly disclose resetting the identifier value for the indicated first image frame of the independent sequence.

However, each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

7. Claims 2 and 11 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) as applied to claims 1 and 10 above, and further in view of Yagasaki et al. (US 5,786,858).

Apostolopoulos discloses all subject matter as discussed in claim 10 except wherein the indication is a separate flag included in the header of a slice.

However, Yagasaki discloses putting a flag for indicating an intra-frame coded block in the slice header (column 10, line 65 – column 11, line 2).

It is desirable to have the indication is a separate flag included in the header of a slice because it prevents a decoding process of the entire bit stream for extraction of the flag (column 11, lines 1-2). Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Yagasaki in the decoder of Apostolopoulos to simplify the extraction process of the identifier.

8. Claims 5, 9, and 13-14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) as applied to claim 10 above, and further in view of Langberg et al. (US 5,852,630).

(1) Regarding claims 5 and 9:

Apostolopoulos discloses an encoder comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame (encoded I1 frame as shown in figure 4), in decoding order, of the independent sequence (decoding of the P frames are depending on the I1 frame), said at least one reference image frame being included in the sequence (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

encoding identifier values for the image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65; the numbering scheme of odd 1,3,5….15 and even 2,4,6…).

Apostolopoulos fails to explicitly disclose (a) resetting the identifier value for the indicated first image frame of the independent sequence; and (b) a computer program

product stored on a non-transitory computer readable medium and executable in a data processing device for implementing the method.

With respect to (a), each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

With respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system (processor) or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg et al. for implementing the decoding method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the encoder.

(2) Regarding claim 13 and 14:

Apostolopoulos discloses a method for decoding comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame (the decoder decode the even frames and odd frames sequence, column 8, lines 40-49 as disclose in figure 4, the first frame is identified as an I1 frame for prediction of the following frames, column 9, lines 60-65), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (all P frames are predict from I1 frame, the examiner interprets the claimed at least one reference image frame as one of the P frames as shown in figure 4);

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (all the other P frames are depend on the I1 frame, therefore, no prediction is need from any image frame prior to I1, column 9, lines 60-65);

decoding identifier values for image frames according to a numbering scheme (the P frames are decoded sequentially from I1, column 9, lines 60-65).

Apostolopoulos fails to explicitly disclose (a) resetting the identifier value for the indicated first image frame of the independent sequence; and (b) the decoder comprising at least one processor and at leas tone memory including computer program code to perform the method.

With respect to (a), each sequence that is encoded is independent and it would have been obvious to one of ordinary skill in the art that it is not necessary to incrementing the identifier of the first image frame because it prevent using extra bit to

represent a higher number of identifier and reduce the amount of data to be transmitted to the decoder.

with respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system (processor) or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg et al. for implementing the decoding method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the decoder.

9. Claim 2 is rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) as applied to claim 10 above, and further in view of Yagasaki et al. (US 5,786,858).

Apostolopoulos discloses all subject matter as discussed in claim 10 except wherein the indication is a separate flag included in the header of a slice.

However, Yagasaki discloses putting a flag for indicating an intra-frame coded block in the slice header (column 10, line 65 – column 11, line 2).

It is desirable to have the indication is a separate flag included in the header of a slice because it prevents a decoding process of the entire bit stream for extraction of the flag (column 11, lines 1-2). Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Yagasaki in the decoder of Apostolopoulos to simplify the extraction process of the identifier.

10. Claim 6 is rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) in view of Langberg et al. (US 5,852,630) as applied to claim 5 above, and further in view of Yagasaki et al. (US 5,786,858).

Apostolopoulos and Langberg discloses all subject matter as discussed in claim 5 except wherein the indication is a separate flag included in the header of a slice.

However, Yagasaki discloses putting a flag for indicating an intra-frame coded block in the slice header (column 10, line 65 – column 11, line 2).

It is desirable to have the indication is a separate flag included in the header of a slice because it prevents a decoding process of the entire bit stream for extraction of the flag (column 11, lines 1-2). Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Yagasaki in the decoder of Apostolopoulos and Langberg to simplify the extraction process of the identifier.

Conclusion

11. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

Hasebe et al. (US 6,483,875 B1) discloses a picture signal processing apparatus.

Shinoda (US 5,680,322) discloses a method and apparatus for dynamic image data transmission.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Subject: Private PAIR Correspondence Notification for Customer Number 10888

Mar 04, 2011 06:00:56 AM

Dear PAIR Customer:

Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437
UNITED STATES

The following USPTO patent application(s) associated with your Customer Number, 10888 , have new outgoing correspondence. This correspondence is now available for viewing in Private PAIR.

The official date of notification of the outgoing correspondence will be indicated on the form PTOL-90 accompanying the correspondence.

Disclaimer:
The list of documents shown below is provided as a courtesy and is not part of the official file wrapper. The content of the images shown in PAIR is the official record.

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.116

Mail Stop AF
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed December 3, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.116.

Claims 1, 2, 4-6, 8-11, 13, and 14 remain pending in the application. Claims 1, 5, 9, 10, 13, and 14 have been amended. No claims have been added or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE SPECIFICATION begin on page 2.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 3 of this paper.

REMARKS/ARGUMENTS begin on page 8.

AMENDMENTS TO THE SPECIFICATION

Please amend the paragraph at page 33, lines 6-16, of the original specification as indicated below.

[0097] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by ~~means of software, by~~ hardware solutions[[,]] or as a combination of ~~the two~~hardware and software. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

AMENDMENTS TO THE CLAIMS

Applicant respectfully requests that the amendments presented below be entered and that this listing of claims replace all prior versions of claims in the application.

1. (Currently amended) A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

encoding identifier values for the image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of [[an]]the independent sequence.

2. (Original) A method according to claim 1, further comprising:

encoding the indication into the video sequence as a separate flag included in the header of a slice.

3. (Canceled)

4. (Original) A method according to claim 1, further comprising:

encoding into the video sequence an identifier value for the independent sequence.

5. (Currently amended) A video encoder ~~for encoding~~comprising at least one processor and at least one memory including computer program code, the at least one memory and the computer program code configured to, with the at least one processor, cause the video

encoder to encode a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order~~, the video encoder being configured to~~by causing the video encoder to at least:

encode into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

encode identifier values for the image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of [[an]]the independent sequence.

6. (Previously presented) A video encoder according to claim 5, wherein the video encoder is configured to

encode the indication into the video sequence as a separate flag included in the header of a slice.

7. (Canceled)

8. (Previously presented) A video encoder according to claim 5, wherein the video encoder is configured to

encode into the video sequence an identifier value for the independent sequence.

9. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order, the computer program product comprising:

a computer program code for encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

a computer code for encoding identifier values for the image frames according to a numbering scheme; and

a computer code for resetting the identifier value for the indicated first image frame of [[an]]the independent sequence.

10. (Currently amended) A method for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order, the method comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame;

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

decoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of [[an]]the independent sequence.

11. (Original) A method according to claim 10, wherein the indication is a separate flag included in the header of a slice.

12. (Canceled)

13. (Currently amended) A video decoder ~~for decoding~~comprising at least one processor and at least one memory including computer program code, the at least one memory and the

computer program code configured to, with the at least one processor, cause the video decoder to decode a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order~~, the video decoder being configured to~~by causing the video decoder to at least:

decode from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame;

start the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; and

decode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of [[an]]the independent sequence.

14. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order, the computer program product comprising:

a computer program code for decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame;

a computer program code for starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

a computer program code for decoding identifier values for image frames according to a numbering scheme; and

a computer program code for resetting the identifier value for the indicated first image frame of [[an]]the independent sequence.

15-16. (Canceled)

REMARKS/ARGUMENTS

The rejections presented in the Office action dated December 3, 2010 (hereinafter Office Action) have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

With respect to the objection to claims 1, 2, 4-6, 8, 10, and 11, claims 1, 5, and 9 have been amended to provide explicit antecedent basis for "the image frames" in accordance with the Examiner's suggestions. Also, claims 1, 5, 9, and 10 have been amended to provide explicit antecedent basis for the claimed independent sequence. Although not identified in the statement of objection, claims 13 and 14 have also been amended to provide explicit antecedent basis for the claimed independent sequence. These changes are believed to overcome the objection; therefore, Applicant requests that the objection be removed.

In view of the above, at least claims 1, 2, 4, 9-11, and 14 are now believed to be in condition for allowance, and Applicant accordingly requests that these claims be allowed consistent with the assertions at page seven *et seq*.

With respect to the § 101 rejections of claims 5, 6, 8, and 13, Applicant respectfully traverses. As acknowledged at page ten of the Office action, claims 5 and 13 are directed to components. While the specification also refers to embodiments involving computer readable media storing program code (*e.g.*, claims 9 and 14), the claimed encoder and decoder are devices constituting statutory subject matter. The terms "encoder" and "decoder" are well-known in the art to refer to a device or circuit. Notably, the specification illustrates structural components of the encoder (*e.g.*, compressor 108 and multiplexer 110) and decoder (*e.g.*, demultiplexer 116 and decompressor 118). Paragraph [0095] teaches examples of a decoder including a low bit rate video decoder as described in the ITU-T recommendation H.263 or H.26L. Moreover, paragraph [0096] describes positioning of the encoder and decoder that would not be possible if they were only software. However, paragraph [0097] has also been amended to remove an interpretation of the claimed encoder and decoder as being software only. Since the claimed encoder and

decoder are directed to statutory subject matter, Applicant requests that the rejection be withdrawn.

With respect to the § 112, first paragraph, rejection of claims 5, 6, 8, and 13, independent claims 5 and 13 have been amended to recite that the respective encoder and decoder comprise at least one processor and at least one memory. Support for these changes may be found in the original specification, for example, at paragraphs [0088], [0089], [0093], [0096], and [0097]; therefore, these changes do not introduce new matter. Since the device claims each recite more than a single component, the rejection is believed to be overcome. Applicant accordingly requests that the rejection be withdrawn.

In view of the above, Applicant believes each of the pending claims is in condition for allowance and requests that the application be allowed.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C2) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the Examiner is invited to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111
If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371
If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office
If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE *3* MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *17 September 2010*.

2a)☒ This action is **FINAL**. 2b)☐ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1,2,4-6,8-11,13 and 14* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *5,6,8 and 13* is/are rejected.

7)☒ Claim(s) *1,2,4,9-11 and 14* is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *25 January 2006* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☒ Certified copies of the priority documents have been received in Application No. 10/306,942.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

DETAILED ACTION

Response to Arguments

1. Applicant's arguments with respect to the 35 U.S.C. 101 rejection of claims 5-8 and 13, filed 9/17/2010 have been fully considered but they are not persuasive.

Applicant's argument:

The claimed encoder and decoder are well known in the art to refer to a device or circuit; the specification illustrates structural component of the encoder (e.g. compressor 108 and multiplexer 110) and decoder (e.g. demultiplexer 116 and decompressor 118). Paragraph 0095 teaches example of a decoder including a low bit rate video decoder as described in the ITU-T recommendation H.263 or H.26L. Moreover, paragraph 0096 describes positioning of the encoder and decoder that would not be possible if they were "pure software".

Examiner's response:

The following recites paragraph 0104 of the publication of the instant application (US 2006/0120451 A1):

> [0104] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

Paragraph 0104 discloses that the video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. Since claim 5 is non-structural per se and is only limited by the functions, therefore, a reasonable broadest interpretation in light of the specification leads to the conclusion that the claimed video encoder covers a hardware embodiment (statutory) as well as a software embodiment (non-statutory), which does not fall within the definition of a process, machine, manufacture, or composition of matter.

With regard to the argument that the specification illustrates structural component of the encoder (e.g. compressor 108 and multiplexer 110), the components are represented by block in figure 1 and only define by the function as disclose in the specification, therefore, it does not exclude a software implementation of these components.

With respect to the argument that Paragraph 0095 teaches example of a decoder including a low bit rate video decoder as described in the ITU-T recommendation H.263

or H.26L. Moreover, paragraph 0096 describes positioning of the encoder and decoder that would not be possible if they were "pure software"; however, it is discloses in the above quoted paragraph (paragraph 0104 of the publication of the instant application (US 2006/0120451 A1)) that encoder and decoder can be implemented as software, as the claim is not structural per se, the examiner interprets the claim covers a software embodiment as well, therefore the rejection is maintained. If the applicant considered that the encoder and decoder can not be “pure software’, the examiner suggests amending paragraph 0104 of the publication of the instant application to remove the software embodiment.

2. Applicant's arguments with respect to the 35 U.S.C. 112, 1st paragraph rejection of claims 5-6, 8, and 13 filed 9/17/2010 have been fully considered but they are not persuasive.

Applicant argument:

Applicant respectfully traverses the § 112, first paragraph, rejection of claims 5, 6, 8, and 13 because the claims are not "single means" claims. First, none of these claims uses a "means recitation" or "means plus function" language. While a claim dependent upon a recited property could result in a fact situation similar to that discussed in the cited Hyatt decision when the claim covers every conceivable structure for achieving the stated property, such is not the case for claims 5, 6, 8, and 13. In contrast the claims are limited to the structures of an encoder (claims 5, 6, and 8) and of a decoder (claim 13), which are well-accepted and understood terms in the art, for

achieving the stated properties of the respective claims. Therefore, the claims are not unduly broad and are enabled by the specification. Applicant accordingly requests that the rejection be withdrawn.

Examiner's response:

The examiner would like to point out that claim 5-6, 8, and 13 are not rejection as a single means claim rejection. Claims 5-6, 8, and 13 are rejected based on the claim only directed to a single structure or component (decoder) and the decoder is defined by the recited properties (functions of the decoder), than a fact situation similar to that discussed in the cited Hyatt decision when the claim covers every conceivable structure for achieving the stated property for achieving the stated property while the specification discloses at most only known to the invention. Therefore, the 35 U.S.C. 112, 1st paragraph rejections of claims 5-6, 8, and 13 are maintained.

3. Applicant's arguments, see page 7-9, filed 9/17/2010, with respect to 35 U.S.C. 102(e) and 103(a) rejections of claims 1-16 have been fully considered and are persuasive. The 35 U.S.C. 102(e) and 103(a) rejections of claims 1-16 has been withdrawn.

With regard to the double patenting rejection of claims 1-2 and 4 are withdrawn because of the combination of claim 3 into claim 1.

Claim Objections

4. Claims 1-2, 4-6, 8, 10-11, are objected to because of the following informalities:

Claim 1, line 9 recites "encoding identifier values for image frames"; since "image frames" was introduced in line 2, the examiner suggests changing to "encoding identifier values for **the** image frames".

Claim 1, line 10-11 recite "resetting the identifier value for the indicated first image frame of an independent sequence"; since "independent sequence" was introduced in line 2, it is unclear whether it is the same independent sequence or another independent sequence.

Claim 5, line 9 recites "encoding identifier values for image frames"; since "image frames" was introduced in line 2, the examiner suggests changing to "encoding identifier values for **the** image frames".

Claim 5, line 10-11 recite "resetting the identifier value for the indicated first image frame of an independent sequence"; since "independent sequence" was introduced in line 2, it is unclear whether it is the same independent sequence or another independent sequence.

Claim 9, line 10 recites "encoding identifier values for image frames"; since "image frames" was introduced in line 3, the examiner suggests changing to "encoding identifier values for **the** image frames".

Claim 9, line 12-13 recite "resetting the identifier value for the indicated first image frame of an independent sequence"; since "independent sequence" was introduced in line 2, it is unclear whether it is the same independent sequence or another independent sequence.

Claim 10, lines 12-13 recite "resetting the identifier value for the indicated first image frame of an independent sequence"; since "independent sequence" was introduced in line 6, it is unclear whether it is the same independent sequence or another independent sequence.

Claim 13, lines 13-14 recite "resetting the identifier value for the indicated first image frame of an independent sequence"; since "independent sequence" was introduced in line 7, it is unclear whether it is the same independent sequence or another independent sequence.

Claim 14, lines 15-16 recite "resetting the identifier value for the indicated first image frame of an independent sequence"; since "independent sequence" was introduced in lines 8-9, it is unclear whether it is the same independent sequence or another independent sequence.

Appropriate correction is required.

Claim Rejections - 35 USC § 101

5. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

Claims 5-8 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter.

The following recites paragraph 0104 of the publication of the instant application (US 2006/0120451 A1):

> [0104] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

Paragraph 0104 discloses that the video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. Since the encoder of claim 5 is non-structural per se and is only limited by the functions, therefore, a reasonable broadest interpretation in light of the specification leads to the conclusion that the claimed video encoder covers a hardware embodiment (statutory) as well as a software embodiment (non-statutory), which does not fall within the definition of a process, machine, manufacture, or composition of matter.

Claim 13 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter.

The following recites paragraph 0104 of the publication of the instant application (US 2006/0120451 A1):

> [0104] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

Paragraph 0104 discloses that the video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. Since the decoder of claim 13 is non-structural per se and is only limited by the functions, therefore, a reasonable broadest interpretation in light of the specification leads to the conclusion that the claimed video decoder covers a hardware embodiment (statutory) as well as a software embodiment (non-statutory), which does not fall within the definition of a process, machine, manufacture, or composition of matter.

Claim Rejections - 35 USC § 112

6. The following is a quotation of the first paragraph of 35 U.S.C. 112:

> The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

Claims 5-8 are rejected under 112, 1st paragraph as being a single component (video encoder) claim, i.e., where a single component (video encoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Claim 13 is rejected under 112, 1st paragraph as being a single component (video decoder) claim, i.e., where a single component (video decoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Allowable Subject Matter

7. Claims 1-2, 4, 9-11, and 14 are objected to because of minor informality, but would be allowable if rewritten to overcome the objection.

8. The following is a statement of reasons for the indication of allowable subject matter:

The present invention describes a method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference

image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame is earlier than the at least one previous image frame in decoding order, the method comprising encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence; encoding identifier values for image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of an independent sequence. the closest prior art, Kim in view of Ueda and Kawashima together disclose a similar method but fails to disclose encoding identifier values for image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of an independent sequence.

The present invention describes a method for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame and wherein the at least one reference frame is earlier than the at least one previous image frame in decoding order, the method comprising decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; decoding identifier values for image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of an independent

sequence. The closest prior art, Kim in view of Ueda and Kawashima together disclose a similar method but fails to disclose decoding identifier values for image frames according to a numbering scheme; and resetting the identifier value for the indicated first image frame of an independent sequence.

Conclusion

9. **THIS ACTION IS MADE FINAL.** Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the mailing date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. §1.97(c)(1) and 37 C.F.R. §1.97 (e)(1)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted after the mailing date of the first Office Action on the merits but before the mailing date of a final Office Action under 37 C.F.R. §1.113 or a Notice of Allowance under 37 C.F.R. §1.311.

The items listed on the enclosed Form 1449 were first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of the information disclosure statement. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449. However, if fees are deemed necessary, authorization is given to charge Deposit Account 50-3581 (TPO.004.C2) for consideration of the information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311. Please charge Deposit Account 50-3581 (TPO.004.C2) the amount of $180.00 under 37 C.F.R. § 1.17(p) for consideration of the items.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action mailed May 25, 2010, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1, 2, 4-6, 8-11, 13, and 14 remain pending in the application. Claims 1, 5, 6, 8-10, 13, and 14 have been amended. No claims have been added, and claims 3, 7, 12, 15, and 16 have been canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 6.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

encoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of an independent sequence.

2. (Original) A method according to claim 1, further comprising:

encoding the indication into the video sequence as a separate flag included in the header of a slice.

3. (Canceled)

4. (Original) A method according to claim 1, further comprising:

encoding into the video sequence an identifier value for the independent sequence.

5. (Currently amended) A video encoder for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the video encoder being ~~arranged~~configured to:

encode into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

encode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of an independent sequence.

6. (Currently amended) A video encoder according to claim 5, wherein the video encoder is ~~arranged~~configured to

encode the indication into the video sequence as a separate flag included in the header of a slice.

7. (Canceled)

8. (Currently amended) A video encoder according to claim 5, wherein the video encoder is ~~arranged~~configured to

encode into the video sequence an identifier value for the independent sequence.

9. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame [[that]]and wherein the at least one reference frame is earlier than the at least one previous ~~reference~~ image frame in decoding order, the computer program product comprising:

a computer program code for encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence;

a computer code for encoding identifier values for image frames according to a numbering scheme; and

a computer code for resetting the identifier value for the indicated first image frame of an independent sequence.

10. (Currently amended) A method for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame [[that]]and wherein the at least one reference frame is earlier than the at least one previous ~~reference~~ image frame in decoding order, the method comprising:

decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; [[and]]

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

decoding identifier values for image frames according to a numbering scheme; and

resetting the identifier value for the indicated first image frame of an independent sequence.

11. (Original) A method according to claim 10, wherein the indication is a separate flag included in the header of a slice.

12. (Canceled)

13. (Currently amended) A video decoder for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the video decoder being ~~arranged~~configured to:

decode from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; [[and]]

start the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame; and

decode identifier values for image frames according to a numbering scheme; and

reset the identifier value for the indicated first image frame of an independent sequence.

14. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame, and wherein the at least one reference image frame ~~that~~ is earlier than the at least one previous ~~reference~~ image frame in decoding order, the computer program product comprising:

a computer program code for decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; [[and]]

a computer program code for starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame;

a computer program code for decoding identifier values for image frames according to a numbering scheme; and

a computer program code for resetting the identifier value for the indicated first image frame of an independent sequence.

15-16. (Canceled)

REMARKS/ARGUMENTS

The rejections presented in the Office action dated May 25, 2010 (hereinafter Office Action), have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Claims 3, 7, 12, 15, and 16 have been canceled, without prejudice, rendering the respective rejections of these claims moot. Applicant accordingly requests that the rejections of each of these claims be withdrawn.

With respect to the objection to claims 1, 2, 4, 5, 6, 8, 10, and 11, the term "the previous reference image frame" in independent claims 1, 5, and 10 has been amended to read "the previous image frame" in order to provide antecedent basis for the term. Applicant accordingly requests that the objection be removed.

With respect to the objection to Fig. 1, Applicant respectfully traverses. In contrast to the assertion that the figure includes "blank boxes", each of the boxes of Fig. 1 is labeled with a reference numeral in accordance with MPEP § 608.02. Moreover, no requirement has been cited for the request to label the boxes with text. Since Fig. 1 complies with the drawing requirements, and in an effort to maintain consistency with the parent application, Applicant requests that the objection be removed.

With respect to the § 101 rejection of claims 5-8 and 13, Applicant respectfully traverses. The Office action incorrectly asserts that the claimed encoder and decoder are "pure software". While the specification refers to embodiments involving computer readable media storing program code (*e.g.*, claims 9 and 14), the claimed encoder and decoder are devices constituting statutory subject matter. The terms "encoder" and "decoder" are well-known in the art to refer to a device or circuit. Notably, the specification illustrates structural components of the encoder (*e.g.*, compressor 108 and multiplexer 110) and decoder (*e.g.*, demultiplexer 116 and decompressor 118). Paragraph [0095] teaches examples of a decoder including a low bit rate video decoder as described in the ITU-T recommendation H.263 or H.26L. Moreover, paragraph [0096] describes positioning of the encoder and decoder that would not be possible if they were "pure

software". Contrary to the assertion, the claimed encoder and decoder are devices constituting statutory subject matter. Applicant accordingly requests that the rejection be withdrawn.

With respect to the § 101 rejection of claims 9 and 14, the claims have been amended to indicate that the claimed computer readable media are non-transitory in accordance with the Examiner's suggestion. Applicant notes that non-transitory computer readable media comprise all computer readable media, with the sole exception being a transitory, propagating signal. Since an interpretation of the claims is now limited to statutory subject matter, Applicant submits that the rejection has been overcome and accordingly requests that the rejection be withdrawn.

Applicant respectfully traverses the § 112, first paragraph, rejection of claims 5, 6, 8, and 13 because the claims are not "single means" claims. First, none of these claims uses a "means recitation" or "means plus function" language. While a claim dependent upon a recited property could result in a fact situation similar to that discussed in the cited *Hyatt* decision when the claim covers every conceivable structure for achieving the stated property, such is not the case for claims 5, 6, 8, and 13. In contrast the claims are limited to the structures of an encoder (claims 5, 6, and 8) and of a decoder (claim 13), which are well-accepted and understood terms in the art, for achieving the stated properties of the respective claims. Therefore, the claims are not unduly broad and are enabled by the specification. Applicant accordingly requests that the rejection be withdrawn.

Applicant respectfully traverses the § 102(e) rejection of claim 1 in view of U.S. Publication No. 2003/0063806 by Kim *et al*. (hereinafter "Kim") because the Office action acknowledges that Kim fails to teach or suggest each of the claimed limitations. In the § 103(a) rejection of claim 1 at page fifteen, the Office action states that "Kim fails to explicitly disclose an indication of the first I frame". Since Kim admittedly fails to correspond to each of the limitations of at least claim 1, the § 102(e) rejection is improper. Applicant accordingly requests that the rejection be withdrawn.

In an effort to facilitate prosecution and without acquiescing to characterizations of the asserted art, Applicant's claimed subject matter, or to the applications of the asserted art

or combinations thereof to Applicant's claimed subject matter, the independent claims have been amended to include the respective limitations of dependent claims 3, 7, and 12; therefore, these changes do not introduce new matter. Since the Office action acknowledges that Kim and U.S. Patent No. 6,094,456 to Ueda fail to teach or suggest each of the limitations of dependent claims 3, 7, and 12, each of the rejections based on these references is overcome. Each of the claims is further believed to be patentable over the asserted references for the reasons set forth below.

In rejecting dependent claims 3, 7, and 12, the Office action relies upon the teachings of U.S. Patent No. 4,390,966 to Kawashima *et al.* (hereinafter "Kawashima") as teaching the claimed resetting of the identifier value for the indicated first image frame of an independent sequence; however, this reliance is misplaced. Kawashima merely teaches that a sequence controller system is capable of setting and resetting flags according to predetermined user instructions. Kawashima's flags fail to at least correspond to the claimed identifier value since Kawashima is silent with respect to the flags being associated with an image frame of a coded video sequence. Also, Kawashima's flags are toggle flags for use in a multi CPU environment where each controller can run sequentially stored code in a parallel environment. There is no correspondence to the claimed resetting of an encoded identifier value for a first image frame of a video sequence. Without correspondence to each of the claimed limitations, the § 103(a) rejections of the subject matter of dependent claims 3, 7, and 12 is improper. Applicant accordingly requests that the rejections be withdrawn.

