CONTINUATION PATENT APPLICATION UNDER 37 C.F.R. § 1.53(b)

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

This is a request for filing a continuation patent application under 37 CFR § 1.53(b) of pending patent application serial number 10/306,942 filed on November 29, 2002, which claims priority under 35 U.S.C. §119 from corresponding Finnish patent application No. 20020127, filed in Finland on January 23, 2002.

We are transmitting herewith the following:

☒ Transmittal sheet containing Certificate under 37 CFR 1.10 (2 pages).
☒ Patent Application: Pages numbered 1-39, with 1pg. Abstract; 31 claims.
☒ 4 sheets of formal drawings, having Figures 1-2, 3A-3B, 4A-4C, 5A-5C, 6A-6C, and 7.
☒ Copy of the executed Declaration from the priority application (3 pages).
☒ A copy of the Change of Correspondence Address submitted in the prior pending application. Please send all future correspondence to the following address:

HOLLINGSWORTH & FUNK, LLC
8009 34th Avenue South, Suite 125
Minneapolis, MN 55425
952.854.2700

☒ The priority pending application is assigned to: Nokia Corporation at Reel/Frame No.: 013741/0536.

Applicant: HANNUKSELA

Docket: TPO.004.C1

Title: GROUPING OF IMAGE FRAMES IN VIDEO CODING

☒ The Power of Attorney in the prior pending application is to: Steven R. Funk, Reg. No. 37,830.

☒ Authorization is given to charge Deposit Account No. 50-3581 (TPO.004.C1) in the amount of $2,150.00 for the filing fees. Authorization is also given to charge/credit Deposit Account No. 50-3581 (TPO.004.C1) for any deficiencies/overpayments.

☒ 1 Return Postcard

The fees are calculated as follows:

Basic Filing Fee =	$ 300.00
Search Fee =	$ 500.00
Examination Fee =	$ 200.00
Fee for total # of claims over 20 = $50 * (31 – 20) =	$ 550.00
Fee for total # of independent claims over 3 = $200 * (6 – 3) =	$ 600.00
TOTAL FILING FEES DUE =	$2,150.00

Respectfully submitted,

GROUPING OF IMAGE FRAMES IN VIDEO CODING

RELATED PATENT DOCUMENTS

[0001] This application is a continuation of U.S. Patent Application Serial No. 10/306,942 filed on November 29, 2002 which is incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

[0002] The invention relates to the grouping of multimedia files, particularly video files and particularly in connection with streaming.

BACKGROUND OF THE INVENTION

[0003] The term 'streaming' refers to simultaneous sending and playback of data, typically multimedia data, such as audio and video files, in which the recipient may begin data playback already before all the data to be transmitted has been received. Multimedia data streaming systems comprise a streaming server and terminal devices that the recipients use for setting up a data connection, typically via a telecommunications network, to the streaming server. From the streaming server the recipients retrieve either stored or real-time multimedia data, and the playback of the multimedia data can then begin, most advantageously almost in real-time with the transmission of the data, by means of a streaming application included in the terminal.

[0004] From the point of view of the streaming server, the streaming may be carried out either as normal streaming or as progressive downloading to the terminal. In normal streaming the transmission of the multimedia data and/or the data contents are controlled either by making sure that the bit rate of the transmission substantially corresponds to the playback rate of the terminal device, or, if the telecommunications network used in the transmission causes a bottleneck in data transfer, by making sure that the bit rate of the transmission substantially corresponds to the bandwidth available in the telecommunications network. In progressive downloading the transmission of the multimedia data and/or the data contents do not necessarily have to be interfered with at all, but the multimedia files are transmitted as such to the recipient, typically by using transfer protocol flow control. The terminals then receive, store and reproduce an exact copy of the data transmitted from the

server, which copy can then be later reproduced again on the terminal without needing to start a streaming again via the telecommunications network. The multimedia files stored in the terminal are, however, typically very large and their transfer to the terminal is time-consuming, and they require a significant amount of storage memory capacity, which is why a normal streaming is often preferred.

[0005] The video files in multimedia files comprise a great number of still image frames, which are displayed rapidly in succession (of typically 15 to 30 frames per s) to create an impression of a moving image. The image frames typically comprise a number of stationary background objects, determined by image information which remains substantially unchanged, and few moving objects, determined by image information that changes to some extent. The information comprised by consecutively displayed image frames is typically largely similar, i.e. successive image frames comprise a considerable amount of redundancy. The redundancy appearing in video files can be divided into spatial, temporal and spectral redundancy. Spatial redundancy refers to the mutual correlation of adjacent image pixels, temporal redundancy refers to the changes taking place in specific image objects in subsequent frames, and spectral redundancy to the correlation of different colour components within an image frame.

[0006] To reduce the amount of data in video files, the image data can be compressed into a smaller form by reducing the amount of redundant information in the image frames. In addition, while encoding, most of the currently used video encoders downgrade image quality in image frame sections that are less important in the video information. Further, many video coding methods allow redundancy in a bit stream coded from image data to be reduced by efficient, lossless coding of compression parameters known as VLC (Variable Length Coding).

[0007] In addition, many video coding methods make use of the above-described temporal redundancy of successive image frames. In that case a method known as motion-compensated temporal prediction is used, i.e. the contents of some (typically most) of the image frames in a video sequence are predicted from other frames in the sequence by tracking changes in specific objects or areas in successive image frames. A video sequence always comprises some compressed image frames the image information of which has not been determined using motion-compensated temporal

prediction. Such frames are called INTRA-frames, or I-frames. Correspondingly, motion-compensated video sequence image frames predicted from previous image frames, are called INTER-frames, or P-frames (Predicted). The image information of P-frames is determined using one I-frame and possibly one or more previously coded P-frames. If a frame is lost, frames dependent on it can no longer be correctly decoded.

[0008] An I-frame typically initiates a video sequence defined as a Group of Pictures (GOP), the P-frames of which can only be determined on the basis of the I-frame and the previous P-frames of the GOP in question. The next I-frame begins a new group of pictures GOP, the image information comprised by which cannot thus be determined on the basis of the frames of the previous GOP. In other words, groups of pictures are not temporally overlapping, and each group of picture can be decoded separately. In addition, many video compression methods employ bi-directionally predicted B-frames (Bi-directional), which are set between two anchor frames (I- and P-frames, or two P-frames) within a group of pictures GOP, the image information of a B-frame being predicted from both the previous anchor frame and the one succeeding the B-frame. B-frames therefore provide image information of higher quality than P-frames, but typically they are not used as anchor frames, and therefore their removal from the video sequence does not degrade the quality of subsequent images. However, nothing prevents B-frames from being used as anchor frames as well, only in that case they cannot be removed from the video sequence without deteriorating the quality of the frames dependent on them.

[0009] Each video frame may be divided into what are known as macroblocks that comprise the colour components (such as Y, U, V) of all pixels of a rectangular image area. More specifically, a macroblock consists of at least one block per colour component, the blocks each comprising colour values (such as Y, U or V) of one colour level in the image area concerned. The spatial resolution of the blocks may differ from that of the macroblocks, for example U- and V-components may be displayed using only half of the resolution of Y-component. Macroblocks can be further grouped into slices, for example, which are groups of macroblocks that are typically selected in the scanning order of the image. Temporal prediction is typically carried out in video coding methods block- or macroblock-specifically, instead of image-frame-specifically.

[0010] To allow for flexible streaming of video files, many video coding systems employ scalable coding in which some elements or element groups of a video sequence can be removed without affecting the reconstruction of other parts of the video sequence. Scalability is typically implemented by grouping the image frames into a number of hierarchical layers. The image frames coded into the image frames of the base layer substantially comprise only the ones that are compulsory for the decoding of the video information at the receiving end. The base layer of each group of pictures GOP thus comprises one I-frame and a necessary number of P-frames. One or more enhancement layers can be determined below the base layer, each one of the layers improving the quality of the video coding in comparison with an upper layer. The enhancement layers thus comprise P- or B-frames predicted on the basis of motion-compensation from one or more upper layer images. The frames are typically numbered according to an arithmetical series.

[0011] In streaming, transmission bit rate must be controllable either on the basis of the bandwidth to be used or the maximum decoding or bit rate value of the recipient. Bit rate can be controlled either at the streaming server or in some element of the telecommunications network, such as an Internet router or a base station of a mobile communications network. The simplest means for the streaming server to control the bit rate is to leave out B-frames having a high information content from the transmission. Further, the streaming server may determine the number of scalability layers to be transmitted in a video stream, and thus the number of the scalability layers can be changed always when a new group of pictures GOP begins. It is also possible to use different video sequence coding methods. Correspondingly, B-frames, as well as other P-frames of the enhancement layers, can be removed from the bit stream in a telecommunications network element.

[0012] The above arrangement involves a number of drawbacks. Many coding methods, such as the coding according to the ITU-T (International Telecommunications Union, Telecommunications Standardization Sector) standard H.263, are familiar with a procedure called reference picture selection. In reference picture selection at least a part of a P-image has been predicted from at least one other image than the one immediately preceding the P-image in the time domain. The selected reference image is signalled in a coded bit stream or in bit stream header fields image-,

image-segment- (such as a slice or a group of macroblocks), macroblock-, or block-specifically. The reference picture selection can be generalized such that the prediction can also be made from images temporally succeeding the image to be coded. Further, the reference picture selection can be generalized to cover all temporally predicted frame types, including B-frames. Since it is possible to also select at least one image preceding an I-image that begins a group of pictures GOP as the reference image, a group of pictures employing reference picture selection cannot necessarily be decoded independently. In addition, the adjusting of scalability or coding method in the streaming server or a network element becomes difficult, because the video sequence must be decoded, parsed and buffered for a long period of time to allow any dependencies between different image groups to be detected.

[0013] A further problem relates to the insertion of a video sequence in the middle of another video sequence, which has typically led to discontinuity in image numbering. The numbering of video sequence images is typically used for detecting the loss of image frames. However, if a separate video sequence, such as a commercial, is inserted into a video sequence, the separate video sequence is typically provided with separate image numbering, which is not in line with the ascending image numbering of the original video sequence. The receiving terminal may therefore interpret the deviating image numbering as a signal of lost image frames and start unnecessary actions to reconstruct the image frames suspected as lost or to request a re-transmission thereof.

[0014] A similar problem is encountered when buffering and indexing reference pictures in the encoder and the decoder. As a part of the indexing, the encoder may intentionally remove a plurality of image frames, which are unnecessary as reference image frames for the temporal prediction process of any remaining image frames. Again, there is no process for informing the decoder a reason for the removal: for example, if a plural number of image frames are removed, the receiving terminal may unnecessarily interpret these intentional removals as protocol errors.

BRIEF DESCRIPTION OF THE INVENTION

[0015] Now there is invented an improved method and equipment implementing the method, which enable the decoder to take into account the image frames the encoder has intentionally removed. Various aspects of the

invention include a method, a video encoder, a video decoder, a video signal, a device, preferably a streaming system element, for adjusting bit rate of a video sequence and a computer program that are characterized by what is stated in the independent claims.

[0016] The preferred embodiments of the invention are disclosed in the dependent claims.

[0017] The invention is based on the idea of decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding. The video sequence includes an indication relating to at least one discontinuity in the numbering of the image frames, which indication is decoded from the video sequence. Then, in response to the indication, the buffer memory is configured to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames, and the image frames in the buffer memory are used in the decoding process. Preferably, said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional, and the number of image frames generated in the buffer memory are used in place of image frames that do not exist at a decoder. The missing image frames cause discontinuities in the numbering of the image frames.

[0018] According to an embodiment, after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames, the entering of the image frames comprised by the video sequence in question into the buffer memory is continued from the correct image frame number.

[0019] According to an embodiment, a number of filler frames corresponding to the discontinuities in the numbering of the image frames is entered into the buffer memory. Preferably, said filler frames are designated by an identifier indicating that the filler frames do not belong to the actual video sequence.

[0020] According to an embodiment, the step of configuring the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image framesis carried out by memory indications, whereby no data is entered into the buffer memory.

[0021] An advantage of the procedure of the invention is that it provides the decoder with the information, which gaps in the image frame numbering are intentional, whereby the decoder does not start unnecessary

error correction actions. A further advantage is that the buffer memories of the encoder and the decoder can be kept in synchronism, which enables a fluent operation of the process of reference picture selection.

BRIEF DESCRIPTION OF THE DRAWINGS

[0022] In the following, the invention will be described in connection with the preferred embodiments and with reference to the accompanying drawings, in which

Figure 1 illustrates a common multimedia data streaming system in which the scalable coding hierarchy of the invention can be applied;

Figure 2 illustrates a scalable coding hierarchy of a preferred embodiment of the invention;

Figures 3a and 3b illustrate embodiments of the invention for adjusting scalability;

Figures 4a, 4b and 4c illustrate embodiments of the invention for adjusting image numbering;

Figures 5a, 5b and 5c illustrate embodiments of the invention for using B-frames in a scalable coding hierarchy;

Figures 6a, 6b and 6c illustrate scalable coding hierarchies of preferred embodiments of the invention in connection with reference picture selection; and

Figure 7 illustrates an arrangement according to a preferred embodiment of the invention for coding scene transition.

DETAILED DESCRIPTION OF THE INVENTION

[0023] In the following, a general-purpose multimedia data streaming system is disclosed, the basic principles of which can be applied in connection with any telecommunications system. Although the invention is described here with a particular reference to a streaming system, in which the multimedia data is transmitted most preferably through a telecommunications network employing a packet-switched data protocol, such as an IP network, the invention can equally well be implemented in circuit-switched networks, such as fixed telephone networks PSTN/ISDN (Public Switched Telephone Network/Integrated Services Digital Network) or in mobile communications networks PLMN (Public Land Mobile Network). Further, the invention can be applied in the streaming of multimedia files in the form of both normal

streaming and progressive downloading, and for implementing video calls, for example.

[0024] It is also to be noted that although the invention is described here with a particular reference to streaming systems and the invention can also be advantageously applied in them, the invention is not restricted to streaming systems alone, but can be applied in any video reproduction system, irrespective of how a video file that is to be decoded is downloaded and where it is downloaded from. The invention can therefore be applied for example in the playback of a video file to be downloaded from a DVD disc or from some other computer memory carrier, for example in connection with varying processing capacity available for video playback. In particular, the invention can be applied to different video codings of low bit rate that are typically used in telecommunications systems subject to bandwidth restrictions. One example is the system defined in the ITU-T standard H.263 and the one that is being defined in H.26L (possibly later to become H.264). In connection with these, the invention can be applied to mobile stations, for example, in which case the video playback can be made to adjust both to changing transfer capacity or channel quality and to the processor power currently available, when the mobile station is used also for executing other applications than video playback.

[0025] It is further to be noted that, for the sake of clarity, the invention will be described below by giving an account of image frame coding and temporal predicting on image frame level. However, in practice coding and temporal predicting typically take place on block or macroblock level, as described above.

[0026] With reference to Figure 1, a typical multimedia streaming system will be described, which is a preferred system for applying the procedure of the invention.

[0027] A multimedia data streaming system typically comprises one or more multimedia sources 100, such as a video camera and a microphone, or video image or computer graphic files stored in a memory carrier. Raw data obtained from the different multimedia sources 100 is combined into a multimedia file in an encoder 102, which can also be referred to as an editing unit. The raw data arriving from the one or more multimedia sources 100 is first captured using capturing means 104 included in the encoder 102, which capturing means can be typically implemented as different interface cards,

driver software, or application software controlling the function of a card. For example, video data may be captured using a video capture card and the associated software. The output of the capturing means 104 is typically either an uncompressed or slightly compressed data flow, for example uncompressed video frames of the YUV 4:2:0 format or motion-JPEG image format, when a video capture card is concerned.

[0028] An editor 106 links different media flows together to synchronize video and audio flows to be reproduced simultaneously as desired. The editor 106 may also edit each media flow, such as a video flow, by halving the frame rate or by reducing spatial resolution, for example. The separate, although synchronized, media flows are compressed in a compressor 108, where each media flow is separately compressed using a compressor suitable for the media flow. For example, video frames of the YUV 4:2:0 format may be compressed using the low bit rate video coding according to the ITU-T recommendation H.263 or H.26L. The separate, synchronized and compressed media flows are typically interleaved in a multiplexer 110, the output obtained from the encoder 102 being a single, uniform bit flow that comprises data of a plural number of media flows and that may be referred to as a multimedia file. It is to be noted that the forming of a multimedia file does not necessarily require the multiplexing of a plural number of media flows into a single file, but the streaming server may interleave the media flows just before transmitting them.

[0029] The multimedia files are transferred to a streaming server 112, which is thus capable of carrying out the streaming either as real-time streaming or in the form of progressive downloading. In progressive downloading the multimedia files are first stored in the memory of the server 112 from where they may be retrieved for transmission as need arises. In real-time streaming the editor 102 transmits a continuous media flow of multimedia files to the streaming server 112, and the server 112 forwards the flow directly to a client 114. As a further option, real-time streaming may also be carried out such that the multimedia files are stored in a storage that is accessible from the server 112, from where real-time streaming can be driven and a continuous media flow of multimedia files is started as need arises. In such case, the editor 102 does not necessarily control the streaming by any means. The streaming server 112 carries out traffic shaping of the multimedia data as regards the bandwidth available or the maximum decoding and playback rate

of the client 114, the streaming server being able to adjust the bit rate of the media flow for example by leaving out B-frames from the transmission or by adjusting the number of the scalability layers. Further, the streaming server 112 may modify the header fields of a multiplexed media flow to reduce their size and encapsulate the multimedia data into data packets that are suitable for transmission in the telecommunications network employed. The client 114 may typically adjust, at least to some extent, the operation of the server 112 by using a suitable control protocol. The client 114 is capable of controlling the server 112 at least in such a way that a desired multimedia file can be selected for transmission to the client, in addition to which the client is typically capable of stopping and interrupting the transmission of a multimedia file.

[0030] When the client 114 is receiving a multimedia file, the file is first supplied to a demultiplexer 116, which separates the media flows comprised by the multimedia file. The separate, compressed media flows are then supplied to a decompressor 118 where each separate media flow is decompressed by a decompressor suitable for each particular media flow. The decompressed and reconstructed media flows are supplied to a playback unit 120 where the media flows are rendered at a correct pace according to their synchronization data and supplied to presentation means 124. The actual presentation means 124 may comprise for example a computer or mobile station display, and loudspeaker means. The client 114 also typically comprises a control unit 122 that the end user can typically control through a user interface and that controls both the operation of the server, through the above-described control protocol, and the operation of the playback unit 120, on the basis of the instructions given by the end user.

[0031] It is to be noted that the transfer of multimedia files from the streaming server 112 to the client 114 takes place through a telecommunications network, the transfer path typically comprising a plural number of telecommunications network elements. It is therefore possible that there is at least some network element that can carry out traffic shaping of multimedia data with regard to the available bandwidth or the maximum decoding and playback rate of the client 114 at least partly in the same way as described above in connection with the streaming server.

[0032] Scalable coding will be described below with reference to a preferred embodiment of the invention and an example illustrated in Figure 2. Figure 2 shows part of a compressed video sequence having a first frame 200,

which is an INTRA frame, or I-frame, and thus an independently determined video frame the image information of which is determined without using motion-compensated temporal prediction. The I-frame 200 is placed on a first scalability layer, which may be referred to as an INTRA layer. Each scalability layer is assigned a unique identifier, such as the layer number. The INTRA layer may therefore be given the number 0, for example, or some other alphanumeric identifier, for example a letter, or a combination of a letter and a number.

[0033] Correspondingly, sub-sequences consisting of groups of one or more video frames are determined for each scalability layer, at least one of the images in a group (typically the first or the last one) being temporally predicted at least from a video frame of another, sub-sequence of typically either a higher or the same scalability layer, the rest of the video frames being temporally predicted either from only the video frames of the same sub-sequence, or possibly also from one or more video frames of said second sub-sequence. A sub-sequence may de decoded independently, irrespective of other sub-sequences, except said second sub-sequence. The sub-sequences of each scalability layer are assigned a unique identifier using for example consecutive numbering starting with number 0 given for the first sub-sequence of a scalability layer. Since the I-frame 200 is determined independently and can also be decoded independently upon reception, irrespective of other image frames, it also forms in a way a separate sub-sequence.

[0034] An essential aspect of the present invention is therefore to determine each sub-sequence in terms of those sub-sequences the sub-sequence is dependent on. In other words, a sub-sequence comprises information about all the sub-sequences that have been directly used for predicting the image frames of the sub-sequence in question. This information is signalled in a video sequence bit stream, preferably separate from the actual image information, and therefore the image data of the video sequence can be preferably adjusted because it is easy to determine video sequence portions that are to be independently decoded and can be removed without affecting the decoding of the rest of the image data.

[0035] Next, within each sub-sequence, the video frames of the sub-sequence are given image numbers, using for example consecutive numbering that starts with the number 0 given to the first video frame of the sub-sequence. Since the I-frame 200 also forms a separate sub-sequence, its

image number is 0. In Figure 2, the I-frame 200 shows the type (I), sub-sequence identifier and image number (0.0) of the frame.

[0036] Figure 2 further shows a next I-frame 202 of the INTRA layer, the frame thus being also an independently determined video frame that has been determined without using motion-compensated temporal prediction. The temporal transmission frequency of I-frames depends on many factors relating to video coding, image information contents and the bandwidth to be used, and, depending on the application or application environment, I-frames are transmitted in a video sequence at intervals of 0.5 to 10 seconds, for example. Since the I-frame 202 can be independently decoded, it also forms a separate sub-sequence. Since this is the second sub-sequence in the INTRA-layer, the consecutive numbering of the sub-sequence identifier of the I-frame 202 is 1. Further, since the I-frame 202 also forms a separate sub-sequence, i.e. it is the only video frame in the sub-sequence, its image number is 0. The I-frame 202 can thus be designated with identifier (I.1.0.) Correspondingly, the identifier of the next I-frame on the INTRA layer is (I.2.0.), etc. As a result, only independently determined I-frames in which the image information is not determined using motion-compensated temporal prediction are coded into the first scalability layer, i.e. the INTRA layer. The sub-sequences can also be determined using other kind of numbering or other identifiers, provided that the sub-sequences can be distinguished from one another.

[0037] The next scalability layer, which has a layer number 1, for example, and which may be referred to as the base layer, comprises coded, motion-compensated INTER or P-frames typically predicted only from previous image frames, i.e. in this case from the I-frames of an upper INTRA layer. The image information of the first P-frame 204 of the base layer shown in Figure 2 is determined using the I-frame 200 of the INTRA layer. A P-frame 204 begins the first sub-sequence of the base layer, and therefore the sub-sequence identifier of the P-frame 204 is 0. Further, since the P-frame 204 is the first image frame of the first sub-sequence of the base layer, the image number of the P-frame 204 is 0. The P-frame 204 can thus be identified with (P.0.0).

[0038] The temporally succeeding P-frame 206 of the base layer is predicted from the previous P-frame 204. The P-frames 204 and 206 thus belong to the same sub-sequence, whereby the P-frame 206 also receives the sub-sequence identifier 0. Since the P-frame 206 is the second image frame in

the sub-sequence 0, the image number of the P-frame 206 is 1, and the P-frame 206 can be identified with (P.0.1).

[0039] The scalability layer succeeding the base layer and having the layer number 2, is called enhancement layer 1. This layer comprises coded, motion-compensated P-frames predicted only from previous image frames, in this case either from I-frames of the INTRA layer or P-frames of the base layer. Figure 2 shows a first image frame 208 and a second image frame 210 of enhancement layer 1, which are both predicted only from the first image frame 200 of the INTRA layer. The P-frame 208 begins the first sub-sequence of enhancement layer 1, the sub-sequence identifier of the P-frame thus being 0. Further, since the P-frame 208 is the first and only image frame in said sub-sequence, the P-frame 208 receives the image number 0. The P-frame 208 can thus be identified with (P.0.0.).

[0040] Since the second image frame 210 is also predicted only from the first image frame 200 of the INTRA layer, the P-frame 210 begins the second sub-sequence of enhancement layer 1 and the sub-sequence identifier of the P-frame 210 is therefore 1. Since the P-frame 210 is the first image frame in the sub-sequence, the image number of the P-frame 210 is 0. The P-frame can thus be identified with (P.1.0.). The temporally succeeding P-frame 212 of enhancement layer 1 is predicted from the previous P-frame 210. The P-frames 210 and 212 thus belong to the same sub-sequence, and therefore the P-frame also receives the sub-sequence identifier 1. The P-frame 212 is the second image frame in the sub-sequence 1, and therefore the P-frame receives the image number 1 and can be identified with (P.1.1).

[0041] The temporally fourth image frame 214 of enhancement layer 1 is predicted from the first image frame 204 of the base layer. The P-frame 214 thus begins a third sub-sequence of enhancement layer 1 and therefore the P-frame 214 receives the sub-sequence identifier 2. Further, since the P-frame 214 is the first and only image frame in the sub-sequence, the image number of the P-frame 214 is 0. The P-frame 208 can therefore be identified with (P.2.0).

[0042] Also the temporally fifth image frame 216 of enhancement layer 1 is predicted only from the first image frame 204 of the base layer, the P-frame 216 thus beginning the fourth sub-sequence of enhancement layer 1, and the sub-sequence identifier of the P-frame 216 is 3. In addition, since the P-frame 216 is the first one in the sub-sequence in question, the image

number of the P-frame 216 is 0. The P-frame 216 can therefore be identified with (P.3.0). The temporally following P-frame 218 of enhancement layer 1 is predicted from the previous P-frame 216. The P-frames 216 and 218 thus belong to the same sub-sequence, and the sub-sequence identifier of the P-frame 218 is also 3. Since the P-frame 218 is the second image frame in the sub-sequence 3, the image number of the P-frame 218 is 1 and the identifier of the P-frame 218 is (P.3.1).

[0043] For simplicity and clarity of illustration the above disclosure only relates to I- and P-frames. However, a person skilled in the art will find it apparent that the scalable video coding of the invention can also be implemented using other known image frame types, such as the above described B-frames and at least SI-frames, SP-frames and MH-frames. SI-frames correspond to I-frames, but together with an SP-frame they allow an identical image to be reconstructed. An SP-frame, in turn, is a P-frame subjected to a particular coding that allows an identical image to be reconstructed together with an SI-frame or another SP-frame. SP-frames are typically placed into a video sequence into points where an access point or a scanning point is desired, or where the changing of the coding parameters of the video stream should be possible. The frames can also be used for error correction and for increasing error tolerance. SP-frames are otherwise similar to ordinary P-frames predicted from previous frames, except that they are defined so that they can be replaced by another video frame of the SP- or SI-type, the result of the decoding of the new frame being identical with the decoding result of the original SP-frame that was in the video stream. In other words, a new SP-frame that is used for replacing the one that was in the video stream is predicted from another sequence or video stream and yet the reconstructed frame has identical contents. SP-frames are described for example in the Applicant's earlier application PCT/FI02/00004.

[0044] Similarly as B-frames, macroblocks of MH (Multi Hypothesis) frames, based on motion-compensated prediction, are predicted from two other frames, which are not, however, necessarily located next to an MH-frame. More precisely, the predicted macroblocks are computed as an average of two macroblocks of two other frames. Instead of two frames, MH-frame macroblocks can naturally be also predicted from one other frame. Reference images may change according to macroblock, in other words, all macroblocks

in one and the same image are not necessarily predicted using the same frames.

[0045] A sub-sequence thus covers a specific period of time in a video sequence. The sub-sequences of the same layer or of different layers may be partly or entirely overlapping. If there are temporally overlapping image frames on the same layer, the frames are interpreted as alternative presentations of the same image content and therefore any mode of image presentation can be used. On the other hand, if there are temporally overlapping image frames on different layers, they form different presentations of the same image content, and therefore presentations differ in image quality, i.e. the quality of image is better on a lower layer.

[0046] The above disclosure referring to Figure 2 illustrates a scalable coding arrangement and a hierarchical structure and numbering of image frames according to a preferred embodiment of the invention. In this embodiment the INTRA-layer only comprises I-frames and the base layer can only be decoded using the information received from the INTRA-layer. Correspondingly, the decoding of enhancement layer 1 typically requires information from both the base layer and the INTRA-layer.

[0047] The number of the scalability layers is not restricted to three, as above, but any number of enhancement layers that is considered necessary for producing sufficient scalability may be used. Consequently, the layer number of enhancement layer 2 is four, that of enhancement layer 3 is five, etc. Since some of the image frames in the above example are given the same identifier (e.g. the identifier of both image frames 204 and 208 is (P.0.0)), by including the layer number in the identifier each image frame can be uniquely identified and, at the same time, the dependencies of each image frame on other image frames is preferably determined. Each image frame is thus uniquely identified, the identifier of image frame 204, for example, being (P.1.0.0), or simply (1.0.0) and, correspondingly, that of image 208 being (P.2.0.0), or (2.0.0).

[0048] According to a preferred embodiment of the invention, the number of a reference image frame is determined according to a specific, pre-determined alpha-numeric series, for example as an integer between 0 and 255. When the parameter value achieves the maximum value N (e.g. 255) in the series concemed, the determining of the parameter value starts from the beginning, i.e. from the minimum value of the series (e.g. 0). An image frame is

thus uniquely identified within a specific sub-sequence up to the point where the same image number is used again. The sub-sequence identifier can also be determined according to a specific, predetermined arithmetic series. When the value of the sub-sequence identifier achieves the maximum value N of the series, the determining of the identifier starts again from the beginning of the series. However, a sub-sequence cannot be assigned an identifier that is still in use (within the same layer). The series in use may also be determined in another way than arithmetically. One alternative is to assign random sub-sequence identifiers, taking into account that an assigned identifier is not be used again.

[0049] A problem in the numbering of image frames arises when the user wishes to start browsing a video file in the middle of a video sequence. Such situations occur for example when the user wishes to browse a locally stored video file backward or forward or to browse a streaming file at a particular point; when the user initiates the playback of a streaming file from a random point; or when a video file that is to be reproduced is detected to contain an error that interrupts the playback or requires the playback to be resumed from a point following the error. When the browsing of a video file is resumed from a random point after previous browsing, discontinuity typically occurs in the image numbering. The decoder typically interprets this as unintentional loss of image frames and unnecessarily tries to reconstruct the image frames suspected as lost.

[0050] According to a preferred embodiment of the invention, this can be avoided in the decoder by defining an initiation image in an independently decodable Group of Pictures GOP that is activated at the random point of the video file, and the number of the initiation image is set at zero. This independently decodable image group can thus be a sub-sequence of an INTRA-layer, for example, in which case an I-frame is used as the initiation image, or, if scaling originating from the base layer is employed, the independently decodable image group is a sub-sequence of the base layer, in which case the first image frame of the sub-sequence, typically an I-frame, is usually used as the initiation image. Consequently, when activated at a random point, the decoder preferably sets the identifier of the first image frame, preferably an I-frame, of the independently decodable sub-sequence at zero. Since the sub-sequence to be decoded may also comprise other image frames whose identifier is zero (for example when the above described alpha-

numeric series starts from the beginning), the beginning of the sub-sequence, i.e. its first image frame, can be indicated to the decoder for example by a separate flag added to the header field of a slice of the image frame. This allows the decoder to interpret the image numbers correctly and to find the correct image frame that initiates the sub-sequence from the video sequence image frames.

[0051] The above numbering system provides only one example of how the unique image frame identification of the invention can be carried out so that interdependencies between the image frames are indicated at the same time. However, video coding methods in which the method of the invention can be applied, such as video coding methods according to the ITU-T standards H.263 and H.26L, employ code tables, which in turn use variable length codes. When variable length codes are used for coding layer numbers, for example, a lower code word index, i.e. a smaller layer number, signifies a shorter code word. In practice the scalable coding of the invention will be used in most cases in such a way that the base layer will consist significantly more image frames than the INTRA-layer. This justifies the use of a lower index, i.e. a smaller layer number, on the base layer than on the INTRA-layer, because the amount of coded video data is thereby advantageously reduced. Consequently, the INTRA-layer is preferably assigned layer number 1 and the base layer is given layer number 0. Alternatively, the code can be formed by using fewer bits for coding the base layer number than the INTRA-layer number, in which case the actual layer number value is not relevant in view of the length of the code created.

[0052] Further, according to a second preferred embodiment of the invention, when the number of the scalability layers is to be kept low, the first scalability layer in particular can be coded to comprise both the INTRA-layer and the base layer. From the point of view of coding hierarchy, the simplest way to conceive this is to leave out the INTRA-layer altogether, and to provide the base layer with coded frames consisting of both independently defined I-frames, the image information of which has not been determined using motion-compensated temporal prediction, and image frames predicted from previous frames, which image frames in this case are motion-compensated P-frames predicted from the I-frames of the same layer. The layer number 0 can thus still be used for the base layer and, if enhancement layers are coded into the video

sequence, enhancement layer 1 is assigned layer number 1. This is illustrated in the following, with reference to Figures 3a and 3b.

[0053] Figure 3a shows a non-scalable video sequence structure, in which all image frames are placed on the same scalability layer, i.e. the base layer. The video sequence comprises a first image frame 300 which is an I-frame (I.0.0) and which thus initiates a first sub-sequence. The image frame 300 is used for predicting a second image frame 302 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 304 of the sub-sequence, i.e. a P-frame (P.0.2), which is in turn used for predicting the next image frame 306, i.e. a P-frame (P.0.3). The video sequence is then provided with an I-frame (I.1.0) coded therein, i.e. an I-frame 308, which thus initiates a second sub-sequence in the video sequence. This kind of non-scalable coding can be used for example when the application employed does not allow scalable coding to be used, or there is no need for it. In a circuit-switched videophone application, for example, channel bandwidth remains constant and the video sequence is coded in real-time, and therefore there is typically no need for scalable coding.

[0054] Figure 3b, in turn, illustrates an example of how scalability can be added, when necessary, to a combined INTRA- and base layer. Here, too, the video sequence base layer comprises a first image frame 310 which is an I-frame (I.0.0) and which initiates a first sub-sequence of the base layer. The image frame 310 is used for predicting a second image frame 312 of the sub-sequence, i.e. a P-frame (P.0.1), which is then used for predicting a third image frame 314 of the sub-sequence, i.e. a P-frame (P.0.2). Enhancement layer 1, however, is also coded into this video sequence and it comprises a first sub-sequence, the first and only image frame 316 of which is a P-frame (P.0.0), which is predicted from the first image frame 310 of the base layer. The first image frame 318 of a second sub-sequence of the enhancement layer is, in turn, predicted from the second image frame 312 of the base layer, and therefore the identifier of this P-frame is (P.1.0). The next image frame 320 of the enhancement layer is again predicted from the previous image frame 318 of the same layer and, therefore, it belongs to the same sub-sequence, its identifier thus being (P.1.1).

[0055] In this embodiment of the invention the sub-sequences of the base layer can be decoded independently, although a base layer sub-sequence may be dependent on another base layer sub-sequence. The

decoding of the base layer sub-sequences requires information from the base layer and/or from the second sub-sequence of enhancement layer 1, the decoding of the sub-sequences of enhancement layer 2 requires information from enhancement layer 1 and/or from the second sub-sequence of enhancement layer 2, etc. According to an embodiment, I-frames are not restricted to the base layer alone, but lower enhancement layers may also comprise I-frames.

[0056] The basic idea behind the above embodiments is that a sub-sequence comprises information about all the sub-sequences it is dependent on, i.e. about all sub-sequences that have been used for predicting at least one of the image frames of the sub-sequence in question. However, according to an embodiment it is also possible that a sub-sequence comprises information about all sub-sequences that are dependent on the sub-sequence in question, in other words, about all the sub-sequences in which at least one image frame has been predicted using at least one image frame of the sub-sequence in question. Since in the latter case the dependencies are typically determined temporally forward, image frame buffers can be advantageously utilized in the coding in a manner to be described later.

[0057] In all the above embodiments the numbering of the image frames is sub-sequence-specific, i.e. a new sub-sequence always starts the numbering from the beginning. The identification of an individual image frame thus requires the layer number, sub-sequence identifier and image frame number to be determined. According to a preferred embodiment of the invention, the image frames can be independently numbered using consecutive numbering in which successive reference image frames in the coding order are indicated with numbers incremented by one. As regards layer numbers and sub-sequence identifiers, the above-described numbering procedure can be used. This allows each image frame to be uniquely identified, when necessary, without using the layer number and sub-sequence identifier.

[0058] This is illustrated with the example shown in Figure 4a in which the base layer comprises a temporally first I-frame 400 (I.0.0). This frame is used for predicting a first image frame 402 of enhancement layer 1, i.e. (P.0.1), which is then used for predicting a second image frame 404 belonging to the same sub-sequence (with sub-sequence identifier 0), i.e. (P.0.2), which is used for predicting a third image frame 406 of the same sub-

sequence, i.e. (P.0.3), which is used for predicting a fourth image frame 408 (P.0.4) and, finally, the fourth frame for predicting a fifth image frame 410 (P.0.5). The temporally next video sequence image frame 412 is located on the base layer, where it is in the same sub-sequence as the I-frame 400, although temporally it is only the seventh coded image frame, and therefore its identifier is (P.0.6). The seventh frame is then used for predicting a first image frame 414 of the second sub-sequence of enhancement layer 1, i.e. (P.1.7), which is then used for predicting a second image frame 416 belonging to the same sub-sequence (with sub-sequence identifier 1), i.e. (P.1.8), which in turn used for predicting a third image frame 418 (P.1.9), the third for predicting a fourth image frame 420 (P.1.10) and, finally, the fourth for predicting a fifth image frame 422 (P.1.11) of the same sub-sequence. Again, the temporally next video sequence image frame 424 is located on the base layer, where it is in the same sub-sequence as the I-frame 400 and the P-frame 412, although temporally it is only the thirteenth coded image frame and therefore its identifier is (P.0.12). For clarity of illustration, the above description of the embodiment does not comprise layer identifiers, but it is apparent that in order to implement scalability, also the layer identifier must be signalled together with the video sequence, typically as part of the image frame identifiers.

[0059] Figures 4b and 4c show alternative embodiments for grouping the image frames of the video sequence shown in Figure 4a. The image frames in Figure 4b are numbered according to sub-sequence, i.e. a new sub-sequence always starts the numbering from the beginning (from zero). Figure 4c, in turn, employs image frame numbering which corresponds otherwise to that used in Figure 4a, except that the P-frames of the base layer are replaced by SP-frame pairs to allow for identical reconstruction of image information.

[0060] As stated above, the procedure of the invention can also be implemented using B-frames. One example of this is illustrated in Figures 5a, 5b and 5c. Figure 5a shows a video sequence in the time domain, the sequence comprising P-frames P1, P4 and P7, with B-frames placed between them, the interdependencies of the B-frames with regard to temporal predicting being shown with arrows. Figure 5b shows a preferred grouping of video sequence image frames in which the interdependencies shown in Figure 5a are indicated. Figure 5b illustrates sub-sequence-specific image frame numbering in which a new sub-sequence always starts the numbering of the

image frames from zero. Figure 5c, in turn, illustrates image frame numbering, which is consecutive in the order of temporal prediction, wherein the following reference frame always receives the next image number as the previously encoded reference frame. The image frame (B1.8) (and (B2.10)) does not serve as a reference prediction frame to any other frame, therefore it does not affect the image frame numbering.

[0061] The above examples illustrate different alternatives of how scalability of video sequence coding can be adjusted by using the method of the invention. From the point of view of the terminal device reproducing the video sequence, the more scalability layers are available, or the more scalability layers it is capable of decoding, the better the image quality. In other words, increase in the amount of image information and in the bit rate used for transferring the information improves the temporal or spatial resolution, or the spatial quality of the image data. Correspondingly, a higher number of scalability layers also sets considerably higher demands on the processing capacity of the terminal device performing decoding.

[0062] In addition, the above examples illustrate the advantage gained by using sub-sequences. With image frame identifiers, the dependencies of each image frame from other image frames in the sub-sequence are indicated in an unambiguous manner. A sub-sequence thus forms an independent whole that can be left out of a video sequence, when necessary, without affecting the decoding of subsequent image frames of the video sequence. In that case, only the image frames of the sub-sequence in question and of those sub-sequences on the same and/or lower scalability layers dependent on it are not decoded.

[0063] The image frame identifier data transmitted together with the video sequence are preferably included in the video sequence header fields or in the header fields of the transfer protocol to be used for transferring the video sequence. In other words, the identifier data of predicted image frames are not included in the image data of the coded video sequence, but always into the header fields, whereby the dependencies of the image frames can be detected without decoding the images of the actual video sequence. The identifier data of the image frames can be stored for example in the buffer memory of the streaming server as the video sequence is being coded for transmission. In addition, the sub-sequences can be independently decoded on each scalability

layer, because the image frames of a sub-sequence are not dependent on other sub-sequences of the same scalability layer.

[0064] According to an embodiment of the invention, the image frames comprised by a sub-sequence may thus depend also on other sub-sequences of the same scalability layer. This dependency must then be signalled for example to the streaming server carrying out traffic shaping, because interdependent sub-sequences located on the same layer cannot be separately removed from a video sequence to be transmitted. A preferred way to carry out the signalling is to include it in the image frame identifiers to be transmitted, for example by listing the layer-sub-sequence pairs the sub-sequence in question depends on. This also provides a preferred way of indicating dependency from another sub-sequence of the same scalability layer.

[0065] The above examples illustrate a situation where image frames are temporally predicted from previous image frames. In some coding methods, however, the reference picture selection has been further extended to also include the predicting of the image information of image frames from temporally succeeding image frames. Reference picture selection offers most diversified means for creating different temporally scalable image frame structures and allows the error sensitivity of the video sequence to be reduced. One of the coding techniques based on reference picture selection is INTRA-frame postponement. The INTRA-frame is not placed into its temporally "correct" position in the video sequence, but its position is temporally postponed. The video sequence image frames that are between the "correct" position of the INTRA-frame and its actual position are predicted temporally backward from the INTRA-frame in question. This naturally requires that uncoded image frames be buffered for a sufficiently long period of time so that all image frames that are to be displayed can be coded and arranged into their order of presentation. INTRA-frame transfer and the associated determining of sub-sequences in accordance with the invention are illustrated in the following with reference to Figure 6.

[0066] Figure 6a shows a video sequence part in which the INTRA-frame comprises a single I-frame 600, which is temporally transferred to the position shown in Figure 6, although the "correct" position of the I-frame in the video sequence would have been at the first image frame. The video sequence image frames between the "correct" position and the real position 600 are thus

temporally predicted backward from the I-frame 600. This is illustrated by a sub-sequence coded into enhancement layer 1 and having a first temporally backward predicted image frame 602, which is a P-frame (P.0.0). This frame is used for temporally predicting a previous image frame 604, i.e. a P-frame (P.0.1), which is used in turn for predicting an image frame 606, i.e. a P-frame (P.0.2), and, finally, the frame 606 for predicting an image frame 608, i.e. a P-frame (P.0.3), which is at the position that would have been the "correct" position of the I-frame 600 in the video sequence. Correspondingly, the I-frame 600 on the base layer is used for temporally forward prediction of a sub-sequence comprising four P-frames 610, 612, 614 and 616, i.e. P-frames (P.0.0), (P.0.1), (P.0.2) and (P.0.3).

[0067] The fact that in this example backward predicted image frames are placed on a lower layer than forward predicted image layers indicates that for purposes of illustration, backward predicted image frames are in this coding example considered subjectively less valuable than forward predicted image frames. Naturally the sub-sequences could both be placed on the same layer, in which case they would be considered equal, or a backward predicted sub-sequence could be on the upper layer, in which case it would be considered subjectively more valuable.

[0068] Figures 6b and 6c show some alternatives for coding a video sequence according to Figure 6a. In Figure 6b both forward and backward predicted sub-sequences are placed on the base layer, the I-frame being only located on the INTRA-layer. The forward predicted sub-sequence on this layer is thus the second sub-sequence and its sub-sequence identifier is 1. In Figure 6c, in turn, an I-frame and a forward predicted sub-sequence based on it are located on the base layer, while a backward predicted sub-sequence is located on enhancement layer 1.

[0069] Moreover, according to a preferred embodiment of the invention, the above-described scalability can be utilized for coding what is known as a scene transition into a video sequence. Video material, such as news reports, music videos and movie trailers, often comprise rapid cuts between separate image material scenes. Sometimes the cuts are abrupt, but often a procedure known as scene transition is used in which transfer from one scene to another takes place by dimming, wiping, mosaic dissolving or scrolling the image frames of a previous scene, and, correspondingly, by presenting those of a later scene. From the point of view of coding efficiency,

the video coding of a scene transition is often most problematic, because the image frames appearing during the scene transition comprise information on the image frames of both the terminating and the initiating scene.

[0070] A typical scene transition, fading, is carried out by gradually reducing the intensity or luminance of the image frames of a first scene to zero, while gradually increasing the intensity of the image frames of a second scene to its maximum value. This scene transition is referred to as cross-faded scene transition.

[0071] Generally speaking, a computer-made image can be thought of as consisting of layers, or image objects. Each object can be defined with reference to at least three information types: the structure of the image object, its shape and transparency, and the layering order (depth) in relation to the background of the image and to other image objects. Shape and transparency are often determined using what is known as an alpha plane, which measures opacity and the value of which is usually determined separately for each image object, possibly excluding the background, which is usually determined as non-transparent. The alpha plane value of a non-transparent image object, such as the background, can thus be set at 1.0, whereas the alpha plane value of a fully transparent image object is 0.0. The values in between define the intensity of the visibility of a specific image object in a picture in proportion to the background and to other, at least partly overlapping, image objects that have a higher depth value than the image object in question.

[0072] The superimposition of image objects in layers according to their shape, transparency and depth position is referred to as scene composition. In practice the procedure is based on the use of weighted averages. First, the image object that is closest to the background, i.e. deepest according to its depth position, is placed onto the background and a combined image is formed of the two. The pixel values of the combined image are formed as an average weighted by the alpha plane values of the background image and the image object in question. The alpha plane value of the combined image is then set at 1.0, after which it serves as a background image for the next image object. The process continues until all image objects are attached to the image.

[0073] In the following, a procedure according to a preferred embodiment of the invention will be described in which video sequence scalability layers are combined with the above described image objects of

image frames and their information types to provide a scene transition with scalable video coding that also has good compression efficiency.

[0074] This embodiment of the invention is illustrated in the following by way of example and in a simplified manner by using cross-faded scene transition, on one hand, and abrupt scene transition, on the other hand, as examples. The image frames to be displayed during a scene transition are typically formed of two superimposed image frames, a first image frame comprising a first image scene and a second image frame a second scene. One of the image frames serves as the background image and other, which is referred to as a foreground image, is placed on top of the background image. The opacity of the background image, i.e. its non-transparency value, is constant. In other words, its pixel-specific alpha plane values are not adjusted.

[0075] In this embodiment of the invention, the background and foreground images are both defined according to scalability layer. This is illustrated in Figure 7, which shows an example of how image frames of two different scenes can be placed on scalability layers during a scene transition of the invention. Figure 7 shows a first image frame 700 of a first (terminating) scene positioned on the base layer. The image frame 700 may be either an I-frame containing image information that has not been determined using motion-compensated temporal predicting, or it may be a P-frame that is a motion-compensated image frame predicted from previous image frames. The coding of a second (initiating) scene starts during the temporally following image frame and, according to the invention, the image frames of the scene are also placed on the base layer. Remaining image frames 702, 704 of the second (terminating) scene are then placed on enhancement layer 1. These image frames are typically P-frames.

[0076] In this embodiment, the image frames of the second (initiating) scene are thus placed on the base layer, at least for the duration of the scene transition. The first image frame 706 of the scene is typically an I-frame, and it is used for temporally predicting the succeeding image frames of the scene. Consequently, the succeeding image frames of the second scene are temporally predicted frames, typically P-frames, such as frames 708 and 710 shown in Figure 7.

[0077] According to a preferred embodiment of the invention, this placing of image frames on scalability layers can be used for implementing a cross-faded scene transition by determining the image layer that is on the base

layer always as a background image of maximum opacity (100%), or non-transparency value. During a scene transition, image frames located on enhancement layers are placed onto the background image and their opacity is adjusted for example by means of suitable filters such that the frames gradually change from non-transparent to transparent.

[0078] In the video sequence of Figure 7, there are no image frames on the lower scalability layers during the first base layer image frame 700. For this time instant, the first image frame 700 is only coded into the video sequence.

[0079] The next image frame 706 of the base layer initiates a new (second) scene, during which the image frame 706 is provided with depth positioning that places it as the background image, and its opacity value is set to the maximum. Temporally simultaneously with the image frame 706 of the base layer, there is an image frame 702 of a terminating (first) scene on enhancement layer 1. To allow a cross-faded scene transition to be produced, the transparency of the frame 702 must be increased. The example of Figure 7 assumes that the opacity of the image frame 702 is set at 67% and, in addition, the image frame 702 is provided with depth positioning that determines it as a foreground image. For this time instant, an image combining the image frames 706 and 702 is coded into the video sequence, image 706 being visible as a weaker image on the background and image 702 as a stronger image at the front, because its opacity value is essentially high (67%).

[0080] During the temporally following image frame, there is a second image frame 708 of the second scene on the base layer, the frame 708 being thus correspondingly provided with depth positioning determining it as a background image, and its opacity value is set to the maximum. Enhancement layer 1 further comprises the last image frame 704 of a temporally simultaneously terminating (first) scene, the opacity value of the frame being set at 33% and, in addition, the image frame 704 being provided with depth positioning that determines it as a foreground image as well. Consequently, for this time instant, an image combined of the image frames 708 and 704 is coded into the video sequence, the image 708 being displayed as a stronger image on the background and the image 704 as a weaker image on the foreground, because the opacity value of the image 704 is no longer more than 33%.

[0081] During the temporally following image frame, the base layer comprises a third image frame 710 of the second scene. Since the first scene has terminated, only the image frame 710 is coded into the video sequence, and the displaying of the second scene continues from the frame 710.

[0082] The above disclosure describes, by way of example, the positioning of image frames according to the invention on scalability layers to implement cross-faded scene transition in a manner that is advantageous from the point of view of coding efficiency. However, it is possible that when a video sequence is being transmitted or decoded, a situation arises in which the bit rate of the video sequence must be adjusted according to the maximum value of the bandwidth and/or terminal device decoding rate available for data transfer. This kind of bit rate control causes problems when the scene transition is to be implemented using prior art video coding methods.

[0083] A preferred embodiment of the present invention now allows one or more scalability layers, or independently decodable sub-sequences included in them, to be removed from a video sequence, whereby the bit rate of the video sequence can be decreased and yet, at the same time, the video sequence can be decoded without reducing image frequency. In the image frame positioning according to Figure 7, this can be implemented by removing enhancement layer 1 from the video sequence. The video sequence is thus only used for displaying the image frames 700, 706, 708 and 710 of the base layer. In other words, a direct transition from the first (terminating) scene to the second (initiating) scene takes place in the form of an abrupt scene transition, i.e. directly from the image frame 700 of the first scene into the I-image frame 706 that initiates the second scene. The transition is thus not a cross-faded scene transition but an abrupt scene transition. Nevertheless, the scene transition can be carried out in an advantageous manner without affecting the quality of the video sequence image, and the viewer usually does not experience an abrupt scene transition carried out instead of a cross-faded scene transition in any way disturbing or faulty. On the contrary, since the prior art implementation does not allow scalability layers to be removed, scene transition would often require image frequency to be reduced, which the viewer would find jerky and disturbing.

[0084] The invention thus provides a preferred means for carrying out multimedia data traffic shaping in a streaming server comprising information about the different sub-sequences of a video sequence: their

average bit rate, location in relation to the entire video sequence, duration and their interdependencies regarding the layers. The streaming server also determines the maximum value of the bandwidth available for the data transfer and/or the decoding rate of the terminal device. On the basis of this information, the streaming server decides how many scalability layers and which sub-sequences are transmitted in the video sequence. Bit rate control can thus be carried out, when necessary, by making first a rough adjustment of the number of the scalability layers, after which finer sub-sequence-specific adjustment can be easily carried out. At its simplest, bit rate control means making sub-sequence-specific decisions on whether a particular sub-sequence will be added to a video sequence or removed from it. In case of removal it is advisable to remove entire sub-sequences from a video sequence, because the removal of separate images may cause errors in other images of the same sub-sequence. For the same reason, all sub-sequences of a lower enhancement layer should be left out if they are dependent on the removed sub-sequence of a higher layer. If there are interdependent sub-sequences on one and the same scalability layer, sub-sequences dependent on an earlier sub-sequence must be removed if the earlier sub-sequence is removed.

[0085] If the image frame identifier data are added to a video sequence that is to be transmitted, traffic shaping can also be carried out in a telecommunications network element to be used for the transfer of the video sequence, for example in an Internet router, in different gateways, or at a base station or base station controller of a mobile communications network. For the network element to be able to maintain and process the sub-sequence information, it must have extra memory and processing capacity. For this reason traffic shaping that is to be carried out in the network is perhaps most probably executed using simple processing methods, such as the DiffServ, i.e. differentiated services, procedure that is supported by some IP-based networks. In the DiffServ method, each IP data packet is assigned a priority, whereby data packets of a higher priority are relayed faster and more reliably to the recipient than packets of a lower priority. This is advantageously applied to the scalability of the invention by determining not only scalability-layer-specific, but also sub-sequence-specific priorities, which enables a highly advanced priorisation.

[0086] There are many alternatives for adding image frame identifier data to a video sequence that is to be transmitted. In addition, it is also

possible not to include any identifier data into the video sequence, in which case traffic shaping is only carried out at the streaming server. The identifier data can be included in the header fields of a video sequence, or in the header fields of the transfer protocol to be used, such as RTP (Real Time Protocol). According to a preferred embodiment, the identifier data can be transferred using a Supplemental Enhancement Information (SEI) mechanism. SEI provides a data delivery mechanism that is transferred synchronously with the video data content, thus assisting in the decoding and displaying of the video sequence. The SEI mechanism, particularly when used for transferring layer and sub-sequence information, is disclosed more in detail in the ITU-T standard document ITU-T Rec. H.264 (ISO/IEC 14496 – 10:2002), Annex D. In the cases, wherein a separate transfer protocol or mechanism is used for identifier data transfer, traffic shaping can be carried out also at one of the network elements of the transfer path. In addition, the receiving terminal device can control the decoding.

[0087] If the encoder or decoder supports reference picture selection, video sequence coding requires that decoded image frames be buffered before the coding so as to allow the relationships between different image frames to be temporally predicted from one or more other image frames. Image frame buffering can be arranged at least in two different ways, either as sliding windowing or as adaptive buffer memory control. In sliding windowing, M image frames that were coded last are used as a buffer. The frames in the buffer memory are in a decoded and reconstructed form, which allows them to be used as reference images in the coding. As the coding proceeds, the image frame buffering functions on the basis of the FIFO principle (First-In-First-Out). Images that are not used as reference images, such as conventional B-images, do not need to be stored in the buffer. Alternatively, the buffering can be also be implemented as adaptive buffer memory control, in which case the image buffering is not restricted to the FIFO principle, but image frames that are not needed can be removed from the buffer in the middle of the process, or, correspondingly, some image frames can be stored in the buffer for a longer period of time, if they are needed as reference images for later image frames. A known reference picture selection is implemented by indexing image frames that are in the buffer memory into a specific order, the image indices being then used to refer to an image in connection with motion-compensation, for example. This indexing method generally provides better compression

efficiency compared to using image numbers, for example, for referring to a specific image when motion-compensation reference images are to be signalled.

[0088] The above reference image indexing method is sensitive to transfer errors, because the buffers of the sender's encoder and the recipient's decoder must contain mutually corresponding reconstructed images in identical order to ensure that the encoder and decoder both form the same indexing order. If the image frames are indexed in different order in the buffers of the encoder and the decoder, an incorrect reference image may be used in the decoder. To prevent this, it is essential that the decoder can be controlled to take into account image frames and sub-sequences that the encoder has intentionally removed from the video sequence. In that case the image frame numbering may comprise gaps, which the decoder typically interprets as errors and tries to reconstruct the image frames interpreted as lost. For this reason, it is essential that the encoder is capable to inform the decoder that the discontinuities in the image numbering of the transmitted image frames are intentional.

[0089] In response to this, and provided that sliding windowing is used for buffering the image frames, the decoder enters into the buffer memory a number of image frames, the contents of which may be fully random, corresponding to the missing image numbers. These random image frames are then designated by an identifier "invalid" to indicate that the frames in question do not belong to the actual video sequence, but are only filler frames entered for purposes of buffer memory management. A filler frame can naturally be implemented using only memory indicators, i.e. no data is preferably entered into the buffer memory, but memory management is used merely to store a reference to a generic "invalid" frame. The entering of the image frames of the actual video sequence continues from the correct image frame number after the number of filler frames indicated by the missing image numbers has been entered into the buffer, which allows the buffer memories of the encoder and the decoder to be kept preferably in synchronism. If during decoding a reference to an image number is detected which is then found to indicate a filler frame located in the buffer, error correction actions are initiated in the decoder to reconstruct the actual reference image, for example by asking the encoder to re-transmit the reference image in question.

[0090] Further, the procedure of the invention allows separate buffer memories to be used on the different scalability layers, or, correspondingly, sub-sequence-specifically. Each scalability layer may thus have a separate buffer memory that is conceptually separate and functions on the basis of the sliding window principle. Similarly, each sub-sequence may also be provided with a conceptually separate buffer memory that also functions on the basis of the sliding window principle. This means that the buffer memory is always emptied when a sub-sequence terminates. Separate buffer memories can be used in a preferred manner for reducing the need for signalling in certain situations in which ordinary sliding window buffering would be inadequate and actively adaptive buffer memory management would need to be used instead.

[0091] The H.26L standard defines a picture order count as a picture position in output order. The decoding process specified in the H.26L standard uses picture order counts to determine default index orderings for reference pictures in B slices, to represent picture order differences between frames and fields for vector scaling in motion vector prediction and for implicit mode weighted prediction in B slices, and to determine when successive slices in decoding order belong to different pictures. The picture order count is coded and transmitted for each picture.

[0092] In one embodiment of the invention, the decoder uses the picture order count to conclude that pictures are temporally overlapping, i.e., pictures that have an equal picture order count are temporally overlapping. Preferably, the decoder outputs only the picture on the highest received layer. In the absence of layer information, the decoder concludes that the latest temporally overlapping picture in decoding order resides on highest received layer.

[0093] The above disclosure describes a procedure for coding video frames for the purpose of producing a scalable, compressed video sequence. The actual procedure is carried out in a video encoder, such as the compressor 108 of Figure 1, which may be any known video encoder. For example a video encoder according to the ITU-T recommendation H.263 or H.26L may be used, the video encoder being arranged to form, in accordance with the invention, a first sub-sequence into a video sequence, at least part of the sub-sequence being formed by coding I-frames; to form at least a second sub-sequence into the video sequence, at least part of the sub-sequence being formed by coding at least P- or B-frames, and at least one video frame of

the second sub-sequence being predicted from at least one video frame of the first sub-sequence; and to determine into the video sequence the identification data of at least the video frames of the second sub-sequence.

[0094] According to the procedure of the invention, each sub-sequence of a particular scalability layer is preferably independently decodable, naturally taking into account dependencies from higher scalability layers and possibly other sub-sequences of the same scalability layer. A scalably compressed video sequence such as the one described above can thus be decoded by decoding a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding at least I-frames, and by decoding at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames, and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence, and by determining the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence, and by reconstructing at least part of the video sequence on the basis of the sub-sequence dependencies.

[0095] The actual decoding takes places in the video decoder, such as the decompressor 118 of Figure 1, which may be any known video decoder. For example, a low bit rate video decoder according to the ITU-T recommendation H.263 or H.26L may be used, which in this invention is arranged to decode a first sub-sequence of a video sequence, at least part of the sub-sequence having been formed by coding I-frames; to decode at least a second sub-sequence of the video sequence, at least part of the second sub-sequence having been formed by coding at least P- or B-frames and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence. The video decoder is arranged to determine the identification and dependency data of at least the video frames comprised by the second sub-sequence of the video sequence and to reconstruct at least part of the video sequence on the basis of the dependencies of the sub-sequences.

[0096] An essential aspect in the operation of the streaming system of the invention is that the encoder and decoder are positioned at least so that the encoder is operationally connected to the streaming server and the decoder is operationally connected to the receiving terminal device. However,

the different elements of the streaming system, terminal devices in particular, may include functionalities that allow two-way transfer of multimedia files, i.e. transmission and reception. The encoder and decoder can thus be implemented in the form of what it known as a video codec integrating both encoder and decoder functionalities.

[0097] It is to be noted that according to the invention the functional elements of the above described streaming system and its elements, such as the streaming server, video encoder, video decoder and terminal are preferably implemented by means of software, by hardware solutions, or as a combination of the two. The coding and decoding methods of the invention are particularly suitable for implementation as computer software comprising computer-readable commands for executing the process steps of the invention. A preferred way of implementing the encoder and the decoder is to store them in a storage means as a program code that can be executed by a computer-like device, for example a personal computer (PC) or a mobile station, to provide coding/decoding functionalities on the device in question.

[0098] Another alternative is to implement the invention as a video signal comprising a scalably compressed video sequence which in turn comprises video frames coded according to at least a first and a second frame format, the video frames according to the first frame format being independent of other video frames, and the video frames of the second frame format being predicted from at least one of the other video frames. According to the invention, the video signal in question comprises at least a first sub-sequence, at least part of which has been formed by coding at least video frames of the first frame format; at least a second sub-sequence, at least part of which has been formed by coding at least video frames of the second frame format; and at least one video frame of the second sub-sequence having been predicted from at least one video frame of the first sub-sequence; and at least one data field that determines video frames belonging to the second sub-sequence.

[0099] It is apparent to a person skilled in the art that as technology advances the basic idea of the invention can be implemented in various ways. The invention and its embodiments are therefore not restricted to the above examples, but they may vary within the scope of the claims.

CLAIMS

1. A method for decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding, the method comprising:

decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames;

configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and

using the image frames in the buffer memory in the decoding process.

2. A method according to claim 1, wherein said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional.

3. A method according to claim 1, further comprising

using the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

4. A method according to claim 1, wherein the number of image frames in the buffer memory are used in sliding window buffering of image frames.

5. A method according to claim 1, further comprising

continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames.

6. A method according to claim 1, further comprising

entering into the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames.

7. A method according to claim 6, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the actual video sequence.

8. A method according to claim 1, wherein

the step of configuring the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image frames is carried out by memory indications, whereby no data is entered into the buffer memory.

9. A method according to claim 3, further comprising

detecting an error in the compressed video sequence on the basis of a reference in the decoding process to an image frame corresponding to a discontinuity in the numbering of image frames.

10. A video decoder for decoding a compressed video sequence, the video decoder being connected to a buffer memory wherein image frames are entered in connection with the decoding, the video decoder being arranged to

decode from the video sequence an indication related to at least one discontinuity of numbering of the image frames;

configure, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and

use the image frames in the buffer memory in the decoding process.

11. A video decoder according to claim 10, wherein

said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

12. A video decoder according to claim 10, wherein the video decoder is further arranged to

use the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

13. A video decoder according to claim 10, wherein

the number of image frames in the buffer memory are used in sliding window buffering of image frames.

14. A video decoder according to claim 10, wherein the video decoder is further arranged to

continue the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of

image frames corresponding to the discontinuities in the numbering of the image frames.

15. A video decoder according to claim 10, wherein the video decoder is further arranged to

enter into the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames.

16. A video decoder according to claim 15, wherein

said filler frames are designated by an identifier indicating that the filler frames do not belong to the actual video sequence.

17. A video decoder according to claim 10, wherein the video decoder is further arranged to

configure the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

18. A computer program product, stored on a computer readable medium and executable in a data processing device, for decoding a compressed video sequence, image frames of said video sequence being entered into a buffer memory in connection with the decoding, the computer program product comprising:

a computer program code for decoding from the video sequence an indication related to at least one discontinuity of numbering of the image frames;

a computer program code for configuring, in response to the indication, the buffer memory to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames; and

a computer program code for including the image frames in the buffer memory in the decoding process.

19. A computer program product according to claim 18, wherein

said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

20. A computer program product according to claim 18, the computer program product further comprising:

a computer program code for including the number of image frames in the buffer memory in place of image frames that do not exist at a decoder due to the discontinuities in the numbering of the image frames.

21. A computer program product according to claim 18, the computer program product further comprising

a computer program code for using the number of image frames in the buffer memory in sliding window buffering of image frames.

22. A computer program product according to claim 18, the computer program product further comprising

a computer program code for continuing the entering of the image frames comprised by the video sequence in question into the buffer memory from the correct image frame number after the buffer memory has been configured to provide the number of image frames corresponding to the discontinuities in the numbering of the image frames.

23. A computer program product according to claim 18, the computer program product further comprising:

a computer program code for entering into the buffer memory a number of filler frames corresponding to the discontinuities in the numbering of the image frames.

24. A computer program product according to claim 23, the computer program product further comprising:

a computer program code for designating said filler frames by an identifier indicating that the filler frames do not belong to the actual video sequence.