Further, the asserted modification of the combination of Kim and Ueda with the teachings of Kawashima is improper since the asserted modification is illogical and the teachings of Kawashima are not analogous to the field of Applicant's endeavor. First, the Office action asserts that it would be desirable to reset the identifier value since the video sequence is independent because it would simplify the identifier value and reset the identifier value. No explanation or evidence has been provided to indicate that resetting Kawashima's flags would simplify a value. Moreover, it is illogical to assert that it is

desirable to reset an identifier value because it would reset the identifier value. Thus, the proposed modification to the combination of Kim and Ueda is illogical and unsupported.

Second, the teachings of Kawashima are nonanalogous art as they are directed to very different technology than the field of video coding. In contrast, Kawashima is directed to the field of multi-core processing. Since Kawashima is in a field different than Applicant's endeavor, to be considered reasonably pertinent, Kawashima would need to address a problem addressed by the application at issue (MPEP § 2141.01(a)). However, the Office action fails to assert or identify any such relationship. Kawashima, directed to very different technology and failing to address video coding, would not have logically commended itself to an inventor of the instant application. Thus, Kawashima is nonanalogous art and fails to support the § 103(a) rejections. Applicant respectfully maintains the request that the § 103(a) rejections based upon Kawashima be withdrawn.

It should also be noted that Applicant does not acquiesce to the Examiner's statements or conclusions concerning what would have been obvious to one of ordinary skill in the art, obvious design choices, common knowledge at the time of Applicant's invention, officially noticed facts, and the like. Applicant reserves the right to address in detail the Examiner's characterizations, conclusions, and rejections in future prosecution.

With respect to the provisional rejections of claims 1-4 under the judicially-created doctrine of obviousness-type double patenting over co-pending and commonly-owned patent application no. 10/306,942 (hereinafter "the '942 application"), Applicant will consider filing a Terminal Disclaimer once the instant application is in condition for allowance or the '942 application issues as a patent. However, Applicant respectfully asserts that, in view of the amendments to the claims and arguments made above, the Examiner is compelled to withdraw the rejections of the claims. Once withdrawn, the only rejection remaining in the instant application would be the provisional obviousness-type double patenting rejection. In view of MPEP § 804 I(B), Applicant respectfully requests that the provisional obviousness-type double patenting rejection be withdrawn and that the instant application be permitted to issue as a patent.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C2) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437

PETITION FOR EXTENSION OF TIME UNDER 37 CFR 1.136(a) **FY 2009** (*Fees pursuant to the Consolidated Appropriations Act, 2005 (H.R. 4818).*)	Docket Number (Optional) TPO.004.C2
Application Number 11/338,934	Filed January 25, 2006
For Grouping of Image Frames in Video Coding	
Art Unit 2611	Examiner Lee, S.

This is a request under the provisions of 37 CFR 1.136(a) to extend the period for filing a reply in the above identified application.

The requested extension and fee are as follows (check time period desired and enter the appropriate fee below):

		Fee	Small Entity Fee	
☑	One month (37 CFR 1.17(a)(1))	$130	$65	$ 130.00
☐	Two months (37 CFR 1.17(a)(2))	$490	$245	$
☐	Three months (37 CFR 1.17(a)(3))	$1110	$555	$
☐	Four months (37 CFR 1.17(a)(4))	$1730	$865	$
☐	Five months (37 CFR 1.17(a)(5))	$2350	$1175	$

☐ Applicant claims small entity status. See 37 CFR 1.27.

☐ A check in the amount of the fee is enclosed.

☐ Payment by credit card. Form PTO-2038 is attached.

☐ The Director has already been authorized to charge fees in this application to a Deposit Account.

☑ The Director is hereby authorized to charge any fees which may be required, or credit any overpayment, to Deposit Account Number 50-3581.

WARNING: Information on this form may become public. Credit card information should not be included on this form. Provide credit card information and authorization on PTO-2038.

I am the

☐ applicant/inventor.

☐ assignee of record of the entire interest. See 37 CFR 3.71.
Statement under 37 CFR 3.73(b) is enclosed (Form PTO/SB/96).

☑ attorney or agent of record. Registration Number 57,125

☐ attorney or agent under 37 CFR 1.34.
Registration number if acting under 37 CFR 1.34 _____

/Erin Nichols Matkaiti/ — Signature

September 17, 2010 — Date

Erin Nichols Matkaiti — Typed or printed name

952-854-2700 — Telephone Number

NOTE: Signatures of all the inventors or assignees of record of the entire interest or their representative(s) are required. Submit multiple forms if more than one signature is required, see below.

☑ Total of 1 forms are submitted.

This collection of information is required by 37 CFR 1.136(a). The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.11 and 1.14. This collection is estimated to take 6 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. §1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office Action on the merits but before the mailing date of a final Office Action under 37 C.F.R. §1.113 or a Notice of Allowance under 37 C.F.R. §1.311. Please charge Deposit Account 50-3581 (TPO.004.C2) the amount of $180.00 under 37 C.F.R. §1.17(p) for consideration of the item.

In accordance with 37 C.F.R. §1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that the reference is "prior art" within the meaning of 35 U.S.C. §§102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. §1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC
8500 Normandale Lake Blvd., Suite 320

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *25 January 2006*.

2a)☐ This action is **FINAL**. 2b)☒ This action is non-final.

3)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

4)☒ Claim(s) *1-16* is/are pending in the application.

4a) Of the above claim(s) _____ is/are withdrawn from consideration.

5)☐ Claim(s) _____ is/are allowed.

6)☒ Claim(s) *1-16* is/are rejected.

7)☐ Claim(s) _____ is/are objected to.

8)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

9)☐ The specification is objected to by the Examiner.

10)☒ The drawing(s) filed on *25 January 2006* is/are: a)☐ accepted or b)☒ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

11)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

12)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☒ Certified copies of the priority documents have been received in Application No. 10/306942.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

DETAILED ACTION

Claim Objections

1. Claims 1-4, 5-8, and 10-12 are objected to because of the following informalities:

Claim 1, line 4 recites “the previous reference image frame”; there is a lack of antecedent basis for this limitation.

Claims 5, line 4 recites “the previous reference image frame”; there is a lack of antecedent basis for this limitation.

Claim 10, line 3 recites “the previous reference image frame”; there is a lack of antecedent basis for this limitation.

Appropriate correction is required.

Drawings

2. The drawings are objected to because Figure 1 does not have sufficiently descriptive labels. Blank boxes in drawings should be labeled descriptively unless it is a well-known component. For example, the blank box, "100" should be labeled as "Multimedia Source". Corrected drawing sheets in compliance with 37 CFR 1.121(d) are required in reply to the Office action to avoid abandonment of the application. Any amended replacement drawing sheet should include all of the figures appearing on the immediate prior version of the sheet, even if only one figure is being amended. The figure or figure number of an amended drawing should not be labeled as “amended.” If a drawing figure is to be canceled, the appropriate figure must be removed from the

replacement sheet, and where necessary, the remaining figures must be renumbered and appropriate changes made to the brief description of the several views of the drawings for consistency. Additional replacement sheets may be necessary to show the renumbering of the remaining figures. Each drawing sheet submitted after the filing date of an application must be labeled in the top margin as either "Replacement Sheet" or "New Sheet" pursuant to 37 CFR 1.121(d). If the changes are not accepted by the examiner, the applicant will be notified and informed of any required corrective action in the next Office action. The objection to the drawings will not be held in abeyance.

Claim Rejections - 35 USC § 101

3. 35 U.S.C. 101 reads as follows:

> Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefor, subject to the conditions and requirements of this title.

Claims 5-8 are rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "video encoder" is non-structural per se and because the specification discloses a "software" embodiment (page 5, paragraph 0014 and page 33, paragraph 0097). Therefore, a reasonable interpretation in light of the specification leads to the conclusion that the claim video encoder as pure software (further confirm in claim 9 that computer program code for encoding a compressed video sequence, claim 9, line 7), which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claim 13 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claimed "video decoder" is non-structural per se and because the specification discloses a "software" embodiment (page 5, paragraph 0014 and page 33, paragraph 0097). Therefore, a broadest reasonable interpretation in light of the specification leads to the conclusion that the claim video decoder as pure software (further confirm in claim 9 that computer program code for decoding from the video sequence, claim 14, line 7), which does not fall within the definition of a process, machine, manufacture or composition of matter.

Claim 9 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine, manufacture or composition of matter. The claim is drawn to a "computer program product stored in a computer readable medium". The specification does not define the computer readable medium, therefore, it includes transitory and non-transitory computer readable medium. The broadest reasonable interpretation of the claim in light of the specification concludes that the claim as a whole covers a transitory signal, which does not fall within the definition of a process, machine, manufacture, or composition of matter (In re Nuijten). Therefore, claim 9 does not fall within a statutory category (the rejection can be overcome by specifying the computer readable medium as "non-transitory computer readable medium").

Claim 14 is rejected under 35 U.S.C. 101 because the claimed invention is directed to non-statutory subject matter. The claim is NOT to a process, machine,

manufacture or composition of matter. The claim is drawn to a "computer program product stored in a computer readable medium". The specification does not define the computer readable medium, therefore, it includes transitory and non-transitory computer readable medium. The broadest reasonable interpretation of the claim in light of the specification concludes that the claim as a whole covers a transitory signal, which does not fall within the definition of a process, machine, manufacture, or composition of matter (In re Nuijten). Therefore, claim 9 does not fall within a statutory category (the rejection can be overcome by specifying the computer readable medium as "non-transitory computer readable medium").

Claim 15-16 are directed to a "video signal"; a signal is not limited to that which falls within a statutory category of invention because it is not limit to a process, machine, manufacture, or a composition of matter. Instead, it includes a form of energy. Energy does not fall with in a statutory category since it is clearly not a series of steps or acts to constitute a process, not a mechanical device or combination of mechanical device to constitute a machine, not a tangible physical article or object which is some form of matter to be a product and constitute a manufacture, and not a composite of two or more substances to constitute a composite of matter.

Claim Rejections - 35 USC § 112

4. The following is a quotation of the first paragraph of 35 U.S.C. 112:

> The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

Claims 5-8 are rejected under 112, 1st paragraph as being a single component (video encoder) claim, i.e., where a single component (video encoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Claim 13 is rejected under 112, 1st paragraph as being a single component (video decoder) claim, i.e., where a single component (video decoder) recitation does not appear in combination with another recited component, is subject to an undue breadth rejection. The single component which covered every conceivable ways for achieving the stated purpose was held nonenabling for the scope of claim because the specification disclosed at most only those known to the inventor. See MPEP §2164.08(a).

Double Patenting

5. The nonstatutory double patenting rejection is based on a judicially created doctrine grounded in public policy (a policy reflected in the statute) so as to prevent the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees. A nonstatutory obviousness-type double patenting rejection is appropriate where the conflicting claims are not identical, but at least one examined application claim is not patentably distinct from the reference claim(s) because the examined application claim is either anticipated by, or would have been obvious over, the reference claim(s). See, e.g., *In re Berg*, 140 F.3d 1428, 46 USPQ2d 1226 (Fed. Cir. 1998); *In re Goodman*, 11 F.3d 1046, 29 USPQ2d 2010 (Fed. Cir. 1993); *In re Longi*, 759 F.2d 887, 225 USPQ 645 (Fed. Cir. 1985); *In re Van Ornum*, 686 F.2d 937, 214 USPQ 761 (CCPA 1982); *In re Vogel*, 422

F.2d 438, 164 USPQ 619 (CCPA 1970); and *In re Thorington*, 418 F.2d 528, 163 USPQ 644 (CCPA 1969).

A timely filed terminal disclaimer in compliance with 37 CFR 1.321(c) or 1.321(d) may be used to overcome an actual or provisional rejection based on a nonstatutory double patenting ground provided the conflicting application or patent either is shown to be commonly owned with this application, or claims an invention made as a result of activities undertaken within the scope of a joint research agreement.

Effective January 1, 1994, a registered attorney or agent of record may sign a terminal disclaimer. A terminal disclaimer signed by the assignee must fully comply with 37 CFR 3.73(b).

6. Claims 1-2, and 4 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 9 of copending Application No. 10/306942 in view of Kim et al. (US 2003/0063806 A1, hereinafter Kim).

Claim	Instant application	Claim	Co-pending application 10/306942
1	A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the	9	Claim 1 A method for coding video frames for the purpose of forming a scalable, compressed video sequence comprising video frames coded according to at least a first and a second frame format, **the video frames of the first frame format being independent of the**

	method comprising: encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence.		**other video frames**, and **the video frames of the second frame format being predicted from at least one of the other video frames**, the method comprising encoding, at an encoder, the video sequence as at least part of a first sub-sequence, at least part of which has been formed by coding video frames of the at least first frame format; and encoding, at the encoder, the video sequence as at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format, and **at least one video frame of the second sub-sequence has been predicted from at least one video frame of the first sub-sequence**; and encoding, at the
2	A method according to claim 1, further comprising: encoding the indication into the video sequence as a separate flag included in the header of a slice.		
4	A method according to claim 1, further comprising: encoding into the video sequence an identifier value for the independent sequence.		

			encoder, into the video sequence information indicating which video frames belong to the second sub-sequence. Claim 3 A method according to claim 2, further comprising coding the video sequence into a plural number of scalability layers; and determining the dependency of the video frames of the second sub-sequence **such that at least one video frame of the second sub-sequence is predicted from a group comprising a video frame of a higher scalability layer, a video frame of another sub-sequence in the same scalability layer**. Claim 7 A method according to claim 3, further comprising **determining a**

			unique identifier for each video frame as a combination of layer number, sub-sequence identifier and image number. Claim 9 A method according to claim 7, further comprising **adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence**.

This is a provisional obviousness-type double patenting rejection.

(1) Regarding claim 1:

The co-pending application discloses a method for encoding a video sequence comprising an independent sequence of image frames (video sequence comprising video frame coded according to at least a first and second fame format), wherein at least one reference image frame (second sub-sequence) is predictable from at least one previous image frame that is earlier than a previous reference image frame in decoding order (at least one video frame of the second sub-sequence has been

predicted from at least one video frame of the first sub-sequence or a video frame of another sub-sequence in the same scalability layer), the method comprising:

encoding into the video sequence an indication (identifier) of at least one image frame (determined a unique identifier for each video frame), which is the first image frame, in decoding order, of the independent sequence (since **each** frame has an identifier added to the header field of the video sequence, therefore, it included the first image frame), said at least one reference image frame being included in the sequence (the video sequence includes at least a second sub-sequence, therefore, the claimed at least one reference image frame is included in the video sequence).

Claim 9 of the instant application does not explicitly disclose at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order.

However, Kim discloses an independent video sequence in figure 7 that at least one reference image frame P frame 708) is predictable from at least one previous image frame (I frame 704) that is earlier than a previous reference image frame in decoding order (P frame 706).

It is desirable to have at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order because it reduces latency when decoding the video sequence. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the teaching of Kim in the method of the co-pending application to reduce latency when decoding the video sequence.

(2) Regarding claim 2 (the examiner interprets "a slice" as the video sequence as claim in claim 1):

The copending application discloses:

encoding the indication into the video sequence as a separate flag included in the header of a slice (adding the identifier to the header field of the video sequence or to the header field of the transfer protocol to be used for transferring the video sequence, the examiner interprets the adding process as the encoding process as claim).

(3) Regarding claim 4:

The co-pending application discloses:

encoding into the video sequence an identifier value for the independent sequence (determining a unique identifier for each video frame and adding the identifier to the header field of the video sequence, the examiner interpret adding the unique identifier to the header as encoding the identifier into the video sequence).

7. Claim 3 are provisionally rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claim 9 of copending Application No. 10/306942 in view of Kim et al. (US 2003/0063806 A1, hereinafter Kim) as apply to claim 1 and further in view of Kawashima et al. (US 4,390,966).

Copending application and Kim discloses all subject matter as discussed in claim 1 and copending application further discloses the encoding identifier values for image frames according to a numbering scheme (layer number, sub-sequence identifier and

image number), but fail to disclose resetting the identifier value for the indicated first image frame of an independent sequence.

However, Kawashima discloses a controller that setting or resetting flags as desired according to user instruction (column 6, lines 37-40).

It is desirable to reset the identifier value for the indicated first image frame of an independent sequence because since the video sequence is independent of other sequences, it would simplify the identifier value and reset the identifier value. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the resetting step as taught by Kawashima in the method of copending application and Kim to simplify the identifier value of the video sequence.

Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456)

Claim Rejections - 35 USC § 102

8. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

9. Claims 1 and 5 are rejected under 35 U.S.C. 102(e) as being anticipated by Kim et al. (US 2003/0063806 A1, hereinafter Kim).

Kim discloses a method and encoder (encoder discloses in figure 1B and 1C) for encoding a video sequence comprising an independent sequence of image frames (independent sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame (a video coding apparatus is provided to receive an indication that a first frame is to be intracoded, paragraph 0018, the examiner interprets the first intracoded frame as the claimed indication), which is the first image frame (the first frame is intracoded), in decoding order, of the independent sequence (independent sequence as shown in figure 7), said at least one reference image frame being included in the sequence (the P frame 708 is included in the sequence).

Claim Rejections - 35 USC § 103

10. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

11. Claims 1, 2, 4, 6, 8, 10, 11, 13, and 15-16 are rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456).

(1) Regarding claim 1:

Kim discloses a method and encoder (encoder discloses in figure 1B and 1C) for encoding a video sequence comprising an independent sequence of image frames (independent sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

encoding into the video sequence at least one image frame (a video coding apparatus is provided to receive an indication that a first frame is to be intracoded, paragraph 0018, the examiner interprets the first intracoded frame as the claimed indication), which is the first image frame (the first frame is intracoded), in decoding order, of the independent sequence (independent sequence as shown in figure 7), said at least one reference image frame being included in the sequence (the P frame 708 is included in the sequence).

Kim fails to explicitly disclose an indication of the first I frame.

However, Ueda discloses an encoded video sequence that comprises a fixed parameter identifier in the header of an input video code that indicates the type of picture from the picture header (I frame, column 10, lines 38-42).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

(2) Regarding claims 2 and 6:

Kim discloses all subject matter as discussed in claims 1 and 5 but fail to disclose encoding the indication into the video sequence as a separate flag included in the header of a slice.

However, Ueda discloses an encoded video sequence that comprises a fixed parameter identifier in the header of an input video code that indicates the type of picture from the picture header (column 10, lines 38-42).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

(3) Regarding claims 4 and 8:

Ueda further discloses encoding into the video sequence an identifier value for the independent sequence (an identifier of six bytes indicative of type of picture, column 7, lines 60-64 and column 10, lines 38-42).

(4) Regarding claims 10 and 13:

Kim discloses a method and decoder for decoding a compressed video sequence (sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising

decoding the first two frames of a sequence that yield the exact frame rate, the first two frame as I frame of figure 7 (paragraph 0071) which is the first image frame (I frame 702 in figure 7 is the first frame of the sequence), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (P frame 708 is included in the sequence) and starting the decoding of the video sequence from said first image frame of the independent sequence (as shown in figure 7, the first I frame 702 and the second I frame 704 is for generating the P frame 706-

712, therefore, the decoding processing is start from I frame 702), whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (as shown in figure 7, the sequence is independent and I frame 702 is the first frame of the sequence and no other frame prior to frame 702 is required).

Kim does not explicitly disclose decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence.

However, Ueda discloses a method that determines from an identifier in the header and determine if the frame is an I frame (step 111 and 112 of figure 12, column 14, lines 31-35).

It is desirable to decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence because it improves the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the decoding method of Kim to improve the reproduction speed of the encoded video sequence.

(5) Regarding claim 11:

Ueda further discloses wherein the indication is a separate flag in the header of a slice (an identifier of six bytes indicative of type of picture, column 7, lines 60-64 and column 10, lines 38-42).

(6) Regarding claim 15:

Kim discloses a signal comprising a compressed video sequence including an independent sequence of image frames (sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

at least one image frame (the first frame is an intracoded frame), which is the first image frame, in decoding order, of the independent sequence (the first I frame 702 is the first frame of the sequence as shown in figure 7), said at least one reference image frame being included in the sequence (P frame 708 is included in the sequence as shown in figure 7).

Kim fails to explicitly disclose an indication of the first I frame.

However, Ueda discloses an encoded video sequence that comprises a fixed parameter identifier in the header of an input video code that indicates the type of picture from the picture header (I frame, column 10, lines 38-42).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

(7) Regarding claim 16:

Ueda further discloses encoding into the video sequence an identifier value for the independent sequence (an identifier of six bytes indicative of type of picture, column 7, lines 60-64 and column 10, lines 38-42).

12. Claims 3 and 7 are rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456) and Kawashima et al. (US 4,390,966).

Kim discloses all subject matter as discussed in claims 1 and 5 except (a) encoding identifier values for image frames according to a numbering scheme, and (b) resetting the identifier value for the indicated first image frame of an independent sequence.

With respect to (a), Ueda discloses a fixed parameter identifier of six bits in the header of an input video code that indicates the type of picture from the picture header (column 7, lines 60-64 and column 10, lines 38-42, the examiner interprets the bits as a representation of numbering scheme in binary).

Since Kim discloses the first frame is an I frame, and Ueda discloses having a fixed parameter identifier in the header to indicate whether the frame is an I frame, it is

obvious to employ the teaching of Ueda in the encoding method of Kim to include in the header a fixed parameter identifier for identifying the first I frame in order to improve the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the method of Kim to improve the reproduction speed of the encoded video sequence.

With respect to (b), Kawashima discloses a controller that setting or resetting flags as desired according to user instruction (column 6, lines 37-40).

It is desirable to reset the identifier value for the indicated first image frame of an independent sequence because since the video sequence is independent of other sequences, it would simplify the identifier value and reset the identifier value. Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to employ the resetting step as taught by Kawashima in the method of copending application and Kim to simplify the identifier value of the video sequence.

13. Claims 9 and 14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Langberg et al. (US 5,852,630).

(1) Regarding claim 9:

Kim discloses a method and encoder (encoder discloses in figure 1B and 1C) for encoding a video sequence comprising an independent sequence of image frames

(independent sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame (a video coding apparatus is provided to receive an indication that a first frame is to be intracoded, paragraph 0018, the examiner interprets the first intracoded frame as the claimed indication), which is the first image frame (the first frame is intracoded), in decoding order, of the independent sequence (independent sequence as shown in figure 7), said at least one reference image frame being included in the sequence (the P frame 708 is included in the sequence).

Kim fails to disclose implementing the encoder by a computer program product, stored on a computer readable medium and executable in a data processing unit.

However, Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Kim would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability,

and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg to implement the method and encoder of Kim in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 14:

Kim discloses a method and decoder for decoding a compressed video sequence (sequence as shown in figure 7), wherein at least one reference image frame (as there is no definition of a reference frame, the examiner interprets a P frame as a reference frame, P frame 708 in figure 7) is predictable from at least one previous image frame (I frame 704 in figure 7) that is earlier than the previous reference image frame (P frame 706 in figure 7) in decoding order, the method comprising

decoding the first two frames of a sequence that yield the exact frame rate, the first two frame as I frame of figure 7 (paragraph 0071) which is the first image frame (I frame 702 in figure 7 is the first frame of the sequence), in decoding order, of an independent sequence, said sequence including the at least one reference image frame (P frame 708 is included in the sequence) and starting the decoding of the video sequence from said first image frame of the independent sequence (as shown in figure 7, the first I frame 702 and the second I frame 704 is for generating the P frame 706-712, therefore, the decoding processing is start from I frame 702), whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame (as shown in figure 7, the sequence is independent and I frame 702 is the first frame of the sequence and no other frame prior to frame 702 is required).

Kim does not explicitly disclose (a) decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence, and (b) implementing the method by a computer program product, stored on a computer readable medium and executable in a data processing unit.

With respect to (a), Ueda discloses a method that determines from an identifier in the header and determine if the frame is a I frame (step 111 and 112 of figure 12, column 14, lines 31-35).

It is desirable to decoding from the video sequence an indication of at least one image frame which is the first image frame, in decoding order of an independent sequence because it improves the reproduction speed (column 2, lines 24-27).

Therefore, it would have been obvious to one of ordinary skill in the art at the time of invention to include in the header a fixed parameter identifier for identifying the first I frame as taught by Ueda in the decoding method of Kim to improve the reproduction speed of the encoded video sequence.

With respect to (b), Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Kim would have been implemented in a software. The implemented

software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg to implement the method and encoder of Kim and Ueda in order to reduce cost and improve the adaptability and flexibility of the communication system.

14. Claim 12 is rejected under 35 U.S.C. 103(a) as being unpatentable over Kim et al. (US 2003/0063806 A1, hereinafter Kim) in view of Ueda (US 6,094,456) as applied to claim 10 and further in vie of Kawashima et al. (US 4,390,966).

Kim and Ueda disclose all subject matter as discussed in claim 10, and Ueda further discloses a fixed parameter identifier of six bits in the header of an input video code that indicates the type of picture from the picture header (column 7, lines 60-64 and column 10, lines 38-42, the examiner interprets the bits as a representation of numbering scheme in binary).

Kim and Ueda fail to disclose resetting the identifier value for the indicated first image frame of an independent sequence.

However, Kawashima discloses a controller that setting or resetting flags as desired according to user instruction (column 6, lines 37-40).

It is desirable to reset the identifier value for the indicated first image frame of an independent sequence because since the video sequence is independent of other sequences, it would simplify the identifier value and reset the identifier value. Therefore, it would have been obvious to one of ordinary skill in the art at the time of

invention to employ the resetting step as taught by Kawashima in the method of copending application and Kim to simplify the identifier value of the video sequence.

Conclusion

15. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure.

Cuccia (US 202/0051621 A1) discloses an instant replay on digital video optimized using non MPEG frame tag.

Hannuksela et al. (US 2001/0040700 A1) discloses a video coding.

Apostolopoulos (US 7,103,669 B2) discloses a video communication method and system employing multiple state encoding and path diversity.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU M. LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 7:30-4:00 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of the foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a

reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of the foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided. Also attached is a copy of the English translation of the Japanese Office Action.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to

establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

The Japanese reference was first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), and the 05 August 2003 Official Gazette Notice, only a copy of the foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided. The U.S. patent (No. 6,266,158) is included as an English-language version of the cited Japanese reference. Also attached is a copy of the Japanese Office Action with an English translation thereof.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

Alexandria, VA 22313-1450

Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

These items were also first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), copies of the foreign references listed on the enclosed Form 1449 are provided. As indicated in the communication from the Chinese patent office (a copy with an English translation is attached) the English-language EP publication corresponds to the cited Chinese reference.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

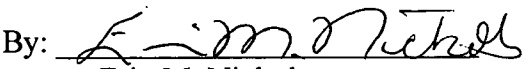
With regard to the above-identified application, the item of information listed on the enclosed Form 1449 is brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the item listed on the enclosed Form 1449.

This item was also first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

Applicant has not provided a copy of the U.S. publication/patent listed on the enclosed Form 1449 in accordance with 37 C.F.R. §1.98(a)(2).

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to



establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT (37 C.F.R. § 1.97(b))

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

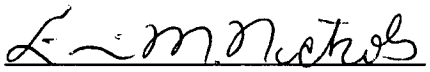
With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted before the mailing date of a first Office Action on the merits for the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

These items were also first cited in a communication from a foreign patent office regarding a counterpart foreign application not more than three months prior to the filing of this information disclosure statement.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached document do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.



No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. § 1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP § 609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

CONTINUATION PATENT APPLICATION UNDER 37 C.F.R. § 1.53(b)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

This is a request for filing a continuation patent application under 37 CFR § 1.53(b) of pending patent application serial number 10/306,942 filed on November 29, 2002, which claims priority under 35 U.S.C. §119 from corresponding Finnish patent application No. 20020127, filed in Finland on January 23, 2002.

We are transmitting herewith the following:

☒ Transmittal sheet containing Certificate under 37 CFR 1.10 (2 pages).
☒ Patent Application: Pages numbered 1-38, with 1pg. Abstract; 16 claims.
☒ 4 sheets of formal drawings, having Figures 1-2, 3A-3B, 4A-4C, 5A-5C, 6A-6C, and 7.
☒ Copy of the executed Declaration from the priority application (3 pages).
☒ A copy of the Change of Correspondence Address submitted in the prior pending application. Please send all future correspondence to the following address:

HOLLINGSWORTH & FUNK, LLC
8009 34th Avenue South, Suite 125
Minneapolis, MN 55425
952.854.2700

☒ The priority pending application is assigned to: Nokia Corporation at Reel/Frame No.: 013741/0536.

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Applicant: HANNUKSELA

Docket: TPO.004.C1

Title: GROUPING OF IMAGE FRAMES IN VIDEO CODING

☒ The Power of Attorney in the prior pending application is to: Steven R. Funk, Reg. No. 37,830.

☒ Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C2) in the amount of $1,800.00 for the filing fees. Authorization is also given to charge/credit Deposit Account No. 50-3581 (TPO.004.C2) for any deficiencies/overpayments.

☒ 1 Return Postcard

The fees are calculated as follows:

Basic Filing Fee =	$ 300.00
Search Fee =	$ 500.00
Examination Fee =	$ 200.00
Fee for total # of claims over 20 = $50 * (16 – 20) =	$ 0.00
Fee for total # of independent claims over 3 = $200 * (7 – 3) =	$ 800.00
TOTAL FILING FEES DUE =	$1,800.00

Respectfully submitted,

GROUPING OF IMAGE FRAMES IN VIDEO CODING

RELATED PATENT DOCUMENTS

[0001] This application is a continuation of U.S. Patent Application Serial No. 10/306,942 filed on November 29, 2002 which is incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

[0002] The invention relates to the grouping of multimedia files, particularly video files and particularly in connection with streaming.

BACKGROUND OF THE INVENTION

[0003] The term 'streaming' refers to simultaneous sending and playback of data, typically multimedia data, such as audio and video files, in which the recipient may begin data playback already before all the data to be transmitted has been received. Multimedia data streaming systems comprise a streaming server and terminal devices that the recipients use for setting up a data connection, typically via a telecommunications network, to the streaming server. From the streaming server the recipients retrieve either stored or real-time multimedia data, and the playback of the multimedia data can then begin, most advantageously almost in real-time with the transmission of the data, by means of a streaming application included in the terminal.

[0004] From the point of view of the streaming server, the streaming may be carried out either as normal streaming or as progressive downloading to the terminal. In normal streaming the transmission of the multimedia data and/or the data contents are controlled either by making sure that the bit rate of the transmission substantially corresponds to the playback rate of the terminal device, or, if the telecommunications network used in the transmission causes a bottleneck in data transfer, by making sure that the bit rate of the transmission substantially corresponds to the bandwidth available in the telecommunications network. In progressive downloading the transmission of the multimedia data and/or the data contents do not necessarily have to be interfered with at all, but the multimedia files are transmitted as such to the recipient, typically by using transfer protocol flow control. The terminals then receive, store and reproduce an exact copy of the data transmitted from the server, which copy can then be later reproduced again on the terminal without

needing to start a streaming again via the telecommunications network. The multimedia files stored in the terminal are, however, typically very large and their transfer to the terminal is time-consuming, and they require a significant amount of storage memory capacity, which is why a normal streaming is often preferred.

[0005] The video files in multimedia files comprise a great number of still image frames, which are displayed rapidly in succession (of typically 15 to 30 frames per s) to create an impression of a moving image. The image frames typically comprise a number of stationary background objects, determined by image information which remains substantially unchanged, and few moving objects, determined by image information that changes to some extent. The information comprised by consecutively displayed image frames is typically largely similar, i.e. successive image frames comprise a considerable amount of redundancy. The redundancy appearing in video files can be divided into spatial, temporal and spectral redundancy. Spatial redundancy refers to the mutual correlation of adjacent image pixels, temporal redundancy refers to the changes taking place in specific image objects in subsequent frames, and spectral redundancy to the correlation of different colour components within an image frame.

[0006] To reduce the amount of data in video files, the image data can be compressed into a smaller form by reducing the amount of redundant information in the image frames. In addition, while encoding, most of the currently used video encoders downgrade image quality in image frame sections that are less important in the video information. Further, many video coding methods allow redundancy in a bit stream coded from image data to be reduced by efficient, lossless coding of compression parameters known as VLC (Variable Length Coding).

[0007] In addition, many video coding methods make use of the above-described temporal redundancy of successive image frames. In that case a method known as motion-compensated temporal prediction is used, i.e. the contents of some (typically most) of the image frames in a video sequence are predicted from other frames in the sequence by tracking changes in specific objects or areas in successive image frames. A video sequence always comprises some compressed image frames the image information of which has not been determined using motion-compensated temporal prediction. Such frames are called INTRA-frames, or I-frames.

Correspondingly, motion-compensated video sequence image frames predicted from previous image frames, are called INTER-frames, or P-frames (Predicted). The image information of P-frames is determined using one I-frame and possibly one or more previously coded P-frames. If a frame is lost, frames dependent on it can no longer be correctly decoded.

[0008] An I-frame typically initiates a video sequence defined as a Group of Pictures (GOP), the P-frames of which can only be determined on the basis of the I-frame and the previous P-frames of the GOP in question. The next I-frame begins a new group of pictures GOP, the image information comprised by which cannot thus be determined on the basis of the frames of the previous GOP. In other words, groups of pictures are not temporally overlapping, and each group of picture can be decoded separately. In addition, many video compression methods employ bi-directionally predicted B-frames (Bi-directional), which are set between two anchor frames (I- and P-frames, or two P-frames) within a group of pictures GOP, the image information of a B-frame being predicted from both the previous anchor frame and the one succeeding the B-frame. B-frames therefore provide image information of higher quality than P-frames, but typically they are not used as anchor frames, and therefore their removal from the video sequence does not degrade the quality of subsequent images. However, nothing prevents B-frames from being used as anchor frames as well, only in that case they cannot be removed from the video sequence without deteriorating the quality of the frames dependent on them.

[0009] Each video frame may be divided into what are known as macroblocks that comprise the colour components (such as Y, U, V) of all pixels of a rectangular image area. More specifically, a macroblock consists of at least one block per colour component, the blocks each comprising colour values (such as Y, U or V) of one colour level in the image area concerned. The spatial resolution of the blocks may differ from that of the macroblocks, for example U- and V-components may be displayed using only half of the resolution of Y-component. Macroblocks can be further grouped into slices, for example, which are groups of macroblocks that are typically selected in the scanning order of the image. Temporal prediction is typically carried out in video coding methods block- or macroblock-specifically, instead of image-frame-specifically.

[0010] To allow for flexible streaming of video files, many video coding systems employ scalable coding in which some elements or element groups of a video sequence can be removed without affecting the reconstruction of other parts of the video sequence. Scalability is typically implemented by grouping the image frames into a number of hierarchical layers. The image frames coded into the image frames of the base layer substantially comprise only the ones that are compulsory for the decoding of the video information at the receiving end. The base layer of each group of pictures GOP thus comprises one I-frame and a necessary number of P-frames. One or more enhancement layers can be determined below the base layer, each one of the layers improving the quality of the video coding in comparison with an upper layer. The enhancement layers thus comprise P- or B-frames predicted on the basis of motion-compensation from one or more upper layer images. The frames are typically numbered according to an arithmetical series.

[0011] In streaming, transmission bit rate must be controllable either on the basis of the bandwidth to be used or the maximum decoding or bit rate value of the recipient. Bit rate can be controlled either at the streaming server or in some element of the telecommunications network, such as an Internet router or a base station of a mobile communications network. The simplest means for the streaming server to control the bit rate is to leave out B-frames having a high information content from the transmission. Further, the streaming server may determine the number of scalability layers to be transmitted in a video stream, and thus the number of the scalability layers can be changed always when a new group of pictures GOP begins. It is also possible to use different video sequence coding methods. Correspondingly, B-frames, as well as other P-frames of the enhancement layers, can be removed from the bit stream in a telecommunications network element.

[0012] The above arrangement involves a number of drawbacks. Many coding methods, such as the coding according to the ITU-T (International Telecommunications Union, Telecommunications Standardization Sector) standard H.263, are familiar with a procedure called reference picture selection. In reference picture selection at least a part of a P-image has been predicted from at least one other image than the one immediately preceding the P-image in the time domain. The selected reference image is signalled in a coded bit stream or in bit stream header fields image-,

image-segment- (such as a slice or a group of macroblocks), macroblock-, or block-specifically. The reference picture selection can be generalized such that the prediction can also be made from images temporally succeeding the image to be coded. Further, the reference picture selection can be generalized to cover all temporally predicted frame types, including B-frames. Since it is possible to also select at least one image preceding an I-image that begins a group of pictures GOP as the reference image, a group of pictures employing reference picture selection cannot necessarily be decoded independently. In addition, the adjusting of scalability or coding method in the streaming server or a network element becomes difficult, because the video sequence must be decoded, parsed and buffered for a long period of time to allow any dependencies between different image groups to be detected.

[0013] A further problem relates to detection of image frames from which a decoder can start the decoding process. The detection is useful for multiple purposes. For example, an end-user may wish to start browsing a video file from the middle of a video sequence. Another example relates to starting the reception of a broadcast or multicast video transmission from the middle of the video transmission. A third example relates to on-demand streaming from a server and occurs when an end-user wishes to start playback from a certain position of a stream.

BRIEF DESCRIPTION OF THE INVENTION

[0014] Now there is invented an improved method and equipment implementing the method, that enable detection of image frames from which a decoder can start the decoding process. Various aspects of the invention include methods, a video encoder, a video decoder, and computer programs that are characterized by what is stated in the independent claims. The preferred embodiments of the invention are disclosed in the dependent claims.

[0015] The invention is based on the idea of encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference picture is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order. An indication of at least one image frame is encoded into the video sequence, which indicated image frame is the first picture, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence. Respectively, in the decoding phase, the indication

of at least one image frame is decoded from the video sequence, and the decoding of the video sequence is started from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

[0016] Consequently, the idea of the present invention is to determine an initiation picture in an independently decodable group of pictures, whereby in the decoding phase any picture prior to said initiation picture is defined as unusable for reference. Accordingly, after decoding the initiation picture, all following pictures of the independently decodable sequence can be decoded without prediction from any picture decoded prior to said initiation picture.

[0017] According to an embodiment, the indication is encoded into the video sequence as a separate flag included in the header of a slice.

[0018] According to an embodiment, identifier values for pictures are encoded according to a numbering scheme, and the identifier value for the indicated first picture of an independent sequence is reset, preferably to zero.

[0019] According to an embodiment, an identifier value for the independent sequence is encoded into the video sequence.

[0020] An advantage of the procedure of the invention is that it enables to start browsing a video sequence from a random point, i.e. it provides the decoder with the information about the first picture of an independently decodable sequence. Thus, the decoder knows that by decoding this first picture, it is possible to continue the decoding process without any prediction from any prior picture. Accordingly, a further advantage is that the decoder may discard any picture decoded prior to said initiation picture from its buffer memory, since the prior pictures are no longer needed in the decoding process. A further advantage is that the procedure of the invention allows a separate video sequence to the easily inserted into another video sequence.

[0021] A further advantage is that enables identification of a picture boundary between two back-to-back initiation pictures by looking at the sub-sequence number of the initiation pictures. A yet further advantage relates to detection of losses of image frames that start an independently decodable sub-sequence. If such an image frame is lost e.g. during transmission, it is unlikely that any error concealment method would result into a subjectively satisfactory image quality. It is therefore an advantage that decoders are provided means

to detect losses of image frames that start an independently decodable sub-sequence. Decoders may react to such a loss by requesting a retransmission or picture refresh, for example.

BRIEF DESCRIPTION OF THE DRAWINGS

[0022] In the following, the invention will be described in connection with the preferred embodiments and with reference to the accompanying drawings, in which

Figure 1 illustrates a common multimedia data streaming system in which the scalable coding hierarchy of the invention can be applied;

Figure 2 illustrates a scalable coding hierarchy of a preferred embodiment of the invention;

Figures 3a and 3b illustrate embodiments of the invention for adjusting scalability;

Figures 4a, 4b and 4c illustrate embodiments of the invention for adjusting image numbering;

Figures 5a, 5b and 5c illustrate embodiments of the invention for using B-frames in a scalable coding hierarchy;

Figures 6a, 6b and 6c illustrate scalable coding hierarchies of preferred embodiments of the invention in connection with reference picture selection; and

Figure 7 illustrates an arrangement according to a preferred embodiment of the invention for coding scene transition.

DETAILED DESCRIPTION OF THE INVENTION

[0023] In the following, a general-purpose multimedia data streaming system is disclosed, the basic principles of which can be applied in connection with any telecommunications system. Although the invention is described here with a particular reference to a streaming system, in which the multimedia data is transmitted most preferably through a telecommunications network employing a packet-switched data protocol, such as an IP network, the invention can equally well be implemented in circuit-switched networks, such as fixed telephone networks PSTN/ISDN (Public Switched Telephone Network/Integrated Services Digital Network) or in mobile communications networks PLMN (Public Land Mobile Network). Further, the invention can be applied in the streaming of multimedia files in the form of both normal

streaming and progressive downloading, and for implementing video calls, for example.

[0024] It is also to be noted that although the invention is described here with a particular reference to streaming systems and the invention can also be advantageously applied in them, the invention is not restricted to streaming systems alone, but can be applied in any video reproduction system, irrespective of how a video file that is to be decoded is downloaded and where it is downloaded from. The invention can therefore be applied for example in the playback of a video file to be downloaded from a DVD disc or from some other computer memory carrier, for example in connection with varying processing capacity available for video playback. In particular, the invention can be applied to different video codings of low bit rate that are typically used in telecommunications systems subject to bandwidth restrictions. One example is the system defined in the ITU-T standard H.263 and the one that is being defined in H.26L (possibly later to become H.264). In connection with these, the invention can be applied to mobile stations, for example, in which case the video playback can be made to adjust both to changing transfer capacity or channel quality and to the processor power currently available, when the mobile station is used also for executing other applications than video playback.

[0025] It is further to be noted that, for the sake of clarity, the invention will be described below by giving an account of image frame coding and temporal predicting on image frame level. However, in practice coding and temporal predicting typically take place on block or macroblock level, as described above.

[0026] With reference to Figure 1, a typical multimedia streaming system will be described, which is a preferred system for applying the procedure of the invention.

[0027] A multimedia data streaming system typically comprises one or more multimedia sources 100, such as a video camera and a microphone, or video image or computer graphic files stored in a memory carrier. Raw data obtained from the different multimedia sources 100 is combined into a multimedia file in an encoder 102, which can also be referred to as an editing unit. The raw data arriving from the one or more multimedia sources 100 is first captured using capturing means 104 included in the encoder 102, which capturing means can be typically implemented as different interface cards,

driver software, or application software controlling the function of a card. For example, video data may be captured using a video capture card and the associated software. The output of the capturing means 104 is typically either an uncompressed or slightly compressed data flow, for example uncompressed video frames of the YUV 4:2:0 format or motion-JPEG image format, when a video capture card is concerned.

[0028] An editor 106 links different media flows together to synchronize video and audio flows to be reproduced simultaneously as desired. The editor 106 may also edit each media flow, such as a video flow, by halving the frame rate or by reducing spatial resolution, for example. The separate, although synchronized, media flows are compressed in a compressor 108, where each media flow is separately compressed using a compressor suitable for the media flow. For example, video frames of the YUV 4:2:0 format may be compressed using the low bit rate video coding according to the ITU-T recommendation H.263 or H.26L. The separate, synchronized and compressed media flows are typically interleaved in a multiplexer 110, the output obtained from the encoder 102 being a single, uniform bit flow that comprises data of a plural number of media flows and that may be referred to as a multimedia file. It is to be noted that the forming of a multimedia file does not necessarily require the multiplexing of a plural number of media flows into a single file, but the streaming server may interleave the media flows just before transmitting them.

[0029] The multimedia files are transferred to a streaming server 112, which is thus capable of carrying out the streaming either as real-time streaming or in the form of progressive downloading. In progressive downloading the multimedia files are first stored in the memory of the server 112 from where they may be retrieved for transmission as need arises. In real-time streaming the editor 102 transmits a continuous media flow of multimedia files to the streaming server 112, and the server 112 forwards the flow directly to a client 114. As a further option, real-time streaming may also be carried out such that the multimedia files are stored in a storage that is accessible from the server 112, from where real-time streaming can be driven and a continuous media flow of multimedia files is started as need arises. In such case, the editor 102 does not necessarily control the streaming by any means. The streaming server 112 carries out traffic shaping of the multimedia data as regards the bandwidth available or the maximum decoding and playback rate

of the client 114, the streaming server being able to adjust the bit rate of the media flow for example by leaving out B-frames from the transmission or by adjusting the number of the scalability layers. Further, the streaming server 112 may modify the header fields of a multiplexed media flow to reduce their size and encapsulate the multimedia data into data packets that are suitable for transmission in the telecommunications network employed. The client 114 may typically adjust, at least to some extent, the operation of the server 112 by using a suitable control protocol. The client 114 is capable of controlling the server 112 at least in such a way that a desired multimedia file can be selected for transmission to the client, in addition to which the client is typically capable of stopping and interrupting the transmission of a multimedia file.

[0030] When the client 114 is receiving a multimedia file, the file is first supplied to a demultiplexer 116, which separates the media flows comprised by the multimedia file. The separate, compressed media flows are then supplied to a decompressor 118 where each separate media flow is decompressed by a decompressor suitable for each particular media flow. The decompressed and reconstructed media flows are supplied to a playback unit 120 where the media flows are rendered at a correct pace according to their synchronization data and supplied to presentation means 124. The actual presentation means 124 may comprise for example a computer or mobile station display, and loudspeaker means. The client 114 also typically comprises a control unit 122 that the end user can typically control through a user interface and that controls both the operation of the server, through the above-described control protocol, and the operation of the playback unit 120, on the basis of the instructions given by the end user.

[0031] It is to be noted that the transfer of multimedia files from the streaming server 112 to the client 114 takes place through a telecommunications network, the transfer path typically comprising a plural number of telecommunications network elements. It is therefore possible that there is at least some network element that can carry out traffic shaping of multimedia data with regard to the available bandwidth or the maximum decoding and playback rate of the client 114 at least partly in the same way as described above in connection with the streaming server.

[0032] Scalable coding will be described below with reference to a preferred embodiment of the invention and an example illustrated in Figure 2. Figure 2 shows part of a compressed video sequence having a first frame 200,

which is an INTRA frame, or I-frame, and thus an independently determined video frame the image information of which is determined without using motion-compensated temporal prediction. The I-frame 200 is placed on a first scalability layer, which may be referred to as an INTRA layer. Each scalability layer is assigned a unique identifier, such as the layer number. The INTRA layer may therefore be given the number 0, for example, or some other alphanumeric identifier, for example a letter, or a combination of a letter and a number.

[0033] Correspondingly, sub-sequences consisting of groups of one or more video frames are determined for each scalability layer, at least one of the images in a group (typically the first or the last one) being temporally predicted at least from a video frame of another, sub-sequence of typically either a higher or the same scalability layer, the rest of the video frames being temporally predicted either from only the video frames of the same sub-sequence, or possibly also from one or more video frames of said second sub-sequence. A sub-sequence may de decoded independently, irrespective of other sub-sequences, except said second sub-sequence. The sub-sequences of each scalability layer are assigned a unique identifier using for example consecutive numbering starting with number 0 given for the first sub-sequence of a scalability layer. Since the I-frame 200 is determined independently and can also be decoded independently upon reception, irrespective of other image frames, it also forms in a way a separate sub-sequence.

[0034] An essential aspect of the present invention is therefore to determine each sub-sequence in terms of those sub-sequences the sub-sequence is dependent on. In other words, a sub-sequence comprises information about all the sub-sequences that have been directly used for predicting the image frames of the sub-sequence in question. This information is signalled in a video sequence bit stream, preferably separate from the actual image information, and therefore the image data of the video sequence can be preferably adjusted because it is easy to determine video sequence portions that are to be independently decoded and can be removed without affecting the decoding of the rest of the image data.

[0035] Next, within each sub-sequence, the video frames of the sub-sequence are given image numbers, using for example consecutive numbering that starts with the number 0 given to the first video frame of the sub-sequence. Since the I-frame 200 also forms a separate sub-sequence, its

image number is 0. In Figure 2, the I-frame 200 shows the type (I), sub-sequence identifier and image number (0.0) of the frame.

[0036] Figure 2 further shows a next I-frame 202 of the INTRA layer, the frame thus being also an independently determined video frame that has been determined without using motion-compensated temporal prediction. The temporal transmission frequency of I-frames depends on many factors relating to video coding, image information contents and the bandwidth to be used, and, depending on the application or application environment, I-frames are transmitted in a video sequence at intervals of 0.5 to 10 seconds, for example. Since the I-frame 202 can be independently decoded, it also forms a separate sub-sequence. Since this is the second sub-sequence in the INTRA-layer, the consecutive numbering of the sub-sequence identifier of the I-frame 202 is 1. Further, since the I-frame 202 also forms a separate sub-sequence, i.e. it is the only video frame in the sub-sequence, its image number is 0. The I-frame 202 can thus be designated with identifier (I.1.0.) Correspondingly, the identifier of the next I-frame on the INTRA layer is (I.2.0.), etc. As a result, only independently determined I-frames in which the image information is not determined using motion-compensated temporal prediction are coded into the first scalability layer, i.e. the INTRA layer. The sub-sequences can also be determined using other kind of numbering or other identifiers, provided that the sub-sequences can be distinguished from one another.

[0037] The next scalability layer, which has a layer number 1, for example, and which may be referred to as the base layer, comprises coded, motion-compensated INTER or P-frames typically predicted only from previous image frames, i.e. in this case from the I-frames of an upper INTRA layer. The image information of the first P-frame 204 of the base layer shown in Figure 2 is determined using the I-frame 200 of the INTRA layer. A P-frame 204 begins the first sub-sequence of the base layer, and therefore the sub-sequence identifier of the P-frame 204 is 0. Further, since the P-frame 204 is the first image frame of the first sub-sequence of the base layer, the image number of the P-frame 204 is 0. The P-frame 204 can thus be identified with (P.0.0).

[0038] The temporally succeeding P-frame 206 of the base layer is predicted from the previous P-frame 204. The P-frames 204 and 206 thus belong to the same sub-sequence, whereby the P-frame 206 also receives the sub-sequence identifier 0. Since the P-frame 206 is the second image frame in

the sub-sequence 0, the image number of the P-frame 206 is 1, and the P-frame 206 can be identified with (P.0.1).

[0039] The scalability layer succeeding the base layer and having the layer number 2, is called enhancement layer 1. This layer comprises coded, motion-compensated P-frames predicted only from previous image frames, in this case either from I-frames of the INTRA layer or P-frames of the base layer. Figure 2 shows a first image frame 208 and a second image frame 210 of enhancement layer 1, which are both predicted only from the first image frame 200 of the INTRA layer. The P-frame 208 begins the first sub-sequence of enhancement layer 1, the sub-sequence identifier of the P-frame thus being 0. Further, since the P-frame 208 is the first and only image frame in said sub-sequence, the P-frame 208 receives the image number 0. The P-frame 208 can thus be identified with (P.0.0.).

[0040] Since the second image frame 210 is also predicted only from the first image frame 200 of the INTRA layer, the P-frame 210 begins the second sub-sequence of enhancement layer 1 and the sub-sequence identifier of the P-frame 210 is therefore 1. Since the P-frame 210 is the first image frame in the sub-sequence, the image number of the P-frame 210 is 0. The P-frame can thus be identified with (P.1.0.). The temporally succeeding P-frame 212 of enhancement layer 1 is predicted from the previous P-frame 210. The P-frames 210 and 212 thus belong to the same sub-sequence, and therefore the P-frame also receives the sub-sequence identifier 1. The P-frame 212 is the second image frame in the sub-sequence 1, and therefore the P-frame receives the image number 1 and can be identified with (P.1.1).

[0041] The temporally fourth image frame 214 of enhancement layer 1 is predicted from the first image frame 204 of the base layer. The P-frame 214 thus begins a third sub-sequence of enhancement layer 1 and therefore the P-frame 214 receives the sub-sequence identifier 2. Further, since the P-frame 214 is the first and only image frame in the sub-sequence, the image number of the P-frame 214 is 0. The P-frame 208 can therefore be identified with (P.2.0).

[0042] Also the temporally fifth image frame 216 of enhancement layer 1 is predicted only from the first image frame 204 of the base layer, the P-frame 216 thus beginning the fourth sub-sequence of enhancement layer 1, and the sub-sequence identifier of the P-frame 216 is 3. In addition, since the P-frame 216 is the first one in the sub-sequence in question, the image

number of the P-frame 216 is 0. The P-frame 216 can therefore be identified with (P.3.0). The temporally following P-frame 218 of enhancement layer 1 is predicted from the previous P-frame 216. The P-frames 216 and 218 thus belong to the same sub-sequence, and the sub-sequence identifier of the P-frame 218 is also 3. Since the P-frame 218 is the second image frame in the sub-sequence 3, the image number of the P-frame 218 is 1 and the identifier of the P-frame 218 is (P.3.1).