25. A computer program product according to claim 18, the computer program product further comprising:

a computer program code for configuring the buffer memory to provide a number of image frames corresponding to the discontinuities in the numbering of the image frames by memory indications, whereby no data is entered into the buffer memory.

26. A video encoder for encoding a video sequence, the video encoder being arranged to

encode the video sequence such that at least one image frame is excluded from the video sequence, causing a discontinuity in the numbering of image frames, and

encode into the video sequence an indication related to the discontinuity of numbering of the image frames.

27. A video encoder according to claim 26, wherein

said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

28. A device for adjusting bit rate of a video sequence, the device being arranged to

receive an encoded video sequence;

exclude at least one image frame from the video sequence, thereby causing a discontinuity in the numbering of image frames; and

include into the video sequence an indication related to the discontinuity of numbering of the image frames.

29. A device according to claim 28, wherein

said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

30. A video signal comprising a compressed video sequence comprising image frames; and

an indication related to the discontinuity of numbering of the image frames in the transmitted video signal,

wherein the indication informs a decoder to use in a decoding process a number of image frames corresponding to the discontinuity in the numbering of the image frames.

31. A video signal according to claim 30, wherein

said indication informs that discontinuities in the numbering of the image frames in the video sequence are intentional.

ABSTRACT

A method of decoding a compressed video sequence, wherein image frames are entered into a buffer memory in connection with the decoding. The video sequence includes an indication relating to at least one discontinuity in the numbering of the image frames, which indication is decoded from the video sequence. Then, in response to the indication, the buffer memory is configured to provide a number of image frames corresponding to a discontinuity in the numbering of the image frames, and the image frames provided by the buffer memory are used in the decoding process. Preferably, said indication informs that at least one discontinuity in the numbering of the image frames in the video sequence are intentional, and the number of image frames provided by the buffer memory are used in place of image frames that do not exist at a decoder.

CRAWFORD MAUNU PLLC

United States Patent Application

COMBINED DECLARATION AND POWER OF ATTORNEY

As a below named inventor I hereby declare that: my residence, post office address and citizenship are as stated below next to my name; that

I verily believe I am the original; first and sole inventor (if only one name is listed below) or a joint inventor (if plural inventors are named below) of the subject matter which is claimed and for which a patent is sought on the invention entitled: **GROUPING OF IMAGE FRAMES IN VIDEO CODING.**

The specification of which

a. ☐ is attached hereto

b. ☒ is entitled **GROUPING OF IMAGE FRAMES IN VIDEO CODING,** having attorney docket number {KOLS.021PA (NC 35273US)}.

c. ☒ was filed on November 29, 2002 as application serial no. 10/306,942 and was amended on (if applicable) (in the case of a PCT-filed application) described and claimed in international no. filed and as amended on (if any), which I have reviewed and for which I solicit a United States patent.

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with Title 37, Code of Federal Regulations, § 1.56 (attached hereto).

I hereby claim foreign priority benefits under Title 35, United States Code, § 119/365 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on the basis of which priority is claimed:

a. ☐ no such applications have been filed.

b. ☒ such applications have been filed as follows:

§ 1.56 Duty to disclose information material to patentability.

(a) A patent by its very nature is affected with a public interest. The public interest is best served, and the most effective patent examination occurs when, at the time an application is being examined, the Office is aware of and evaluates the teachings of all information material to patentability. Each individual associated with the filing and prosecution of a patent application has a duty of candor and good faith in dealing with the Office, which includes a duty to disclose to the Office all information known to that individual to be material to patentability as defined in this section. The duty to disclose information exists with respect to each pending claim until the claim is canceled or withdrawn from consideration, or the application becomes abandoned. Information material to the patentability of a claim that is canceled or withdrawn from consideration need not be submitted if the information is not material to the patentability of any claim remaining under consideration in the application. There is no duty to submit information which is not material to the patentability of any existing claim. The duty to disclose all information known to be material to patentability is deemed to be satisfied if all information known to be material to patentability of any claim issued in a patent was cited by the Office or submitted to the Office in the manner prescribed by §§ 1.97(b)-(d) and 1.98. However, no patent will be granted on an application in connection with which fraud on the Office was practiced or attempted or the duty of disclosure was violated through bad faith or intentional misconduct. The Office encourages applicants to carefully examine:

(1) prior art cited in search reports of a foreign patent office in a counterpart application, and

(2) the closest information over which individuals associated with the filing or prosecution of a patent application believe any pending claim patentably defines, to make sure that any material information contained therein is disclosed to the Office.

(b) Under this section, information is material to patentability when it is not cumulative to information already of record or being made of record in the application, and

(1) It establishes, by itself or in combination with other information, a prima facie case of unpatentability of a claim; or

(2) It refutes, or is inconsistent with, a position the applicant takes in:

(i) Opposing an argument of unpatentability relied on by the Office, or

(ii) Asserting an argument of patentability.

- A prima facie case of unpatentability is established when the information compels a conclusion that a claim is unpatentable under the preponderance of evidence, burden-of-proof standard, giving each term in the claim its broadest reasonable construction consistent with the specification, and before any consideration is given to evidence which may be submitted in an attempt to establish a contrary conclusion of patentability.

(c) Individuals associated with the filing or prosecution of a patent application within the meaning of this section are:

(1) Each inventor named in the application:

(2) Each attorney or agent who prepares or prosecutes the application; and

(3) Every other person who is substantively involved in the preparation or prosecution of the application and who is associated with the inventor, with the assignee or with anyone to whom there is an obligation to assign the application.

(d) Individuals other than the attorney, agent or inventor may comply with this section by disclosing information to the attorney, agent, or inventor.

INFORMATION DISCLOSURE STATEMENT (37 C.F.R. §1.97(b))

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

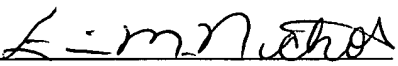
Dear Sir:

With regard to the above-identified application, the items of information listed on the enclosed Form 1449 are brought to the attention of the Examiner.

This statement should be considered because it is submitted either within three months of the filing date or before the first Office Action of the above-identified application. Accordingly, no fee is due for consideration of the items listed on the enclosed Form 1449.

In accordance with 37 C.F.R. §1.98(a)(2), and the 5 August 2003 Official Gazette Notice, only a copy of each foreign document or other non-patent published document listed on the enclosed Form 1449 is provided.

Please note that any notations or markings on the attached documents do not reflect particular relevance, or lack thereof, to the present application, nor were they necessarily made by anyone affiliated with the prosecution of the present application.



No representation is made that a reference is "prior art" within the meaning of 35 U.S.C. §§102 and 103 and Applicant reserves the right, pursuant to 37 C.F.R. §1.131 or otherwise, to establish that the reference(s) are not "prior art." Moreover, Applicant does not represent that a reference has been thoroughly reviewed or that any relevance of any portion of a reference is intended.

Consideration of the items listed is respectfully requested. Pursuant to the provisions of MPEP §609, it is requested that the Examiner return a copy of the attached Form 1449, marked as being considered and initialed by the Examiner, to the undersigned with the next official communication.

Respectfully submitted,

HOLLINGSWORTH & FUNK, LLC

(54) Title: DATA TRANSMISSION
(54) Titre: TRANSMISSION DE DONNEES

(57) Abstract

A data transmission system (10) is provided for transmitting a data signal between a server (12, 14, 16, 18) and a communications terminal (20, 22) over a transmission link having a variable bandwidth. The data signal is a scalable compressed multimedia clip comprising a sequence of images. Each image has a base layer and a number of enhancement layers. To cope with variability in the bandwidth, the sequence is re-ordered so that the base layers have greater safety times than the enhancement layers. This allows all of the base layers to arrive in time to be played at the expense of the enhancement layers.

(57) Abrégé

L'invention concerne un système de transmission de données (10) qui assure la transmission d'un signal de données entre un serveur (12, 14, 16, 18) et un terminal de communication (20, 22) sur une liaison à largeur de bande variable. Le signal de données est un signal écrêté multimédia comprimé variable comprenant une séquence d'images. Chaque image comporte une couche de base et un certain nombre de couches d'accentuation. Pour tenir compte de la variabilité de la largeur de bande, on réordonne la séquence pour que la couche de base dispose de temps de sécurité accrus par rapport aux couches d'accentuation. Cela permet aux couches de base de se présenter à temps pour être sollicitées aux dépens des couches d'accentuation.

Description

DATA TRANSMISSION

This invention relates to data transmission and is particularly, but not exclusively, related to transmission of data representative of picture sequences, such as video. It is particularly suited to transmission over links susceptible to errors and loss of data.

During the past few years, the amount of multimedia content available through the Internet has increased considerably. Since data delivery rates to mobile terminals are becoming high enough to enable such terminals to be able to retrieve multimedia content, it is becoming desirable to enable mobile terminals to retrieve video and other multimedia content from the Internet. An example of a high-speed data delivery system is the upcoming GSM phase 2+.

The term multimedia as used herein applies to both sound and pictures, to sound only and to pictures only. Sound may include speech and music.

Network traffic through the Internet is based on a transport protocol called the Internet Protocol (IP). IP is concerned with transporting data packets from one location to another. It facilitates the routing of packets through intermediate gateways, that is, it allows data to be sent to machines that are not directly connected in the same physical network. The unit of data transported by the IP layer is called an IP datagram. The delivery service offered by IP is connectionless, that is IP datagrams are routed around the Internet independently of each other. Since no resources are permanently committed within the gateways to any particular connection, the gateways may occasionally have to discard datagrams because of lack of buffer space or other resources. Thus, the delivery service offered by IP is a best effort service rather than a guaranteed service.

Internet multimedia is typically streamed over the User Datagram Protocol (UDP), the Transmission Control Protocol (TCP) or the Hypertext Transfer Protocol (HTTP).

UDP is a connectionless lightweight transport protocol. It offers very little above the service offered by IP. Its most important function is to deliver datagrams between specific transport endpoints. Consequently, the transmitting application has to take care of how to packetize data to datagrams. Headers used in UDP contain a checksum that allows the UDP layer at the receiving end to check the validity of the data. Otherwise, degradation of IP datagrams will in turn affect UDP datagrams. UDP does not check that the datagrams have been received, does not retransmit missing datagrams, nor does it guarantee that the datagrams are received in the same order as they were transmitted.

UDP introduces a relatively stable throughput having a small delay since there are no retransmissions. Therefore it is used in retrieval applications to deal with the effect of network congestion and to reduce delay (and jitter) at the receiving end. However, the client must be able to recover from packet losses and possibly conceal lost content. Even with reconstruction and concealment, the quality of a reconstructed clip suffers somewhat. On the other hand, playback of the clip is likely to happen in real-time without annoying pauses. Firewalls, whether in a company or elsewhere, may forbid the usage of UDP because it is connectionless.

TCP is a connection-orientated transport protocol and the application using it can transmit or receive a series of bytes with no apparent boundaries as in UDP. The TCP layer divides the byte stream into packets, sends the packets over an IP network and ensures that the packets are error-free and received in their correct order. The basic idea of how TCP works is as follows. Each time TCP sends a packet of data, it starts a timer. When the receiving end gets the packet, it immediately sends an acknowledgement back to the sender. When the sender receives the acknowledgement, it knows all is well, and cancels the timer. However, if the IP layer loses the outgoing segment or the return acknowledgement, the timer at the sending end will expire. At this point, the sender will retransmit the segment. Now, if the sender waited for an acknowledgement for each packet before sending the next one, the overall

transmission time would be relatively long and dependent on the round-trip delay between the sender and the receiver. To overcome this problem, TCP uses a sliding window protocol that allows several unacknowledged packets to be present in the network. In this protocol, an acknowledgement packet contains a field filled with the number of bytes the client is willing to accept (beyond the ones that are currently acknowledged). This window size field indicates the amount of buffer space available at the client for storage of incoming data. The sender may transmit data within the limit indicated by the latest received window size field. The sliding window protocol means that TCP effectively has a slow start mechanism. At the beginning of a connection, the very first packet has to be acknowledged before the sender can send the next one. Typically, the client then increases the window size exponentially. However, if there is congestion in the network, the window size is decreased (in order to avoid congestion and to avoid receive buffer overflow). The details how the window size is changed depend on the particular TCP implementation in use.

A multimedia content creation and retrieval system is shown in Figure 1. The system has one or more media sources, for example a camera and a microphone. Alternatively, multimedia content can also be synthetically created without a natural media source, for example animated computer graphics and digitally generated music. In order to compose a multimedia clip consisting of different media types, such as video, audio, text, images, graphics and animation, raw data captured from the sources are edited by an editor. Typically the storage space taken up by raw (uncompressed) multimedia data is huge. It can be megabytes for a video sequence which can include a mixture of different media, for example animation. In order to provide an attractive multimedia retrieval service over low bit rate channels, for example 28.8 kbps and 56 kbps, multimedia clips are compressed in the editing phase. This typically occurs off-line. The clips are then handed to a multimedia server. Typically, a number of clients can access the server over one or more networks. The server is able to respond to the requests presented by the clients. The main task of the server is to transmit a desired multimedia clip to the client which the client decompresses and plays. During

playback, the client utilizes one or more output devices, such as a screen and a loudspeaker. In some circumstances, clients are able to start playback while data are still being downloaded.

It is convenient to deliver a clip by using a single channel which provides a similar quality of service for the entire clip. Alternatively different channels can be used to deliver different parts of a clip, for example sound on one channel and pictures on another. Different channels may provide different qualities of service. In this context, quality of service includes bit rate, loss or bit error rate and transmission delay variation.

In order to ensure multimedia content of a sufficient quality is delivered, it is provided over a reliable network connection, such as TCP, which ensures that received data are error-free and in the correct order. Lost or corrupted protocol data units are retransmitted. Consequently, the channel throughput can vary significantly. This can even cause pauses in the playback of a multimedia stream whilst lost or corrupted data are retransmitted. Pauses in multimedia playback are annoying.

Sometimes retransmission of lost data is not handled by the transport protocol but rather by some higher-level protocol. Such a protocol can select the most vital lost parts of a multimedia stream and request the retransmission of those. The most vital parts can be used for prediction of other parts of the stream, for example.

In order to understand the invention better, descriptions of the elements of the retrieval system, namely the editor, the server and the client, are set out below.

A typical sequence of operations carried out by the multimedia clip editor is shown in Figure 2. Raw data are captured from one or more data sources. Capturing is done using hardware, device drivers dedicated to the hardware and a capturing application which controls the device drivers to use the hardware. Capturing hardware may consist of a video camera connected to a PC video grabber card,

for example. The output of the capturing phase is usually either uncompressed data or slightly compressed data with irrelevant quality degradations when compared to uncompressed data. For example, the output of a video grabber card could be in an uncompressed YUV 4:2:0 format or in a motion-JPEG format. The YUV colour model and the possible sub-sampling schemes are defined in Recommendation ITU-R BT.601-5 "Studio Encoding Parameters of Digital Television for Standard 4:3 and Wide-Screen 16:9 Aspect Ratios". Relevant digital picture formats such as CIF, QCIF and SQCIF are defined in Recommendation ITU-T H.261 "Video Codec for Audiovisual Services at p x 64 kbits" (section 3.1 "Source Formats").

During editing separate media tracks are tied together in a single timeline. It is also possible to edit the media tracks in various ways, for example to reduce the video frame rate. Each media track may be compressed. For example, the uncompressed YUV 4:2:0 video track could be compressed using ITU-T recommendation H.263 for low bit rate video coding. If the compressed media tracks are multiplexed, they are interleaved so that they form a single bitstream. This clip is then handed to the multimedia server. Multiplexing is not essential to provide a bitstream. For example, different media components such as sounds and images may be identified with packet header information in the transport layer. Different UDP port numbers can be used for different media components.

A typical sequence of operations carried out by the multimedia server is shown in Figure 3. Typically multimedia servers have two modes of operation; they deliver either pre-stored multimedia clips or a live (real-time) multimedia stream. In the first mode, clips are stored in a server database, which is then accessed on-demand by the server. In the second mode, multimedia clips are handed to the server as a continuous media stream that is immediately transmitted to clients. Clients control the operation of the server by an appropriate control protocol being at least able to select a desired media clip. In addition, servers may support more advanced controls. For example, clients may be able to stop the transmission of a clip, to pause and resume transmission of a clip, and to control the media flow in

case of a varying throughput of the transmission channel in which case the server must dynamically adjust the bitstream to fit into the available bandwidth.

A typical sequence of operations carried out by the multimedia retrieval client is shown in Figure 4. The client gets a compressed and multiplexed media clip from a multimedia server. The client demultiplexes the clip in order to obtain separate media tracks. These media tracks are then decompressed to provide reconstructed media tracks which are played out with output devices. In addition to these operations, a controller unit is provided to interface with end-users, that is to control playback according to end-user input and to handle client-server control traffic. It should be noted that the demultiplexing-decompression-playback chain can be done on a first part of the clip while still downloading a subsequent part of the clip. This is commonly referred to as streaming. An alternative to streaming is to download the whole clip to the client and then demultiplex it, decompress it and play it.

A typical approach to the problem of varying throughput of a channel is to buffer media data in the client before starting the playback and/or to adjust the transmitted bit rate in real-time according to channel throughput statistics.

One way of tackling the problem of pauses is by using dynamic bit rate adjustment in the multimedia server. However, the server may not react to network congestion sufficiently quickly to avoid pausing in the client. In addition, the server cannot control the retransmission mechanism of TCP (or other underlying protocols, such as IP).

Even if dynamic bit rate adjustment is used, the client has to do some initial buffering in any case to avoid delivery delays caused by re-transmission. If a constant channel bit rate is assumed, one can calculate the point in time at which a data unit is supposed to have been completely received. In addition, one can calculate the point in time by which a data unit is supposed to have been played. The time difference between these two points in time is referred to as the safety

time. Another way of defining the safety time is to state that it is the maximum time between two consecutively received data units which does not cause pausing in the playback.

When calculating the safety times for a clip, each data unit has to be considered separately. The calculations assume that no throughput drops occur before the data unit that is currently being processed. If the maximum throughput of the channel is equal to the average bit rate of the multimedia clip, the client cannot recover from a drop in the amount of received bits after throughput has dropped. The only way to guarantee some protection against throughput drops is to buffer some data before starting playback. If the channel stops providing data, the client can still play the stream while there are data in a buffer. Thus, the average safety time is approximately equal to the initial buffering time. Since the bit rate of the clip may vary, the safety time also may vary and the minimum safety time is thus equal to or less than the initial buffering delay.

HTTP, the Hypertext Transfer Protocol, is the basis of the World Wide Web (WWW). It is a simple protocol. A client establishes a TCP connection to a server, issues a request, and reads back the server's response. The server denotes the end of its response by closing the connection. The arrangement of protocol layers is typically HTTP on TCP which is on IP.

The most common HTTP request is called GET. The GET request is associated with a universal resource identifier (URI) which uniquely specifies the requested item. The server responds to the GET request by returning the file corresponding to the specified URI. The file returned by the server normally contains pointers (hypertext links) to other files that can reside on other servers. A user can therefore easily follow the links from file to file.

Servers used for Internet multimedia retrieval are either dedicated multimedia servers or normal WWW servers.

Dedicated multimedia servers are typically capable of transmission over HTTP, TCP and UDP protocols. They may be able to readjust the contents of media clips dynamically to meet the available network bandwidth and to avoid network congestion. They may also support fast forward and fast rewind operations as well as live multimedia streaming. They can provide a number of streams simultaneously.

Multimedia servers based on normal WWW servers are also referred to as server-less or HTTP multimedia solutions. The multimedia clips are streamed over HTTP. Since this type of server has no control over the contents of the stream, no flow (bandwidth) control can be applied, and it cannot respond to network congestion. Therefore, sudden pauses in the playback can occur. Consequently there must be a relatively long initial buffering delay in the client before starting the playback to avoid such sudden pauses. Fast-forwarding a multimedia stream from a standard WWW server is not possible. Live multimedia streaming must be implemented using special tricks, such as Java programming.

When a streamed multimedia clip is received, a suitable independent media player application or a browser plug-in can be used to play it. Such multimedia players differ largely from browser to browser. Newer browsers may have some integrated plug-ins for the most popular streaming video players.

There are a number of different data transmission methods available for transmitting data between mobile terminals and their networks. One of the best known methods is GSM (Global System for Mobile communications).

The current GSM data service called Circuit Switched Data (CSD) offers a 9.6 kbps circuit-switched channel. It is intended for GSM to provide a 14.4 kbps data channel having forward error correction (FEC) and status information. High Speed Circuit Switched Data (HSCSD) provides multiple 9.6 kbps or 14.4 kbps time slots for a single user at the same time. There are symmetric and asymmetric connections. In a symmetric connection, the air interface resources are allocated

symmetrically, and provide the same data transmission rate in both directions. In an asymmetric connection, different data rates are supported for up-link and for down-link. However, asymmetric air interface connections are applicable only in non-transparent mode (see below).

Circuit-switched GSM data systems, CSD and HSCSD, offer two basic connection types, namely transparent (T) and non-transparent (NT). These are distinguished by the way they correct transmission errors. In a transparent connection, error correction is done solely by a forward error correction mechanism provided by the radio interface transmission scheme. The connection is considered as a synchronous circuit. The available throughput is constant, and the transmission delay is fixed. The transmitted data are likely to contain bit inversion errors. In a non-transparent connection, the GSM circuit connection is regarded as a packet (or frame) data flow although the end-to-end service is circuit-switched. Each frame includes redundancy bits to enable a receiver to detect remaining errors. There are two sources of error, packet drops and corruption due to interference in the radio frequency path. The latter can be recovered by redundancy checking. The Radio Link Protocol (RLP) is used to provide retransmission in case of remaining errors in frame. If a frame is found to be correct, the receiver acknowledges this fact. If it is found not to be correct, a negative acknowledgement is sent and the indicated frame is retransmitted. Consequently, a non-transparent connection is error-free but throughput and transmission delay vary.

Other network types exist, for example GPRS (General Packet Radio System). In GPRS the transmissions are truly packet based.

A video sequence consists of a series of still pictures. Video compression methods are based on reducing redundant and perceptually irrelevant parts of video sequences. The redundancy in video sequences can be categorised into spatial, temporal and spectral redundancy. Spatial redundancy means the correlation between neighbouring pixels. Temporal redundancy means that the same objects

appear in consecutive pictures. Reducing the temporal redundancy reduces the amount of data required to represent a particular image sequence and thus compresses the data. This can be achieved by generating motion compensation data, which describe the motion between the current and a previous (reference) picture. In effect, the current picture is predicted from the previous one. Spectral redundancy means the correlation between the different colour components of the same picture.

Simply reducing the redundancy of the sequence does not usually compress it enough. Therefore, some video encoders try to reduce the quality of those parts of a video sequence which are subjectively the least important. In addition, the redundancy of the encoded bitstream is reduced by means of efficient lossless coding of compression parameters and coefficients. The main technique is to use variable length codes.

Video compression methods typically differentiate between pictures that can use temporal redundancy reduction and those that cannot. Compressed pictures, which do not use temporal redundancy reduction methods, are usually called INTRA or I-frames whereas temporally predicted pictures are called INTER or P-frames. In the INTER frame case, the predicted (motion-compensated) picture is rarely precise enough, and therefore a spatially compressed prediction error picture is also associated with each INTER frame.

Temporal scalability provides a mechanism for enhancing perceptual quality by increasing the picture display rate. This is achieved by taking a pair of consecutive reference pictures and bi-directionally predicting a B-picture from either one or both of them. The B-picture can then be played in sequence between the two anchor pictures. This is illustrated in Figure 5. Bi-directional temporal prediction yields a more accurately predicted picture than uni-directional prediction. Thus, for the same quantization level, B-pictures yield increased compression as compared to forwardly predicted P-pictures. B-pictures are not used as reference pictures, that is other pictures are never predicted from them. Since they can be discarded

without impacting the picture quality of future pictures, they provide temporal scalability. It should be noted that while B-pictures provide better compression performance than P-pictures, they are more complex to construct and require more memory. Furthermore they introduce additional delays because bi-directional interpolation requires both reference pictures to have been received and additional calculations are required. In addition, B-pictures require more side information in the bitstream.

The term scalability refers to the capability of a compressed sequence to be decoded at different data rates. In other words, a scalable multimedia clip can be edited relatively easily while it is compressed so that it can be streamed over channels with different bandwidths and still be decoded and played back in real-time.

Scalable multimedia is typically ordered so that there are hierarchical layers of data. A base layer contains a basic representation of the multimedia clip whereas enhancement layers contain refinement data on top of underlying layers. Consequently, the enhancement layers improve the quality of the clip.

Scalability is a desirable property for heterogeneous and error prone environments. This property is desirable in order to counter limitations such as constraints on bit rate, display resolution, network throughput, and decoder complexity.

Scalability can be used to improve error resilience in a transport system where layered coding is combined with transport prioritisation. The term transport prioritisation here refers to various mechanisms to provide different qualities of service in transport, including unequal error protection, to provide different channels having different error/loss rates. Depending on their nature, data are assigned differently, for example, the base layer may be delivered through a channel with high degree of error protection, and the enhancement layers may be transmitted through more error-prone channels.

Generally, scalable multimedia coding suffers from a worse compression efficiency than non-scalable coding. In other words, a multimedia clip coded as a scalable multimedia clip with all enhancement layers requires greater bandwidth than if it had been coded as a non-scalable single-layer clip with equal quality. However, exceptions to this general rule exist, for example the temporally scalable B-frames in video compression.

In the following, scalability is discussed with reference to the ITU-T H.263 video compression standard. H.263 is an ITU-T recommendation for video coding in low bit rate communication which generally means data rates below 64 kbps. The recommendation specifies the bitstream syntax and the decoding of the bitstream. Currently, there are two versions of H.263. Version 1 consists of the core algorithm and four optional coding modes. H.263 version 2 is an extension of version 1 providing twelve new negotiable coding modes.

Pictures are coded as luminance and two colour difference (chrominance) components (Y, C_B and C_R). The chrominance pictures are sampled with a half of the pixels along the both co-ordinate axes when compared to the luminance picture.

The scalability mode (Annex O) of H.263 specifies syntax to support temporal, signal-to noise ratio (SNR), and spatial scalability capabilities.

Spatial scalability and SNR scalability are closely related, the only difference being the increased spatial resolution provided by spatial scalability. An example of SNR scalable pictures is shown in Figure 6. SNR scalability implies the creation of multi-rate bit streams. It allows for the recovery of coding errors, or differences between an original picture and its reconstruction. This is achieved by using a finer quantizer to encode the difference picture in an enhancement layer. This additional information increases the SNR of the overall reproduced picture.

Spatial scalability allows for the creation of multi-resolution bit streams to meet varying display requirements and/or constraints. A spatially scalable structure is illustrated in Figure 7. It is essentially the same as in SNR scalability except that a spatial enhancement layer attempts to recover the coding loss between an up-sampled version of the reconstructed reference layer picture and a higher resolution version of the original picture. For example, if the reference layer has a quarter common intermediate format (QCIF) resolution, and the enhancement layer has a common intermediate format (CIF) resolution, the reference layer picture must be scaled accordingly such that the enhancement layer picture can be predicted from it. The QCIF standard allows the resolution to be increased by a factor of two in the vertical direction only, horizontal direction only, or both the vertical and horizontal directions for a single enhancement layer. There can be multiple enhancement layers, each increasing the picture resolution over that of the previous layer. The interpolation filters used to up-sample the reference layer picture are explicitly defined in the H.263 standard. Aside from the up-sampling process from the reference to the enhancement layer, the processing and syntax of a spatially scaled picture are identical to those of an SNR scaled picture.

In either SNR or spatial scalability, the enhancement layer pictures are referred to as EI- or EP-pictures. If the enhancement layer picture is upwardly predicted from a picture in the reference layer, then the enhancement layer picture is referred to as an Enhancement-I (EI) picture. In this type of scalability, the reference layer means the layer "below" the current enhancement layer. In some cases, when reference layer pictures are poorly predicted, over-coding of static parts of the picture can occur in the enhancement layer, causing an unnecessarily excessive bit rate. To avoid this problem, forward prediction is permitted in the enhancement layer. A picture that can be predicted in the forward direction from a previous enhancement layer picture or, alternatively, upwardly predicted from the reference layer picture is referred to as an Enhancement-P (EP) picture. Note that computing the average of the upwardly and forwardly predicted pictures can provide bi-directional prediction for EP-pictures. For both EI- and EP-pictures, upward prediction from the reference layer picture implies that no motion vectors are

required. In the case of forward prediction for EP-pictures, motion vectors are required.

In multi-point and broadcast multimedia applications, constraints on network throughput may not be foreseen at the time of encoding. Thus, a scalable bitstream should be used. Figure 8 shows an IP multicasting arrangement where each router can strip the bitstream according to its capabilities. It shows a server S providing a bitstream to a number of clients C. The bitstreams are routed to the clients by routers R. In this example, the server is providing a clip which can be scaled to at least three bit rates, 120 kbit/s, 60 kbit/s and 28 kbit/s.

If the client and server are connected via a normal uni-cast connection, the server may try to adjust the bit rate of the transmitted multimedia clip according to the temporary channel throughput. One solution is to use a layered bit stream and to adapt to bandwidth changes by varying the number of transmitted enhancement layers.

According to a first aspect of the invention there is provided a method of transmitting a data signal having a sequence of data units in a predetermined order over a transmission link between a data source and a data sink comprising the step of sending the data units in an order determined by their relative importance rather than their predetermined order.

According to a second aspect of the invention there is provided a data transmission system for transmitting a data signal having a sequence of data units in a predetermined order over a transmission link between a data source and a data sink the data units being sent in an order determined by their relative importance rather than their predetermined order.

According to a third aspect of the invention there is provided a server for transmitting a data signal having a sequence of data units in a predetermined

order over a transmission link the data units being sent in an order determined by their relative importance rather than their predetermined order.

Preferably the server comprises re-ordering means. Preferably the server comprises an editor for providing a scalable data signal.

According to a fourth aspect of the invention there is provided a computer program product stored on a computer usable medium comprising computer readable program means for causing transmission of a data signal having a sequence of data units in a predetermined order over a transmission link the data units being sent in an order determined by their relative importance rather than their predetermined order.

Preferably the computer program product comprises a server. In this sense it is meant that the when the computer program is loaded into hardware it causes the hardware to operate as a server device. Preferably the computer program product comprises an editor for providing a scalable data signal. Preferably the computer program product comprises re-ordering means for re-ordering the data units.

According to a fifth aspect of the invention there is provided a data signal having a sequence of data units for transmission over a transmission link between a data source and a data sink the data units being in an order determined by their relative importance rather than their predetermined order.

Preferably where the data units or layers of the data units are ordered into a sequence other than their original sequence, the invention also includes means or a step for returning the data units or layers of the data units into their original sequence.

The transmission link may simply be a bottleneck where congestion is occurring and the invention is used to overcome the bottleneck.

An advantage of the invention is that it can provide larger safety times than prior art arrangements with the same initial buffering. In addition, it provides some degree of protection against decreased transmission throughput. Therefore it helps in reducing the occurrence of pauses without sacrificing compression efficiency.

The invention also helps in transmitting over a unreliable network connection using transmission protocols which do not automatically retransmit but only retransmit those missing parts chosen by a higher level function, for example in response to feedback. In this case, it provides more time for retransmission of the vital parts of a data signal than prior art arrangements. Thus, vital parts of a stream are more likely to be transmitted successfully and the ultimate end user of the data signal is likely to perceive a better output quality.

Preferably the bandwidth of the transmission link available to the data signal is variable. This may be because the amount of data traffic using the link is variable, for example due to the need to re-transmit lost or corrupted data.

The invention provides a way of altering a data signal so that it can be transmitted over a transmission link having a bandwidth which would otherwise not be sufficient for it or for allowing certain of the bandwidth of its transmission link to be made available for other data, for example control information.

Preferably the effect of the invention is to increase the safety times of some data units relative to, or even at the expense of, the safety times of other data units.

Preferably the data signal is arranged in a hierarchy having a base layer and at least one enhancement layer. The term base layer means a most fundamental layer. The base layer may represent the least refined version of the data signal. In each unit, the (or each) enhancement layer, when combined with the base layer, refines the base layer to make it more like the data unit. Each enhancement layer

may add more refinement to the base layer. Preferably the safety time of the base layer is increased relative to the safety times of the enhancement layers.

Preferably the data signal is scalable. The base layer and the or each enhancement layer may have a scaled relationship with respect to each other. The signal may be scalable in the temporal, the spatial, the spectral or the SNR domains.

Preferably by virtue of re-ordering the sequence the layers have safety times which depend on their position in the hierarchy. For example the base layer of a particular data unit may have a greater safety time than enhancement layers. Advantageously, the finer the level of refinement represented by a layer, the shorter its safety time.

Preferably the source is a server. Alternatively it is an editor.

Preferably the sink is a client. It may be a destination of the data signal such as a mobile terminal, for example a mobile telephone.

Preferably the data units are frames. In one embodiment the data units represent a sequence of pictures. Conveniently it is a video sequence. Most preferably, it comprises multimedia data.

It should be understood that the terms "layer" and "layers" are being used figuratively and refer to blocks of data which can be applied to each other rather than to a strictly positional relationship.

The invention will now be described by way of example only with reference to the accompanying drawings in which:

Figure 1 shows a multimedia content creation and retrieval system;

Figure 2 shows operations of a multimedia clip editor;

Figure 3 shows operations of a multimedia server;

Figure 4 shows operations of a multimedia retrieval client;
Figure 5 shows an illustration of B picture prediction;

Figure 12 shows safety times of a re-ordered sequence and an original sequence;
Figure 13 shows receiving and playback of a re-ordered sequence;
Figure 14 also shows receiving and playback of a re-ordered sequence; and
Figure 15 shows another multimedia content creation and retrieval system.

Figures 1 to 8 have been discussed above.

A mobile multimedia retrieval system 10 according to the invention is shown in Figure 9. Although only a single client 22 is shown it will be appreciated that there can be, and in preferred embodiments will be, a number of such clients. It will also be appreciated that at least part of the transmission link connecting a server 18 and the client 22 will be wireless.

The system 10 comprises an editor 12 which produces a compressed clip, a server database 14 for storing the compressed clip, re-ordering means 16 for re-ordering the sequence of the compressed clip, a server 18 for sending the re-ordered compressed clip and a client comprising order recovery means 20 to recover the original sequence of the compressed clip. The client 22 controls the operation of the server, for example by specifying which data are sent and how they are sent. Clearly, the re-ordering means 16 and the order recovery means 20 need to be compatible so that the latter can recover the original order. The re-ordering means 16 could be located to operate on data before they reach the server database 14 rather than the embodiment shown in Figure 9. Certain types of data, such as a live stream, may by-pass the database 14 and be sent by the

editor 12 directly to the re-ordering means 16. Although they are shown separately in Figure 9, the editor 12, the server database 14, the re-ordering means 16 and the server 18 can all be configured into a single unit or entity which can also be referred to as a server.

Figure 10 shows operation of an editor according to the invention. Raw data captured in the form of one or more uncompressed streams are edited to produce one or more uncompressed tracks. These tracks are compressed in a compression step to produce compressed tracks. The compressed tracks are multiplexed together to produce a compressed multimedia clip. The multimedia clips are coded scalably. The resulting bitstream consists of basic units, such as frames in video compression. These basic units are not all of equal importance; some are primary basic units which are vital to decode the bitstream and some are secondary basic units which improve the quality of the bitstream. Elimination of the secondary basic units causes only a quality loss in the decoded multimedia clip. In effect, the primary basic units are a base layer of the bitstream and the secondary units are enhancement layers.

Instead of organising the basic units into the original transmission order, that is the sequence in which they are produced by editing and compression of raw data, the invented method re-orders their sequence by prioritising the primary basic units so that they pre-empt the secondary basic units in the transmission order. Reordering can take place before or after the multiplexing process depending on the nature of the system and the data. In Figure 10 it is shown as taking place after multiplexing.

A re-ordering algorithm is used to re-order the sequence. In a preferred embodiment, the algorithm conducts stream analysis to identify primary and secondary basic units and to collect bit rate statistics. These may include the number of bits per frame. The bitstream is then re-ordered with iterative re-ordering steps to minimise the initial buffering time needed for full-quality playback with full channel throughput and reduced-quality playback with a reduced channel throughput. An example of such a re-ordering algorithm is given below. It should

be noted that the expected reduced channel throughput has to be estimated in advance since it is one of the input parameters of the algorithm. The estimation can be based on the statistics obtained from the channel behaviour, for example.

Re-ordering of the basic units means that the primary basic units are likely to be received earlier than indicated in their playback time even though some decrease in the channel throughput occurs. However, secondary basic units are vulnerable to transmission delay variations since the method schedules them to be received just before their indicated playback time. In this way the client is still likely to be able to play the primary basic units without pausing the playback, even if the channel throughput decreases considerably. The secondary basic units, on the other hand, may arrive later than their scheduled playback time and will not be used in playback.

Figure 11 shows operation of a client according to the invention. The bitstream is received by the client, re-ordered to produce the original compressed clip, demultiplexed to produce the compressed tracks and then decompressed to reconstruct the tracks. The basic unit order recovery step in the client can be applied either before or after demultiplexing (depending in when it occurs in the content editor). In Figure 11 it is shown as occurring before demultiplexing, to correspond to the order described in Figure 10. In this way re-ordering and order recovery are both applied to the multiplexed bitstream. Order recovery organises the basic units back into their natural sequence for decompression and discards all late-arriving secondary basic units.

On receipt of a basic unit by the client, it is time-stamped with a time by which it should be played. This time-stamp is compared with the current playback time. If the time-stamp is greater than the current playback time the basic unit is not decompressed and it is discarded. If the time-stamp is less than the current playback time the basic unit is decompressed and the two times are compared after decompression. If the time stamp is less than the current playback time the basic unit is played. Otherwise, it is discarded.

In the particular case in which re-ordering is performed after multiplexing, the multiplexing/demultiplexing format used needs to allow re-ordering of the basic units and recovery of the original order.

Figure 15 shows another view of a multimedia content creation and retrieval system according to the invention. The system 50 comprises an editor 52, a server 54 and a client 56.

The editor comprises a compressor 58 for compressing a raw data stream typically being in the form of a sequence of images into a form suitable for transmission, a multiplexer 60 for multiplexing the compressed raw data stream with other compressed data streams together to produce a compressed bitstream and a layer generation means 62 for producing primary basic frames which are vital to decode the bitstream and secondary basic frames which improve the quality of the bitstream.

The server 54 comprises re-ordering means 64 for arranging the frames in an order which depends on their importance in helping to reconstruct the raw data stream at the client 56 rather than their natural sequential order.

The server 54 and the client 56 each comprise transmitting/receiving means 66 and 70 respectively for data transmission over a transmission link 68 between the server 54 and the client 56.

The client 56 comprises order recovery means 72 for putting the frames back into their natural sequential order, a demultiplexer 74 for demultiplexing the bitstream and a decompressor 76 for decompressing the compressed data streams to reproduce the raw data stream. The client comprises playing/output means 78 for playing or otherwise outputting the raw data stream. The client also comprises a controller 80 which applies a control signal to the server 54 to control the re-ordering means in response to receipt of frames in the client 56.

Example

An embodiment of the invention was tested using an H.263 compliant encoder and a frame re-ordering tool. The encoder was capable of producing B-frames. The re-ordering tool comprised a re-ordering algorithm and could be adjusted to produce frame ordering for different decreased channel data rates.

A standard ITU-T test sequence of video frames called Glasgow was used. The sequence had a QCIF resolution, that is a luminance picture size of 176 x 144 pixels and a chrominance picture size of 88 x 72 pixels.

The first 297 frames of the Glasgow sequence were compressed to produce a temporally scalable bitstream comprising INTRA (I) frames, INTER (P) frames and bi-directionally predicted (B) frames. The I and P frames are referred to as primary frames and the B frames are referred to as secondary frames. The frame rate of the original (default) sequence was 12.5 frames per second (fps) and so the compressed sequence corresponded to 23.68 seconds. Each frame was compressed. The first frame was an INTRA frame, and the second one was an INTER frame. After that, there were alternate INTER frames and B-frames. A constant quantizer was used to produce a bitstream having an average bit rate of 41073 bps consisting of an average bit rate for the primary frames of 28984 bps and an average bit rate for the secondary frames of 12089 bps.

For the sake of simplicity, the example does not include multiplexing of the bitstream with another bitstream.

Re-ordering of the frame sequence was optimised separately for bit rates corresponding to sums of the primary frame bit rate (A) and (i) 25%; (ii) 50%; and (iii) 75 % of the secondary frame bit rate (B). It should be noted that 100% of the secondary bit rate (B) corresponds to the average bit rate required in order to obtain full quality playback. The summed bit rates were 32007, 35029 and 38051 bps respectively. For convenience, in the following description, these bit rates are

referred to as 25% (A+0.25B), 50% (A+0.5B) and 75% (A+0.75B), and the corresponding re-ordered sequences are referred to as 25-ordered, 50-ordered and 75-ordered. It was expected that the full rate of the channel would be the average bit rate of the sequence.

The reordering algorithm used two values:
FQFR (full quality full rate), which is the minimum initial buffering time to ensure full-quality playback assuming a full rate channel; and
RQRR (reduced quality reduced rate) which is the minimum initial buffering time to ensure reduced-quality playback in which the primary frames are played and some or all secondary frames may not be played (assuming a reduced secondary bit rate of 25%, 50% or 75%).

In calculating FQFR and RQRR for a particular channel, the algorithm assumes that it has a constant bit rate. Using the bit rate statistics the likely number of bits per frame is calculated. The time instant at which a particular frame is to be played is known from the time stamp. A time is determined by which a frame will be ready for display as a picture (allowing, of course, for the time needed to receive the bits for a frame and to prepare them) and this time is compared with the time stamp of the frame. If the frame will be received after it is to be displayed, the buffering time is increased, if it is received in time then the next frame can be dealt with. Once the algorithm has compared the likely times of receipt of all of the frames against their playback times and adjusted to buffering time accordingly so that they should all be received in time, the minimum buffering time has been calculated.

The algorithm was applied to a sequence having its original order. In this case, FQFR is smaller than RQRR because in order to obtain full quality playback, you have to wait longer in starting playback if you have a reduced rate channel. The algorithm seeks to minimise the initial buffering time needed for full-quality playback with full channel throughput and at the same time for reduced-quality playback with a reduced channel throughput. In other words, the algorithm seeks to find a value where FQFR and RQRR are approximately equal. It should be

noted that the algorithm is not optimal, that is the algorithm does not necessarily re-order the sequence so that the minimum initial buffering delay is found. The algorithm consists of the following steps:

1. Calculate FQFR and RQRR.

2. If FQFR is greater than or equal to RQRR, stop re-ordering. The minimum initial buffering delay is the greater of FQFR or RQRR. Otherwise, continue with the next step.

3. Shift all primary frames towards the beginning of the sequence by one frame step. For example, if the initial sequence is:

I0, P1, P2, B3, P4, B5, P6, B7, P8, B9, P10, ...,

shifting changes the sequence to:

I0, P1, P2, P4, B3, P6, B5, P8, B7, P10, B9, ...

where I0 is the first frame. It can be seen that where a secondary frame is earlier in sequence than an adjacent primary frame, the positions of the primary and secondary frames are exchanged.

4. Continue from step 1.

The buffering time needed to ensure pause-less playback in the reduced bit rate channel is greater for the original sequence than for the re-ordered sequence. It is desirable to have a short initial buffering time. The re-ordering process makes a trade-off between the minimum buffering time needed for a full-rate channel and the minimum buffering time needed for expected reduced-rate channels. Without re-ordering, less initial buffering time would have been needed to provide full-quality playback in the full-rate channel. However, without re-ordering, more initial buffering time would have been required to provide reduced-quality playback in the reduced-rate channel.

In the example, safety times were also investigated. Initial buffering time was set to be the minimum for reduced quality playback of the re-ordered sequence at 25% secondary bit rate. Figure 12 shows how safety time varies with playback of the 25-ordered sequence and the original order sequence. It shows that throughout playback, the 25-ordered sequence (represented by the upper line) has a longer safety time than the original order sequence.

Results were also obtained for the 50% and 75% secondary bit rates. The average safety times (in seconds) for all primary frames in a sequence are shown in the following table for all three reduced bit rates. The safety times are characterised by minimum safety time and average safety time.

		25%	50%	75%
Minimum	Re-ordered	4.79	2.51	1.06
	Default	3.46	1.63	0.64
	Difference	1.33	0.88	0.42
Average	Re-ordered	5.90	3.51	2.12
	Default	4.66	2.83	1.84
	Difference	1.24	0.67	0.28

It can be seen that both the minimum and average safety times of the re-ordered sequences are longer than those of the original sequence.

In contrast, set out below is a table showing the required buffering delays in seconds for full-quality playback at different average bit rates. This is to minimise pauses in playback.

	25%	50%	75%
Re-ordered	10.04	6.03	3.53
Default	7.02	4.64	3.02

It can be seen that the re-ordered sequence needs a longer buffering delay for full-quality playback because the secondary frames are transmitted out of their natural order and time is required to put all the frames back into their natural order. However, this is not important because the invention sets out to provide reduced quality playback with minimal initial buffering delay. To illustrate this, the following

table shows the buffering delays required to ensure pause-less reduced quality playback:

	25%	50%	75%
Re-ordered	5.28	3.49	2.47
Default	6.91	4.46	2.84

These results show that where the bit rate of the transmission channel is reduced, the invented method requires a shorter buffering delay before playback can be started.

The effect of the invention is illustrated in Figure 13 which shows playback of the 25-ordered sequence at 25% bit rate (that is A+0.25B as discussed above). Playback times, that is the times at which the frames are intended or supposed to be played to a viewer, are represented as a straight line. To be played in sequence, without requiring pauses, each frame must be received before its playback time. Any symbol located below the playback time line represents a frame which is received before its scheduled playback time and any symbol located above the playback time line represents a frame which is received after its scheduled playback time. In the example of Figure 13, the primary frames were all received in time to be played and the secondary frames were all received too late. Therefore the secondary frames were all discarded without being played.

It should be understood that if the sequence had not been re-ordered, there is a likelihood that some of the primary frames would have arrived after their playback times and so would have required playback to be paused (since a primary frame cannot be discarded without also discarding all of the frames predicted from it).

Figure 14 shows how the 25-ordered sequence is received and played when the channel throughput is not reduced. It can be seen that all frames are received in time to be played. Again, the upper line represents when secondary frames are received and the lower line represents when primary frames are received.

Of course, the exact appearance of Figures 13 and 14 depends on the nature of the original sequence, as well as the bit rate and the re-ordering that is performed. Differences can be expected in other systems which re-order data in different ways.

In use, the invention can be applied on-line to prepare a bitstream for transmission at some future point. For example, assuming that there may be considerable variation in the available bandwidth of a given transmission channel, the algorithm may be applied to a bitstream and re-ordered sequences may be calculated for several alternative bandwidths, such as 25%, 50% and 75%. In transmission, if problems are encountered, for example with pausing, the re-ordered sequence currently being used may be changed to one better suited to a lower available bandwidth. Equally, if transmission is proceeding better than expected, a sequence better suited for a higher bandwidth may be used. The invention may check the progress of transmission and/or playback a number of times during transmission and adjust the sequence accordingly. It is advantageous if this adjustment can be programmed dynamically whilst transmission is occurring. In this way, intermittent problems can de dealt with.

The part of the invention which re-orders a bitstream is located in an editor or in a server. The part of the invention which recovers the order is located in a client.

A further improvement is provided if the proportion of bits belonging to the primary frames is reduced by replacing some of the primary frames with B-frames. This reduces the compression efficiency slightly because B-frames are predicted from reference frames (P-frames) which are further away in time and so the B-frames and P-frames are less alike. This yields a poorer predicted B-frame and so more bits must be used to code the corresponding prediction error image. Since in this arrangement there are now more bits belonging to secondary frames which can be discarded, re-ordering the frames can provide even better protection against transmission delays and pauses.

One way of looking at the invention is to say that it sacrifices the safety times of the secondary frames in order to maintain maximum safety times for the primary frames.

The invention is particularly suitable for streaming-type multimedia retrieval.

While preferred embodiments of the invention have been shown and described, it will be understood that such embodiments are described by way of example only. For example, although the invention has been described applied to a temporally scalable bitstream, it can also be applied to other types of scalability, including spatial, spectral and SNR. Numerous variations, changes and substitutions will occur to those skilled in the art without departing from the scope of the present invention. Accordingly, it is intended that the following claims cover all such variations as fall within the spirit and scope of the invention.

Claims

Claims

1. A server for transmitting a data signal having a sequence of data units in a predetermined order over a transmission link the data units being sent in an order determined by their relative importance rather than their predetermined order.

2. A server according to claim 1 in which the data units represent a base layer and at least one enhancement layer.

3. A server according to claim 2 comprising re-ordering means to change the order of the data units.

4. A server according to any preceding claim in which the data signal is scalable.

5. A server according to claim 4 in which the signal is scalable in a domain selected from a group consisting of the temporal, the spatial, the spectral and the SNR domains.

6. A server according to any preceding claim which comprises an editor for providing the data signal.

7. A server according to any preceding claim in which the data signal represents a sequence of pictures to produce a moving image.

8. A server according to claim 7 in which the data signal represents a video sequence.

9. A server according to any preceding claim in which the data signal comprises multimedia data.

10. A data transmission system for transmitting a data signal having a sequence of data units in a predetermined order over a transmission link between a data

source and a data sink the data units being sent in an order determined by their relative importance rather than their predetermined order.

11. A transmission system according to claim 10 in which the data units each comprise a base layer and at least one enhancement layer and when re-ordered the base layer of a particular data unit has a greater safety time than of the or each enhancement layer of the particular data unit.

12. A transmission system according to claim 10 or claim 11 in which the source is a server.

13. A transmission system according to any of claims 10 to 12 in which the source is an editor.

14. A transmission system according to any of claims 10 to 13 in which the sink is a client.

15. A transmission system according to any of claims 10 to 14 in which the sink is a mobile terminal.

16. A transmission system according to claims 10 to 15 in which the sink is a mobile telephone.

17. A transmission system according to claims 10 to 16 in which means are provided to check the progress of transmission and to change the order being used to one better suited to available bandwidth.

18. A method of transmitting a data signal having a sequence of data units in a predetermined order over a transmission link between a data source and a data sink comprising the step of sending the data units in an order determined by their relative importance rather than their predetermined order.

19. A method according to claim 18 in which the data units are returned to their original sequence once they have been transmitted over the transmission link.

20. A method according to claim 18 or claim 19 in which the progress of transmission is checked and the order being used is changed to one better suited to available bandwidth.

21. A computer program product stored on a computer usable medium comprising computer readable program means for causing transmission of a data signal having a sequence of data units in a predetermined order over a transmission link the data units being sent in an order determined by their relative importance rather than their predetermined order.

22. A computer program product according to claim 21 comprising a server.

23. A computer program product according to claim 21 or claim 22 comprising an editor for providing a scalable data signal.

24. A computer program product according to any of claims 22 to 23 comprising re-ordering means for providing the layers of the or each data units with different safety times.

25. A data signal having a sequence of data units for transmission over a transmission link between a data source and a data sink the data units being in an order determined by their relative importance rather than their predetermined order.

(54) Title: VIDEO COMPRESSION FOR MULTICAST ENVIRONMENTS USING SPATIAL SCALABILITY AND SIMULCAST CODING

(57) Abstract: An optimal system for determining whether simulcast coding (400) or spatial scalability coding (100) should be used to encode video for clients with a specific communication link. Operating points (A', B', C') for both simulcast coding and spatial scalability are also determined. Adaptive switching (3130, 3140) is provided, with the operating points and decision boundaries being used to guide the switching to optimize the quality of the higher-resolution data based on a bit allocation to the associated lower-resolution data. A system for determining the point (A', C') of equal quality in both layers of simulcast and spatial scalability coding is also disclosed. The proportion of bits allocated to the base layer to achieve equal quality is essentially independent of the total bit rate for both simulcast and spatial scalability.

WO 01/47283 A1

VIDEO COMPRESSION FOR MULTICAST ENVIRONMENTS USING SPATIAL SCALABILITY AND SIMULCAST CODING

BACKGROUND OF THE INVENTION

This application claims the benefit of U.S. Provisional Application No. 60/171,774, filed December 22, 1999.

The present invention relates to digital television and the like, and more particularly to a video coding scheme for multicast applications. The invention is particularly suitable for providing a streaming video server for multicast video over computer networks, such as Internet protocol (IP) networks. A multicast transmission can use simulcast ("Sim.") or spatial scalability ("SS") coding.

Usually, three major factors in a multicast video service need to be considered:

(1) The costs of reaching the audience (from the video-coding point of view);

(2) Quality of Service (e.g. visual quality); and

(3) Encoding complexity vs. decoding complexity.

Some multicast systems have chosen to use simulcast coding (the independent coding of bitstreams to achieve video scalability) exclusively. The simulcast approach does not require additional encoder or decoder complexity and thus satisfies the third factor listed above.

For some application environments, codec complexity may not be an issue and the first two factors are the main concerns. For these services, the selection of the video compression (coding) scheme to be used often follows the rule that for a given total combined allocation of two or more service rates, a coding scheme that can achieve the highest peak signal-to-noise ratio (PSNR) for clients is desired. Also, for a given quality requirement (e.g., PSNR for each bitstream), a coding scheme that can achieve the smallest total bit allocation is desired.

Intuitively, scalable bitstreams (dependently coded bitstreams) are expected to perform better than simulcast coding. This reasoning suggests that a multicast implementation without complexity constraints should only use spatial scalability. However, the present inventors have found that simulcast coding outperforms spatial scalability for certain operating regions. This surprising discovery enables a determination to be made as to which approach to use for a given application and to provide an adaptive switching technique between the two coding approaches.

It would be advantageous to provide an optimal method for selecting between spatial scalability and simulcast coding for multicast video services. Such a method should enable a determination to be made as to whether simulcast coding or spatial scalability should be used to encode video for clients with a specific

communication link. It would be further advantageous if, in addition to guiding decisions for specific cases, the methodology could be used to construct decision regions to guide more general scenarios, or used to adaptively switch between the two approaches. Operating points for both simulcast coding and spatial scalability, in terms of bit allocations among clients, should also be determinable by using such a method.

The present invention provides a system having the aforementioned and other advantages.

SUMMARY OF THE INVENTION

An optimal technique is provided for selecting between spatial scalability and simulcast coding to provide an efficient compression algorithm. In particular, simulcast coding can outperform spatial scalability when a small proportion of bits is allocated to the base layer.

A technique is also provided for determining whether simulcast coding or spatial scalability should be used to encode video for clients with a specific communication link. Operating points for both simulcast coding and spatial scalability are also determined. Adaptive switching between the two approaches is also provided, with the operating regions being used to guide the switching.

The invention also provides a method for determining the point of equal quality in both layers of simulcast coding. The proportion of bits allocated to the base layer to achieve equal quality is independent of the total bit rate for both simulcast and spatial scalability.

Corresponding methods and apparatuses are presented.

FIG. 31 illustrates an adaptive simulcast/spatial scalability encoder apparatus in accordance with the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The present invention provides techniques for selecting between simulcast coding and spatial scalability for multicast services, such as multicast video.

A brief review of general scalable coding (temporal scalability in addition to spatial scalability) is first provided. Simulations have been performed with an MPEG-4 codec to gain insight into the issues involved in transmitting the same video sequence at multiple spatial resolutions. In addition to deciding between simulcast coding and spatial scalability, one issue is the proper allocation of bits to the different layers.

General guidelines are provided and a scenario for achieving equal quality in both layers is examined in detail. The results obtained using quarter common intermediate format (QCIF) and common intermediate format (CIF) resolution sequences may be directly applied to applications such as video transmission in a multicast environment.

While QCIF is used as an example of lower-resolution data, and CIF is used as an example of higher-resolution data, these are examples only, and other suitable data formats can be used.

CIF was developed so that computerized video images can be shared from one computer to another. An

image that is digitized to CIF has a resolution of 352 x 288 or 352 x 240, which is essentially one-half of the resolution of CCIR 601. The CCIR 601 recommendation of the International Radio Consultative Committee for the digitization of color video signals deals with color space conversion from RGB to YCrCb, the digital filters used for limiting the bandwidth, the sample rate (defined as 13.5 MHz), and the horizontal resolution (720 active pixels).

Many applications desire the capability to transmit and receive video at a variety of resolutions and/or qualities. One method to achieve this is with scalable or layered coding, which is the process of encoding video into an independent base layer and one or more dependent enhancement layers. This allows some decoders to decode the base layer to receive basic video and other decoders to decode enhancement layers in addition to the base layer to achieve higher temporal resolution, spatial resolution, and/or video quality.

The general concept of scalability is illustrated in FIG. 1 for a codec with two layers. Note that additional layers can be used. The scalable encoder 100 takes two input sequences and generates two bitstreams for multiplexing at a mux 140. Specifically, the input base video stream or layer is processed at a base layer encoder 110, and upsampled at a midprocessor 120 to provide a reference image for

predictive coding of the input enhanced video stream or layer at an enhancement layer encoder 130.

Note that coding and decoding of the base layer operate exactly as in the non-scalable, single layer case. In addition to the input enhanced video, the enhancement layer encoder uses information about the base layer provided by the midprocessor to efficiently code the enhancement layer. After communication across a channel, which can be, e.g., a computer network such as the Internet, or a broadband communication channel such as a cable television network, the total bitstream is demultiplexed at a demux 150, and the scalable decoder 160 simply inverts the operations of the scalable encoder 100 using a base layer decoder 170, a midprocessor 180, and an enhancement layer decoder 190.

The MPEG-2 standard defines scalable tools for spatial, temporal and quality (SNR) scalability. The main commercial applications that MPEG-2 was targeted to were digital video disks and digital television, applications where the additional functionality of scalability is often not used. Thus, there has been limited commercial interest in MPEG-2 scalable coding in the past. However, new applications such as streaming video could greatly benefit from scalability. One example where scalable coding may be useful is for video transmission in a multicast environment. Clients have a wide range of processing power, memory resources and available bandwidth. This requires a server to

provide different resolutions and/or qualities of video to be able to satisfy the different capabilities of their clients. The recently completed multimedia standard MPEG-4 version 1 offers two types of scalability: temporal and spatial. In addition to applying scalability to frames (pictures) of video, the standard also defines scalability for arbitrary shaped objects.

This document focuses on frame-based scalability, although the concepts of the invention are generally applicable to arbitrarily shaped objects. In addition to temporal and spatial scalability, a third type of scalable coding for quality scalability called Fine Granular Scalability (FGS) is currently being evaluated for inclusion in MPEG-4. A brief review of temporal and spatial scalability in MPEG-4 is presented before discussion of simulcast coding.

Temporal scalability permits an increase in the temporal resolution by using one or more enhancement layers in addition to the base layer.

FIG. 2 shows an example of temporal scalable coding with two layers. Basic video is obtained by decoding only the independent base layer 200, which is done in the same manner as in the non-scalable, single layer case. Use of the dependent enhancement layer 250 provides video with, e.g., seven times the temporal resolution of the basic video. The same spatial resolution is obtained whether or not the enhancement

layer 250 is used. A frame in the enhancement layer 250 can use motion compensated prediction from the previous or next frame in display order belonging to the base layer as well as the most recently decoded frame in the same layer.

Spatial scalability permits an increase in the spatial resolution by using enhancement layers in addition to the base layer. FIG. 3 shows an example of spatial scalable coding with two layers. Basic video is obtained by decoding only the independent base layer 300, which is done in the same manner as in the non-scalable, single layer case. Use of the dependent enhancement layer 350 provides video with, e.g., twice the spatial resolution of the basic video. The same temporal resolution is obtained whether or not the enhancement layer is used. A frame in the enhancement layer can use motion compensated prediction from the temporally coincident frame in the base layer as well as the most recently decoded frame in the same layer.

Another method to transmit video at multiple resolutions or qualities is simulcast coding. FIG. 4 shows an example of simulcast coding with two bitstreams. For simulcast coding, the streams are independent, whereas scalable coding usually refers to an independent base layer with one or more dependently-coded enhancement layers. For comparison with scalable coding, one of the simulcast streams (termed a lower-resolution stream) has the same resolution as the base

layer, and the other simulcast bitstream (termed a higher-resolution stream) has the same resolution as the enhancement layer.

First and second input bitstreams are coded at corresponding video encoders 420 and 410, respectively. The input video #1 is assumed to be a lower-resolution stream, while the input video #2 is assumed to be a higher-resolution stream. This involves coding each representation independently and is usually less efficient than scalable coding since similar information in another bitstream is not exploited. The bitstreams are then multiplexed at a mux 430, transmitted across some channel, demultiplexed at a demux 440, and decoded independently at video decoders 470 and 460, respectively, in a simulcast decoder 450. Unlike scalable coding, no additional decoder complexity is required to decode the higher-resolution video. This may be important for commercial applications since additional decoder complexity often increases the cost of receivers.

This invention focuses on the performance of spatial scalability and its simulcast counterpart. Simulations have been performed with an MPEG-4 encoder on rectangular video to gain insight into the issues with transmitting video at a variety of spatial resolutions. One issue with layered coding is the proper allocation of bits between layers. In addition to examining the differences between simulcast coding

and spatial scalability, investigations in connection with the invention focus on determining guidelines for bit allocation.

Six different video sequences were examined, namely Basket, Bus, Carphone, Foreman, News, and Silentvoice. This set of sequences has a wide range of complexity, so the results should be generally applicable to other sequences. The Basket and Bus sequences have a large amount of motion and may stress most encoders. The News and Silentvoice sequences have large stationary backgrounds making them easy to compress efficiently. The original sequences were in CIF format (288 x 352 pixels) and QCIF format (144 x 176 pixels). The sequences were created by downsampling (without use of any anti-aliasing filter, i.e., decimation). Each sequence was 150 frames long and the source material and display frame rates were 30 frames per second. An MPEG-4 encoder was used to encode the simulcast and spatial scalable streams at various fixed quantization levels with no rate control. The parameters used for the simulations are shown in Table 1. "VOP" refers to a Video Object Plane, as known from the MPEG-4 standard.

	Lower Layer of Simulcast Streams	Upper Layer of Simulcast Streams	Base Layer of Scalable Streams	Enhancement Layer of Scalable Streams
Q_I	{4, 6, 8, …, 24}	{4, 6, 8, …, 24}	{4, 6, 8, …, 24}	{6, 8, 10, …, 24}
Q_P	min (1.4Q_I , 32)	min (1.4Q_I , 32)	min (1.4Q_I , 32)	min (1.4Q_I , 32)
Q_B	min (1.8Q_I , 32)	min (1.8Q_I , 32)	min (1.8Q_I , 32)	min (1.8Q_I , 32)
Structure	IPPBPPB…	IPPBPPB…	IPPBPPB…	PBBPBBPBB…
M	3	3	3	12
N	12	12	12	---
Range	8	16	8	16
Q_I	Quantizer for I-VOPs			
Q_P	Quantizer for P-VOPs			
Q_B	Quantizer for B-VOPs			
Structure	Picture Structure			
M	Period between consecutive P-VOPs			
N	Period between consecutive I-VOPs			
Range	Search range for motion vectors			

Table 1: Parameters of Simulations

The measure of quality here is the PSNR, which is defined to be the Peak Signal-to-Noise Ratio of the luminance (Y) component of the decoded video compared to the input video at the same resolution. While PSNR is the quality measure used here, other possible measures include, e.g., MSE (Mean Square Error) and a Perceptual Distortion Measure. PSNR as used here is defined to be 20*log10(MSE) (dB).

Single Layer Coding

Single layer coding results for the QCIF and CIF Carphone sequences are shown in FIG. 5 and FIG. 6. The legend "150-30fps" indicates a sequence of 150 frames at 30 frames per second. Note that 150 frames was an arbitrarily chosen length and many suitable sequence lengths could be used. Conceptually, switching between spatial scalability and simulcast coding can occur as frequently as at every picture. However, this may result in syntax problems. Switching between groups of pictures (GOPs) is a realistic possibility.

Moreover, here and in the other figures, the bit rate is an average bit rate over a sequence. The circles denote the empirical results and the dotted lines 500, 600, respectively, represent logarithmic fits to the data using the following model:

$$\mathrm{PSNR} = A\ln(\mathrm{Bitrate}) + B .$$

The model allows each single layer to be represented by two parameters (constants) A and B (along with the range of bit rates where this model is valid). "ln" denotes the natural logarithm. "Bitrate" is the "x" parameter in the figures.

Simulcast Coding

A typical scenario encountered when transmitting multiple sequences is a constraint on the total bandwidth.