[0043] For simplicity and clarity of illustration the above disclosure only relates to I- and P-frames. However, a person skilled in the art will find it apparent that the scalable video coding of the invention can also be implemented using other known image frame types, such as the above described B-frames and at least SI-frames, SP-frames and MH-frames. SI-frames correspond to I-frames, but together with an SP-frame they allow an identical image to be reconstructed. An SP-frame, in turn, is a P-frame subjected to a particular coding that allows an identical image to be reconstructed together with an SI-frame or another SP-frame. SP-frames are typically placed into a video sequence into points where an access point or a scanning point is desired, or where the changing of the coding parameters of the video stream should be possible. The frames can also be used for error correction and for increasing error tolerance. SP-frames are otherwise similar to ordinary P-frames predicted from previous frames, except that they are defined so that they can be replaced by another video frame of the SP- or SI-type, the result of the decoding of the new frame being identical with the decoding result of the original SP-frame that was in the video stream. In other words, a new SP-frame that is used for replacing the one that was in the video stream is predicted from another sequence or video stream and yet the reconstructed frame has identical contents. SP-frames are described for example in the Applicant's earlier application PCT/FI02/00004.

[0044] Similarly as B-frames, macroblocks of MH (Multi Hypothesis) frames, based on motion-compensated prediction, are predicted from two other frames, which are not, however, necessarily located next to an MH-frame. More precisely, the predicted macroblocks are computed as an average of two macroblocks of two other frames. Instead of two frames, MH-frame macroblocks can naturally be also predicted from one other frame. Reference images may change according to macroblock, in other words, all macroblocks

in one and the same image are not necessarily predicted using the same frames.

[0045] A sub-sequence thus covers a specific period of time in a video sequence. The sub-sequences of the same layer or of different layers may be partly or entirely overlapping. If there are temporally overlapping image frames on the same layer, the frames are interpreted as alternative presentations of the same image content and therefore any mode of image presentation can be used. On the other hand, if there are temporally overlapping image frames on different layers, they form different presentations of the same image content, and therefore presentations differ in image quality, i.e. the quality of image is better on a lower layer.

[0046] The above disclosure referring to Figure 2 illustrates a scalable coding arrangement and a hierarchical structure and numbering of image frames according to a preferred embodiment of the invention. In this embodiment the INTRA-layer only comprises I-frames and the base layer can only be decoded using the information received from the INTRA-layer. Correspondingly, the decoding of enhancement layer 1 typically requires information from both the base layer and the INTRA-layer.

[0047] The number of the scalability layers is not restricted to three, as above, but any number of enhancement layers that is considered necessary for producing sufficient scalability may be used. Consequently, the layer number of enhancement layer 2 is four, that of enhancement layer 3 is five, etc. Since some of the image frames in the above example are given the same identifier (e.g. the identifier of both image frames 204 and 208 is (P.0.0)), by including the layer number in the identifier each image frame can be uniquely identified and, at the same time, the dependencies of each image frame on other image frames is preferably determined. Each image frame is thus uniquely identified, the identifier of image frame 204, for example, being (P.1.0.0), or simply (1.0.0) and, correspondingly, that of image 208 being (P.2.0.0), or (2.0.0).

[0048] According to a preferred embodiment of the invention, the number of a reference image frame is determined according to a specific, pre-determined alpha-numeric series, for example as an integer between 0 and 255. When the parameter value achieves the maximum value N (e.g. 255) in the series concerned, the determining of the parameter value starts from the beginning, i.e. from the minimum value of the series (e.g. 0). An image frame is

thus uniquely identified within a specific sub-sequence up to the point where the same image number is used again. The sub-sequence identifier can also be determined according to a specific, predetermined arithmetic series. When the value of the sub-sequence identifier achieves the maximum value N of the series, the determining of the identifier starts again from the beginning of the series. However, a sub-sequence cannot be assigned an identifier that is still in use (within the same layer). The series in use may also be determined in another way than arithmetically. One alternative is to assign random sub-sequence identifiers, taking into account that an assigned identifier is not be used again.

[0049] A problem in the numbering of image frames arises when the user wishes to start browsing a video file in the middle of a video sequence. Such situations occur for example when the user wishes to browse a locally stored video file backward or forward or to browse a streaming file at a particular point; when the user initiates the playback of a streaming file from a random point; or when a video file that is to be reproduced is detected to contain an error that interrupts the playback or requires the playback to be resumed from a point following the error. When the browsing of a video file is resumed from a random point after previous browsing, discontinuity typically occurs in the image numbering. The decoder typically interprets this as unintentional loss of image frames and unnecessarily tries to reconstruct the image frames suspected as lost.

[0050] According to a preferred embodiment of the invention, this can be avoided in the decoder by defining an initiation image in an independently decodable Group of Pictures GOP that is activated at the random point of the video file, and the number of the initiation image is set at zero. This independently decodable image group can thus be a sub-sequence of an INTRA-layer, for example, in which case an I-frame is used as the initiation image, or, if scaling originating from the base layer is employed, the independently decodable image group is a sub-sequence of the base layer, in which case the first image frame of the sub-sequence, typically an I-frame, is usually used as the initiation image. Consequently, when activated at a random point, the decoder preferably sets the identifier of the first image frame, preferably an I-frame, of the independently decodable sub-sequence at zero. Since the sub-sequence to be decoded may also comprise other image frames whose identifier is zero (for example when the above described alpha-

numeric series starts from the beginning), the beginning of the sub-sequence, i.e. its first image frame, can be indicated to the decoder for example by a separate flag added to the header field of a slice of the image frame. This allows the decoder to interpret the image numbers correctly and to find the correct image frame that initiates the sub-sequence from the video sequence image frames.

[0051] The above numbering system provides only one example of how the unique image frame identification of the invention can be carried out so that interdependencies between the image frames are indicated at the same time. However, video coding methods in which the method of the invention can be applied, such as video coding methods according to the ITU-T standards H.263 and H.26L, employ code tables, which in turn use variable length codes. When variable length codes are used for coding layer numbers, for example, a lower code word index, i.e. a smaller layer number, signifies a shorter code word. In practice the scalable coding of the invention will be used in most cases in such a way that the base layer will consist significantly more image frames than the INTRA-layer. This justifies the use of a lower index, i.e. a smaller layer number, on the base layer than on the INTRA-layer, because the amount of coded video data is thereby advantageously reduced. Consequently, the INTRA-layer is preferably assigned layer number 1 and the base layer is given layer number 0. Alternatively, the code can be formed by using fewer bits for coding the base layer number than the INTRA-layer number, in which case the actual layer number value is not relevant in view of the length of the code created.

[0052] Further, according to a second preferred embodiment of the invention, when the number of the scalability layers is to be kept low, the first scalability layer in particular can be coded to comprise both the INTRA-layer and the base layer. From the point of view of coding hierarchy, the simplest way to conceive this is to leave out the INTRA-layer altogether, and to provide the base layer with coded frames consisting of both independently defined I-frames, the image information of which has not been determined using motion-compensated temporal prediction, and image frames predicted from previous frames, which image frames in this case are motion-compensated P-frames predicted from the I-frames of the same layer. The layer number 0 can thus still be used for the base layer and, if enhancement layers are coded into the video

sequence, enhancement layer 1 is assigned layer number 1. This is illustrated in the following, with reference to Figures 3a and 3b.

[0053] Figure 3a shows a non-scalable video sequence structure, in which all image frames are placed on the same scalability layer, i.e. the base layer. The video sequence comprises a first image frame 300 which is an I-frame (I.0.0) and which thus initiates a first sub-sequence. The image frame 300 is used for predicting a second image frame 302 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 304 of the sub-sequence, i.e. a P-frame (P.0.2), which is in turn used for predicting the next image frame 306, i.e. a P-frame (P.0.3). The video sequence is then provided with an I-frame (I.1.0) coded therein, i.e. an I-frame 308, which thus initiates a second sub-sequence in the video sequence. This kind of non-scalable coding can be used for example when the application employed does not allow scalable coding to be used, or there is no need for it. In a circuit-switched videophone application, for example, channel bandwidth remains constant and the video sequence is coded in real-time, and therefore there is typically no need for scalable coding.

[0054] Figure 3b, in turn, illustrates an example of how scalability can be added, when necessary, to a combined INTRA- and base layer. Here, too, the video sequence base layer comprises a first image frame 310 which is an I-frame (I.0.0) and which initiates a first sub-sequence of the base layer. The image frame 310 is used for predicting a second image frame 312 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 314 of the sub-sequence, i.e. a P-frame (P.0.2). Enhancement layer 1, however, is also coded into this video sequence and it comprises a first sub-sequence, the first and only image frame 316 of which is a P-frame (P.0.0), which is predicted from the first image frame 310 of the base layer. The first image frame 318 of a second sub-sequence of the enhancement layer is, in turn, predicted from the second image frame 312 of the base layer, and therefore the identifier of this P-frame is (P.1.0). The next image frame 320 of the enhancement layer is again predicted from the previous image frame 318 of the same layer and, therefore, it belongs to the same sub-sequence, its identifier thus being (P.1.1).

[0055] In this embodiment of the invention the sub-sequences of the base layer can be decoded independently, although a base layer sub-sequence may be dependent on another base layer sub-sequence. The

decoding of the base layer sub-sequences requires information from the base layer and/or from the second sub-sequence of enhancement layer 1, the decoding of the sub-sequences of enhancement layer 2 requires information from enhancement layer 1 and/or from the second sub-sequence of enhancement layer 2, etc. According to an embodiment, I-frames are not restricted to the base layer alone, but lower enhancement layers may also comprise I-frames.

[0056] The basic idea behind the above embodiments is that a sub-sequence comprises information about all the sub-sequences it is dependent on, i.e. about all sub-sequences that have been used for predicting at least one of the image frames of the sub-sequence in question. However, according to an embodiment it is also possible that a sub-sequence comprises information about all sub-sequences that are dependent on the sub-sequence in question, in other words, about all the sub-sequences in which at least one image frame has been predicted using at least one image frame of the sub-sequence in question. Since in the latter case the dependencies are typically determined temporally forward, image frame buffers can be advantageously utilized in the coding in a manner to be described later.

[0057] In all the above embodiments the numbering of the image frames is sub-sequence-specific, i.e. a new sub-sequence always starts the numbering from the beginning. The identification of an individual image frame thus requires the layer number, sub-sequence identifier and image frame number to be determined. According to a preferred embodiment of the invention, the image frames can be independently numbered using consecutive numbering in which successive reference image frames in the coding order are indicated with numbers incremented by one. As regards layer numbers and sub-sequence identifiers, the above-described numbering procedure can be used. This allows each image frame to be uniquely identified, when necessary, without using the layer number and sub-sequence identifier.

[0058] This is illustrated with the example shown in Figure 4a in which the base layer comprises a temporally first I-frame 400 (I.0.0). This frame is used for predicting a first image frame 402 of enhancement layer 1, i.e. (P.0.1), which is then used for predicting a second image frame 404 belonging to the same sub-sequence (with sub-sequence identifier 0), i.e. (P.0.2), which is used for predicting a third image frame 406 of the same sub-

sequence, i.e. (P.0.3), which is used for predicting a fourth image frame 408 (P.0.4) and, finally, the fourth frame for predicting a fifth image frame 410 (P.0.5). The temporally next video sequence image frame 412 is located on the base layer, where it is in the same sub-sequence as the I-frame 400, although temporally it is only the seventh coded image frame, and therefore its identifier is (P.0.6). The seventh frame is then used for predicting a first image frame 414 of the second sub-sequence of enhancement layer 1, i.e. (P.1.7), which is then used for predicting a second image frame 416 belonging to the same sub-sequence (with sub-sequence identifier 1), i.e. (P.1.8), which in tum used for predicting a third image frame 418 (P.1.9), the third for predicting a fourth image frame 420 (P.1.10) and, finally, the fourth for predicting a fifth image frame 422 (P.1.11) of the same sub-sequence. Again, the temporally next video sequence image frame 424 is located on the base layer, where it is in the same sub-sequence as the I-frame 400 and the P-frame 412, although temporally it is only the thirteenth coded image frame and therefore its identifier is (P.0.12). For clarity of illustration, the above description of the embodiment does not comprise layer identifiers, but it is apparent that in order to implement scalability, also the layer identifier must be signalled together with the video sequence, typically as part of the image frame identifiers.

[0059] Figures 4b and 4c show alternative embodiments for grouping the image frames of the video sequence shown in Figure 4a. The image frames in Figure 4b are numbered according to sub-sequence, i.e. a new sub-sequence always starts the numbering from the beginning (from zero). Figure 4c, in turn, employs image frame numbering which corresponds otherwise to that used in Figure 4a, except that the P-frames of the base layer are replaced by SP-frame pairs to allow for identical reconstruction of image information.

[0060] As stated above, the procedure of the invention can also be implemented using B-frames. One example of this is illustrated in Figures 5a, 5b and 5c. Figure 5a shows a video sequence in the time domain, the sequence comprising P-frames P1, P4 and P7, with B-frames placed between them, the interdependencies of the B-frames with regard to temporal predicting being shown with arrows. Figure 5b shows a preferred grouping of video sequence image frames in which the interdependencies shown in Figure 5a are indicated. Figure 5b illustrates sub-sequence-specific image frame numbering in which a new sub-sequence always starts the numbering of the

image frames from zero. Figure 5c, in turn, illustrates image frame numbering, which is consecutive in the order of temporal prediction, wherein the following reference frame always receives the next image number as the previously encoded reference frame. The image frame (B1.8) (and (B2.10)) does not serve as a reference prediction frame to any other frame, therefore it does not affect the image frame numbering.

[0061] The above examples illustrate different alternatives of how scalability of video sequence coding can be adjusted by using the method of the invention. From the point of view of the terminal device reproducing the video sequence, the more scalability layers are available, or the more scalability layers it is capable of decoding, the better the image quality. In other words, increase in the amount of image information and in the bit rate used for transferring the information improves the temporal or spatial resolution, or the spatial quality of the image data. Correspondingly, a higher number of scalability layers also sets considerably higher demands on the processing capacity of the terminal device performing decoding.

[0062] In addition, the above examples illustrate the advantage gained by using sub-sequences. With image frame identifiers, the dependencies of each image frame from other image frames in the sub-sequence are indicated in an unambiguous manner. A sub-sequence thus forms an independent whole that can be left out of a video sequence, when necessary, without affecting the decoding of subsequent image frames of the video sequence. In that case, only the image frames of the sub-sequence in question and of those sub-sequences on the same and/or lower scalability layers dependent on it are not decoded.

[0063] The image frame identifier data transmitted together with the video sequence are preferably included in the video sequence header fields or in the header fields of the transfer protocol to be used for transferring the video sequence. In other words, the identifier data of predicted image frames are not included in the image data of the coded video sequence, but always into the header fields, whereby the dependencies of the image frames can be detected without decoding the images of the actual video sequence. The identifier data of the image frames can be stored for example in the buffer memory of the streaming server as the video sequence is being coded for transmission. In addition, the sub-sequences can be independently decoded on each scalability

layer, because the image frames of a sub-sequence are not dependent on other sub-sequences of the same scalability layer.

[0064] According to an embodiment of the invention, the image frames comprised by a sub-sequence may thus depend also on other sub-sequences of the same scalability layer. This dependency must then be signalled for example to the streaming server carrying out traffic shaping, because interdependent sub-sequences located on the same layer cannot be separately removed from a video sequence to be transmitted. A preferred way to carry out the signalling is to include it in the image frame identifiers to be transmitted, for example by listing the layer-sub-sequence pairs the sub-sequence in question depends on. This also provides a preferred way of indicating dependency from another sub-sequence of the same scalability layer.

[0065] The above examples illustrate a situation where image frames are temporally predicted from previous image frames. In some coding methods, however, the reference picture selection has been further extended to also include the predicting of the image information of image frames from temporally succeeding image frames. Reference picture selection offers most diversified means for creating different temporally scalable image frame structures and allows the error sensitivity of the video sequence to be reduced. One of the coding techniques based on reference picture selection is INTRA-frame postponement. The INTRA-frame is not placed into its temporally "correct" position in the video sequence, but its position is temporally postponed. The video sequence image frames that are between the "correct" position of the INTRA-frame and its actual position are predicted temporally backward from the INTRA-frame in question. This naturally requires that uncoded image frames be buffered for a sufficiently long period of time so that all image frames that are to be displayed can be coded and arranged into their order of presentation. INTRA-frame transfer and the associated determining of sub-sequences in accordance with the invention are illustrated in the following with reference to Figure 6.

[0066] Figure 6a shows a video sequence part in which the INTRA-frame comprises a single I-frame 600, which is temporally transferred to the position shown in Figure 6, although the "correct" position of the I-frame in the video sequence would have been at the first image frame. The video sequence image frames between the "correct" position and the real position 600 are thus

temporally predicted backward from the I-frame 600. This is illustrated by a sub-sequence coded into enhancement layer 1 and having a first temporally backward predicted image frame 602, which is a P-frame (P.0.0). This frame is used for temporally predicting a previous image frame 604, i.e. a P-frame (P.0.1), which is used in turn for predicting an image frame 606, i.e. a P-frame (P.0.2), and, finally, the frame 606 for predicting an image frame 608, i.e. a P-frame (P.0.3), which is at the position that would have been the "correct" position of the I-frame 600 in the video sequence. Correspondingly, the I-frame 600 on the base layer is used for temporally forward prediction of a sub-sequence comprising four P-frames 610, 612, 614 and 616, i.e. P-frames (P.0.0), (P.0.1), (P.0.2) and (P.0.3).

[0067] The fact that in this example backward predicted image frames are placed on a lower layer than forward predicted image layers indicates that for purposes of illustration, backward predicted image frames are in this coding example considered subjectively less valuable than forward predicted image frames. Naturally the sub-sequences could both be placed on the same layer, in which case they would be considered equal, or a backward predicted sub-sequence could be on the upper layer, in which case it would be considered subjectively more valuable.

[0068] Figures 6b and 6c show some alternatives for coding a video sequence according to Figure 6a. In Figure 6b both forward and backward predicted sub-sequences are placed on the base layer, the I-frame being only located on the INTRA-layer. The forward predicted sub-sequence on this layer is thus the second sub-sequence and its sub-sequence identifier is 1. In Figure 6c, in turn, an I-frame and a forward predicted sub-sequence based on it are located on the base layer, while a backward predicted sub-sequence is located on enhancement layer 1.

[0069] Moreover, according to a preferred embodiment of the invention, the above-described scalability can be utilized for coding what is known as a scene transition into a video sequence. Video material, such as news reports, music videos and movie trailers, often comprise rapid cuts between separate image material scenes. Sometimes the cuts are abrupt, but often a procedure known as scene transition is used in which transfer from one scene to another takes place by dimming, wiping, mosaic dissolving or scrolling the image frames of a previous scene, and, correspondingly, by presenting those of a later scene. From the point of view of coding efficiency,

the video coding of a scene transition is often most problematic, because the image frames appearing during the scene transition comprise information on the image frames of both the terminating and the initiating scene.

[0070] A typical scene transition, fading, is carried out by gradually reducing the intensity or luminance of the image frames of a first scene to zero, while gradually increasing the intensity of the image frames of a second scene to its maximum value. This scene transition is referred to as cross-faded scene transition.

[0071] Generally speaking, a computer-made image can be thought of as consisting of layers, or image objects. Each object can be defined with reference to at least three information types: the structure of the image object, its shape and transparency, and the layering order (depth) in relation to the background of the image and to other image objects. Shape and transparency are often determined using what is known as an alpha plane, which measures opacity and the value of which is usually determined separately for each image object, possibly excluding the background, which is usually determined as non-transparent. The alpha plane value of a non-transparent image object, such as the background, can thus be set at 1.0, whereas the alpha plane value of a fully transparent image object is 0.0. The values in between define the intensity of the visibility of a specific image object in a picture in proportion to the background and to other, at least partly overlapping, image objects that have a higher depth value than the image object in question.

[0072] The superimposition of image objects in layers according to their shape, transparency and depth position is referred to as scene composition. In practice the procedure is based on the use of weighted averages. First, the image object that is closest to the background, i.e. deepest according to its depth position, is placed onto the background and a combined image is formed of the two. The pixel values of the combined image are formed as an average weighted by the alpha plane values of the background image and the image object in question. The alpha plane value of the combined image is then set at 1.0, after which it serves as a background image for the next image object. The process continues until all image objects are attached to the image.

[0073] In the following, a procedure according to a preferred embodiment of the invention will be described in which video sequence scalability layers are combined with the above described image objects of

image frames and their information types to provide a scene transition with scalable video coding that also has good compression efficiency.

[0074] This embodiment of the invention is illustrated in the following by way of example and in a simplified manner by using cross-faded scene transition, on one hand, and abrupt scene transition, on the other hand, as examples. The image frames to be displayed during a scene transition are typically formed of two superimposed image frames, a first image frame comprising a first image scene and a second image frame a second scene. One of the image frames serves as the background image and other, which is referred to as a foreground image, is placed on top of the background image. The opacity of the background image, i.e. its non-transparency value, is constant. In other words, its pixel-specific alpha plane values are not adjusted.

[0075] In this embodiment of the invention, the background and foreground images are both defined according to scalability layer. This is illustrated in Figure 7, which shows an example of how image frames of two different scenes can be placed on scalability layers during a scene transition of the invention. Figure 7 shows a first image frame 700 of a first (terminating) scene positioned on the base layer. The image frame 700 may be either an I-frame containing image information that has not been determined using motion-compensated temporal predicting, or it may be a P-frame that is a motion-compensated image frame predicted from previous image frames. The coding of a second (initiating) scene starts during the temporally following image frame and, according to the invention, the image frames of the scene are also placed on the base layer. Remaining image frames 702, 704 of the second (terminating) scene are then placed on enhancement layer 1. These image frames are typically P-frames.

[0076] In this embodiment, the image frames of the second (initiating) scene are thus placed on the base layer, at least for the duration of the scene transition. The first image frame 706 of the scene is typically an I-frame, and it is used for temporally predicting the succeeding image frames of the scene. Consequently, the succeeding image frames of the second scene are temporally predicted frames, typically P-frames, such as frames 708 and 710 shown in Figure 7.

[0077] According to a preferred embodiment of the invention, this placing of image frames on scalability layers can be used for implementing a cross-faded scene transition by determining the image layer that is on the base

layer always as a background image of maximum opacity (100%), or non-transparency value. During a scene transition, image frames located on enhancement layers are placed onto the background image and their opacity is adjusted for example by means of suitable filters such that the frames gradually change from non-transparent to transparent.

[0078] In the video sequence of Figure 7, there are no image frames on the lower scalability layers during the first base layer image frame 700. For this time instant, the first image frame 700 is only coded into the video sequence.

[0079] The next image frame 706 of the base layer initiates a new (second) scene, during which the image frame 706 is provided with depth positioning that places it as the background image, and its opacity value is set to the maximum. Temporally simultaneously with the image frame 706 of the base layer, there is an image frame 702 of a terminating (first) scene on enhancement layer 1. To allow a cross-faded scene transition to be produced, the transparency of the frame 702 must be increased. The example of Figure 7 assumes that the opacity of the image frame 702 is set at 67% and, in addition, the image frame 702 is provided with depth positioning that determines it as a foreground image. For this time instant, an image combining the image frames 706 and 702 is coded into the video sequence, image 706 being visible as a weaker image on the background and image 702 as a stronger image at the front, because its opacity value is essentially high (67%).

[0080] During the temporally following image frame, there is a second image frame 708 of the second scene on the base layer, the frame 708 being thus correspondingly provided with depth positioning determining it as a background image, and its opacity value is set to the maximum. Enhancement layer 1 further comprises the last image frame 704 of a temporally simultaneously terminating (first) scene, the opacity value of the frame being set at 33% and, in addition, the image frame 704 being provided with depth positioning that determines it as a foreground image as well. Consequently, for this time instant, an image combined of the image frames 708 and 704 is coded into the video sequence, the image 708 being displayed as a stronger image on the background and the image 704 as a weaker image on the foreground, because the opacity value of the image 704 is no longer more than 33%.

[0081] During the temporally following image frame, the base layer comprises a third image frame 710 of the second scene. Since the first scene has terminated, only the image frame 710 is coded into the video sequence, and the displaying of the second scene continues from the frame 710.

[0082] The above disclosure describes, by way of example, the positioning of image frames according to the invention on scalability layers to implement cross-faded scene transition in a manner that is advantageous from the point of view of coding efficiency. However, it is possible that when a video sequence is being transmitted or decoded, a situation arises in which the bit rate of the video sequence must be adjusted according to the maximum value of the bandwidth and/or terminal device decoding rate available for data transfer. This kind of bit rate control causes problems when the scene transition is to be implemented using prior art video coding methods.

[0083] A preferred embodiment of the present invention now allows one or more scalability layers, or independently decodable sub-sequences included in them, to be removed from a video sequence, whereby the bit rate of the video sequence can be decreased and yet, at the same time, the video sequence can be decoded without reducing image frequency. In the image frame positioning according to Figure 7, this can be implemented by removing enhancement layer 1 from the video sequence. The video sequence is thus only used for displaying the image frames 700, 706, 708 and 710 of the base layer. In other words, a direct transition from the first (terminating) scene to the second (initiating) scene takes place in the form of an abrupt scene transition, i.e. directly from the image frame 700 of the first scene into the I-image frame 706 that initiates the second scene. The transition is thus not a cross-faded scene transition but an abrupt scene transition. Nevertheless, the scene transition can be carried out in an advantageous manner without affecting the quality of the video sequence image, and the viewer usually does not experience an abrupt scene transition carried out instead of a cross-faded scene transition in any way disturbing or faulty. On the contrary, since the prior art implementation does not allow scalability layers to be removed, scene transition would often require image frequency to be reduced, which the viewer would find jerky and disturbing.

[0084] The invention thus provides a preferred means for carrying out multimedia data traffic shaping in a streaming server comprising information about the different sub-sequences of a video sequence: their

average bit rate, location in relation to the entire video sequence, duration and their interdependencies regarding the layers. The streaming server also determines the maximum value of the bandwidth available for the data transfer and/or the decoding rate of the terminal device. On the basis of this information, the streaming server decides how many scalability layers and which sub-sequences are transmitted in the video sequence. Bit rate control can thus be carried out, when necessary, by making first a rough adjustment of the number of the scalability layers, after which finer sub-sequence-specific adjustment can be easily carried out. At its simplest, bit rate control means making sub-sequence-specific decisions on whether a particular sub-sequence will be added to a video sequence or removed from it. In case of removal it is advisable to remove entire sub-sequences from a video sequence, because the removal of separate images may cause errors in other images of the same sub-sequence. For the same reason, all sub-sequences of a lower enhancement layer should be left out if they are dependent on the removed sub-sequence of a higher layer. If there are interdependent sub-sequences on one and the same scalability layer, sub-sequences dependent on an earlier sub-sequence must be removed if the earlier sub-sequence is removed.