FIG. 7 is a plot of PSNR vs. fraction of total bits allocated to the lower-resolution stream, for a

total bandwidth of 0.29, 0.32, and 0.35 Mbps for QCIF/CIF simulcast. The figure shows examples of the different qualities that can be achieved by limiting the total bandwidth to 0.29, 0.32 and 0.35 Mbps, respectively, for simulcast ("Sim.") transmission of the Carphone QCIF and CIF sequences. Both qualities are plotted as functions of the fraction of total bits allocated to the lower-resolution stream (i.e., the QCIF stream). In particular, the solid lines 700, 710, 720 represent the PSNR of the lower-resolution (QCIF) sequence for total bit rates of 0.29, 0.32, and 0.35 Mbps, respectively. The dotted lines 750, 760, 770 represent the PSNR of the higher-resolution (CIF) sequence for total bit rates of 0.29, 0.32, and 0.35 Mbps, respectively.

Note the monotonicity of the data for both layers. That is, the PSNR either increases or decreases steadily (without a peak or valley).

While some of the figures refer to the fraction of bits that are allocation to the base layer or enhancement layer (for SS), or to the lower-resolution stream or higher-resolution stream (for Sim.), note that these values can also be expressed in terms of an absolute number of bits, a percentage, a fraction or percentage of a fixed reference value, or any other linear or non-linear metric or scale.

The independence of the single streams in simulcast coding causes an improvement in quality with

an allocation of more bits to the QCIF stream, and degradation of the other, (CIF) stream. This makes sense since the additional bits that are given to one stream are taken away from the other stream to maintain the same total bandwidth.

The curve crosses in the figures denote the point where the functions intersect, i.e., the point where the PSNR of both streams is equal. This point can be found using the logarithmic fits to the data of each stream and a bisection algorithm since the PSNR of each stream is a monotonic function of the bit rate of the lower-resolution stream.

In particular, the monotonicity of the PSNR for both layers implies that if the functions intersect, they will intersect at only one point. In some cases, there may be no intersection point due to insufficient or excess total bandwidth. An additional exit condition checking the difference in bit rates can be used to determine if there is no intersection. This has been omitted from the following algorithm for simplicity. Therefore, the algorithm below assumes that a proper total bit rate has been selected allowing the functions to intersect. A bisection algorithm using the difference in PSNR between the layers can be used to find the point of equal quality. An example algorithm follows:

1. Assume fixed total bitrate R_{TOT} and a threshold for convergence $T > 0$.

2. Let R_1 and R_2 be the minimum and maximum bitrates for single layer coding of the lower layer.

3. Let $R_3 = \frac{R_1 + R_2}{2}$.

4. Compute $PSNR_{lower}$ and $PSNR_{upper}$ for R_3 using the logarithmic fits to each layer:

$$PSNR_{lower} = A_{lower} \ln(R_3) + B_{lower}$$
$$PSNR_{upper} = A_{upper} \ln(R_{TOT} - R_3) + B_{upper}$$

where A_{lower} and B_{lower} are the parameters for the lower (lower-resolution) layer and A_{upper} and B_{upper} are the parameters for the upper (higher-resolution) layer.

5. Let DIFF = $PSNR_{lower}$ - $PSNR_{upper}$.

6. If the absolute value of DIFF is less than T,

the algorithm is finished and R_3 is the lower layer bitrate to achieve equal quality in both layers of simulcast coding.

Otherwise,

Set $R_1 = R_3$ if DIFF < 0.

Set $R_2 = R_3$ if DIFF > 0.

Go back to step 3.

This algorithm is just one example of how the crossover point can be found. Other techniques are possible, such as a linear interpolation.

FIG. 8 gives an example of the iterations needed to obtain the point 800 of equal quality in both streams of the QCIF/CIF simulcast coding of the

carphone sequence, for the 0.32 Mbps case. $R_1(i)$ and $R_2(i)$ represent the bit rates R_1 and R_2, respectively, for the lower-resolution stream at iteration i of the algorithm. Note that FIG. 8 shows the absolute bit rate of the lower-resolution stream, whereas FIG. 7 shows the fraction of the total bits that are allocated to the lower-resolution stream. It should be easily understood here and elsewhere how to convert between these two types of scales.

The point where the PSNRs intersect in FIG. 7 can be interpreted as the bit allocation where both streams are coded at approximately the same quality since PSNR is normalized with respect to picture size. Note that this point may not occur with some total bandwidths due to the limited dynamic range of each stream's coding.

The ability to transmit two streams of different resolutions that have roughly the same quality may be desirable in applications such as streaming video over the Internet with the resolutions used here. However, other applications may have different requirements. For example, consider two different agendas for the same simulcast system. One application may desire relatively higher quality in the lower-resolution stream to satisfy a larger number of receivers receiving the lower resolution. Another application may desire a relatively higher quality in the higher-resolution streams to satisfy the receivers receiving the higher resolution because of the higher cost of the

bandwidth required to receive the entire simulcast stream. The analysis in the following sections focuses on achieving the same quality for both streams, but this may not be the goal of some applications and this issue is revisited hereinbelow.

Additionally, FIG. 7 illustrates that the fraction of bits allocated to the lower-resolution stream to achieve equal quality in the two streams is essentially independent of the total bit rate. This is a very useful result and its significance can be seen by the following example. Assume that a multiplexer is combining simulcast bitstreams and has already determined the proper bit allocation between streams. The preceding result suggests that the multiplexer does not have to redetermine the proper bit allocation when reacting to a change in the total bandwidth. Instead, the proportion of bits allocated to each stream should remain the same.

FIGs 9 and 10 show the results of performing the same analysis as described above for different sequences at a wide variety of constrained total bandwidths. In particular, FIG. 9 shows the PSNR versus bitrate for the test sequences Basket 900, Bus 910, Carphone 920, Foreman 930, News 940, and Silentvoice 950.

The quality of both the lower-resolution (QCIF) and higher-resolution (CIF) streams is shown by only one curve for each sequence since the data in this plot

was obtained by requiring equal PSNR for both streams, and the bitrate shown is the total bitrate. For example, for the Basket sequence 900, when the total bitrate is 1 Mbps, both streams have a PSNR of approximately 24 dB. As the total bitrate is slowly increased, the PSNR of both streams increases, up to approximately 32 dB when the total bit rate is 4.5 Mbps.

FIG. 10 shows the fraction of total bits allocated to the lower-resolution streams versus total bitrate for the test sequences Basket 1000, Bus 1010, Carphone 1020, Foreman 1030, News 1040, and Silentvoice 1050. The data show that approximately 40 ± 4 % of the total bandwidth should be allocated to the lower-resolution stream to achieve equal quality in both streams of simulcast coding. This result can be used as a general guide for the bit allocation of simulcast bitstreams.

Spatial Scalable Coding

Results for the spatial scalable ("SS") coding of the Carphone QCIF and CIF sequences are shown in FIG. 11. The abscissa of each data point (on the horizontal axis) is the total bit rate of both streams, and the ordinate (on the vertical axis) represents the PSNR of the enhancement layer (the higher, CIF resolution) using spatial scalability. Each set of curves uses the same lower-resolution QCIF base layer (and therefore base layer bit rate and PSNR) with different enhancement layer bit rates. The circles denote

empirical results, and the dotted lines are logarithmic fits to each set of curves using the same base layer. Table 2 lists the bit rate (in Mbps) and PSNR of the QCIF base layer as well as the parameters (A and B) of the logarithmic fit ($Y = A \ln(X) + B$) for each set of curves.

Base Bitrate (Mbps)	Base PSNR	A	B
0.286	36.46	9.40	41.34
0.171	34.11	6.89	40.90
0.108	32.73	5.70	40.45
0.0835	31.69	5.36	40.26
0.0714	31.04	5.32	40.26
0.0625	30.46	5.36	40.34
0.0561	29.92	5.40	40.41
0.0518	29.48	5.47	40.49
0.0492	29.09	5.55	40.53
0.0472	28.76	5.62	40.61
0.0456	28.44	5.66	40.62

Table 2: Base (QCIF) Layer Characteristics of Spatial Scalable Coding for QCIF/CIF (Carphone)

In FIG. 11, the 0.286, 0.171, and 0.108 base layer bit rates are shown at curves 1100, 1110, and 1120, respectively. The remaining bit rates of 0.0835 through 0.0456 are shown at the aggregate curves 1130.

A constraint on the total bandwidth is examined for spatial scalable coding of the Carphone QCIF and CIF sequences. FIG. 12 is a plot of PSNR vs. the fraction of total bits allocated to the base layer, for

total bandwidths of 0.29, 0.32 and 0.35 Mbps for QCIF/CIF spatial scalability. The figure shows examples of the different qualities that can be achieved by limiting the total bandwidth to 0.29, 0.32 and 0.35 Mbps. The solid lines represent the PSNR of the base layer (QCIF) sequence and the dotted lines represent the PSNR of the enhancement layer (CIF) sequence. In particular, the solid lines 1200, 1210, 1220 represent the PSNR of the QCIF sequence for 0.29, 0.32, and 0.35 Mbps, respectively. The dotted lines 1250, 1260, 1270 represent the PSNR of the CIF sequence for 0.29, 0.32, and 0.35 Mbps, respectively.

Note the PSNR of the CIF sequences is not a monotonic function of the fraction of bits allocated to the base layer. That is, there is a peak in the PSNR for the CIF sequences near 20%.

As expected, the PSNR of the QCIF sequence is a monotonically increasing function of the fraction of total bits allocated to it. Moreover, it appears that allocating less than approximately 20% of the total bitstream to the base layer gives declining performance in both layers. The decline is relatively slight for the CIF layer, but rather sharp for the QCIF layer. This trend is also present with the other test sequences. This result is different from the one seen in the simulcast approach, where both layers are independent, and is due to the dependence of the CIF enhancement layer on the upsampled QCIF base layer.

This result of 20% allocation for the base layer can be a useful minimum boundary for the allocation of base layer bits for spatial scalable encoders.

Additionally, FIG. 12 shows that the fraction of bits allocated to the base layer to achieve equal quality in the two layers is essentially independent from the total bit rate. This result is similar to the conclusions obtained after analysis of the simulcast experiments and can be very useful for allocating spatial scalable bitstreams.

FIGs 13 and 14 show the results of performing the same analysis as described above for different sequences at a wide variety of constrained total bandwidths, where the base layer and enhancement layer have the same PSNR for a given total bit rate. In particular, FIG. 13 shows the PSNR versus total bitrate for the test sequences Basket 1300, Bus 1310, Carphone 1320, Foreman 1330, News 1340, and Silentvoice 1350. FIG. 14 shows the fraction of total bits allocated to the base layer versus total bitrate for the test sequences Basket 1400, Bus 1410, Carphone 1420, Foreman 1430, News 1440, and Silentvoice 1450. The data of FIG. 14 shows that approximately 45 ± 5 % of the total bandwidth should be allocated to the base layer to achieve equal quality in both layers of spatial scalable coded bitstreams. This percentage can be used as a general guide for the bit allocation of spatial scalable bitstreams.

FIGs 15 through 20 show the simulcast and spatial scalability results for each test sequence, where the QCIF and CIF video sequences have the same PSNR for a given total bit rate.

In particular, FIG. 15 shows the PSNR for spatial scalability 1500 and simulcast 1510 for the carphone sequence, FIG. 16 shows the PSNR for spatial scalability 1600 and simulcast 1610 for the news sequence, FIG. 17 shows the PSNR for spatial scalability 1700 and simulcast 1710 for the foreman sequence, FIG. 18 shows the PSNR for spatial scalability 1800 and simulcast 1810 for the basket sequence, FIG. 19 shows the PSNR for spatial scalability 1900 and simulcast 1910 for the silentvoice sequence, and FIG. 20 shows the PSNR for spatial scalability 2000 and simulcast 2010 for the bus sequence.

The operating regions of simulcast coding and spatial scalability are often different, with spatial scalability being the only option at relatively low total bit rates, and simulcast coding at relatively high total bit rates. Specifically, at relatively low bit rates, spatial scalability can be used if a coarse quantizer is used for residual coding. Simulcast coding may not be possible since the bandwidth may be too low to encode sequences at the higher resolution even with the coarsest quantizer. Note that much more information must be encoded for the simulcast case

since no information is available from the base layer. That is, there usually is a lot less signal energy in the residual (the difference between the uncoded enhancement layer and an upsampled version of the decoded base layer) than in the original signal. The enhancement layer of spatial scalability can be thought of as encoding the residual while the second, higher-resolution stream of simulcast coding is encoding the original, high resolution signal. Since we are using the same range of quantizers for both the enhancement layer of spatial scalability and the second layer of simulcast coding, it is not surprising that there are different ranges for the coded bitrates for the two methods.

Except for some regions with the Basket sequence, there is an improvement in quality gained by using spatial scalability at bit rates where both simulcast coding and spatial scalability are possible. Table 3 lists the range of PSNR improvements for each sequence using spatial scalability where both simulcast and scalable coding are possible. The negative value for the minimum PSNR improvement for the Basket sequence indicates that simulcast coding achieves higher quality video for part of the common operating region.

Note that the decision between simulcast coding and spatial scalability for a commercial application generally involves more than looking at the differences in PSNR or other quality measure. The lower layer bit

rate is smaller for simulcast coding, which favors simulcast coding since less bandwidth is required for reception of only the base layer. Additional decoder complexity is also required to decode spatial scalability bitstreams.

Sequence	Maximum PSNR Improvement Using Spatial Scalability	Minimum PSNR Improvement Using Spatial Scalability
Carphone	0.74	0.41
News	1.06	0.79
Foreman	0.75	0.68
Basket	0.71	-0.25
Silentvoice	1.27	1.18
Bus	0.65	0.11

Table 3: Range of PSNR Improvements Using Spatial Scalability Where Both Simulcast and Scalable Coding Are Possible

The previous analysis focused on achieving equal PSNR in both layers. As discussed earlier, this may not be the goal of some applications. A different view of this operating point reveals some additional insight into the general differences between simulcast coding and spatial scalability.

FIGs 21 through 23 show the results of both simulcast and scalable coding for the QCIF and CIF Carphone sequences with fixed total bandwidths of 0.29, 0.32 and 0.35 Mbps, respectively. The results are plotted as functions of the fraction of bits allocated

to the base layer (for SS), or the lower-resolution stream (for Sim.).

In particular, FIG. 21 shows the PSNR for 0.29 Mbps for simulcast CIF 2100, spatial scalability CIF 2110, and QCIF 2120 (which is the same for simulcast or spatial scalability). FIG. 22 shows the PSNR for 0.32 Mbps for simulcast CIF 2200, spatial scalability CIF 2210, and QCIF 2220. FIG. 23 shows the PSNR for 0.35 Mbps for simulcast CIF 2300, spatial scalability CIF 2310, and QCIF 2320.

Note that simulcast ("Sim.") outperforms spatial scalability ("SS") if a relatively small percentage of the total bit rate is assigned to the base layer. One general trend appears to be the increasing advantage of spatial scalability with more bits allocated to the base layer.

As an example, FIG. 21 provide visual markers to aid the following discussion. Point A' is the operating point for equal PSNR in both streams using simulcast coding. Point B' is the corresponding point for spatial scalability using the same amount of bits allocated to the base layer as Point A'. Point C' is the operating point for equal PSNR in both layers using spatial scalability. Note that the use of the operating points that achieves equal quality in both streams or layers (Points A' and C', respectively) causes different amounts of bits to be allocated to the lower-resolution stream or base layer depending,

respectively, on whether simulcast (Point A') or spatial scalability (Point C') is used.

Comparison of simulcast coding and spatial scalability with the same amount of bits allocated to the lower-resolution stream and base layer (Points A' and B', respectively) shows that spatial scalability results in a higher PSNR at the higher CIF resolution. Note that the PSNR at the lower QCIF resolution is the same for both simulcast coding and spatial scalability. Moreover, this is different from the gain in both the QCIF and CIF resolutions obtained by using the operating point for equal quality in both layers (Point C'). One way to interpret this concept is that part of the PSNR gain in the enhancement layer by using spatial scalable coding can be "exchanged" for an increase in the base layer by "moving" bits from the enhancement to the base layer. In fact, more bits can also be "moved" from the base layer to the enhancement layer. This concept can be visualized by simultaneously moving along the QCIF and CIF curves in FIG. 21. This allows different distributions, such as the points between Points B' and C' (for SS), or between Points A' and C' (for Sim.), to be achievable.

In general, the bit allocation problem involves two bit rates (the base and enhancement bitstreams for SS., and the lower-resolution and higher-resolution bitsreams for Sim.), and the choice between simulcast coding and spatial scalability. Note that more than

two streams or layers may be used, in which case the bit allocation problem is extended accordingly.

One method to obtain this three-dimensional data (assuming two streams or layers) is to fix the rate of the base layer (or lower-resolution stream), and decide between simulcast coding and spatial scalability for different bit rates for the enhancement layer or higher-resolution stream. By combining the data at different base layer (lower-resolution stream) rates, the complete three-dimensional data can be constructed.

FIGs 24 and 25 are examples of fixing the bit rate (and therefore, PSNR) of the base layer (or lower-resolution stream), for the transmission of the Carphone QCIF and CIF sequences. In particular, FIG. 24 shows the PSNR of the higher-resolution stream or enhancement layer, respectively, for simulcast 2400 and spatial scalability 2410 at 0.29 Mbps, and FIG. 25 shows the corresponding PSNR for simulcast 2500 and spatial scalability 2510 at 0.05 Mbps. Note that the curve for spatial scalability has a smaller dynamic range.

In FIG. 24, fixing the QCIF data results in a PSNR of 36.45 for that data. The total bit rate is then 0.29 Mbps + the enhancement layer or higher-resolution stream layer bit rate. The data point at (0 Mbps, 30 dB) results if no enhancement layer data is used, i.e., the base layer is simply upsampled (using bilinear interpolation) to create the enhancement layer.

In FIG. 25, the fixed QCIF bit rate results in a PSNR of 28.36 for that data. The total bit rate is then 0.05 Mbps + the enhancement layer or higher-resolution stream bit rate. The data point at (0 Mbps, 27 dB) results if no enhancement layer data is used, i.e., the base layer is simply upsampled (using bilinear interpolation) to create the enhancement layer. The general trend is for spatial scalability to be more efficient at lower enhancement layer/higher-resolution stream bit rates, while simulcast coding is more efficient at higher enhancement layer/higher-resolution stream bit rates. An important result is to determine the boundary where simulcast coding and spatial scalability are equivalent. This boundary can then be used to determine whether one should use simulcast coding or spatial scalability.

The functions for simulcast coding and spatial scalability may not intersect, but the curves can be extrapolated to find an intersection point by fitting both curves to logarithms and finding the intersection of the logarithmic fits. In particular, assume the two logarithmic functions are:

$$Y_1 = A \ln\left(X\right) + B$$

$$Y_2 = C \ln\left(X\right) + D$$

Y1 is the PSNR for one curve, e.g., the simulcast coding curve, with curve fit constants A and B. Y2 is the PSNR for the other curve, e.g., the spatial

scalability curve, with curve fit constants C and D. Solving for the point of intersection between the two logarithmic functions yields:

$$Y_1 = Y_2$$
$$A\ln(X) + B = C\ln(X) + D$$
$$(A - C)\ln(X) = D - B$$
$$\ln(X) = \frac{D - B}{A - C}$$
$$X = e^{\frac{D-B}{A-C}}$$

The crosses in the figures (point 2420 in FIG. 24, and point 2520 in FIG. 26) represent the estimated points of intersection.

FIG. 26 shows the results of applying this technique of estimating the boundary between simulcast coding and spatial scalability for all the test sequences. This figure shows the test sequences Basket 2600, Bus 2610, Carphone 2620, Foreman 2630, News 2640, and Silentvoice 2650. For each video sequence, the data indicates that operating points above the curve should use simulcast coding and points below the curve should use spatial scalability to obtain the highest PSNR for the CIF video sequence (e.g., the enhancement layer or higher-resolution stream). Note that specifying the base bit rate uniquely determines the PSNR of the QCIF sequence since this resolution is single layer coded. The decision boundaries tend to have the same shape with different scales.

FIG. 27 demonstrates the similarity of the decision boundaries this by normalizing the base layer and the enhancement layer bit rates (for SS), and by normalizing the lower-resolution stream and higher-resolution stream bit rates (for Sim.), using the range of the data and the following formula:

$$Normalized\ Bitrate = \frac{Bitrate - Minimum}{Maximum - Minimum}.$$

This formula maps the minimum absolute bit rate to a zero normalized bit rate and the maximum absolute bit rate to a normalized bit rate of one.

FIG. 27 shows normalized decision boundaries for the test sequences Basket 2700, Bus 2710, Carphone 2720, Foreman 2730, News 2740, and Silentvoice 2750.

The results above allow one to choose between simulcast and spatial scalability strictly on the basis of which mode provides higher quality. Considering other issues such as the additional receiver complexity required for spatial scalability may require not only determining which mode is better, but how much improvement is obtained, especially when factors support the other mode. This requires looking at the three-dimensional data. Note that determining which mode is better regardless of the PSNR difference is equivalent to a projection of the three-dimensional data onto a two-dimensional space. Visualizing and establishing decision criteria for surfaces is

difficult for general scenarios and may be best handled in a case-by-case manner.

Multicast environment

The present invention can be applied to video broadcasting in a multicast environment, such as a video server providing video (e.g., movies) to users via a computer network such as the Internet. The users may receive the data via an appliance such as a personal computer, Internet-capable set-top box, or the like. In this environment, multiple clients require different types of service due to variations in their processing power, memory resources and available bandwidth. The server would like to provide different resolutions and/or qualities of the same video sequence to satisfy each type of client. Note that the server should provide content for all the service rates continuously, otherwise, an entire client type does not receive service.

This scenario is different from the unicast environment, where different levels of service are provided to account for dynamic changes in the point-to-point transmission. In this case, the server can adaptively switch between bitstreams to provide service commensurate with the available resources. Therefore, only one bitstream is transmitted at any instance and it can be tailored to the target bit rate. This scheme provides high quality video, and benefits from low

decoder complexity since single-layer decoding is always used.

Different services may involve improving the spatial resolution, temporal resolution and/or quality of the video transmission with increasing bit rates. This discussion focuses on providing different levels of spatial resolution. Consider the following example with two levels of service. Clients at the lower service rate receive QCIF resolution video and those at the higher service rate receive CIF resolution video. Both service rates receive video with the same temporal resolution.

One approach to providing multicast service is to simulcast code the sequence at all of the service rates. This approach produces high quality video at all service rates. However, since service must be provided to all client types, the encoder must transmit a large amount of data, i.e., the sum of all the service rates. The main expense in multicast transmission is the total used bandwidth (in terms of total number of packets transmitted). Network congestion is also a problem, so it may be necessary to constrain the total combined rate of all the service rates. The minimum bandwidth necessary is the largest single service rate that is able to provide adequate service to all clients. The following discussion assumes that a constraint on the total bandwidth is imposed where the constrained rate is between the

largest single service rate and the sum of all the service rates.

The simulcast approach can still be used to provide two levels of service by reducing the higher bitstream to the difference between the constrained total and the lower bitstream. Another approach is to use spatially scalability. Intuitively, one expects spatial scalability to perform better since the information in the base layer (QCIF) sequence is used to assist construction of the enhancement layer (CIF) sequence. In general, this is true, but it has been found in connection with the present invention that simulcast coding can outperform spatial scalability when a small proportion of bits are allocated to the base layer/lower-resolution stream. This is counterintuitive, since spatial scalability "reuses" information in the base layer and its enhancement layer has the same bit rate as the single layer bitstream used by simulcast coding. One explanation may be that the overhead incurred by using a scalable coding syntax surpasses the gain obtained. The base layer also may not provide good prediction when a small amount of bits is allocated to it.

FIGs 28 and 29 are examples of multicast broadcasting using simulcast coding and spatial scalability, respectively, when the total used bandwidth is constrained to 200 kbps and the user service rates are 50 kbps and 200 kbps.

In FIG. 28, a server 2800 provides simulcast-coded lower-resolution and higher-resolution streams at 40 and 160 kbps, respectively, to a 200 kbps channel 2810 and a switching device, such as a router 2820. The 40 kbps stream is routed to the first service via a path 2830, and the 160 kbps stream is routed to the second service via a path 2850. The router 2820 does not route the 160 kbps stream to the first service since the first service cannot handle this data rate. Moreover, the router 2820 does not route the 40 kbps stream to the second service since this service only has use for one of the streams, and can handle the higher resolution 160 kbps stream.

Any known computer-network routing protocol may be used to achieve this result. In particular, the router 2820 should be informed of which services can handle which data rates. Each service can represent many end users.

In FIG. 29, a server 2900 provides spatial scalability-coded base and enhancement layers at 40 and 160 kbps, respectively, to a 200 kbps channel 2910 and a switching device, such as a router 2920. The 40 kbps base layer is routed to the first service via a path 2930, and both the 40 kbps base layer and 160 kbps enhancement layer are routed to the second service via paths 2940 and 2950, respectively (which may be the same path). The second service receives both the

layers since they must be used together to obtain the maximum information (e.g., image resolution).

Note that the video for the 50 kbps service rate is identical regardless of which coding approach is used. That is, the user with the 50 kbps service receives only the 40 kbps lower-resolution stream when simulcast coding is used, or the equivalent 40 kbps base layer when scalability coding is used.

The 200 kbps service in the simulcast coding approach (FIG. 28) constructs video for the higher service rate using the 160 kbps stream. This service does not use the 40 kbps single layer stream since it is independent from the 160 kbps layer and therefore there is no benefit to using it.

However, the 200 kbps service in the spatial scalability approach (FIG. 29) can use the 40 kbps base layer in addition to the 160 kbps enhancement layer, allowing it to construct video for the higher service rate using 200 kbps. These figures support the intuition that spatial scalability can outperform simulcast coding.

As discussed, FIG. 22 shows the results of encoding the QCIF and CIF Carphone sequences using both spatial scalability and simulcast coding with different bit allocations, but a fixed total bandwidth of 0.32 Mbps. Note that spatial scalability outperforms simulcast coding for many different bit allocations. However, simulcast coding is more efficient if less

than about 20% of the total bandwidth is allocated to the base layer/lower-resolution stream.

FIG. 30 shows a decision boundary 2620 (from FIG. 26) between simulcast coding and spatial scalability for the Carphone QCIF and CIF sequences. In accordance with the invention, operating points above the decision boundary should use simulcast coding, and points below it should use spatial scalability coding. The definition of operating point used here is the average bitrate over the entire sequence. Note that similar analysis can be performed using a smaller subset of the sequence such as a group of pictures. The methods described in this document can be used to construct this curve and then used to determine whether simulcast coding or spatial scalability should be used to encode the video.

A fixed total bitrate gives only one constraint on two variables (the base and enhancement bit rates), therefore, one can use any distribution of the total bitrate. For example, assume that 0.5 Mbps total bitrate is available. In one case, 0.25 Mbps is used for the QCIF resolution, and 0.25 Mbps is used for the CIF resolution. Since this operating point 3000 is below the curve 2620, spatial scalability should be used to obtain the best quality for the CIF data. In another case, 0.1 Mbps is used for the QCIF resolution, and 0.4 Mbps is used for the CIF resolution. Since this operating point 3020 is above the curve 2620,

simulcast coding should be used to achieve the best quality for the CIF data. Recall that the quality of the QCIF data is the same regardless of whether simulcast coding or scalability coding is used.

While the simulations described here used a number of encoding and decoding experiments before settling on which transmission mode to use, one may be able to determine model parameters without having to run encoding/decoding experiments for every sequence.

Determining new model parameters for each sequence may not be necessary if one already has good model parameters. This may be the case for sequences that are similar. For example, in FIG. 26, the sequences carphone 2620, news 2640, and silentvoice 2650 have a similar coding decision boundary. Using the boundary obtained with one of these sequences to assist the simulcast/scalable coding decision may still be optimal for the coding of a different sequence, as long as the data points are not close to the decision boundary. Determining new model parameters for each sequence may be desirable, especially if one wants to maximize the quality of video delivery, despite the increased computational costs.

FIG. 31 illustrates an adaptive simulcast/spatial scalability encoder apparatus in accordance with the present invention. A higher-resolution video sequence (such as CIF), and a lower-resolution video sequence (such as QCIF) are provided to an analysis function

3110, and to respective switches 3130 and 3140. The analysis function 3110 analyzes the video sequences based on the above discussion to provide a select signal to the switches 3130, 3140 to route both of the sequences to either the simulcast encoder 400 or the scalable encoder 100. See Figures 1 and 4, respectively.

The analysis function 3110 may include a decoder and encoder, where the PSNR of a layer is determined by comparing the output of the decoder to the input to the encoder.

Successive sequences, each having several (e.g., 150) pictures/frames, may be analyzed to adaptively route each sequence to either the simulcast encoder 400 or the scalable encoder 100. Moreover, the analysis may occur off-line, prior to when the video is transmitted to a user. In this manner, unnecessary processing delays are avoided. For example, the video data may be recovered from a memory, analyzed, then returned to the storage device. Each sequence of analyzed data may be marked to indicate whether it is to be subsequently routed to either the simulcast encoder 400 or the scalable encoder 100. This marking may be achieved any number of ways, such as providing overhead control bits with the video data.

Moreover, note that the decoders should have the capability to determine whether they are receiving a simulcast-coded or scalability-coded stream. This can

be achieved according to the relevant data standard (e.g., MPEG-4). Moreover, the decoders should have scalable decoding capabilities and single layer decoding capabilities. Advantageously, the invention can be carried out without modification to such decoders.

It should now be appreciated that the present invention provides for the compression of video data for multicast environments. Spatial scalability and simulcast coding are used in the compression process. Simulations are provided to compare the performance of spatial scalability and simulcast coding of lower-resolution (e.g., QCIF) and higher-resolution (e.g., CIF) sequences. The main results and conclusions of this work are:

- The use of a logarithmic model to represent single layer coding results. This model can then be used to easily compute the bit allocation that achieves equal quality in both layers of simulcast coding.
- Allocating 40 ± 4 % (e.g., 36-44%) of the total bandwidth to the lower-resolution stream achieves equal quality in both streams of simulcast coding.
- Allocating less than 20% of the total bandwidth to the base layer for spatial scalable coding is inefficient.
- Allocating 45 ± 5 % (e.g., 40-50%) of the total bandwidth to the base layer achieves equal quality in both layers of spatial scalable coding.

- Spatial scalability may be the only option at relatively low enhancement bit rates, and simulcast coding may be the only option at relatively high enhancement bit rates, but spatial scalability usually gives higher quality in the common operating region.
- Decision boundaries can be generated to guide the decision between spatial scalability and simulcast coding.
- Simulcast coding can outperform spatial scalability when a small proportion of bits is allocated to the base layer/lower-resolution stream. This may be due to the overhead of the scalable coding syntax and/or bad prediction from the base layer.

Although the invention has been described in connection with various preferred embodiments, it should be appreciated that various modifications and adaptations may be made thereto without departing from the scope of the invention as set forth in the claims.

What is claimed is:

1. A method for coding video data, comprising the steps of:

modeling a quality of lower resolution video data, and of corresponding higher resolution video data, for varying bit allocations between the lower and higher resolution video data;

determining a crossover point of the modeled qualities wherein the lower and higher resolution video data have an approximately equal quality, and the corresponding bit allocation; and

coding the video data in accordance with the corresponding bit allocation.

2. The method of claim 1, wherein:

the video data coded in said coding step comprises a sequence of pictures.

3. The method of claim 1, wherein:

the corresponding bit allocation is an average over a sequence of pictures that comprise the lower and higher resolution video data.

4. The method of claim 1, wherein:

the video data coded in said coding step is different than the video data used in said modeling step.

5. The method of claim 1, wherein:

the video data coded in said coding step is the same as the video data used in said modeling step.

6. The method of claim 1, wherein:

the quality comprises a peak signal-to-noise ratio (PSNR).

7. The method of claim 1, wherein:

said modeling step uses a logarithmic model.

8. The method of claim 1, wherein:

the coded video data is coded in independent simulcast streams.

9. The method of claim 1, wherein:

the coded video data is coded using spatial scalability coding in a base layer and at least one enhancement layer.

10. The method of claim 1, wherein:

the crossover point is determined in accordance with a bisection algorithm.

11. The method of claim 1, wherein:

the crossover point is extrapolated.

12. A method for coding video data, comprising the steps of:

modeling a quality of lower resolution video data, and of corresponding higher resolution video data, for varying bit allocations between the lower and higher resolution video data, by using each of: (a) simulcast coding, and (b) spatial scalability coding; and

coding the video data at a desired bit allocation for the lower and higher resolution video data using one of the simulcast coding and the spatial scalability coding according to whichever results in a larger modeled quality at the desired bit allocation.

13. The method of claim 12, wherein:

the video data comprises a sequence of pictures.

14. The method of claim 12, wherein:

the desired bit allocation is an average over a sequence of pictures that comprise the lower and higher resolution video data.

15. The method of claim 12, wherein:

the video data coded in said coding step is different than the video data used in said modeling step.

16. The method of claim 12, wherein:

the video data coded in said coding step is the same as the video data used in said modeling step.

17. The method of claim 12, wherein:

the modeled qualities comprise a peak signal-to-noise ratio (PSNR).

18. The method of claim 12, wherein:

said modeling step uses a logarithmic model.

19. A method for coding video data, comprising the steps of:

(a) determining a bit allocation decision boundary for varying bit allocations for lower resolution video data;

wherein, for the varying bit allocations for the lower resolution data, the decision boundary designates a bit allocation for corresponding higher resolution video data;

(b) determining an operating point for the video data based on desired bit allocations for lower resolution video data thereof and corresponding higher resolution video data thereof;

(c) coding the video data using simulcast coding if the operating point indicates the desired bit allocation of the higher resolution video data of said

step (b) exceeds a bit allocation designated by the decision boundary; and

(d) coding the video data using simulcast coding if the operating point indicates the desired bit allocation of the higher resolution video data of said step (b) is less than a bit allocation designated by the decision boundary.

20. The method of claim 19, wherein:

the decision boundary corresponds to a bit allocation of approximately 20% of an available bandwidth to the lower resolution video data in said step (a) and approximately 80% of the available bandwidth to the higher resolution video data in said step (a).

21. The method of claim 19, wherein:

the video data comprises a sequence of pictures.

22. The method of claim 21, wherein:

the desired bit allocations in said step (b) are averages over the sequence of pictures.

23. The method of claim 19, wherein:

the video data coded in said coding steps is different from the video data used in said step (a).

24. The method of claim 19, wherein:

the video data coded in said coding steps is the same as the video data used in said step (a).

25. A method for coding video data comprising lower resolution data and corresponding higher resolution data, comprising the steps of:

(a) allocating a first portion of an available bandwidth to the lower resolution data, and a remainder of the available bandwidth to the higher resolution data; and

(b) coding the video data using simulcast coding if the first portion is less than approximately 20% of the available bandwidth, and using spatial scalability coding if the first portion is greater than approximately 20% of the available bandwidth.

26. A method for coding video data comprising lower resolution data and corresponding higher resolution data, comprising the step of:

allocating approximately 36-44% of an available bandwidth to the lower resolution data, and a remainder of the available bandwidth to the higher resolution data to achieve an approximately equal quality for the lower and higher resolution data when they are simulcast coded.

27. The method of claim 26, wherein:

the quality comprises a peak signal-to-noise ratio (PSNR).

28. A method for coding video data comprising lower resolution data and corresponding higher resolution data, comprising the step of:

allocating approximately 40-50% of an available bandwidth to the lower resolution data, and a remainder of the available bandwidth to the higher resolution data to achieve an approximately equal quality for the lower and higher resolution data when they are spatial scalability coded.

29. The method of claim 28, wherein:

the quality comprises a peak signal-to-noise ratio (PSNR).

30. A method for communicating video data comprising lower resolution data and corresponding higher resolution data to at least a first user via a network that adaptively uses spatial scalability coding and simulcast coding, comprising the step of:

configuring a switching device in the network to selectively forward at least one of the lower and higher resolution data to the first user according to which of the spatial scalability coding and the

simulcast coding is being used, and according to a data service capacity of the first user.

31. The method of claim 30, wherein:

when the simulcast coding is used, the switching device is configured to: (a) forward the higher resolution data to the first user if a data rate of the higher resolution data is within the data service capacity, and (b) to forward the lower resolution data to the first user if the data rate of the higher resolution data is not within the data service capacity, but a data rate of the lower resolution data is within the data service capacity.

32. The method of claim 30, wherein:

when spatial scalability coding is used, the switching device is configured to: (a) forward both the higher and lower resolution data to the first user if a combined data rate thereof is within the data service capacity, and (b) to forward the lower resolution data to the first user if the combined data rate is not within the data service capacity, but a data rate of the lower resolution data is within the data service capacity.

33. The method of claim 30, wherein:

the switching device comprises a router.

34. An apparatus for coding video data, comprising:

means for modeling a quality of lower resolution video data, and of corresponding higher resolution video data, for varying bit allocations between the lower and higher resolution video data;

means for determining a crossover point of the modeled qualities wherein the lower and higher resolution video data have an approximately equal quality, and the corresponding bit allocation; and

means for coding the video data in accordance with the corresponding bit allocation.

35. An apparatus for coding video data, comprising:

means for modeling a quality of lower resolution video data, and of corresponding higher resolution video data, for varying bit allocations between the lower and higher resolution video data, by using each of: (a) simulcast coding, and (b) spatial scalability coding; and

means for coding the video data at a desired bit allocation for the lower and higher resolution video data using one of the simulcast coding and the spatial scalability coding according to whichever results in a larger modeled quality at the desired bit allocation.

36. An apparatus for coding video data, comprising:

(a) means for determining a bit allocation decision boundary for varying bit allocations for lower resolution video data;

wherein, for the varying bit allocations for the lower resolution data, the decision boundary designates a bit allocation for corresponding higher resolution video data;

(b) means for determining an operating point for the video data based on desired bit allocations for lower resolution video data thereof and corresponding higher resolution video data thereof;

(c) means for coding the video data using simulcast coding if the operating point indicates the desired bit allocation of the higher resolution video data of said means (b) exceeds a bit allocation designated by the decision boundary; and

(d) means coding the video data using simulcast coding if the operating point indicates the desired bit allocation of the higher resolution video data of said means (b) is less than a bit allocation designated by the decision boundary.

37. An apparatus for coding video data comprising lower resolution data and corresponding higher resolution data, comprising:

(a) means for allocating a first portion of an available bandwidth to the lower resolution data, and a remainder of the available bandwidth to the higher resolution data; and

(b) means for coding the video data using simulcast coding if the first portion is less than approximately 20% of the available bandwidth, and using spatial scalability coding if the first portion is greater than approximately 20% of the available bandwidth.

38. An apparatus for coding video data comprising lower resolution data and corresponding higher resolution data, comprising:

means for allocating approximately 36-44% of an available bandwidth to the lower resolution data, and a remainder of the available bandwidth to the higher resolution data to achieve an approximately equal quality for the lower and higher resolution data when they are simulcast coded.

39. An apparatus for coding video data comprising lower resolution data and corresponding higher resolution data, comprising:

means for allocating approximately 40-50% of an available bandwidth to the lower resolution data, and a remainder of the available bandwidth to the higher resolution data to achieve an approximately equal

quality for the lower and higher resolution data when they are spatial scalability coded.

40. An apparatus for communicating video data comprising lower resolution data and corresponding higher resolution data to at least a first user via a network that adaptively uses spatial scalability coding and simulcast coding, comprising:

means for configuring a switching device in the network to selectively forward at least one of the lower and higher resolution data to the first user according to which of the spatial scalability coding and the simulcast coding is being used, and according to a data service capacity of the first user.

(54) Title: SWITCHING BETWEEN BIT-STREAMS IN VIDEO TRANSMISSION

(57) Abstract: The invention relates to a method for transmitting video information, in which at least a first bit-stream (510) and a second bit-stream are formed. The first bit-stream (510) comprises at least one video frame, and the second bit-stream (520) comprises at least one predictive video frame (524). At least partly different encoding parameters are used with encoding of the frames of said first bit-stream (510) and said second bit-stream (520). At least one frame of said first bit-stream (510) is being transmitted, and the transmission is switched over from said first (510) to said second bit-stream (520). In switching the transmission over from said first (510) to said second bit-stream (520), a secondary switching frame (550) is transmitted, which have been encoded using the encoding parameters of the second bit-stream (520) and at least one reference frame from the first bit-stream (510). Said secondary switching frame (550) is used as a reference frame in the reconstruction of said at least one predictive video frame (524) of the second set of video frames. The invention also relates to an encoder for encoding video information, a decoder for decoding a video information, and a signal representing encoded video information.

SWITCHING BETWEEN BIT-STREAMS IN VIDEO TRANSMISSION

The present invention relates to a method for transmitting video information, in which at least a first bit-stream and a second bit-stream are formed from the video information, the first bit-stream comprises a first set of frames comprising at least one video frame, and the second bit-stream comprises a second set of frames comprising at least one predictive video frame, at least partly different encoding parameters are used with encoding of the frames of said first bit-stream and said second bit-stream, at least one frame of said first bit-stream is being transmitted, and the transmission is switched over from said first bit-stream to said second bit-stream. The invention also relates to an encoder comprising means for forming at least a first bit-stream and a second bit-stream from a video information, the first bit-stream comprises a first set of frames comprising at lest one video frame, and the second bit-stream comprises a second set of frames comprising at least one predictive video frame, and means for using at least partly different encoding parameters with encoding of the frames of said first bit-stream and said second bit-stream, means for transmitting at least one frame of said first bit-stream, and means for switching the transmission over from said first bit-stream to said second bit-stream. The invention further relates to a decoder for decoding a video information from a signal comprising frames from at least a first bit-stream and a second bit-stream, which are formed from the video information, the first bit-stream comprises a first set of frames comprising at lest one video frame, and the second bit-stream comprises a second set of frames comprising at least one predictive video frame, and at least partly different encoding parameters are used with encoding of the frames of said first bit-stream and said second bit-stream. The invention further relates to a signal representing encoded video information, and comprising frames from at least a first bit-stream and a second bit-stream, which are formed from the video information, the first bit-stream comprises a first set of frames comprising at lest one video frame, and the second bit-stream comprises a second set of frames comprising at least one predictive video frame, at least partly

CONFIRMATION COPY

different encoding parameters are used with encoding of the frames of said first bit-stream and said second bit-stream.

BACKGROUND

Recently, multimedia applications that include streaming audio and video information have come into greater use. Several international standardization organizations have established and proposed standards for compressing/encoding and decompressing/decoding the audio and video information. MPEG standards, established by the Motion Picture Expert Group, are the most widely accepted international standards in the field of the multimedia applications. VCEG is the "Video Coding Experts Group", working under the direction of the ITU Telecommunication Standardization Sector (ITU-T). This group works on the standard H.26L for the coding of moving pictures.

A typical video stream comprises a sequence of pictures, often referred to as frames. The frames comprise pixels arranged into a rectangular form. In existing video coding standards, such as H.261, H.262, H.263, H.26L and MPEG-4, three main types of pictures are defined: Intra frames (I-frames), Predictive frames (P-frames) and Bi-directional frames (B-frames). Each picture type exploits a different type of redundancy in a sequence of images and consequently results in different level of compression efficiency and, as explained in the following, provides different functionality within the encoded video sequence. An intra frame is a frame of video data that is coded by exploiting only the spatial correlation of the pixels within the frame itself without using any information from the past or the future frames. Intra frames are used as the basis for decoding/decompression of other frames and provide access points to the coded sequence where decoding can begin.

A predictive frame is a frame that is encoded/compressed using motion compensated prediction from a so-called reference frame, *i.e.* one or more previous/subsequent Intra frames or Predictive frames available in an encoder or in a decoder. A bi-directional frame is a frame that is

encoded/compressed by prediction from a previous Intra frame or Predictive frame and/or a subsequent Intra frame or Predictive frame.

Since adjacent frames in a typical video sequence are highly correlated, higher compression can be achieved when using Bi-directional or Predictive frames instead of Intra frames. On the other hand, when the temporal predictive coding is employed within the coded video stream, B-frames and/or P-frames cannot be decoded without correctly decoding all the other previous and/or subsequent reference frames which were used with coding of the Bi-directional and Predictive frames. In situations in which the reference frame(s) used in the encoder and respective reference frame(s) in the decoder are not identical either due to errors during transmission or due to some intentional action on the transmitting side, the subsequent frames that make use of prediction from such a reference frame can not be reconstructed on the decoding side to yield a decoded frame identical to that originally encoded on the encoding side. This mismatch is not only confined to a single frame but further propagates in time due to the use of motion compensated coding.

Figs. 1A-1C illustrate the types of encoded/compressed video frames used in a typical video encoding/decoding system. Advantageously, prior to encoding, the pictures of the video sequence are represented by these matrices of multiple-bit numbers, one representing the luminance (brightness) of the image pixels, and the other two each representing a respective one of two chrominance (colour) components. Fig. 1A depicts the way in which an Intra frame 200 is encoded using only image information present in the frame itself. Fig. 1B illustrates construction of a Predictive frame 210. Arrow 205a represents the use of motion compensated prediction to create the P-frame 210. Fig. 1C depicts construction of Bi-directional frames 220. B-frames are usually inserted between I-frames or P-frames. Fig. 2 represents a group of pictures in display order and illustrates how B-frames inserted between I-and P-frames, as well as showing the direction in which motion compensation information flows. In Figures 1B, 1C and 2, arrows 205a depict forward motion compensation

prediction information necessary to reconstruct P-frames 210, whereas arrows 215a and 215b depict motion compensation information used in reconstructing B-frames 220 in forward direction (215a) and backward direction (215b). In other words, the arrows 205a and 215a show the flow of information when predictive frames are predicted from frames that are earlier in display order than the frame being reconstructed, and arrows 215b show the flow of information when predictive frames are predicted from frames that are later in display order than the frame being reconstructed.

In motion compensated prediction, the similarity between successive frames in a video sequence is utilized to improve coding efficiency. More specifically, so-called motion vectors are used to describe the way in which pixels or regions of pixels move between successive frames of the sequence. The motion vectors provide offset values and error data that refer to a past or a future frame of video data having decoded pixel values that may be used with the error data to compress/encode or decompress/decode a given frame of video data.

The capability to decode/decompress P-frames requires the availability of the previous I- or P-reference frame, furthermore in order to decode a B-frame requires the availability of the subsequent I- or P-reference frame is also required. For example, if an encoded/compressed data stream has the following frame sequence or display order:

$I_1\ B_2\ B_3\ P_4\ B_5\ P_6\ B_7\ P_8\ B_9\ B_{10}\ P_{11} \ldots P_{n-3}\ B_{n-2}\ P_{n-1}\ I_n,$

the corresponding decoding order is:

$I_1\ P_4\ B_2\ B_3\ P_6\ B_5\ P_8\ B_7\ P_{11}\ B_9\ B_{10} \ldots P_{n-1}\ B_{n-2}\ I_n.$

The decoding order differs from the display order because the B-frames require future I- or P-frames for their decoding. Fig. 2 displays the beginning of the above frame sequence and can be referred to in order to understand the dependencies of the frames, as described earlier. P-frames require the previous I- or P-reference frame be

available. For example, P_4 requires I_1 to be decoded. Similarly, frame P_6 requires that P_4 be available in order to decode/decompress frame P_6. B-frames, such as frame B_3, require a past and/or a future I- or P-reference frame, such as P_4 and I_1 in order to be decoded. B-frames are frames between I-or P-frames during encoding.

A prior art system for encoding and decoding is shown in Figures 3 and 4. Referring to the encoder 300 of Figure 3, the frame 301 being coded I(x,y), called the current frame, is partitioned into rectangular regions of KxL pixels. The coordinates (x,y) denote the location of the pixels within the frame. Each block is encoded using either intra coding (i.e. using only the spatial correlation of the image data within the block) or inter coding (i.e. utilising both spatial and temporal prediction). The following description considers the process by which inter-coded blocks are formed. Each inter-coded block is predicted 360 from one of the previously (or subsequently) coded and transmitted frames R(x,y) in the frame memory 350, called a reference frame. The motion information used for the prediction is obtained from motion estimation and coding block 370 by using the reference frame and the current frame 305. The motion information is represented by a two-dimensional motion vector (Δx, Δy) where Δx is a horizontal and Δy is a vertical displacement. In the motion compensated (MC) prediction block, the motion vectors are used together with the reference frame to construct prediction frame P(x,y):

$$P(x,y) = R(x+\Delta x, y+\Delta y).$$

Subsequently the prediction error E(x,y), i.e. the difference between the current frame and the prediction frame P(x,y), is calculated 307 according to

$$E(x,y)= I(x,y)-P(x,y).$$

In transform block 310, the prediction error for each KxL block is represented as weighted sum of a transform basis functions $f_{ij}(x,y)$,

$$E(x, y) = \sum_{i=1}^{K} \sum_{j=1}^{L} c_{err}(i,j)\, f_{ij}(x, y).$$

The weights $c_{err}(i,j)$ corresponding to the basis functions are called transform coefficients. These coefficients are subsequently quantised in quantisation block 320 to give

$$I_{err}(i,j)=Q(c_{err}(i,j),QP)$$

where $I_{err}(i,j)$ are the quantised transform coefficients. The quantisation operation Q() introduces loss of information, but the quantised coefficients can be represented with smaller number of bits. The level of compression (loss of information) is controlled by adjusting the value of the quantisation parameter QP.

Before the motion vectors and quantised transform coefficients are supplied to the multiplexer 380, they are further encoded using Variable Length Codes (VLC). This reduces the number of bits needed to represent the motion vectors and quantised transform coefficients. The encoded motion vectors, quantised transform coefficients as well as other additional information needed to represent each coded frame is multiplexed in the multiplexer 380, and the resulting bit-stream is transmitted 415 to the decoder. The quantised transform coefficients are also forwarded to the inverse quantisation block 330 to obtain inverse quantised transform coefficients and further to the inverse transform block 340 to obtain the prediction error information $E_c(x,y)$ for the current frame. The prediction error information $E_c(x,y)$ is added to the predicted frame P(x,y) in a summing element to obtain a video frame that can be subsequently stored in the frame memory 350.

In the following, decoding video frames will be described with reference to Figure 4. The decoder 400 receives the multiplexed video bit-stream 415 from the encoder, and the demultiplexer 410 demultiplexes the bit-stream to obtain the constituent parts of the video frames to be decoded. These parts comprise at least the coded quantised prediction

error transform coefficients and the coded motion vectors, which are subsequently decoded (not shown) to obtain quantised prediction error transform coefficients and motion vectors. The quantised transform coefficients are inverse quantised in inverse quantisation block 420 to obtain inverse quantised transform coefficients $d_{err}(i,j)$ according to the following relation:

$$d_{err}(i,j)=Q^{-1}(I_{err}(i,j), QP).$$

In inverse transform block 430, the inverse quantised transform coefficients are subjected to an inverse transform to obtain prediction error $E_c(x,y)$:

$$E_c(x,y) = \sum_{i=1}^{K}\sum_{j=1}^{L} c_{err}(i,j)\, f_{ij}\,(x,y).$$

The pixels of the current coded frame are reconstructed by finding the prediction pixels in the reference frame R(x,y) obtained from frame memory 440, and using the received motion vectors together with the reference frame in motion compensation prediction block 450, to obtain a predicted frame P(x,y). The predicted frame P(x,y) and the prediction error information $E_c(x,y)$ are summed together in a summing element 435 according to the following relation:

$$I_c(x,y)= R(x+\Delta x, y+\Delta y)+E_c(x,y).$$

These values $I_c(x,y)$ can further be filtered to obtain decoded video frames 445. The values $I_c(x,y)$ are also stored in the frame buffer 440. The reconstructed values $I_c(x,y)$ can be filtered in a filtering block (not shown in Figure 4) after the summation block 435.

Video streaming has emerged as an important application in the fixed Internet. It is further anticipated that video streaming will also be important in and in the near future in 3G wireless networks. In streaming applications the transmitting server starts transmitting a pre-

encoded video bit stream via a transmission network to a receiver upon a request from the receiver. The receiver plays back the video stream back while receiving it. The best-effort nature of present networks causes variations in the effective bandwidth available to a user due to the changing network conditions. To accommodate these variations, the transmitting server can scale the bit rate of the compressed video. In the case of a conversational service characterized by real-time encoding and point-to-point delivery, this can be achieved by adjusting the source encoding parameters on the fly. Such adjustable parameters can be, for example, a quantisation parameter, or a frame rate. The adjustment is advantageously based on feedback from the transmission network. In typical streaming scenarios when a previously encoded video bit stream is to be transmitted to the receiver, the above solution cannot be applied.

One solution to achieve bandwidth scalability in case of pre-encoded sequences is to produce multiple and independent streams having different bit-rates and quality. The transmitting server then dynamically switches between the streams to accommodate variations in the available bandwidth. The following example illustrates this principle. Let us assume that multiple bit streams are generated independently with different encoding parameters, such as quantisation parameter, corresponding to the same video sequence. Let $\{P_{1,n-1}, P_{1,n}, P_{1,n+1}\}$ and $\{P_{2,n-1}, P_{2,n}, P_{2,n+1}\}$ denote the sequence of decoded frames from bit streams 1 and 2, respectively. Since the encoding parameters are different for the two bit streams, frames reconstructed from them at the same time instant, for example, frames $P_{1,n-1}$ and $P_{2,n-1}$, are not identical. If it is now assumed that the server initially sends encoded frames from bit stream 1 up to time *n* after which it starts sending encoded frames from bit stream 2, the decoder receives frames $\{P_{1,n-2}, P_{1,n-1}, P_{2,n}, P_{2,n+1}, P_{2,n+2}\}$. In this case $P_{2,n}$ cannot be correctly decoded since its reference frame $P_{2,n-1}$ is not received. On the other hand, the frame $P_{1,n-1}$, which is received instead of $P_{2,n-1}$, is not identical to $P_{2,n-1}$. Therefore switching between bit streams at arbitrary locations leads to visual artefacts due to the mismatch between the reference frames used for motion compensated prediction in the different sequences.

These visual artefacts are not only confined to the frame at the switching point between bit streams, but propagates in time due to the continued motion compensated coding in the remaining part of the video sequence.

In current video encoding standards, perfect (mismatch-free) switching between bit streams is only possible at positions where the current and future frames or regions thereof do not use any information previous to the current switching location, i.e., at I-frames. Furthermore, by placing I-frames at fixed (e.g. 1 sec) intervals, VCR functionalities, such as random access or "Fast Forward" and "Fast Backward" (increased playback rate) for streaming video content, are achieved. The user may skip a portion of the video sequence and restart playing at any I-frame location. Similarly, an increased playback rate can be achieved by transmitting only I–frames. The drawback of using I-frames in these applications is that since I-frames do not exploit any temporal redundancy they require a much larger number of bits than P-frames at the same quality.

SUMMARY OF THE INVENTION

It is an aim of the present invention to provide a new method and a system for transmitting video images in variable transmission environments. The invention is based on the idea that correct (mismatch-free) switching between video streams is enabled by forming a new type of a compressed video frame and inserting frames of the new type into video bit-streams at locations where switching from one bit-stream to another is to be allowed. In this description, the new type of compressed video frame will be referred to generally as an S-frame. More specifically, S-frames may be classified as SP-frames, which are formed at the decoder using motion compensated prediction from already decoded frames using motion vector information, and SI-frames, which are formed at the decoder using spatial (intra) prediction from already decoded neighbouring pixels within a frame being decoded. In general, an S-frame according to the invention is formed on a block-by-block basis and may comprise both inter-coded (SP)

blocks as well as intra-coded (SI) blocks. The method according to the present invention is primarily characterized in that in switching the transmission over from said first bit-stream to said second bit-stream, the secondary bit-stream comprises at least one primary switching frame, a secondary switching frame is transmitted, the secondary switching frame having been encoded using the encoding parameters of the second bit-stream and at least one reference frame from the first bit-stream, and said secondary switching frame is used in place of the primary switching frame as a reference frame to be used in the reconstruction of said at least one predictive video frame of the second set of video frames. The encoder according to the present invention is primarily characterized in that said means for switching the transmission over from said first bit-stream to said second bit-stream comprise means for encoding a secondary switching frame using the encoding parameters of the second bit-stream and reference frames from the first bit-stream to enable to switch the transmission over from said first bit-stream to said second bit-stream. The decoder according to the present invention is primarily characterized in that the decoder comprises means for decoding a secondary switching frame, said secondary switching frame having been encoded using the encoding parameters of the second bit-stream and at least one reference frame from the first bit-stream, and added to said signal in place of a primary switching frame as a reference frame to be used in the reconstruction of said at least one predictive video frame of the second set of video frames, and that said means for decoding a secondary switching frame comprise means for using decoding parameters of the second bit-stream and reference frames from the first bit-stream. The signal according to the present invention is primarily characterized in that in switching the transmission over from said first bit-stream to said second bit-stream, the secondary bit-stream comprises at least one primary switching frame, said signal comprises a secondary switching frame having been encoded using the encoding parameters of the second bit-stream and at least one reference frame from the first bit-stream, and said secondary switching frame is in place of the primary switching frame as a reference frame to be used in the reconstruction

of said at least one predictive video frame of the second set of video frames.

Considerable advantages are achieved by the present invention compared to the methods and systems of prior art. The invention allows switching between bit streams to occur not only at the locations of I-frames but also at the locations of the SP-frames. The coding efficiency of an SP-frame is much better than the coding efficiency of a typical I-frame wherein less bandwidth is needed to transmit bit streams having SP-frames in locations where, according to prior art, I-frames would be used, while still providing enough adaptability to changing transmission conditions. The switching of one bit stream into another can be performed at locations in which an SP-frame according to the invention is placed in the encoded bit stream. The images reconstructed from the bit stream by the decoder is not degraded as a result of changing from one bit stream to another. The invention also has the advantage that random access, fast-forward and fast rewind operations can be performed on the bit stream. The system according to the invention offers improved error recovery and resiliency properties compared with the described prior art solutions.

These and other features, aspects, and advantages of embodiments of the present invention will become apparent with reference to the following description in conjunction with the accompanying drawings. It is to be understood, however, that the drawings are designed solely for the purposes of illustration and not as a definition of the limits of the invention, for which reference should be made to the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

In the following the invention will be described in more detail with reference to the appended drawings, in which

DETAILED DESCRIPTION OF THE INVENTION

In the following the invention is described in a system in which multiple bit streams are formed from a video signal. The video signal can be any digital video signal comprising multiple images, *i.e.* an image sequence. The digital video signal is encoded in an encoder to form multiple bit streams. Each bit stream is encoded from the same video signal using at least partly different encoding parameters. For example, the bit rate can be altered by selecting the encoding parameters differently, and in this way bit streams with different bit rates can be formed. The encoding parameters can be, for example, frame rate, quantisation parameter, spatial resolution, or another factor affecting the images size, known as such to a person skilled in the art. The encoder also inserts at least one Intra frame to each bit stream. Typically, at least the first frame of each bit stream is preferably an Intra frame. This enables the decoder to start reconstruction of the video signal. The encoder used in the encoding of the I-frames, P-frames and B-frames can be any prior art encoder which performs the encoding of the video signal, or there may exist more than one prior art encoder each using different encoding parameters to form multiple bit streams. However, to encode a video signal containing also SP-frames and/or SI-frames according to the invention, new functionality is needed in the encoder. This will be explained later in greater detail.

The encoder also inserts frames encoded using motion compensated predictive coding (P-frames and optionally B-frames) into the bit streams. The encoder also inserts a new type of frames, referred to as S-frames in this description, into each bit stream at locations where switching between different bit streams will be allowed according to the invention. The S-frames may be used at locations where in prior art methods an Intra coded frame would be inserted, or the S-frames may be used in addition to using Intra coded frames in the video sequence.

Advantageously, the different bit streams are stored into storage means for later use. However, it is also possible that transmission may take place substantially immediately after encoding wherein it is not necessary to store complete video sequences, but storing the necessary reference frames suffices. Transmission of the encoded video stream may be performed *e.g.* by a transmitting server, which has means for retrieving the stored bit streams for transmission, and/or means for receiving the bit streams directly from the encoder. The transmitting server also has means for transmitting the bit stream to the transmission network (not shown).

In the following, a method according to an advantageous embodiment of the invention will be described. Fig. 5 depicts part of a first bit stream 510 and part of a second bit stream 520, which are formed in the encoder. Only a few P-frames of the respective bit streams are shown. Specifically, the first bit stream 510 is shown to comprise P-frames 511, 512, 514 and 515, while the second bit stream 520 comprises corresponding P-frames 521, 522, 524 and 525. Both the first bit stream 510 and the second bit stream 520 also comprise S-frames 513 (also labelled S_1), 523 (also labelled S_2) at corresponding locations. It is assumed that the two bit streams 510 and 520 correspond to the same sequence encoded at different bit rates for example by using different frame rates, different spatial resolutions or different quantisation parameters. It is further assumed that the first bit stream 510 is being transmitted from the transmitting server to a decoder 600, 1200, 1300 (Figs. 6, 12 and 13, respectively) via a transmission network, and that the transmitting server receives a request from the transmission network to change the bit rate of the video stream being transmitted.

As mentioned above, S-frames are placed in the bit stream during the encoding process at those locations within the video sequences where switching from one bit stream to another is allowed. As can be seen from Figure 5, in an advantageous embodiment of the invention a further S-frame 550 (also labelled S_{12}) is associated with S-frames S_1 and S_2. This S-frame is called a secondary representation of the S-

frame (or secondary S-frame for short), and is only transmitted during bit stream switching. This secondary S-frame S_{12} is generated by a special encoding of the nth frame in the video sequence using the encoding parameters of the corresponding S-frame 523 (S_2) in the second bit stream 520 and using motion compensated prediction from the reference frames of the nth frame in the first bit stream 510. It should be noted that in the situation shown in Figure 5, S-frame S_2 uses the previously reconstructed frames from the second bit stream 520 as reference frames and the secondary S-frame S_{12} uses the previously reconstructed frames from the first bit stream 510 as reference frames. However, the reconstructed pixel values of both S_2 and S_{12} are identical. S-frame S_{12} is transmitted only when switching from the first bit stream 510 to the second bit stream 520 is actually performed. Therefore it is not necessary to form the secondary S-frames during the encoding phase but only when switching is performed. On the other hand, it may be useful to have at least some secondary S-frames formed earlier at the time when the different bit streams are formed to reduce computational load during transmission.

When the transmitting server reaches the frame of the video sequence encoded as S-frame 513 (S_1) in the first bit stream 510, it can begin the necessary operations to continue transmission of the video stream using the encoded frames of the second bit stream 520. At that point the transmitting server has already transmitted P-frames 511 and 512 from the first bit stream 510 and the decoder 600, 1200, 1300 has received and decoded the respective P-frames 511, 512. Thus, those frames have already been stored in the frame memory 640, 1250, 1360 of the decoder 600, 1200, 1300. The frame memory 640, 1250, 1360 comprises sufficient memory to store all those frames, which are needed to reconstruct a P-frame or a B-frame, *i.e.* the necessary information of all the reference frames required by the current frame to be reconstructed.

The transmitting server performs the following operations to continue the transmission of the video stream using the encoded frames of the second bit stream 520. The transmitting server notices, for example, by

examining the type information of the frame, that the current frame to be transmitted is an S-frame, so it is possible to perform switching between the bit streams. Of course, switching is only performed if a request to do so has been received or there is for some other reason a need to perform the switch. The transmitting server inputs the corresponding S-frame 523 of the second bit stream, uses it to form the secondary S-frame 550 (S_{12}), and transmits the secondary S-frame (S_{12}) to the decoder 600, 1200, 1300. The transmitting server does not transmit the S-frame S_2 of the second bit stream, but sends the secondary S-frame S_{12} in its place. The secondary S-frame is formed in such a way that by decoding the secondary S-frame S_{12} the decoder 600 can reconstruct an image identical to that which would be produced if it were using respective frames 521, 522 and the S-frame 523 of the second bit stream 520. After the transmission of the secondary S-frame the transmitting server continues to transmit the encoded frames if the second bit stream 520, i.e., 524, 525, and so on.

The S-frame 513, 523, 550 can comprise blocks encoded using only spatial correlation among the pixels (intra blocks) and blocks encoded using both spatial and temporal correlation (inter blocks). For each inter block the prediction of this block, P(x,y), is formed in the decoder 600, 1200, 1300 using received motion vectors and a reference frame. The transform coefficients c_{pred} for P(x,y) corresponding to basis functions $f_{ij}(x,y)$ are calculated and quantised. The quantised values of the transform coefficients c_{pred} are denoted as l_{pred} and the dequantised values of the quantised transform coefficients l_{pred} are denoted as d_{pred}. Quantised coefficients l_{err} for the prediction error are received from the encoder. The dequantised values of these coefficients will be denoted as d_{err}. Value of each pixel S(x,y) in the inter block is decoded as a weighted sum of the basis functions $f_{ij}(x,y)$ where the weight values d_{rec} will be called dequantised reconstruction image coefficients. The values of d_{rec} have to be such that coefficients c_{rec} exist from which by quantisation and dequantisation d_{rec} can be obtained. In addition, values d_{rec} have to fulfill one of the following conditions:

$d_{rec} = d_{pred} + d_{err}$, or

$c_{rec} = c_{pred} + d_{err}$.

Values S(x,y) can further be normalized and filtered.

Next, encoding of the S-frames placed within the bit stream, e.g. S-frames 513 (S_1) and 523 (S_2) is described.

Generally, an S-frame according to the invention such as frames 513, 523 in Figure 5 is constructed on a block-by-block basis. As explained earlier, each of the blocks may be coded either in such a way as to take advantage of the spatial correlations among pixels of the image being coded (intra or SI-blocks) or in such a way as to take advantage of the temporal correlation between blocks of pixels in successive frames of a video sequence (inter or SP-blocks).

The encoding of S-frames according to the invention will be described with reference to Figure 11 which is a block diagram of an S-frame encoder 1100 according to a first embodiment of the invention.

A video frame to be encoded in S-frame format is first partitioned into blocks and each block is then encoded as either an SP-block, an SI-block, or an intra-block, an intra-block being known as such from prior art. Switch 1190 is operated as appropriate to switch between the SI and SP encoding modes, i.e., the switch 1190 is a construction used in the description of the invention, not necessarily a physical device. In SP-encoding mode switch 1190 is operated to obtain a motion compensated prediction for the current block 1170. Motion compensated prediction block 1170 forms a prediction P(x,y) for the current block of the frame being encoded in a manner analogous to that used in motion compensated prediction known from prior art. More specifically, motion compensated prediction block 1170 forms the prediction P(x,y) for the current block of the frame being encoded by determining a motion vector describing the relationship between the pixels in the current block and pixel values of a reconstructed reference frame held in frame memory 1146.

In SI-encoding mode switch 1190 is operated to obtain a prediction for the current block of the frame being coded from intra prediction block 1180. Intra prediction block 1180 forms the prediction P(x,y) for the current block of the frame being encoded in a manner analogous to that used in intra prediction known from prior art. More specifically, intra prediction block 1180 forms the prediction P(x,y) for the current block of the frame being encoded using spatial prediction from already encoded neighbouring pixels within the frame being encoded.

In both SP- and SI-coding modes the prediction P(x,y) takes the form of a block of pixel values. A forward transform, for example a Discrete Cosine Transform (DCT), is applied to the predicted block of pixel values P(x,y) in block 1160 and the resulting transform coefficients, referred to as c_{pred}, are subsequently quantised in quantisation block 1150 to form quantised transform coefficients l_{pred}. Corresponding operations are also performed on the original image data. More specifically, the current block of pixel values of the original image being encoded is applied to transform block 1110. Here, a forward transform (e.g., a DCT) is applied to the pixel values of the original image block to form transform coefficients c_{orig}. These transform coefficients are passed to quantisation block 1120 where they are quantised to form quantised transform coefficients l_{orig}. The summing element 1130 receives both sets of quantised transform coefficients l_{pred} and l_{orig} from the respective quantisation blocks 1150 and 1120 and generates a set of quantised prediction error coefficients l_{err} according to the relationship:

$$l_{err} = l_{orig} - l_{pred} .$$

The quantised prediction error coefficients l_{err} are passed to multiplexer 1135. If the current block is encoded in SP-format/mode, multiplexer 1135 also receives the motion vectors for the SP-coded block. If the current block is encoded in SI-format/mode, information concerning the intra prediction mode used to form the prediction for the SI-coded block in intra prediction block 1180 is passed to the multiplexer. Advantageously, variable length coding is applied to the quantised

prediction error coefficients I_{err} and to the motion vector or intra prediction mode information in the multiplexer 1135, a bit-stream is formed by multiplexing together the various forms of information and the bit-stream thus formed is transmitted to a corresponding decoder 1200, 1300 (see Figs. 12 and 13).

The S-frame encoder 1100 according to the invention also comprises local decoding functionality. The quantised prediction transform coefficients I_{pred} formed in quantisation block 1150 are supplied to the summing element 1140 which also receives the quantisation error coefficients I_{err} . The summing element 1140 recombines the quantised prediction transform coefficients I_{pred} and the quantised prediction error coefficients I_{err} to form a set of reconstructed quantised transform coefficients I_{rec} according to the relationship:

$$I_{rec} = I_{pred} + I_{err} .$$

The reconstructed quantised transform coefficients are passed to inverse quantisation block 1142 which inverse quantises the reconstructed quantised transform coefficients to form inverse quantised reconstructed transform coefficients d_{rec}. The inverse quantised reconstructed transform coefficients are further passed to inverse transform block 1144 where they are subjected to e.g. an Inverse Discrete Cosine Transform (IDCT), or any other inverse transform corresponding to the transform performed in block 1160. As a result, a block of reconstructed pixel values is formed for the image block in question and is stored in frame memory 1146. As subsequent blocks of the frame being encoded in S-frame format undergo the previously described encoding and local decoding operations, a decoded version of the current frame is progressively assembled in the frame memory from where it can be accessed and used in intra prediction of subsequent blocks of the same frame or in inter (motion compensated) prediction of subsequent frames in the video sequence.

Operation of a generic S-frame decoder according to a first embodiment of the invention will now be described with reference to Figure 12.

The bit-stream generated by the S-frame encoder previously described in connection with Figure 11 is received by decoder 1200 and is demultiplexed into its constituent parts by demultiplexer 1210. The decoder reconstructs a decoded version of the S-frame on a block-by-block basis. As previously described, an S-frame may comprise intra-blocks, SP-coded and SI-coded image blocks. For SP-format image blocks, the information in the received bit-stream comprises VLC encoded motion coefficient information and VLC encoded quantised prediction error coefficients I_{err}. For image blocks encoded in SI-format the information in the received bit-stream comprises VLC coded information relating to the intra prediction mode used to form the intra prediction for the SI-coded block together with VLC coded quantised prediction error coefficients I_{err}.

When decoding an SP-coded block, demultiplexer 1210 first applies appropriate variable length decoding (VLD) to the received bit-stream to recover the motion vector information and quantised prediction error coefficients I_{err}. It then separates the motion vector information from the quantised prediction error coefficients I_{err}. The motion vector information is supplied to motion compensated prediction block 1260 and the quantised prediction error coefficients recovered from the bit-stream are applied to one input of summing element 1220. The motion vector information is used in motion compensated prediction block 1260 together with pixel values of a previously reconstructed frame held in frame memory 1250 to form a prediction P(x,y) in a manner analogous to that employed in the encoder 1100.

When decoding an SI-coded block, demultiplexer 1210 applies appropriate variable length decoding to the received intra prediction mode information and the quantised prediction error coefficients I_{err}. The intra prediction mode information is then separated from the quantised prediction error coefficients and supplied to intra prediction

block 1270. The quantised prediction error coefficients I_{err} are supplied to one input of the summing element 1220. The intra prediction mode information is used in intra prediction block 1270 in conjunction with previously decoded pixel values of the current frame held in frame memory 1250 to form a prediction P(x,y) for the current block being decoded. Again, the intra prediction process performed in decoder 1200 is analogous to that performed in encoder 1100 and previously described.

Once a prediction for the current block of the frame being decoded has been formed, switch 1280 is operated so that the prediction P(x,y) which comprises predicted pixel values is supplied to transform block 1290. Again, switch 1280 is an abstract construction used in the description of the invention, not necessarily a physical device. In the case of an SP-coded block, switch 1280 is operated to connect motion compensated prediction block 1260 to transform block 1290, while in the case of an SI-coded block it is operated to connect intra prediction block 1270 to transform block 1290.

In block 1290, a forward transform, e.g., a Discrete Cosine Transform (DCT), is applied to the predicted block of pixel values P(x,y) and the resulting transform coefficients c_{pred} are supplied to quantisation block 1295 where they are quantised to form quantised transform coefficients I_{pred}. Quantised transform coefficients I_{pred} are then supplied to the second input of summing element 1220 where they are added to the prediction error coefficients I_{err} to form reconstructed quantised transform coefficients I_{rec} according to the relationship:

$$I_{rec} = I_{pred} + I_{err}.$$

The reconstructed quantised transform coefficients I_{rec} are further supplied to inverse quantisation block 1230 where they are inverse quantised to form inverse quantised reconstructed transform coefficients d_{rec}. The inverse quantised transform coefficients d_{rec} are then passed to inverse transform block 1240 where they are subjected to e.g. an Inverse Discrete Cosine Transform (IDCT), or any other

inverse transform corresponding to the transform performed in block 1290. In this way, a block of reconstructed pixel values is formed for the image block in question. The reconstructed pixel values are supplied to the video output and to frame memory 1250. As subsequent blocks of the S-frame being decoded undergo the previously described decoding operations, a decoded version of the current frame is progressively assembled in frame memory 1250 from where it can be accessed and used in the intra prediction of subsequent blocks of the same frame or in the inter (motion compensated) prediction of subsequent frames in the video sequence.

Having reviewed the structure and function of an S-frame encoder and decoder according to a first embodiment of the invention, it is now possible to understand how S-frames according to the invention make it possible to switch between bit-streams without mismatch errors such as those encountered in prior video encoding/decoding systems. Referring once more to the bit-stream switching example depicted in Figure 5, switching from the first bit-stream 510 to the second bit-stream 520 occurs at the location of S-frames S_1 (513) and S_2 (523) in the respective bit-streams. As previously noted, when switching is performed, a secondary S-frame, denoted S_{12} (550) is encoded and transmitted. The secondary S-frame S_{12} is encoded using the encoding parameters of the second bit-stream 520 and reference frames from the first bit-stream 510 in such a way that when the secondary frame S_{12} is decoded its reconstructed pixel values are identical to those that would have resulted from transmission of frame S_2 in the second bit-stream.

Let I^2_{err} and I^2_{pred} denote the quantised coefficients of the prediction error and the prediction frame, respectively, obtained from encoding of the SP-frame S_2 with the procedure described above, and let I^2_{rec} denote the quantised reconstructed image coefficients of the S-frame S_2. The encoding of the secondary S-frame 550 (S_{12}) follows the same procedures as in the encoding of the S-frame 523 (S_2) with the following exceptions: 1) The reference frame(s) used in the prediction of each block of the secondary S-frame S_{12} are the reconstructed

frames obtained by decoding the first bit stream 510 up to the current n^{th} frame in the video sequence, 2) The quantised prediction error coefficients are calculated as follows: $I^{12}_{err} = I^{2}_{rec} - I^{12}_{pred}$ where I^{12}_{pred} denotes the quantised prediction transform coefficients. The quantised prediction error coefficients I^{12}_{err} and the motion vectors are transmitted to the decoder 1200.

When decoding the secondary S-frame S_{12} in the decoder 1200 using the reconstructed frames from the first bit stream 510 before the switch as reference frames, coefficients I^{12}_{pred} of the secondary S-frame are constructed and added to the received quantised prediction error coefficients I^{12}_{err} as described above, i.e., $I^{12}_{rec} = I^{12}_{err} + I^{12}_{pred} = I^{2}_{rec} - I^{12}_{pred} + I^{12}_{pred} = I^{2}_{rec}$. It can be noted from this equation that I^{12}_{rec} and I^{2}_{rec} are identical. Therefore, although the secondary S-frame S_{12} and the S-frame of the second bit stream S_2 have different reference frames, when S_{12} is decoded it produces an image with reconstructed pixel values identical to those that would result from decoding S-frame S_2.

From the foregoing description of the encoding and decoding of S-frames according to the invention, it will be appreciated that a significant difference exists compared with encoding and decoding of P-frames and I-frames according to prior art, specifically, it should be appreciated that when encoding or decoding an image block in SP or SI -format, the prediction P(x,y) for the block in question is transformed into the transform coefficient domain by applying a transformation such as a Discrete Cosine Transform. The transform coefficients thus produced are subsequently quantised and a prediction error is determined in the quantised coefficient domain. This contrasts with predictive coding according to prior art in which a prediction error is determined in the spatial (pixel value) domain.

In the following, operation of the decoder 1200 during switching between bit-streams 510 and 520 is described in detail. At the position in the video sequence where switching from the first bit-stream to the second bit-stream 520 takes place, the decoder 1200 has already

received and decoded the previous P-frames 511 and 512 of the first bit-stream 510. The decoded frames are stored in frame memory 1250 and are thus available for use as reference frames. When switching from the first bit-stream 510 to the second bit-stream 520 takes place, encoder 1100 (figure 11) constructs and encodes secondary S-frame S_{12} (550) and transmits the encoded video information representing S_{12} to decoder 1200.

As previously explained, encoding is performed on a block-by-block basis. Specifically, secondary S frame S_{12} is encoded as an assembly of image blocks and generally each image block is encoded as either an SP-coded block or an SI-coded block or an intra-block. For the SP-coded blocks of the secondary S-frame S_{12}, the compressed video information transmitted from encoder to decoder takes the form of quantised prediction error transform coefficients I^{12}_{err} and motion vector information. For the SI-coded blocks of the secondary S-frame S_{12} the compressed video information comprises quantised prediction error transform coefficients I^{12}_{err} and information relating to the intra prediction mode used in forming the prediction for the SI-coded block in the encoder. As previously explained, the compressed video information is subjected to appropriate variable length coding (VLC) prior to transmission from the encoder in order to further reduce the number of bits required for its representation.

The compressed video information for a given image block is received at decoder 1200 and is first subjected to appropriate variable length decoding (VLD) and is separated into its constituent parts by demultiplexer 1210. The quantised prediction error coefficients I^{12}_{err} extracted from the received bit-stream are applied to the first input of summer 1220 and a block of predicted pixel values P(x,y) is formed for each image block according to its coding mode (SP or SI). In the case of an SP-coded block, the block of predicted pixel values P(x,y) is formed in motion compensated prediction block 1260 using a reference frame from the first bit-stream (e.g. P-frame 511 or 512) available in frame memory 1250 and the motion vector information extracted from the encoded video information of secondary S-frame S_{12} by

demultiplexer 1210. In the case of an SI-coded block, a block of predicted pixel values P(x,y) is formed in intra prediction block 1270 using previously decoded pixels of the secondary S-frame S_{12} also stored in frame memory 1250. Intra prediction is performed according to the intra prediction mode information extracted from the received video information for secondary S-frame S_{12} by demultiplexer 1210.

Once a prediction for the current block of the secondary S-frame has been formed the predicted pixel values P(x,y) are passed to transform block 1290. Here a forward transform (e.g. a Discrete Cosine Transform (DCT)) is applied the predicted pixel values P(x,y) to form a set of transform coefficients c_{pred}. These transform coefficients are then passed to quantisation block 1295 where they are quantised to form quantised transform coefficients l^{12}_{pred}. The quantised transform coefficients l^{12}_{pred} are, in turn, applied to the second input of summer 1220. Summer 1220 combines the quantised transform coefficients l^{12}_{pred} with quantised prediction error transform coefficients l^{12}_{err} to form reconstructed quantised transform coefficients l^{12}_{rec} according to the relationship:

$$l^{12}_{rec} = l^{12}_{pred} + l^{12}_{err}.$$

The reconstructed quantised transform coefficients l^{12}_{rec} are then supplied to inverse quantisation block 1230 where they are inverse quantised to form inverse quantised reconstructed transform coefficients d^{12}_{rec}. The inverse quantised reconstructed transform coefficients d^{12}_{rec} are then passed to inverse transform block 1240 where they are subjected to an inverse transform operation (e.g. an Inverse Discrete Cosine Transform (IDCT)). As a result, a block of reconstructed pixel values is formed for the current block of the secondary S-frame S_{12}. The reconstructed pixel values $I_c(x,y)$ are supplied to the video output and to frame memory 1250. As subsequent blocks of the secondary S-frame S_{12} are encoded, transmitted from encoder 1100 to decoder 1200 and subsequently decoded, a decoded version of the secondary S-frame is progressively built up in frame memory 1250. From there, the already decoded

blocks of the secondary S-frame can be retrieved and used by intra prediction block 1270 to form predicted pixel values P(x,y) for subsequent blocks of the secondary S-frame S_{12}. Here it should be remembered that the quantised prediction error transform coefficients for each image block of the secondary S-frame S_{12} are generated in encoder 1100 according to the relationship:

$$I^{12}_{err} = I^{2}_{rec} - I^{12}_{pred}$$

where I^{2}_{rec} are quantised reconstructed transform coefficient values produced by encoding and subsequently decoding S-frame S_2 in the second bit-stream. This means that the reconstructed transform coefficients I^{12}_{rec} produced by decoding the compressed video information for secondary S-frame S_{12} are identical to those which would have been produced if S-frame S_2 from the second bit-stream had been transmitted and decoded. As previously explained, this follows since:

$$I^{12}_{rec} = I^{12}_{pred} + I^{12}_{err}$$

$$= I^{12}_{pred} + I^{2}_{rec} - I^{12}_{pred} = I^{2}_{rec}$$

Thus, $I^{12}_{rec} = I^{2}_{rec}$.

Therefore it can be seen that by constructing a secondary S-frame S_{12} according to the method of the invention, transmitting it from encoder to decoder and subsequently decoding it, mis-match-free switching between a first and a second bit-stream can be achieved.

Consider the case that the secondary S-frame is an SI-frame while the S-frame within the bit stream is an SP-frame. In this case, a frame which uses motion-compensated prediction is represented by a frame which uses only spatial prediction. This special case has implications in random access and error resiliency which will described later.

It should be noted that in encoder 1100 and decoder 1200 according to the first embodiment of the invention, described above, the quantisation applied to the transform coefficients c_{pred} produced in transform blocks 1160 (encoder) and 1290 (decoder) to yield quantised transform coefficients l_{pred} is the same as that used to generate the quantised prediction error transform coefficients l_{err}. More specifically, in the first embodiment of the invention, when a block of predicted pixel values P(x,y) is produced for an image block of an S-frame which is being encoded/decoded, the quantisation parameter QP used to quantise the transform coefficients c_{pred} corresponding to the predicted block of pixel values P(x,y) should be the same as the quantisation parameters used in generating the quantised prediction error transform coefficients l_{err}. This is advantageous since the summation performed in order to produce reconstructed transform coefficients l_{rec} is performed in the quantised transform coefficient domain, i.e. since

$$l_{rec} = l_{pred} + l_{err},$$

failure to use identical quantisation parameters in the construction of l_{pred} and l_{err} will lead to errors in the reconstructed quantised transform coefficients l_{rec}.

Figure 15 shows a block diagram of an S-frame encoder 1500 according to a second embodiment of the invention which provides greater flexibility in the choice of quantisation parameters to generate the quantised transform coefficients l_{pred} and l_{err}. As can be seen by comparing Figure 15 with Figure 11, the principal difference between the S-frame encoder 1500 according to a second embodiment of the invention and S-frame encoder 1100 according to a first embodiment of the invention concerns the location of quantisation blocks 1525 and 1550. The operation of the S-frame encoder 1500 according to the second embodiment of the invention will now be described in detail with reference to Figure 15.

According to the second embodiment of the invention a video frame to be encoded in S-frame format is first partitioned into blocks and each

block is then encoded as either on SP-block or on SI-block. Switch 1585 is operated as appropriate to switch between the SP and SI coding modes. In SP coding mode switch 1585 is operated to obtain a motion compensated prediction for the current block of the frame being encoded from motion compensated prediction block 1575. Motion compensated prediction block 1575 forms a block of predicted pixel values P(x,y) for the current block of the frame being encoded by determining a motion vector describing the relationship between the pixels of the current block and pixel values of a reconstructed reference frame held in frame memory 1570.

In SI-coding, mode switch 1585 is operated to obtain a prediction for the current block of the frame being encoded from intra prediction block 1580. Intra prediction block 1580 operates in a manner analogous to that described in connection with the first embodiment of the invention to form a block of predicted pixel values P(x,y) for the current block of the frame being encoded using spatial prediction from already encoded neighbouring pixels within the frame being encoded.

In both SP- and SI-coding modes a forward transform, for example a Discrete Cosine Transform (DCT), is applied to the predicted block of pixel values P(x,y) in transform block 1590. The resulting transform coefficients c_{pred} are supplied to summers 1520 and 1540. The original image data, comprising the actual pixel values of the image block currently being encoded, are passed to transform block 1510 where they too are subjected to a forward transform (e.g DCT). The resulting transform coefficients c_{orig} are then passed to summer 1520 which forms a difference between c_{orig} and c_{pred} to generate prediction error transform coefficients c_{err} according to the relationship:

$$c_{err} = c_{orig} - c_{pred}.$$

The prediction error transform coefficients are supplied to quantisation block 1525 where they are quantised using quantisation parameter PQP to form quantised prediction error transform coefficients l_{err} which are, in turn passed to multiplexer 1540.

If the current block is being encoded in SP-format, multiplexer 1540 also receives information relating to the motion vectors used in formation of the motion compensated prediction P(x,y) for the SP-coded block. If the current block is being encoded in SI-format information concerning the intra prediction mode used to form the prediction P(x,y) for the SI-coded block is also passed to the multiplexer. Advantageously, multiplexer 1540 applies appropriate variable length coding (VLC) to the quantised prediction error transform coefficients l_{err} and to the motion vector or intra prediction mode information and forms a bit-stream for transmission to a corresponding decoder by multiplexing together the various forms of information.

The quantised prediction error transform coefficients l_{err} are passed from quantisation block 1525 to inverse quantisation block 1530 where they are inverse quantised using quantisation parameter PQP to form inverse quantised prediction error transform coefficients d_{err}. The inverse quantised prediction error transform coefficients d_{err} are next passed to summer 1540 where they are combined with the transform coefficients c_{pred} produced from the predicted pixel values P(x,y) for the current block. More specifically, summer 1540 adds transform coefficients c_{pred} and inverse quantised prediction error transform coefficients d_{err} to form reconstructed transform coefficients c_{rec} according to the relationship:

$$c_{rec} = c_{pred} + d_{err}$$

The reconstructed transform coefficients c_{rec} are then passed to quantisation block 1550 where they are quantised using quantisation parameter SPQP to produce quantised reconstructed transform coefficients l_{rec}. It should be noted that quantisation parameter SPQP used to quantise the reconstructed transform coefficients is not necessarily the same as the quantisation parameter PQP used to quantise the prediction error transform coefficients c_{err} in quantisation block 1525. In particular, a finer quantisation can be applied to reconstructed transform coefficients c_{rec} and a courser quantisation can

be applied to prediction error coefficients c_{err}. This ultimately results in a smaller reconstruction error (distortion) when a decoded image is formed in the decoder.

Quantised reconstructed transform coefficients l_{rec} are next supplied to inverse quantisation block 1560 where they are inverse quantised using quantisation parameter SPQP to form inverse quantised reconstructed transform coefficients d_{rec}. The inverse quantised reconstructed transform coefficients d_{rec} are then passed to inverse transform block 1565 where they are subjected to an inverse transform operation e.g. an Inverse Discrete Cosine Transform (IDCT). As a result of this operation, a block of reconstructed pixel values $l_c(x,y)$ is formed for the image block in question. The block of reconstructed pixel values $l_c(x,y)$ is subsequently stored in frame memory 1570. As subsequent blocks of the frame being encoded in S-frame format undergo the previously described encoding and local decoding operations, a decoded version of the current frame is progressively assembled in frame memory 1570 from where it can be accessed and used in intra prediction of subsequent blocks of the same frame or in inter (motion compensated) prediction of subsequent frames in the video sequence.

Operation of an S-frame decoder 1300 according to the second embodiment of the invention will now be described with reference to Figure 13. The bit-stream generated by the S-frame encoder 1500 according to the second embodiment of the invention and described above in connection with Figure 15 is received by decoder 1300 and is demultiplexed into its constituent parts. The decoder reconstructs a decoded version of the S-frame on a block-by-block basis. As previously described, an S-frame generally comprises both SP-coded and SI-coded image blocks. For SP-coded image blocks, the information in the received bit-stream comprises VLC encoded motion vector information and VLC encoded quantised prediction error transform coefficients l_{err}. For image blocks encoded in SI-format, the information in the received bit-stream comprises VLC encoded information relating to the intra prediction mode used to form the intra

prediction for the SI-coded block, as well as VLC encoded quantised prediction error transform coefficients I_{err}.

When decoding an SP-coded image block, demultiplexer 1310 first applies appropriate variable length decoding (VLD) to the received bit-stream to recover the motion vector information and quantised prediction error coefficients I_{err}. It then separates the motion vector information from the quantised prediction error coefficients I_{err}. The motion vector information is supplied to motion compensated prediction block 1370 and the quantised prediction error coefficients I_{err} recovered from the received bit-stream are applied to inverse quantisation block 1320. The motion vector information recovered from the received bit-stream is used in motion compensated prediction block 1370 together with pixel values of a previously reconstructed frame held in frame memory 1360 to form a prediction P(x,y) for the current block being decoded, in a manner analogous to that employed in encoder 1500.

When decoding an SI-coded image block, demultiplexer 1310 applies appropriate variable length decoding to the received intra prediction mode information and the quantised prediction error transform coefficients I_{err}. The intra prediction mode information is then separated from the quantised prediction error transform coefficients I_{err} and is supplied to intra prediction block 1380. The quantised prediction error transform coefficients I_{err} are supplied to inverse quantisation block 1320. The intra prediction mode information recovered from the received bit-stream is used in intra prediction block 1380 in conjunction with previously decoded pixel values of the current frame held in frame memory 1360 to form a prediction P(x,y) for the current block being decoded. Again, the intra prediction process performed in decoder 1200 is analogous to that performed in the corresponding encoder 1500 previously described.

For both SP- and SI- coded image blocks the quantised prediction error transform coefficients I_{err} recovered from the received bit-stream are inverse quantised in inverse quantisation block 1320 using quantisation parameter PQP to form inverse quantised prediction error transform

coefficients d_{err}. The inverse quantised prediction error transform coefficients d_{err} are applied to one input of summer 1325.

Once a prediction P(x,y) for the current block of the frame being decoded has been formed, either by motion compensated prediction in motion compensated prediction block 1370 or by intra prediction in intra prediction block 1380, switch 1385 is operated as appropriate to supply the predicted pixel values P(x,y) to transform block 1390. Here a forward transform, for example a Discrete Cosine Transform (DCT) is applied to the predicted block of pixel values P(x,y) to form transform coefficients c_{pred}. Transform coefficients c_{pred} are then supplied to the second input of summer 1325 where they are combined with the inverse quantised prediction error transform coefficients received from inverse quantisation block 1320, to form reconstructed transform coefficients c_{rec}. More specifically, the reconstructed transform coefficients are determined by adding together transform coefficients c_{pred} and inverse quantised prediction error transform coefficients d_{err} according to the relationship:

$$c_{rec} = c_{pred} + d_{err}.$$

The reconstructed transform coefficients c_{rec} are then passed to quantisation block 1330 where they are quantised to produce quantised reconstructed transform coefficients l_{rec} using quantisation parameter SPQP. The quantised reconstructed transform coefficients l_{rec} are, in turn, supplied to inverse quantisation block 1340 where they are inverse quantised using quantisation parameter SPQP to form inverse quantised reconstructed transform coefficients d_{rec}. The inverse quantised reconstructed transform coefficients d_{rec} are then passed to inverse transform block 1350 where they are subjected to an inverse transform operation, for example an Inverse Discrete Cosine Transform (IDCT). As a result of the inverse transformation applied in inverse transform block 1350, a block of reconstructed image pixels $l_c(x,y)$ is formed for the image block in question. The block of reconstructed pixels $l_c(x,y)$ is supplied to the video output of the decoder and to frame memory 1360, where the pixels are stored. As subsequent blocks of

the S-frame undergo the decoding operations described above, a decoded version of the current frame is progressively assembled in frame memory 1360. From there in can be accessed and used in the intra prediction of subsequent blocks of the same frame or in inter (motion compensated) prediction of subsequent frames in the video sequence.

In Fig. 16, an encoder according to a third embodiment of the invention is shown. In this embodiment, the transform coefficients c_{pred} undergo quantisation and inverse quantisation using the same quantisation parameter SPQP both in the encoder section (blocks 1625 and 1630) and in the decoder section (blocks 1692 and 1694). Therefore, the encoder does not introduce any additional quantisation error to the prediction loop, and error build-up in the prediction loop is thus effectively prevented. The blocks 1610, 1620, 1625, 1630, 1640, 1650, 1660, 1665, 1670, 1675, 1680, 1685, 1690 have similar functionality to the blocks 1510, 1520, 1525, 1530, 1540, 1550, 1560, 1565, 1570, 1575, 1580, 1585, 1590 presented in Fig. 15, respectively.

In Fig. 6, a decoder 600 according to an advantageous embodiment of the invention is described. Most of the elements of the decoder 600 are the same than of the decoder 1200 presented in Fig. 12. The operational blocks of the decoder 600 are arranged to decode the prediction blocks of the frames, wherein no switching means are not shown in Fig. 6. Other blocks 610, 615, 620, 630, 640, 650, 660 and 670 have similar functionality to the blocks 1210, 1220, 1230, 1240, 1250, 1260, 1290 and 1295 presented in Fig. 12, respectively.

In Fig. 9, a decoder 600 according to another advantageous embodiment of the invention is described. The decoder 600 presented in Fig. 9 is a modification from the decoder 600 shown in Fig. 6. The difference between the decoder presented in Fig. 9 and the decoder presented in Fig. 12 is that a normalisation block 680 is inserted between the demultiplexer 610 and one input of summing element 615. Other blocks 610, 615, 620, 630, 640, 650, 660 and 670 have similar

functionality to the blocks 1210, 1220, 1230, 1240, 1250, 1260, 1290 and 1295 presented in Fig. 12, respectively.

In Fig. 10, a decoder 600 according to yet another advantageous embodiment of the invention is described. Most of the elements of the decoder 600 are the same than of the decoder 1300 presented in Fig. 13. The operational blocks of the decoder 600 are arranged to decode the prediction blocks of the frames, wherein no switching means are not shown in Fig. 10. The other difference between the decoder presented in Fig. 13 and the decoder presented in Fig. 10 is that a normalisation block 680 is used instead of inverse quantisation block 1230. Other blocks 610, 615, 620, 630, 640, 650, 660 and 670 have similar functionality to the blocks 1310, 1325, 1330, 1340, 1350, 1360, 1370 and 1390 presented in Fig. 13, respectively.

The encoding of a video frame can be performed block-by-block basis such that in the same encoded video frame there can exist differently encoded areas. For example, some parts of the frame can be inter coded and some other parts of the frame can be intra coded. The above procedures are applied to each part of the frame appropriately, according to the encoding procedure of the part in question.

In addition to the transmission network, the request for the change of the bit stream transmission properties may also be originated by other parts of the transmission system. For example, the receiver may request the transmitting server to change the parameters for some reason. This request is delivered to the transmitting server *e.g.* via the transmission network.

Although H.26L is used as an example of a standard, embodiments of the present invention and any variations and modifications are deemed to be within the scope of the present invention.

Bit stream switching is not the only application in which the present invention can be applied. If one of the bit streams has a lower temporal resolution, e.g. 1 frame/sec, this bit stream can be used to provide fast-

forward functionality. Specifically, decoding from the bit stream with a lower temporal resolution and then switching to the bit stream with a normal frame rate would provide such functionality. Fig. 8 depicts two bit streams the second of which comprises only S-frames predicted from each other at intervals greater than the frame repetition interval of the first bit-stream. Furthermore, "Fast Forward" can start and stop at any location in the bit-stream. In the following, some other applications of the present invention are described.

Splicing and Random Access

The bit stream-switching example discussed earlier considered bit streams belonging to the same sequence of images. However, this is not necessarily the case in all situations where bit stream switching is needed. Examples include: switching between bit streams arriving from different cameras capturing the same event but from different perspectives, or cameras placed around a building for surveillance; switching to local/national programming or insertion of commercials in a television broadcast; video bridging, etc. The general term for the process of concatenating encoded bit streams is splicing.

When switching occurs between bit streams that belong to different sequence of images, this only affects the encoding of the S-frames used to switch between bit streams, i.e., the secondary S-frame S_{12} in Fig. 5. Specifically, the use of motion-compensated prediction of frames in one sequence of images using reference frames from a different sequence of images is not as efficient as when both bit streams belong to the same sequence of images. In this case, it is most likely that spatial prediction of the secondary S-frames frames would be more efficient. This is illustrated in Fig. 7 where the switching frame is an SI-frame using only spatial prediction, which identically reconstructs the corresponding SP-frame S_2. This method can be used as a random access mechanism into a bit stream and has further implications in error recovery and resilience as described in the following.

Error recovery

Multiple representations of a single frame in the form of S-frames predicted from different reference frames, e.g., predicted from the immediately preceding reconstructed frame and a reconstructed frame further back in time can be used to increase error resilience of an encoded video sequence and/or to improve recovery from errors in the bit-stream. This is illustrated in Fig. 14. In a situation where a packet loss occurs during streaming of a pre-encoded bit stream and a frame or slice is lost, the receiver informs the transmitter of the lost frame/slice and the transmitter responds by sending one of the alternative representations of the next S-frame. The alternative representation, *e.g.* frame S_{12} in Fig. 14, uses reference frames that have already been correctly received by the receiver. For slice based packetization and delivery, the sender could further estimate the slices that would be affected by such a slice/frame loss and update only those slices in the next S-frame with their alternative representations.

Similarly, and as mentioned earlier in the discussion of splicing, the secondary representation of the S-frame can be generated without using any reference frames, i.e., an SI_2-frame such as that shown in Fig. 14. In this case, the sender would send the secondary SI-frame, i.e., SI_2 instead of S_2 to stop error propagation. This approach could also be extended in a straight forward manner to slice-based encoding/packetization. More specifically, the server sends the slices in the next S-frame, which would be affected by the packet loss, from SI-frame.

Error resilience

The encoding of a video frame can be performed block-by-block basis such that in the same encoded video frame there can exist differently encoded areas. For example, some parts of the frame can be inter coded and some other parts of the frame can be intra coded. And as already discussed, the intra-block coding, since it doesn't employ any

temporal correlation, stops any error propagation which might be started due to transport impairments.

In lossy transport networks, an intra macroblock refresh strategy can provide significant error resiliency/recovery performance. In an interactive client/server scenario, the encoder on the server side decides to encode the frames/macroblocks either based on specific feedback received from the client, e.g., the exact location of the lost/corrupted frame/slice/macro block, or based on the expected network conditions calculated through negotiation or the measured network conditions. This kind of intra-macroblock update strategy improves the quality of the received video by providing error resiliency and error recovery. The optimal intra-macroblock update refresh rate, i.e., the frequency at which macroblocks are intra-coded, depends on the transport channel conditions, e.g., packet loss and/or bit error rate. However, when already encoded bit streams are sent, which is the case in typical streaming applications, the above strategy cannot be applied directly. Either the sequence needs to be encoded with the worst-case expected network conditions or additional error resiliency/recovery mechanisms are required.

From the earlier discussion concerning the use of S-frames in error recovery and splicing applications, it can be noted that S-frames or slices within them can easily be represented as SI-frames/slices that do not use any reference frames while still leading to identical reconstruction of the S-frame. This feature can be exploited in the adaptive intra refresh mechanism discussed above. First, a sequence of images is encoded with some predefined ratio of S-macroblocks. Then during the transmission, some of the S-macroblocks are sent in their secondary representation that is as SI-macro blocks. The number of S-macroblocks to be sent in SI representation can be calculated in a manner similar to the method used in the real-time encoding/delivery approach previously described.

Video Redundancy Coding

S-frames have other uses in applications in which they do not act as replacements of I-frames. Video Redundancy Coding (VRC) can be given as an example. The principle of the VRC method is to divide a sequence of pictures into two or more threads in such a way that all pictures in the sequence are assigned to one of the threads in a round-robin fashion. Each thread is coded independently. At regular intervals, all threads converge into a so-called sync frame. From this sync frame, a new thread series is started. If one of the threads is damaged e.g. because of a packet loss, the remaining threads typically stay intact and can be used to predict the next sync frame. It is possible to continue the decoding of the damaged thread, which leads to slight degradation in picture quality, or to stop the decoding of the damaged thread, which leads to a drop in the frame rate. Sync frames are always predicted from one of the undamaged threads. This means that the number of transmitted I-frames can be kept small, because there is no need for complete re-synchronization. For the sync frame more than one representation (P-frame) is sent, each one using a reference frame from a different thread. Due to the use of P-frames these representations are not identical. Therefore mismatch is introduced when some of the representations cannot be decoded and their counterparts are used when decoding the following threads. The use of S-frames as sync frames eliminates this problem.

It is obvious that the present invention is not limited to the above described embodiments but it can be modified within the scope of the appended claims.

Claims:

1. A method for transmitting video information, in which at least a first bit-stream (510) and a second bit-stream are formed from the video information, the first bit-stream (510) comprises a first set of frames comprising at least one video frame, and the second bit-stream (520) comprises a second set (520) of frames comprising at least one predictive video frame (524), at least partly different encoding parameters are used with encoding of the frames of said first bit-stream (510) and said second bit-stream (520), at least one frame of said first bit-stream (510) is being transmitted, and the transmission is switched over from said first bit-stream (510) to said second bit-stream (520), **characterized** in that in switching the transmission over from said first bit-stream (510) to said second bit-stream (520), the secondary bit-stream comprises at least one primary switching frame (523), a secondary switching frame (550) is transmitted, the secondary switching frame (550) having been encoded using the encoding parameters of the second bit-stream (520) and at least one reference frame from the first bit-stream (510), and said secondary switching frame (550) is used in place of the primary switching frame (523) as a reference frame to be used in the reconstruction of said at least one predictive video frame (524) of the second set of video frames.

2. The method according to claim 1, **characterized** in that the first bit-stream (510) comprises at least one primary switching frame (513).

3. The method according to claim 1 or 2, **characterized** in that the first bit-stream (510) comprises only one intra frame and one primary switching frame (513) to perform a changeover from one location of the video information to another location of the video information.

4. The method according to claim 1 or 2, **characterized** in that the first bit-stream (510) comprises only intra frames and primary switching frames (513) to perform fast forward operation to the video information.

5. The method according to any of the claims 2 to 4, **characterized** in that said primary switching frame (523) is a predictive video frame (524), in which prediction information comprises only intra prediction information.

6. The method according to any of the claims 1 to 5, **characterized** in that the primary switching frame (513) is formed so that transform coefficients c_{pred} are calculated and quantised to form quantised values of the transform coefficients l_{pred}, that quantised coefficients l_{err} for prediction error are defined, that dequantised reconstruction image coefficients d_{rec} are defined so that coefficients c_{rec} exist from which by quantisation and dequantisation, dequantised reconstruction image coefficients d_{rec} can be obtained, and that dequantised reconstruction image coefficients d_{rec} fulfil one of the following conditions:

$d_{rec} = d_{pred} + d_{err}$, or
$c_{rec} = c_{pred} + d_{err}$,

in which d_{err} are dequantised values of the prediction error, and
d_{pred} are the dequantised values of the quantised transform coefficients l_{pred}.

7. The method according to claim 6, **characterized** in that same quantisation parameters are used with quantisation of the transform coefficients l_{pred}, and with quantisation of prediction error.

8. The method according to claim 6, **characterized** in that different quantisation parameters are used with quantisation of the transform coefficients l_{pred}, than with quantisation of prediction error.

9. The method according to any of the claims 1 to 8, **characterized** in that said secondary switching frame (550) is used for recovering from transmission errors, wherein said primary switching frame (523) is a predictive video frame (524), in which prediction information comprises prediction information from previous video frames than the preceding frame of the predictive video frame (524).

10. The method according to any of the claims 1 to 8, **characterized** in that said secondary switching frame (550) is used for recovering from transmission errors, wherein said primary switching frame (523) is a predictive video frame (524), in which prediction information comprises only intra prediction information.

11. The method according to any of the claims 1 to 10, **characterized** in that both said at least one primary switching frame (523) and said secondary switching frame (550) produce the same reconstruction result of said at least one predictive video frame (524).

12. An encoder comprising means for forming at least a first bit-stream (510) and a second bit-stream from a video information, the first bit-stream comprises a first set of frames comprising at lest one video frame, and the second bit-stream comprises a second set (520) of frames comprising at least one predictive video frame (524), and means for using at least partly different encoding parameters with encoding of the frames of said first bit-stream (510) and said second bit-stream (520), means for transmitting at least one frame of said first bit-stream (510), and means for switching the transmission over from said first bit-stream (510) to said second bit-stream (520), **characterized** in that said means for switching the transmission over from said first bit-stream (510) to said second bit-stream (520) comprise means for encoding a secondary switching frame (550) using the encoding parameters of the second bit-stream (520) and reference frames from the first bit-stream (510) to enable to switch the transmission over from said first bit-stream (510) to said second bit-stream (510).

13. The encoder according to claim 12, **characterized** in that it comprises means (1670, 1675) for producing prediction information by using said reference frames, and means (1692, 1694) for performing quantisation and dequantisation to the prediction information.

14. A decoder for decoding a video information from a signal comprising frames from at least a first bit-stream (510) and a second bit-stream, which are formed from the video information, the first bit-stream comprises a first set of frames comprising at lest one video frame, and the second bit-stream comprises a second set (520) of frames comprising at least one predictive video frame (524), and at least partly different encoding parameters are used with encoding of the frames of said first bit-stream (510) and said second bit-stream (520), **characterized** in that the decoder comprises means for decoding a secondary switching frame (550), said secondary switching frame (550) having been encoded using the encoding parameters of the second bit-stream (520) and at least one reference frame from the first bit-stream (510), and added to said signal in place of a primary switching frame (523) as a reference frame to be used in the reconstruction of said at least one predictive video frame (524) of the second set of video frames, and that said means for decoding a secondary switching frame (550) comprise means for using decoding parameters of the second bit-stream (520) and reference frames from the first bit-stream (510).

15. The decoder according to claim 14, **characterized** in that the primary switching frame (513) comprises areas encoded by intra prediction using only spatial correlation, and areas encoded by inter prediction using motion compensation, wherein the decoder comprises means for using motion compensation information with reconstruction, means for using spatial correlation information with reconstruction, and switching means to perform the reconstruction of each area either by said means for using motion compensation information or by said means for using spatial correlation information, depending on the prediction method used by encoding of the respective area.

16. A signal representing encoded video information, and comprising frames from at least a first bit-stream (510) and a second bit-stream, which are formed from the video information, the first bit-stream comprises a first set of frames comprising at lest one video frame, and the second bit-stream comprises a second set (520) of frames

comprising at least one predictive video frame (524), at least partly different encoding parameters are used with encoding of the frames of said first bit-stream (510) and said second bit-stream (520), **characterized** in that in switching the transmission over from said first bit-stream (510) to said second bit-stream (520), the secondary bit-stream comprises at least one primary switching frame (523), said signal comprises a secondary switching frame (513, 523) having been encoded using the encoding parameters of the second bit-stream (520) and at least one reference frame from the first bit-stream (510), and said secondary switching frame (550) is in place of the primary switching frame (523) as a reference frame to be used in the reconstruction of said at least one predictive video frame (524) of the second set of video frames.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/FI 02/00004

A. CLASSIFICATION OF SUBJECT MATTER

IPC7: H04N 7/26, H04N 7/58
According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC7: H04N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

SE,DK,FI,NO classes as above

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-INTERNAL, WPI DATA, INSPEC, COMPENDEX, TDB

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

(54) Rate control for an MPEG transcoder without a priori knowledge of picture type

(57) A rate control system suitable for use with a digital video transcoder, such as one conforming to the MPEG standard. The proposed rate control system starts coding without a priori knowledge of the Group of Pictures (GOP) parameters, thereby avoiding a processing delay of about one GOP which would otherwise be incurred to extract the complete GOP structure information. In addition, the system avoids the need to store the data corresponding to the GOP, thereby reducing the memory required for transcoding. An initially allocated bit budget is gradually corrected as successive pictures are coded according to their picture types. Changes in the GOP structure of pre-compressed bitstreams can be addressed, for example, when switching channels or inserting commercials. Target rates with incorrect starting GOP parameters will converge within a few GOPs.

(54) Rate control for an MPEG transcoder without a priori knowledge of picture type

(57) A rate control system suitable for use with a digital video transcoder, such as one conforming to the MPEG standard. The proposed rate control system starts coding with any reasonable set of assumed Group of Pictures (GOP) parameters, thereby avoiding a processing delay of about one GOP which would otherwise be incurred to extract the complete GOP structure information from a pre-compressed bit stream. In addition, the system avoids the need to store the data corresponding to the GOP, thereby reducing the memory required for transcoding. Encoding of a first picture in a sequence or GOP begins without *a priori* knowledge of the picture type of subsequent pictures. A reasonable set of GOP parameters is assumed to determine an encoding bit budget. The bit budget is gradually corrected as successive pictures are coded according to their picture types. Changes in the GOP structure of pre-compressed bitstreams can be addressed, for example, when switching channels, inserting commercials, and the like. Target rates with incorrect starting GOP parameters will converge within a few GOPs.

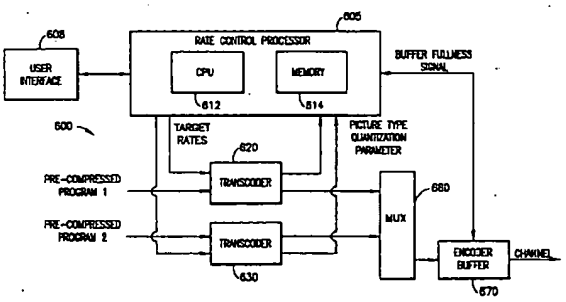

FIG.6

EP 1 005 232 A2

Description

BACKGROUND OF THE INVENTION

[0001] The present invention relates to a digital video transcoder and method for allocating bits for encoding successive pictures in a group of pictures (GOP) without *a priori* knowledge of the picture types in the GOP.

[0002] With digital video coding standards such as MPEG, input pictures can be coded in three different picture types, namely I, P and B. The three pictures require quite different numbers of bits for encoding because of the different nature of their temporal processing. Hence, an intelligent bit allocation strategy should assign a number of bits for encoding according to the picture's type. This implies a requirement of *a priori* knowledge of the picture types for a given bit budget. This requirement is not a problem for a standalone encoder as the encoder can determine the picture type for each input picture.

[0003] In fact, the encoder can plan ahead for the types of the input pictures. In contrast, a transcoder has no such *a priori* knowledge regarding a picture's type before actually processing the picture. This creates difficulty in allocating an appropriate number of bits for encoding pictures in a transcoder.

[0004] Accordingly, it would be desirable to have a method and apparatus for allocating bits for encoding pictures in a transcoder without *a priori* knowledge of the picture type. The system should avoid a processing delay of about one GOP which would otherwise be incurred to extract the complete GOP structure information from a pre-compressed bit stream. In addition, the system should avoid the need to store the data corresponding to the GOP, thereby reducing the memory required for transcoding.

[0005] The system should be compatible with both variable bit rate and constant bit rate bitstreams.

[0006] The system should be compatible with statistical multiplexing and remultiplexing systems.

[0007] The present invention provides an apparatus and method having the above and other advantages.

SUMMARY OF THE INVENTION

[0008] The present invention relates to a digital video transcoder and method for allocating bits for encoding successive pictures in a group of pictures (GOP) without *a priori* knowledge of the arrangement of picture types in the GOP.

1. Progressive Refresh Sequence:

[0009] A method for allocating bits for coding a progressive refresh sequence of pictures in a bitstream received at a digital video transcoder includes the steps of: (a) providing an assumed distance M' between a first picture of the bitstream and the next closest subsequent P-picture of the bitstream (in display order); (b) providing an assumed bit budget as a function of the assumed distance M'; (c) coding the first picture in accordance with the assumed bit budget; (d) determining a picture type of a second picture that immediately follows the first picture in the bitstream; (e) adjusting the assumed bit budget according to the picture type of the second picture; and (f) allocating bits for coding the second picture in accordance with the adjusted bit budget.

[0010] Thus, a bit budget for coding the pictures is initially assumed for the first picture, and the bit budget is updated as the second picture type is known. A target number of bits is allocated for coding each picture according to the bit budget. The first and second picture types generally indicate the picture distribution in the sequence.

[0011] The assumed bit budget is proportional to the assumed distance and a bit rate of the bitstream, and inversely proportional to a frame rate of the bitstream.

[0012] The pictures in the bitstream may form a progressive refresh sequence, where there is no GOP structure.

1.1 P-picture followed by B-picture:

[0013] When the first picture is a P-picture and the second picture is a B-picture, the method includes the further step of: determining an actual distance M" between the first picture and the next closest subsequent P-picture (in display order) according to the picture type of the first picture and the picture type of the second picture.

[0014] The actual distance M" is determined according to a difference between a temporal reference of the first picture, in a display order of the bitstream, and a temporal reference of the second picture, in the display order, plus one picture.

[0015] The method may include the further step of allocating bits for coding the remaining M"-1 pictures following the first picture in accordance with the adjusted bit budget.

[0016] The assumed bit budget is adjusted in the adjusting step (f) by +(M"-M')*"bit rate"/"frame rate", where "bit rate" is a bit rate of the bitstream, and "frame rate" is a frame rate of the bitstream.

1.2 P-picture followed by P-picture:

[0017] When the first and second pictures are P-pictures, the method includes the further step of: determining an actual distance M" between the first picture and the next closest subsequent P-picture (in display order)

according to the picture type of the first picture and the picture type of the second picture. The actual distance M" is determined according to a difference between a temporal reference of the second picture and a temporal reference of the first picture. The temporal references are determined in relation to a display order of the bitstream.

[0018] The assumed bit budget is adjusted in the adjusting step (f) by -(M'-1)*"bit rate"/"frame rate", where "bit rate" is a bit rate of the bitstream, and "frame rate" is a frame rate of the bitstream.

[0019] The method includes the further step of allocating bits for coding a series of M" pictures following an initial M" pictures that includes the first and second pictures in the bitstream in accordance with the adjusted bit budget. Thus, the adjustments to the bit budget in one series of pictures is carried over to the next series to allow correct coding of the next series.

2. Non-progressive Refresh Sequence:

[0020] Generally, the invention enables transcoding to begin by assuming a reasonable set of GOP parameters, including M, the distance between each I-picture and the next P-picture, and N, the GOP length. M and N are adjusted during transcoding as additional information becomes available regarding the GOP structure, e.g., the distribution of picture types in the GOP and the length of the GOP.

[0021] The assumed M can be corrected to the actual value within two frames, and the assumed N can be corrected to the actual value within one GOP. M should be verified, and adjusted if necessary, after each I- or P-picture, and N should be verified, and adjusted if necessary, after each I-picture. When M and/or N are adjusted, a bit rate R for coding the pictures, and n_I, n_P, and n_B, the remaining numbers of I, P and B-pictures in the current GOP, respectively, are also adjusted.

[0022] A method for allocating bits for coding a non-progressive refresh sequence of pictures in a bitstream received at a digital video transcoder, includes the steps of: (a) providing an assumed length N' of a particular group of pictures (GOP) of the bitstream; (b) providing an assumed bit budget as a function of the assumed length N'; providing an assumed distance M' between the first picture and the next closest subsequent P-picture of the bitstream (in display order); (c) allocating bits for coding a first picture of the particular GOP in accordance with the assumed bit budget, and N' and M'; (d) determining a picture type of a second picture that immediately follows the first picture; (e) adjusting the assumed bit budget according to the picture type of the second picture; and (f) allocating bits for coding the second picture in accordance with the adjusted bit budget.

[0023] The assumed bit budget is proportional to the assumed length N' and a bit rate of the bitstream, and inversely proportional to a frame rate of the bitstream.

[0024] M" may change within a GOP. Thus, the method may include the step of periodically verifying M" throughout the GOP. For example, M" may be calculated at every I-picture and/or P-picture that follows the first I-picture. The assumed bit budget is adjusted each time in accordance with M".

2.1 I-picture followed by I-picture:

[0025] When the first and second pictures are I-pictures, the method comprises the further step of: determining an actual distance M" between the first picture and the next closest subsequent I-picture of the bitstream according to the picture type of the second picture, and adjusting the assumed bit budget in accordance with M"

[0026] The actual distance M" is determined according to a difference between a temporal reference of the second picture, in a display order of the bitstream, and a temporal reference of the first picture, in the display order.

[0027] The adjusting step (e) comprises the step of: adjusting the assumed bit budget by -(N'-1)*"bit rate"/"frame rate", where "bit rate" is a bit rate of the bitstream, "frame rate" is a frame rate of the bitstream, and N=M=M".

[0028] The method comprises the further step of: allocating bits for coding the remaining pictures in the particular GOP following the second picture in accordance with the adjusted bit budget.

2.2 I-picture followed by P-picture:

[0029] When the first picture is an I-picture and the second picture is a P-picture, the method comprises the further steps of: determining an actual distance M" between the first picture and the next closest subsequent P-picture (in display order) according to the picture type of the second picture; and adjusting the assumed length N' of the GOP in accordance with the actual distance M" to provide an adjusted assumed length N"; wherein: the adjusting step (e) is responsive to the adjusted assumed length N'.

[0030] The assumed length N' of the particular GOP is adjusted in the adjusting step thereof by a factor, M(N'/M'), where M=M", to provide the adjusted assumed length N".

[0031] The adjusting step (e) comprises the step of: adjusting the assumed bit budget by a factor (N"- N')*"bit rate"/"frame rate", where "bit rate" is a bit rate of the bitstream, and "frame rate" is a frame rate of the bitstream.

[0032] The adjusting step (e) comprises the still further step of: adjusting the assumed bit budget by a factor, (M"-1')*"bit rate"/"frame rate", where "bit rate" is a bit rate of the bitstream, "frame rate" is a frame rate of the bitstream, and M=M".

[0033] Thus, both the GOP length and the distance M are used to adjust the bit budget, which in turn affects the target bit allocation for each picture.

[0034] The method includes the further step of allocating bits for coding the remaining pictures in the particular GOP following the second picture in accordance with the adjusted bit budget.

[0035] The method includes the further steps of determining if N">N or N"<N, where N is an actual length of the current GOP, after coding N" pictures in the current GOP. This is accomplished by observing the picture that is reached after coding N" pictures. For example, if the picture reached after coding N" pictures is a P-picture in the current GOP, then N"<N. If the picture reached after coding N" pictures is an I-picture, this signals the start of the next GOP, so N"=N. If an I-picture is coded before the N" are all coded, this indicates N">N. The already adjusted bit budget is then further adjusted based on whether N"<N or N">N, and bits are allocated for coding pictures in the bitstream following the N" coded pictures according to the further adjusted bit budget.

2.3 I-picture followed by B-picture:

[0036] When the first picture is an I-picture and the second picture is a B-picture, the method comprises the further steps of: determining an actual distance M" between the first picture and the next closest subsequent P-picture (in display order) according to the picture type of the second picture; and adjusting the assumed length N' of the GOP in accordance with the actual distance M" to provide an adjusted assumed length N"; wherein: the adjusting step (e) is responsive to the adjusted assumed length N'.

[0037] The assumed length N' of the particular GOP is adjusted in the adjusting step thereof by a factor, M(N'/M'), where M=M", to provide the adjusted assumed length N".

[0038] The adjusting step (e) comprises the step of: adjusting the assumed bit budget by a factor (N"- N')*"bit rate"/"frame rate", where "bit rate" is a bit rate of the bitstream, and "frame rate" is a frame rate of the bitstream.

[0039] The method comprises the further steps of: allocating bits for coding the remaining pictures in the particular GOP following the second picture in accordance with the adjusted bit budget.

[0040] Additionally, as discussed above, the already adjusted bit budget may be further adjusted based on whether N"<N or N">N, and bits may be allocated for coding pictures in the bitstream following the N" coded pictures according to the further adjusted bit budget.

[0041] Thus, the information learned regarding GOP length and M, the distance between I and/or P-pictures, in one GOP are used in coding the following GOPs. Target rates with incorrect starting GOP parameters will converge within a few GOPs.

[0042] Corresponding apparatus structures are also presented.

BRIEF DESCRIPTION OF THE DRAWINGS

[0043]

FIG. 1(a) illustrates a progressive refresh sequence of pictures in display order for continuing GOPs.

FIG. 1(b) illustrates the sequence of pictures of FIG. 1(a) in encoding order.

FIG. 2(a) illustrates a progressive refresh sequence of pictures in display order for an initial GOP in a bitstream followed by continuing GOPs.

FIG. 2(b) illustrates the sequence of pictures of FIG. 2(a) in encoding order.

FIG. 3 illustrates an MPEG-2 bitstream structure.

FIG. 4(a) illustrates a coding method for a progressive refresh picture sequence in accordance with the present invention.

FIG. 4(b) illustrates a coding method for a non-progressive refresh picture sequence in accordance with the present invention.

FIG. 4(c) illustrates a continuation of the coding method of FIG. 4(b) in accordance with the present invention.

FIG. 5 illustrates an estimated GOP length N" in accordance with the present invention.

FIG. 6 illustrates a rate control system in accordance with the present invention.

FIGs 7(a)-7(d) illustrate a C-language flowchart for implementing the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0044] The present invention relates to a digital video transcoder and method for allocating bits for encoding

successive pictures in a group of pictures (GOP) without *a priori* knowledge of the picture types in the GOP.

[0045] A novel rate control scheme and apparatus is presented for a digital video transcoder, such as one conforming to the MPEG standard, that requires no *a priori* (e.g., beforehand) knowledge of the picture types. Studies indicate that the picture target rates determined by the proposed rate control system with and without *a priori* knowledge of the picture types are very close.

[0046] MPEG defines three picture types in terms of temporal processing. They are the intra-frame coded picture (I-picture), forward temporal predictive coded picture (P-picture), and the bi-directional temporal predictive coded picture (B-picture). In MPEG video coding, pictures of an input video sequence are often grouped into groups of pictures (GOPs), where each GOP may contain one I-picture, a number of P-pictures, and optionally one or more B-pictures between I or P-pictures. The structure of a GOP can often be described by two variables: (1)N - the number of pictures in a GOP, or the GOP length, and (2) M - the distance between I or P-pictures. An example of a GOP with N = 15 and M = 3, in display order, is:

$$\cdots B_{m-2}B_{m-1}I_mB_{m+1}B_{m+2}P_{m+3}B_{m+4}B_{m+5}P_{m+6}\cdots P_{m+N-3}B_{m+N-2}B_{m+N-1}I_{m+N}B_{m+N+1}\cdots$$

where the subscripts are the picture's temporal references, and the consecutive numbers denote consecutively displayed pictures.

[0047] In general, I-pictures require many more bits for encoding than P- and B-pictures because I-pictures do not take advantage of temporal correlations between successive pictures (e.g., frames). B-pictures use the least numbers of bits for encoding because they have two temporal references and can therefore be temporally predicted more efficiently than P-pictures. P-pictures use a number of bits for encoding that is generally between that used for B- and I-pictures.

[0048] Clearly, the bits assigned to each picture for encoding should be based on its type, or its need. Furthermore, a GOP can have all the three types of pictures, and the organization of the three picture types within a GOP can be very flexible. Therefore, to wisely allocate a bit budget for encoding the pictures within a GOP, it is necessary to have *a prion* knowledge of the types of pictures in the GOP, or the GOP structure. This requirement is not a problem for a standalone encoder (i.e., an encoder that is not part of a transcoder) since the encoder can decide the type for each picture, and plan ahead in allocating bits based on the type and arrangement of pictures in a GOP. In other words, the information on GOP structure is available to the encoder.

[0049] In contrast to the standalone encoder, a transcoder converts a pre-compressed bitstream into another bitstream at a new rate. The inputs to a transcoder are pre-compressed bitstreams. Before processing a picture, the transcoder has no *a priori* knowledge of the picture's type, and hence no *a priori* knowledge of the GOP structures of the pre-compressed bitstreams.

[0050] Moreover, some transcoding schemes re-use the motion vector (MV) fields of the received pre-compressed bitstream for encoding the output bitstream at the new data rate. In this case, the picture types of the pre-compressed pictures are maintained. This means that the transcoder has no control of the GOP structures of the new output bitstreams.

[0051] Furthermore, with conventional schemes, it is possible for the GOP structure information to be extracted from the pre-compressed bitstreams. For example, after scanning a pre-compressed bitstream by the first two I-pictures, a transcoder should be able to determine the GOP structure. However, this requires a processing delay of about one GOP and a requirement of extra memory to hold all the bits for the GOP.

[0052] The present invention discloses a novel rate control system for a digital video transcoder, such as that conforming to the MPEG standard, with no requirement of *a priori* knowledge of the GOP structures of the pre-compressed bitstreams. A rate control scheme is disclosed that causes no processing delay and requires no extra memory. The scheme starts with any reasonable set of GOP parameters, and then gradually corrects these GOP parameters, if necessary, as successive pre-compressed pictures are received at the transcoder. The scheme compensates for changing GOP parameters used by the encoder(s).

[0053] Furthermore, we analyze the differences in target bit rates determined by the proposed rate control scheme with and without *a priori* knowledge of the GOP structure of the pre-compressed bitstream. We show that the target rates with and without *a priori* knowledge of GOP structure tend to be the same within only one or two GOPs. We demonstrate the differences in target rates in both numerical examples and real video sequences.

[0054] Below, in section 1, we will first overview the rate control for MPEG video coding. In section 2, we present the novel rate control for MPEG transcoder. In section 3, we analyze the differences in target rates determined by the proposed rate control with and without *a priori* knowledge of GOP structure. In section 4, we present the simulation and comparison results. Conclusions are discussed in section 5.

1. RATE CONTROL FOR MPEG VIDEO CODING

[0055] In MPEG video coding, pictures of all the three types (I, P or B) undergo the block Discrete Cosine Transform (DCT). The DCT coefficients are then quantized and variable length encoded. The resulting number of bits for each picture depends on the complexity of its corresponding block DCT image. I-pictures are coded without reference to any other pictures and, therefore, their DCT images usually require the most number of bits. P-pictures are first forward temporally predicted, and their temporal prediction difference images are then coded. The temporal prediction difference images usually contain much less information than the original pictures, and therefore need less bits for coding. B-pictures with two temporal references can often be better temporally predicted than P-pictures. Hence, B-pictures require the least number of bits. An intelligent bit allocation strategy should assign

the bits to a picture based on the picture's type, or the picture's complexity.

[0056] Let X_n be the complexity measure for picture n in a GOP of N pictures. In MPEG Test Model 5 (TM5), the complexity measure for a picture is defined as the product of the average quantization parameter used for the picture and the resulting number of bits. Logically, the bits allocated for a picture should be proportional to the picture's complexity measure, X_n, i.e.,

$$T_n = CX_n \qquad n = 0,1,...,N-1 \qquad (1)$$

where C is a constant. Here, we have assumed a linear model between the picture complexity measure and the number of bits required for coding. Furthermore, without any bias, a GOP of N pictures should be allocated

$$R_{GOP,N} = N \cdot \frac{bits\_rate}{frame\_rate} \text{ bits.} \qquad (2)$$

[0057] Clearly, the total number of bits assigned to all the pictures within a GOP of N pictures should be equal to $R_{GOP,N}$, i.e.,

$$R_{GOP,N} = \sum_{n=0}^{N-1} T_n = \sum_{n=0}^{N-1} CX_n = C\sum_{n=0}^{N-1} X_n \qquad (3)$$

[0058] From equations (1) and (3), we have

$$T_n = \frac{X_n}{\sum_{n=0}^{N-1} X_n} R_{GOP,N} \qquad (4)$$

[0059] Assume that all the pictures of the same type, i.e., I, P or B, have the same complexity measure, which is a reasonable assumption, at least for continuous scenes. We only need three complexity measures, one for each picture type. That is, X_I for I-pictures, X_P for P-pictures, and X_B for B-pictures. The target rate for frame n of type $t \in \{I,P,B\}$ and complexity measure $X_{n,t \in \{I,P,B\}}$ can therefore be written as:

$$T_n = \frac{X_{n,t}}{N_I X_I + N_P X_P + N_B X_B} R_{GOP,N} \qquad (5)$$

where N_I, N_P and N_B are the numbers of I, P and B-pictures, respectively, in the GOP. By eqn. (5), the pictures of the same type are assigned the same number of bits. This bit allocation strategy can be further modified by considering only the distribution of the remaining number of bits over the remaining pictures in the current GOP, i.e.,

$$T_n = \frac{X_{n,t}}{n_I X_I + n_P X_P + n_B X_B} R \qquad (6)$$

where n_I, n_P and n_B are, respectively, the remaining numbers of I, P and B-pictures in the current GOP, and R is the remaining number of bits, defined as

$$R \Leftarrow R - \sum_{n'=0}^{n-1} T_{n'} \qquad (7)$$

where $\Leftarrow$ denotes the assignment statement.