[0085] If the image frame identifier data are added to a video sequence that is to be transmitted, traffic shaping can also be carried out in a telecommunications network element to be used for the transfer of the video sequence, for example in an Internet router, in different gateways, or at a base station or base station controller of a mobile communications network. For the network element to be able to maintain and process the sub-sequence information, it must have extra memory and processing capacity. For this reason traffic shaping that is to be carried out in the network is perhaps most probably executed using simple processing methods, such as the DiffServ, i.e. differentiated services, procedure that is supported by some IP-based networks. In the DiffServ method, each IP data packet is assigned a priority, whereby data packets of a higher priority are relayed faster and more reliably to the recipient than packets of a lower priority. This is advantageously applied to the scalability of the invention by determining not only scalability-layer-specific, but also sub-sequence-specific priorities, which enables a highly advanced priorisation.

[0086] There are many alternatives for adding image frame identifier data to a video sequence that is to be transmitted. In addition, it is also

possible not to include any identifier data into the video sequence, in which case traffic shaping is only carried out at the streaming server. The identifier data can be included in the header fields of a video sequence, or in the header fields of the transfer protocol to be used, such as RTP (Real Time Protocol). According to a preferred embodiment, the identifier data can be transferred using a Supplemental Enhancement Information (SEI) mechanism. SEI provides a data delivery mechanism that is transferred synchronously with the video data content, thus assisting in the decoding and displaying of the video sequence. The SEI mechanism, particularly when used for transferring layer and sub-sequence information, is disclosed more in detail in the ITU-T standard document ITU-T Rec. H.264 (ISO/IEC 14496 – 10:2002), Annex D. In the cases, wherein a separate transfer protocol or mechanism is used for identifier data transfer, traffic shaping can be carried out also at one of the network elements of the transfer path. In addition, the receiving terminal device can control the decoding.

[0087] If the encoder or decoder supports reference picture selection, video sequence coding requires that decoded image frames be buffered before the coding so as to allow the relationships between different image frames to be temporally predicted from one or more other image frames. Image frame buffering can be arranged at least in two different ways, either as sliding windowing or as adaptive buffer memory control. In sliding windowing, M image frames that were coded last are used as a buffer. The frames in the buffer memory are in a decoded and reconstructed form, which allows them to be used as reference images in the coding. As the coding proceeds, the image frame buffering functions on the basis of the FIFO principle (First-In-First-Out). Images that are not used as reference images, such as conventional B-images, do not need to be stored in the buffer. Alternatively, the buffering can be also be implemented as adaptive buffer memory control, in which case the image buffering is not restricted to the FIFO principle, but image frames that are not needed can be removed from the buffer in the middle of the process, or, correspondingly, some image frames can be stored in the buffer for a longer period of time, if they are needed as reference images for later image frames. A known reference picture selection is implemented by indexing image frames that are in the buffer memory into a specific order, the image indices being then used to refer to an image in connection with motion-compensation, for example. This indexing method generally provides better compression

efficiency compared to using image numbers, for example, for referring to a specific image when motion-compensation reference images are to be signalled.

[0088] The above reference image indexing method is sensitive to transfer errors, because the buffers of the sender's encoder and the recipient's decoder must contain mutually corresponding reconstructed images in identical order to ensure that the encoder and decoder both form the same indexing order. If the image frames are indexed in different order in the buffers of the encoder and the decoder, an incorrect reference image may be used in the decoder. To prevent this, it is essential that the decoder can be controlled to take into account image frames and sub-sequences that the encoder has intentionally removed from the video sequence. In that case the image frame numbering may comprise gaps, which the decoder typically interprets as errors and tries to reconstruct the image frames interpreted as lost. For this reason, it is essential that the encoder is capable to inform the decoder that the discontinuities in the image numbering of the transmitted image frames are intentional.

[0089] In response to this, and provided that sliding windowing is used for buffering the image frames, the decoder enters into the buffer memory a number of image frames, the contents of which may be fully random, corresponding to the missing image numbers. These random image frames are then designated by an identifier "invalid" to indicate that the frames in question do not belong to the actual video sequence, but are only filler frames entered for purposes of buffer memory management. A filler frame can naturally be implemented using only memory indicators, i.e. no data is preferably entered into the buffer memory, but memory management is used merely to store a reference to a generic "invalid" frame. The entering of the image frames of the actual video sequence continues from the correct image frame number after the number of filler frames indicated by the missing image numbers has been entered into the buffer, which allows the buffer memories of the encoder and the decoder to be kept preferably in synchronism. If during decoding a reference to an image number is detected which is then found to indicate a filler frame located in the buffer, error correction actions are initiated in the decoder to reconstruct the actual reference image, for example by asking the encoder to re-transmit the reference image in question.

[0090] Further, the procedure of the invention allows separate buffer memories to be used on the different scalability layers, or, correspondingly, sub-sequence-specifically. Each scalability layer may thus have a separate buffer memory that is conceptually separate and functions on the basis of the sliding window principle. Similarly, each sub-sequence may also be provided with a conceptually separate buffer memory that also functions on the basis of the sliding window principle. This means that the buffer memory is always emptied when a sub-sequence terminates. Separate buffer memories can be used in a preferred manner for reducing the need for signalling in certain situations in which ordinary sliding window buffering would be inadequate and actively adaptive buffer memory management would need to be used instead.

[0091] The H.26L standard defines a picture order count as a picture position in output order. The decoding process specified in the H.26L standard uses picture order counts to determine default index orderings for reference pictures in B slices, to represent picture order differences between frames and fields for vector scaling in motion vector prediction and for implicit mode weighted prediction in B slices, and to determine when successive slices in decoding order belong to different pictures. The picture order count is coded and transmitted for each picture.

[0092] In one embodiment of the invention, the decoder uses the picture order count to conclude that pictures are temporally overlapping, i.e., pictures that have an equal picture order count are temporally overlapping. Preferably, the decoder outputs only the picture on the highest received layer. In the absence of layer information, the decoder concludes that the latest temporally overlapping picture in decoding order resides on highest received layer.

[0093] The above disclosure describes a procedure for coding video frames for the purpose of producing a scalable, compressed video sequence. The actual procedure is carried out in a video encoder, such as the compressor 108 of Figure 1, which may be any known video encoder. For example a video encoder according to the ITU-T recommendation H.263 or H.26L may be used, the video encoder being arranged to form, in accordance with the invention, a first sub-sequence into a video sequence, at least part of the sub-sequence being formed by coding I-frames; to form at least a second sub-sequence into the video sequence, at least part of the sub-sequence being formed by coding at least P- or B-frames, and at least one video frame of

the second sub-sequence being predicted from at least one video frame of the first sub-sequence; and to determine into the video sequence the identification data of at least the video frames of the second sub-sequence.

[0094] According to the procedure of the invention, each sub-sequence of a particular scalability layer is preferably independently decodable, naturally taking into account dependencies from higher scalability layers and possibly other sub-sequences of the same scalability layer. A scalably compressed video sequence such as the one described above can thus be decoded by decoding a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding at least I-frames, and by decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence, and by determining the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence, and by reconstructing at least part of the video sequence on the basis of the sub-sequence dependencies.

[0095] The actual decoding takes places in the video decoder, such as the decompressor 118 of Figure 1, which may be any known video decoder. For example, a low bit rate video decoder according to the ITU-T recommendation H.263 or H.26L may be used, which in this invention is arranged to decode a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding I-frames; to decode at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. The video decoder is arranged to determine the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence and to reconstruct at least part of the video sequence on the basis of the dependencies of the sub-sequences.

[0096] An essential aspect in the operation of the streaming system of the invention is that the encoder and decoder are positioned at least so that the encoder is operationally connected to the streaming server and the decoder is operationally connected to the receiving terminal device. However,

the different elements of the streaming system, terminal devices in particular, may include functionalities that allow two-way transfer of multimedia files, i.e. transmission and reception. The encoder and decoder can thus be implemented in the form of what it known as a video codec integrating both encoder and decoder functionalities.

[0097] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

[0098] Another alternative is to implement the invention as a video signal comprising a scalably compressed video sequence which in turn comprises video frames coded according to at least a first and a second frame format, the video frames according to the first frame format being independent of other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames. According to the invention, the video signal in question comprises at least a first sub-sequence, at least part of which has been formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format; and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field that determines video frames belonging to the second sub-sequence.

[0099] It is apparent to a person skilled in the art that as technology advances the basic idea of the invention can be implemented in various ways. The invention and its embodiments are therefore not restricted to the above examples, but they may vary within the scope of the claims.

CLAIMS

1. A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the method comprising:

encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence.

2. A method according to claim 1, further comprising:

encoding the indication into the video sequence as a separate flag included in the header of a slice.

3. A method according to claim 1, further comprising:

encoding identifier values for image frames according to a numbering scheme, and

resetting the identifier value for the indicated first image frame of an independent sequence.

4. A method according to claim 1, further comprising:

encoding into the video sequence an identifier value for the independent sequence.

5. A video encoder for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the video encoder being arranged to

encode into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence.

6. A video encoder according to claim 5, wherein the video encoder is arranged to

encode the indication into the video sequence as a separate flag included in the header of a slice.

7. A video encoder according to claim 5, wherein the video encoder is arranged to

encode identifier values for image frames according to a numbering scheme, and

reset the identifier value for the indicated first image frame of an independent sequence.

8. A video encoder according to claim 5, wherein the video encoder is arranged to

encode into the video sequence an identifier value for the independent sequence.

9. A computer program product, stored on a computer readable medium and executable in a data processing device, for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the computer program product comprising:

a computer program code for encoding into the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence.

10. A method for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the method comprising

decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; and

starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

11. A method according to claim 10, wherein the indication is a separate flag included in the header of a slice.

12. A method according to claim 10, further comprising:

decoding identifier values for image frames according to a numbering scheme, and

resetting the identifier value for the indicated first image frame of an independent sequence.

13. A video decoder for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the video decoder being arranged to

decode from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; and

start the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

14. A computer program product, stored on a computer readable medium and executable in a data processing device, for decoding a compressed video sequence, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the computer program product comprising:

a computer program code for decoding from the video sequence an indication of at least one image frame, which is the first image frame, in decoding order, of an independent sequence, said sequence including the at least one reference image frame; and

a computer program code for starting the decoding of the video sequence from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

15. A video signal comprising a compressed video sequence including an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order, the video signal further comprising:

an indication of at least one image frame, which is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence.

16. A video signal according to claim 15, the video signal further comprising an identifier value for the independent sequence.

ABSTRACT

A method for encoding a video sequence comprising an independent sequence of image frames, wherein at least one reference image frame is predictable from at least one previous image frame that is earlier than the previous reference image frame in decoding order. An indication of at least one image frame is encoded into the video sequence, which indicated image frame is the first image frame, in decoding order, of the independent sequence, said at least one reference image frame being included in the sequence. In the decoding phase, the indication of at least one image frame is decoded from the video sequence, and the decoding of the video sequence is started from said first image frame of the independent sequence, whereby the video sequence is decoded without prediction from any image frame decoded prior to said first image frame.

§ 1.56 Duty to disclose information material to patentability.

(a) A patent by its very nature is affected with a public interest. The public interest is best served, and the most effective patent examination occurs when, at the time an application is being examined, the Office is aware of and evaluates the teachings of all information material to patentability. Each individual associated with the filing and prosecution of a patent application has a duty of candor and good faith in dealing with the Office, which includes a duty to disclose to the Office all information known to that individual to be material to patentability as defined in this section. The duty to disclose information exists with respect to each pending claim until the claim is canceled or withdrawn from consideration, or the application becomes abandoned. Information material to the patentability of a claim that is canceled or withdrawn from consideration need not be submitted if the information is not material to the patentability of any claim remaining under consideration in the application. There is no duty to submit information which is not material to the patentability of any existing claim. The duty to disclose all information known to be material to patentability is deemed to be satisfied if all information known to be material to patentability of any claim issued in a patent was cited by the Office or submitted to the Office in the manner prescribed by §§ 1.97(b)-(d) and 1.98. However, no patent will be granted on an application in connection with which fraud on the Office was practiced or attempted or the duty of disclosure was violated through bad faith or intentional misconduct. The Office encourages applicants to carefully examine:

(1) prior art cited in search reports of a foreign patent office in a counterpart application, and

(2) the closest information over which individuals associated with the filing or prosecution of a patent application believe any pending claim patentably defines, to make sure that any material information contained therein is disclosed to the Office.

(b) Under this section, information is material to patentability when it is not cumulative to information already of record or being made of record in the application, and

(1) It establishes, by itself or in combination with other information, a prima facie case of unpatentability of a claim; or

(2) It refutes, or is inconsistent with, a position the applicant takes in:

(i) Opposing an argument of unpatentability relied on by the Office, or

(ii) Asserting an argument of patentability.

- A prima facie case of unpatentability is established when the information compels a conclusion that a claim is unpatentable under the preponderance of evidence, burden-of-proof standard, giving each term in the claim its broadest reasonable construction consistent with the specification, and before any consideration is given to evidence which may be submitted in an attempt to establish a contrary conclusion of patentability.

(c) Individuals associated with the filing or prosecution of a patent application within the meaning of this section are:

(1) Each inventor named in the application:

(2) Each attorney or agent who prepares or prosecutes the application; and

(3) Every other person who is substantively involved in the preparation or prosecution of the application and who is associated with the inventor, with the assignee or with anyone to whom there is an obligation to assign the application.

(d) Individuals other than the attorney, agent or inventor may comply with this section by disclosing information to the attorney, agent, or inventor.

Abstract of JP 8265694 (A)

PURPOSE: To rightly restore the encoded image data after an edition is performed by preventing the image for which a second inter-encoding is performed from being outputted by using the image belonging to an original preceding group as a predicted image when an edition flag is set. CONSTITUTION: By using the image belonging to an original preceding group as a predicted image, an edition flag SLPG is set to the group including the encoded data corresponding to the image for which a second inter-encoding which is possible to use the images existing before and after in the time in a display order as predicted images is performed.; A frame order reverse rearranging circuit 90 executes the processing rearranging from the frame order according to a decoding processing to the frame order based on an inut image signal and executes an edition reproduction processing by referring to the edition flag SLPG. Namely, when the edition flag SLPG is set, the image belonging to the original preceding frame group is used as the the predicted image, an interpolation frame is not outputted, the intraframe encoded just before is outputted and an encoding is performed.

(54)【発明の名称】　符号化データ復号化方法及び符号化データ復号化装置

(57)【要約】
【課題】画像信号を複数のフレームを含む複数のグループに分割して符号化した場合、このグループを分断するような編集を行うと、編集後の画像を再生した際の画質が劣化する問題があつた。
【解決手段】編集フラグの有無を検出し、編集フラグが設定されていた場合には先行するグループに属する画像を予測画像に用いて、表示順上で時間的に前後にある画像を予測画像として用いることが可能なインター符号化によつて生成された画像を出力しないようにしたことにより、編集後の符号化画像データを正しく復元し得る符号化データ復号化方法及び装置を実現できる。

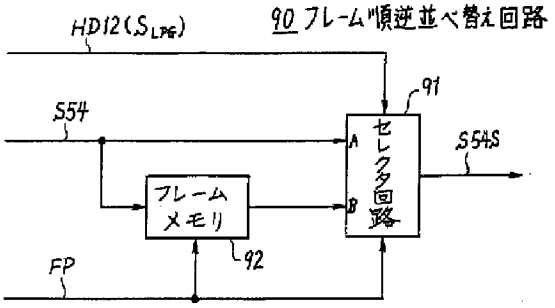

図１２　フレーム順逆並べ替え回路

【特許請求の範囲】
【請求項１】イントラ符号化によつて生成された第１の符号化データと、表示順上で時間的に前にある画像のみを予測画像として用いることが可能な第１のインター符号化によつて生成された第２の符号化データと、表示順上で時間的に前後にある画像を予測画像として用いることが可能な第２のインター符号化によつて生成された第３の符号化データとを含む符号化画像データが、それぞれいくつかの画像に対応する符号化データを含む複数のグループにグループ化され、上記符号化画像データは、元の先行するグループとは異なるグループに先行されるあるグループを少なくとも１つ含むように編集されてなり、上記あるグループは、上記元の先行するグループに属する画像を上記予測画像に用いて上記第２のインター符号化がなされた画像に対応する符号化データを含み、上記あるグループには編集フラグが設定されているような符号化画像データを復号化する符号化データ復号化方法において、
上記編集フラグの設定の有無を検出し、
上記編集フラグが設定されていた場合、上記元の先行するグループに属する画像を上記予測画像に用いて第２のインター符号化された画像を出力しないようにすることを特徴とする符号化データ復号化方法。
【請求項２】上記元の先行するグループに属する画像を上記予測画像に用いて第２のインター符号化された画像のかわりに、直前に復号化されたイントラ符号化された画像を出力することを特徴とする請求項１に記載の符号化データ復号化方法。
【請求項３】イントラ符号化によつて生成された第１の符号化データと、表示順上で時間的に前にある画像のみを予測画像として用いることが可能な第１のインター符号化によつて生成された第２の符号化データと、表示順上で時間的に前後にある画像を予測画像として用いることが可能な第２のインター符号化によつて生成された第３の符号化データとを含む符号化画像データが、それぞれいくつかの画像に対応する符号化データを含む複数のグループにグループ化され、上記符号化画像データは、元の先行するグループとは異なるグループに先行されるあるグループを少なくとも１つ含むように編集されてなり、上記あるグループは、上記元の先行するグループに属する画像を上記予測画像に用いて上記第２のインター符号化がなされた画像に対応する符号化データを含み、上記あるグループには編集フラグが設定されているような符号化画像データを復号化する符号化データ復号化装置において、
上記編集フラグの設定の有無を検出する手段と、
上記編集フラグが設定されていた場合、上記元の先行するグループに属する画像を上記予測画像に用いて第２のインター符号化された画像を出力しないようにする復号化手段とを具えることを特徴とする符号化データ復号化装置。
【請求項４】上記復号化手段は、上記元の先行するグループに属する画像を上記予測画像に用いて第２のインター符号化された画像のかわりに、直前に復号化されたイントラ符号化された画像を出力することを特徴とする請求項３に記載の符号化データ復号化装置。

課題を解決するための手段
発明の実施の形態
（１）動画符号化／復号化装置の全体構成（図１～図５）
（２）実施例による動画符号化データの記録順序（図６～図９）
（３）実施例による動画符号化データのエデイツト処理（図６～図１１）
（４）実施例によるエデイツトされた符号化データの復号化方法（図８及び図１２）
（５）他の実施例（図１３～図１５）
発明の効果
【０００２】
【発明の属する技術分野】本発明は符号化データ復号化方法及び装置に関し、例えばエデイツト可能に符号化した符号化データを復号する際に適用して好適なものである。
【０００３】
【従来の技術】従来動画映像でなる映像信号をフレーム内符号化データ及びフレーム間符号化データに高能率符号化して、例えば光磁気デイスク構成のコンパクトデイスク（ＣＤ－ＭＯデイスク）に高密度記録し、当該記録された動画符号化データを必要に応じて検索して再生し得るようになされた記録再生装置が提案されている（特開昭63-1183号公報、特願平1-267049号）。
【０００４】すなわち、例えば図１６（Ａ）に示すように、時点ｔ＝t_1、t_2、t_3……において動画を構成する各画像ＰＣ１、ＰＣ２、ＰＣ３……をデイジタル符号化して、例えばＣＤ－ＭＯ記録再生装置でなる伝送系に伝送する場合、映像信号には時間の経過に従つて自己相関が大きい特徴がある点を利用して伝送すべき画像データを圧縮処理することにより伝送効率を高めるような処理をするもので、フレーム内符号化処理は画像ＰＣ１、ＰＣ２、ＰＣ３……を例えば画素データを所定の基準値と比較して差分を求めるような圧縮処理を実行し、かくして各画像ＰＣ１、ＰＣ２、ＰＣ３……について同一フレーム内における画素データ間の自己相関を利用して圧縮されたデータ量の画像データを伝送する。

【０００５】またフレーム間符号化処理は、図１６（Ｂ）に示すように、順次隣合う画像ＰＣ１及びＰＣ２、ＰＣ２及びＰＣ３……間の画素データの差分でなる画像データＰＣ１２、ＰＣ２３……を求め、これを時点ｔ＝t_1 における初期画像ＰＣ１についてフレーム内符号化処理された画像データと共に伝送する。かくして画像ＰＣ１、ＰＣ２、ＰＣ３……をそのすべての画像データを伝送する場合と比較して格段的にデータ量が少ないデイジタルデータに高能率符号化してＣＤ－ＭＯ記録再生装置に伝送することができる。

【０００６】かかる映像信号の符号化処理は、図１７に示す構成の動画符号化データ発生装置１において実行される。動画符号化データ発生装置１は入力映像信号ＶＤを前処理回路２において処理することにより片フイールド落し処理及び片フイールドライン間引き処理等の処理をした後、輝度信号及びクロマ信号を16画素（水平方向に）×16画素（垂直方向に）分のデータでなる伝送単位ブロツク（これをマクロブロツクと呼ぶ）データＳ１１に変換して画像データ符号化回路３に供給する。

【０００７】画像データ符号化回路３は予測符号化回路４において形成される予測現フレームデータＳ１２を受けてマクロブロツクデータＳ１１との差分を求めることによつてフレーム間符号化データを発生し（これをフレーム間符号化モードと呼ぶ）、又はマクロブロツクデータＳ１１と基準値データとの差分を求めることによりフレーム内符号化データを形成してこれを差分データＳ１３として変換符号化回路５に供給する。

【０００８】変換符号化回路５はデイスクリートコサイン変換回路で構成され、差分データＳ１３を直交変換することによつて高能率符号化してなる変換符号化データＳ１４を量子化回路６に与えることにより量子化画像データＳ１５を送出させる。かくして量子化回路６から得られる量子化画像データＳ１５は可変長符号化回路を含んでなる再変換符号化回路７において再度高能率符号化処理された後、伝送画像データＳ１６として伝送バツフアメモリ８に供給される。

【０００９】これに加えて量子化画像データＳ１５は予測符号化回路４において逆量子化、逆変換符号化処理されることより差分データに復号化された後予測前フレームデータを差分データによつて修正演算することにより新たな予測前フレームデータを保存すると共に、マクロブロツクデータＳ１１に基づいて形成される動き検出データによつて予測符号化回路４に保存されている予測前フレームデータを動き補償することにより予測現フレームデータを形成して画像データ符号化回路３に供給できるようになされ、これにより現在伝送しようとするフレーム（すなわち現フレーム）のマクロブロツクデータＳ１１と予測現フレームデータＳ１２との差分を差分データＳ１３として得るようになされている。

【００１０】図１７の構成において、図１６について上述した動画像を伝送する場合、先ず図１６（Ａ）の時点t_1 において画像ＰＣ１の画像データがマクロブロツクデータＳ１１として与えられたとき、画像データ符号化回路３はフレーム内符号化モードになつてこれをフレーム内符号化処理された差分データＳ１３として変換符号化回路５に供給し、これにより量子化回路６、再変換符号化回路７を介して伝送バツフアメモリ８に伝送画像データＳ１６を供給する。

【００１１】これと共に、量子化回路６の出力端に得られる量子化画像データＳ１５が予測符号化回路４において予測符号化処理されることにより、伝送バツフアメモリ８に送出された伝送画像データＳ１６を表す予測前フレームデータが前フレームメモリに保持され、続いて時点t_2 において画像ＰＣ２を表すマクロブロツクデータＳ１１が画像データ符号化回路３に供給されたとき、予測現フレームデータＳ１２に動き補償されて画像データ符号化回路３に供給される。

【００１２】かくして時点ｔ＝t_2 において画像データ符号化回路３はフレーム間符号化処理された差分データＳ１３を変換符号化回路５に供給し、これにより当該フレーム間の画像の変化を表す差分データが伝送画像データＳ１６として伝送バツフアメモリ８に供給されると共に、その量子化画像データＳ１５が予測符号化回路４に供給されることにより予測符号化回路４において予測前フレームデータが形成されると共に保存される。

【００１３】以下同様の動作が繰り返されることにより、画像データ符号化回路３がフレーム間符号化処理を実行している間、前フレームと現フレームとの間の画像の変化を表す差分データだけが伝送バツフアメモリ８に順次送出されることになる。伝送バツフアメモリ８はこのようにして送出されて来る伝送画像データＳ１６を一旦記憶し、伝送路９の伝送容量によつて決まる所定のデータ伝送速度で記憶された伝送画像データＳ１６を順次伝送データD_{TRANS} として引き出して伝送路９に伝送する。

【００１４】これと同時に伝送バツフアメモリ８は残留しているデータ量を検出して当該残留データ量に応じて変化する残量データＳ１７を量子化回路６にフイードバツクして残量データＳ１７に応じて量子化ステツプサイズを制御することにより、伝送画像データＳ１６として発生されるデータ量を調整することにより伝送バツフアメモリ８内に適正な残量（オーバーフロー又はアンダーフローを生じさせないようなデータ量）のデータを維持できるようになされている。

【００１５】因に伝送バツフアメモリ８のデータ残量が許容上限にまで増量して来たとき、残量データＳ１７によつて量子化回路６の量子化ステツプＳＴＰＳ（図１８）のステツプサイズを大きくすることにより、量子化回路６において粗い量子化を実行させることにより伝送画像データＳ１６のデータ量を低下させる。

【００１６】これとは逆に伝送バツフアメモリ８のデータ残量が許容下限値まで減量して来たとき、残量データＳ１７は量子化回路６の量子化ステツプＳＴＰＳのステツプサイズを小さい値になるように制御し、これにより量子化回路６において細かい量子化を実行させるようにすることにより伝送画像データＳ１６のデータ発生量を増大させる。

【００１７】

【発明が解決しようとする課題】ところでかかる構成の動画符号化データ発生装置１から送出される伝送データD_{TRANS}においては、図１９（Ａ）及び（Ｂ）に示すようにフレーム内符号化処理された完全フレーム内処理フレーム（以下これをイントラフレームと呼び、符号「Ａ」で表す）Ａ１、Ａ９、……と、フレーム内符号化処理された前フレーム予測処理フレーム（以下これを予測フレームと呼び、符号「Ｂ」で表す）Ｂ３、Ｂ５、Ｂ７、……及びそれらに応じた補間予測処理フレーム（以下これを補間フレームと呼び、符号「Ｃ」で表す）Ｃ２、Ｃ４、Ｃ６、……が、画像データＶＤの入力フレーム順に伝送されている。