[0060] The remaining number of bits, R, needs to be updated at the beginning of each GOP as,

$$R = R + R_{GOP,N} = R + N \cdot \frac{bit\_rate}{frame\_rate} \qquad (8)$$

[0061] We now show that eqn. (6) also assigns the same number of bits to the pictures of the same type as long as the encoder can meet the target rate at each picture. For example, assume that frame n is a B-picture. Frame n can actually be either an I, P or B-picture. The encoder meets the nominal rate, T_n, for frame n. The target rate for frame $n+1$, Tn_{+1}, is therefore:

$$T_{n+1} = \frac{X_{s+1,t}}{n_I X_I + n_P X_P + (n_B - 1) X_B}(R - T_n) \quad (9a)$$

$$= \frac{X_{s+1,t}}{n_I X_I + n_P X_P + (n_B - 1) X_B}\left(R - \frac{X_B}{n_I X_I + n_P X_P + n_B X_B} R\right) \quad (9b)$$

$$= \frac{X_{s+1,t}}{n_I X_I + n_P X_P + (n_B - 1) X_B}\left(\frac{n_I X_I + n_P X_P + n_B X_B - X_B}{n_I X_I + n_P X_P + n_B X_B}\right) R \quad (9c)$$

$$= \frac{X_{s+1,t}}{n_I X_I + n_P X_P + n_B X_B} R \quad (9d)$$

[0062] As seen, the target rate for frame n+1, Tn_{+1}, depends upon only the type of frame n+1, i.e., $Xn_{+1}t$. In other words, regardless of the type (either I, P or B) of frame n, frame n+1 will be assigned the same number of bits according to its own type. This implies that equations (5) and (6) are actually the same if the pictures of the same type have the same complexity measure, and the encoder can meet the target rate at each picture. Equation (6) is, however, more practical as it addresses the changes in picture complexity measures and the difference between the target and actual rates at each picture.

[0063] In practice, the quality requirement may not be the same for the different picture types. For example, B-pictures are never used as references in the future temporal prediction. Hence, they can tolerate more distortion than I- and P-pictures. To address this concern of different quality requirements, we can further introduce a weighting factor for each picture type, $K_{n,t}$, as

$$T_n = CX_{n,t} / K_{n,t} \quad (10)$$

where

$$K_t = \begin{cases} K_I & for\ I\ picture \\ K_P & for\ P\ picture \\ K_B & for\ B\ picture \end{cases} \quad (11)$$

[0064] The bit allocation strategies (e.g., equations 5 and 6) now become:

$$T_n = \frac{X_{s,t}/K_{s,t}}{N_I X_I / K_I + N_P X_P / K_P + N_B X_B / K_B} R_{GOP,N} \quad (5b)$$

and

$$T_n = \frac{X_{s,t}/K_{s,t}}{n_I X_I / K_I + n_P X_P / K_P + n_B X_B / K_B} R \quad (6b)$$

[0065] Equation (6b) is the same one used in MPEG TM5 when $K_I = K_P = 1$ and $K_B = 1.4$.

[0066] The bit allocation strategy (e.g., equations 5 and 6) requires *a priori* knowledge of GOP structure, i.e., the numbers of I-, P- and B-pictures in a GOP, N_I,N_P,and N_B, or the remaining number of I, P and B-picture in the current GOP, n_I,n_P and n_B Given a pair of GOP structure variables, N and M, we can have $N_I = 1$, $N_P = NIM-N_I$ and $N_B = N-N_P-N_I$. FromN_I,N_P,and N_B, we can also calculate n_I,n_P and n_B during encoding. For example, if a P-picture is just encoded, the remaining number of P-pictures in the current GOP is decreased by 1, i.e., $n_P = n_P$-1.

[0067] As discussed, this information is unfortunately not available for a transcoder. Without a complete knowledge of the GOP structure of pre-compressed bitstreams, it is difficult to perform an intelligent bit allocation strategy. A transcoder can learn the GOP structure of a pre-compressed bitstream by scanning the bitstream through the first two I-pictures. This, however, may cause a processing delay by one GOP and require extra memory for holding the bits of the GOP.

2. RATE CONTROL FOR A TRANSCODER

[0068] We now describe a novel rate control system for a transcoder with no requirement of *a priori* knowledge of GOP structure of the pre-compressed bitstreams. The proposed rate control system causes no processing delay and requires no extra memory. It can start with any reasonable set of GOP parameters, and then gradually corrects these GOP parameters as encoding progresses, if necessary.

[0069] Table 1(a) shows all the possible picture organizations where the subscripts are the pictures' temporal references, in display order. Each picture refers to a frame or field, or portion thereof. For example, the present invention is compatible with coding of video object planes (VOPs) as known from the MPEG-4 standard. The present invention is compatible with both progressive scan and interlaced scan video.

[0070] For the sequence GOP(N=M=1), there are only I-pictures. For the sequence GOP(N,M=1), there are only I- and P-pictures. For the sequence GOP(N=M), there are only I- and B-pictures. For the sequence GOP(N,M), there are I-, P- and B-pictures. For the sequence GOP(M=1), there are only P-pictures. For the sequence GOP(M), there are only P- and B-pictures.

[0071] The first four cases in Table 1(a) are non-progressive refresh sequences since they have I-pictures. The last two case (e.g., GOP(M=1) and GOP(M)) have no I-pictures, but use a progressive refresh where P-pictures contain I-slices. An I-slice is an intra-coded portion of a picture typically extending horizontally across the picture. The location of the I-slice changes in successive P-pictures to refresh a different portion of the successive P-pictures. Hence, with a progressive refresh, the GOP length N is no longer necessary in describing the picture organization. Nevertheless,M can still be used to indicate the distance between two consecutive P-pictures. The "distance" is measured in terms of number of pictures herein, although any corresponding measure, such as time, can be used. In terms of bit allocation, we can set$N = M$, $N_I = 0$ (as there is no I pictures for progressive refresh sequence), $N_P = N/M\text{-}N_I = 1$,$N_B = N\text{-}N_P\text{-}N_I = N\text{-}N_P$ in $N = M$ bit allocation equation (5) for progressive refresh.

[0072] Table 1(b) shows the corresponding forms of picture organizations in encoding order (e.g., in bitstream order) for the picture sequences of Table 1(a). If $M = 1$ (there is no B-picture in the sequence), the encoding order is actually the same as the display order. On the other hand, if $M \neq 1$ (e.g., there are M -1 B-pictures between successive I- or P-pictures), the future I- or P-pictures have to be encoded before the M -1 B-pictures.

[0073] Furthermore, for the first GOP (e.g., initial or non-continuous GOP, designated GOP_0) in a video sequence with $M \neq 1$, there may not be any B-pictures before the first I or P-picture, as shown in Table 2(a). Table 2(a) shows possible picture organizations of the first (initial) GOP after a sequence header in a video stream, in display order. The initial GOPs are designated GOP_0. For example, for GOP_0(M), the first picture is designated P_0. An initial GOP may be processed by a transcoder when a bitstream is initially acquired or re-acquired, for example.

[0074] Table 2(b) shows the first GOP of Table 2(a) in encoding order. Here, an initial GOP with $M \neq 1$ is shown, where the second I- or P-picture is encoded before any B-picture. The second picture in encoding order will be either an I or P-picture, as shown in Table 2(b).

Table 1(a)

GOP(N = M = 1):	... I_{m-1} I_m I_{m+1} I_{m+2} ...
GOP(N,M = 1):	... P_{m-1} I_m P_{m+1} P_{m+2} ... P_{m+N-1} I_{m+N} P_{m+N+1} ...
GOP(N = M):	... B_{m-1} I_m B_{m+1} B_{m+2} ... B_{m+M-1} I_{m+M} B_{m+M+1} ...
GOP(N,M):	... B_{m-1} I_m B_{m+1} B_{m+2} ... B_{m+M-1} P_{m+M} B_{m+M+1} ... P_{m+2M} ... I_{m+N} ...
GOP(M = 1):	... P_{m-1} P_m P_{m+1} P_{m+2} ...

[0075] FIG. 1(a) illustrates a progressive refresh sequence of pictures in display order for continuing GOPs. Specifically, the progressive refresh sequence GOP(M) from Table 1(a) is illustrated for a distance between P-pictures of M=3, and for a continuing (e.g., non-initial, or open) GOP. Additionally, the GOP length is N=M=3 pictures.

[0076] In the video sequence 100, a first GOP 110 includes pictures P_7, B_8 and B_9, while a second GOP 120 includes pictures P_{10}, B_{11} and B_{12}, and a third GOP 130 includes pictures P_{13}, B_{14}, and B_{15}. The subscript "7" for P_7 is chosen simply as an example. A subsequent GOP includes P_{16} as its first picture.

[0077] FIG. 1(b) illustrates the sequence of pictures of FIG. 1(a) in encoding order. The encoded video sequence

150 corresponds to the sequence GOP(M) from Table 1(b). Since B_8 and B_9 are temporally backward predicted from P_{10}, B_8 and B_9 follow P_{10} in the encoded sequence 150. Similarly, B_{11} and B_{12} follow P_{13}, and B_{14} and B_{15} follow P_{16}.

[0078] FIG. 2(a) illustrates a progressive refresh sequence of pictures in display order for an initial GOP in a bitstream followed by continuing GOPs. Specifically, the progressive refresh sequence $GOP_0(M)$ from Table 2(a) is illustrated for a distance between P-pictures of M=3, and a GOP length is N=M=3 pictures.

[0079] In the video sequence 200, a first, initial GOP 210 includes pictures P_0, B_1 and B_2, while a second, continuing GOP 220 includes pictures P_3, B_4 and B_5, and a third, continuing GOP 230 includes pictures P_6, B_7, and B_8. A subsequent GOP includes P_9 as its first picture.

[0080] FIG. 2(b) illustrates the sequence of pictures of FIG. 2(a) in encoding order. The encoded video sequence 250 corresponds to the sequence $GOP_0(M)$ from Table 2(b). Since B_1 and B_2 are temporally backward predicted from P_3, B_1 and B_2 follow P_3 in the encoded sequence 250. Essentially, the B-pictures that would use P_0 for backward temporal prediction are not present, so P_3, B_1 and B_2 follow P_0. Similarly, B_4 and B_5 follow P_6, and B_7 and B_8 follow P_9.

[0081] FIG. 3 illustrates an MPEG-2 bitstream structure. A sequence layer 300 includes a sequence header 302, followed by a number of GOPs, e.g., GOPs 304, 306 and 308, followed by additional sequence headers and GOPs, including sequence header 312. A GOP layer 320 includes a GOP header 322, followed by data from a number of pictures, e.g., pictures 324, 326 and 328. A picture layer 330 includes a picture header 332, followed by a number of slices, e.g., slices 334 and 336. A slice layer 335 includes a slice header 337, followed by a number of macroblocks, e.g., macroblocks 338 and 339. A macroblock layer 340 includes a macroblock header 342, followed by a number of blocks, e.g., blocks 344, 346 and 348. A block layer includes DCT coefficients 352.

[0082] For a given pre-compressed bitstream, the transcoder can start processing anywhere in the bitstream. Initially, the transcoder will skip all the bits until reaching the sequence header 300, which contains information about picture size, frame rate, and the like. Optionally, the GOP header 322 may follow the sequence header 302 (for non-progressive refresh only). If a GOP header does follow the sequence header 302, the bitstream is definitely a non-progressive refresh sequence. Otherwise, the bitstream may, or may not, be of progressive refresh. The picture layer 330 then follows.

[0083] The picture immediately following the sequence header (i.e., the first picture in the GOP, i.e., picture 324) can be either an I or P-picture. If it is an I-picture, the bitstream is a non-progressive refresh sequence. Otherwise, the bitstream is a progressive refresh sequence. The bit allocation procedures of the present invention for bitstreams with progressive refresh and non-progressive refresh are slightly different. In the following two subsections, we detail both.

[0084] The following notation will be used:

N,M - the actual values (i.e., reflecting the true GOP structure) of the GOP parameters, N and M;

N',M' - the initial assumed values of the GOP parameters, N and M;

N'',M'' - the (current) updated values of the GOP parameters, N and M;

N_I,N_P,N_B - the numbers of I, P and B pictures, respectively, in a GOP;

n_I,n_P,n_B - the number of I, P and B pictures, respectively, remaining in the current GOP;

R - the number of remaining bits for the current GOP;

bit_rate - the effective output bit rate in bits per second that may be variable (we assume that bit_rate is available to transcoder);

frame_rate - the *effective* frame_rate in frames per second, which may not be the same as the frame_rate embedded in the sequence header due to the presence of the repeat_first_field (we assume that frame_rate is available to transcoder);

div - Integer division with truncation of the result toward zero; and

⇐ - Assignment statement (from the right to the left).

(i) Progressive Refresh

[0085] For a progressive refresh sequence, there will be no GOP header, and the first picture immediately following the sequence header (in encoding order) has to be a P-picture. See sequences GOP(M=1) and GOP(M) in Table 1(b) and $GOP_0(M)$ in Table 2(b). Instead of waiting to correctly determine M, we proceed to process the first P-picture with any reasonable assumed M, say M', and a bit budget of $R = R_{GOP,M} = M' \cdot (bit\_rate/frame\_rate)$ bits in calculating the target bit rate (see eqn. 6). Note that with M', we have $N_P = 1$ and $N_B = M' - N_P$. For example, refer to FIG. 1(a) or 2(a), where the distance between P-pictures is M'=3, the number of P-pictures in a GOP is one, and the

number of B-pictures in a GOP is two.

[0086] The second picture in the GOP, in encoding order, can be either a B-picture ($GOP(M)$) or a P-picture ($GOP(M = 1)$ or $GOP_0(M)$), as shown in Tables 1(b) and 2(b), respectively.

[0087] In either case, we can calculate the actual value of M from the temporal references of the first two pictures of a GOP in encoding order. Specifically, let *temp_ref_picture*1 and *temp_ref_picture*2 be the temporal references for the first and second pictures, respectively. The temporal reference may be embedded in the picture header. If the second picture is a B-picture, e.g., sequence ($GOP(M)$) in Table 1(b), the correct value of M, say M', is:

$$M' = temp\_ref\_picture\,1 - temp\_ref\_picture\,2 + 1. \qquad (12)$$

[0088] For example, in FIG. 1(b), consider P_{10} and B_8 as first and second pictures, respectively, in an encoded video sequence. Then, temp_ref_picture1 is the temporal reference of P_{10} (e.g., "10"), temp_ref_picture2 is the temporal reference of B_8 (e.g., "8"), and M"=10-8+1=3. Note that the temporal references refer to the display order of the pictures.

[0089] Otherwise, if the second picture is a P-picture, e.g., sequence ($GOP(M = 1)$ in Table 1(b), or sequence $GOP_0(M)$) in Table 2(b), the correct value of the distance between P-pictures is:

$$M' = temp\_ref\_picture\,2 - temp\_ref\_picture\,1. \qquad (13)$$

[0090] For example, in FIG. 2(b), consider P_0 and P_3 as first and second pictures, respectively, in an encoded video sequence. Then, temp_ref_picture1 is the temporal reference of P_0 (e.g., "0"), temp_ref_picture2 is the temporal reference of P_3 (e.g., "3"), and M"=3-0=3.

[0091] With a correct value of M, say M', the remaining number of bits, R (see eqn. 7), is adjusted accordingly. Specifically, if the second picture is a B-picture, as with sequence ($GOP(M)$) in Table 1(b), R is updated as

$$R = R + (M' - M) \cdot \frac{bit\_rate}{frame\_rate}. \qquad (14)$$

[0092] As seen, for $M'' > M'$ (actual distance between P-pictures is greater than assumed distance), the first P-picture has been assigned relatively more bits and, therefore, the remaining pictures will be assigned relatively fewer bits. For $M'' < M'$ (actual distance between P-pictures is less than assumed distance), the first P-picture has been assigned relatively fewer bits and the remaining pictures will be assigned relatively more bits.

[0093] On the other hand, if the second picture is a P-picture, e.g., as with sequences ($GOP(M = 1)$ in Table 1(b), or sequence $GOP_0(M)$) in Table 2(b), there are no B-pictures between the first two P-pictures in the encoded video sequence. Hence, the bits allocated for the assumed M'-1 B-pictures between two P pictures (in encoding order) should be subtracted from R, as

$$R = R - (M' - 1) \cdot \frac{bit\_rate}{frame\_rate}. \qquad (15)$$

[0094] We then set $M = M'$. If the transcoder can meet the target rate at each picture, at the end of the first M pictures, we will have $R = 0$. Hence, we will have a bit budget $R = R_{GOP,M} = M \cdot (bit\_rate/frame\_rate)$ bits for next M pictures. To address any subsequent change in M, we check the value of M after each P-picture.

[0095] FIG. 4(a) illustrates a coding method for a progressive refresh picture sequence in accordance with the present invention. The aforementioned bit allocation technique for progressive refresh sequences is summarized as follows.

[0096] At block 400, the pre-compressed digital video bitstream is received at a transcoder. The coded pictures are in an encoding order. At block 405, the bitstream is processed to detect a sequence header. At block 410, the picture type of the first picture following the sequence header is determined. If it is an I-picture, processing continues at block "A" in FIG. 4(b).

[0097] If the first picture following the sequence header is a P-picture, processing continues at block 415, where an assumed distance M' is set. M' is defined herein as a distance between the first picture following the sequence header, and the next P-picture in the display order. At block 420, an assumed bit budget R is determined based on M', the bit rate and the frame rate of the bitstream. At block 422, a target bit rate T is set in accordance with eqn. 6b. At block 425, the first picture is coded according to T. At block 430, if the next picture (e.g., the second picture) is a P-picture, the actual distance M" is determined at block 435 according to eqn. 13. At block 440, the bit budget R is adjusted using eqn. 15. At block 445, M is set to M".

[0098] At block 430, if the next picture in the sequence, e.g., the second picture, is a B-picture, the actual distance M" is determined at block 450 according to eqn. 12. At block 455, the bit budget R is adjusted using eqn. 14. At block 460, M is set to M". At block 462, the target bit rate T is set (e.g., using eqn. 6). Next, the remaining M-1 pictures (including the second picture) are coded according to T at block 465.

[0099] At block 470, the next picture is processed. This may be the first picture of the next series of M" pictures, for example. At block 475, processing returns, e.g., to block 415. However, note that, instead of blindly assuming the length and bit budgets at blocks 415 and 420, respectively, the values determined in the previous series of M" pictures may be used. Nevertheless, the actual distance M" may be verified, e.g., after every P-picture.

(ii) Non-Progressive Refresh

[0100] For non-progressive refresh, there may be an optional GOP header following the sequence header. Then, a picture layer follows. The first picture immediately following a sequence header, or a GOP header, has to be an I-picture. For an intelligent bit allocation, we need to know both N and M. We can, however, start transcoding of a pre-compressed bitstream with any reasonable pair of N and M, say N' and M', and with a bit budget of $R = R_{GOP,N} = N' \cdot (bit\_rate/frame\_rate)$ bits in determining the target rate for the first I-picture (see eqn. 6).

[0101] Note that with N' and M', we have $N_I = 1, N_P = N'/M' - N_I$ and $N_B = N' - N_I - N_P$. The actual value of M, say M'', can then be calculated from the temporal references of the first two pictures, similar to progressive refresh. If the second picture is an I- or P-picture, eqn. (13) is used in calculating the value of M. Otherwise, the second picture is a B-picture, and eqn. (12) is used. We then set $M = M''$.

[0102] If the second picture is also an I-picture ($GOP(N = M = 1)$ and $GOP_0(N = M)$), we actually have had the correct N value too, i.e., $N = M$, as shown in Table 1(b) and 2(b). The remaining number of bits, R (see eqn. 7), is adjusted accordingly, as:

$$R = R - (N' - 1) \cdot \frac{bit\_rate}{frame\_rate}. \qquad (16)$$

[0103] This is because there are no P- and B-pictures between the first and second I-pictures. Hence, the bits allocated to the assumed N-1 (P and B) pictures between two I pictures should be deducted from R.

[0104] If the second picture is not an I-picture, it will take somewhat longer to obtain the correct value of N, by about one GOP. The assumed N' may not be dividable by the correct M. Hence, we need to adjust N', and accordingly, n_P and nB. We adjust N to N'' with the correct M value, and n_P and n_B, as

$$N'' = (N'/M) \cdot M; \qquad (17)$$
$$n_p = N''/M - 1; \text{ and} \qquad (18a)$$
$$n_B = N''/M - n_p - 1. \qquad (18b)$$

[0105] We then adjust the remaining number of bits, R (see eqn. 7), with N'' as

$$R = R + (N'' - N') \cdot \frac{bit\_rate}{frame\_rate}. \qquad (19)$$

[0106] Furthermore, if the second picture is a P-picture, GOP(N,M=1) or GOP_0(N,M) as shown in Tables 1(b) and 2(b), the remaining number of bits, R, needs additional adjustment as

$$R = R - (M - 1) \cdot \frac{bit\_rate}{frame\_rate} \qquad (19b)$$

[0107] This is because there are M-1 fewer B-pictures than assumed before the first I-picture.

[0108] There can be only three scenarios, i.e.,

1. N''=N, that is, the current GOP length N'' is equal to the actual GOP length N;
2. N''<N, that is, the current GOP length N'' is smaller than the actual GOP length N; and
3. N''>N, that is, the current GOP length N'' is greater than the actual GOP length N.

[0109] Clearly, if $N = N''$, we will reach an I-picture after processing N'' pictures - the beginning of the second GOP. We have a correct N, so we maintain it.

[0110] If $N'' < N$, the GOP length is shorter than the actual GOP length. The assumed GOP length is at least M pictures shorter than the actual GOP length because of the nature of the GOP structure (see Tables 1(b) and 2(b)). Here, we have assumed that the value of M will not change within a GOP.

[0111] Note that M may be checked periodically within a GOP, such as after each I- and/or P-picture, if there is a chance that M may change within a GOP. Additionally, if M changes within the GOP, N and R should be adjusted accordingly.

[0112] We extend the GOP of N'' pictures by M additional pictures, i.e.,

$$N'' = N'' + M, \qquad (21)$$

and adjust R by adding $R_{GOP,M}$ additional bits for the M additional pictures, i.e.,

$$R = R + R_{GOP,M} = R + M \cdot \frac{bit\_rate}{frame\_rate}. \qquad (22)$$

[0113] If the extended GOP length is still shorter than the actual GOP length, we repeat the above procedure until reaching the end of the actual GOP.

[0114] If $N'>N$, the GOP length is longer than the actual GOP length. At the end of the actual GOP, we will have a correct GOP length, N, and we will use the correct length N for the rest of the GOPs. Since the assumed GOP length (N') is longer than the actual GOP length (N), there will be some bits left over from the first actual GOP for coding pictures in the second actual GOP. Hence, the bits allocated for the second actual GOP need to be adjusted as:

$$R = 2R_{GOP,N'}-(R_{GOP,N'}-R)=2N\cdot\frac{bit\_rate}{frame\_rate}-(N'\cdot\frac{bit\_rate}{frame\_rate}-R) \qquad (23)$$

where $R_{GOP,N'}-R$ is the number of bits used for encoding the first N pictures.

[0115] FIG. 4(b) illustrates a coding method for a non-progressive refresh picture sequence in accordance with the present invention. The aforementioned bit allocation technique for non-progressive refresh sequences is summarized as follows.

[0116] At block "A" processing continues from block "A" of FIG. 4(a). At block 500, an assumed GOP length N' is provided, and at block 502, an assumed distance M' is provided. M' here is a distance between the first I-picture in a GOP and the next I- or P-picture in the display order. This distance may or may not be the same as the GOP length. Generally, compatible values of N' and M' should be selected, for example, N'>M' and N' is dividable by M'. At block 504, an assumed bit budget R is provided according to N', and at block 505, a target bit rate T is determined, e.g., using eqn. 6, for coding the pictures in the GOP.

[0117] At block 506, the first picture in the GOP is coded. At block 508, if the next picture, e.g., the second picture of the GOP, is an I-picture, processing continues at block 510, where the actual distance M" is determined using eqn. 13. At block 514, M is set to M", and at block 516 N is set to M since the distance M" and the GOP length are the same.

[0118] At block 518, the bit budget is adjusted according to eqn. 16, and at block 524 processing returns, e.g., to block 500. Note that, at blocks 500 and 502, N' and M' can be set to the values N and M, respectively, of the previous GOP. N and M can be verified for each GOP.

[0119] At block 508, if the next picture, e.g., the second picture in the GOP, is a P-picture, processing continues at block 530, where the actual distance M" is determined using eqn. 13. At block 532, M is set to M". At block 534, the GOP length is updated as N"=M[N'/M']. At block 536, the remaining number of B-pictures in the current GOP, n_B, is adjusted using eqn. 18. At block 538, the bit budget is adjusted using eqn. 19, and at block 540, the bit budget is adjusted again, using eqn. 19b, and processing continues at "B".

[0120] At block 508, if the next picture, e.g., the second picture in the GOP, is a B-picture, processing continues at block 542, where the actual distance M" is determined using eqn. 12. At block 544, M is set to M". At block 546, the GOP length is updated as N"=M[N'/M']. At block 548, the remaining number of B-pictures in the current GOP, n_B, is adjusted using eqn. 18. At block 550, the bit budget is adjusted using eqn. 19, and processing continues at "B".

[0121] FIG. 4(c) illustrates a continuation of the coding method of FIG. 4(b) in accordance with the present invention. Processing continues at "B" from FIG. 4(b). At block 552, the target bit rate T is set using eqn. 6, and at block 554, a counter is set to one. At block 556, the next picture in the GOP is coded. At block 558, counter is incremented. "Counter" essentially tracks the position of the current picture in the GOP. At block 560, a determination is made as to whether the end of the current GOP has been reached. If so, a determination is made at box 562 as to whether counter=N". If so, this indicates that N" is the same as N, the actual GOP length. Essentially, the assumed GOP length N" turned out to be correct. Processing continues at block 566, where the next GOP is coded.

[0122] If the condition at block 562 is false, this indicates that N">N (e.g., the assumed GOP length N" is too large), and the bit rate is adjusted at block 564 using eqn. 23. Processing continues at block 566, where the next GOP is coded.

[0123] If the end of the current GOP has not been reached yet at block 560, a determination is made at block 570 as to whether counter=N". If not, process continues at block 556. If counter=N" at block 570, this indicates that N"<N (e.g., the assumed GOP length N" is too small). At block 572, the assumed GOP length N" is incremented by M. at block 574, the bit budget is adjusted using eqn. 22, at block 576, the next M pictures are coded, and at block 578 a determination is made as to whether the end of the current GOP has been reached. If not, processing continues at block 572, where the assume GOP length N" is again incremented by M.

[0124] When the end of the current GOP is reached, at block 578, processing continues at block 566, where the next GOP is coded.

[0125] The coding method of FIG. 4(c) can be understood further with reference to FIG. 5.

[0126] FIG. 5 illustrates an estimated GOP length N" in accordance with the present invention. A sequence of pictures is shown generally, in display order, at 500. A first GOP, GOP(N,M) 520, begins at an I-picture 502, and the next GOP 580 begins at an I-picture 510. A subsequent GOP begins at an I-picture 515.

[0127] The estimated GOP length N" 530 is equal to the actual GOP length N. However, the estimated GOP length N" 540 is less than the actual GOP length N by two M distances 542 and 544. In particular, the estimated GOP length N" 540 extends from the I-picture 502 to a P-picture 504, the M-distance 542 extends from the P-picture 504 to a P-picture 506, and the M-distance 544 extends from the P-picture 506 to the I-picture 510. The estimated GOP length N" 550 extends from the I-picture 502 to a P-picture 512, and is therefore greater than the actual GOP length N.

Generally, N" should be selected initially as a multiple of the estimated distance between I and/or P-pictures.

[0128] A C-language pseudo code for the bit-allocation procedure, both with and without progressive refresh, is shown below. The same algorithm is represented by the flowchart in FIGs 7(a)-7(d). A single bitstream can switch arbitrarily between the progressive refresh and I-picture (non-progressive) refresh modes.

```
/*
* The following is a brief description of the variables:
*
* N     Estimated open GOP length (pictures)
* M     Number of consecutive B-pictures plus 1
* N'    Initial guess for the GOP length in pictures
* M'    Initial guess for the number of consecutive B-pictures plus 1
* N"    Updated estimate of the open GOP length
* M"    Updated estimate of number of consecutive B-pictures plus 1
* R     Number of bits remaining in this GOP
* n     Number of pictures remaining in this GOP
* ni    Number of I-pictures remaining in this GOP
* np    Number of P-pictures remaining in this GOP
* nb    Number of B-pictures remaining in this GOP
* Xi    Complexity of an I-picture
* Xp    Complexity of a P-picture

         * in original picture type (I, P or B). This function returns
         * the actual size of the transcoded picture in bits. This func-
         * tion updates the complexity (Xi, Xp, Xb) for each picture type.
         */
        R -= transcode_picture(pict_type, T);
}
```

[0129] This pseudo-code is expressed in a flowchart 700 in FIGs 7(a)-7(d). Note that ni, np and nb are the same as n_I, n_P and n_B, respectively, as used elsewhere.

[0130] Box 702 denotes searching for the video sequence header in order to obtain parameters necessary to begin transcoding. Initialization for the loop over transcoded pictures occurs here.

[0131] Box 704 is the call to "get_pict_header()" which consumes the picture header and all higher level syntax. The picture type (I, P or B picture) is returned. "GOP_flag" is true (non-zero) if a GOP header was encountered; "seq_hdr_flag" is true (non-zero) if a video sequence header occurred before the current coded picture and after the previous coded picture.

[0132] Box 706 tests "seq_hdr_flag". If true, "prog_refresh" is set to 1 (true) if the current picture is not an I-picture in box 708

[0133] Box 710 is the switch statement based on picture types. Although not shown in the code or flowchart, an MPEG-2 D-picture is treated like an I-picture in this algorithm.

[0134] If the previous picture type was not a B-picture (box 712), then a new value of M is determined from the temporal references. If the GOP is being shortened, the excess bits due to the expected GOP length are deleted from "R" and the new values of "M", "N", "n" are set (box 714). "R" is the target number of bits (not the actual number) remaining to code the rest of the GOP. If the actual GOP size is different, the difference in bits (positive or negative) remains in "R" and affects the target size for the next GOP. This forms a feedback loop to drive the average GOP size to "N*bit_rate() / frame_rate()".

[0135] The function "bit_rate()" returns the current target transcoder output bitrate which may change due to channel capacity or statistical multiplexing considerations. The function "frame_rate()" is the average coded frame rate, which is the frame rate specified in the video sequence header modified by the effects of the repeat_first_field flag in the various coded pictures. The quantity "bit_rate() / frame_rate()" denotes the desired current average coded picture size (in bits) to be output by the transcoder. It is an average because it does not consider the different MPEG picture types. Thus the target number of bits for a GOP, "N * bit_rate() / frame_rate()",

is N (the GOP length in pictures) times the average picture size.

[0136] If the transcoder is operating in progressive refresh mode, this mode is disabled because the current picture is an I-picture and N is set to the initial guess for GOP length (boxes 716 and 718).

[0137] If the condition in 720 is true, the correct value of "N" has been used. In this case, R is updated with the number of bits needed for a new GOP of length N (box 722). If the 720 condition is false, the our previous estimate of "N" is wrong (the GOP is shorter than expected) and N and R are updated accordingly (box 724).

[0138] Box 726 resets the picture type down counters ("ni", "np", "nb") according to the GOP type, the number of picture to go in the GOP (n), calculates the normalized I-picture complexity (X) and updates the previous picture type.

[0139] Box 728 is the start of the P-picture case in the switch statement. If the previous picture was not a B-picture (box 730), then a new value of M (M") is calculated from the temporal references. The difference between the two 10-bit temporal reference number will be negative a wrap around occurred; this is why 1024 is added. When no wrap around occurs, the 0x3FF, which is the hexadecimal representation of the binary number 1111111111, removes the 2^{10}à bit leaving the positive difference; otherwise the addition of 1024 make the negative difference positive and this result is not modified by the bit-wise AND operation. Since the previous picture was not a B-picture, potential corrections to "n" (number of pictures left in the GOP), "nb" (number of B-picture left in the GOP) and "R" (number of bits allocated for the remaining picture in the GOP) may be required.

[0140] If M has changed and the transcoder is not in progressive refresh mode (box 732), then corrections to "N", "n", "np", "nb" and "R" are made in box 734.

[0141] Box 736 updates M (previously calculated in M").

[0142] If the end of GOP has been reached, (n less than or equal to zero - box 738), then the GOP is actually longer than expected. In this case, the values of "N", "R", "n", "ni", "np" and "nb" are updated to reflect an increase GOP length of M pictures (one P-picture and M-1 B-pictures) in box 740.

[0143] Box 742 calculates the normalized P-picture complexity, "X", and resets "prev_temp_ref" to be the current temporal reference.

[0144] For B-pictures, where the previous picture was not a B-picture (conditional in box 744), the new value of M (in M") is computed. (see box 746) from the difference in temporal reference. This calculation provide for the possibility that the 10-bit temporal reference may have wrapped around (hence the +1024 and the mask to 10 bits).

[0145] If the value of M has changed (condition tested in box 748), then the state variables must be updated depending on "prog_refersh" (box 750). In the progressive refresh case, "nb" and "R" need to be modified (box 752). If I-picture refresh is in progress, "N", "np", "nb", "n" and "R" all need to change (box 754).

[0146] A new normalized complexity for B-picture is computed in box 758.

[0147] Following the switch statement, the target size, "T", for the next picture is calculated in box 760. This number is the intended size of the current picture when transcoded to the new bit rate. The actual size, returned by "transcode_picture()" is used to decrement R (see box 770). Following the calculation of "T", the number of picture remaining in the GOP, "n", and the number of pictures of the current type ("ni", "np" or "nb") must be decremented (see boxes 762 to 768).

3. DIFFERENCE IN TARGET RATES

[0148] The target bit rates for a picture determined with different sets of GOP parameters can be different (see equations 5 and 6). We now analyze the differences in target rates with and without a correct starting GOP structure. For sake of simplification in analysis, we assume that:

1. The transcoder can meet the target rate at each picture. This implies that the remaining number of bits at the end of a GOP is equal to zero, and that a GOP of N pictures is assigned exactly $R_{GOP,N} = N \cdot (bit\_rate/frame\_rate)$ bits.

2. Within a GOP, all the pictures of the same type have the same complexity measure.

3. We have a correct M value. In fact, we can have a correct M right after reading the header of the second picture.

[0149] Note that the above assumptions are only for simplifying the analysis, and may not be 100% true for a real transcoder. For example, a transcoder may not 100% meet the target rate at a frame, and therefore at the end of a GOP, the remaining number of bits R may not be zero bits.

[0150] It has been shown that with conditions 1 and 2, equations (5) and (6) will be identical. That is, all the pictures of the same type in a GOP are assigned the same number of bits. We use eqn. (5) in our analysis of differences in target rates. Assume that a pre-compressed bitstream is coded with a set of GOP parameters as follows:

$$N,M \rightarrow N_I,N_P,N_B$$

[0151] For comparison, we start transcoding of the pre-compressed bitstream with two different GOP structures, one with a correct GOP structure (I) and the second with an incorrect GOP structure (II) as follows:

Starting GOP(I): $N,M \rightarrow N_I,N_P,N_B$

Starting GOP(II): $N',M' \rightarrow N_I,N_P,N_B$

[0152] Let T_n and T'_n be the target rates for frame n with GOP(I) and GOP(II), respectively. The difference between these two target rates is:

$$\Delta=T_n-T'_n=(1-\frac{T'_n}{T_n})\cdot T_n \qquad (24a)$$

$$=(1-\frac{\frac{X_{n,I}}{K_{n,I}}}{N'_I\frac{X_I}{K_I}+N'_P\frac{X_P}{K_P}+N'_B\frac{X_B}{K_B}}R_{GOP,N'}\div\frac{\frac{X_{n,I}}{K_{n,I}}}{N_I\frac{X_I}{K_I}+N_P\frac{X_P}{K_P}+N_B\frac{X_B}{K_B}}R_{GOP,N})\cdot T_n \qquad (24b)$$

$$=(1-\frac{N_I\frac{X_I}{K_I}+N_P\frac{X_P}{K_P}+N_B\frac{X_B}{K_B}}{N'_I\frac{X_I}{K_I}+N'_P\frac{X_P}{K_P}+N'_B\frac{X_B}{K_B}}\cdot\frac{N'}{N})\cdot T_n \qquad (24c)$$

$$=\frac{(NN'_I-N'N_I)\frac{X_I}{K_I}+(NN'_P-N'N_P)\frac{X_P}{K_P}+(NN'_B-N'N_B)\frac{X_B}{K_B}}{(N'_I\frac{X_I}{K_I}+N'_P\frac{X_P}{K_P}+N'_B\frac{X_B}{K_B})}\cdot\frac{1}{N}\cdot T_n. \qquad (24d)$$

[0153] To better understand this difference in target bit rate, let us examine two numerical examples. In the first example, we assume the starting GOP (II) is shorter than the actual GOP, i.e.,

$$N=15\ M=3\rightarrow N_I=1\ N_P=4\ N_B=10$$
$$N'=12\ M'=3\rightarrow N'_I=1\ N'_P=3\ N'_B=8$$

[0154] If we set $K_I=K_P=1$ and $K_B=1.4$, and use the complexity measures as initialized in MPEG TM5, i.e.,

$$X_I=160\cdot bit\_rate/frame\_rate$$
$$X_P=60\cdot bit\_rate/frame\_rate \qquad (25)$$
$$X_B=40\cdot bit\_rate/frame\_rate$$

we have the difference between the two target rates as follows:

$$\Delta=T_n-T'_n=\frac{(15-12)\ x_I\ +\ (15\cdot3-12\cdot4)x_P\ +\ (15\cdot8-12\cdot10)x_B/1.4}{(x_I\ +\ 3x_P\ +\ 8x_B/1.4)}\cdot\frac{1}{15}\cdot T_n=3.5\%\cdot T \qquad (26)$$

Here, the target rate with *a prion* knowledge of the GOP structure is 3.5% higher than the rate without *a priori* knowledge of the GOP structure using the rate control system of the present invention. A shorter GOP results in smaller target rates for all three types of pictures.

[0155] In the second numerical example, the starting GOP (II) has a length longer than the actual one, i.e.,

$$N=15\ M=3\rightarrow N_I=1\ N_P=4\ N_B=10$$
$$N'=18\ M'=3\rightarrow N'_I=1\ N'_P=5\ N'_B=12$$

[0156] The difference in target rates is

$$\Delta=T_n-T'_n=\frac{(15-18)\,x_I+(15\cdot5-18\cdot4)x_P+(15\cdot12-18\cdot10)x_B/1.4}{(x_I+5x_P+12x_B/1.4)}\cdot\frac{1}{15}\cdot T_n=-1.7\% \qquad (27)$$

[0157] Here, the target rate with *a priori* knowledge of the GOP structure is 1.7% lower than the rate without *a priori* knowledge of the GOP structure using the rate control system of the present invention. A longer GOP results in the assignment of more bits to all the pictures of three types.

[0158] The differences in target bit rates will remain until the end of either the starting GOP or the actual GOP, depending on whether the starting GOP is shorter or longer than the actual GOP length.

[0159] If the starting GOP is shorter than the actual GOP (i.e. $N' < N$), at the end of the starting GOP, we will extend the GOP of N' pictures by M pictures with additional bits of $R_{GOP}M$. The remaining number of bits is therefore equal to

$$R = R+R_{GOP,M} = M\cdot\frac{bit\_rate}{frame\_rate} \qquad (28)$$

[0160] Note that we have assumed $R = 0$ at the end of the starting GOP of N' pictures. The additional M pictures actually form another GOP of $N=M$ pictures with $N'_I = 0$, $N'_P = 1$ and $N'_B = M-1$, and a bit budget of $M\cdot(bit\_rate/frame\_rate)$ bits. The differences in target rates for the M additional pictures of either P or B type (see eqn. 24) can be simplified as:

$$\Delta = T_n - T'_n = \frac{(-MN_I)\frac{X_I}{K_I}+(N-MN_P)\frac{X_P}{K_P}+(NN'_B-MN_B)\frac{X_B}{K_B}}{(\frac{X_P}{K_P}+N'_B\frac{X_B}{K_B})}\cdot\frac{1}{N}\cdot T_n \qquad (29)$$

[0161] For the first numerical example, the difference in target bit rates is:

$$\Delta=T_n-T'_n=\frac{(-3)\,x_I+(15-3\cdot4)x_P+(15\cdot2-3\cdot10)x_B/1..4}{(x_P+2x_B/1.4)}\cdot\frac{1}{15}\cdot T_n=17.0\%\cdot T_n \qquad (30)$$

[0162] Here, the target rate with *a priori* knowledge of the GOP structure is 17.0% higher than the rate without *a priori* knowledge of the GOP structure using the rate control system of the present invention. Relatively more bits are assigned to the pictures of the extended GOP since relatively fewer bits were assigned to the previous pictures. If the extended GOP of M pictures still cannot end the actual GOP of N pictures, we repeat the above procedure until reaching the end of the actual GOP. The differences in target rates for the pictures in the extended GOPs of M pictures will remain the same because all the extended GOPs of M pictures have the same pattern of picture organization and the same bit budget.

[0163] At the end of the first actual GOP of N pictures and also at the end of the last extended GOP of M pictures, we have complete information about the actual GOP structure with the remaining number of bits $R = 0$. Hence, from the second GOP, there will be no difference in target rates. Two target rates with and without *a priori* knowledge of GOP structure using the rate control system of the present invention will be the same from the second actual GOP.

[0164] On the other hand, if the assumed starting GOP length is longer than the actual GOP length (i.e. $N'>N$), at the end of the actual GOP, we have the complete information about the actual GOP structure, but the remaining number of bits $R \neq 0$. That is, there will be some left over bits to allocate over the second (actual) GOP. Hence, instead of simply giving $R_{GOP}N$ bits to the second (actual) GOP, we have to adjust R as $R = 2R_{GOP,N}-(R_{GOP,N}-R)$ (see eqn. 23). The target bit rates with correct and incorrect starting GOP structures will still not be the same in the second (actual) GOP. The difference in target rates in the second (actual) GOP is

$$\Delta = T_n-T'_n \qquad (31a)$$

$$=\frac{\frac{X_{n,I}}{K_{n,I}}}{N_I\frac{X_I}{K_I}X_I+N_P\frac{X_P}{K_P}+N_B\frac{X_B}{K_B}}(R_{GOP,N}-(2R_{GOP,N}-(R_{GOP,N'}-R))) \qquad (31b)$$

$$= \frac{\frac{X_{n,t}}{K_{n,t}}}{N_I \frac{X_I}{K_I} X_I + N_P \frac{X_P}{K_P} + N_B \frac{X_B}{K_B}} (-R_{GOP,N} + (R_{GOP,N'} - R)) \qquad (31c)$$

[0165] Here, R_{GOP} N-R is the number of bits assigned for the first N pictures, which is equal to:

$$R_{GOP,N'} - R = \frac{N_I \frac{X_I}{K_I} + N_P \frac{X_P}{K_P} + N_B \frac{X_B}{K_B}}{N'_I \frac{X_I}{K_I} + N'_P \frac{X_P}{K_P} + N'_B \frac{X_B}{K_B}} R_{GOP,N'} . \qquad (32)$$

[0166] Hence, the difference in target rate becomes:

$$\Delta = \frac{\frac{X_{n,t}}{K_{n,t}}}{N_I \frac{X_I}{K_I} + N_P \frac{X_P}{K_P} + N_B \frac{X_B}{K_B}} (-R_{GOP,N} + \frac{N_I \frac{X_I}{K_I} + N_P \frac{X_P}{K_P} + N_B \frac{X_B}{K_B}}{N'_I \frac{X_I}{K_I} + N'_P \frac{X_P}{K_P} + N'_B \frac{X_B}{K_B}} R_{GOP,N'}) \qquad (33a)$$

$$= -\frac{(NN'_I - N'N_I)\frac{X_I}{K_I} + (NN'_P - N'N_P)\frac{X_P}{K_P} + (NN'_B - N'N_B)\frac{X_B}{K_B}}{(N'_I \frac{X_I}{K_I} + N'_P \frac{X_P}{K_P} + N'_B \frac{X_B}{K_B})} \cdot \frac{1}{N} \cdot T_n \qquad (33b)$$

[0167] By comparing equations (24) and (33), we should see the differences in target rates in the first and second actual GOP have the same absolute values, but different signs. In fact, a longer starting GOP uses more bits for the first actual GOP and therefore leaves less bits for the second actual GOP. For the second numerical example, the differences in target rates for pictures in the second actual GOP are:

$$\Delta = T_n - T'_n = 1.7\% \cdot T_n \qquad (34)$$

[0168] At the end of the second actual GOP, the remaining number of bits R = 0. The third actual GOP will be assigned R_{GOP} N bits. From the third actual GOP, there will be no difference in target rates.

[0169] Target rates with respect to frame number for the two numerical examples were analyzed. The target rate with a correct starting GOP(N = 15, M = 3) was the benchmark for comparison. Comparative data was obtained for a starting GOP(N = 12, M = 3), and for a starting GOP(N = 18, M = 3). It was verified that all the pictures of the same type are assigned the same number of bits. Moreover, if the starting GOP is shorter than the actual GOP, fewer bits are assigned to the pictures before the end of the starting GOP, and more bits are assigned to the pictures of an extended GOP of M pictures. There is no difference in target rates starting from the second actual GOP.

[0170] On the other hand, if the starting GOP is longer than the actual one, slightly more bits are assigned to the pictures in the first actual GOP and fewer bits for the pictures in the second actual GOP. From the third actual GOP, the target rates are the same.

4. SIMULATION RESULTS

[0171] Simulations were conducted in evaluating the rate control system of the present invention. Test sequences were first coded at a bit rate of 15 Mbits/sec. with different sets of GOP parameters, as shown in Table I. The compressed bitstreams were then transcoded to a new rate of 3 Mbits/s with a starting GOP of N = 15 and M = 3.

	GOP1	GOP2	GOP3
N	30	12	8

	GOP1	GOP2	GOP3
M	3	2	1

[0172] Target rates were analyzed for a correct starting set of GOP parameters, and for a starting GOP of $N = 15$ and $M = 3$. Note that, in practice, a transcoder (or encoder) may not always meet the target rates at each frame. Hence, the remaining number of bits at the end of each GOP, R, may not be zero. The non-zero R will be passed to the next GOP (see eqn. 8). This implies that GOPs may be given slightly different number of bits. It was seen that a longer starting GOP assigns more bits for the pictures in the first GOP, as compared with a correct starting GOP. Hence, fewer bits are left for the pictures in the second GOP. The target rates with correct and incorrect GOP starts converging at the third GOP. On the other hand, a shorter starting GOP results in smaller target rates for the first few pictures and then more bits for the rest in the first GOP. Target rates become close from the second GOP.

[0173] To prove the effectiveness of the bit rate allocation system under a variety of test conditions, a sequence was coded with various GOP lengths, e.g., $N = 15, 12, 12, 18, 18, 15, 15, 9, 9, 30$. Target rates were analyzed at each GOP for the correct GOP length, and by using the previous GOP structure length as the starting GOP length for each GOP. The results were close with this stress test.

[0174] FIG. 6 illustrates a rate control system in accordance with the present invention. Pre-compressed bitstreams, e.g., program 1 and program 2, are provided to respective transcoders 620 and 630. One or several bitstreams and transcoders may be present. The bitstreams may be received real-time at the transcoders from a remote source, such as via a satellite broadcast, or may be provided from a local storage medium, for example.

[0175] The transcoders 620, 630 partially decompress the respective bitstreams, and encode the partially decompressed data at a different data rate, typically by using a different quantization parameter, according to a target bit rate signal provided by a rate control processor 605.

[0176] The rate control processor 605 receives information from the transcoders, including the picture type of the current picture, and the quantization parameter used to encode the current picture. This information is processed as described herein to set the target bit rates. The rate control processor 605 may include known processing circuitry, such as a central processing unit (CPU) 612, and a memory 614. The memory 614 may be a non-volatile memory that stores data, for example, for providing the initial distances M' and N' discussed previously. The rate control processor includes computing circuitry for executing the C-language like pseudo-code discussed previously.

[0177] A user interface 608 may communicate with the rate control processor 605 to set the default distances M' and N' or other relevant parameters in the rate control process.

[0178] The transcoded data from the transcoders 620, 630 is provided to a multiplexer (MUX) 660, and then to an encoder buffer 670. A buffer fullness signal is provided from the encoder buffer 670 to the rate control processor 605. The encoded data is finally transmitted over a channel at its new transcoded data rate.

5. CONCLUSION

[0179] A novel rate control system suitable for use with a digital video transcoder, such as one conforming to the MPEG standard, has been presented. The proposed rate control causes no processing delay and requires no extra memory. It can start with any reasonable set of GOP parameters, and then gradually corrects them when necessary as successive pictures are coded. Hence, it is able to address changes in the GOP structure of pre-compressed bitstreams, for example, when switching channels, inserting commercials, and the like. It has been shown that the target rates with correct and incorrect starting GOP parameters will converge within one or two GOPs. The differences in target rates are within a fairly small margin. Moreover, similar target rates correspond to a similar PSNR or picture quality.

[0180] Although the invention has been described in connection with various specific embodiments, those skilled in the art will appreciate that numerous adaptations and modifications may be made thereto without departing from the spirit and scope of the invention as set forth in the claims.

Claims

1. A method for allocating bits for coding pictures in a bitstream received at a digital video transcoder, comprising the steps of:

   (a) providing an assumed distance M' between a first picture of said bitstream and the next closest subsequent P-picture of said bitstream in a display order of said bitstream;

   (b) providing an assumed bit budget as a function of said assumed distance M';

   (c) coding said first picture in accordance with said assumed bit budget;

(d) determining a picture type of a second picture that immediately follows said first picture in said bitstream in an encoding order of said bit stream;

(e) adjusting said assumed bit budget according to said picture type of said second picture; and

(f) allocating bits for coding said second picture in accordance with said adjusted bit budget.

2. The method of claim 1, wherein:

said assumed bit budget is proportional to said assumed distance and a bit rate of said bitstream, and inversely proportional to a frame rate of said bitstream.

3. The method of claim 1 or 2, wherein:

said pictures in said bitstream form a progressive refresh sequence.

4. The method of one of claims 1 to 3, wherein said first picture is a P-picture and said second picture is a B-picture, comprising the further step of:

determining an actual distance M" between said first picture and said next closest subsequent P-picture, in said display order, according to said picture type of said second picture.

5. The method of claim 4, wherein:

said actual distance M" is determined according to a difference between a temporal reference of said second picture, in said display order, and a temporal reference of said first picture, in said display order, plus one picture.

6. The method of claim 4 or 5, comprising the further step of:

allocating bits for coding the remaining M"-1 pictures following said first picture in accordance with said adjusted bit budget.

7. The method of one of claims 4 to 6, wherein:

said adjusting step (e) comprises the step of adjusting said assumed bit budget by +(M"-M')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

8. The method of claim 1, wherein said first and second pictures are P-pictures, comprising the further step of:

determining an actual distance M" between said first picture and said next closest subsequent P-picture, in said display order, according to said picture type of said second picture.

9. The method of claim 8, wherein:

said actual distance M" is determined according to a difference between a temporal reference of said second picture, in said display order, and a temporal reference of said first picture, in said display order.

10. The method of claim 8 or 9, wherein said adjusting step (e) comprises the step of:

adjusting said assumed bit budget by -(M'-1)*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

11. The method of one of claims 8 to 10, comprising the further step of:

allocating bits for coding the remaining M"-1 pictures following said first picture in accordance with said adjusted bit budget.

12. The method of one of claims 1 to 5 or 8 to 11, comprising the further step of:

allocating bits for coding a series of M" pictures following an initial M" picture that includes said first and second pictures in said bitstream in accordance with said adjusted bit budget.

13. A method for allocating bits for coding a sequence of pictures in a bitstream received at a digital video transcoder, comprising the steps of:

(a) providing an assumed length N' of a particular group of pictures (GOP) of said bitstream;

(b) providing an assumed bit budget as a function of said assumed length N';

(c) allocating bits for coding a first picture of said particular GOP in accordance with said assumed bit budget;

(d) determining a picture type of a second picture that immediately follows said first picture;

(e) adjusting said assumed bit budget according to said picture type of said second picture; and

(f) allocating bits for coding said second picture in accordance with said adjusted bit budget.

14. The method of claim 13, wherein:

said assumed bit budget is proportional to said assumed length N' and a bit rate of said bitstream, and inversely proportional to a frame rate of said bitstream.

15. The method of claim 13 or 14, wherein said first and second pictures are I-pictures, comprising the further steps of:

determining an actual distance M" between said first picture and the next closest subsequent I-picture of said bitstream according to the picture type of said second picture; and

adjusting said assumed bit budget in accordance with said actual distance M".

16. The method of claim 15, wherein:

said actual distance M" is determined according to a difference between a temporal reference of said second picture, in a display order of said bitstream, and a temporal reference of said first picture, in said display order.

17. The method of one of claims 13 to 16, wherein said adjusting step (e) comprises the step of:

adjusting said assumed bit budget by -(N'-1)*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

18. The method of one of claims 13 to 17, comprising the further step of:

allocating bits for coding the remaining pictures in said particular GOP following said second picture in accordance with said adjusted bit budget.

19. The method of one of claims 13 to 18, comprising the further step of:

providing an assumed distance M' between said first picture and the next closest subsequent P-picture of said bitstream, in a display order of said bitstream;
wherein said bits are allocated for coding said first picture in said step (c) in accordance with said assumed distance M'.

20. The method of claim 19, wherein said first picture is an I-picture and said second picture is a P-picture, comprising the further steps of:

determining an actual distance M" between said first picture and the next closest subsequent P-picture, in said display order, according to said picture type of said second picture; and

adjusting said assumed length N' of said GOP in accordance with said actual distance M" to provide an adjusted assumed length N"; wherein:

said adjusting step (e) is responsive to said adjusted assumed length N'.

21. The method of claim 20, wherein:

said assumed length N' of said particular GOP is adjusted in said adjusting step thereof by a factor, M(N'/M'), to provide said adjusted assumed length N", where M=M".

22. The method of claim 20 or 21, wherein said adjusting step (e) comprises the step of:

adjusting said assumed bit budget by a factor(N"-N')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

23. The method of claim 20 or 21, wherein said adjusting step (e) comprises the further step of:

adjusting said assumed bit budget by a factor, (M"-1')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

24. The method of one of claims 20 to 23, comprising the further step of:

allocating bits for coding the remaining pictures in said particular GOP following said second picture in accordance with said adjusted bit budget.

25. The method of one of claims 20 to 24, comprising the further steps of:

determining if N">N, an actual length of said particular GOP, after coding N" pictures in said particular GOP; and, if N">N:

further adjusting said adjusted bit budget according to N and N"; and

allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget.

26. The method of one of claims 20 to 24, comprising the further steps of:

determining if N"<N, an actual length of said particular GOP, after coding N" pictures in said particular GOP; and, if N"<N:

further adjusting said adjusted bit budget according to M=M"; and

allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget.

27. The method of claim 13, wherein said first picture is an I-picture and said second picture is a B-picture, comprising the further step of:

providing an assumed distance M' between said first picture and the next closest subsequent P-picture of said bitstream, in a display order of said bitstream;
wherein said bits are allocated for coding said second picture in accordance with said assumed distance M'.

28. The method of claim 27, comprising the further steps of:

determining an actual distance M" between said first picture and the next closest subsequent P-picture, in said display order, according to said picture type of said second picture; and

adjusting said assumed length N' of said GOP in accordance with an actual distance M=M" to provide an adjusted assumed length N"; wherein:

said adjusting step (e) is responsive to said adjusted assumed length N'.

29. The method of claim 28, wherein:

said assumed length N' of said particular GOP is adjusted in said adjusting step thereof by a factor, M(N'/M'), to provide said adjusted assumed length N".

30. The method of claim 28 or 29, wherein said adjusting step (e) comprises the step of:

adjusting said assumed bit budget by a factor(N"-N')*"bit rate"/'frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

31. The method of one of claims 28 to 30, comprising the further step of:

allocating bits for coding the remaining pictures in said particular GOP following said second picture in accordance with said adjusted bit budget.

32. The method of one of claims 28 to 31, comprising the further step of:

determining if N">N, an actual length of said particular GOP, after coding N" pictures in said particular GOP; and, if N">N:

further adjusting said adjusted bit budget according to N and N"; and

allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget.

33. The method of one of claims 28 to 32, comprising the further steps of:

determining if N"<N, an actual length of said particular GOP, after coding N" pictures in said particular GOP; and, if N"<N:

further adjusting said adjusted bit budget according to M=M"; and

allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget.

34. The method of one of claims 13 to 33, comprising the further step of:

allocating bits for coding a GOP following said particular GOP in accordance with said adjusted bit budget.

35. The method of one of claims 13 to 34, comprising the further step of:

accounting for changes in an actual distance M" between I-pictures and/or P-pictures in said particular GOP by determining an actual distance M" between an I-picture or P-picture that follows said first picture in said particular GOP, in a display order of said bitstream, and a subsequent I-picture or P-picture in said particular GOP; and

adjusting said assumed bit budget in accordance with said actual distance M".

36. An apparatus for allocating bits for coding pictures in a bitstream received at a digital video transcoder, comprising:

(a) means for providing an assumed distance M' between a first picture of said bitstream and the next closest subsequent P-picture of said bitstream in a display order of said bitstream;

(b) means for providing an assumed bit budget as a function of said assumed distance M';

(c) means for coding said first picture in accordance with said assumed bit budget;

(d) means for determining a picture type of a second picture that immediately follows said first picture in said bitstream in an encoding order of said bit stream;

(e) means for adjusting said assumed bit budget according to said picture type of said second picture; and

(f) means for allocating bits for coding said second picture in accordance with said adjusted bit budget.

37. The apparatus of claim 36, wherein:

said assumed bit budget is proportional to said assumed distance and a bit rate of said bitstream, and inversely proportional to a frame rate of said bitstream.

38. The apparatus of claim 36 or 37, wherein:

said pictures in said bitstream form a progressive refresh sequence.

39. The apparatus of one of claims 36 to 38, wherein said first picture is a P-picture and said second picture is a B-picture, further comprising:

means for determining an actual distance M" between said first picture and said next closest subsequent P-picture, in said display order, according to said picture type of said second picture.

40. The apparatus of claim 39, wherein:

said actual distance M" is determined according to a difference between a temporal reference of said second picture, in said display order, and a temporal reference of said first picture, in said display order, plus one picture.

41. The apparatus of claim 39 or 40, further comprising:

means for allocating bits for coding the remaining M"-1 pictures following said first picture in accordance with said adjusted bit budget.

42. The apparatus of one of claims 39 to 41, wherein:

said adjusting means (e) comprises means for adjusting said assumed bit budget by +(M"-M')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

43. The apparatus of one of claims 36 to 42, wherein said first and second pictures are P-pictures, further comprising:

means for determining an actual distance M" between said first picture and said next closest subsequent P-picture, in said display order, according to said picture type of said second picture.

44. The apparatus of claim 43, wherein:

said actual distance M" is determined according to a difference between a temporal reference of said second

picture, in said display order, and a temporal reference of said first picture, in said display order.

45. The apparatus of claim 43 or 44, wherein said adjusting means (e) comprises:

means for adjusting said assumed bit budget by - (M'-1)*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

46. The apparatus of one of claims 43 to 45, further comprising:

means for allocating bits for coding the remaining M"-1 pictures following said first picture in accordance with said adjusted bit budget.

47. The apparatus of one of claims 36 to 45, further comprising:

means for allocating bits for coding a series of M" pictures following an initial M" pictures that includes said first and second pictures in said bitstream in accordance with said adjusted bit budget.

48. An apparatus for allocating bits for coding a sequence of pictures in a bitstream received at a digital video transcoder, comprising:

(a) means for providing an assumed length N' of a particular group of pictures (GOP) of said bitstream;

(b) means for providing an assumed bit budget as a function of said assumed length N';

(c) means for allocating bits for coding a first picture of said particular GOP in accordance with said assumed bit budget;

(d) means for determining a picture type of a second picture that immediately follows said first picture;

(e) means for adjusting said assumed bit budget according to said picture type of said second picture; and

(f) means for allocating bits for coding said second picture in accordance with said adjusted bit budget.

49. The apparatus of claim 48, wherein:

said assumed bit budget is proportional to said assumed length N' and a bit rate of said bitstream, and inversely proportional to a frame rate of said bitstream.

50. The apparatus of claim 48 or 49, wherein said first and second pictures are I-pictures, further comprising:

means for determining an actual distance M" between said first picture and the next closest subsequent I-picture of said bitstream according to the picture type of said second picture; and

means for adjusting said assumed bit budget in accordance with said actual distance M".

51. The apparatus of claim 50, wherein:

said actual distance M" is determined according to a difference between a temporal reference of said second picture, in a display order of said bitstream, and a temporal reference of said first picture, in said display order.

52. The apparatus of one of claims 48 to 51, wherein said adjusting means (e) comprises:

means for adjusting said assumed bit budget by - (N'-1)*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

53. The apparatus of one of claims 48 to 52, further comprising:

means for allocating bits for coding the remaining pictures in said particular GOP following said second picture in accordance with said adjusted bit budget.

54. The apparatus of one of claims 48 to 53, further comprising:

means for providing an assumed distance M' between said first picture and the next closest subsequent P-picture of said bitstream, in a display order of said bitstream;
wherein said bits are allocated for coding said first picture by said coding means (c) in accordance with said assumed distance M'.

55. The apparatus of claim 54, wherein said first picture is an I-picture and said second picture is a P-picture, further comprising:

means for determining an actual distance M" between said first picture and the next closest subsequent P-picture, in said display order, according to said picture type of said second picture; and

means for adjusting said assumed length N' of said GOP in accordance with said actual distance M" to provide an adjusted assumed length N"; wherein:

said adjusting means (e) is responsive to said adjusted assumed length N'.

56. The apparatus of claim 55, wherein:

said assumed length N' of said particular GOP is adjusted by said adjusting means thereof by a factor, M(N'/M'), to provide said adjusted assumed length N", where M=M".

57. The apparatus of claim 55 or 56, wherein said adjusting means (e) comprises:

means for adjusting said assumed bit budget by a factor (N"-N')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

58. The apparatus of claim 57, wherein said adjusting means (e) comprises:

means for adjusting said assumed bit budget by a factor, (M"-1')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

59. The apparatus of one of claims 55 to 58, further comprising:

means for allocating bits for coding the remaining pictures in said particular GOP following said second picture in accordance with said adjusted bit budget.

60. The apparatus of one of claims 55 to 59, further comprising:

means for determining if N">N, an actual length of said particular GOP, after coding N" pictures in said particular GOP;

means for further adjusting said adjusted bit budget according to N and N" if N">N; and

means for allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget if N">N.

61. The apparatus of one of claims 55 to 59, further comprising:

means for determining if N"<N, an actual length of said particular GOP, after coding N" pictures in said particular GOP;

means for further adjusting said adjusted bit budget according to M=M" if N"<N; and

means for allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget if N"<N.

62. The apparatus of claim 48, wherein said first picture is an I-picture and said second picture is a B-picture, further comprising:

means for providing an assumed distance M' between said first picture and the next closest subsequent P-picture of said bitstream, in a display order of said bitstream;
wherein said bits are allocated for coding said second picture in accordance with said assumed distance M'.

63. The apparatus of claim 62, further comprising:

means for determining an actual distance M" between said first picture and the next closest subsequent P-picture, in said display order, according to said picture type of said second picture; and

means for adjusting said assumed length N' of said GOP in accordance with an actual distance M=M" to provide an adjusted assumed length N"; wherein:

said adjusting means (e) is responsive to said adjusted assumed length N'.

64. The apparatus of claim 63, wherein:

said assumed length N' of said particular GOP is adjusted by said adjusting means thereof by a factor, M(N'/M'), to provide said adjusted assumed length N".

65. The apparatus of claim 63 or 64, wherein said adjusting means (e) comprises:

means for adjusting said assumed bit budget by a factor (N"-N')*"bit rate"/"frame rate", where "bit rate" is a bit rate of said bitstream, and "frame rate" is a frame rate of said bitstream.

66. The apparatus of one of claims 63 to 65, further comprising:

means for allocating bits for coding the remaining pictures in said particular GOP following said second picture in accordance with said adjusted bit budget.

67. The apparatus of one of claims 63 to 66, further comprising:

means for determining if N">N, an actual length of said particular GOP, after coding N" pictures in said particular GOP;

means for further adjusting said adjusted bit budget according to N and N" if N">N; and

means for allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget if N">N.

68. The apparatus of one of claims 63 to 66, further comprising:

means for determining if N"<N, an actual length of said particular GOP, after coding N" pictures in said particular GOP;

means for further adjusting said adjusted bit budget according to M=M" if N"<N; and

means for allocating bits for coding pictures in said bitstream following the N" coded pictures according to said further adjusted bit budget if N"<N.

69. The apparatus of one of claims 48 to 68, further comprising:

means for allocating bits for coding a GOP following said particular GOP in accordance with said adjusted

bit budget.

70. The apparatus of one of claims 48 to 69, further comprising:

means for accounting for changes in an actual distance M" between I-pictures and/or P-pictures in said particular GOP by determining an actual distance M" between an I-picture or P-picture that follows said first picture in said particular GOP, in a display order of said bitstream, and a subsequent I-picture or P-picture in said particular GOP; and

means for adjusting said assumed bit budget in accordance with said actual distance M".

71. A method for allocating bits for coding a sequence of pictures in a bitstream received at a digital video transcoder, comprising the steps of:

(a) providing a length of groups of pictures (GOPs) of said bitstream;

(b) providing a distance between each I-picture and a next successive P-picture in said GOPs;

(c) maintaining a count of a number of remaining I-, P- and B-pictures, respectively, in each GOP as each picture in said GOPs is coded;

(d) providing an assumed bit budget in response to said steps (a), (b) and (c) for coding pictures in said GOPs;

(e) verifying, and adjusting, if necessary, said length after each I-picture in said GOPs is coded;

(f) verifying, and adjusting, if necessary, said distance after each I-picture and/or P-picture in said GOPs is coded;

(g) verifying, and adjusting, if necessary, the count of the number of remaining I-, P- and B-pictures, in response to said steps (e) and (f); and

(g) adjusting, if necessary, said assumed bit budget in response to said steps (e), (f) and (g).

72. The method of claim 71, wherein:

said distance is assumed when initially coding said GOPs and is corrected to an actual distance within a time for coding two pictures in said bitstream.

73. The method of claim 71 or 72, wherein:

said length is assumed when initially coding said GOPs and is corrected to an actual length within a time for coding one GOP in said bitstream.

74. An apparatus for allocating bits for coding a sequence of pictures in a bitstream received at a digital video transcoder, comprising:

(a) means for providing a length of groups of pictures (GOPs) of said bitstream;

(b) means for providing a distance between each I-picture and a next successive P-picture in said GOPs;

(c) means for maintaining a count of a number of remaining I-, P- and B-pictures, respectively, in each GOP as each picture in said GOPs is coded;

(d) means for providing an assumed bit budget in response to said means (a), (b) and (c) for coding pictures in said GOPs;

(e) means for verifying, and adjusting, if necessary, said length after each I-picture in said GOPs is coded;

(f) means for verifying, and adjusting, if necessary, said distance after each I-picture and/or P-picture in said GOPs is coded;

(g) means for verifying, and adjusting, if necessary, the count of the number of remaining I-, P- and B-pictures, in response to said means (e) and (f); and

(g) means for adjusting, if necessary, said assumed bit budget in response to said means (e), (f) and (g).

75. The apparatus of claim 74, wherein:

said distance is assumed when initially coding said GOPs and is corrected to an actual distance within a time for coding two pictures in said bitstream.

76. The apparatus of claim 74 or 75, wherein:

said length is assumed when initially coding said GOPs and is corrected to an actual length within a time for coding one GOP in said bitstream.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Joint Video Team (JVT) of ISO/IEC MPEG and ITU-T VCEG

Document: **JVT-E146d37**
File: JVT-E146d37ncm.doc
Generated: 2002-11-17

5th Meeting: Geneva, Switzerland, 9-17 October, 2002

Title: Editor's Proposed Draft Text Modifications for Joint Video Specificati on (ITU-T Rec. H.264 | ISO/IEC 14496-10 AVC), Geneva modifications draft 37

Status: Draft Output Document of JVT

Contact: Thomas Wiegand
Heinrich Hertz Institute (HHI), Einsteinufer 37, D-10587 Berlin, Germany
Tel: +49 - 30 - 31002 617, Fax: +49 - 030 - 392 72 00, wiegand@hhi.de

Purpose: Report

[Ed. Notes:

Modifications in JVT-E146d0 relative to JVT-E022d7:

- Mike Nilsson's edits on *decoded picture* buffer
- Mike Nilsson's edits on SP frames
- Mike Nilsson's edits on intra_pred_mode
- Mike Nilsson's edits on CAVLC
- Input on Mb-adaptive frame-field

Modifications in JVT-E146d1 relative to JVT-E146d0:

- minor edits and field updates

Modifications in JVT-E146d2 relative to JVT-E146d1:

- incorporation of text regarding the adopti on of JVT-E088

Modifications in JVT-E146d3 relative to JVT-E146d2:

- From JVT-E152r1

Changes related to HRD (JVT-E075, all except item 1):

- Changed name of "decoded pictures buffer (DPB)" to "decoded picture buffer (DPB)" to eliminate conflict of DPB with "slice data partition B." Added DPB acronym.
- Changed name of "pre-decoder buffer" to "coded picture buffer (CPB)," which was already in the list of definitions.

  - pdb_cnt -> cpb_cnt

- Changed name of "pre_dec_removal_delay" to "cpb_removal_delay."
- Changed name of "initial_pre_dec_removal_delay" to "initial_cpb_removal_delay."
- Removed references to "VBV."
- Changed name of "HRD Picture SEI Message" to "Picture Timing SEI Message"
- Two Ed.Notes in D.3.9 about random access definition. *Gary says the issue is real and we should fix it by eliminating the preroll thingie.*
- Changed semantics of "cpb_removal_delay" so that the delay is now with respect to the previous random access point rather than the previous picture. The "entropy coding" of the syntax element is al so changed to be a fixed length code of specifiable length. *Random access point is not clearly defined.*
- Added language specifying that the "initial_cpb_removal_delay" must not exceed the time -equivalent of the CPB size.
- Changed name of "coded_pic_buffer_ size_value" to "cpb_size_value" and "coded_pic_buffer_size_scale" to "cpb_size_scale."

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- 3.3.6 modify description of IDR picture's action on decoded picture buffer
- Change 8.3.6.7.6 "reset" to "reset_reference" add "reset_nonreference" and "reset_all"

EDITORIAL

- Change "reference picture" to "decode d picture" in several places
- Sec 7.3.3.3 change ref_ to dec_

Modification to support frame store implementations and unify to single decoded picture buffer JVT -E034

TECHNICAL (NOT INCORPORATED !!!!!!)

- A new field max_sliding_window_size_minus_one added to sequence parameter set
- Define operation of the sliding window supporting frame stores and consistent with a single decoded picture buffer.
- Operation defined to support frame storage. Dangling fields occupy an entire frame store.

EDITORIAL

- Modify definition of decoded picture buffer
- Remove definition of reference picture buffer
- Replace reference picture buffer with decoded picture buffer.
- Replace mention of long-term and short-term buffers describing elements of decoded picture buffer
- Add "reference" before "frame" as needed
- Modify description of constructing picture numbers for field indexing or frame indexing.
- Replace " max_long_term_idx_plus1" with "max_long_term_pic_idx_plus1"
- max_long_term_idx_plus1 MINUS 1 is the largest long -term frame index

INCLUDED RESPONSE to comments raised during review.

- Replaced "decoded pictures buffer" with "decoded picture buffer"
- Modified discussion in Annex A to reflect use of single decoded picture buffer simultaneously included text for HRD DPB verifier since this is tied to the discussion modified in Annex A.
- Note the HRD DPB was added to this document since it references the modifications to Annex A

- Delete "as un-used" in definition of IDR.
- Correct check for while loop in Decoded picture buffer management syntax
- Change non-reference_pictures_reset_flag and reordering_pictures_reset_flag to non_reference_pictures_reset_flag
- Change text that were not syntax nor variable names to English
    - Reset_all → reset all referece and non-reference pictures
    - Reset_reference → reset all reference pictures
    - Reset_non-reference → reset all non-reference pictures
- Clean up some text and spelling

Modifications in JVT-E146d5 relative to JVT-E146d4:

Editorial from TK's e-mail

- removed redundent definition in IDR picture.
- replaced definition of 1 picture with 1 slices.
- Indentation for dec_pic_buffer_management( ) in the syntax table
- Changed non_reference_pictures_reset_flag to non_ref_pic_reset_flag
- Changed remaining ref_pic_..... syntax element to dec_pic_.....
- Add missing references to Unused pictu re marking

Modifications in JVT-E146d6 relative to JVT-E146d5:

Technical from JVT-E156

- reduction of sample dependencies for 4x4 intra prediction (JVT -E111)

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- change of direct temporal mode to 8x8 MC blocks (JVT -E037)
- removal of special position (JVT-E161)

Moved switch from slice header to switch at Sequence Parameter Set of special 8x8 MC block mode

Modifications in JVT-E146d7 relative to JVT-E146d6:

- Moved S pictures into clause 8
- Removal of ABT
- Removal of Intra_8x8
- Removal of 1/8-pel MC

Modifications in JVT-E146d8 relative to JVT-E146d7:

Outstanding items from JVT-E135

- Suggested CAVLC semantics
- Editorial correction and clarifications
- Addition of chroma_qp_index_offset

Modifications in JVT-E146d10 relative to JVT-E146d8

- Moved the table 9.3 to subclause 7.4. 4
- Removed Mapped Golomb code from clause 9
- Change me(v) to ue(v) in Syntax table
- Change xe(v) to te(v) in Syntax table
- Delete definition of me(v)
- Changed coded_block_patternY to CodedBlockPatternLuma
- Changed nc to CodedBlockPatternChroma
- Change diagram for macroblock to remove CBPY.
- Change code_num to CodeNumber
- Change field and frame reference for ref_idx_10 text into tables.

Modifications in JVT-E146d11 relative to JVT-E146d10

- incorporation of text regarding of JVT -E086
- PCM mode for CABAC
- incorporation of text regarding to JVT-E059
- removal of CABAC text related to ABT
- modifications for removal of intra_8x8 sub MB type
- modifications of init tables
- incorporation of text regarding of JVT -E154

Modifications in JVT-E146d12 relative to JVT-E146d11

- Replace num_of_ref_frames -> num_ref_frames
- nal_storage_idc should be restricted to the same value for all slices in a picture – Strike that, it should be restricted such that it is either zero for all slices in a picture or non-zero for all slices in a picture, but not necessarily the same non-zero value for all NAL units of a picture. – This is stated already in the semantics of nal_reference_idc.
- Editorial correction of default list 0 and list 1 reference indices for B slices. List 0 orders past pictures from most recent to oldest, the future pictures from current time towards the future, then long -term pictures. List 1 orders the future pictures from current time towards the future past, then past pictures from most recent to oldest, then long-term pictures.
- Added text to define more precisely the default orders for field pictures. Default order is as frame order, but is ordered same parity followed by opposite parity.

TECHNICAL changes:

- Added two fields to VUI HRD parameters specifying the length of the cpb_removal_delay syntax elements.
- Removed references to "prev_buf_period_duration."

Changes related to temporal reference (JVT-E122 and JVT-E078):

- Defined "dpb_output_delay" in the Picture Timing SEI Message to replace "temporal_ref_value." Added its sementics. Added description of initial and final DPB output times.
- Added one fields to VUI HRD parameters specifying the length of the dpb_output_delay syntax element.
- Added "output _type" syntax and semantics to the Picture Timing SEI Message.
- Added "field_delay_value" to the Picture Timing SEI Message.
- Added two more fields to VUI HRD parameters specifying the length of the dpb_output_delay and field_delay_value syntax elements.

Changes related to film mode support (JVT-E078):

- Changed "pic_structure" to "field_pic_flag" and "bottom_field_flag" as appropriate.
- Modified several syntax tables to use the new elements.

Changes related to clock timestamp support (JVT-E122):

- Added "ct_type" and "nuit_field_based_flag" to the clock timestamp SEI message (syntax and semantics).
- Modified Equation D-1 to use nuit_field_based_flag.
- Moved syntactical constraints out of Annex C.

Modifications in JVT-E146d0ncm_hrd_edits_r5 relative to JVT-E146d0ncm_hrd_edits:

- Removed some references to "packet stream" in HRD description.
- Removed *more* references to "prev_buf_period_duration."
- change "hrd_picture" to "pic_timing" in two pl aces
- combined the Clock Timestamp SEI message and the HRD Picture message into a single Picture Timing SEI message.

Changes related to modified CAT proposal (JVT-E133):

- Added syntax element "initial_cpb_removal_delay_offset."
- Added description of "initial_cpb_removal_delay_offset" effect on HRD operation in Annex C.1 and informative text in C.2.

Changes related to clock timestamp support (JVT-E122):

- Renamed "output_type" to "pic_structure"
- Placed clock timestamp syntax inside pic_structure if statement, and allowed multiple copies of the clock timestamp syntax elements.
- Removed reserved bits.
- Removed two no longer existent SEI payload types.
- Added semantics for equal EquivalentTimestamps.

Changes related to clock timestamp support (JVT-E032):

- Added description of DPB operation

Modifications in JVT-E152r1 relative to JVT-E152:

- Changed description of CPB removal time in C.1.1.2 to accurately reflect the adoptions in this meeting.

Various changes based on input from reviewers of JVT-E152.

Modifications in JVT-E146d4 relative to JVT-E146d3:

From JVT-E149r1

Modifications for JVT-E121 (Incorpoation of TK's revisions)

TECHNICAL

- 7.4.3.2 change mmco command "reset" to "reset_reference", add commands "reset_nonreference" and "reset_all" modify and add descriptions
- Table 7-9 modify entry 5 add entries 6 and 7

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- 8.3.6.6 Sliding window operation
- A.6.1 must conform to DPB verifier with capacity determined by the level
- A.6.2 replaced reference memory with decoded picture buffer memory
- A.6.3 Defined capacity of DPB in frames used in HRD
- C.1.2.(1-4) Reorder and modify text of operations: Decode, Mark, Remove, Add. Conformance is only tested in addition step this ordering simplifies the description.
- C.1.2.5 Conformance references DPBcapacity calculated in A.6.3

Modifications in JVT-E146d13 relative to JVT-E146d12

- Edits on MB-AFF and Picture Order Codes in Chapters 7, 8, and 10.
- Also a statement that successive IDR pictures are forbidden.
- SEI DPB output times shall have the same ordering as Picture Order Counts.

Modifications in JVT-E146d14 relative to JVT-E146d13

- limitation of cbp_cnt to be no greater than 32 (shouldn't we be using cpb_cnt_minus1 inst ead of cpb_cnt with a value of 0 being prohibited?) from JVT-E123
- limitation of entropy_coding_mode to not exceed 1 from JVT-E123 [This constraint then disappeared somewhere between draft 16 and draft 22 and was put it back in draft 25.]
- increased the maximum number of sequence parameter sets to 31 from JVT-E123
- increased the maximum number of picture parameter sets to 128 from JVT-E123
- removed non_stored_content_flag and non_stored_pic_flag redundant syntax element from JVT-E123
- moved deblocking_filter_parameters_present_flag and constrained_intra_pred_flag from the sequence parameter set to the picture parameter set from JVT-E123
- removed redundant entries in sample aspect ratio table and made sar_width and sar_height u(16)'s. from JVT-E123
- removed motion_resolution from JVT-E123
- made frame_cropping_flag and timing_info_flag u(1) instead of ue(v) from JVT.-E123 [The frame_cropping_flag change part of this was somehow missed and was put back in draft 25.]
- changed some high-level syntax elements from e(v) to ue(v) from JVT-E123

Modifications in JVT-E146d15 relative to JVT-E146d14

- from JVT-E146d10AG.doc
- AG's paper edits

Modifications in JVT-E146d16 relative to JVT-E146d15

- from JVT-E159 changes for alternate scan
- from JVT-E162 changes regarding deblocking filter:
  - Figure 8-14 was updated to deal with the MB-AFF case. Text was added to explain that
  - Text added to explain how to compute QPav for the deblocking filter in the case where any of the blocks if composed of fields with different QP

Formatted: Indent: Left: 0.8", Bulleted + Level: 1 + Aligned at: 0.55" + Tab after: 0.8" + Indent at: 0.8", Tabs: Not at 0.8"

- from JVT-E154r4
  - "long" and "short" SCPs removed – there is now only one SCP length (3 bytes), but sometimes an extra byte of value 0 is stuffed before it. (per meeting)
  - JVT-E054 incorporated. (change to 3-byte short SCPs from 2-byte short SCPs, send (what was) Long SCP only on Parameter Sets and first slice of each picture)
  - Specified that reserved NAL unit types shall be ignored by decoders.
  - Changes to maximum bit rates and buffer capacities (esp. levels 3 to 5), specify VCL = 1, VCL+NAL = 1.2. [Do we have a clear definition of wh at counts in VCL and what counts in NAL?]
  - Removal of field pictures (all interlace-oriented decoding tools) in baseline profile
  - Updated informative table in Annex A to reflect new Levels table values.

Formatted: Indent: Left: 0.8", Bulleted + Level: 1 + Aligned at: 0.55" + Tab after: 0.8" + Indent at: 0.8", Tabs: Not at 0.8"

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- Reworded the HRD semantics for xxx_hrd_parameters_present_flag to reflect the new bitstrea m conformance requirements.
- Moved the semantics for low_delay_hrd into the correct location in the sequence VUI subclause.
- Minor edits to first three paragraphs of C.1.
- Two new paragraphs in C.1 explaining the operation of the HRD and the various locations of HRD-related syntax and semantics.
- Minor edits to C.1.1
- Added definition of "random access point" to the list of definitions.
- Corrected range of index values for chroma DC coefficient scaling equations (USNB subject 25)

Modifications in JVT-E146d26 rela tive to JVT-E146d25

- Swapped RBSP trailing bits and RBSP slice trailing bits syntax and semantics sections with each other (this way everything that uses RBSP trailing bits precedes the definition of that structure rather than some being before and some aft er)
- Clarification of byte-stream and cabac_stuffing_word issues.
- Range of values specifications for weighted prediction syntax elements.
- Addition of editor's notes regarding need for clarification of issues surrounding MB -AFF.
- Clarification of calculation of motion vector components and reference picture indices.
- Clarification of B-picture issues.
- Clarification of weighted prediction issues.
- Added overscan_info_present_flag and overscan_appropriate_flag to sequence VUI per JVT -E055.
- Removed HRD picture SEI message syntax (was apparently left in by accident, although the semantics had been removed).
- Removed clock timestamp SEI message syntax (was apparently left in by accident, although its content had been subsumed into the picture timing SEI message).
- Added maximum output rate constraint to Section C.1.2.4. Updated C.1.1.3 maximum removal rate definition. Now both limits are in terms of the maximum macroblocks per second (A.6.2) and the number of macroblocks in the picture. Definition works for fields. F rom JVT-E123.
- Aligned the numbering of the subclauses 8.5.3.1 -4 for the four chroma intra prediction modes with the order of the modes in the VLC table 7-15. At request of USNB Subject 15.
- Added new SEI messages from JVT-E038 (full-frame freeze & release, full-frame snapshot, progressive refinement segment start & end) and cleaned up SEI payload type syntax to remove old deleted messages.
- Swapped the order of buffering period SEI message and picture timing SEI message in syntax and semantics (since buffering period is how you start the HRD process and picture timing is how you then continue it).

Modifications in JVT-E146d27 relative to JVT-E146d26

- Correction of Figure 8-5 – Differential motion vector decoding with scaled motion vector.
- Removed motion vector clipping to +/- 19 samples off edge of picture per USNB subject 14.
- Clarification of nal_storage_idc, including renaming of nal_storage_idc to nal_reference_idc.
- Clarification and bounding of ranges of sub -sequence SEI messages.
- Reserved a range of values of pan_scan_rect_id, progressive_refinement_id, and snapshot_id for future use by ITU-T | ISO/IEC.

Modifications in JVT-E146d28 relative to JVT-E146d27

- Added editorial note re problem in Figure 9-6 for CABAC.
- Corrected variable name "symbol" to "S" in sub clause 9.2.1.3.
- Redefinition and relaxation of minimum compression ratio requirement per USNB subject 32.
- Clarification of clock_timestamp per USNB subject 40.
- Clarification of broken_link_flag per USNB subject 42.
- Clarification and bounding of ranges for pan-scan rectangle SEI messages.
- Correction of CPB buffer size for Level 5.

- from JVT-E146d14ncm_gjs
  - added max_dec_frame_reordering and constrained its range of values
  - constrained the range of values for the frame cropping rectangle.
  - constrained the range of the maximum motion vector length parameters
  - clarified and constrained the range of the syntax elements that limit the number of b its per picture and the number of bits per MB
- from JVT-E146d7_hrd_hrd
  - E.3.2 added text indicating limits on bit_rate[k] and cpb_size[k].
  - D.3.1 Added details and clarifications.
  - For the second time, the obsolete syntax element removal_time_tolerance is rem oved from vui_seq_parameters().
  - Edits to preamble part of C.1.1 to reflect agreed HRD conformance status.
  - Figure C-1 updated to replace "bitstream" with byte stream.
  - Fixed cross-references in Annex C; unable to fix all because the Figures C-3 to C-5 do not appear in the list of Figures and can't be properly cross-referenced.
  - Similar problem with the tables in Annex D.
  - NOTE – I believe vcl_hrd_flag should be removed. It is no longer normative to produce a stream for which the vcl does not confrom to the HRD .

Modifications in JVT-E146d17 relative to JVT-E146d16

- from JVT-E165r3
- integrated the B picture clause into subclause 8.4
- from JVT-E146d16ncm_e60

Modifications in JVT-E146d18 relative to JVT-E146d17

- from JVT-E146d16_jill
- from JVT-E146d16AMT
- Changed POD to DiffPicOrderCount: Difference of Picture Order Counts

Modifications in JVT-E146d19 relative to JVT-E146d18

- from JVT-E157
  - from JVT-E124 changes for
  - Adding frame_coding_only_flag into sequence parameter set, to skip signalling field_pic_flag and bottom_field_flag in slice header.
  - IDR picture is always stored as a reference picture
  - Restricitions on slice header parameter values
  - Picture order count mode 2 (done already in JVT-E146d16)
  - from JVT-E125 changes for
  - Picture boundary detection based on field parity (done already in JVT-E146d16)
  - from JVT-E126 changes for
  - Clarification and bug fixes of the sub-sequence SEI messages
  - from JVT-E128 changes for
  - Moving mb_slice_group_map_type 2 to the last order (6), then types 3~6 become 2~5.
  - from JVT-E130 changes for

Formatted: Indent: Left: 0.8", Bulleted + Level: 1 + Aligned at: 0.55" + Tab after: 0.8" + Indent at: 0.8", Tabs: Not at 0.8"

Formatted: Indent: Left: 0.8", Bulleted + Level: 1 + Aligned at: 0.55" + Tab after: 0.8" + Indent at: 0.8", Tabs: Not at 0.8"

Formatted: Indent: Left: 0.83", Bulleted + Level: 1 + Aligned at: 0.55" + Tab after: 0.8" + Indent at: 0.8", Tabs: Not at 0.8"

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- Replacement of Figure C-5 (some kind of problem had made it not visible)

Modifications in JVT-E146d29 relative to JVT-E146d28

- Clauses 8 and 9 describe processes or provide a specif ication for the processes -> changed all clause and subclause names to contain the phrase "process" or "specifaication ... for ... process"
- Added for processes with input/output:

  Input to this process is/are ??? [Ed.Note: specify input to this process]

  Output of this process is/are ??? [Ed.Note: specify output of this process]
- Added for initialisation processes:

  This intitialization process is invoked when ... [Ed.Note: specify]

  Output of this process is/are ??? [Ed.Note: specify output of this process]
- Worked on geometrical concepts
- Clarified exp-Golomb entropy coding.

Modifications in JVT-E146d30 relative to JVT-E146d29

- Added constraint of no more than 16 MVs per two consecutive MBs at levels 3.1 and above.
- Added constraint of 8x8 or larger block size for direct and bi-pred for level 3.1 and above and removed such constraint from level 3 and below.
- Added constraint of no more than 3200 bits per macroblock.
- Added semantics of pcm_alignment_bit and pcm_byte.
- Refined description of exp-Golomb code parsing

Modifications in JVT-E146d31 relative to JVT-E146d30

- Replaced text marked in Finnish with English (UK).
- Clarification of sub-sequence SEI semantics
- Clarification of meaning of decoding process conformance (numerically identical results) in response to USNB Subject 17.
- Added sentence to NAL unit semantics to clarify which NAL units are considered VCL NAL units.
- Clarification of CAVLC parsing process.

Modifications in JVT-E146d32 relative to JVT-E146d31

- Introduced 4 functions in subclause 5.6
- Introduced inverse scanning processes and derivation processes for macroblock and macroblock pair indices in subclause 6.4:
  - Limin, Peter B. - please let me know if these processes work for specifying MB-AFF
  - Limin, Jill, Alexis, Lowell - please let me know whether these processes work for specifying inter prediction
  - Gary - please let me know if these processes work for specifying transform decoding
  - Peter L., Anthony - please let me know if these processes work for specifying deblocking
  - Karl - please let me know if these processes work for specifying CAVLC
  - Detlev - please let me know if these processes work for specifying CABAC
- Rewrote the Intra_4x4 prediction subclause 8.5.1 using the geometric concepts ... first run ... wording could be improved and made less verbose

Modifications in JVT-E146d33 relative to JVT-E146d32

- corrected some MS Word problems
- change data partitioning to slice data partitioning
- removed subclause titles with Introduction or General
- improved subclause 8.3.1 (Intra_4x4)
- changed start of decoding process clause.

Modifications in JVT-E146d34 relative to JVT-E146d33

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- Adding six definitions of related to redundant slices to clause 3. [Note that numbering of the definitions is not correct and it was not correct in E146d16 either. In addition, some of the definitions are in the wrong places, e.g. "decoded picture buffer mana gement"].
- Change to the semantics of redundant_pic_cnt.
- Bug fix for redundant slices: adding redundant_pic_cnt to headers of slice data partition B and C.
- Change to the semantics of slice_id
- Text changes on 8.2.1 NAL unit decoding order (the subclause is e ntirely modified)
- from JVT-E132 changes for
- Typo correction in 7.3.28 "rsbp" → "rbsp"
- Clarification of mb_slice_group_map_type 3# (old value, the new type number is 2#)
- "MAX_MB_LOCATION " → "MAX_MB_ADDRESS"
- Clarification of scene information SEI message
- from JVT-E141 changes for
- An improvement on the spare picture SEI message: delta_frame_num → target_frame_num
- Bug fix: a "}" was missing

Modifications in JVT-E146d20 relative to JVT-E146d19

- from JVT-E146d16ncm_gjs ... start code clarifications from Gary
- from JVT-E146d15AG ... align names and description for the qp parameters

Modifications in JVT-E146d21 relative to JVT-E146d20

- from JVT-E146d8_aj_deblock
- Changes to macroblock_layer syntax, definition of delta_qp, and deblocking filter interaction with MB AFF from JVT-E162
- Chroma deblocking filter simplifications from JVT -E089
- Clarification and new mode for disable_deblocking_filter_idc from JVT -E123

Formatted: Indent: Left: 0.79", Hanging: 0.3", Bulleted + Level: 1 + Aligned at: 0.55" + Tab after: 0.8" + Indent at: 0.8", Tabs: Not at 0.8"

Modifications in JVT-E146d22 relative to JVT-E146d21

- Some terminology consistency changes (e.g., change "motion comp ensation" to "inter prediction")
- Some changes to POC description (e.g., define same temporal direction based on POC)
- Some fixes relating to MB-AFF and direct prediction and weighted prediction from Boyce, Tourapis, and Wang [Ed. Note: I don't like the use of an ordinary english word with capitalization of the first letter to indicate something special – e.g., "Direct"]

Modifications in JVT-E146d23 relative to JVT-E146d22

- Conversion to automatic numbering for definition and abbreviation numbering
- Conversion to automatic numbering for equation numbering through clause 8 (still need to put in the automatic cross-references).
- Added max_dec_frame_buffering and reworded semantics of max_dec_frame_reordering.
- Eliminated unused DIV operator definition and clarified other operators
- Eliminated pre-roll count from random access point SEI message
- Clarified aspects of start-code-related things now that the new Bossen end-of-slice CABAC stuffing is in.

Modifications in JVT-E146d24 relative to JVT-E146d23

- Clarification of edges controlled by macroblocks in slice
- Clarification of terminology

Modifications in JVT-E146d25 relative to JVT-E146d24

- Added statement "A given reference picture may appear at more than one index position in the remapped list 0 or list 1" (should probably also mention this concept in weighted prediction section, and should probably disallow multiple entries for the same picture unless weighted prediction is in use)

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- changed names of mb_types and mb prediction types. applied changes to all clauses except 9 ff:
  - Introduced I, SI, P, and B collective macroblock types
  - Introduced Intra_4x4 and Intra_16x16 prediction modes
  - Introduced Intra and Inter prediction modes als collective terms
  - We may be able to remove names for mb_type
- changed "Category" in tables to "C" to save space
- changed mb prediction type indices from 1&2 to 0&1.
- changed syntax table index naming to MbPartIdx , SubMbIdx, SubMbPartIdx
- introduced column in I macroblock table for Intra_16x16 prediction mode showing Intra16x16PredMode, CodedBlockPatternChroma, CodedACblockPatternLuma
- improved clause 9.3
- minor changest to clause 0 (introduction)
- minor changes to clause 3 (definitions).
- minor revisions of clause 4 (abbreviations) – removed SAR abbreviation (was not used in the text anywhere) and SMPTE abbreviation (only used in a few places in Annex E, so just spelled it out when used)
- minor revisions of clause 5 (conventions) – added definition of "+=" and " –=", etc.
- minor revisions of subclauses 7.2 (definition of functions, categories, and descriptors) and 7.3 (syntax) - replacing u(n) with f(n) for several fixed-value syntax elements, removal of undefined three_reserved_bits syntax element, definition of read_bits(n), correction of several descriptor definitions to use read_bits(n) rather than next_bits(n) (because next_bits(n) does not advance the bitstream pointer), and typos.
- moved statement about which deblocking edges are controlled by a macroblock to the deblocking filter process subclause rather than the semantics subclause.
- improved transform level parsing subclause in clause 7.

Modifications in JVT-E146d35 relative to JVT-E146d34

- Changes from Miska and Ragip clarifying especially
  - SP pictures
  - required_frame_num_update_behaviour_flag
  - slice group stuff
- Changes from Gary centered on
  - inverse transform section
  - cross-references, typos, consistency issues, application of "keep with next" to prevent tables from splitting across page boundaries.
- [I suggest changing
  NumBitsInMbAddress → NumBitsInMBaddress,
  ChromaDCLevel → ChromaDClevel,
  ChromaACLevel → ChromaAClevel,
  MbIdx → MBidx,
  CtxMbTypeI → CtxMBtypeI,
  PicWidthInMbs → PicWidthInMBs
  etc.
  (the rule being that there is a case change when a new word starts – this way "MB" is macroblock instead of "Mb" and other acronyms stay as all-text]
- Replaced text marked in Portuguese (Brazil) with English (U.K.)

Modifications in JVT-E146d36 relative to JVT-E146d35

- CABAC clarifications
- Fix of num_ref_idx_active_l0_minus1 and num_ref_idx_active_l0_minus1 semantics for slices and bounds on values.
- Clarified next_bits(*n*) return value equal to 0 for insufficient data.
- Picture order count clarifications
- Removal of discussion of time in semantics of non_ref_pic_reset_flag

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- Modification for consistency of use of terms luma and chroma and clarity of their definition
- Work on definitions and clarifications for MB -AFF
- Fix-up of slice_data() syntax bugs (elimination of first_nonskip_mb_in_pair(), provision for FMO, etc.)

Modifications in JVT-E146d37 relative to JVT-E146d36

- Changes from Detlev for further CABAC clarifications
- Changed slice termination syntax table for CABAC to correctly reflect JVT -E086 changes
- Replaced some (but perhaps not all) text labeled as "English (U.S.)" with "English (U.K.)"
- Replaced some text labeled as "German (Germany)" with "English (U.K.)"
- Replaced text marked in Portuguese (Brazil) with English (U.K.)
- Renamed syntax element names xyz_picture_xyz → xyz_pic_xyz and reference_xyz → ref_xyz and xyz_count_xyz → xyz_cnt_xyz for syntax naming consistency
- Fixed indentation in pic_timing( ) SEI message syntax
- Changed description of range of pan_scan_rect_id
- Changed description of checking for emulation prevention in NAL_unit( ) syntax
- Changed description of detection of end of byte streams.
- Clarified note describing potential external use of forbidden_bit.
- Clarified 172 fps limit in regard to accounting for field pictures
- Corrected calculation of AbsFrameNum with num_ref_frames_ in_pic_order_cnt_cycle equal to 0
- Clarified/corrected deblocking filter process from Anthony Joch
- Clarified/corrected parts of MB-AFF description
- Specified limits on range of a few syntax elements

Reminder: Please start all editorial notes with the string "[Ed".

Note: Anyone proposing any change to this draft must familiarize themselves with the content of the H.264/AVC drafting guide (version 7 or later) and the common text template. If you don't have these or don't know exactly what these are, ask Thomas or Gary for a copy.

End Ed. Notes]

7.4.2.4 Picture delimiter RBSP semantics 42
7.4.2.5 Filler data RBSP semantics 42
7.4.2.6 Slice layer RBSP semantics 42
7.4.2.7 Slice data partition RBSP semantics 42
7.4.2.7.1 Slice data partition A RBSP semantics 42
7.4.2.7.2 Slice data partition B RBSP semantics 43
7.4.2.7.3 Slice data partition C RBSP semantics 43
7.4.2.8 RBSP slice trailing bits semantics 43
7.4.2.9 RBSP trailing bits semantics 43
7.4.3 Slice header semantics 43
7.4.3.1 Reference index reordering semantics 46
7.4.3.2 Prediction weight table semantics 47
7.4.3.3 Decoded picture buffer management semantics 47
7.4.4 Slice data semantics 49
7.4.5 Macroblock layer semantics 49
7.4.5.1 Macroblock prediction semantics 55
7.4.5.2 Sub-macroblock prediction semantics 56
7.4.5.3 Residual data semantics 57
7.4.5.3.1 Residual 4x4 block CAVLC semantics 58
7.4.5.3.2 Residual 4x4 block CABAC semantics 58
8 Decoding process 58
8.1 NAL unit decoding process *59*
8.2 Slice decoding process *59*
8.2.1 Detection process of coded picture boundaries 59
8.2.2 Decoding process for picture order count 59
8.2.2.1 Decoding process for picture order count type 0 60
8.2.2.2 Decoding process for picture order count type 1 61
8.2.2.3 Examples for the decoding process for picture order count types 0 and 1 (informative) 62
8.2.3 Decoding process for redundant slices 64
8.2.4 Decoding process for macroblock to slice group map 64
8.2.4.1 Specification of allocation order for box-out for decoding process for macroblock to slice group map 65
8.2.4.2 Specification of the mapping for raster scan for decoding process for macroblock to slice group map . 66
8.2.4.3 Specification of allocation order for wipe for decoding process for macroblock to slice group map 66
8.2.4.4 Specification of allocation order for macroblock level adaptive frame and field coding for decoding process for macroblock to slice group map 66
8.2.5 Decoding process for slice slice data partitioning 67

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

8.2.6 Decoding process for reference picture reordering 67
8.2.6.1 Decoding process for picture numbers 67
8.2.6.2 Decoding process for frame numbers 68
8.2.6.3 Initialization process for reference indices 69
8.2.6.3.1 Initialization process for reference indices for P and SP slices in frames 69
8.2.6.3.2 Initialization process for reference indices for P and SP slices in fields 69
8.2.6.3.3 Initialization process for reference indices for B slices in frames 70
8.2.6.3.4 Initialization process for reference indices for B slices in fields 71
8.2.6.4 Assignment process for reference indices 72
8.2.6.4.1 Assignment process for reference indices for short-term pictures 72
8.2.6.4.2 Assignment process for reference indices for long-term pictures 73
8.2.7 Decoded picture buffer management process 73
8.2.7.1 Sequence of operations for decoded picture buffer management process 74
8.2.7.2 Sliding window decoded picture buffer management process 74
8.2.7.3 Adaptive Memory Control decoded picture buffer management process 75
8.2.7.3.1 Assignment process for short-term pictures to "unused for reference" 75
8.2.7.3.2 Assignment process for long-term pictures to "unused for reference" 75
8.2.7.3.3 Assignment process for a long-term index to a short-term reference picture 75
8.2.7.3.4 Decoding process for maximum long-term index 76
8.2.7.3.5 Assignment process for all reference pictures to "unused for reference" 76
8.2.7.3.6 Assignment process for all non-reference pictures to "unused" 76
8.2.7.3.7 Assignment process for all reference and non-reference pictures to "unused" 77
8.2.8 Decoding process for macroblock level frame/field adaptive coding 77
8.2.8.1 Derivation process for frame or field decoding mode for a skipped macroblock pair in P or SP slices 78
8.2.8.2 Derivation process for frame or field decoding mode for skipped macroblock pair in B slice 78
8.3 Intra prediction process 78
8.3.1 Intra_4x4 prediction process 78
8.3.1.1 Derivation process for the available samples 78
8.3.1.1.1 Derivation process for the available samples for macroblocks 78
8.3.1.1.2 Derivation process for the available samples for macroblock pairs 79
8.3.1.2 Derivation process for the Intra4x4LumaPredMode 80
8.3.1.2.1 Derivation process for neighbouring macroblock addresses and their availability 81
8.3.1.2.2 Derivation process for neighbouring macroblock pair indices and their availability 81
8.3.1.2.3 Derivation process for the Intra_4x4 prediction modes from neighboring macroblocks 81
8.3.1.2.3.1 Derivation process for the Intra_4x4 prediction modes from left neighbouring macroblock 81
8.3.1.2.3.2 Derivation process for the Intra_4x4 prediction modes from above neighbouring macroblock 81
8.3.1.2.4 Derivation process for the Intra_4x4 prediction modes from neighboring macroblock pairs 82
8.3.1.2.4.1 Derivation process for the Intra_4x4 prediction modes from neighboring macroblock pairs when current macroblock pair is coded in frame decoding mode 82
8.3.1.2.4.2 Derivation process for the Intra_4x4 prediction modes from neighboring macroblock pairs when current macroblock pair is coded in field decoding mode 82
8.3.1.2.5 Derivation process for Intra4x4LumaPredMode for the current macroblock 84
8.3.1.2.6 Derivation process for Intra4x4LumaPredMode for the current macroblock pair 85
8.3.1.3 Decoding process for Intra_4x4 prediction modes 85
8.3.1.3.1 Specification of Intra_4x4_Vertical prediction mode 85
8.3.1.3.2 Specification of Intra_4x4_Horizontal prediction mode 85
8.3.1.3.3 Specification of Intra_4x4_DC prediction mode 86
8.3.1.3.4 Specification of Intra_4x4_Diagonal_Down_Left prediction mode 86
8.3.1.3.5 Specification of Intra_4x4_Diagonal_Down_Right prediction mode 86
8.3.1.3.6 Specification of Intra_4x4_Vertical_Right prediction mode 86
8.3.1.3.7 Specification of Intra_4x4_Horizontal_Down prediction mode 87
8.3.1.3.8 Specification of Intra_4x4_Vertical_Left prediction mode 87
8.3.1.3.9 Specification of Intra_4x4_Horizontal_Up prediction mode 87
8.3.2 Intra_16x16 prediction process 88
8.3.2.1 Mode 0: vertical prediction process 88
8.3.2.2 Mode 1: horizontal prediction process 88
8.3.2.3 Mode 2: DC prediction process 88
8.3.2.4 Mode 3: plane prediction process 89
8.3.3 Intra prediction process for chroma blocks 89
8.3.3.1 Mode 0: DC prediction process 89
8.3.3.2 Mode 1: horizontal prediction process 90
8.3.3.3 Mode 2: vertical prediction process 90
8.3.3.4 Mode 3: plane prediction 90

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

8.4 Inter prediction process *90*
8.4.1 Derivation process for motion vector components and reference pictur e indices 91
8.4.1.1 Derivation process for the neighbouring blocks for motion vector and reference index prediction 92
8.4.1.2 Derivation process for the luma motion vector predictors in the neighbouring blocks 93
8.4.1.2.1 Derivation process for the luma motion vector predictors in the neighbouring blocks in P and SP slices 93
8.4.1.2.2 Derivation process for the luma motion vector predictors in the neighbouring blocks in B slices .. 94
8.4.1.3 Derivation process for the luma motion vector prediction method 95
8.4.1.3.1 Decoding process for median luma motion vector prediction 95
8.4.1.3.2 Decoding process for directional segmentation luma motion vector prediction 95
8.4.1.4 Derivation process for luma motion vectors for skipped and Direct prediction macroblocks 96
8.4.1.4.1 Derivation process for luma motion vectors for skipped macroblocks in P and SP slices 96
8.4.1.4.2 Derivation process for luma moti on vectors for skipped, Direct_16x16 and Direct_8x8 in B slices 96
8.4.1.4.2.1 Derivation process for the co-located macroblock 97
8.4.1.4.2.2 Derivation process for spatial direct luma motion vector and reference picture index prediction mode 97
8.4.1.4.2.3 Derivation process for temporal direct luma motion vector and refer ence picture index prediction mode 98
8.4.1.5 Calculation of the resulting luma motion vector 102
8.4.1.6 [Ed, Note: This whole para graph is covered in 8.4.1]Derivation process for chroma motion vectors . 103
8.4.2 Decoding process for inter prediction samples 103
8.4.2.1 Reference picture selection process 104
8.4.2.2 Fractional sample interpolation process 104
8.4.2.2.1 Luma sample interpolati on process 104
8.4.2.2.2 Chroma sample interpolation process 106
8.4.2.3 Weighted sample prediction process 106
8.4.2.3.1 Default weighted sample prediction process 106
8.4.2.3.2 Weighted sample prediction process 107
8.5 Transform coefficient decoding process and picture construction process prior to deblocking filter process 109
8.5.1 Zig-zag scanning process and field scanning process 109
8.5.2 Scaling and transformation process 109
8.5.2.1 Scaling and transformation process for luma DC coefficients for Intra_16x16 macr oblock type 110
8.5.2.2 Scaling and transformation process for chroma DC coefficients 111
8.5.2.3 Scaling and transformation process for residual 4x4 blocks 111
8.5.3 Picture construction process prior to deblocking filter process 113
8.6 Decoding process for SP a nd SI slices 113
8.6.1 SP decoding process for non-switching pictures 113
8.6.1.1 Luma transform coefficient decoding process 114
8.6.1.2 Chroma transform coefficient decoding process 115
8.6.2 SP and SI slice decoding process for switching pictures 116
8.6.2.1 Luma transform coefficient decoding process 116
8.6.2.2 Chroma transform coefficient decoding process 117
8.7 Deblocking filter process 117
8.7.1 Derivation process for the content dependent boundary filtering strength 118
8.7.2 Derivation process for the thresholds for each block boundary 120
8.7.3 Filtering process for edges with Bs smaller than 4 121
8.7.4 Filtering process for edges for Bs equal to 4 122
9 Parsing process 123
9.1 Parsing process for exp-Golomb codes 123
9.1.1 Mapping process for unsigned exp -Golomb and for truncated unsigned exp -Golomb codes 124
9.1.2 Mapping process for signed Exp-Golomb codes 125
9.2 CAVLC parsing process for transform coefficients 125
9.2.1 Parsing process for total number of coeffi cients and trailing ones 125
9.2.1.1 Table selection process 128
9.2.2 Parsing process for level information 129
9.2.2.1 Table selection 132
9.2.3 Parsing process for run information 132
9.2.3.1 Parsing process for total number of zeros 132
9.2.3.2 Parsing process for run before each coefficient 134
9.3 CABAC parsing process for sli ce data 135
9.3.1 Initialisation process 135
9.3.1.1 Initialisation process for contexts 135

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

9.3.1.2 Initialisation process for the arithmetic decoding engine 145
9.3.1.3 Initialisation process for the arithmetic encoding engine (informative) 145
9.3.2 Binarization process 146
9.3.2.1 Unary (U) binarization process 147
9.3.2.2 Truncated unary (TU) binarization process 148
9.3.2.3 Concatenated unary/ k^{th}-order Exp-Golomb (UEGk) binarization process 148
9.3.2.4 Fixed-length (FL) binarization process 148
9.3.2.5 Binarization process for macroblock type and sub -macroblock type 149
9.3.2.6 Binarization process for motion vectors 152
9.3.2.7 Binarization process for coded block pattern 152
9.3.2.8 Binarization process for mb_qp_delta 152
9.3.3 Decoding process flow 153
9.3.3.1 Derivation process for the Ctxldx 153
9.3.3.1.1 Assignment process of CtxIdxInc for context templates using two neighbouring syntax elements 156
9.3.3.1.2 Assignment process of CtxIdxInc for context templates usi ng prior decoded bin values 158
9.3.3.1.3 Assignment process of CtxIdxInc for context identifiers used for transform coefficients 158
9.3.3.2 Arithmetic decoding process 159
9.3.3.2.1 Probability estimation process 160
9.3.3.2.2 Table-based arithmetic decoding pro cess 162
9.3.3.2.2.1 Decoding process for a decision 162
9.3.3.2.2.2 Renormalization process in the arithmetic decoding engine 163
9.3.3.2.2.3 Arithmetic decoding process for decisions with uniform pdf using arithmetic decoder bypass 164
9.3.3.2.2.4 Decoding process for decisions before termination 164
9.3.3.2.3 Table-based arithmetic encoding process (informative) 165
9.3.3.2.3.1 Encoding pro cess for a decision (informative) 166
9.3.3.2.3.2 Renormalization process in the arithmetic encoding engine (informative) 167
9.3.3.2.3.3 Writing process for compressed bytes (informative) 168
9.3.3.2.3.4 Arithmetic encoding process for decisions with uniform pdf using encoder bypass (informative) 169
9.3.3.2.3.5 Encoding process for a decision before termination (informative) 169
Annex A Profiles and levels 170
A.1 Requirements on video decoder capability 171
A.2 Profiles 171
A.2.1 Baseline profile 171
A.2.2 Main profile 171
A.2.3 X profile 172
A.3 Levels 172
A.3.1 Level limits 173
A.3.2 Decoded picture buffer capacity 173
A.3.3 Effect of level limits on frame rate (informative) 174
Annex B Byte stream format 174
B.1 Byte stream NAL unit syntax and semantics 175
B.1.1 Byte stream NAL unit syntax 175
B.1.2 Byte stream NAL unit semantics 175
B.2 Decoder byte-alignment recovery (informative) 175
Annex C Hypothetical Reference Decoder 176
C.1 Hypothetical reference decoder and buffering verifiers 176
C.1.1 Operation of coded picture buffer 177
C.1.1.1 Timing of bitstream arrival 177
C.1.1.2 Timing of coded picture removal 178
C.1.1.3 Conformance constraints on coded bitstreams 178
C.1.2 Operation of the decoded picture buffer (DPB) verifier 179
C.1.2.1 Removal of pictures from the DPB 179
C.1.2.2 Picture decoding 179
C.1.2.2.1 Storage of Reference Pictures into the DPB 179
C.1.2.2.2 Storage of Non-reference Pictures into the DPB 180
C.1.2.3 Unused picture marking 180
C.1.2.4 Conformance constraints 180
C.2 Informative description of the HRD 180
C.2.1 Constrained arrival time leaky bucket (CAT -LB) model 181

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

C.2.1.1 Operation of the CAT-LB HRD 181
C.2.1.2 Low-delay operation 184
C.2.1.3 Bitstream / packet stream constraints 184
C.2.1.3.1 Underflow 185
C.2.1.3.2 Overflow 185

Foreword

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications. The ITU Telecommunication Standardization Sector (ITU -T) is a permanent organ of ITU. ITU -T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis. The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU -T study groups which, in turn, produce Recommendations on these topics. The approval of ITU -T Recommendations is covered by the procedure laid down in WTSA Resolution 1. In some areas of information technology which fall within ITU -T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

ISO (the International Organisation for Standardisation) and IEC (the International Electrotechnical Commission) form the specialised system for world-wide standardisation. National Bodies that are members of ISO and IEC participate in the development of International Standards throu gh technical committees established by the respective organisation to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organisations, governmental and non -governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC1. Draft International Standards adopted by the joint technical committee are ci rculated to national bodies for voting. Publication as an International Standard requires approval by at least 75% of the national bodies casting a vote.

This Recommendation | International Standard is being submitted for approval to the ITU -T and ISO/IEC JTC1/SC29. It was prepared jointly by ITU-T SG16 Q.6 also known as VCEG (Video Coding Experts Group) and by ISO/IEC JTC1/SC29/WG11, also known as MPEG (Moving Picture Experts Group). VCEG was formed in 1997 to maintain prior ITU-T video coding standards an d develop new video coding standard(s) appropriate for a wide range of conversational and non-conversational services. MPEG was formed in 1988 to establish standards for coding of moving pictures and associated audio for various applications such as digita l storage media, distribution and communication.

In this Recommendation | International Standard Annexes A through E contain normative requirements and are an integral part of this Recommendation | International Standard.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

0 Introduction

0.1 Prolog

As processing power and memory costs have reduced, network support for coded video data has diversified, and advances in video coding technology have progressed, the need has arisen for an industy standard for compressed video representation with substantially increase d coding efficiency and enhanced robustness to network environments. Toward these ends the ITU-T video coding experts group (VCEG) and the ISO/IEC moving picture experts group (MPEG) formed a joint video team (JVT) in 2001 for development of a new ITU -T Recommendation | International Standard.

0.2 Purpose

This Recommendation | International Standard was developed in response to the growing need for higher compression of moving pictures for various applications such as videoconferencing, digital storage media, television broadcasting, internet streaming and communication. It is also designed to enable the use of the coded video representation in a flexible manner for a wide variety of network environments. The use of this Recommendation | Insternational Standar d allows motion video to be manipulated as a form of computer data and to be stored on various storage media, transmitted and received over existing and future networks and distributed on existing and future broadcasting channels.

0.3 Applications

This Recommendation | International Standard is designed to cover a broad range of applications for video content including but not limited to the following:

CATV	Cable TV on optical networks, copper, etc.
DBS	Direct broadcast satellite video services
DSL	Digital subscriber line video services
DTTB	Digital terrestrial television broadcasting
ISM	Interactive storage media (optical disks, etc.)
MMM	Multimedia mailing
MSPN	Multimedia services over packet networks
RTC	Real-time conversational services (videoconferencing, videophone, etc.)
RVS	Remote video surveillance
SSM	Serial storage media (digital VTR, etc.)

0.4 Profiles and levels

This Recommendation | International Standard is designed to be generic in the sense that it serves a wide range of applications, bit rates, resolutions, qualities and services. Applications should cover, among other things, digital storage media, television broadcasting and real-time communications. In the course of creating this Specification, various requirements from typical applications have been considered, necessary algorithmic elements have been developed, and they have been integrated into a single syntax. Hence, this Specification will facilitate video data interchange among different applications.

Considering the practicality of impleme nting the full syntax of this Specification, however, a limited number of subsets of the syntax are also stipulated by means of "profile" and "level". These and other related terms are formally defined in clause 4.

A "profile" is a subset of the entire bitstream syntax that is specified by this Recommendation | International Standard. Within the bounds imposed by the syntax of a given profile it is still possible to require a very large variation in the performance of encoders and decoders depending upon the values taken by parameters in the bitstream such as the specified size of the decoded pictures. It is currently neither practical nor economic to implement a decoder capable of dealing with all hypothetical uses of the syntax within a particular profile.

In order to deal with this problem, "levels" are specified within each profile. A level is a specified set of constraints imposed on parameters in the bitstream. These constraints may be simple limits on numbers. Alternatively they may take the form of constraints on arithmetic combinations of the parameters (e.g. frame width multiplied by frame height multiplied by frame rate).

Coded video content conforming to this Specification uses a common syntax. In order to achieve a subs et of the complete syntax, flags and parameters are included in the bitstream that signal the presence or otherwise of syntactic elements that occur later in the bitstream. In order to specify constraints on the syntax (and hence define a profile), it is

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

thus only necessary to constrain the values of these flags and parameters that specify the presence of later syntactic elements. [Ed. Note: This is not strictly true. There are characteristics like ASO that have no flag that control them yet are used to define profiles.]

0.5 Overview of the syntax

The coded representation specified in the syntax achieves a high compression capability for a desired image quality. The algorithm is not lossless as the exact source sample values are typically not preserved through the encoding and decoding processes. A number of techniques may be used to achieve highly efficient compression. The expected encoding algorithm (not specified in this Recommendation | International Standard) in inter coding first uses block-based inter prediction to exploit temporal statistical dependencies or in intra coding first uses spatial prediction to exploit spatial statistical dependencies in the source signal. Motion vectors and intra prediction modes may be specified for a variety of block sizes in the picture. The prediction residual is then further compressed using a transform to remove spatial correlation inside the transform block before it is quantised, producing an irreversible process that typically discards less important information while forming a close approximation to the source samples. Finally, the motion vectors or intra prediction modes are combined with the quantised transform coefficient information and encoded using either variable length codes or arithmetic coding.

0.5.1 Predictive coding

Because of the conflicting requirements of random access and highly efficient compression, two main coding types are specified. Intra coding is done without reference to other pictures. Intra coding may provide access points to the coded sequence where decoding can begin and continue correctly, but typically also shows only moderate compression efficiency. Inter coding (predictive or bi-predictive) is more efficient using inter prediction of each block of sample values from some previously decoded picture selected by the encoder. In contrast to some other video coding standards, pictures using bi-predictive inter coding may be used as references for inter coding of other pictures.

The application of the three coding types to pictures in a sequence is flexible, and the order of the decoding process is generally not the same as the order of the source picture capture process in the encoder or the output order from the decoder for display. The choice is left to the encoder and will depend on the requirements of the application. The decoding order is specified such that the decoding of pictures that use inter-picture prediction follows later in decoding order than other pictures that are referenced in the decoding process.

0.5.2 Coding interlaced video

Each frame of interlaced video consists of two fields which are separated in capture time. This Recommendation | International Standard allows either the representation of complete frames or the representation of individual fields. Frame encoding or field encoding can be adaptively selected on a picture-by-picture basis and also on a more localized basis within a coded frame. Frame encoding is typically preferred when the video scene contains significant detail with limited motion. Field encoding, in which the second field can be predicted from the first, works better when there is fast picture-to-picture motion.

0.5.3 Picture partition into macroblocks and smaller partitions

As in previous video coding Recommendations and International Standards, a macroblock consisting of a 16x16 block of luma samples and two corresponding blocks of chroma samples is used as the basic processing unit of the video decoding process.

A macroblock can be further partitioned for inter prediction. The selection of the size of inter prediction partitions is a result of a trade-off between the coding gain provided by using motion compensation with smaller blocks and the quantity of data needed to represent the data for motion compensation. In this Recommendation | International Standard the inter prediction process can form segmentations for motion representation as small as 4x4 luma samples in size, using motion vector accuracy of one-quarter of the luma sample grid spacing displacement. The inter prediction process for inter prediction of a sample block can also involve the selection of the picture to be used as the reference picture from a number of stored previously-decoded pictures. Motion vectors are encoded differentially with respect to predicted values formed from nearby encoded motion vectors.

Typically, the encoder calculates appropriate motion vectors and other data elements represented in the video data stream. This motion estimation process in the encoder and the selection of whether to use inter prediction for the representation of each region of the video content is not specified in this Recommendation | International Standard.

0.5.4 Spatial redundancy reduction

Both source pictures and prediction residuals have high spatial redundancy. This Recommendation | International Standard is based on the use of a block-based transform method for spatial redundancy removal. After inter prediction from previously-decoded samples in other pictures or spatial-based prediction from previously-decoded samples within the current picture, the resulting prediction residual is split into 4x4 blocks. These

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

are converted into the transform domain where they are quantised. After quantisation many of the transform coefficients are zero or have low amplitude and can thus be represented with a small amount of enco ded data. The processes of transformation and quantization in the encoder are not specified in this Recommendation | International Standard.

0.6 How to read this specification

It is recommended that the reader starts with clause 1 (Scope) and moves on to clause 3 (Definitions). Clause 6 should be read for the geometrical relationship of the source, input, and output of the decoder. Clause 7 (Syntax and semantics) specifies the order to parse syntax elements from the bitstream. See subclauses 7.1-7.3 for syntax order and see subclause 7.4 for semantics, i.e., the scope, restrictions, and conditions that are imposed on the syntax elements. The actual parsing for most syntax elements is specified in clause 9 (Parsing process). Finally, clause 8 (Decoding process) specifies how the syntax elements are mapped into decoded samples. Throughout reading this specification, the reader should refer to clauses 2 (Normative references), 4 (Abbreviations), and 5 (Conventions) as needed. [Ed. Note: And what about clause 9 and the five annexes?]

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

1 Scope

This document specifies ITU-T Recommendation H.264 | ISO/IEC International Standard ISO/IEC 14496-10 video coding.

2 Normative references

The following Recommendations and International Standards contain provisions which, through reference in this text, constitute provisions of this Recommendation | International Standard. At the time of publication, the editions indicated were valid. All Recommendations and Standards are subject to revision, and parties to agreements based on this Recommendation | International Standard are encouraged to investigate the possibility of applying the most recent edition of the Recommendations and Standards listed below. Members of IEC and ISO maintain registers of currently valid International Standards. The Telecommunication Standardization Bureau of the ITU maintains a list of currently valid ITU-T Recommendations.

- ITU-T Recommendation T.35 (2000), *Procedure for the allocation of ITU-T defined codes for non-standard facilities*

3 Definitions

For the purposes of this Recommendation | International Standard, the following definitions apply.

3.1 **AC coefficient**: Any *transform coefficient* for which the frequency index in one or both dimensions is non-zero.

3.2 **arbitrary slice ordering**: An ordering of *slices* in which the *macroblock address* of the first *macroblock* of some *slice* may be smaller than the *macroblock address* of the first *macroblock* of some other *slice* of the *picture* that precedes it in *decoding order*.

3.3 **B slice**: A *bi-predictive slice*.

3.4 **bi-predictive slice**; A *slice* that is coded in a manner in which a weighted average of two *inter prediction blocks* may be used for *inter prediction*.

3.5 **bitstream**: A sequence of bits that forms the representation of data and coded *fields* and *frames*. Bitstream is a collective term used to refer either to the *NAL unit stream* or the *byte stream format*.

3.6 **block**: An MxN (M-column by N-row) array of samples, or an MxN array of *transform coefficients*.

3.7 **bottom field**: One of two *fields* that comprise a *frame*. Each row of a *bottom field* is spatially located immediately below a corresponding row of a *top field*.

3.8 **bottom macroblock (of a macroblock pair)**: The *macroblock* within a *macroblock pair* that contains the samples in the bottom row of samples for the *macroblock pair*. For a *field macroblock pair*, the bottom macroblock represents the samples from the region of the *bottom field* of the *frame* that lie within the spatial region of the *macroblock pair*. For a *frame macroblock pair*, the bottom macroblock represents the samples of the *frame* that lie within the bottom half of the spatial region of the *macroblock pair*.

3.9 **byte**: A sequence of 8 bits, ordered from the first and most significant bit on the left to the last and least significant bit on the right.

3.10 **byte-aligned**: A bit in a *bitstream* is *byte-aligned* if its position is a multiple of 8 bits from the first bit in the *bitstream*.

3.11 **byte stream format**: An encapuslation of a *NAL unit stream* containing *start code prefixes* and *NAL units* as specified in Annex B.

3.12 **category**: A number associated with each syntax element that specifies the allocation of syntax elements to *NAL units* for *slice data partitioning*. It may also be used by the systems *layer* to refer to classes of syntax elements in a manner not specified in this Recommendation | International Standard.

3.13 **chroma**: An adjective specifying that a sample array or single sample is representing one of the two colour difference signals related to the primary colours. The symbols used for a chroma array or sample are Cr and Cb. The term chroma is used rather than the term chrominance in order to avoid the implication of the use of linear light transfer characteristics that is often associated with the term chrominance.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

3.14 **coded field**: A coded representation of a *field*.

3.15 **coded frame**: A coded representation of a *frame*.

3.16 **coded picture buffer (CPB)**: A first-in first-out buffer containing coded pictures in *decoding order* specified in the *hypothetical reference decoder* in Annex C.

3.17 **coded representation**: A data element as represented in its coded form.

3.18 **common intermediate format (CIF)**: A video frame that is 22 *macroblocks* wide and 18 *macroblocks* high.

3.19 **component**: An array or single sample from one of the three arrays (*luma* and two *chroma*) that make up a *field* or *frame*.

3.20 **context**: The numerical value of the *context variable* when decoding a *symbol*.

3.21 **context modelling**: The choice and specification of prior *decoded symbols* that are to be used in the *decoding* of a *symbol*.

3.22 **context variable**: A parameter specified for the decoding process of a *symbol* by an equation containing recently *decoded symbols* as defined by *context modelling*.

3.23 **DC coefficient**: The *transform coefficient* for which the frequency index is zero in both dimensions. [Ed.Note: define frequency index]

3.24 **decoded picture**: A *decoded picture* is obtained by decoding a *coded picture*. A *decoded picture* is either a *decoded frame*, or a *decoded field*. A *decoded field* is either a *decoded top field* or a *decoded bottom field*.

3.25 **decoded picture buffer (DPB)**: A buffer holding *decoded pictures* for reference, output reordering, or output timing.

3.26 **decoded picture buffer management**: specifies in the coded data, how the *decoding process* applies to the *decoded pictures buffer* and in particular to the *decoded picture buffer*. [Ed.Note: revisit]

3.27 **decoder**: An embodiment of a *decoding process*.

3.28 **decoding order**: The nominal order in which syntax elements are processed by the *decoding process*.

3.29 **decoding process**: The process specified in this Recommendation | International Standard that reads a *NAL unit stream* and produces decoded *fields* or *frames*.

3.30 **direct prediction**: An *inter prediction* for a *block* for which no *motion vector* is decoded. [Ed.Note: Is There a need to define temporal and spatial]

3.31 **encoder**: An embodiment of an *encoding process*.

3.32 **emulation prevention byte**: A byte equal to 0x03 that may be present within a *NAL unit*. The presence of emulation prevention bytes ensures that no sequence of consecutive byte -aligned bytes in the *NAL unit* contains a *start code prefix*.

3.33 **encoding process**: A process, not specified in this Recommendation | International Standard, that reads a sequence of *fields* and *frames* and produces a conforming *NAL unit stream* as specified in this Recommendation | International Standard.

3.34 **field**: An assembly of alternate rows of a *frame*. A *frame* is composed of two *fields*, a *top field* and a *bottom field*.

3.35 **field macroblock**: A macroblock containing samples from a single *field*. All *macroblocks* of a *coded field* are field macroblocks. When *macroblock-adaptive frame/field decoding* is in use, some macroblocks of a *coded frame* may be field macroblocks.

3.36 **field macroblock pair**: A *macroblock pair* decoded as two *field macroblocks*.

3.37 **field scan**: A specific sequential ordering of *transform coefficients* that differs from the *zig-zag* scan by scanning columns more rapidly than rows. Field scan is used for *transform coefficients* in *field macroblocks*.

3.38 **flag**: A variable which can take one of only two possible values.

3.39 **frame**: A *frame* contains an array of luma samples and two corresponding arrays of chroma samples. A *frame* consists of two *fields*, a *top field* and a *bottom field*. For interlaced video, one of these *fields* is sampled temporally later than the other.

3.40 **frame macroblock**: A *macroblock* representing samples from two *fields* of a *coded frame*. When *macroblock-adaptive frame/field decoding* is not in use, all macroblocks of a *coded frame* are frame macroblocks. When

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

macroblock-adaptive frame/field decoding is in use, some macroblocks of a *coded frame* may be frame macroblocks.

3.41 **field macroblock pair**: A *macroblock pair* decoded as two *frame macroblocks*.

3.42 **frame number**: A number assigned to each video *frame* for use as a frame identifier in the *decoding process*.

3.43 **hypothetical reference decoder (HRD)**: A hypothetical *decoder* model that specifies a constraint on the variability of the *NAL unit stream* that an encoder or editing process may produce.

3.44 **I slice**: An *intra slice*.

3.45 **instantaneous decoder refresh (IDR) picture**: A *coded picture* containing only *I* or *SI slice types* that causes the *decoder* to mark all *reference pictures* in the *decoded picture buffer* as unused for reference immediately before *decoding* the *IDR picture*, and to indicate that later *coded pictures* in *decoding order* can be *decoded* without *inter prediction* from any *picture* decoded prior to the *IDR picture*.

3.46 **inter coding**: Coding of a *block*, *macroblock*, *slice*, or *picture* that uses *inter prediction*.

3.47 **inter prediction**: A *prediction* derived from decoded samples of *pictures* other than the current *decoded picture*. *Inter prediction* is a collective term for the *prediction process* of some *macroblocks* in *P*, *SP*, and *B slices*.

3.48 **interlaced video:** A form of video content in which each *frame* represents two *fields* which are separated in capture time.

3.49 **intra coding**: Coding of a *block*, *macroblock*, *slice* or *picture* that uses *intra prediction*.

3.50 **intra prediction**: A *prediction* derived from the decoded samples of the same *decoded picture*. [Ed. Note: collective term of ?]

3.51 **intra slice:** A *slice* that is coded using prediction only from decoded samples within the same *slice*.

3.52 **inverse transform**: A part of the *decoding process* by which a *block* of *transform coefficients* is converted into a *block* of spatial-domain values, or by which a *block* of *transform coefficients* is converted into a *block* of *DC coefficients*.

3.53 **layer**: One of a set of syntactical structures in a non-branching hierarchical relationship. Higher layers contain lower layers. The coding layers are the sequence, *picture*, *slice*, reference picture selection, *macroblock*, prediction block and 4x4 block layers.

3.54 **level**: A defined set of constraints on the values which may be taken by the parameters of this Recommendation | International Standard. The same set of level definitions are used with all profiles, but individual implementations may support a different level for each supported profile. In a different context, *level* is the value of a *transform coefficient* prior to *scaling*.