【００１８】ところがこのような伝送データD_{TRANS}を受け、例えば補間フレームＣ２を復号化する際には、図１９（Ｃ）に示すようにイントラフレームＡ１及び予測フレームＢ３が必要になり、動画符号化データの復号化装置としてはイントラフレームＡ１及び予測フレームＢ３を受けるまでの間、補間フレームＣ２を遅延させるメモリやその制御回路が必要になり、その分回路構成が複雑になると共に遅延量が多大になることを避け得なかつた。

【００１９】このため伝送データD_{TRANS}を図１９（Ｃ）に示すように復号化処理に必要な順序で伝送することが考えられ、このような場合例えば伝送データD_{TRANS}はイントラフレームＡ１、Ａ９、……間の８フレーム分（Ａ１、Ｃ２、Ｂ３、Ｃ４、Ｂ５、Ｃ６、Ｂ７、Ｃ８）でなるフレーム群ＧＯＦ１、ＧＯＦ２がＣＤ－ＭＯデイスクの20セクタ分として記録するようになされている。

【００２０】ところがこのようなフレーム順でＣＤ－ＭＯデイスクに記録された動画符号化データについて、例えばフレーム群ＧＯＦ１を編集して書き換えるエデイツト処理を実行し、先頭から順次再生する際には、フレーム群ＧＯＦ１中の第８の補間フレームＣ８は、フレーム群ＧＯＦ１中の新たな第７の予測フレームＢ７とフレーム群ＧＯＦ２中の古い第１のイントラフレームＡ９に基づいて補間されることにより映像信号を得ることができず、結局エデイツト結果を正しく再生できないという問題があつた。

【００２１】本発明は以上の点を考慮してなされたもので、従来の問題を一挙に解決して、編集された動画像符号化データを、簡易な構成で正しく再生することができる符号化データ復号化方法及び装置を提案しようとするものである。

【００２２】

【課題を解決するための手段】かかる課題を解決するため本発明においては、イントラ符号化によつて生成された第１の符号化データと、表示順上で時間的に前にある画像のみを予測画像として用いることが可能な第１のインター符号化によつて生成された第２の符号化データと、表示順上で時間的に前後にある画像を予測画像として用いることが可能な第２のインター符号化によつて生成された第３の符号化データとを含む符号化画像データVD_{REC}が、それぞれいくつかの画像に対応する符号化データを含む複数グループＧＯＦにグループ化され、符号化画像データV_{REC}は、元の先行するグループＧＯＦとは異なるグループＧＯＦに先行されるあるグループＧＯＦを少なくとも１つ含むように編集されてなり、上記あるグループＧＯＦは、元の先行するグループＧＯＦに属する画像を予測画像に用いて第２のインター符号化がなされた画像に対応する符号化データを含み、上記あるグループＧＯＦには編集フラグS_{LPG}が設定されているような符号化画像データVD_{REC}（VD_{PB}）を復号化する符号化データ復号化装置２１において、編集フラグS_{LPG}の設定の有無を検出する手段９０と、編集フラグS_{LPG}が設定されていた場合、上記元の先行するグループＧＯＦに属する画像を上記予測画像に用いて第２のインター符号化された画像を出力しないようにする復号化手段とを設けるようにする。

【００２３】また本発明においては、復号化手段は、元の先行するグループＧＯＦに属する画像を予測画像に用いて第２のインター符号化された画像のかわりに、直前に復号化されたイントラ符号化された画像を出力するようにする。

【００２４】

【発明の実施の形態】以下図面について、本発明を動画符号化データ記録再生装置に適用した場合の実施例を詳述する。

【００２５】（１）動画符号化／復号化装置の全体構成図１及び図２において動画符号化／復号化装置２１は動画符号化装置２１Ａ及び動画復号化装置２１Ｂによつて構成され、動画符号化装置２１Ａは入力映像信号VD_{IN}を入力回路部２２において前処理した後、アナログ／デイジタル変換回路２３において16×16画素分の画素データでなる伝送単位ブロツクデータ、すなわちマクロブロツクＭＢの画素データでなる入力画像データＳ２１を画素データ処理系ＳＹＭ１に送り込むと共に、当該画素データ処理系ＳＹＭ１の各処理段においてマクロブロツクＭＢを単位として画素データが処理されるタイミングにおいて当該処理されるデータに対応する処理情報データがヘツダデータ処理系ＳＹＭ２を介して順次伝送されて行くようになされ、かくして画素データ及びヘツダデー

タがそれぞれ画素データ処理系ＳＹＭ１及びヘツダデータ処理系ＳＹＭ２において並列処理される。

【００２６】この実施例の場合、入力画像データＳ２１として順次送出されて来るマクロブロツクデータは、図３に示すような手法でフレーム画像データＦＲＭから抽出される。第１に入力映像信号VD_{IN}がＱＣＩＦの画サイズ（ 176× 144画素）でなる場合、先ず１枚のフレーム画像データＦＲＭは図３（Ａ１）に示すように１個（水平方向に）×３個（垂直方向に）のブロツクグループＧＯＢに分割され、各ブロツクグループＧＯＢが図３（Ｂ）に示すように11個（水平方向に）×３個（垂直方向に）のマクロブロツクＭＢを含むようになされ、各マクロブロツクＭＢは図３（Ｃ）に示すように16×16画素分の輝度信号データY_{00}～Y_{11}（それぞれ８×８画素分の輝度信号データでなる）及び輝度信号データY_{00}～Y_{11}の全画素データに対応する色信号データでなる色信号データC_b 及びC_r を含んでなる。

【００２７】これに対して第２に入力映像信号VD_{IN}がＣＩＦの画サイズ（252 ×288 画素）でなる場合、１枚のフレーム画像データＦＲＭは図３（Ａ２）に示すように２個（水平方向に）×６個（垂直方向に）のブロツクグループＧＯＢに分割され、各ブロツクグループＧＯＢが図３（Ｂ）に示すように11個（水平方向に）×３個（垂直方向に）のマクロブロツクＭＢを含むようになされ、各マクロブロツクＭＢは図３（Ｃ）に示すように16×16画素分の輝度信号データY_{00}～Y_{11}（それぞれ８×８画素分の輝度信号データでなる）及び輝度信号データY_{00}～Y_{11}の全画素データに対応する色信号データでなる色信号データC_b 及びC_r を含んでなる。

【００２８】かくしてマクロブロツクＭＢごとに送出される入力画像データＳ２１は動き補償回路２５に与えられ、動き補償回路２５はヘツダデータ処理系ＳＹＭ２に対して設けられている動き補償制御ユニツト２６から与えられる動き検出制御信号Ｓ２２に応動して予測前フレームメモリ２７の予測前フレームデータＳ２３と入力画像データＳ２１とを比較して動きベクトルデータMVD(x)及びMVD(y)を検出して動き補償制御ユニツト２６に第１のヘツダデータＨＤ１（図４）のデータとして供給すると共に、動き補償回路本体２５Ａにおいて予測前フレームデータＳ２３に対して動きベクトルデータMVD(x)及びMVD(y)分の動き補償をすることにより予測現フレームデータＳ２４を形成して現在処理しようとしている入力画像データＳ２１でなる現フレームデータＳ２５と共に画像データ符号化回路２８に供給する。

【００２９】ここで動き補償制御ユニツト２６は、図４に示すように、第１のヘツダデータＨＤ１として現在処理しているマクロブロツクごとに、フレーム画像データＦＲＭの伝送順序を表す伝送フレーム番号データTR Counterと、そのブロツクグループＧＯＢ（図３（Ａ１）、（Ａ２））を表すブロツクグループ番号データGOB address と、そのうちのマクロブロツクＭＢを表すマクロブロツク番号データMB addressとを付加することによつて順次画素データ処理系ＳＹＭ１の各処理段に伝送されて行くマクロブロツクＭＢを表示するようになされていると共に、当該処理対象マクロブロツクＭＢの処理ないし処理形式を表すフラグデータFLAGS と、当該マクロブロツクＭＢの動きベクトルデータMVD(x)及びMVD(y)と、その評価値を表す差分データΣ｜Ａ－Ｂ｜とを形成する。

【００３０】フラグデータFLAGS は図５に示すように、最大限１ワード（16ビツト）分のフラグをもち得るようになされ、第０ビツトには、当該処理対象マクロブロツクＭＢについて動き補償モードで処理すべきか否かを表す動き補償制御フラグMC on/off がセツトされる。またフラグデータFLAGS の第１ビツトには、当該処理対象マクロブロツクＭＢをフレーム間符号化モードで処理すべきであるか又はフレーム内符号化モードで処理すべきであるかを表すフレーム間／フレーム内フラグInter/Intra がセツトされる。

【００３１】またフラグデータFLAGS の第２ビツトには、動き補償回路２５のループフイルタ２５Ｂを使用するか否かを表すフイルタフラグFilter on/off が設定される。またフラグデータFLAGS の第３ビツトには、当該処理対象マクロブロツクに含まれるブロツクデータY_{00}～C_r （図３（Ｃ））を伝送すべきであるか否かを表す送信フラグCoded/Not-coded を設定できるようになされている。

【００３２】またフラグデータFLAGS の第４ビツトには、当該処理対象マクロブロツクＭＢを駒落しするか否かを表す駒落しフラグDrop frame flag を設定し得るようになされている。またフラグデータFLAGS の第５ビツトには、当該処理対象マクロブロツクＭＢを強制リフレツシユするか否かを表す強制リフレツシユフラグRefresh on/offを設定できるようになされている。

【００３３】またフラグデータFLAGS の第６ビツトには、マクロブロツクパワー評価フラグMBP appreciateを設定できるようになされている。また差分データΣ｜Ａ－Ｂ｜は、現フレームデータＳ２５の現在処理しようとするマクロブロツクデータＡと、予測前フレームデータＳ２３の検出用動きベクトルによつて補償されたマクロブロツクデータＢとの差分のうちの最小値を表し、これにより検出された動きベクトルの評価をなし得るようになされている。

【００３４】画像データ符号化回路２８はフレーム内符号化モードのとき動き補償回路２５から与えられる現フレームデータＳ２５をそのまま差分データＳ２６として変換符号化回路２９に供給し、これに対してフレーム間符号化モードのとき現フレームデータＳ２５の画素データと予測現フレームデータＳ２４の画素データとの差分でなる差分データＳ２６を変換符号化回路２９に供給する。

【００３５】ヘツダデータ処理系ＳＹＭ２には画像データ符号化回路２８に対応するようにフレーム間／フレーム内符号化制御ユニツト３０が設けられ、動き補償制御ユニツト２６から供給されるヘツダデータＨＤ１及び画像データ符号化回路２８から供給される演算データＳ３１に基づいて、画像データ符号化回路２８の符号化モードを指定するためのフレーム間／フレーム内フラグInter/Intra （図５）及び動き補償回路２５のループフイルタ２５Ｂの動作を制御するためのフイルタフラグFilter on/off （図５）とを得るのに必要なデータを演算して第２のヘツダデータＨＤ２としてフイルタ制御ユニツト３１に送出する。

【００３６】第２のヘツダデータＨＤ２は、図４に示すように、ヘツダデータＨＤ１を構成する伝送フレーム番号データTR Counter～差分データΣ｜Ａ－Ｂ｜をそのまま引き継ぐと共に、フイルタ制御ユニツト３１においてフレーム間／フレーム内符号化モード切換信号Ｓ３３及びフイルタオン／オフ信号Ｓ３４を形成するために必要なパワーデータΣ（A)^2（Ｌ）及びΣ（A)^2（Ｈ）、Σ（Ａ－Ｂ)^2（Ｌ）及びΣ（Ａ－Ｂ)^2（Ｈ）、Σ（Ａ－ＦＢ)^2（Ｌ）及びΣ（Ａ－ＦＢ)^2（Ｈ）、Σ（Ａ）をフレーム間／フレーム内符号化制御ユニツト３０において付加されるようになされている。

【００３７】ここで、パワーデータΣ（A)^2（Ｌ）及びΣ（A)^2（Ｈ）は現フレームデータＳ２５のマクロブロツク画素データＡの２乗和の下位ビツト及び上位ビツトを表し、パワーデータΣ（Ａ－Ｂ)^2（Ｌ）及びΣ（Ａ－Ｂ)^2（Ｈ）は現フレームデータＳ２５のマクロブロツク画素データＡとループフイルタ２５Ｂを介さずに形成された予測現フレームデータＳ２４のマクロブロツク画素データＢとの差分Ａ－Ｂの２乗和の下位ビツト及び上位ビツトを表し、パワーデータΣ（Ａ－ＦＢ)^2（Ｌ）及びΣ（Ａ－ＦＢ)^2（Ｈ）は現フレームデータＳ２５のマクロブロツク画素データＡとループフイルタ２５Ｂを介して形成された予測現フレームデータＳ２４のマクロブロツク画素データＦＢとの差分Ａ－ＦＢの２乗和の下位ビツト及び上位ビツトを表し、パワーデータΣ（Ａ）は現フレームデータＳ２５のマクロブロツク画素データＡの和を表し、それぞれ処理するデータの大きさを評価するためにデータ量をパワー値として表現したもの（２乗和は符号に無関係な値として求めた）である。

【００３８】フイルタ制御ユニツト３１は、フレーム間／フレーム内符号化制御ユニツト３０から渡された第２のヘツダデータＨＤ２と、伝送バツフアメモリ３２から供給される残量データＳ３２とに基づいて、画像データ符号化回路２８に対してフレーム間／フレーム内符号化モード切換信号Ｓ３３を送出すると共に、ループフイルタ２５Ｂに対してフイルタオン／オフ信号Ｓ３４を送出すると共に、当該フイルタオン／オフ信号Ｓ３４の内容を表すフイルタフラグFilter on/off を第２のヘツダデータＨＤ２に付加して第３のヘツダデータＨＤ３としてスレシヨルド制御ユニツト３５に渡す。ここでフイルタ制御ユニツト３１は第１に、フレーム間符号化処理をした場合の伝送データ量の方がフレーム内符号化処理をした場合の伝送データ量より大きくなつたとき画像データ符号化回路２８をフレーム内符号化モードに制御する。

【００３９】またフイルタ制御ユニツト３１は第２に、フレーム間符号化モードで処理をしている状態においてループフイルタ２５Ｂにおける処理を受けた予測現フレームデータＳ２４より当該処理を受けない予測現フレームデータＳ２４の方が差分値が小さい場合には、フイルタオン／オフ信号Ｓ３４によつてフイルタリング動作をさせないようにループフイルタ２５Ｂを制御する。

【００４０】またフイルタ制御ユニツト３１は第３に、強制リフレツシユモードになつたとき、フレーム間／フレーム内符号化モード切換信号Ｓ３３によつて画像データ符号化回路２８をフレーム内符号化モードに切り換える。さらにフイルタ制御ユニツト３１は第４に、伝送バツフアメモリ３２から供給される残量データＳ３２に基づいて伝送バツフアメモリ３２がオーバーフローするおそれがある状態になつたとき、これを検出して駒落し処理をすべきことを命令するフラグを含んでなる第３のヘツダデータＨＤ３をスレシヨルド制御ユニツト３５に送出する。

【００４１】かくして画像データ符号化回路２８は現フレームデータＳ２５と予測現フレームデータＳ２４との差分が最も小さくなるようなモードで符号化してなる差分データＳ２６を変換符号化回路２９に供給する。

【００４２】第３のヘツダデータＨＤ３は、図４に示すように、ヘツダデータＨＤ２から伝送フレーム番号データTR Counter～動きベクトルデータMVD(x)及びMVD(y)を引き継ぐと共に、フイルタ制御ユニツト３１においてブロツクデータY_{00}～C_r に対応する６ビツト分のフイルタフラグFilter on/off を付加される。

【００４３】変換符号化回路２９はデイスクリートコサイン変換回路でなりデイスクリートコサイン変換後の係数値を６個のブロツクY_{00}、Y_{01}、Y_{10}、Y_{11}、C_b、C_rごとにジグザグスキヤンしてなる変換符号化データＳ３５として伝送ブロツク設定回路３４に送出する。

【００４４】伝送ブロツク設定回路３４は変換符号化データＳ３５として送出されて来る６個のブロツクデータY_{00}～C_r （図３（Ｃ））について、それぞれ先頭の係数データからｎ個までの２乗和を演算して当該演算結果をパワー検出データＳ３６としてスレシヨルド制御ユニツト３５に渡す。

【００４５】このときスレシヨルド制御ユニツト３５は各ブロツクデータY_{00}～C_r ごとにパワー検出データＳ３６を所定のスレシヨルドと比較し、パワー検出データＳ３６が当該スレシヨルドより小さいとき当該ブロツクデータの伝送を許容せず、これに対して大きいとき許容

することを表す６ビット分の伝送可否データＣＢＰＮを形成してこれをフイルタ制御ユニット３１から渡された第３のヘッダデータＨＤ３に付加して第４のヘッダデータＨＤ４として量子化制御ユニット３６に渡すと共に、伝送ブロック設定回路３４から対応するブロックデータY_{00}～C_rを量子化回路３７に送信ブロックパターン化データＳ３７として送出させる。

【００４６】ここで第４のヘッダデータＨＤ４は図４に示すように、ヘッダデータＨＤ３の伝送フレーム番号データTR Counter～フイルタフラグFilter on/off をそのまま引き継ぐと共に、スレショルド制御ユニット３５においてブロックY_{00}～C_rに対応して発生する６ビット分の送信可否フラグＣＢＰＮが付加される。

【００４７】量子化制御ユニット３６はスレショルド制御ユニット３５から渡された第４のヘッダデータＨＤ４と、伝送バッファメモリ３２から送出される残量データＳ３２とに基づいて、量子化ステップサイズ決定処理を実行して得られる量子化ステップサイズ制御信号Ｓ３８を量子化回路３７に与え、これにより量子化回路３７をマクロブロックＭＢに含まれるデータに適応した量子化ステップサイズで量子化処理させ、その結果量子化回路３７の出力端に得られる量子化画像データＳ３９を可変長符号化回路３８に供給させる。

【００４８】これと共に量子化制御ユニット３６は、図４に示すように、第５のヘッダデータＨＤ５として、ヘッダデータＨＤ４に基づいてブロックデータ　Y_{00}～C_r　（図３（Ｃ））にそれぞれ対応するフラグデータFLAGS 及び動きベクトルデータMVD(x)及びMVD(y)に分離してこれを直列に配列させたデータを形成して可変長符号化回路３８及び逆量子化回路４０に渡す。

【００４９】ここで、ヘッダデータＨＤ５は、図４に示すように、ヘッダデータＨＤ４のうち伝送フレーム番号データTR Counter～マクロブロック番号データMB addressをそのまま引き継ぐと共に、量子化制御ユニット３６において量子化サイズデータQNT と、ブロックデータY_{00}～C_rに対するフラグデータFLAGS 、動きベクトルデータMVD(x)及びMVD(y)を付加する。

【００５０】可変長符号化回路３８はヘッダデータＨＤ５及び量子化画像データＳ３９を可変長符号化処理して伝送画像データＳ４０を形成し、これを伝送バッファメモリ３２に供給する。可変長符号化回路３８はブロックデータY_{00}～C_rを可変長符号化する際に、対応するフラグデータFLAGS に基づいて「駒落し」、又は「送信不可」が指定されているとき、当該ブロックデータを伝送画像データＳ４０として送出させずに捨てるような処理をする。

【００５１】伝送バッファメモリ３２は伝送画像データＳ４０を溜め込んで行くと共に、これを所定の伝送速度で読み出してマルチプレクサ４１において音声データ発生装置４２から送出される伝送音声データＳ４１と合成して動画符号化データVD_{REC}としてＣＤ－ＭＯ装置に送出する。

【００５２】逆量子化回路４０は量子化回路３７から送出される量子化画像データＳ３９をヘッダデータＨＤ５に基づいて逆量子化した後、当該逆量子化データＳ４２を逆変換符号化回路４３に供給することにより逆変換符号化データＳ４３に変換させた後デコーダ回路４４に供給させ、かくして伝送画像データＳ４０として送出された画像情報を表す符号化差分データＳ４４を予測前フレームメモリ２７に供給させる。このとき予測前フレームメモリ２７は、符号化差分データＳ４４を用いてそれまで保存していた予測前フレームデータを修正演算して新たな予測前フレームデータとして保存する。

【００５３】かくして図１の構成の動画符号化装置２１Ａによれば、ヘッダデータ処理系ＳＹＭ２から供給されるヘッダ情報に基づいて画素データ処理系ＳＹＭ１において画素データがマクロブロック単位でパイプライン処理されて行くのに対して、これと同期するようにヘッダデータ処理系ＳＹＭ２においてヘッダデータを受け渡して行くようにすることにより、ヘッダデータ処理系ＳＹＭ２の各処理段において必要に応じてヘッダデータを付加又は削除することにより画素データを必要に応じて適応処理できる。

【００５４】動画復号化装置２１Ｂは図２に示すように、ＣＤ－ＭＯ装置から再生される動画符号化データVD_{PB}をデマルチプレクサ５１を介して伝送バッファメモリ５２に受けると共に、伝送音声データＳ５１を音声データ受信装置５３に受ける。

【００５５】伝送バッファメモリ５２に受けた画像データは可変長逆変換回路５４において受信画像データＳ５２及びヘッダデータＨＤ１１に分離され、逆量子化回路５５において逆量子化データＳ５３に逆量子化された後、逆変換符号化回路５６においてデイスクリート逆変換処理されて逆変換符号化データＳ５４に逆変換される。

【００５６】この逆変換符号化データＳ５４は逆量子化回路５５において形成されたヘッダデータＨＤ１２と共にデコーダ回路５７に与えられ、符号化差分データＳ５５としてフレームメモリ５８に蓄積される。

【００５７】かくしてフレームメモリ５８には符号化差分データＳ５５に基づいて伝送されてきた画像データが復号化され、当該復号化画像データＳ５６がデイジタル／アナログ変換回路５９においてアナログ信号に変換された後、出力回路部６０を介して出力映像信号VD_{OUT}として送出される。

【００５８】（２）実施例による動画符号化データの記録順序

図１及び図２との対応部分に同一符号を付して示す図６において、７０は全体として本発明による符号化データ復号化方法を適用した動画符号化データ記録再生装置を

示す。この動画符号化データ記録再生装置７０の場合、入力映像信号VD_{IN}が上述した動画符号化／復号化装置２１を通じて高能率符号化され、この結果得られる動画符号化データVD_{REC}がＣＤ－ＭＯ装置７１に入力されてＣＤ－ＭＯデイスク（図示せず）に記録される。

【００５９】逆にＣＤ－ＭＯ装置７１から得られる再生信号が動画符号化データVD_{PB}として、動画符号化／復号化装置２１に入力され、この結果動画符号化データVD_{PB}を復号化して得られる出力映像信号VD_{OUT}が送出される。この動画符号化データ記録再生装置７０の場合、動画符号化／復号化装置２１はバス７２を通じてＣＰＵ（中央処理ユニツト）を含む記録再生制御回路７３に接続され、この記録再生制御回路７３によつて入力映像信号VD_{IN}の符号化及び動画符号化データVD_{PB}の復号化が制御される。

【００６０】これに加えてＣＤ－ＭＯ装置７１はＳＣＳＩ(small computer system interface)を内蔵し、ＳＣＳＩバス７４、ＳＣＳＩ制御回路７５及びバス７２を通じて、記録再生制御回路７３に接続され、これにより記録再生制御回路７３によつて記録再生動作が制御される。

【００６１】ここで動画符号化／復号化装置２１から送出される動画符号化データVD_{REC}は、図７に示すような階層（レイヤ）構造を有するフオーマツトでＣＤ－ＭＯ装置７１に入力され、またＣＤ－ＭＯ装置７１から同様のフオーマツトで動画符号化データVD_{PB}として動画符号化／復号化装置２１に入力される。

【００６２】すなわち動画符号化データVD_{REC}及びVD_{PB}においては、フレーム群レイヤとして入力画像信号VD_{IN}の８フレーム分に対応したデータを１フレーム群ＧＯＦとして、当該１フレーム群の開始を表すフレーム群スタートコード(GOFSC)、直前のＧＯＦとの連続関係を表すリンクフラグ(LPG)、伝送するフレームの水平、垂直サイズや水平及び垂直方向の画素数比等を表すデータ(HORSIZE、VERSIZE、HVPRAT)、伝送フレームのレートを表すデータ(RATE)、１フレーム分の画像データでなるピクチヤレイヤのデータ（P.data）の８フレーム分及びスタツフイングビツト(TSB)から構成されている（図７（Ａ））。

【００６３】ピクチヤレイヤのデータ（P.data）の１フレーム分は、１フレームの開始を表すフレームスタートコード(PSC)、フレーム番号(TR)、拡張情報を表すデータ(PEI、PSPARE)及びブロツク単位の画像データでなるブロツクグループレイヤのデータ(GOB data)の１フレーム分から構成されている（図７（Ｂ））。

【００６４】ブロツクグループレイヤのデータ(GOB data)の１ブロツクグループ分は、１ブロツクグループの開始を表すブロツクグループスタートコード(GBSC)、ブロツクグループのアドレスデータ（GN）、ブロツクグループ単位の再量子化ステツプサイズに関するデータ(GQUANT)、拡張情報を表すデータ(GEI、GSPARE)及びマクロブロツクレイヤのデータ(MB data)の１ブロツクグループ分から構成されている（図７（Ｃ））。

【００６５】マクロブロツクレイヤのデータ(MB data)の１マクロブロツク分は、マクロブロツクのアドレスを表すデータ(MBA)、マクロブロツクのタイプを表すデータ(MTYPE)、マクロブロツクにおける再量子化ステツプサイズのデータ(MQUANT)、マクロブロツク毎の動きベクトルのデータ(MVD1、MVD2)、マクロブロツク内のブロツクパターンのデータ(CBP)及びブロツクレイヤのデータ(Block data)の１マクロブロツク分から構成されている（図７（Ｄ））。

【００６６】ブロツクレイヤのデータ(Block data)の１ブロツク分は、所定数の係数データ(TCOEF)とブロツクレイヤの終わりを表すデータ(EOB)から構成されている（図７（Ｅ））。

【００６７】ここでこの実施例による動画符号化装置２１Ａにおいては、図８（Ａ）に示す従来同様の入力画像信号VD_{IN}に基づくフレーム記録順序に代え、図８（Ｂ）に示すように動画復号化装置２１Ｂ側の復号化処理に応じたフレーム記録順序でなる動画符号化データVD_{REC}をＣＤ－ＭＯ装置７１に送出し記録するようになされ、ＣＤ－ＭＯ装置７１から再生された動画符号化データVD_{PB}がこのフレーム記録順序で動画復号化装置２１Ｂに入力される。

【００６８】このようにすれば、例えば補間フレームＣ２を復号化する際、復号化に必要なイントラフレームＡ１及び予測フレームＢ３がすでに入力され、また例えば補間フレームＣ４を復号化する際、復号化に必要な予測フレームＢ３及びＢ５がすでに入力され、これにより動画復号化装置２１Ｂは直ちに補間フレームＣ２又はＣ４の復号化処理を実行することができる。