3.55 **luma**: An adjective specifying that a sample array or single sample is representing the monochrome signal related to the primary colours. The symbol used for luma is Y. The term luma is used rather than the term luminance in order to avoid the implication of the use of linear light transfer characteristics that is often associated with the term luminance.

3.56 **macroblock**: A 16x16 *block* of *luma* samples and two corresponding blocks of *chroma* samples. The division of a *slice* or a *macroblock pair* into macroblock is a *partitioning*.

3.57 **macroblock address**: When *macroblock-adaptive frame/field decoding* is not in use, a macroblock address is the *raster scan order* number of a macroblock starting with zero for the top left *macroblock* in a *picture*. When *macroblock-adaptive frame/field decoding* is in use, a macroblock address is 2 times the *macroblock pair address* for the *top macroblock*, and is two times the *macroblock pair address* plus 1 for the *bottom macroblock*.

3.58 **macroblock-adaptive frame/field decoding**: A *decoding process* for *coded frames* in which some *macroblocks* may be decoded as *frame macroblocks* and others may be decoded as *field macroblocks*.

3.59 **macroblock to slice group map**: A means of categorizing the *macroblocks* of a picture into *slice groups*. The macroblock to slice group map consists of an array of numbers, one for each coded *macroblock*, indicating the *slice group* to which each coded *macroblock* belongs.

3.60 **macroblock location**: The two dimensional coordinates of a *macroblock* in a *picture* denoted by (x,y). For the top left *macroblock* of the *picture* (x,y)=(0,0). x is incremented by 1 for each *macroblock* column from left to right. When *macroblock-adaptive frame/field decoding* is not in use, y is incremented by 1 for each *macroblock* row from top to bottom. When *macroblock-adaptive frame/field decoding* is in use, y is

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

incremented by 2 for each *macroblock pair* row from top to bottom, and is incremented by an additional 1 if a macroblock is a *bottom macroblock*.

3.61 **macroblock pair**: A pair of vertically-contiguous *macroblocks* in a *picture* that is coupled for use in *macroblock-adaptive frame/field decoding* processing. The division of a *slice* into macroblock pairs is a *partitioning*.

3.62 **macroblock pair address**: The *raster scan order* number of a *macroblock pair* starting with zero for the top left corner in a *frame*.

3.63 **motion vector**: A two-dimensional vector used for *inter prediction* that provides an offset from the coordinate positions in the *decoded picture* to the coordinates in a *reference picture*.

3.64 **NAL unit**: A syntax structure containing an indication of the type of data to follow and bytes containing that data in the form of an RBSP interspersed as necessary with *emulation prevention bytes*.

3.65 **NAL unit stream**: A sequence of *NAL units* containing the syntax structures associated with the coded video content.

3.66 **network abstraction layer (NAL)**: A definition of syntax structures and additional information including framing and timing that are supported by a system.

3.67 **non-reference picture**: a *decoded picture* that is marked as not used for *inter prediction*. [Ed.Note: this should be changed – How?]

3.68 **opposite parity**: The *opposite parity* of *top* is *bottom*, and vice versa.

3.69 **output order**: The order in which the *decoded pictures* are intended for output.

3.70 **output reordering delay**: A delay between decoding a *coded picture* and output of the *decoded picture* that is caused when the order of pictures specified for output is different from the order specified for decoding.

3.71 **P slice**: A *predictive slice*.

3.72 **parity**: The *parity* of a *field* can be *top* or *bottom*.

3.73 **partitioning**: The division of a set into subsets such that each element of the set is in exactly one of the subsets.

3.74 **picture**: A collective term for a *field* or a *frame*.

3.75 **picture order count**: *Picture* position in output order, relative to the latest previous IDR *picture* in *decoding order*.

3.76 **picture reordering**: The process of reordering the decoded *pictures* when the *decoding order* is different from the *output order*.

3.77 **prediction**: An embodiment of the *prediction process*.

3.78 **prediction process**: The use of a *predictor* to provide an estimate of the sampl e value or data element currently being decoded.

3.79 **prediction residual**: The difference between the represented value of a sample or data element and its *predictor*.

3.80 **predictive slice:** A *slice* that is coded using *inter prediction* from previously-decoded *reference pictures*, using at most one *motion vector* and *reference picture index* to *predict* the sample values of each *block*.

3.81 **predictor**: A combination of previously decoded sample values or data elements used in the *decoding process* of subsequent sample values or data elements.

3.82 **primary coded picture**: a primary coded representation of a *picture*.

3.83 **primary coded slice**: a *slice* belonging to a *primary coded picture*.

3.84 **primary slice data partition**: a *slice data partition* belonging to a *primary coded picture*.

3.85 **probability model**: The set of probability distributions used by the arithmetic decoding process when decoding a symbol. The *context* determines which probability distribution is to be used when decoding a particular symbol at a particular point, block, macroblock, etc. i n the picture. For each symbol, the number of probability distributions in the set is equal to the number of possible values for the *context variable*, i.e., the number of *contexts*.

3.86 **profile**: A specified subset of the syntax of this Recommendation | International Standard.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

3.87 **progressive-scan video:** A form of video content in which each *frame* represents two *fields* which have the same capture time.

3.88 **quantisation parameter**: A parameter used by the *decoding process* for *scaling* of *transform coefficient levels*. [Ed. Note: only mentioned once. Do we need this definition ?]

3.89 **quarter common intermediate format (QCIF)**: A video frame that is 11 *macroblocks* wide and 9 *macroblocks* high.

3.90 **random access**: The ability to start the decoding of a coded *NAL unit stream* at a point other than the beginning of the stream and recover an exact or approximate representation of the *decoded pictures* represented by that *NAL unit stream*.

3.91 **random access point**: A point in the *NAL unit stream* at which random access is possible.

3.92 **raster scan**: A mapping of a rectangular two-dimensional pattern to a one-dimensional pattern such that the first entries in the one-dimensional pattern are from the first top row of the two-dimensional pattern scanned from left to right, followed similarly by the second, third, etc. rows of the pattern (going down) each scanned from left to right.

3.93 **raw byte sequence payload (RBSP):** A syntactical data structure containing an integer number of bytes encapsulated in a *NAL unit* that is either null or has the form of a *string of data bits* containing syntax elements, followed by an *RBSP stop bit*, and followed by zero or more subsequent bits equal to 0.

3.94 **raw byte sequence payload stop bit:** A bit equal to 1 present with in a *raw byte sequence payload (RBSP)* after a *string of data bits*. The location of the end of the *string of data bits* within an *RBSP* can be identified by searching from the end of the *RBSP* for the *RBSP stop bit*, which is the last non-zero bit in the *RBSP*.

3.95 **redundant coded picture**: a redundant coded representation of a *picture* that shall not be used for decoding unless the *primary coded picture* is missing or corrupted. The *decoded redundant picture* [Ed. Note: No such term defined.] may not cover the entire picture area. [Ed. Note: If that's true, then why do we call it a picture – why not just refer to redundant slices?] There should be no noticeable difference between the co-located areas of the *primary decoded picture* [Ed. Note: No such term defined.] and any *redundant decoded slices*. [Ed. Note: No such term defined.]

3.96 **redundant coded slice**: a slice belong to a *redundant coded picture*.

3.97 **redundant slice data partition**: a *slice data partition* belonging to a *redundant coded picture*.

3.98 **reference field**: A *reference field* is used for *inter prediction* when *P*, *SP*, and *B slices* of a *coded field* or a *coded frame* are decoded. See also *reference picture*.

3.99 **reference frame**: A *reference frame* is used for *inter prediction* when *P*, *SP*, and *B slices* of a *coded frame* are decoded. See also *reference picture*.

3.100 **reference index list**: A list of indices that is assigned to the *reference pictures* in the *decoded picture buffer*.

3.101 **reference index list 0**: The list of *reference indices* for use in *reference list 0 prediction* for a *P*, *B*, or *SP slice*. All *inter prediction* used for *P* and *SP* slices is considered *reference list 0 prediction*. The *reference index list 0* is one of *two reference index lists* used for a *B slice*, with the other being the *reference index list 1*.

3.102 **reference list 0 motion vector**: A *motion vector* associated with a *reference index* pointing into the *reference index list 0*.

3.103 **reference list 0 prediction**: *Inter prediction* of the content of a *slice* using a *reference index* into the *reference index list 0*.

3.104 **reference index list 1**: A list of *reference indices* defined for use in *inter prediction* for a *B slice*. The *reference index list1* is one of two lists of *reference indices* used by a *B slice*, with the other being the *reference index list 0*.

3.105 **reference list 1 motion vector**: A *motion vector* associated with a *reference index* pointing into the *reference index list 1*. [Ed. Note: Do we need the word "reference" in this term? How about just "list 1 prediction" ?]

3.106 **reference list 1 prediction**: *Inter prediction* of the content of a *B slice* using a *reference index* into the *reference index list 1*.

3.107 **reference picture**: A *picture* coded with nal_reference_idc not equal to 0. A *reference picture* contains samples that may be used for *inter prediction* of subsequent *pictures* in *decoding order*.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

3.108 **reserved**: The term "reserved", when used in the clauses defining some values of a par ticular syntax element means that these values may be used in extensions of this Recommendation | International Standard by ITU-T | ISO/IEC, and that these values shall not be used unless so specified.

3.109 **residual**: The decoded difference between a *prediction* of a sample or data element and its decoded value.

3.110 **run**: A number of consecutive data elements represented in the decoding process. In one context, the number of zero-valued *transform coefficients* preceding a non-zero *transform coefficient*, in the *block scan* order. In another context, the number of *skipped macroblocks*. [Ed. Note: Do we ever use the first of those two meanings anymore?]

3.111 **sample aspect ratio**: Specifies, for assisting the display process not specified in this Recommendation | International Standard, the ratio between the intended horizontal distance between the rows and the intended vertical distance between the columns of the *luma* sample array in a *frame*. Expressed as *h*:*v*, where *h* is horizontal width and *v* is vertical height (in arbitrary units of spatial distance).

3.112 **scaling**: The process of *scaling* the *transform coefficient levels* resulting in *transform coefficients*.

3.113 **SI slice**: A *switching I slice*.

3.114 **skipped macroblock**: A *macroblock* for which no data is coded other than an indication that the *macroblock* is to be decoded as "skipped". This indication may be common to several *macroblocks*.

3.115 **slice**: An integer number of *macroblocks* or *macroblock pairs* ordered contiguously in *raster scan order* within a particular *slice group*. The division of a *slice group* into slices is a *partitioning*. Although a slice contains *macroblocks* or *macroblock pairs* that are contiguous in raster scan order within a slice group, these *macroblocks* or *macroblock pairs* are not necessarily contiguous within the picture. The addresses of the *macroblocks* are derived from the address of the first *macroblock* or *macroblock pair* in a slice (as represented in the *slice header*) and the *macroblock to slice group map*.

3.116 **slice data partitioning**: A method of partitioning selected syntax elements into syntactical structures based on a *category* associated with each of the syntax elements.

3.117 **slice group**: A subset of the *macroblocks* of a *picture*. The division of the *picture* into slice groups is a *partitioning* of the *picture*. The partition is specified by the *macroblock to slice group map*.

3.118 **slice header**: A part of a *coded slice* containing the *coded representation* of data elements pertaining to the *macroblocks* or *macroblock pairs* represented in the slice.

3.119 **source**: Term used to describe the video material or some of its attributes before encoding.

3.120 **SP slice**: A *switching P slice*.

3.121 **string of data bits (SODB)**: A sequence of some number of bits representing syntax elements present within a *raw byte sequence payload* prior to the *raw byte sequence payload stop bit*.

3.122 **switching I slice**: A *slice* that is coded using prediction only from decoded samples within the same *slice*, encoded such that it can be reconstructed identically to an *SP slice*.

3.123 **switching P slice**: A *slice* that is coded using *inter prediction* from previously-decoded *reference pictures*, using at most one *motion vector* and *reference picture index* to *predict* the sample values of each *block*, encoded such that it can be reconstructed identically to another *SP slice* or an *SI slice*.

3.124 **start code prefix**: A unique sequence of three bytes equal to 0x000001 embedded in the *byte stream format* as a prefix to each *NAL unit*. The location of a *start code prefix* can be used by a decoder to identify the beginning of a new *NAL unit* and the end of a previous *NAL unit*. Emulation of *start code prefixes* is prohibited within *NAL units*.

3.125 **string of data bits (SODB)**: An ordered sequence of some finite number of bits, in which the left-most bit is considered to be the first and most significant bit (MSB) and the right-most bit is considered to be the last and least significant bit (LSB).

3.126 **sub-macroblock**: One quarter of the samples of the samples of a *macroblock*, an 8x8 region aligned to *macroblock* boundaries on both horizontal and vertical edges. [Ed. Note: The second half of that definition needs work – only two of the four edges of a sub-macroblock are aligned to the edges of a macroblock.]

3.127 **symbol**: A *syntax element*, or part thereof, to be decoded.

3.128 **top field**: One of two *fields* that comprise a *frame*. Each row of a *top field* is spatially located immediately above the corresponding row of the *bottom field*.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

3.129 **top macroblock (of a macroblock pair)**: The *macroblock* within a *macroblock pair* that contains the samples in the top row of samples for the *macroblock pair*. For a *field macroblock pair*, the top macroblock represents the samples from the region of the *top field* of the *frame* that lie within the spatial region of the *macroblock pair*. For a *frame macroblock pair*, the top macroblock represents the samples of the *frame* that lie within the bottom half of the spatial region of the *macroblock pair*.

3.130 **transform coefficient**: A scalar quantity, considered to be in a frequency domain, that is associated with a particular two-dimensional frequency index in the *inverse transform* of the decoding process.

3.131 **variable length coding (VLC)**: A reversible procedure for entropy coding that assigns shorter codewords to *symbols* expected to be more frequent and longer codewords to *symbols* expected to be less frequent.

3.132 **XYZ profile decoder**: A decoder able to decode coded data conformin g to the specifications of the XYZ profile (with XYZ being any of the defined Profile names).

3.133 **zig-zag scan**: A specific sequential ordering of *transform coefficients* from (approximately) the lowest spatial frequency to the highest. Zig-zag scan is used for *transform coefficients* in *field macroblocks*

4 Abbreviations

4.1 **ASO**: Arbitrary Slice Order

5 Conventions

The mathematical operators used in this Specification are similar to those used in the C programming language. However, integer division and arithmetic shift oper ations are specifically defined. Numbering and counting conventions generally begin from 0.

5.1 Arithmetic operators

The following arithmetic operators are defined as follows

+	Addition
–	Subtraction (as a two-argument operator) or negation (as a unary prefi x operator)
×	Multiplication
*	Multiplication
	Multiplication
$a^{\wedge}b$	Exponentiation. Indicates a to the power of b.
a^b	Exponentiation. Indicates a to the power of b. In other contexts, such notation is used for superscripting not intended for interpret ation as exponentiation.
/	Integer division with truncation of the result toward zero. For example, 7/4 and −7/−4 are truncated to 1 and −7/4 and 7/−4 are truncated to −1.
÷	Used to denote division in mathematical equations where no truncation or rounding is intended.
$\frac{a}{b}$	Used to denote division in mathematical equations where no truncation or rounding is intended.
$\sum_{i=a}^{b} f(i)$	The summation of the $f(i)$ with i taking all integer values from a up to and including b.
a % b	Modulus. Remainder of a divided by b, defined only for a and b both positive integers

5.2 Logical operators

The following logical operators are defined as follows

a && b	Boolean logical "and" of a and b
a || b	Boolean logical "or" of a and b
!	Logical NOT

5.3 Relational operators

The following relational operators are defined as follows

>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
==	Equal to
!=	Not equal to

5.4 Bit-wise operators

The following bit-wise operators are defined as follows

&	AND
|	OR
a >> b	Arithmetic right shift of a two's complement i nteger representation of a by b binary digits. This function is defined only for positive values of b. Bits shifted into the MSBs as a result of the right shift shall have a value equal to the MSB of a prior to the shift operation.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$a << b$ Arithmetic left shift of a two's complement integer representation of a by b binary digits. This function is defined only for positive values of b. Bits shifted into the LSBs as a result of the left shift have a value equal to 0.

5.5 Assignment

The following arithmetic operators are defined as follows

= Assignment operator

$x = a..b$ x takes on values starting from a to b inclusive, with x, a, and b being integer numbers. [Ed. Note: Is this really an assignment operator (I don't think so), and is it really used anywhere?]

++ Increment, i.e. x++ is equivalent to $x = x + 1$; when used in an array index, evaluates to the value of the variable prior to the increment operation.

-- Decrement, i.e. x-- is equivalent to $x = x - 1$; when used in an array index, evaluates to the valu e of the variable prior to the decrement operation.

+= Increment by amount specified, i.e., x += 3 is equivalent to x = x + 3, and x += (-3) is equivalent to x = x + (-3).

-= Decrement by amount specified, i.e., x -= 3 is equivalent to x = x - 3, and x -= (-3) is equivalent to x = x - (-3).

5.6 Mathematical functions

The following mathematical functions are defined as follows

$$\text{Abs}(x) = \begin{cases} x & ; \quad x \geq 0 \\ -x & ; \quad x < 0 \end{cases} \tag{5-1}$$

Ceil(x) rounds x up to the nearest integer greater than or equal to x. (5-2)

$$\text{Clip1}(x) = \text{Clip3}(0, 255, x) \tag{5-3}$$

$$\text{Clip3}(a, b, c) = \begin{cases} a & ; \quad c < a \\ b & ; \quad c > b \\ c & ; \quad \text{otherwise} \end{cases} \tag{5-4}$$

$$\text{InverseRasterScan}(a, b, c, d, e) = \begin{cases} (a\%(d/b))*b; & e == 0 \\ (a/(d/b))*c; & e == 1 \end{cases} \tag{5-5}$$

Log2(x) returns the base-2 logarithm of x. (5-6)

$$\text{Min}(x, y) = \begin{cases} x & ; \quad x \leq y \\ y & ; \quad x > y \end{cases} \tag{5-7}$$

$$\text{RasterScan}(x, y, N_x) = x + y * N_x$$

$$\text{RasterTo4x4LumaBlkOffset}(x) = \{ [(x \% 4) / 2] - [(x / 4) \% 2] \} * 2 \tag{5-8}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$$\text{Sign}(x) = \begin{cases} 1 & ; \quad x \geq 0 \\ -1 & ; \quad x < 0 \end{cases} \tag{5-9}$$

$$\text{4x4LumaBlkScan}(x, y) = (x / 2) * 4 + (y / 2) * 8 + \text{RasterScan}(x \,\%\, 2, y \,\%\, 2, 2) \tag{5-10}$$

[Ed. Note: I don't like starting variable names with numerical characters – and it 's illegal to do that in C.]

6 Source, coded, decoded, and output data formats

6.1 Bitstream formats

This subclause specifies the relationship between the NAL unit stream and byte stream, eith er of which are referred to as the bitstream.

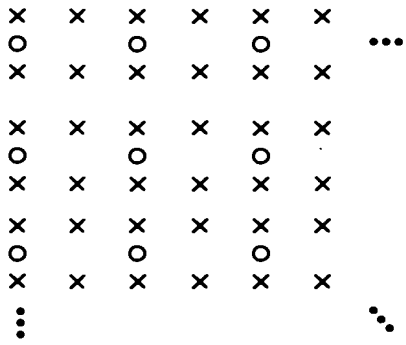
The bitstream can be in one of two formats: the NAL unit stream format or the byte stream format. The NAL unit stream format is conceptually the more "basic" type. It consists of a sequence of syntax structure s called NAL units. This sequence is ordered in decoding order. There are constraints imposed on the decoding order (and contents) of the NAL units in the NAL unit stream.

The byte stream format can be constructed from the NAL unit stream format by orde ring the NAL units in decoding order and prefixing each NAL unit with a start code prefix and zero or more zero -valued bytes to form a stream of bytes. The NAL unit stream format can be extracted from the byte stream format by searching for the location o f the unique start code prefix pattern within this stream of bytes. Methods of framing the NAL units in a manner other than use of the byte stream format are outside the scope of this Recommendation | International Standard. The byte stream format is specified in Annex B.

6.2 Source, decoded, and output picture formats

This subclause specifies the relationship between source and decoded frames and fields that is given via the bitstream.

The video source that is represented by the bitstream is a sequence of frames and/or fields (called collectively pictures) in decoding order.



The source and decoded pictures (frames or fields) are each comprised of three sample arrays, one luma and two chroma sample arrays.

The width and height of the luma arrays are multiples of 16 samples. This Recommendation | International Standard represents colour sequences using 4:2:0 chroma sampling. I.e. the width and height of each of the two chroma samples ' arrays are half of the width and height of the lum a array of the same picture. The width and height of chroma arrays are multiple of 8 samples. The height of a luma array that is coded as two separate fields or in macroblock -based frame field adaptive mode (see below) is a multiple of 32 samples. The heig ht of each chroma array that is coded as two separate fields or in macroblock-based frame field adaptive mode (see below) is a multiple of 16 samples. The width or height of pictures output from the decoder need not be a multiple of 16 and can be specified using a cropping rectangle.

The width of fields coded referring to a specific sequence parameter set is the same as that of frames coded referring to the same sequence parameter set (see below). The height of fields coded referring to a specific sequence parameter set, is half that of frames coded referring to the same sequence parameter set (see below).

The nominal vertical and horizontal relative locations of luma and chroma samples in frames are shown in Figure 6-1. Alternative chroma sample relative locations may be indicated in video usability information (see Annex E).

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Guide:

× = Location of luminance sample

○ = Location of chrominance sample

Figure 6-1 – Nominal vertical and horizontal locations of 4:2:0 luma and chroma samples in a frame

This Recommendation | International Standard specifies a syntax and decoding process for video that originated in either progressive-scan or interlaced-scan form, which may be mixed together in the same sequence.

A video frame consists of two fields as described below. A coded picture may represent a frame or an individual field. A video sequence conforming to this Recommendation | International Standard may contain arbitrary combinations of coded frames and coded fields. The decoding process is also specified in a manner that allows smaller regions of a coded frame to be coded as a representation either as frame or field region.

Source and decoded fields are one of two types: top field or bottom field. The nominal vertical and horizontal relative locations of luma and chroma samples in fields are shown in Figure 6-2. Alternative chroma sample relative locations may be indicated in the video usability information (see Annex E).

When two fields are output at the same time, or combined to be used as a reference frame (see below), the two fields (which must be of opposite parity) are interleaved. The first (i.e., top), third, fifth, etc. rows of a decoded frame are the top field rows. The second, fourth, sixth, etc. rows of a decoded frame are the bottom field rows. A top field picture consists of only the top field rows of a decoded frame. When the top field or bottom field of a frame is used as a reference field (see below) only the even rows (for a top field) or the odd rows (for a bottom field) of the frame are used.

The two decoded fields of an interlaced frame are separated in time. They may be decoded separately as two fields or together as a frame.

NOTE - A progressive frame should always be coded as a single frame picture. However, a progressive frame is still considered to consist of two fields (at the same instant in time) and may be represented using coded fields.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

The nominal vertical and horizontal relative locations of luma and chroma samples in interlaced fields are shown in Figure 6-2. The vertical sampling relative locations of the chroma samples in a top field of an interlaced frame are specified as shifted up by 1/4 luma sample height relative to the field -sampling grid in order for these samples to align vertically to the usual location relative to the full -frame sampling grid. The vertical sampling locations of the chroma samples in a bottom field of an interlaced frame are specified as shifted down by 1/4 luma sample height relative to the field-sampling grid in order for these samples to align vertically to the usual location relative to the full -frame sampling grid. The horizontal sampling relative locations of the chroma samples are specified as unaffected by the application of interlaced field coding.

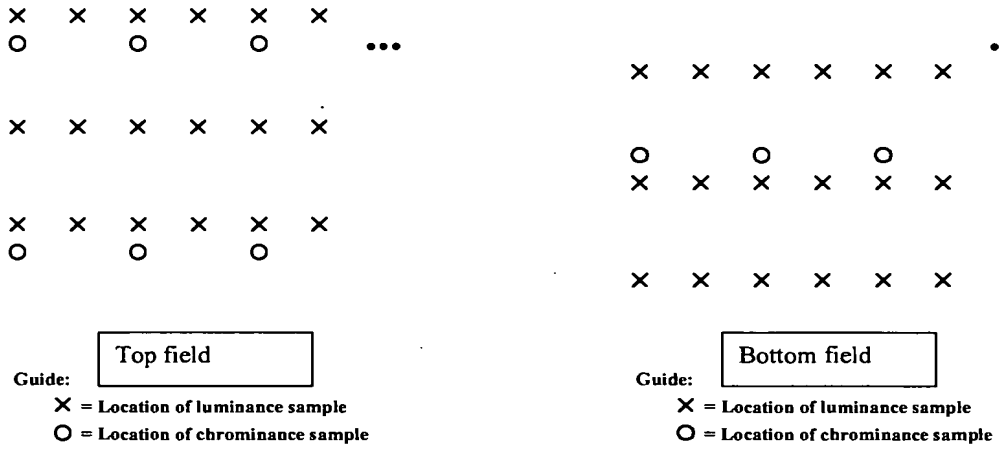


Figure 6-2 – Nominal vertical and temporal sampling locations of samples in 4:2:0 interlaced frames

6.3 Spatial subdivision of pictures, slices, macroblocks, and sub-macroblocks

This subclause specifies how a picture is partitioned into slices and macroblocks. Pictures are divided into slices. A slice is a sequence of macroblocks or macroblock pairs. [Ed. Note: Need to integrate Horowitz input for MB -AFF]

Slices are partitioned into macroblocks. Each macroblock of a picture is in no more than one slice. [Ed. Note: Work on redundant pictures – in a redundant picture, some macroblocks may not be represented in any slice, but in primary coded pictures each macroblock of the pi cture shall be in some slice.]

Each macroblock is comprised of a one 16x16 luma and two 8x8 chroma sample arrays. When macroblock -adaptive frame/field decoding is not in use, each macroblock represents a spatial rectangular region of the picture. For ins tance, a QCIF picture may be divided into two slices as shown in Figure 6-3. If the first slice contains 48 macroblocks, then the second slice contains 51 macroblocks, since the entire QCIF picture is divided into 99 macroblocks as shown in Figure 6-3.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

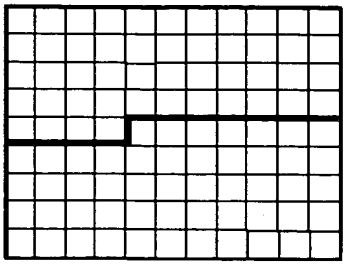

Figure 6-3 – A picture with 11 by 9 macroblocks (QCIF picture)

A macroblock location in the picture is given by a pair of indices where the first index is the macroblock column index starting with 0 for the leftmost column, and the second index is the macroblock row index starting with 0 for the topmost row. [Ed. Note: Not true for MB-AFF. Much of this description is redundant with the definitions section.]

When macroblock-adaptive frame/field decoding is in use, the picture is partitioned into slices containing an integer number of macroblock pairs as shown in Figure 6-4. Each macroblock pair consists of two macroblocks.

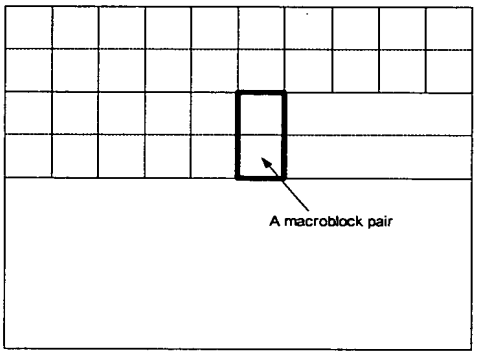

Figure 6-4 – Partitioning of the decoded frame into macroblock pairs.

Macroblocks or sub-macroblocks may be partitioned and the paritions are scanned for inter prediction as shown in Figure 6-5. The outer quadrats refer to the samples in a macroblock or sub-macroblock, respectively. The rectangles or quadrats refer to the partitions. The numbers in eacb quadrat or rectangle specify the index of the inverse macroblock partition scan or inverse sub-macroblock partition scan.

Figure 6-5 – Macroblock partitions, sub-macroblock partitions, inverse macroblock partition scans, and inverse sub-macroblock partition scans. [Ed. Note: Figure does not print properly on at least one printer.]

6.4 Inverse scanning processes

This subclause specifes inverse scanning processes, i.e., the mapping of indices to locations.

6.4.1 Inverse macroblock scanning process

[Ed.Note: the use of macroblock addresses may make the use of macroblock indices not necessary]

Input to this process is the macroblock index MbIdx.

Output of this process is the location of the upper -left luma sample (MbLumaLoc) for the macroblock with index MbIdx relative to the upper-left sample of the picture.

The variable SliceGroupMbIdxList[MbIdx] specifies the macroblock index in a scan that assumes one slice group and one slice in the picture. [Ed.Note: specify how this variable is obtained].

The inverse macroblock scann ing process is specified by

PartIdx = SliceGroupMbIdxList[MbIdx]

Width = (frame_width_in_mbs_minus1 + 1) * 16

MbLumaLoc[MbIdx][0] = InverseRasterScan(PartIdx, 16, 16, Width, 0)

MbLumaLoc[MbIdx][1] = InverseRasterScan(PartIdx, 16, 16, Width, 1)

6.4.2 Inverse macroblock pair scanning process

[Ed.Note: the use of macroblock pair addresses may make the use of macroblock pair indices not necessary]

Input to this process is the macroblock index MbPairIdx.

Output of this process is the location of the u pper-left luma sample (MbPairLumaLoc) for the macroblock pair with index MbPairIdx relative to the upper -left sample of the picture.

The variable SliceGroupMbPairIdxList[MbPairIdx] specifies the macroblock pair index in a scan that assumes one slice group and one slice in the picture. [Ed.Note: specify how this variable is obtained].

The inverse macroblock scanning process is specified by

PartIdx = SliceGroupMbPairIdxList[MbPairIdx]

Width = (frame_width_in_mbs_minus1 + 1) * 16

MbPairLumaLoc[MbPairIdx][0] = InverseRasterScan(PartIdx, 16, 16, Width, 0)

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

MbPairLumaLoc[MbPairIdx][1] = InverseRasterScan(PartIdx, 16, 16, Width, 1)

6.4.3 Inverse macroblock in macroblock pair scanning process

[Ed.Note: the use of macroblock addresses may make the use of macroblock indices not necessary]

Input to this process is the macroblock index MbInMbPairIdx.

Output of this process is the location of the upper-left luma sample (MbLumaLoc) for the macroblock pair with index MbInMbPairIdx relative to the upper-left sample of the macroblock pair.

The inverse macroblock in macroblock pair scanning process is specified by

MbInMbPairLumaLoc[MbInMbPairIdx][0] = InverseRasterScan(MbInMbPairIdx, 16, 16, 16, 0)

MbInMbPairLumaLoc[MbInMbPairIdx][1] = InverseRasterScan(MbInMbPairIdx, 16, 16, 16, 1)

NOTE - The inverse macroblock in macroblock pair scanning process is independent of whether the macroblock pair is coded in frame or field decoding mode.

The macroblock with index 0 is referred to as the top-macroblock, the macroblock with index 1 is referred to as the bottom-macroblock.

6.4.4 Inverse macroblock partition scanning process [Ed.Note: may not be needed as separate scan spec]

Input to this process is the index of the macroblock partition MbPartIdx, the width of the mac roblock partition MbPartWidth, and the height of the macroblock partition MbPartHeight.

Output of this process is the location of the upper-left luma sample (MbPartLumaLoc) for the macroblock partition with index MbPartIdx relative to the upper-left sample of the macroblock.

The inverse macroblock partition scanning process is specified by

MbPartLumaLoc[MbPartIdx][0] = InverseRasterScan(MbPartIdx, MbPartWidth, MbPartHeight, 16, 0)

MbPartLumaLoc[MbPartIdx][1] = InverseRasterScan(MbPartIdx, MbPart Width, MbPartHeight, 16, 1)

[Ed.Note: we may need to specify MbPartWidth and MbPartHeight for 16x8 and 8x16 to be clear]

6.4.5 Inverse sub-macroblock partition scanning process [Ed.Note: may not be needed as separate scan spec]

Input to this process is the index of the sub-macroblock partition SubMbPartIdx, the width of the sub-macroblock partition MbPartWidth, and the height of the sub-macroblock partition SubMbPartHeight.

Output of this process is the location of the upper-left luma sample (SubMbPartLumaLoc) for the sub-macroblock partition with index SubMbPartIdx relative to the upper-left sample of the sub-macroblock.

The inverse sub-macroblock partition scanning process is specified by

SubMbPartLumaLoc[MbPartIdx][0] = InverseRasterScan(SubMbPartIdx, SubMbPartWidth, SubMbPartHeight, 8, 0)

SubMbPartLumaLoc[MbPartIdx][1] = InverseRasterScan(SubMbPartIdx, SubMbPartWidth, SubMbPartHeight, 8, 1)

[Ed.Note: we may need to specify SubMbPartWidth and SubMbPartHeight for 8x4 and 4x8 to be clear]

6.4.6 Inverse 4x4 luma block scanning process

Input to this process is the index of the 4x4 luma block 4x4LumaBlkIdx.

Output of this process is the location of the upper-left luma sample (4x4LumaBlkLoc) for the 4x4 luma block with index 4x4LumaBlkIdx relative to the upper-left sample of the macroblock.

The inverse 4x4 luma block scanning process is specified by

4x4LumaBlkLoc[4x4LumaBlkIdx][0] = InverseRasterScan(4x4LumaBlkIdx / 4, 8, 8, 16, 0) +
InverseRasterScan(4x4LumaBlkIdx % 4, 4, 4, 8, 0)

4x4LumaBlkLoc[4x4LumaBlkIdx][1] = InverseRasterScan(4x4LumaBlkIdx / 4, 8, 8, 16, 1) +
InverseRasterScan(4x4LumaBlkIdx % 4, 4, 4, 8, 1)

6.4.7 Derivation process of the availability for neighbouring macroblock addresses

Inputs to this process are a macroblock address (MbAddress).

Output of this process is the availability of the macroblock MbAddress.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

The macroblock is marked available, unless one of the following conditions is true in which case the macroblock shall be marked as not available:

MbAddress < 0

MbAddress > MaxMbAddress – 1

the macroblock with address MbAddress belongs to a different slice

the macroblock with address MbAddress is at a later position in the decoding order.

6.4.8 Derivation process of the availability for neighbouring macroblock pair addr esses

Inputs to this process are a macroblock pair address (MbPairAddress).

Output of this process is the availability of the macroblock pair MbPairAddress.

The macroblock pair is marked available, unless one of the following conditions is true in which ca se the macroblock pair shall be marked as being not available:

MbPairAddress < 0

MbPairAddress > MaxMbPairAddress – 1

the macroblock pair with address MbPairAddress belongs to a different slice

the macroblock pair with address MbPairAddress is at a lat er position in the decoding order.

7 Syntax and semantics

7.1 Method of describing the syntax in tabular form

The syntax is described in a manner that closely follows the C -language syntactic constructs. Syntax elements in the bitstream are represented in **bold** type. Each syntax element is described by its name (all lower case letters with underscore character to separae, as needed, groups of letters), its syntax category and descriptor for its method of coded representation. A decoder behaves according to the val ue of the syntax element and on the values of previously decoded syntax elements. When a value of a syntax element is used in the syntax tables or the text, it apears in regular (i.e. not bold type). In some cases the syntax tables may use the values of ot her varaibales derived from syntax elements values. Such variables appear in the syntax tables, or text, named by a mixture of lower case and upper case letters, starting with an upper case letter, and without any underscore characters. The derivation is s pecified in the text. In some cases, "mnemonic" names for syntax elements or variable are used interchangeably with their numerical values. The association of values and names is specified in the text. The names are constructed from one or more groups of l etters separated by an underscore character. Each group starts with an upper case letter and may contain more upper case letters.

Hexadecimal notation may be used instead of binary notation when the number of bit is a multiple of 4.

Square parentheses are used for indexing.

The syntax tables describe a superset of the syntax of all correct and error -free input bitstreams. [Ed.Note: remove error or change to NOTE] Additional constraints on the syntax form may be specified in other clauses. An actual decoder must implement correct means for identifying entry points into the bitstream for proper decoding and to identify and handle errors in the bitstream [Ed.Note: remove error or change to NOTE]. The methods for identifying and handling errors and other such s ituations are not described here.

Following C-language conventions, a value equal to 0 represents a FALSE condition in a test statement. The value TRUE is represented by 1, but any other value different than zero is also understood as TRUE.

The following table lists examples of pseudo code used to describe the syntax. When syntax_element appears, it indicates that a data element is read (extracted) from the bitstream and the bitstream pointer advances to the bit following the last bit of the data element ex tracted.

[Ed.Note: specify function of functions, specify passing of parameters, explain bold vs. not bold syntax elements, specify variables PayloadType ..., mention meaning of vertical bar in category and descriptor]

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

7.2 Definitions of functions, categories and descriptors

The functions presented here are used in the syntactical description. These functions assume the existence of a bitstream pointer with an indication of the position of the next bit to be read by the decoder from the bitstream. Function names are constructed as syntax element names with left and right round parentheses including zero or more parameter names (for definition) or values (for usage), separated by commas (if more than one parameter). [Ed.Note: fix bitstream vs. byte stream vs. coded stream vs. NAL unit stream]

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

byte_aligned( )

- Returns TRUE if the current position in the bitstream is on a byte boundary, i.e., the next bit in the bitstream is the first bit in a byte. Otherwise it returns FALSE.

more_data_in_byte_stream( )

- Returns TRUE if more data follows in the byte stream. Otherwise it returns FALSE. Used only in the byte stream NAL unit syntax structure specified in Annex B.

more_rbsp_data( )

- Returns TRUE if there is more data in an RBSP before rbsp_trailing_bits( ). Otherwise it returns FALSE. The method for enabling determination of whether there is more data in the RBSP is specified by the system (or in Annex B for systems that use the byte stream format).

more_rbsp_trailing_data( )

- Returns TRUE if there is more data in an RBSP. Other wise it returns FALSE.

next_bits(*n*)

- Provides the next bits in the bitstream as an unsigned integer value for comparison purposes, without advancing the bitstream pointer. Provides a look at the next *n* bits in the bitstream with *n* being its argument. If used within the byte stream NAL unit syntax structure specified in Annex B, returns a value of 0 if fewer than *n* bits remain within the byte stream.

next_mb_address(*i*)

- Provides the macroblock address of the next macroblock in the slice group after the ma croblock with macroblock address *i* in macroblock address order.

read_bits(*n*)

- Reads the next *n* bits from the bitstream and advances the bitstream pointer by *n* bit positions. If *n* is equal to 0, then read_bits(*n*) is defined to return a value equal to 0 and to not advance the bitstream pointer.

total_coeff( )

- Returns the number of coefficients from coeff_token. See subclause 7.3.5.3.1.

trailing_ones( )

- Returns the trailing ones from coeff_token. See subclause 7.3.5.3.1.

Categories (labelled in the table as C) specify the slice data partition for slice data into three partitions. Partition A contains all syntax elements of category 4. Partition B contains all syntax el ements of category 5. Partition C contains all syntax elements of Category 6. The meaning of other category values is not specified.

The following descriptors specify the parsing process of each syntax element. For some syntax elements, two descriptors, separated by a vertical bar, are used. In these cases, the left descriptors apply when entropy_coding_mode is equal to 0 and the right descriptor applies when entropy_coding_mode is equal to 1.

- **ae(v)**: context-adaptive arithmetic entropy-coded syntax element. The parsing process for this descriptor is specified in subclause 9.3.
- **b(8)**: byte having any pattern of bit string (8 bits). The parsing process for this descriptor is specified by the return value of the function read_bits (8).
- **ce(v)**: context-adaptive variable-length entropy-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.2.
- **f(*n*)**: fixed-pattern bit string using *n* bits written (from left to right) with the left bit first. The parsing process for this descriptor is specified by the return value of the function read_bits(*n*).
- **i(*n*)**: signed integer using *n* bits. If *n* is "v", the number of bits varies in a manner dependent on the value of other syntax elements. The parsing process for this descriptor is specified by the return value of the function read_bits(*n*) interpreted as a two's complement representation with most significant bit written first.
- **se(v)**: signed integer Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.1.
- **te(v)**: truncated Exp-Golomb-coded syntax element with left bit first. The parsing process for this descriptor is specified in subclause 9.1.

Formatted: Indent: Left: 0.25", Bulleted + Level: 1 + Aligned at: 0.5" + Tab after: 0.75" + Indent at: 0.75", Tabs: 0.25", List tab

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- **u(*n*)**: unsigned integer using *n* bits. If *n* is "v", the number of bits varies in a manner dependent on the value of other syntax elements. The parsing process for this descriptor is specified by the return value of the function read_bits(*n*) interpreted as a binary representation of an unsigned integer with most significant bit written first.
- **ue(v)**: unsigned integer Exp-Golomb-coded syntax element with the left bit first. The parsing process for this descriptor is specified in subclause 9.1.

7.4 Semantics

7.4.1 NAL unit semantics

NOTE - The Video Coding Layer (VCL) is specified to efficiently represent the content of the video data. The Network Abstraction Layer (NAL) is specified to format that data and provide header information in a manner appropriate for conveyance by the transport layers or storage media. All data are contained in NAL units, each of which contains an integer number of bytes. A NAL unit specifies a generic format for use in both packet-oriented and bitstream systems. The format of NAL units for both packet-oriented transport and bitstream is identical except that each NAL unit can be preceded by a start code prefix in a bitstream-oriented transport layer.

NumBytesInNALunit specifies the size of the NAL unit in bytes. This value is required for decoding of the NAL unit and shall be conveyed by external means. Framing of NAL units is necessary to enable inference of NumBytesInNALunit. Such framing into a byte stream format is specified in Annex B and other methods for framing may be specified outside of this Recommendation | International Standard.

forbidden_bit shall be equal to 0.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

NOTE - The forbidden_bit may be used by external specifications to signal potentially corrupt NAL units for enhanced-capability uses not specified in the Recommendation | International Standard.

nal_ref_idc equal to 0 indicates that the content of the NAL unit belongs to a picture that is not marked for use as a reference picture in the decoded picture buffer, or contains SEI data or filler data. nal_ref_idc shall not be equal to 0 for sequence parameter set or picture parameter set NAL units. If nal_ref_idc is equal to 0 for one slice or slice data partition NAL unit of a particular picture, it shall be equal to 0 for all slice and slice data partition NAL units of the picture. nal_ref_idc greater than 0 indicates that the conten t of the NAL unit belongs to a decoded picture that is stored and marked for use as a reference picture in the decoded picture buffer.

NOTE - In addition to signalling whether a picture is marked for use as a reference picture, external specifications may use nal_ref_idc to indicate the relative transport priority of the NAL unit in a manner not specified in this Recommendation | International Standard. The value 0 should be used to signal the lowest transport priority and the priority should grow in ascending order of nal_ref_idc values.

nal_unit_type indicates the type of RBSP data structure contained in the NAL unit according to the types specified in Table 7-1. VCL NAL units are defined as those NAL units having nal_unit_type e qual to 1, 2, 3, 4, 5, or 10.

Table 7-1 – NAL unit type codes

nal_unit_type	Content of NAL unit and RBSP syntax structure	C
0	For external use	
1	Coded slice slice_layer_no_partitioning_rbsp( )	4, 5, 6
2	Coded slice data partition A slice_data_partition_a_layer_rbsp( )	4
3	Coded slice data partition B slice_data_partition_b_layer_rbsp( )	5
4	Coded slice data partition C slice_data_partition_c_layer_rbsp( )	6
5	Coded slice of an IDR picture slice_layer_no_partitioning_rbsp( )	4, 5
6	Supplemental enhancement information (SEI) sei_rbsp( )	7
7	Sequence parameter set (SPS) seq_parameter_set_rbsp( )	0
8	Picture parameter set (PPS) pic_parameter_set_rbsp( )	1
9	Picture delimiter (PD) pic_delimiter_rbsp( )	8
10	Filler data (FD) filler_data_rbsp( )	9
11 - 23	Reserved	
24 - 31	For external use	

[Ed.Note: This paragraph should be revised and possibly moved?] An instantaneous decoder refresh picture (IDR picture) implies that all pictures in the multi-picture buffer are marked as non-reference pictures. Moreover, the maximum long-term index is reset to zero. An IDR picture contains only I or SI slices, and nal_unit_type equal to 5 (IDR) shall be used for all slices of an IDR picture. nal_ref_idc shall be no t be equal to 0 for IDR NAL units. An IDR picture shall not immediately follow another IDR picture in decoding order.

The decoding process for NAL unit types 0 and 24-31 is not specified in this Recommendation | International Standard.

Note – NAL unit types 0 and 24-31 may be used as defined externally, for purposes such as NAL unit aggregation/fragmentation.

Decoders shall ignore (remove from the bitstream and discard) the contents of all NAL units which use reserved values of nal_unit_type.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

rbsp[i] a raw byte sequence payload is specified as an ordered sequence of bytes.

The RBSP contains an SODB in the following form:

a) If the SODB is null, the RBSP is also null.

b) Otherwise, the RBSP contains the SODB in the following form:

1) The first byte of the RBSP contains the (most significant, left-most) eight bits of the SODB; the next byte of the RBSP shall contain the next eight bits of the SODB, etc.; until fewer than eight bits of the SODB remain.

2) rbsp_trailing bits( ) are present after the SODB as follows:

i) The first (most significant, left-most) bits of the final RBSP byte contains the remaining bits of the SODB, if any,

ii) The next bit consists of a single rbsp_stop_bit equal to 1, and

iii) If the rbsp_stop_bit is not the last bit of a byte-aligned byte, one or more rbsp_alignment_bit is present to result in byte alignment.

3) One or more cabac_zero_word 16-bit syntax elements equal to 0x0000 may be present after the rbsp_trailing_bits() at the end of the RBSP.

Syntax structures having these RBSP properties are denoted in the syntax tables using an "_rbsp" suffix. These structures shall be carried within NAL units as the content of the rbsp[i] data bytes. The association of the RBSP syntax structures to the NAL units shall be as specified in Table 7-1.

If the boundaries of the RBSP are known, the decoder can extract the SODB from the RBSP by concatenating the bits of the bytes of the RBSP and discarding the rbsp_stop_bit, which is the last (least significant, right-most) bit equal to 1, and discarding any following (less significant, farther to the right) bits that follow it, which are equal to 0. The data necessary for the decoding process is contained in the SODB part of the RBSP.

emulation_prevention_byte is a byte equal to 0x03. If an emulation_prevention_byte is present in the NAL unit, it shall be discarded.

The last byte of the NAL unit shall not be equal to 0x00.

Within the NAL unit, the following three-byte sequences shall not occur at any byte-aligned position:

- 0x000000
- 0x000001
- 0x000002

The use of the byte-aligned 3-byte sequence 0x000002 within the NAL unit is reserved for future use by ITU-T | ISO/IEC. [Ed. Note: What is the decoder supposed to do if it sees that value in a byte stream? My guess is that it should choke, so maybe we don't need to state that we reserve that byte string.]

Within the NAL unit, any four-byte sequence which starts with 0x000003 other than the following sequences shall not occur at any byte-aligned position:

- 0x00000300
- 0x00000301
- 0x00000302
- 0x00000303

7.4.1.1 Example encoder procedure (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

The form of encapsulation of an SODB within an RBSP and the use of the emulation_prevention_byte for encapsulation of an RBSP within a NAL unit is specified for the following purposes:

- to prevent the emulation of start codes within NAL units while allowing any arbitrary SODB to be represented within a NAL unit,
- to enable identification of the end of the SODB within the NAL unit by searching the RBSP for the rbsp_stop_bit starting at the end of the RBSP, and
- to enable a NAL unit to have a size larger than that of the SODB under some circumstances (using one or more cabac_zero_word).

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

The encoder can produce a NAL unit from an RBSP by the following procedure:

The RBSP data is searched for byte-aligned bits of the following binary patterns:

'00000000 00000000 000000xx' (where xx represents any 2 bit pattern: 00, 01, 10 or 11),

and a byte equal to 0x03 is inserted to replace these bit patterns with the patterns

'00000000 00000000 00000011 000000xx',

and finally, if the last byte of the RBSP data is equal to 0x00 (which can only occur if the RBSP ends in a cabac_zero_word), a final byte equal to 0x03 is appended to the end of the data.

The resulting sequence of bytes is then prefixed with the first byte of the NAL unit containing the indication of the type of RBSP data structure it contains. This results in the construction of the entire NAL unit.

This process can allow any SODB to be represented in a NAL unit while ensuring that

- no byte-aligned start code prefix is emulated within the NAL unit, and
- no sequence of 8 zero-valued bits followed by a start code prefix, regardless of byte-alignment, is emulated within the NAL unit.

7.4.2 Raw byte sequence payloads and RBSP trailing bits semantics

7.4.2.1 Sequence parameter set RBSP semantics

[Ed.Note: Move the following pars. to the NAL unit order semantics clause. Change the meaning of "active"] A sequence parameter set is called an active sequence parameter set when an IDR NAL unit refers to it. The parameters of an active sequence parameter set shall be replaced only when an IDR NAL unit refers to a different sequence parameter set.

A picture parameter set includes the parameters that remain unchanged within a coded picture. Every picture parameter set shall refer to the active sequence parameter set. A decoded picture parameter set is an active picture parameter set when the first slice NAL unit or first slice data partitionA NAL unit of a coded picture refers to it. The picture parameters of an active picture parameter set shall be replaced only when the first slice NAL unit or slice data partition A NAL unit of a picture refers to a different picture parameter set.

NOTE - The sequence and picture parameter set mechanism decouples the transmission of infrequently changing information from the transmission of coded macroblock data. The sequence parameter set, the picture parameter set, and the slice header contain all the parameters needed to decode the slice data. It is recommended to convey sequence and picture parameter sets out-of-band using a reliable transport mechanism. However, if an application requires a self-contained bitstream, in-band parameter set information units may be used. In error-prone transmission environments, in-band sequence and picture parameter set information units should be protected in a way that assures their successful reception. Synchronization between in-band and out-of-band transmission of the sequence and picture parameter set information is outside of the scope of this Recommendation | International Standard.

profile_idc and **level_idc** indicate profile and level as specified in Annex A. The value of profile_idc shall be in the range from 65 to 90, inclusive. The value of level_idc shall be in the range from 0 to 109, inclusive.

seq_parameter_set_id identifies the sequence parameter set to be referred. The value of seq_parameter_set_id shall be in the range of 0 to 31, inclusive.

log2_max_frame_num_minus4 specifies the MaxFrameNum used in frame number related arithmetic as follows:

$$\text{MaxFrameNum} = 2^{(\text{log2\_max\_frame\_num\_minus4} + 4)} \quad (7\text{-}1)$$

The value of log2_max_frame_num_minus4 shall be in the range of 0 to 12, inclusive.

pic_order_cnt_type equal to 0 or 1 indicates the method to code picture order count (see subclause 8.2.2). If pic_order_cnt_type equals 2, no picture order count information is coded , and there shall be no B slices and no two consecutive non-reference pictures in decoding order in the sequence. The value of pic_order_cnt_type shall be in the range of 0 to 2, inclusive.

delta_pic_order_always_zero_flag equal to 1 indicates that delta_pic_order_cnt[0] and delta_pic_order_cnt[1] are always 0 and are not coded. delta_pic_order_always_zero_flag equal to 0 indicates that delta_pic_order_cnt[0] is coded and delta_pic_order_cnt[1] may be coded.

offset_for_non_ref_pic indicates an expected picture order count difference of a non-reference picture compared to the expected picture order count of the most recently decoded reference picture having a frame_num one less (modulo MaxFrameNum) than that of the non-reference picture. The value of offset_for_non_ref_pic shall be in the range from -2^{31} to $2^{31}-1$, inclusive.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

offset_for_top_to_bottom_field indicates an expected picture order count difference from the top field to the bottom field of a frame picture. The value of offset_for_top_to_botto m_field shall be in the range from -2^{31} to $2^{31}-1$, inclusive.

num_ref_frames_in_pic_order_cnt_cycle signals the number of frame numbers in a picture order count cycle. A picture order count cycle is a repetitive pattern of picture order count differences, e ach of which corresponds to a frame_num increment of one. The value of num_ref_frames_in_pic_order_cnt_cycle shall be in the range from 0 to 255.

offset_for_ref_frame indicates an expected difference of picture order count corresponding to a frame_num incr ement of one. The notation offset_for_ref_frame [i] indicates the offset_for_ref_frame corresponding to index 'i' in the picture order count cycle. The value of offset_for_ref_frame shall be in the range from -2^{31} to $2^{31}-1$, inclusive.

num_ref_frames specifies the maximum total number of short - and long-term reference pictures in the decoded picture buffer. num_ref_frames also determines the size of the Sliding Window operation as specified in subclause 8.2.7.2. Min value is 0. [Ed.Note: really? clash with successive IDRs rule.]. Max value is specified in Annex A.

required_frame_num_update_behaviour_flag equal specifies the decoder behaviour in case of missing frame numbers as specified in subclause 8.2.6.2.

frame_width_in_mbs_minus1 and **frame_height_in_mbs_minus1** specify the width and height, respectively, of the decoded frame in units of macroblocks. The frame width and height in units of macroblocks is computed by adding 1 to the decoded values of each of these parameters. The allowed range of values for these syntax elements is specified in Annex A. If mb_adaptive_frame_field_flag is equal to 1 or field_pic_flag is equal to 1, frame_height_in_mbs_minus1+1 shall be an integer multiple of 2. [Ed.Note: ch ange to frame_height_in_mb_pairs_minus1]

The picture width in units of macroblocks, PicWidthInMbs, is equal to frame_width_in_mbs_minus1 + 1. If a picture is a coded frame, the picture height in units of macroblocks, PicHeightInMbs, shall be equal to frame_height_in_mbs_minus1 + 1. If the picture is a coded field, PicHeightInMbs shall be calculated according to:

$$\text{PicHeightInMbs} = (\text{frame\_height\_in\_mbs\_minus1} + 1) / 2 \quad (7\text{-}2)$$

The maximum macroblock address, MaxMbAdd ress, shall be calculated according to:

$$\text{MaxMbAddress} = \text{PicWidthInMbs} * \text{PicHeightInMbs} - 1 \quad (7\text{-}3)$$

frame_coding_only_flag equal to 0 specifies that a coded picture can be a coded field or a coded frame. frame_coding_only_flag equal to 1 specifies that every coded picture is coded as a frame.

mb_frame_field_adaptive_flag equal to 0 indicates no switching between frame and field decoding mode at the macroblock layer, whereas equal to 1 indicates the possible use of s witching between frame and field decoding mode at the macroblock layer. If a picture is a coded field (if field_pic_flag is 1), then the value of mb_frame_field_adaptive_flag shall be ignored.

direct_temporal_constrained_flag specifies the method used in t he decoding process to determine the prediction values of temporal direct prediction. Subclause 8.4.1.4.2 describes the temporal direct prediction and how the motion parameters are calculated based on the value of direct_tempora l_constrained_flag. If this flag is equal to 1 then 4x4, 4x8, and 8x4 partition sizes are not allowed in temporal direct mode macroblocks.

vui_seq_parameters_present_flag equal to 0 specifies that default parameter values for the VUI sequence parameters shall be applied. Equal to 1 specifies that VUI sequence parameters are coded next. VUI sequence parameters are specified in Annex E.

7.4.2.2 Picture parameter set RBSP semantics

pic_parameter_set_id identifies the picture parameter set to be referred. The value of pic_parameter_set_id shall be in the range of 0 to 127, inclusive.

seq_parameter_set_id identifies the sequence parameter set that is used with this picture parameter set. The value of seq_parameter_set_id shall be in the range of 0 to 31, inclusive.

entropy_coding_mode selects the entropy decoding method to be applied for the syntax elements for which two descriptors appear in the syntax tables. If entropy_coding_mode is equal to 0 the method indicated by the left descriptor is applied (exp-Golomb coded, see subclause 9.1 or CAVLC, see subclause 9.2), whereas if entropy_coding_mode is equal to 1 the method indicated by the right descriptor is applied (CABAC, see subclause 9.3). The value of entropy_coding_mode shall be in the range of 0 to 1, inclusive. [Ed.Note: turn this into a flag, which it is at the end of the day]

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

pic_order_present_flag equal to 0 indicates that only delta_pic_order_cnt[0] (without delta_pic_order_cnt[1]) is sent in the slice_header, while equal to 1 indicates that both delta_pic_order_cnt[0] and delta_pic_order_cnt[1] are sent in the slice_header.

num_slice_groups_minus1 the number of slice groups is equal to num_slice_groups_minus1 + 1. If num_slice_groups_minus1 is zero, all slices of the picture belong to the same slice group. Allowed range is specified in Annex A.

NOTE – One slice group means that no flexible macroblock ordering is applied. If num_slice_groups_minus1 is greater than zero, flexible macroblock ordering is in use.

mb_slice_group_map_type indicates how the mapping of macroblocks to slice groups is coded. The value of mb_slice_group_map_type shall be in the range of 0 to 6, inclusive.

mb_slice_group_map_type 0 is used to indicate interleaved slices.

mb_slice_group_map_type 1 is used to indicate a dispersed macroblock mapping to slice groups.

mb_slice_group_map_type 2 is used to indicate one or more "foreground" slice groups and a "leftover" slice group.

mb_slice_group_map_types 3, 4 and 5 are used to indicate changing slice groups. num_slice_groups_minus1 shall be 1, when mb_slice_group_map_type is equal to 3, 4 or 5.

mb_slice_group_map_type 6 is used to explicitly assign a slice group to each macroblock or macroblock pair location in raster scan order.

If macroblock-adaptive frame/field coding is not in use, the mapping of macroblocks to slice groups operates in units of macroblocks. If macroblock-adaptive frame/field coding is in use, the macroblock allocation map works in units of macroblock pairs.

If mb_slice_group_map_type is 0, the run_length syntax element follows for each slice group.

run_length[i] indicates the number of consecutive macroblocks or macroblock pairs that are assigned to the ith slice group in macroblock or macroblock pair raster scan. After the macroblocks or macroblock pairs of the last slice group have been assigned, the process begins again from the first slice group. The process ends when all the macroblocks of a picture have been assigned. The value of run_length shall be in the range from 0 to MaxMbAddress, inclusive. [Ed.Note: broken, since you don't know how many mbs are in a picture if you don't know whether it is a frame or field at this point. Not entirely broken (you can parse the pic param set once you have the slice header), but undesirable.]

NOTE - Example: To signal macroblock row interleaving in a QCIF picture (where all even numbered macroblocks are in slice group 0, and all odd numbered macroblocks are in slice group 1), the number of slice groups is two and run_length is 11 for both slice groups.

If mb_slice_group_map_type is equal to 1, the macroblock or macroblock pair mapping to slice groups is formed using the following formula, where n is the number of columns in the picture (in macroblocks) and p is the number of slice groups to be coded. Specifically, macroblock or macroblock pair position x is assigned to slice group S according to:

$$S(x, n, p) = ((x \% n) + (((x / n) * p) / 2)) \% p \qquad (7\text{-}4)$$

[Ed. Note: Pick a longer string for the name and move this to subclause 5.6]

If mb_slice_group_map_type is equal to 2, **top_left_mb[i]** and **bottom_right_mb[i]** are specified for the ith slice group except for the last one in ascending order of slice group IDs starting from 0.

top_left_mb[i] and **bottom_right_mb[i]** specify the top-left and bottom-right corners of a rectangle, respectively. top_left_mb[i] and bottom_right_mb[i] are indicated as macroblock addresses or macroblock pair addresses. For each rectangle i, top_left_mb[i] shall be smaller than bottom_right_mb[i]. The rectangles may overlap. Slice groups are allocated in ascending order of slice group IDs. Slice group 0 contains the macroblocks that are within the indicated rectangle top_left_mb[0] and bottom_right_mb[0]. A slice group having slice group ID greater than 0 contains the macroblocks that are within the indicated rectangle for that slice group and that do not belong to any slice group having a smaller slice group ID, i.e. the slice group with the largest slice group ID contains the macroblocks that are not covered by the other slice groups. Each slice groups shall contain at least one macroblock. The size of the top_left_mb and bottom_right_mb parameters shall be NumBitsInMbAddress. [Ed. Note (Karsten): this is broken. We cannot calculate NumBitsInMbAddress with the current definition at this point. (see Note above). Not entirely broken (you can parse the pic param set once you have the slice header), but undesirable.]

The NumBitsInMbAddress indicates the number of bits used to represent a macroblock address with a fixed-length unsigned integer.

If macroblock-adaptive frame/field coding is not in use for a picture (if mb_adaptive_frame_field_flag is equal to 0 or if field_pic_flag is equal to 1), then NumBitsInMbAddress shall be calculated according to:

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$NumBitsInMbAddress = Ceil(Log2(MaxMbAddress + 1)) \quad (7\text{-}5)$$

If macroblock-adaptive frame/field coding is in use for a picture (if mb_adaptive_frame_field_flag is equal to 1 and field_pic_flag is equal to 0), NumBitsInMbAddress shall be calculated according to:

$$NumBitsInMbAddress = Ceil(Log2(MaxMbAddress + 1) - 1) \quad (7\text{-}6)$$

slice_group_change_direction_flag is used with mb_slice_group_map_type to indicate the refined type of the mb_slice_group_map according to Table 7-2 when mb_slice_group_map_type is 3, 4, or 5. The macroblock to slice group map is generated each time the decoder starts decoding of a new picture as described in subclause 8.2.4.

Table 7-2– Refined macroblock to slice group map type

mb_slice_group_map_type	slice_group_change_direction_flag	refined macroblock to slice group map type
4	0	Box-out clockwise
4	1	Box-out counter-clockwise
5	0	Raster scan
5	1	Reverse raster scan
6	0	Wipe right
6	1	Wipe left

slice_group_change_rate_minus1 is the minimum [Ed.Note: ?] non-zero number of macroblocks or macroblock pairs by which the size a slice group can change from one picture to the next. The SliceGroupChangeRate variable is specified as follows:

$$SliceGroupChangeRate = slice\_group\_change\_rate\_minus1 + 1 \quad (7\text{-}7)$$

The value of slice_group_change_rate_minus1 shall be in the range of 0 to MaxMbAddress – 1, inclusive.

If mb_slice_group_map_type is equal to 6, **slice_group_id** identifies a slice group of a macroblock or macroblock pair. The size of the slice_group_id parameter is Ceil(Log2(num_slice_groups_minus1)) bits. The value of slice_group_id shall be in the range of 0 to num_slice_groups_minus1, inclusive.

NOTE - slice_group_id is repeated as often as there are macroblocks in the picture.

num_ref_idx_l0_active_minus1 specifies the maximum reference picture index minus 1 in the reference list 0 that are used to decode the picture. The value of num_ref_idx_l0_active_minus1 is in the range of 0 to 14, inclusive.

num_ref_idx_l1_active_minus1 specifies the maximum reference picture index minus 1 in the reference list 1 that are used to decode the picture. The value of num_ref_idx_l1_active_minus1 is in the range of 0 to 14, inclusive.

weighted_pred_flag equal to 0 indicates that weighted prediction is not applied to P and SP slices. weighted_pred_flag equal to 1 indicates that weighted prediction is applied to P and SP slices.

weighted_bipred_explicit_flag equal to 0 indicates that explicit weighted prediction is not applied to B slices. weighted_bipred_explicit_flag equal to 1 indicates that explicit weighted prediction is applied to B slices. weighted_bipred_explicit_flag shall be equal to 0 if weighted_bipred_implicit_flag is one.

weighted_bipred_implicit_flag equal to 0 indicates that implicit weighted prediction is not applied to B slices. weighted_bipred_implicit_flag equal to 1 indicates that implicit weighted prediction is applied to B slices. weighted_bipred_implicit_flag shall be equal to 0 if weighted_bipred_explicit_flag is equal to 1.

pic_init_qp_minus26 specifies the initial value minus 26 of QP_Y for each slice. The initial value is modified at the slice layer when a non-zero value of slice_qp_delta is decoded, and is modified further when a non-zero value of mb_qp_delta is decoded at the macroblock layer. The value of pic_init_qp_minus26 shall be in the range of -26 to +25, inclusive.

pic_init_qs_minus26 specifies the initial value minus 26 of QS_Y for all macroblocks in SP or SI slices The initial value is modified at the slice layer when a non-zero value of slice_qs_delta is decoded. The value of pic_init_qs_minus26 shall be in the range of -26 to +25, inclusive.

chroma_qp_index_offset specifies the offset that shall be added to QP_Y and QS_Y for addressing the table of QP_C values. The value of chroma_qp_index_offset shall be in the range from -12 to +12, inclusive.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

deblocking_filter_parameters_present_flag specifies whether a set of parameters controlling the characteristics of the deblocking filter is indicated in the slice header.

constrained_intra_pred_flag equal to 0 indicates that intra prediction allows use of neighbouring non -intra macroblock data and decoded samples for the prediction of intra macroblocks, whereas constrained_intra_pred_flag equal to 1 indicates constrained intra prediction, where no intra prediction only uses data and decoded samples from I or SI macroblock types.

redundant_slice_flag indicates the presence of the redundant_pic_cnt parameter in all slice headers referencing the picture parameter set.

vui_pic_parameters_flag equal to zero specifies that default parameter values for the vui picture parameters shall be applied. [Ed.Note: mention Annex E]

7.4.2.3 Supplemental enhancement information RBSP semantics

Supplemental Enhancement Information (SEI) co ntains information that is not necessary to decode VCL data correctly but is helpful for decoding or presentation purposes.