【００６９】ここでこの実施例の動画符号化装置２１Ａの場合、図９に示すように、動き補償回路２５に内蔵されたフレーム順並べ替え回路８０を用いて、入力画像信号VD_{IN}に基づくフレーム記録順序を上述のように復号化処理に応じたフレーム記録順序に並べ替えるようになされている。

【００７０】このフレーム順並べ替え回路８０においては、第１～第３の１フレーム遅延回路８１、８２及び８３を有して構成されており、フレーム順の並べ替え処理に加えて、動きベクトルの検出処理を実行し得るようになされている。すなわち入力画像信号VD_{IN}は入力回路部２２及びアナログデイジタル変換回路２３において所定の処理が施され、この結果得られる入力画像データＳ２１が第１の１フレーム遅延回路８１に入力される。

【００７１】この第１の１フレーム遅延回路８１から送出された第１の遅延データS_{D1}は、第２の１フレーム遅延回路８２に入力されると共に、第１のフレーム選択回路８４の第１の入力端ａに入力される。また第２の１フ

レーム遅延回路８２から送出される第２の遅延データS_{D2}は第３の１フレーム遅延回路８３を通じ、さらに１フレーム分遅延され第３の遅延データS_{D3}として第１のフレーム選択回路８４の第２の入力端ｂに入力される。

【００７２】これによりこのフレーム順並べ替え回路８０においては、１フレーム毎のタイミングで順次入力画像データＳ２１を入力すると共に、これに同期したフレームパルスＦＰのタイミングで順次第１のフレーム選択回路８４の第１又は第２の入力端ａ又はｂを選択制御することにより、フレーム順の並べ替え処理を実行し得るようになれている。

【００７３】なお入力画像データＳ２１及び第１の遅延データS_{D1}は第１の動きベクトル検出回路８５に入力され、この結果得られる入力画像データＳ２１及び第１の遅延データS_{D1}間の動きベクトルデータD_{MV1}及び差分データD_{DR1}が動き補償ユニツト２６に送出される。

【００７４】また第２及び第３の遅延データS_{D2}及びS_{D3}が第２のフレーム選択回路８６の第１及び第２の入力端ａ及びｂに入力され、フレームパルスＦＰのタイミングで何れか一方が選択されて第２の動きベクトル検出回路８７に入力される。この第２の動きベクトル検出回路８７には、これに加えて第１の遅延データS_{D1}が入力されており、この結果得られる第１の遅延データS_{D1}及び第２又は第３の遅延データS_{D2}又はS_{D3}間の動きベクトルデータD_{MV2}及び差分データD_{DR2}が動き補償ユニツト２６に送出される。かくして入力画像信号VD_{IN}について高能率符号処理して動画符号化データVD_{REC}を得る際に、入力画像信号VD_{IN}に基づくフレーム順序に代えて、復号化処理に応じたフレーム順序に並べ替えるようにしたことにより、復号化処理側の回路構成及び制御を簡略かつ効率化し得る動画符号化データ伝送方法を実現できる。

【００７５】（３）実施例による動画符号化データのエデイツト処理

ここでこの動画符号化データ記録再生装置７０の記録再生制御回路７３は、外部から入力されたエデイツト命令に応動して、図１０に示すエデイツト処理手順ＲＴ０を実行し、これにより図１１に示すように、ＣＤ－ＭＯデイスク上の20セクタ毎に１フレーム群分記録された動画符号化データVD_{REC}を１フレーム群単位で書換え、かくしてエデイツト処理を実行するようになされている。

【００７６】なおこの実施例の場合動画符号化データVD_{IN}においては、図８（Ｃ）に示すようにイントラフレームから続く補間フレーム及び予測フレームＡ１、Ｃ２、Ｂ３、Ｃ４、Ｂ５、Ｃ６、Ｂ７、Ｃ８の８フレーム分を１フレーム群ＧＯＦ１、ＧＯＦ２、……とした従来の方法に代え、イントラフレームＡ１の直前の補間フレームＣ０に続くイントラフレーム、補間フレーム及び予測フレームＣ０、Ａ１、Ｃ２、Ｂ３、Ｃ４、Ｂ５、Ｃ６、Ｂ７を１フレーム群ＧＯＦ１１、ＧＯＦ１２、……として伝送するようになされている。

【００７７】このようにして１フレーム群ＧＯＦ１１、ＧＯＦ１２、……内のフレームが、他のフレーム群ＧＯＦ１１、ＧＯＦ１２、……に含まれてしまう不都合を未然に防止し得るようになされている。実際上記録再生制御回路７３は、図１０に示すエデイツト処理手順ＲＴ０から入つて次のステツプＳＰ１においてエデイツト命令の解析処理を実行する。

【００７８】ここで例えば図１１に示す第３及び第４のフレーム群ＧＯＦ３及びＧＯＦ４の40セクタ分について、新たな動画符号化データVD_{REC}と書き換えることが指示されると、記録再生制御回路７３は次のステツプＳＰ２に移る。

【００７９】このステツプＳＰ２において、記録再生制御回路７３はＳＣＳＩ制御回路７５にエデイツト命令に応じた制御命令を送出し、これによりＳＣＳＩバス７４を通じてＣＤ－ＭＯデイスクの書き換え制御を実行する。なおこのときバス７２を通じた記録再生制御回路７３の制御によつて、新たな２フレーム群ＧＯＦ３Ｎ、ＧＯＦ４Ｎ分の入力映像信号VD_{IN}が動画符号化／復号化装置２１を通じて動画符号化データVD_{REC}としてＣＤ－ＭＯ装置７１に入力される。

【００８０】続いて記録再生制御回路７３は次のステツプＳＰ３を実行し、書換え処理が終了したか否かを判断し、ここで否定結果を得るとステツプＳＰ２に戻りＣＤ－ＭＯデイスクの書き換え制御を継続し、やがて肯定結果を得るとステツプＳＰ４に移る。このステツプＳＰ４において記録再生制御回路７３は、エデイツトしたＣＤ－ＭＯデイスクの先頭セクタ（この実施例の場合、第40セクタでなる）の内容を読む。

【００８１】これにより記録再生制御回路７３は次のステツプＳＰ５において、先頭セクタの先頭から25ビツト目に存在するフレーム群レイヤのリンクフラグ(LPG) をエデイツトフラグとして設定し、これをＣＤ－ＭＯデイスクの読み出したセクタ位置に書き込む。

【００８２】続いて記録再生制御回路７３はステツプＳＰ６において、エデイツトしたＣＤ－ＭＯデイスクの最終セクタに続くセクタ（この実施例の場合、第80セクタでなる）の内容を読む。これにより記録再生制御回路７３は次のステツプＳＰ７において、当該セクタの先頭から25ビツト目に存在するフレーム群レイヤのリンクフラグ(LPG) を上述と同様にエデイツトフラグとして設定し、これをＣＤ－ＭＯデイスクの読み出したセクタ位置に書き込み、次のステツプＳＰ８において当該エデイツト処理手順ＲＴ０を終了する。

【００８３】実際上このようにしてエデイツトされてＣＤ－ＭＯデイスク上に記録された動画符号化データVD_{REC}は、記録再生制御回路７３の制御によつて読み出され、この結果再生信号として得られる動画符号化データVD_{PB}が動画符号化／復号化装置２１に入力される。

【００８４】（４）実施例によるエデイツトされた符号化データの復号化方法
この実施例の場合動画復号化装置２１Ｂにおいては、図１２に示すようにデコーダ回路５７に含まれるフレーム順逆並べ替え回路９０を用いて、復号化処理に応じたフレーム順序から入力画像信号VD_{IN}に基づくフレーム順序に並べ替える逆並べ替え処理を実行すると共に、フレーム群レイヤのリンクフラグ(LPG) に設定されたエデイツトフラグを参照してエデイツト再生処理を実行するようになされている。
【００８５】すなわち逆変換符号化回路５６から送出される逆変換符号化データＳ５４は、デコーダ回路５７のセレクタ回路９１の第１の入力端Ａに直接入力されると共に、フレームメモリ９２を通じて例えば２フレーム分遅延されて第２に入力端Ｂに入力される。
【００８６】このセレクタ回路９１及びフレームメモリ９２はそれぞれフレームパルスＦＰのタイミングで動作し、これにより復号化処理に応じたフレーム順序（図８（Ｂ））から入力画像信号VD_{IN}に基づくフレーム順序（図８（Ａ））への逆並べ替え処理を実行するようになされている。
【００８７】なおこのセレクタ回路９１には、逆量子化回路５５において形成されたヘツダデータＨＤ１２のうちリンクフラグ(LPG) に設定されたエデイツトフラグに応じたエデイツトフラグ信号S_{LPG}が入力され、このエデイツトフラグ信号S_{LPG}が設定されていることを表すときのみセレクト動作を中断し、次に到来するフレームをそのまま出力する。
【００８８】このようにして例えばエデイツトされた新たなフレーム群ＧＯＦＮ３、ＧＯＦＮ４中のフレームデータに対して、古いフレーム群ＧＯＦ１、ＧＯＦ２、ＧＯＦ５、……中のフレームデータが混入して再生画像に乱れが生じるおそれを未然に防止し得るようになれている。因に図８（Ｄ）に示すフレーム群ＧＯＦ１２にエデイツトフラグが設定されている場合には、逆並べ替え後の第８の補間フレームＣ８に代えて、イントラフレームＡ９が２フレーム分出力される。
【００８９】以上の構成によれば、エデイツトされたフレーム群及びエデイツト直後のフレーム群のリンクフラグ(LPG) にエデイツトフラグS_{LPG}が設定されてなる編集後の動画符号化データを復号化する際に、エデイツトフラグS_{LPG}の有無を検出し、エデイツトフラグS_{LPG}が設定されている場合には元の先行するフレーム群に属する画像を予測画像に用いて補間フレームを出力せずに、直前に復号化したイントラフレームを出力するようにして復号化するようにしたことにより、編集後の動画符号化データを正しく再生することができる。
【００９０】（５）他の実施例
（５－１）上述の実施例においては、記録された動画符号化データについてフレーム群単位でエデイツト処理を実行する際、エデイツトされたフレーム群及びエデイツト直後のフレーム群のリンクフラグ(LPG) にエデイツトフラグを設定した場合について述べたが、これに代え、例えばエデイツト処理したフレーム群を記録再生制御回路７３が記憶している場合には、エデイツト直後のフレーム群のリンクフラグ(LPG) にエデイツトフラグを設定するのみで良好にエデイツト処理を実行し得る。
【００９１】（５－２）また上述の実施例においては、記録された動画符号化データについてフレーム群単位でエデイツト処理を実行する際、エデイツトされたフレーム群及びエデイツト直後のフレーム群のリンクフラグ(LPG) にエデイツトフラグを設定した場合について述べたが、これに代え、動画符号化装置２１Ａ側でピクチヤレイヤのフレーム番号(TR)に、記録再生制御回路７３で発生した所定の乱数から始まる連番を順次付加し、エデイツト再生処理時にこのフレーム番号(TR)の不連続を検出したタイミングで上述したエデイツトフラグ信号S_{LPG}と同様の信号を発生するようにすれば、上述の実施例と同様の効果を実現できる。
【００９２】因に、この場合フレーム番号(TR)の不連続は、図１３に示すような不連続検出回路９５で検出される。すなわちこの不連続検出回路９５においては、上述のフレーム順逆並べ替え回路９０に併設され、逆変換符号化データＳ５４に含まれるピクチヤレイヤのフレーム番号(TR)が比較回路９６及びラツチ回路９７に入力される。
【００９３】このラツチ回路９７はフレームパルスＦＰのタイミングでラツチ動作を実行し、この結果１フレーム分遅延したフレーム番号(TR)が加算回路９８に入力されて値「１」が加算され、比較フレーム番号C_{TR}として比較回路９６に入力される。これにより比較回路９６は、フレーム番号(TR)及び比較フレーム番号C_{TR}の値を比較し、両者が不一致のとき論理「Ｈ」レベルでなる不一致検出信号を発生し、これをアンド回路９９に送出する。
【００９４】アンド回路９９にはこれに加えて、先頭フレーム群の再生処理のとき論理「Ｈ」レベルを有する先頭フレーム群信号ＧＯＦＦが反転回路１００を通じて反転して入力されており、これにより先頭フレーム群の再生処理のとき、不一致検出信号を論理「Ｌ」レベルに制御し、それ以外のとき不一致検出信号に応じた論理レベルを有するエデイツトフラグ信号S_{LPG}をフレーム順逆並べ替え回路９０のセレクタ回路９１に送出する。
【００９５】（５－３）さらに上述の実施例においては、動画符号化データについてフレーム群単位でエデイツト処理を実行する際、エデイツトフラグやフレーム番号(TR)を用いてエデイツトされたフレーム群を識別するようにしたが、フレーム群の各補間フレームＣについてフレーム群内のイントラフレームＡ及び予測フレームＢのみを用いて補間し、フレーム群内で各フレームの関係

が完結するようにすれば、画質について多少の劣化が生じても容易かつ自在にエデイツト処理を実行し得る動画符号化データ記録方法を実現できる。

【００９６】（５－４）さらに上述の実施例においては、イントラフレームＡ、予測フレームＢ及び補間フレームＣが、図８（Ａ）に示すように配置された動画符号化データのフレーム順序を並べ替えるようにした場合について述べたが、動画符号化データのフレーム配置はこれに限らず、図１４（Ａ）や図１５（Ａ）に示すような場合でも、要は図１４（Ｂ）や図１５（Ｂ）に示すように復号化側の処理順に応じたフレーム順に並べ替えて伝送するようにすれば、上述の実施例と同様の効果を実現できる。

【００９７】またこの場合図１４（Ｃ）や図１５（Ｃ）に示すフレーム群ＧＯＦ１、ＧＯＦ２、……の配置に代え、図１４（Ｄ）や図１５（Ｄ）に示すようなフレーム群ＧＯＦ２１、ＧＯＦ２２、……やＧＯＦ３１、ＧＯＦ３２、……の配置にすれば、エデイツト処理についても上述の実施例と同様の効果を実現できる。

【００９８】（５－５）さらに上述の実施例においては、映像信号を高能率符号化してＣＤ－ＭＯデイスクに記録し再生する場合について述べたが、記録媒体はこれに限らず、他の光デイスクや磁気デイスク、磁気テープ等に広く適用して好適なものである。

【００９９】（５－６）さらに上述の実施例においては、映像信号を高能率符号化してＣＤ－ＭＯデイスクに記録し再生する場合について述べたが、本発明はこれに限らず、映像信号を高能率符号化して伝送する動画符号化データ伝送方法に広く適用して好適なものである。

【０１００】

【発明の効果】上述のように本発明によれば、編集フラグの有無を検出し、編集フラグが設定されていた場合には先行するグループに属する画像を予測画像に用いて、表示順上で時間的に前後にある画像を予測画像として用いることが可能なインター符号化によつて生成された画像を出力しないようにしたことにより、編集後の符号化画像データを正しく復元し得る符号化データ復号化方法及び装置を実現できる。

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

SUPPLEMENTAL INFORMATION DISCLOSURE STATEMENT
UNDER 37 C.F.R. § 1.97(c)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

Applicant respectfully submits the items of information on the enclosed Form 1449 for the attention of the Examiner in the above-identified application.

This statement should be considered because it is submitted after the mailing date of the first Office action on the merits but before the mailing date of a final Office action under 37 C.F.R. § 1.113 or a Notice of Allowance under 37 C.F.R. § 1.311. Please charge Deposit Account 50-3581 (TPO.004.C1) the amount of $180.00 under 37 C.F.R. § 1.17(p) for consideration of the items.

In accordance with 37 C.F.R. § 1.98(a)(2), only a copy of each foreign document or non-U.S. patent/application listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.

No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§ 102 and 103. In addition, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended, and reserves the right to establish otherwise under 37 C.F.R. § 1.131 or others.

Consideration of the items listed is respectfully requested. According to MPEP § 609, Applicant requests that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

AMENDMENT & RESPONSE UNDER 37 C.F.R. § 1.111

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action dated August 9, 2011, setting a three (3) month shortened statutory period for response, Applicant submits the present amendment and response under 37 C.F.R. § 1.111.

Claims 1, 3-10, 12-18, and 20-25 remain pending in the application. Claims 1, 10, and 18 have been amended. No claims have been added, and claims 2, 11, and 19 have been canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

AMENDMENTS TO THE CLAIMS are reflected in the listing of claims which begins on page 2 of this paper.

REMARKS/ARGUMENTS begin on page 8.

AMENDMENTS TO THE CLAIMS

This listing of claims replaces all prior versions of claims in the application.

1. (Currently amended) A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising:

decoding from the compressed video sequence an indication ~~related to~~informing an intentional discontinuity of numbering of the image frames;

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. (Canceled)

3. (Previously presented) A method according to claim 1, further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

4. (Original) A method according to claim 1, wherein the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. (Previously presented) A method according to claim 1, further comprising

continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

6. (Previously presented) A method according to claim 1, further comprising

entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

7. (Previously presented) A method according to claim 6, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

8. (Previously presented) A method according to claim 1, wherein

configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. (Previously presented) A method according to claim 3, further comprising

detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image frame corresponding to the at least one discontinuity in the numbering of image frames.

10. (Currently amended) A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the compressed video sequence an indication ~~related to~~informing an intentional discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. (Canceled)

12. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

13. (Original) A video decoder according to claim 10, wherein

the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

continue the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

15. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

enter into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

16. (Previously presented) A video decoder according to claim 15, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

17. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

configure the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. (Currently amended) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, the computer program product comprising:

a computer program code for decoding from the compressed video sequence an indication ~~related to~~informing an intentional discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. (Canceled)

20. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

21. (Original) A computer program product according to claim 18, the computer program product further comprising

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. (Previously presented) A computer program product according to claim 18, the computer program product further comprising

a computer program code for continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

23. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

24. (Previously presented) A computer program product according to claim 23, the computer program product further comprising:

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the compressed video sequence.

25. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

26-31. (Canceled)

REMARKS/ARGUMENTS

The rejections presented in the Office action dated August 9, 2011 (hereinafter "Office action"), have been considered. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Claims 2, 11, and 19, have been canceled without prejudice or disclaimer rendering the respective objections and rejections of these claims moot. Applicant reserves the opportunity to pursue the subject matter of these claims in continuing applications and requests that the respective objections and rejections be removed and withdrawn.

Applicant respectfully traverses the §§ 102(e) and 103(a) rejections based on the teachings of U.S. Patent No. 7,103,669 to Apostolopoulos (hereinafter "Apostolopoulos"); however, in the interests of advancing prosecution and in a *bona fide* attempt to advance the application to allowance, the independent claims have been amended to clarify particular aspects of the claimed invention. For example, the independent claims have been amended to characterize that the decoded indication informs an intentional discontinuity of numbering of the image frames. Support for these changes may be found in the original specification, for example, in original (and previously allowed) claims 2, 11, and 19; and at paragraph [0017]; therefore, the changes do not introduce new matter. Since neither Apostolopoulos nor Langberg teaches or suggests at least an indication that informs an intentional discontinuity of numbering, as now claimed in the independent claims, the rejections would be improper. Applicant accordingly requests that the rejections be withdrawn.

As set forth above, neither of the asserted references teaches or suggests at least decoding an indication that informs an intentional discontinuity of numbering of the image frames. Again, Apostolopoulos fails to teach or suggest each of the now-claimed elements of the independent claims since the asserted indication of Apostolopoulos addresses only discontinuities of numbering caused by errors. In view of these changes, elements now included in each of the pending claims are not found in Apostolopoulos, either alone or as modified, therefore, each of the prior art rejections would be improper. Applicant accordingly requests that each of the § 102(e) and § 103(a) rejections be withdrawn.

To the extent that the current response does not respond to any characterization in the Office action of the asserted art or of the claimed subject matter, or to any application in the Office action of the asserted art to any claimed subject matter, it is stated for the record that any such lack of response should not be interpreted as an acquiescence to such characterizations or applications. A detailed discussion of each of the Office action's characterizations, or any other assertions or statements beyond that provided above is unnecessary in view of the present response. The right to address in detail any such assertions or statements in the future is reserved.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C1) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111
If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371
If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office
If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

	SIU LEE	2611	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE *3* MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

1)☒ Responsive to communication(s) filed on *07 November 2011*.

2a)☒ This action is **FINAL**. 2b)☐ This action is non-final.

3)☐ An election was made by the applicant in response to a restriction requirement set forth during the interview on _____; the restriction requirement and election have been incorporated into this action.

4)☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

5)☒ Claim(s) *1,3-10,12-18 and 20-25* is/are pending in the application.

5a) Of the above claim(s) _____ is/are withdrawn from consideration.

6)☐ Claim(s) _____ is/are allowed.

7)☒ Claim(s) *1,3-7,9,10,12-16,18 and 20-24* is/are rejected.

8)☒ Claim(s) *8,17 and 25* is/are objected to.

9)☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

10)☐ The specification is objected to by the Examiner.

11)☒ The drawing(s) filed on *25 January 2006* is/are: a)☒ accepted or b)☐ objected to by the Examiner.

Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).

Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).

12)☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

13)☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

a)☒ All b)☐ Some * c)☐ None of:

1.☐ Certified copies of the priority documents have been received.

2.☒ Certified copies of the priority documents have been received in Application No. 10/306,942.

3.☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

DETAILED ACTION

Response to Arguments

1. Applicant's arguments with respect to claims 1-27 have been considered but are moot in view of the new ground(s) of rejection because of the amendment.

Claim Rejections - 35 USC § 102

2. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

> A person shall be entitled to a patent unless –
>
> (e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

3. Claims 1, 3, 5, 9-10, 12, and 14 are rejected under 35 U.S.C. 102(e) as being anticipated by Apostolopoulos (US 7,103,669 B2).

(1) Regarding claim 1:

Apostolopoulos disclose a method for decoding a compressed video sequence (video sequence 354 in figure 5), wherein image frames are entered into a buffer memory in connection with the decoding (frame memory for storing the decoded frames from decode 320 of the video sequence 356 as shown in figure 5), the method comprising:

decoding from the compressed video sequence an indication (frame number of the video sequence 354) related to an intentional discontinuity of numbering of the image frame (due to the diversity transmission of the video sequence as shown in figure 3 (2 paths, one for odd frame and one for even frame) or in figure 1 (3 paths), the frame number of the video sequences 356 and 354 in figure 5 indicate an intentional discontinuity numbering of the image frame as shown in figure 4);

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (frame memory for video sequence 356 provide diversity frame to the state recovery 526 for recovery of one of lost video frame in the video sequence 354, column 11, lines 4-52); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well as P1 and P3, column 11, lines 14-18, therefore, the usage of even frame in the recovery of the odd frame as used in the decoding process).

(2) Regarding claim 10:

Apostolopoulos discloses a video decoder (multiple state video decoding 128 in figure 1 comprises decode block 320 and 322 as shown in figure 5) for decoding a compressed video sequence, the video decoder being connected to a buffer memory

(frame memory as shown in figure 5) wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the compressed video sequence (video sequence 354 in figure 5) an indication related to an intentional discontinuity of numbering of the image frames (due to the diversity transmission of the video sequence as shown in figure 3 (2 paths, one for odd frame and one for even frame) or in figure 1 (3 paths), the frame number of the video sequences 356 and 354 in figure 5 indicate an intentional discontinuity numbering of the image frame as shown in figure 4); and

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (frame memory for video sequence 356 provide diversity frame to the state recovery 526 for recovery of one of lost video frame in the video sequence 354, column 11, lines 4-52); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, therefore, the usage of even frame in the recovery of the odd frame as used in the decoding process).

(3) Regarding claims 3 and 12:

Apostolopoulos further disclose using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames (the video sequence 356 comprises image frame that is not in the video sequence 354 and the merging of the video frames in sequence 356 into the missing frames in the video sequence 354 to reconstruct the video 344 as shown in figure 4, column 9, lines 23-26).

(4) Regarding claim 9:

Apostolopoulos further disclose detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image frame corresponding to the at least one discontinuity in the numbering of image frames (detection of the error occur in the transmission of the encoded odd frame corresponds to the even frame sequence since the odd frame is missing in the even frame sequence, column 9, lines 66-67).

(5) Regarding claims 5 and 14:

Apostolopoulos further disclose continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (the receiver 332 includes a state recovery 526 for recovering the lost P-frame P5 of the stream 354 using the information provided by the stream 356, the recovery of P5 enables the decode block 322 to continue with its prediction loop by correctly updating its state information and reconstruct p7 to P13,

column 10, lines 55-60; as the frames are correctly decode by the decoder, frames are enter into the frame memory as a previous decoded frames as shown in figure 5).

Claim Rejections - 35 USC § 103

4. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

> (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

5. Claims 6-7, 15-16, 18, 20-24 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2) in view of Langberg (US 5,852,630).

(1) Regarding claim 18:

Apostolopoulos disclose a method for decoding a compressed video sequence (video sequence 354 in figure 5), wherein image frames are entered into a buffer memory in connection with the decoding (frame memory for storing the decoded frames from decode 320 of the video sequence 356 as shown in figure 5), the method comprising:

decoding from the compressed video sequence an indication (frame number of the video sequence 354) related to an intentional discontinuity of numbering of the image frame (due to the diversity transmission of the video sequence as shown in figure 3 (2 paths, one for odd frame and one for even frame) or in figure 1 (3 paths), the frame

number of the video sequences 356 and 354 in figure 5 indicate an intentional discontinuity numbering of the image frame as shown in figure 4);

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (frame memory for video sequence 356 provide diversity frame to the state recovery 526 for recovery of one of lost video frame in the video sequence 354, column 11, lines 4-52); and

using the image frames in the buffer memory in the decoding process (the examiner interprets the process within the dot line as shown in figure 9 as the decoding process, as the state recovery block 526 may recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstruction full frame versions of P2, P4, and P6 through P14, as well we P1 and P3, column 11, lines 14-18, therefore, the usage of even frame in the recovery of the odd frame as used in the decoding process).

Apostolopoulos discloses all of the subject matter as described above except for the method is perform by a computer program product, stored on a non-transitory computer readable medium and executable in a data processing device.

However, Langberg et al. teaches that the method and apparatus for a transceiver warm start activation procedure with precoding can be implemented in software stored in a computer-readable medium. The computer-readable medium is an electronic, magnetic, optical, or other physical device or means that can be contain or store a computer program for use by or in connection with a computer-related system or

method (column 3, lines 51-65). One skilled in the art would have clearly recognized that the method of Apostolopoulos would have been implemented in a software. The implemented software would perform same function of the hardware for less expense, adaptability, and flexibility. Therefore, it would have been obvious to have used the software as taught by Langberg for implementing the method of Apostolopoulos in order to reduce cost and improve the adaptability and flexibility of the communication system.

(2) Regarding claim 20:

Apostolopoulos further disclose using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames (the video sequence 356 comprises image frame that is not in the video sequence 354 and the merging of the video frames in sequence 356 into the missing frames in the video sequence 354 to reconstruct the video 344 as shown in figure 4, column 9, lines 23-26).

(3) Regarding claim 21:

Apostolopoulos disclose all subject matter as discussed in claim 1 but fails to explicitly disclose wherein the number of image frames in the buffer memory is used in sliding widow buffering of image frames.

However, as shown in figure 5, decoded frame as input into the frame memory as previous decode frames, these frames are used for recovery of a lost frame (recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstructed full frame versions of P2, P4, P6 through P14 as well as P1 and P3, column 11, lines 14-18), therefore, the frame

memory have to store the decoded frame P2 to P14 in the frame memory on the even frame number sequence and obviously, the frame memory have to store the decoded frame P1 to P13 in the frame memory on the odd frame number sequence, therefore, the examiner interprets the frame memory are used in sliding window buffering of the decode image frame.

It is desirable to have the number of image frames in the buffer memory are used in sliding widow buffering of image frames because the buffer of image frame is need for recovering of a full frame version of a lost frame and provide the benefit of increase the image quality of the recovered video sequence.

(4) Regarding claim 22:

Apostolopoulos further disclose continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames (the receiver 332 includes a state recovery 526 for recovering the lost P-frame P5 of the stream 354 using the information provided by the stream 356, the recovery of P5 enables the decode block 322 to continue with its prediction loop by correctly updating its state information and reconstruct p7 to P13, column 10, lines 55-60; as the frames are correctly decode by the decoder, frames are enter into the frame memory as a previous decoded frames as shown in figure 5).

(5) Regarding claims 6, 15, and 23:

Apostolopoulos discloses all subject matter as discussed in claim 1 except explicitly discloses entering into the buffer memory a number of filter frames corresponding to the at least one discontinuity in the numbering of the image frame.

However, Apostolopoulos discloses the entering of the decoded frames to the frame memory in figure 5 corresponding to the discontinuity in the numbering of the other even or odd frame sequence, these odd or even decoded frames are used to replace error frames in the other video sequence (even or odd) by the method as discloses in column 11, lines 48-52, the lost frame may be estimated by replacing it by another correctly decoded frame, the examiner interprets the correctly decode frame that replace the lost frame as the claimed “filler frame”; therefore, the claimed limitation is met.

(6) Regarding claims 7, 16, and 24:

Apostolopoulos further discloses wherein said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence (when using the correctly decoded frames of the other sequence (e.g. Even frame sequence) to replace an odd error frame, the even frame number (identifier) of the even frame sequence indicates that the even frames do not belong to the odd frame sequence as shown in figure 4).

6. Claims 4 and 13 are rejected under 35 U.S.C. 103(a) as being unpatentable over Apostolopoulos (US 7,103,669 B2).

Apostolopoulos disclose all subject matter as discussed in claim 1 but fails to explicitly disclose wherein the number of image frames in the buffer memory is used in sliding widow buffering of image frames.

However, as shown in figure 5, decoded frame as input into the frame memory as previous decode frames, these frames are used for recovery of a lost frame (recover the full frame version of P5 by interpolating or estimating the full frame version of P5 by employing any combination of the reconstructed full frame versions of P2, P4, P6 through P14 as well as P1 and P3, column 11, lines 14-18), therefore, the frame memory have to store the decoded frame P2 to P14 in the frame memory on the even frame number sequence and obviously, the frame memory have to store the decoded frame P1 to P13 in the frame memory on the odd frame number sequence, therefore, the examiner interprets the frame memory are used in sliding window buffering of the decode image frame.

It is desirable to have the number of image frames in the buffer memory are used in sliding widow buffering of image frames because the buffer of image frame is need for recovering of a full frame version of a lost frame and provide the benefit of increase the image quality of the recovered video sequence.

Allowable Subject Matter

7. Claims 8, 17 and 25 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Conclusion

8. Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP § 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 6:15-3:45 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

RESPONSE UNDER 37 C.F.R. § 1.116

Mail Stop AF
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action dated January 9, 2012, setting a three (3) month shortened statutory period for response, Applicant submits the present response under 37 C.F.R. § 1.116.

Claims 1, 3-10, 12-18, and 20-25 remain pending in the application. No claims have been amended, added, or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

THE CLAIMS are reflected in the listing of claims which begins on page 2.

REMARKS/ARGUMENTS begin on page 8.

THE CLAIMS

While no amendments, additions, or cancellations of claims are effected via this paper, this listing of claims is provided for the convenience of the Examiner.

1. (Previously presented) A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising:

decoding from the compressed video sequence an indication informing an intentional discontinuity of numbering of the image frames;

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. (Canceled)

3. (Previously presented) A method according to claim 1, further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

4. (Original) A method according to claim 1, wherein the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. (Previously presented) A method according to claim 1, further comprising

continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

6. (Previously presented) A method according to claim 1, further comprising

entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

7. (Previously presented) A method according to claim 6, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

8. (Previously presented) A method according to claim 1, wherein

configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. (Previously presented) A method according to claim 3, further comprising

detecting an error in the compressed video sequence on a basis of a reference in the decoding process to an image frame corresponding to the at least one discontinuity in the numbering of image frames.

10. (Previously presented) A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being configured to

decode from the compressed video sequence an indication informing an intentional discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. (Canceled)

12. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

13. (Original) A video decoder according to claim 10, wherein

the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

continue the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

15. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

enter into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

16. (Previously presented) A video decoder according to claim 15, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the compressed video sequence.

17. (Previously presented) A video decoder according to claim 10, wherein the video decoder is further configured to

configure the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. (Previously presented) A computer program product, stored on a non-transitory computer readable medium and executable in a data processing device, for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, the computer program product comprising:

a computer program code for decoding from the compressed video sequence an indication informing an intentional discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. (Canceled)

20. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the at least one discontinuity in the numbering of the image frames.

21. (Original) A computer program product according to claim 18, the computer program product further comprising

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. (Previously presented) A computer program product according to claim 18, the computer program product further comprising

a computer program code for continuing the entering of the image frames comprised by the compressed video sequence into the buffer memory from a correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the at least one discontinuity in the numbering of the image frames.

23. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for entering into the buffer memory a number of filler frames corresponding to the at least one discontinuity in the numbering of the image frames.

24. (Previously presented) A computer program product according to claim 23, the computer program product further comprising:

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the compressed video sequence.

25. (Previously presented) A computer program product according to claim 18, the computer program product further comprising:

a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the at least one discontinuity in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

26-31. (Canceled)

REMARKS/ARGUMENTS

The rejections presented in the Office action dated January 9, 2012 (hereinafter "Office action"), have been considered but are believed to be in error. Reconsideration of the pending claims and allowance of the application in view of the present response is respectfully requested.

Applicant appreciates the indication of allowability for claims 8, 17, and 25, but respectfully declines the opportunity to amend the claims at this time.

Applicant respectfully traverses each of the rejections (§§ 102(e) and 103(a)) based on the teachings of U.S. Patent No. 7,103,669 to Apostolopoulos (hereinafter "Apostolopoulos") because Apostolopoulos does not teach or suggest each of the asserted claim elements. For example, Apostolopoulos has not been shown to teach or suggest at least configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames, as claimed in each of the independent claims. While the Examiner alleges that the frame memory provides a diversity frame to the state recovery 526, Apostolopoulos does not mention the term "diversity frame." Also, the frame supplied to the state recovery 526 is used to average, interpolate, or estimate a missing odd frame based on image data from even frames (Col. 11, lines 4-23) – it does not correspond to the discontinuity in the numbering of the image frames, as claimed. Notably, state recovery block 526 is no buffer memory, but is instead an operational block for recovering an odd frame (such as P5) missing from a sequence of even frames. Apostolopoulos is directed to creating a full frame version of the odd frame (*e.g.*, P5) missing between two even frames (*e.g.*, P4 and P6), wherein extensive data processing and calculations are needed. Thus, Apostolopoulos does not teach or suggest a buffer memory, which provides a number of image frames corresponding to a discontinuity in the numbering of the image frames, as claimed. Without correspondence to each of the claimed elements, the rejections are in error.

With particular respect to the § 102(e) rejection, to anticipate a claim the asserted reference must teach every element of the claim. "A claim is anticipated only if each and every element as set forth in the claim is found, either expressly or inherently described, in a

single prior art reference." *Verdegaal Bros. v. Union Oil Co. of California*, 2 USPQ2d 1051, 1053 (Fed. Cir. 1987). The Federal Circuit also recently held that "Because the hallmark of anticipation is prior invention, the prior art reference—in order to anticipate under 35 U.S.C. § 102—must not only disclose all elements of the claim within the four corners of the document, but must also disclose those elements 'arranged as in the claim.'" (*Net Moneyin, Inc. v. Verisign, Inc.*, 545 F.3d 1359, 2008 WL 4614511 (Fed. Cir. 2008) quoting *Connell v. Sears, Roebuck & Co.*, 722 F.2d 1542, 1548 (Fed. Cir. 1983)). Therefore, all claim elements, must be found in the prior art reference to maintain a rejection based on 35 U.S.C. § 102. Applicant respectfully submits that Apostolopoulos does not teach every element of independent claims 1, 10, and 18, in the requisite detail, and therefore fails to anticipate claims 1, 3, 5, 9, 10, 12, and 14. Applicant accordingly requests that the rejection be withdrawn.

By similar reasoning, the claims which depend on claims 1, 10, or 18, are also not anticipated by, or obvious in view of, Apostolopoulos, whether the reference is considered alone or modified as asserted. Applicant respectfully requests withdrawal of the rejection of claims 1, 3-10, 12-18, and 20-25, and submits that all claims are in condition for allowance.

It should be noted that Applicant does not acquiesce to the Examiner's statements or conclusions concerning what would have been obvious to one of ordinary skill in the art, obvious design choices, common knowledge at the time of Applicant's invention, officially noticed facts, and the like. Applicant reserves the right to address in detail the Examiner's characterizations, conclusions, and rejections in future prosecution.

Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C1) any necessary fees for this filing. If the Examiner believes it necessary or helpful, the undersigned attorney of record invites the Examiner to contact the undersigned attorney to discuss any issues related to this case.

Respectfully submitted,

New Applications Under 35 U.S.C. 111
If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371
If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office
If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

This collection of information is required by 37 CFR 1.16. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

RESPONSE UNDER 37 C.F.R. § 1.116

Mail Stop AF
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

In response to the Office action dated January 9, 2012, setting a three (3) month shortened statutory period for response, Applicant submits the present response under 37 C.F.R. § 1.116.

Claims 1, 3-10, 12-18, and 20-25 remain pending in the application. No claims have been amended, added, or canceled. Applicant respectfully requests reconsideration and allowance of all pending claims.

THE CLAIMS are reflected in the listing of claims which begins on page 2.

REMARKS/ARGUMENTS begin on page 8.

TITLE OF INVENTION: GROUPING OF IMAGE FRAMES IN VIDEO CODING

APPLN. TYPE	SMALL ENTITY	ISSUE FEE DUE	PUBLICATION FEE DUE	PREV. PAID ISSUE FEE	TOTAL FEE(S) DUE	DATE DUE
nonprovisional	NO	$1740	$300	$0	$2040	06/19/2012

THE APPLICATION IDENTIFIED ABOVE HAS BEEN EXAMINED AND IS ALLOWED FOR ISSUANCE AS A PATENT. PROSECUTION ON THE MERITS IS CLOSED. THIS NOTICE OF ALLOWANCE IS NOT A GRANT OF PATENT RIGHTS. THIS APPLICATION IS SUBJECT TO WITHDRAWAL FROM ISSUE AT THE INITIATIVE OF THE OFFICE OR UPON PETITION BY THE APPLICANT. SEE 37 CFR 1.313 AND MPEP 1308.

THE ISSUE FEE AND PUBLICATION FEE (IF REQUIRED) MUST BE PAID WITHIN THREE MONTHS FROM THE MAILING DATE OF THIS NOTICE OR THIS APPLICATION SHALL BE REGARDED AS ABANDONED. THIS STATUTORY PERIOD CANNOT BE EXTENDED. SEE 35 U.S.C. 151. THE ISSUE FEE DUE INDICATED ABOVE DOES NOT REFLECT A CREDIT FOR ANY PREVIOUSLY PAID ISSUE FEE IN THIS APPLICATION. IF AN ISSUE FEE HAS PREVIOUSLY BEEN PAID IN THIS APPLICATION (AS SHOWN ABOVE), THE RETURN OF PART B OF THIS FORM WILL BE CONSIDERED A REQUEST TO REAPPLY THE PREVIOUSLY PAID ISSUE FEE TOWARD THE ISSUE FEE NOW DUE.

HOW TO REPLY TO THIS NOTICE:

I. Review the SMALL ENTITY status shown above.

If the SMALL ENTITY is shown as YES, verify your current SMALL ENTITY status:

A. If the status is the same, pay the TOTAL FEE(S) DUE shown above.

B. If the status above is to be removed, check box 5b on Part B - Fee(s) Transmittal and pay the PUBLICATION FEE (if required) and twice the amount of the ISSUE FEE shown above, or

If the SMALL ENTITY is shown as NO:

A. Pay TOTAL FEE(S) DUE shown above, or

B. If applicant claimed SMALL ENTITY status before, or is now claiming SMALL ENTITY status, check box 5a on Part B - Fee(s) Transmittal and pay the PUBLICATION FEE (if required) and 1/2 the ISSUE FEE shown above.

II. PART B - FEE(S) TRANSMITTAL, or its equivalent, must be completed and returned to the United States Patent and Trademark Office (USPTO) with your ISSUE FEE and PUBLICATION FEE (if required). If you are charging the fee(s) to your deposit account, section "4b" of Part B - Fee(s) Transmittal should be completed and an extra copy of the form should be submitted. If an equivalent of Part B is filed, a request to reapply a previously paid issue fee must be clearly made, and delays in processing may occur due to the difficulty in recognizing the paper as an equivalent of Part B.

III. All communications regarding this application must give the application number. Please direct all communications prior to issuance to Mail Stop ISSUE FEE unless advised to the contrary.

IMPORTANT REMINDER: Utility patents issuing on applications filed on or after Dec. 12, 1980 may require payment of maintenance fees. It is patentee's responsibility to ensure timely payment of maintenance fees when due.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), to: Mail **Mail Stop ISSUE FEE**
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450
or Fax (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence including the Patent, advance orders and notification of maintenance fees will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications.

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

10888 7590 03/19/2012
Hollingsworth & Funk
8500 Normandale Lake Blvd., Suite 320
Minneapolis, MN 55437

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

Certificate of Mailing or Transmission
I hereby certify that this Fee(s) Transmittal is being deposited with the United States Postal Service with sufficient postage for first class mail in an envelope addressed to the Mail Stop ISSUE FEE address above, or being facsimile transmitted to the USPTO (571) 273-2885, on the date indicated below.

1. Change of correspondence address or indication of "Fee Address" (37 CFR 1.363).
- ❑ Change of correspondence address (or Change of Correspondence Address form PTO/SB/122) attached.
- ❑ "Fee Address" indication (or "Fee Address" Indication form PTO/SB/47; Rev 03-02 or more recent) attached. **Use of a Customer Number is required.**

2. For printing on the patent front page, list
(1) the names of up to 3 registered patent attorneys or agents OR, alternatively,
(2) the name of a single firm (having as a member a registered attorney or agent) and the names of up to 2 registered patent attorneys or agents. If no name is listed, no name will be printed.
1 _____
2 _____
3 _____

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)

PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document has been filed for recordation as set forth in 37 CFR 3.11. Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE (B) RESIDENCE: (CITY and STATE OR COUNTRY)

Please check the appropriate assignee category or categories (will not be printed on the patent) : ❑ Individual ❑ Corporation or other private group entity ❑ Government

4a. The following fee(s) are submitted:
- ❑ Issue Fee
- ❑ Publication Fee (No small entity discount permitted)
- ❑ Advance Order - # of Copies _____

4b. Payment of Fee(s): **(Please first reapply any previously paid issue fee shown above)**
- ❑ A check is enclosed.
- ❑ Payment by credit card. Form PTO-2038 is attached.
- ❑ The Director is hereby authorized to charge the required fee(s), any deficiency, or credit any overpayment, to Deposit Account Number _____ (enclose an extra copy of this form).

5. **Change in Entity Status** (from status indicated above)
- ❑ a. Applicant claims SMALL ENTITY status. See 37 CFR 1.27.
- ❑ b. Applicant is no longer claiming SMALL ENTITY status. See 37 CFR 1.27(g)(2).

NOTE: The Issue Fee and Publication Fee (if required) will not be accepted from anyone other than the applicant; a registered attorney or agent; or the assignee or other party in interest as shown by the records of the United States Patent and Trademark Office.

Authorized Signature _____ Date _____

Typed or printed name _____ Registration No. _____

This collection of information is required by 37 CFR 1.311. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, Virginia 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450.

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

DATE MAILED: 03/19/2012

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b)
(application filed on or after May 29, 2000)

The Patent Term Adjustment to date is 1146 day(s). If the issue fee is paid on the date that is three months after the mailing date of this notice and the patent issues on the Tuesday before the date that is 28 weeks (six and a half months) after the mailing date of this notice, the Patent Term Adjustment will be 1146 day(s).

If a Continued Prosecution Application (CPA) was filed in the above-identified application, the filing date that determines Patent Term Adjustment is the filing date of the most recent CPA.

Applicant will be able to obtain more detailed information by accessing the Patent Application Information Retrieval (PAIR) WEB site (http://pair.uspto.gov).

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Customer Service Center of the Office of Patent Publication at 1-(888)-786-0101 or (571)-272-4200.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

Notice of Allowability	Application No.	Applicant(s)	
	11/338,996	HANNUKSELA, MISKA	
	Examiner	Art Unit	
	SIU LEE	2611	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address--

All claims being allowable, PROSECUTION ON THE MERITS IS (OR REMAINS) CLOSED in this application. If not included herewith (or previously mailed), a Notice of Allowance (PTOL-85) or other appropriate communication will be mailed in due course. **THIS NOTICE OF ALLOWABILITY IS NOT A GRANT OF PATENT RIGHTS.** This application is subject to withdrawal from issue at the initiative of the Office or upon petition by the applicant. See 37 CFR 1.313 and MPEP 1308.

1. ☒ This communication is responsive to *after final amendment filed on 3/5/2012*.

2. ☐ An election was made by the applicant in response to a restriction requirement set forth during the interview on _____; the restriction requirement and election have been incorporated into this action.

3. ☒ The allowed claim(s) is/are *1, 3-10,12-18 and 20-25*.

4. ☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
   a) ☒ All b) ☐ Some* c) ☐ None of the:
      1. ☐ Certified copies of the priority documents have been received.
      2. ☒ Certified copies of the priority documents have been received in Application No. *10/306,942* .
      3. ☐ Copies of the certified copies of the priority documents have been received in this national stage application from the International Bureau (PCT Rule 17.2(a)).

   * Certified copies not received: _____.

Applicant has THREE MONTHS FROM THE "MAILING DATE" of this communication to file a reply complying with the requirements noted below. Failure to timely comply will result in ABANDONMENT of this application.
THIS THREE-MONTH PERIOD IS NOT EXTENDABLE.

5. ☐ A SUBSTITUTE OATH OR DECLARATION must be submitted. Note the attached EXAMINER'S AMENDMENT or NOTICE OF INFORMAL PATENT APPLICATION (PTO-152) which gives reason(s) why the oath or declaration is deficient.

6. ☐ CORRECTED DRAWINGS (as "replacement sheets") must be submitted.
   (a) ☐ including changes required by the Notice of Draftsperson's Patent Drawing Review (PTO-948) attached
      1) ☐ hereto or 2) ☐ to Paper No./Mail Date _____.
   (b) ☐ including changes required by the attached Examiner's Amendment / Comment or in the Office action of Paper No./Mail Date _____.

Identifying indicia such as the application number (see 37 CFR 1.84(c)) should be written on the drawings in the front (not the back) of each sheet. Replacement sheet(s) should be labeled as such in the header according to 37 CFR 1.121(d).

7. ☐ DEPOSIT OF and/or INFORMATION about the deposit of BIOLOGICAL MATERIAL must be submitted. Note the attached Examiner's comment regarding REQUIREMENT FOR THE DEPOSIT OF BIOLOGICAL MATERIAL.

Attachment(s)

1. ☐ Notice of References Cited (PTO-892)
2. ☐ Notice of Draftperson's Patent Drawing Review (PTO-948)
3. ☐ Information Disclosure Statements (PTO/SB/08), Paper No./Mail Date _____
4. ☐ Examiner's Comment Regarding Requirement for Deposit of Biological Material
5. ☐ Notice of Informal Patent Application
6. ☐ Interview Summary (PTO-413), Paper No./Mail Date _____ .
7. ☐ Examiner's Amendment/Comment
8. ☒ Examiner's Statement of Reasons for Allowance
9. ☐ Other _____.

/Siu M Lee/
Primary Examiner, Art Unit 2611

DETAILED ACTION

Allowable Subject Matter

1. Claims 1, 3-10, 12-18, 20-25 are allowed.

2. The following is an examiner's statement of reasons for allowance:

The present invention describes a method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising decoding from the compressed video sequence an indication informing an intentional discontinuity of numbering of the image frames; configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames; and using the image frames in the buffer memory in the decoding process. The closest prior art, Apostolopoulos (US 7,103,669 B2) discloses a video communication system that employ multiple state encoding and path diversity but fails to disclose decoding from the compressed video sequence an indication informing an intentional discontinuity of numbering of the image frames; configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to at least one discontinuity in the numbering of the image frames, this distinct features has been added to independent claims 1, 10 and 18, thus rendering claims 1, 3-10, 12-18, and 20-25 allowable.

Any comments considered necessary by applicant must be submitted no later than the payment of the issue fee and, to avoid processing delays, should preferably accompany the issue fee. Such submissions should be clearly labeled "Comments on Statement of Reasons for Allowance."

Any inquiry concerning this communication or earlier communications from the examiner should be directed to SIU LEE whose telephone number is (571)270-1083. The examiner can normally be reached on Mon-Fri, 6:15-3:45 with every other Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Chieh Fan can be reached on (571) 272-3042. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

PATENT & TRADEMARK OFFICE

Statement Under 37 C.F.R. 3.73(b)

Owner: **Nokia Corporation**

Application No.: **See Attached**

Nokia Corporation, a corporation
(Name of Assignee) (Type of Assignee)

states that it is:

the assignee of the entire right, title and interest in:

the patent applications **identified on the attached list** by virtue of assignment(s) from the inventor(s) of the patent application(s).

The assignments were recorded in the United States Patent and Trademark Office on the Reel and Frame numbers listed on the attached list.

The undersigned is authorized to act on behalf of the assignee.

Thomas Arria

NOKIA

LIMITED POWER OF ATTORNEY

that we, the undersigned, under the authority granted to each of us to sign jointly on behalf of

NOKIA CORPORATION
Keilalahdentie 4
02150 Espoo
Finland

hereby authorize the following person

Thomas Arria
Nokia Corporation
5 Wayside Road
01803 Burlington
U.S.A.

Nokia Corporation
P.O.Box 226,
FI-00045 NOKIA GROUP, Finland
(Keilalahdentie 4, 02150 ESPOO)

Tel. +358 7180 08000
Fax +358 7180 38226

Business Identity Code
0112038-9, Helsinki

in his capacity as Senior IP Specialist, Patenting, to sign alone in the name of Nokia Corporation all the documents that relate to the filing, prosecution and registration of patent applications, as well as post-grant operations relating to patents granted based on such patent applications. Such documents may include without limitation case-specific Powers of Attorney, Assignment Deeds for assigning the ownership of an invention to Nokia, Novelty Declarations and Inventorship Declarations.

The rights granted under this Power of Attorney may not be transferred further, other than as specified above.

The authority granted by this Power of Attorney shall expire six (6) months from the date of execution.

Notwithstanding the foregoing, the authority granted by this Power of Attorney shall expire when the authorized person's employment with Nokia ends.

This Power of Attorney is duly signed on this day of January 1, 2012.

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)

PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document has been filed for recordation as set forth in 37 CFR 3.11. Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE: Nokia Corporation

(B) RESIDENCE: (CITY and STATE OR COUNTRY): Espoo, Finland

Please check the appropriate assignee category or categories (will not be printed on the patent): ☐ Individual ☒ Corporation or other private group entity ☐ Government

4a. The following fee(s) are submitted:
- ☒ Issue Fee
- ☒ Publication Fee (No small entity discount permitted)
- ☐ Advance Order - # of Copies _____

4b. Payment of Fee(s): **(Please first reapply any previously paid issue fee shown above)**
- ☐ A check is enclosed.
- ☐ Payment by credit card. Form PTO-2038 is attached.
- ☒ The Director is hereby authorized to charge the required fee(s), any deficiency, or credit any overpayment, to Deposit Account Number 50-1924 (enclose an extra copy of this form).

5. **Change in Entity Status** (from status indicated above)
- ☐ a. Applicant claims SMALL ENTITY status. See 37 CFR 1.27.
- ☐ b. Applicant is no longer claiming SMALL ENTITY status. See 37 CFR 1.27(g)(2).

NOTE: The Issue Fee and Publication Fee (if required) will not be accepted from anyone other than the applicant; a registered attorney or agent; or the assignee or other party in interest as shown by the records of the United States Patent and Trademark Office.

Authorized Signature _____ Date May 14, 2012

Typed or printed name Jerry Stanton Registration No. 46,008

This collection of information is required by 37 CFR 1.311. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, Virginia 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450.

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

ISSUE NOTIFICATION

The projected patent number and issue date are specified above.

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b)
(application filed on or after May 29, 2000)

The Patent Term Adjustment is 1879 day(s). Any patent to issue from the above-identified application will include an indication of the adjustment on the front page.

If a Continued Prosecution Application (CPA) was filed in the above-identified application, the filing date that determines Patent Term Adjustment is the filing date of the most recent CPA.

Applicant will be able to obtain more detailed information by accessing the Patent Application Information Retrieval (PAIR) WEB site (http://pair.uspto.gov).

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Application Assistance Unit (AAU) of the Office of Data Management (ODM) at (571)-272-4200.

APPLICANT(s) (Please see PAIR WEB site http://pair.uspto.gov for additional applicants):

Miska Hannuksela, Tampere, FINLAND;