7.4.2.3.1 Supplemental enhancement information message semantics

An SEI NAL unit contains one or more SEI messages. Each SEI message consists of SEI header and SEI payload. The type and size of the SEI payload are coded using an extensible syntax. The SEI payload size is indicated in bytes. SEI payload types are specified in Annex C.

The SEI payload may have an SEI payload header. For example, a payload beader may indicate to which picture the particular data belongs. The payload header shall be specified for each payload type separately.

An SEI message is associated with the next slice or slice data partition RBSP in decoding order. [Ed.Note: isn't it associated with a complete picture ? Will it remain active for the next pictures ?]

byte_ff is a byte equal to 0xFF identifying a need for a longer representation of the syntax structure it is used within.

last_payload_type_byte identifies the payload type of the last entry in an SEI message.

last_payload_size_byte identifies the size of the last entry in an SEI message.

7.4.2.4 Picture delimiter RBSP semantics

The picture delimiter may be used to signal the boundary between pictures, i.e., if present, it shall be inserted before the first [Ed.Note: Which is the first?] NAL unit of a picture in decoding order. There is no normative decoding process associated with the picture delimiter.

pic_type indicates which slice types are used in the following picture in decoding order. Table 7-3 shows the slice types that can occur in a picture with a given pic_type.

Table 7-3– Meaning of pic_type

pic_type	slice_type's allowed in picture
0	I
1	I, P
2	I, P, B
3	SI
4	SI, SP
5	I, SI
6	I, SI, P, SP,
7	I, SI, P, SP, B

7.4.2.5 Filler data RBSP semantics

The filler data RBSP contains bytes whose value shall be equal to 0xFF.

byte_ff is a byte equal to 0xFF.

7.4.2.6 Slice layer RBSP semantics

The slice layer RBSP consists of a slice header and slice data.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

7.4.2.7 Slice data partition RBSP semantics

7.4.2.7.1 Slice data partition A RBSP semantics

When slice data partitioning is in use, the coded data for a single slice is divided into three separate partitions. Partition A contains all symbols of Category 4.

NOTE - Category 4 consists of the header symbols of all coded macroblocks.

slice_id each slice of a picture is associated a unique slice identifier within the picture, when redundant_slice_flag is equal to 0. If redundant_slice_flag is equal to 1, each slice has a unique slice identifier among the slices having the same redundant_pic_cnt. Within any primary or redundant coded picture, the first coded slice of the picture shall have identifier equal to 0 and the identifier shall be incremented by one per each coded slice in decoding order. The range of slice_id is specified in Annex A. [Ed.Note: not yet done in Annex A. If not specified otherwise, this will become 0 to MaxMbAddress.]

7.4.2.7.2 Slice data partition B RBSP semantics

When slice data partitioning is in use, the coded data for a single slice is divided into three separate partitions. Slice data partition B contains all symbols of Category 5.

NOTE - Category 5 consists of the coded block patterns and coefficients for I and SI macroblock types.

slice_id each slice of a picture is associated a unique slice identifier within the picture, when redundant_slice_flag is equal to 0. If redundant_slice_flag is equal to 1, each slice has a unique slice identifier among the slices having the same redundant_pic_cnt. Within any primary or redundant coded picture, the first coded slice of the picture shall have identifier equal to 0 and the identifier shall be incremented by one per each coded slice in decoding order. The range of slice_id is specified in Annex A. [Ed.Note: not yet done in Annex A. If not specified otherwise, this will become 0 to MaxMbAddress.]

redundant_pic_cnt is equal to 0 for slices and slice data partitions belonging to the primary coded picture. The redundant_pic_cnt is greater than 0 for redundant coded slices and slice data partitions with max value being 127.

7.4.2.7.3 Slice data partition C RBSP semantics

When slice data partitioning is in use, the coded data for a single slice is divided into three separate partitions. Slice dat a partition C contains all symbols of Category 6.

NOTE - Category 6 consists of the coded block patterns and coefficients for P and B macroblock types.

slice_id each slice of a picture is associated a unique slice identifier within the picture, when redund ant_slice_flag is equal to 0. If redundant_slice_flag is equal to 1, each slice has a unique slice identifier among the slices having the same redundant_pic_cnt. Within any primary or redundant coded picture, the first coded slice of the picture shall have identifier equal to 0 and the identifier shall be incremented by one per each coded slice in decoding order. The range of slice_id is specified in Annex A. [Ed.Note: not yet done in Annex A. If not specified otherwise, this will become 0 to MaxMbAddress.]

redundant_pic_cnt is equal to 0 for slices and slice data partitions belonging to the primary coded picture. The redundant_pic_cnt is greater than 0 for redundant coded slices and slice data partitions with max value being 127.

7.4.2.8 RBSP slice trailing bits semantics

cabac_zero_word is a byte-aligned string of two bytes equal to 0x0000. When entropy_coding_mode is equal to 1, the number of bins (excluding end_of_slice_flag) resulting from decoding the contents of the slice layer NAL unit shall not exceed 32*NumBytesInNALunit.

NOTE – The constraint on the maximum number of bins resulting from decoding the contents of the slice layer NAL unit can be met by inserting a number of cabac_zero_word syntax elements to increase the value of NumBytesInNALunit. Each cabac_zero_word is represented in the NAL unit by the three-byte sequence 0x000003 (as a result of the constraints on NAL unit contents that result in requiring inclusion of an emulation_prevention_byte for each cabac_zero_word).

7.4.2.9 RBSP trailing bits semantics

rbsp_stop_bit is a single bit equal to 1.

rbsp_alignment_bit is a single bit equal to 0.

7.4.3 Slice header semantics

pic_parameter_set_id indicates the picture parameter set in use. The value of pic_parameter_set_id shall be in the range of 0 to 127, inclusive.

frame_num identifies the frame for the picture. frame_num shall be incremented by 1 for each coded picture in decoding order, in modulo MaxFrameNum operation, relative to the frame_num of the last previous reference picture in

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

decoding order that has a different value of frame_num. An IDR picture shall have frame_num equal to 0. A frame picture shall not have the same frame_num as the reference picture that immediately precedes it in decoding order. A field picture shall not have the same frame_num as the reference picture that immediately precedes it in decoding order unless that picture is another field picture and has opposite parity. The decoding order of primary coded pictures shall be non-decreasing in frame number order. For non-reference pictures with the same frame number, the decoding order shall be non-decreasing in picture order count. The frame_num serves as a unique identifier for each reference frame in the decoded picture buffer. Therefore, a reference frame cannot be kept in the buffer aft er its frame_num has been used by another reference frame unless it has been assigned a long -term frame index as specified below. The frame_num of a reference frame to be added to the decoded picture buffer shall not be equal to the frame_num of any other among the short-term reference frames in the decoded picture buffer.

A picture including a memory_management_control_operation equal to 5 (reset all reference pictures) or 7 (reset all reference and non-reference pictures) shall have frame_num as describe d above, but after processing of the memory_management_control_operations, shall be considered to have frame_num equal to 0. frame_num is represented by log2_max_frame_num_minus4 + 4 bits in the bitstream.

field_pic_flag equal to 1 indicates that the pictu re is a coded field and equal to 0 indicates that the picture is a coded frame.

bottom_field_flag is only present when field_pic_flag is equal to 1. If bottom_field_flag is present and equal to 1, the picture is a coded bottom field. If bottom_field_flag is present and equal to 0, the picture is a coded top field.

first_mb_in_slice specifies the location of the first macroblock contained in this slice. The size of the first_mb_in_slice parameter is NumBitsInMbAddress. first_mb_in_slice shall be in the ran ge of 0 to MaxMbAddress, inclusive.

When macroblock-adaptive frame/field coding is not in use (when mb_adaptive_frame_field_flag is equal to 0 or field_pic_flag is equal to 1), first_mb_in_slice contains a macroblock address.

When macroblock-adaptive frame/field coding is in use (when mb_adaptive_frame_field_flag is equal to 1 and field_pic_flag is equal to 0), first_mb_in_slice contains a macroblock pair address and the number of macroblocks in the slice shall be an integer multiple of 2.

slice_type indicates the coding type of the slice according to Table 7-4.

Table 7-4 – Name association to slice_type

slice_type	Name of slice_type
0	P (P slice)
1	B (B slice)
2	I (I slice)
3	SP (SP slice)
4	SI (SI slice)

delta_pic_order_cnt[0] indicates the picture order count difference from the expected picture order count for the top field of a coded frame or for a coded field as described in subclause 8.2.2. If delta_pic_order_always_zero_flag is equal to 1, then delta_pic_order_cnt[0] is set equal to 0 and is not coded. The value of delta_pic_order_cnt[0] shall be in the range of -2^{31} to $2^{31}-1$, inclusive.

delta_pic_order_cnt[1] indicates the picture order count difference from the expected picture order count for the bottom field of a coded frame described in subclause 8.2.2. If delta_pic_order_always_zero_flag is equal to 1, then delta_pic_order_cnt[1] is set equal to 0 and is not coded. The value of delta_pic_order_cnt[0] shall be in the range of -2^{31} to $2^{31}-1$, inclusive.

redundant_pic_cnt is equal to 0 for slices and slice data partitions belonging to the primary coded picture. The redundant_pic_cnt is gre ater than 0 for redundant coded slices and slice data partitions with max value being 127.

NOTE - There should be no noticeable difference between the co-located areas of the decoded primary picture and any decoded redundant pictures.

Redundant slices and slice data partitions having the same value of redundant_pic_cnt belong to the same redundant picture. Decoded slices within the same redundant picture may not cover the entire picture area and shall not overlap. If the value of nal_ref_idc in a primary pi cture is equal to 0, the nal_ref_idc in corresponding redundant pictures shall be equal to 0. If the value of nal_ref_idc in a primary picture is greater than 0, the nal_ref_idc in corresponding redundant pictures shall be greater than 0.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

The slices of a redundant picture shall have the same values of field_pic_flag and bottom_field_flag as the corresponding primary picture. The frame_num of a redundant picture shall be the same as the frame_num in the primary picture, or both the redundant picture and the primary picture shall issue a reset memory management control operation (which resets the frame number to 0). The calculated picture order count of a redundant picture shall be the same as for the corresponding primary picture.

direct_spatial_mv_pred_flag specifies the method used in the decoding process to determine the prediction values direct prediction. If direct_spatial_mv_pred_flag is equal to 0, then direct mode motion parameters are calculated from the picture order count as described in subclause 8.4.1.4.2.3. If this flag is equal to 1, then direct mode motion parameters are calculated using the spatial motion vector prediction technique as described in subclause 8.4.1.4.2.2. [Ed.Note: semantics should be more specific]

num_ref_idx_active_override_flag equal to 0 indicates that the num_ref_idx_l0_active_minus1 and num_ref_idx_l1_active_minus1 specified in the referred picture parameter set are in effect. num_ref_idx_active_override_flag equal to 1 indicates that the num_ref_idx_l0_active_minus1 and num_ref_idx_l1_active_minus1 specified in the referred picture parameter set are overridden for the current slice only by the following values in the slice header.

num_ref_idx_l0_active_minus1 specifies the maximum reference picture index minus 1 in the reference picture list 0 that are used to decode the slice. The range of num_ref_idx_l0_active_minus1 is specified in Annex A. [Ed. Note: Not yet specified there. If not specified otherwise, it will be 0 to 14, inclusive.]

num_ref_idx_l1_active_minus1 specifies the maximum reference picture index minus 1 in the reference picture list 1 that are used to decode the slice. The range of num_ref_idx_l1_active_minus1 is specified in Annex A. [Ed. Note: Not yet specified there. If not specified otherwise, it will be 0 to 14, inclusive.]

non_ref_pic_reset_flag indicates how the non-reference pictures are treated for an IDR picture. A value of 1 indicates that the non-reference pictures are removed from the decoded picture buffer. A value of 0 indicates that the non-reference pictures remain in the decoded picture buffer.

slice_qp_delta specifies the initial value of QP_Y to be used for all the macroblocks in the slice until modified by the value of mb_qp_delta in the macroblock layer. The initial QP_Y parameter for the slice is computed as:

$$QP_Y = 26 + pic\_init\_qp\_minus26 + slice\_qp\_delta \quad (7\text{-}8)$$

The value of slice_qp_delta shall be limited such that QP_Y is in the range of 0 to 51, inclusive.

sp_for_switch_flag indicates the decoding process to be used to decode the SP slice. [Ed.Note: How about details? What further detail is necessary here?]

slice_qs_delta specifies the value of QS_Y for all the macroblocks in SP and SI slices. The QS_Y parameter for the slice is computed as:

$$QS_Y = 26 + pic\_init\_qs\_minus26 + slice\_qs\_delta \quad (7\text{-}9)$$

The value of slice_qs_delta shall be limited such that QS_Y is in the range of 0 to 51, inclusive. This value of QS_Y is used for the decoding of all macroblocks in the slice.

NOTE - This syntax element is signalled for SP and SI slices only.

disable_deblocking_filter_idc indicates whether the operation of the deblocking filter shall be disabled across some block edges of the slice and indicates on which edges the filtering is disabled. If disable_deblocking_filter_idc is not present in the slice header, the value of disable_deblocking_filter_idc shall be inferred to be equal to 0.

If disable_deblocking_filter_idc is equal to 0, the deblocking filter shall be applied across all edges controlled by the macroblocks within the current slice.

If disable_deblocking_filter_idc is equal to 1, the deblocking filter shall not be applied across any edges controlled by the macroblocks within the current slice.

If disable_deblocking_filter_idc is equal to 2, the deblocking filter shall be applied across all edges controlled by the macroblocks within the current slice, with the exception of the macroblock edges that are also slice boundaries.

The value of disable_deblocking_filter_idc shall be in the range of 0 to 2.

slice_alpha_c0_offset_div2 specifies the offset used in accessing the α and C0 deblocking filter tables for filtering operations controlled by the macroblocks within the slice. From this value, the offset that shall be applied when addressing these tables shall be computed as:

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$$FilterOffsetA = slice\_alpha\_c0\_offset\_div2 << 1 \quad (7\text{-}10)$$

The value of slice_alpha_c0_offset_div2 shall be in the range of -6 to +6, inclusive. If slice_alpha_c0_offset_div2 is not present in the slice header the value of slice_alpha_c0_offset_div2 shall be inferred to be equal to 0.

slice_beta_offset_div2 specifies the offset used in accessing the β deblocking filter table for filtering operations controlled by the macroblocks within the slice. From this value, the offset that is applied when addressing the β table of the deblocking filter shall be computed as:

$$FilterOffsetB = slice\_beta\_offset\_div2 << 1 \quad (7\text{-}11)$$

The value of slice_beta_offset_div2 shall be in the range of -6 to +6, inclusive. If slice_beta_offset_div2 is not present in the slice header the value of slice_beta_offset_div2 shall be inferred to be equal to 0.

slice_group_change_cycle × SliceGroupChangeRate indicates the number of macroblocks in slice group 0. The value of slice_group_change_cycle is represented in the bitstream by the following number of bits

$$Ceil(Log2(Ceil((MaxMbAddress+1) \div SliceGroupChangeRate))).$$

The minimum value of slice_group_change_cycle is 0. The maximum value of slice_group_change_cycle is

$$Ceil((MaxMbAddress+1) \div SliceGroupChangeRate).$$

The value of pic_parameter_set_id, frame_num, field_pic_flag, bottom_field_flag, delta_pic_order_cnt[0], delta_pic_order_cnt[1], sp_for_switch_flag, and slice_group_change_cycle shall be the same in all slice headers of a redundant or primary coded picture. Moreover, the parameter values included in the dec_pic_buf_management( ) function shall remain unchanged in all slice headers of a redundant or primary coded picture.

7.4.3.1 Reference index reordering semantics

The syntax elements remapping_of_pic_nums_idc, abs_diff_pic_num_minus1, and long_term_pic_idx specify the change from the default reference index lists to the reference index lists used for decoding the slice.

ref_idx_reordering_flag_l0 equal to 1 indicates that the syntax elements remapping_of_pic_nums_idc, abs_diff_pic_num_minus1, and long_term_pic_idx are present for specifying the reference index list 0, while ref_idx_reordering_flag_l0 equal to 0 indicates that these syntax elements are not present.

ref_idx_reordering_flag_l1 equal to 1 indicates that the syntax elements remapping_of_pic_nums_idc, abs_diff_pic_num_minus1, and long_term_pic_idx are present for specifying the reference index list 1, while ref_idx_reordering_flag_l1 equal to 0 indicates that these syntax elements are not present.

remapping_of_pic_nums_idc together with abs_diff_pic_num_minus1 and long_term_pic_idx indicates which of the reference pictures are re-mapped. The values of remapping_of_pic_nums_idc are specified in Table 7-5. The number of signalling remapping_of_pic_nums_idc is limited to the num_ref_idx_l0_active_minus1 + 1. [Ed.Note: is this true with weighted prediction ? Yes, because num_ref_idx_active_minus1+1 is or should be the number of indexes active, not the number of pictures active.]

Table 7-5 – remapping_of_pic_nums_idc operations for re-mapping of reference pictures

remapping_of_pic_nums_idc	Re-mapping specified
0	abs_diff_pic_num_minus1 is present and corresponds to a negative difference to add to a picture number prediction value
1	abs_diff_pic_num_minus1 is present and corresponds to a positive difference to add to a picture number prediction value
2	long_term_pic_idx is present and specifies the long-term index for a reference picture
3	End loop for re-mapping of reference picture set relative indexing default order

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

abs_diff_pic_num_minus1 plus 1 indicates the absolute difference between the picture number of the picture being remapped and the picture number prediction value. When field_pic_flag is equal to 0, the value of abs_diff_pic_num_minus1 shall be in the range of 0 to MaxFrameNum -1, inclusive. When field_pic_flag is equal to 1, the value of abs_diff_pic_num_minus1 shall be in the range of 0 to 2*MaxFrameNum -1, inclusive. [Ed.Note: I'm not completely sure about this.]

long_term_pic_idx indicates the long-term picture index of the picture being remapped. In the case of frame -structured pictures, it shall be less than max_long_term_pic_idx_plus1; while decoding a field, it shall be less than 2 * max_long_term_pic_idx_plus1.

7.4.3.2 Prediction weight table semantics

[Ed.Note: the coupling of this with picture re -mapping is not yet worked out.]

luma_log_weight_denom is the binary logarithm of the denominator for all luma weighting factors. The value of luma_log_weight_denom shall be in t he range of 0 to 7, inclusive.

chroma_log_weight_denom is the binary logarithm of the denominator for all chroma weighting factors. The value of chroma_log_weight_denom shall be in the range of 0 to 7, inclusive.

luma_weight_l0_flag equal to 1 indicates that weighting factors are present for the luma component of list 0 prediction, while equal to 0 indicates that these weighting factors are not present. If luma_weight_l0_flag is equal to 0, then luma_weight_l0[i] shall be inferred as equal to $2^{luma\_log\_weight\_denom}$ and luma_offset_l0[i] shall be inferred as equal to 0.

luma_weight_l0[i] is the weighting factor applied to the luma prediction value for reference index i in list 0 prediction. Allowed range is –128 to 128, inclusive.

luma_offset_l0[i] is the additive offset applied to the luma prediction value for reference index i in list 0 prediction. Allowed range is –256 to 255, inclusive.

chroma_weight_l0_flag equal to 1 indicates that weighting factors are present for the Cb and Cr components of list 0 prediction while equal to 0 indicates that these weighting factors are not present. If chroma_weight_l0_flag is equal to 0 , chroma_weight_l0[i] shall be inferred as equal to $2^{chroma\_log\_weight\_denom}$ and chroma_offset_l0[i] shall be inferred as equal to 0.

chroma_weight_l0[i][0] is the weighting factor applied to the Cb prediction values for reference index i in list 0 prediction. Allowed range is –128 to 128, inclusive.

chroma_offset_l0[i][0] is the additive offset applied to the Cb pre diction values for reference index i in list 0 prediction. Allowed range is –256 to 255, inclusive.

chroma_weight_l0[i][1] is the weighting factor applied to the Cr prediction values for reference index i in list 0 prediction. Allowed range is –128 to 128, inclusive.

chroma_offset_l0[i][1] is the additive offset applied to the Cr prediction values for reference index i in list 0 prediction. Allowed range is –256 to 255, inclusive.

luma_weight_l1_flag equal to 1 indicates that weighting factors are present for the luma component of the list 1 prediction while equal to 0 indicates that these weighting factors are not present. If luma_weight_l1_flag is equal to 0, luma_weight_l1[i] shall be inferred as equal to $2^{luma\_log\_weight\_denom}$ and luma_offset_l1[i] shall be inferred as equal to 0.

luma_weight_l1[i] is the weighting factor applied to the luma prediction values for reference index i in list 1 prediction. Allowed range is –128 to 128, inclusive.

luma_offset_l1[i] is the additive offset applied to the luma prediction value for reference index i in list 1 prediction. Allowed range is –128 to 128, inclusive.

chroma_weight_l1_flag equal to 1 indicates that weighting factors are present for the chroma component of the list 1 prediction while equal to 0 indicates that these weighting factors are not present. If chroma_weight_l1_flag is equal to 0, chroma_weight_l1[i][j] shall be inferred as equal to $2^{chroma\_log\_weight\_denom}$ and chroma_offset_l1[i][j] shall be inferred as equal to 0.

chroma_weight_l1[i][0] is the weighting factor applied to the Cb prediction values for reference index i in list 1 prediction. Allowed range is –128 to 128, inclusive.

chroma_offset_l1[i][0] is the additive offset applied to the Cb prediction values fo r reference index i in list 1 prediction. Allowed range is –256 to 255, inclusive.

chroma_weight_l1[i][1] is the weighting factor applied to the Cr prediction values for reference index i in list 1 prediction. Allowed range is –128 to 128, inclusive.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

chroma_offset_l[i][1] is the additive offset applied to the Cr prediction values for reference index i in list 1 prediction. Allowed range is –256 to 255, inclusive.

7.4.3.3 Decoded picture buffer management semantics

The syntax elements num_ref_frames, adapt ive_ref_pic_buffering_mode_flag, memory_management_control_operation, difference_of_pic_nums_minus1, long_term_pic_idx, and max_long_term_pic_idx_plus1 specify the management of pictures in the decoded picture buffer. Further, the decoded picture buffer ca n be modified by marking reference pictures as "unused for reference", by assigning long -term picture indices and by removing [Ed.Note: Meaning?] reference and/or non-reference pictures from the decoded picture buffer. The syntax elements adaptive_ref_pic_ buffering_mode_flag, memory_management_control_operation, difference_of_pic_nums_minus1, long_term_pic_idx, and max_long_term_pic_idx_plus1 shall be identical for all coded slices of a coded picture.

adaptive_ref_pic_buffering_mode_flag specifies the reference picture buffering mode of the currently decoded picture and specifies how the decoded picture buffer is modified after the current picture is decoded. The values for adaptive_ref_pic_buffering_mode_flag are specified in Table 7-6.

Table 7-6 – Interpretation of adaptive_ref_pic_buffering_mode_flag

adaptive_ref_pic_buffering_mode_flag	Reference picture buffering mode specified
0	Sliding window reference picture buffering mode; A simple buffering mode providing a first-in first-out mechanism for reference pictures that are not assigned a long-term index
1	Adaptive reference picture buffering mode; A more flexible reference picture buffering mode than sliding window reference picture buffering mode providing syntax elements to specify marking reference pictures as "unused for reference", to assign long-term picture indices, and to remove pictures from the decoded picture buffer.

memory_management_control_operation specifies a control operation to be applied to manage the decoded picture buffer. The memory_management_control_operation parameter is followed by data necessary for the operation specified by the value of memory_management_control_operation. memory_management_control_oper ation commands do not affect the buffer contents or the decoding process for the decoding of the current frame. They specify the necessary buffer status for the decoding of subsequent coded pictures. The values and control operations associated with memory_management_control_operation are specified in Table 7-7.

If memory_management_control_operation is 5 (reset all reference pictures), all frames and fields marked as "used for prediction" in the decoded picture buffer shall be rem oved from the decoded picture buffer. Moreover, the maximum long-term reference picture index shall be reset to 0.

If memory_management_control_operation is 6 (reset all non -reference pictures), all frames and fields marked as "unused for prediction" shall be removed from the decoded picture buffer.

If memory_management_control_operation is 7 (reset all reference and non -reference pictures), all frames and fields shall be removed from the decoded picture buffer. Moreover, the maximum long -term picture index shall be reset to zero.

The frame height and width shall not change within [Ed.Note: meaning?] the bitstream except within a picture containing memory_management_control_operation commands 5 (reset all reference pictures) or 7 (reset all reference and no n-reference pictures).

If nal_ref_idc of the current picture is equal to 0, the value of the memory_management_control_operation shall not contain any of the following types of memory_management_control_operation commands:

a) Any reset all reference pictures, reset all non-reference pictures, and reset all reference and non -reference pictures memory_management_control_operation commands,

b) Any memory_management_control_operation command which marks any other reference picture (other than the current pictur e) as a non-reference pictures that has not also been previously marked as a non - reference pictures, or

c) Any memory_management_control_operation command which assigns a long -term index to a picture that has not also been assigned the same long -term index previously.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 7-7 – Memory management control operation (memory_management_control_operation) values

memory_management_control_operation	Memory Management Control Operation
0	End memory_management_control_operation Loop
1	Mark a short-term picture as "Unused for reference"
2	Mark a long-term picture as "Unused for reference"
3	Assign a long-term index to a picture
4	Specify the maximum long-term picture index
5	Reset all reference pictures
6	Reset all non-reference pictures
7	Reset all reference and non-reference pictures

difference_of_pic_nums_minus1 is used to assign a long-term index to a short-term reference picture or to mark a short-term reference picture as "unused for reference". When field_pic_flag is equal to 0, the value of difference_of_pic_nums_minus1 shall be in the range of 0 to MaxFrameNum -1, inclusive. When field_pic_flag is equal to 1, the value of difference_of_pic_nums_minus1 shall be in the range of 0 to 2*MaxFrameNum -1, inclusive. [Ed.Note: I'm not completely sure about this.]

long_term_pic_idx is used to assign a long-term index to a picture or to mark a long-term picture as "unused for reference". The value of long_term_pic_idx shall be in the range of 0 to max_long_term_pic_idx_plus1, inclusive.

max_long_term_pic_idx_plus1 minus 1 indicates the maximum index allowed for long-term reference frames (until receipt of another value of max_long_term_pic_idx_plus1). The decoder shall initially infer that max_long_term_pic_idx_plus1 is 0 until some other value has been received. The range of max_long_term_pic_idx_plus1 is specified in Annex A. [Ed.Note: specify in Annex A. If not specified otherwise, should be 0 to 16.]

7.4.4 Slice data semantics

cabac_alignment_bit is bit equal to 0. [Ed. Note: Shouldn't it be equal to 1? Seems foolish, as all other similar junk bits are set equal to 1, which is a better value for start-code emulation prevention.]

mb_skip_run is present only when entropy_coding_mode is equal to 0. mb_skip_run indicates the number of consecutive skipped macroblocks, in P slices, or number of consecutive macroblocks of Direct_16x16 macroblock type for which no additional transform coefficients are present, in B slices. The value of mb_skip_run is in the range of 0 to MaxMbAddress+1.

mb_skip_flag is present only when entropy_coding_mode is equal to 1. mb_skip_flag equal to 1 indicates that the next macroblock is skipped, in a P slice, or is of Direct_16x16 macroblock type without additional transform coefficients coded, in a B slice. mb_skip_flag equal to 0 indicates that the next macroblock is not skipped, in a P slice, or is not of Direct_16x16 macroblock type without additional transform coefficients coded, in a B slice.

mb_field_decoding_flag equal to 0 indicates that the current macroblock pair is decoded in frame decoding mode and equal to 1 indicates that the macroblock pair is decoded in field decoding mode.

end_of_slice_flag equal to 0 indicates that another macroblock is following, whereas end_of_slice_flag equal to 1 indicates the end of the slice and that no further macroblock follows. end_of_slice_flag is only present if entropy_coding_mode is equal to 1 for each macroblock except for the last macroblock of the picture.

When decoding a frame and mb_adaptive_frame_field_flag is equal to 1, the number of macroblocks, including skipped macroblocks, in the slice shall be an integer multiple of 2.

7.4.5 Macroblock layer semantics

mb_type indicates the macroblock type. The semantics of mb_type depend on the slice type.

Tables and semantics are specified for the various macroblock types for I, SI, P, SP, and B slices. Each table presents the value of mb_type, the name of mb_type, the number of macroblock partitions used (given by the num_mb_part(mb_type) function), the prediction mode of the macroblock (if it is not partitioned) or the first partition (given by the mb_part_pred_mode(mb_type, 1) function) and the prediction mode of the second partition (given by the

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

mb_part_pred_mode(mb_type, 2) function). When a value is not applicable it is designated by "na". A column of the table including only not applicable ("na") values does not appear in the table. In the text, the value of mb_type may be referred to as the macroblock type and a value X of mb_part_pred_mode may be referred to in the text by "X macroblock (partition) prediction mode" and the macroblock types may be referred to as "X prediction macroblocks".

Table 7-8 shows the allowed collective macroblock types for each slice_type. [E d.Note: It is proposed to delete the table as e.g. there are some macroblock types with Pred_L0 prediction mode that can not belong to a B slice]

Table 7-8 – Allowed collective macroblock types for slice_type

slice_type	allowed collective macroblock types
I (slice)	I (see Table 7-9) (macroblock types)
P (slice)	P (see Table 7-11) and I (see Table 7-9) (macroblock types)
B (slice)	B (see Table 7-12) and I (see Table 7-9) (macroblock types)
SI (slice)	SI (see Table 7-10) and I (see Table 7-9) (macroblock types)
SP (slice)	P (see Table 7-11) and I (see Table 7-9) (macroblock types)

Macroblock types which may be collectively referred to as I macroblock types are specified in Table 7-9.

The macroblock types for I slices are only I macroblock types.

Table 7-9 – Macroblock types for I slices

mb_type	Name of mb_type	mb_part_pred_mode (mb_type, 0)	Intra16x16 PredMode	CodedBlock PatternChroma	CodedAC PatternLuma
0	I_4x4	Intra_4x4	na	na	na
1	I_16x16_0_0_0	Intra_16x16	0	0	0
2	I_16x16_1_0_0	Intra_16x16	1	0	0
3	I_16x16_2_0_0	Intra_16x16	2	0	0
4	I_16x16_3_0_0	Intra_16x16	3	0	0
5	I_16x16_0_1_0	Intra_16x16	0	1	0
6	I_16x16_1_1_0	Intra_16x16	1	1	0
7	I_16x16_2_1_0	Intra_16x16	2	1	0
8	I_16x16_3_1_0	Intra_16x16	3	1	0
9	I_16x16_0_2_0	Intra_16x16	0	2	0
10	I_16x16_1_2_0	Intra_16x16	1	2	0
11	I_16x16_2_2_0	Intra_16x16	2	2	0
12	I_16x16_3_2_0	Intra_16x16	3	2	0
13	I_16x16_0_0_1	Intra_16x16	0	0	1
14	I_16x16_1_0_1	Intra_16x16	1	0	1
15	I_16x16_2_0_1	Intra_16x16	2	0	1
16	I_16x16_3_0_1	Intra_16x16	3	0	1
17	I_16x16_0_1_1	Intra_16x16	0	1	1
18	I_16x16_1_1_1	Intra_16x16	1	1	1
19	I_16x16_2_1_1	Intra_16x16	2	1	1

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

20	I_16x16_3_1_1	Intra_16x16	3	1	1
21	I_16x16_0_2_1	Intra_16x16	0	2	1
22	I_16x16_1_2_1	Intra_16x16	1	2	1
23	I_16x16_2_2_1	Intra_16x16	2	2	1
24	I_16x16_3_2_1	Intra_16x16	3	2	1

The following semantics are assigned to the macroblock types in Table 7-9:

I_4x4: the macroblock is coded as Intra_4x4 prediction macroblock.

I_16x16_0_0_0, I_16x16_1_0_0, I_16x16_2_0_0, I_16x16_3_0_0, I_16x16_0_1_0, I_16x16_1_1_0, I_16x16_2_1_0, I_16x16_3_1_0, I_16x16_0_2_0, I_16x16_1_2_0, I_16x16_2_2_0, I_16x16_3_2_0, I_16x16_0_0_1, I_16x16_1_0_1, I_16x16_2_0_1, I_16x16_3_0_1, I_16x16_0_1_1, I_16x16_1_1_1, I_16x16_2_1_1, I_16x16_3_1_1, I_16x16_0_2_1, I_16x16_1_2_1, I_16x16_2_2_1, I_16x16_3_2_1: the macroblocks is coded as Intra_16x16 prediction macroblock.

To each Intra_16x16 prediction macroblock, an Intra16x1 6PredMode is assigned which indicates the Intra_16x16 prediction mode, CodedBlockPatternChroma contains the coded block pattern bits for chroma as specified below in this subclause, and CodedACPatternLuma indicates whether non -zero AC levels are present. CodedACPatternLuma equal to 0 indicates that there are no AC transform levels in the luma component of the macroblock. CodedACPatternLuma equal to 1 indicates that at least one AC transform level is in the luma component of the macroblock, requiring scann ing of AC coefficient values for all 16 of the 4x4 blocks in the 16x16 block.

Intra_4x4 specifies the macroblock prediction mode and indicates that the Intra_4x4 prediction process is invoked as specified in subclause 8.3.18.3.2. Intra_4x4 is an Intra macroblock prediction mode.

Intra_16x16 specifies the macroblock prediction mode and indicates that the Intra_16x16 prediction process is invoked as specified in subclause 8.3.2. Intra_16x16 is an Intra macroblock prediction mode.

A macroblock type which may be referred to as SI macroblock type is specified in Table 7-10.

The macroblock types for SI slices are specified in Table 7-10 and Table 7-9. The mb_type value 0 is specified in Table 7-10 and the mb_type values 1 to 25 are specified in Table 7-9, indexed by subtracting 1 from the value of mb_type.

Table 7-10 – Macroblock type with value 0 for SI slices

mb_type	Name of mb_type	mb_part_pred_mode(mb_type, 0)
0	SI	Intra_4x4

The following semantics are assigned to the macroblock type in Table 7-10: the SI macroblock is coded as Intra_4x4 prediction macroblock.

Macroblock types which may be collectively referred to as P macroblock types are specified in Table 7-11.

The macroblock types for P and SP slices a re specified in Table 7-11 and Table 7-9. The mb_type values 0 to 4 are specified in Table 7-11 and the mb_type values 5 to 29 are specified in Table 7-9, indexed by subtracting 5 from the value of mb_type.

Table 7-11 – Macroblock type values 0 to 4 for P and SP slices

mb_type	Name of mb_type	num_mb_part (mb_type)	mb_part_pred_mode (mb_type, 0)	mb_part_pred_mode (mb_type, 0)
0	P_L0_16x16	1	Pred_L0	na
1	P_L0_L0_16x8	2	Pred_L0	Pred_L0
2	P_L0_L0_8x16	2	Pred_L0	Pred_L0
3	P_8x8	4	na	na

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

4	P_8x8ref0	4	na	na

The following semantics are assigned to the macroblock types in Table 7-11:

P_L0_16x16, P_L0_L0_16x8, P_L0_L0_8x16, and P_8x8: the macroblock is predicted from a past picture with luma block sizes 16x16, 16x8, 8x16, and 8x8, respectively, and the associated chroma blocks. For the macroblock types NxM=16x16, 16x8, and 8x16, a moti on vector difference is decoded for each NxM luma block and the associated chroma blocks. If N=M=8, for each sub-macroblock an additional syntax element is decoded which indicates in which type the corresponding sub-macroblock is decoded (see subclause 7.4.5.2). Depending on N, M and the sub-macroblock types there may be 1 to 16 sets of motion vector difference for the for a macroblock.

P_8x8ref0: same as P_8x8 but ref_idx_l0 is not present in the bitstream and set equal to 0 f or all sub-macroblocks. P_8x8ref0 is only present when entropy_coding_mode is equal to 0.

Pred_L0 specifies the macroblock (partition) prediction mode and indicates that the Inter prediction process is invoked using list 0 prediction. Pred_L0 is an Inter m acroblock prediction mode.

Macroblock types which may be collectively referred to as B macroblock types are specified in Table 7-12.

The macroblock types for B slices are specified in Table 7-12 and Table 7-9. The mb_type values 0 to 22 are specified in Table 7-12 and the mb_type values 23 to 47 are specified in Table 7-9, indexed by subtracting 23 from the value of mb_type.

Table 7-12 – Macroblock type values 0 to 22 for B slices

mb_type	Name of mb_type	num_mb_part (mb_type)	mb_part_pred_mode (mb_type, 0)	mb_part_pred_mode (mb_type, 1)
0	B_Direct_16x16	1	Direct	na
1	B_L0_16x16	1	Pred_L0	na
2	B_L1_16x16	1	Pred_L1	na
3	B_Bi_16x16	1	BiPred	na
4	B_L0_L0_16x8	2	Pred_L0	Pred_L0
5	B_L0_L0_8x16	2	Pred_L0	Pred_L0
6	B_L1_L1_16x8	2	Pred_L1	Pred_L1
7	B_L1_L1_8x16	2	Pred_L1	Pred_L1
8	B_L0_L1_16x8	2	Pred_L0	Pred_L1
9	B_L0_L1_8x16	2	Pred_L0	Pred_L1
10	B_L1_L0_16x8	2	Pred_L1	Pred_L0
11	B_L1_L0_8x16	2	Pred_L1	Pred_L0
12	B_L0_Bi_16x8	2	Pred_L0	BiPred
13	B_L0_Bi_8x16	2	Pred_L0	BiPred
14	B_L1_Bi_16x8	2	Pred_L1	BiPred
15	B_L1_Bi_8x16	2	Pred_L1	BiPred
16	B_Bi_L0_16x8	2	BiPred	Pred_L0
17	B_Bi_L0_8x16	2	BiPred	Pred_L0
18	B_Bi_L1_16x8	2	BiPred	Pred_L1

20	B_Bi_Bi_16x8	2	BiPred	BiPred

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

21	B_Bi_Bi_8x16	2	BiPred	BiPred
22	B_8x8	4	na	na

The macroblock types in Table 7-12 are collectively referred to a B macroblock types.

The following semantics are assigned to the macroblock types in Table 7-12:

B_Direct_16x16 type: no motion vector data or reference picture index is transmitted.

B_x_y_NxM, x,y=L0,L1,Bi: each N xM luma block and the associated chroma blocks of a macroblock are predicted by using decoded motion vector differences and reference pictures. As shown in Table 7-12, for 16x16 macroblock partitions, 3 different macroblock types that differ in their prediction modes can be decoded for a macroblock. For the 16x8 and 8x16 macroblock partitions, 18 different combinations of prediction modes can be decoded for a macroblock. If a macroblock is coded as B_8x8 macroblock type, an addition al codeword for each 8x8 macroblock partition, referred to as sub-macroblock, indicates the decomposition of the sub -macroblock (see Table 7-19).

B_8x8: the macroblock is partitioned into sub -macroblocks. The coding [Ed.Note: Meani ng?] of eacb sub-macroblock is specified using sub_mb_type.

Direct specifies the macroblock (partition) prediction mode and indicates that no data are present in the bitstream for the prediction process. The variables for the Inter prediction process are d erived may be using list 0 or list 1 prediction. Direct is an Inter macroblock prediction mode.

Pred_L1 specifies the macroblock (partition) prediction mode and indicates that the Inter prediction process is invoked using list 1 prediction. Pred_L1 is an I nter macroblock prediction mode.

BiPred specifies the macroblock (partition) prediction mode and indicates that the Inter prediction process is invoked using list 0 and list 1 prediction. BiPred is an Inter macroblock prediction mode.

pcm_alignment_bit is a bit equal to 1.

pcm_byte is a sample value. pcm_byte shall not be equal to 0. The first 256 pcm_byte values represent luma sample values in raster scan order within the macroblock. The next 64 pcm_byte values represent Cb sample values in raster scan order within the macroblock. The last 64 pcm_byte values represent Cr sample values in raster scan order within the macroblock.

coded_block_pattern specifies which of the 8x8 blocks - luma and chroma - contain transform coefficients. An indication that an 8x8 block contains coefficients means that one or more of its four 4x4 blocks contains coefficients'. The four least significant bits of coded_block_pattern contain information on which of four 8x8 luma blocks in the macroblock contains nonzero coeffici ents. These four bits are denoted as CodedBlockPatternLuma. The inverse scan of 8x8 blocks in the luma component of the macroblock is an inverse raster scan. A bit equal to zero in position n of coded_block_pattern (binary representation) indicates that the corresponding 8x8 block has no coefficients and a bit equal to 1 indicates that the 8x8 block has one or more non -zero coefficients.

The two most significant bits of coded_block_pattern contain information on the chroma blocks. The 3 possibilities ar e specified in Table 7-13.

Table 7-13 – Specification of CodedBlockPatternChroma values

CodedBlockPatternChroma	Description
0	All chroma coefficients are 0.
1	One or more chroma DC coefficients are non-zero. All chroma AC coefficients are 0.
2	Zero or more chroma DC coefficients are non-zero. One or more chroma AC coefficients are non-zero.

The value of coded_block_pattern for a macroblock is given by

coded_block_pattern = CodedBlo ckPatternLuma + 16 × CodedBlockPatternChroma

[Ed.Note: need for equations for CodedBlockPatternLuma and CodedBlockPatternChroma as there is a "missing link" between bits and unsigned integer value through unsigned integer binary representation]

Table 7-14 shows the coded_block_pattern for macroblock prediction modes Intra_4x4 and Inter.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

47	41	41

mb_qp_delta the value of QP_Y can be changed in the macroblock layer by the parameter mb_qp_delta. The mb_qp_delta parameter is present only for non -skipped macroblocks, as specified by:

- If coded_block_pattern indicates that there are nonzero transform coefficients in the macroblock or
- If the macroblock is 16x16 based intra coded

The decoded value of mb_qp_delta shall be in the range from -26 to +25, inclusive. This specifies the value of QP_Y in the range [0..51], as given by

$$QP_Y = (QP_Y + mb\_qp\_delta + 52) \% 52 \quad (7\text{-}12)$$

7.4.5.1 Macroblock prediction semantics

All samples of the macroblock are predicted. The prediction modes are derived using the following syntax elements.

prev_intra4x4_pred_mode_flag[4x4LumaBlkIdx] and **rem_intra4x4_pred_mode**[4x4LumaBlkIdx] indicate the Intra_4x4 prediction of the 4x4 luma block with index 4x4LumaBlkIdx.

intra_chroma_pred_mode indicates the type of spatial prediction used for chroma whenever any part of t he luma macroblock is intra coded. This is shown in Table 7-15.

Table 7-15 – Relationship between intra_chroma_pred_mode and spatial prediction modes

intra_chroma_pred_mode	[Ed.Note Intra_16x16] Prediction Mode
0	DC
1	Horizontal
2	Vertical
3	Plane

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

ref_idx_l0, when present, indicates the reference picture to be used for prediction. The value of ref_idx_l0 shall be in the range of 0 to num_ref_idx_l0_active_minus1, inclusive. [Ed.N ote: relationship with weighted prediction may not be fully worked out yet.]

If field_pic_flag indicates that the current picture is a frame picture, then the reference picture is a previous frame in list 0 that was either indicated as a single frame pictu re or a frame that was indicated as two field pictures and has been reconstructed as a frame. [Ed.Note: Indexing into an ordered list is simple and does not need the following tables.] For reference frame indexing, Table 7-16 illustrates the reference frame:

Table 7-16 – Reference frame indicated by ref_idx_10 for frame picture (informative)

ref_idx_10	Reference frame
0	The first frame in list 0
1	The second frame in list 0
2	The third frame in list 0
...	...

If field_pic_flag indicates that the current picture is a field picture, then the reference picture is a previous field in list 0 that was either coded as part of a frame-structured picture or coded as a field-structured picture. [Ed. Note: What about field macroblocks in a frame picture in MB-AFF?] For reference field indexing, Table 7-17 illustrates the reference field:

Table 7-17 – Reference field indicated by ref_idx_10 for field picture (informative)

ref_idx_10	Reference field
0	The first field in list 0
1	The second field in list 0
2	The third field in list 0
...	...

If num_ref_idx_l0_active_minus1 is equal to 0, ref_idx_l0 is not present. If num_ref_i dx_l0_active_minus1 is equal to 1, only a single encoded bit is used to represent ref_idx_l0. If num_ref_idx_l0_active_minus1 is greater than 1, the value of ref_idx_l0 is represented by a decoded index.

ref_idx_l1 has the same semantics as ref_idx_l0, ex cept that it is applied to the reference index list 1. The value of ref_idx_l1 shall be in the range of 0 to num_ref_idx_l1_active_minus1, inclusive. [Ed.Note: relationship with weighted prediction may not be fully worked out yet.]

mvd_l0 indicates the difference between a vector component to be used and its prediction. The horizontal motion vector component difference is decoded first in decoding order. If so indicated by mb_type, vector data for 1 to 16 blocks are transmitted. For the coded motion vector, a prediction is formed for the horizontal and vertical components of the motion vector. The prediction for the motion vector component is added to the motion vector component difference mvd_l0 to form the motion vector component used in inter prediction. The range of mvd_l0 is constrained by constraints on decoded motion vector values specified in Annex A.

mvd_l1 has the same semantics as mvd_l0, except that it is applied to the reference index list 1. The range of mvd_l1 is constrained by constraints on motion vector values specified in Annex A.

7.4.5.2 Sub-macroblock prediction semantics

sub_mb_type indicates the sub-macroblock types.

Tables and semantics are specified for the various sub -macroblock types for I, SI, P, SP, and B slices. Each table presents the value of sub_mb_type, the name of sub_mb_type, the number of sub -macroblock partitions used (given by the num_sub_mb_part(sub_mb_type) function) and the prediction mode of the sub-macroblock (given by the sub_mb_part_pred_mode(sub_mb_type) function). In the text, the value of sub_mb_type may be referred to in the text by "sub-macroblock type". In the text, the value of sub_mb_part_pred mode may be referred to by "[Ed.Note: sub -macroblock] prediction mode".

The sub-macroblock types for P macroblock type s are specified in Table 7-18.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 7-18 – Sub-macroblock types in P macroblocks

sub_mb_type	Name of sub_mb_type	num_sub_mb_part (sub_mb_type)	sub_mb_pred_mode (sub_mb_type)
0	P_L0_8x8	1	Pred_L0
1	P_L0_8x4	2	Pred_L0
2	P_L0_4x8	2	Pred_L0
3	P_L0_4x4	4	Pred_L0

The following semantics are assigned to the sub -macroblock types in Table 7-18:

P_L0_ XxY, X,Y=4,8 the corresponding partition of the sub -macroblock is predicted from a past picture with luma block size 8x8, 8x4, 4x8, and 4x4, respectively, and the associated chroma blocks. A motion vector is transmitted for each NxM=8x8, 8x4, 4x8, and 4x4 block. Depending on N and M, up to 4 motion vector component differences may be decoded for a sub-macroblock, and thus up to 16 motion vector component differences maybe dedoced for a macroblock.

The sub-macroblock types for B macroblock types are specified in Table 7-19.

Table 7-19 – Sub-macroblock types in B macroblocks

sub_mb_type	Name of sub_mb_type	num_sub_mb_part (sub_mb_type)	sub_mb_pred_mode (sub_mb_type)
0	B_Direct_8x8	1	Direct
1	B_L0_8x8	1	Pred_L0
2	B_L1_8x8	1	Pred_L1
3	B_Bi_8x8	1	BiPred
4	B_L0_8x4	2	Pred_L0
5	B_L0_4x8	2	Pred_L0
6	B_L1_8x4	2	Pred_L1
7	B_L1_4x8	2	Pred_L1
8	B_Bi_8x4	2	BiPred
9	B_Bi_4x8	2	BiPred
10	B_L0_4x4	4	Pred_L0
11	B_L1_4x4	4	Pred_L1
12	B_Bi_4x4	4	BiPred

The following semantics are assigned to the sub-macroblock types in Table 7-19:

Pred_L0_XxY, X,Y=4,8, have the same semantics as in Table 7-18.

B_Z_X_Y, Z=L1,Bi, X,Y=4,8 [Ed.Note: I need input here !!!]

7.4.5.3 Residual data semantics

When entropy_coding_mo de is equal to 0, residual_block is equal to residual_block_cavlc which is used for parsing the syntax elements for transform levels.

When entropy_coding_mode is equal to 1, residual_block is equal to residual_block_cabac which is used for parsing the syntax elements for transform levels.

Depending on mb_type, luma or chroma, residual_block(Level, X) is invoked with the arguments Level and X. Level is an array containing the X transform levels that are parsed.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

When mb_part_pred_mode(mb_type, 0) is equal to Intra_16x16, the transform levels are parsed into two arrays: Intra16x16DCLevel and Intra16x16ACLevel. Intra16x16DCLevel contains the 16 transform levels of the DC transform levels for each 4x4 luma block. Intra16x16ACLevel[i8x8 * 4 + i4x4] contains for each 4x4 luma block indexed by i8x8 * 4 + i4x4 the 15 AC coefficients.

When mb_part_pred_mode(mb_type, 0) is equal not to Intra_16x16, the 16 transform levels for each 4x4 luma block indexed by i8x8 * 4 + i4x4 are contained in LumaResidualLevel[i8x8 * 4 + i4x4].

The 4 DC coefficients of all 4x4 chroma blocks per chroma component are parsed into ChromaDCLevel[CbCrIdx] with CbCrIdx indicating the chroma component.

The 15 AC coefficients for each 4x4 chroma coefficient which is indexed by i4x4 for ea ch chroma block and CbCrIdx for each chroma component are contained in ChromaACLevel[CbCrIdx][i4x4].

7.4.5.3.1 Residual 4x4 block CAVLC semantics

coeff_token indicates the total number of non-zero coefficients and the number of trailing one coefficients in a coefficient scan. A trailing one coefficient is one of up to three consecutive non -zero coefficients at the end of the zig-zag scan of non-zero coefficients that have a level with an absolute value of 1. The range of coeff_token is specified in subclause 9.2.

trailing_ones_sign[i **]** indicates the sign of the $(i+1)^{th}$ trailing one coefficient in a zig-zag scan. A trailing_ones_sign equal to 0 indicates that the level of the corresponding transform coefficient is +1. A trailing_ones_si gn equal to 1 indicates that the level of the corresponding transform coefficient is -1.

coeff_level[i **]** indicates the level and sign of the $(i+1)^{th}$ non-zero transform coefficient. The range of coeff_level is specified in subclause 9.2.

total_zeros indicates the total number of zero -valued coefficients that are located before the position of the last non -zero coefficient in a zig-zag or field scan of coefficients. The range of total_zeros is specified in subclause 9.2.

run_before[i **]** indicates the number of consecutive coefficient scanning positions with zero -valued coefficients before the $(i+1)^{th}$ non-zero coefficient in the zig-zag scan of coefficients. range of run_before[i] is specified in subcla use 9.2.

Level contains MaxNumCoeff transform levels for the current array.

7.4.5.3.2 Residual 4x4 block CABAC semantics

coded_block_flag indicates whether the block contains non -zero transform coefficients. If coded_block_flag is equal t o 0, the block contains no non -zero transform coefficients. If coded_block_flag is equal to 1, the block contains at least one non-zero transform coefficient.

significant_coeff_flag[i **]** indicates whether the transform coefficient at scanning position i is non-zero. If significant_coeff_flag[i] is equal to 0, the transform coefficient at scanning position i is equal to zero; if significant_coeff_flag[i] is equal to 1, the transform coefficient at scanning position i has a non -zero value.

last_significant_coeff_flag[i **]** indicates for the scanning position i whether there are non -zero transform coefficients for subsequent scanning positions i+1 to max_numcoeff -1. If all following transform coefficients (in scanning order) of the block have value equal to zero last_significant_coeff_flag[i] is equal to 1. If last_significant_coeff_flag[i] is equal to 0, there are further non-zero transform coefficients along the scanning path.

coeff_absolute_value_minus1 is the absolute value of the transform coefficien t minus 1. The value of coeff_absolute_value_minus1 shall be in the range of 0 to ???. [Ed.Note: 255*16 or smaller. Anything that obeys the constraints expressed in the inverse tranform decoding process to work is OK. No further contraint needs to be specified.]

coeff_sign_flag indicates the sign of the transform coefficient. If coeff_sign_flag is equal to 0, the corresponding transform coefficient has a positive value. If coeff_sign_flag is equal to 1, the corresponding transform coefficient has a negative value.

Level contains MaxNumCoeff transform levels for the current array.

8 Decoding process

Input to this process are syntax elements or variables from clause 7.

Output of this process are decoded samples.

This clause describes the decoding process given syntax elements or variables from clause 7.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

The decoding process is defined such that all decoders shall produce numerically identical results. Any decoding process that produces identical results to the process described here conforms to the decoding process requirements of this Recommendation | International Standard.

Subclause 8.1 describes the decoding process for NAL units with nal_unit_type equal to 1 through 10. [Ed.Note: for SEI and VUI only syntax and semantics, no decoding process]

Subclause 8.2 describes the decoding process for NAL units with nal_unit_type equal to 1 through 5.

Subclause 8.3 describes the decoding process for slice data in NAL units with nal_unit_type equal to 1, 2, and 5.

Subclause 8.4 describes the decoding process for slice data in NAL units with nal_unit_type equal to 1 and 2.

Subclause 8.5 describes the decoding process for slice data in NAL units with nal_unit_type equal to 1, 3, 4 and 5.

Subclause 8.6 describes the decoding process for slice data in NAL units with nal_unit_type equal to 1, 3, 4 and 5.

Subclause 8.7 describes the decoding process for NAL units with nal_unit_type equal to 1 through 5.

[Ed.Note: specify necessary order.]

8.1 NAL unit decoding process

Input to this process are NAL units.

Output of this process is ??? [Ed.Note: specify output of this process]

[Ed. Note: Waiting for input.]

8.2 Slice decoding process

8.2.1 Detection process of coded picture boundaries

Input to this process are the slice header of the slice to be decoded, nal_ref_idc of the NAL unit containing the slice to be decoded, the picture order count for the slice to be decoded, the slice header of the previously decoded slice, the nal_ref_idc of the NAL unit that contained the previously decoded slice, and the picture order count of the previously decoded slice.

Output of this process is an indication if decoding of a new picture is started from the slice to be decoded.

Decoding of a new picture is started from the slice to be decoded, herein called the current slice, if the slice is not a redundant slice and if one of the following conditions is true:

1. The frame number of the current slice is different from the frame number of the previously decoded slice.
2. The field_pic_flag of the previously decoded slice is different from the field_pic_flag of the current slice.
3. The bottom_field_flag exists in both the previously decoded slice and the current slice but is not equal in the two slices, or the bottom_field_flag exists in only one of the previously decoded slice and the current slice.
4. The nal_ref_idc of the previously decoded slice is different from the nal_ref_idc of the current slice, and either nal_ref_idc is equal to 0.
5. The frame number of the current slice is the same as the frame number in the previously decoded slice, and either delta_pic_order_cnt[0] is different from the delta_pic_order_cnt[0] in the previously decoded slice, or delta_pic_order_cnt[1] is different from the delta_pic_order_cnt[1] in the previously decoded slice
6. The frame number of the current slice is the same as the previously de coded slice, and pic_order_cnt_type is less than 2, and the calculated picture order counts are different for the two slices.

8.2.2 Decoding process for picture order count

Inputs to this process are pic_order_cnt_type, pic_order_present_flag, frame_num, field_pic_flag, bottom_field_flag, num_ref_frames_in_pic_order_cnt_cycle, delta_pic_order_cnt[], offset_for_non_ref_pic, offset_for_ref_frame[], and offset_for_top_to_bottom_field.

Outputs of this process are TopPicOrderCnt, BottomPicOrderCnt, FramePicOrderCnt, P icOrder, and DiffPicOrderCount.

Each field is associated with a picture order count, called TopPicOrderCnt for a top field and BottomPicOrderCnt for a bottom field, which indicates the output order of each field relative to the first output field of last 1 DR picture in decoding order. Each coded frame is associated with two picture order counts, called TopPicOrderCnt and BottomPicOrderCnt, which respectively indicate the output orders of its top field and bottom field relative to first output

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

field of the last IDR picture in decoding order. In addition, for a frame the Frame PicOrderCnt is defined to be the smaller of TopPicOrderCnt and BottomPicOrderCnt for the fields in the frame; if only one of TopPicOrderCnt and BottomPicOrderCnt is defined in the frame, then that value is the FramePicOrderCnt. TopPicOrderCnt and BottomPicOrderCnt are defined for every field in the decoded picture buffer.

Picture order counts are used to determine default index orderings for reference pictures in B slices (subclause 8.2.6.3.3 and 8.2.6.3.4), to represent picture order differences between frames and fields for vector scaling in motion vector prediction (subclause 8.4.1.2.2) and for implicit mode weighted prediction in B slices (subclause 0 [Ed. Note: Bad cross-reference]), and to determine when successive slices belong to different pictures (subclause 8.2.1).

The bitstream shall not contain data that results in a FramePicOrderCnt not equal to 0 for an IDR picture. Thus one of TopPicOrderCnt and BottomPicOrderCnt must be 0 for the fields of a frame whose FramePicOrderCnt is equal to zero. The FramePicOrderCnt, TopPicOrderCnt, and Bottom PicOrderCnt of each reference frame shall be stored as long as the frame stays in the decoded picture buffer.

The signed picture order difference from X to Y, DiffPicOrderCount(X, Y), between two fields or frames is defined as follows:

```
if (Z is a frame) PicOrder(Z) = FramePicOrderCnt of frame Z
else if (Z is a top field) PicOrder(Z) = TopPicOrderCnt of frame containing Z          (8-1)
else if (Z is a bottom field) PicOrder(Z) = BottomPicOrderCnt of frame containi ng Z
```

```
DiffPicOrderCount(X,Y) = PicOrder(X) - PicOrder(Y)                                    (8-2)
```

The bitstream shall not contain data that results in values of DiffPicOrderCount(X,Y) used in the decoding process that exceed the range from -2^{15} to $2^{15}-1$, inclusive.

If X is the current picture and Y and Z are reference pictures, Y and Z are considered to be in the same temporal direction from X if both DiffPicOrderCount(X,Y) and DiffPicOrderCount(X,Z) are positive or both are negative.

There are three modes for coding picture order counts. [Ed. Note: Modes or types? See the drafting guide. There seems to be a mix of these terms (e.g., see heading of next subclause).] The first two modes, mode 0 and mode 1, use values in the sequence parameter set to predict the picture order count for each field and encode only the difference between the predicted value and the true picture order count in the slice header. Mode 0 predicts the value of the picture order count from the picture order count of the most recently decoded reference picture. Mode 1 predicts the value of the picture order count from the picture order count of the most recent IDR picture. Thus both modes 0 and 1 are resilient to the loss of non-reference pictures. In addition, mode 1 is re silient to the loss of non-IDR reference pictures. In the third mode, mode 2, no picture order count information is present . Mode 2 shall not be used in a sequence that contains B slices and shall not be used in a sequence that contains two ore more cons ecutive non-reference frames in decoding order.

When field_pic_flag is equal to 0 and pic_order_present_flag is equal to 0, delta_pic_order_cnt[0] is coded but delta_pic_order_cnt[1] is not coded and is inferred to be equal to 0. If field_pic_flag is equal to 0 and pic_order_present_flag is equal to 1, then both delta_pic_order_cnt[0] and delta_pic_order_cnt[1] are coded; delta_pic_order_cnt[0] is used to calculate TopPicOrderCnt, and delta_pic_order_cnt[1] is used to calculate BottomPicOrderCnt.

The bitstream shall not contain data that results in values of Frame PicOrderCnt, TopPicOrderCnt, and BottomPicOrderCnt, FrameNumOffset, AbsFrameNum, or PicOrderCntCycleCnt used in the decoding process as specified in subclauses 8.2.2.1 and 8.2.2.2 that exceed the range of values from 0 to $2^{32}-1$, inclusive.

8.2.2.1 Decoding process for picture order count type 0

Inputs to this process are pic_order_cnt_type, pic_order_present_flag, field_pic_flag, bottom_field_flag, delta_pic_order_cnt[], offset_for_non_ref_pic, offset_for_ref_frame[].

Outputs of this process are TopPicOrderCnt, BottomPicOrderCnt, FramePicOrderCnt.

If pic_order_cnt_type is 0, the calculations in this subclause shall be used for TopPicOrderCnt and BottomPicOrderCnt.

If the pic_order_present_flag is equal to 0 or field_pic_flag is equal to 1 , delta_pic_order_cnt[1] is not coded and is set to zero in the following equations.

For an IDR picture, the values TopPreviousPicOrderCnt and BottomPrevio usPicOrderCnt are defined to be 0 in the equations below. Otherwise, TopPreviousPicOrderCnt is defined to be equal to the TopPicOrderCnt of the top field of the most recently decoded reference frame or field, and BottomPicOrderCnt is defined to be equal t o the BottomPicOrderCnt of the bottom field of the most recently decoded reference frame or field.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

If the picture is a non-reference picture, then OffsetPicOrderCnt is equal to offset_for_non_ref_pic, and if it is a reference picture then OffsetPicOrderCnt is equal to offset_for_ref_frame[0].

For a frame picture (i.e., when field_pic_flag is equal to 0), TopPicOrderCnt and BottomPicOrderCnt are calculated according to Equations 8-3 and 8-4.

$$\text{TopPicOrderCnt} = \text{TopPreviousPicOrderCnt} + \text{OffsetPicOrderCnt} + \text{delta\_pic\_order\_cnt}[\,0\,] \quad (8\text{-}3)$$

$$\text{BottomPicOrderCnt} = \text{TopPicOrderCnt} + \text{offset\_for\_top\_to\_bottom\_field} + \text{delta\_pic\_order\_cnt}[\,1\,] \quad (8\text{-}4)$$

For a top field picture (i.e., when field_pic_flag is equal to 1 and bottom_field_flag is equal to 0), TopPicOrderCnt is calculated according to Equation 8-3, and BottomPicOrderCnt is not changed (since, if present, it is coded in a different field picture).

For a bottom field picture (i.e., when field_pic_flag is equal to 1 and bottom_field_flag is equal to 1), BottomPicOrderCnt is calculated according to Equation 8-5, and TopPicOrderCnt is not changed (since, if present, it is coded in a different field picture).

$$\text{BottomPicOrderCnt} = \text{BottomPreviousPicOrderCnt} + \text{OffsetPicOrderCnt} + \text{delta\_pic\_order\_cnt}[\,0\,] \quad (8\text{-}5)$$

8.2.2.2 Decoding process for picture order count type 1

Input to this process are pic_order_cnt_type, pic_order_present_flag, frame_num, field_pic_flag, bottom_field_flag, num_ref_frames_in_pic_order_cnt_cycle, delta_pic_order_cnt[], offset_for _non_ref_pic, offset_for_ref_frame[], offset_for_top_to_bottom_field.

Output of this process are TopPicOrderCnt, BottomPicOrderCnt, FramePicOrderCnt.

If pic_order_cnt_type is 1, the calculations in this subclause shall be used for TopPicOrderCnt and Bottom PicOrderCnt.

TopPicOrderCnt and BottomPicOrderCnt are calculated as follows, wherePreviousFrameNum is the frame_num of the previous picture in decoding order.

First, the FrameNumOffset is updated according to

```
if ( picture is an IDR picture )
    FrameNumOffset = 0
else if (frame_num < PreviousFrameNum)                    (8-6)
    FrameNumOffset = FrameNumOffset + MaxFrameNum
```

Second, the AbsFrameNum (the frame number relative to the last IDR picture) is calculated according to:

```
if( num_ref_frames_in_pic_order_cnt_cycle != 0 )
  AbsFrameNum = FrameNumOffset + frame_num
else                                                      (8-7)
  AbsFrameNum = 0
if( nal_ref_idc == 0 && AbsFrameNum > 0)
  AbsFrameNum = AbsFrameNum – 1
```

Third, if AbsFrameNum > 0, the PicOrderCntCycleCnt and FrameNumInPicOrderCntCycle are calculated according to:

```
if(AbsFrameNum > 0) {
  PicOrderCntCycleCnt =
       (AbsFrameNum – 1) / num_ref_frames_in_pic_order_cnt_cycle   (8-8)
  FrameNumInPicOrderCntCycle =
      (AbsFrameNum – 1) % num_ref_frames_in_pic_order_cnt_cycle
}
```

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

If the pic_order_present_flag is equal to 0 or field_pic_flag is equal to 1, delta_pic_order_cnt[1] is not coded and is inferred to be equal to 0 in the following equations.

In the following, the ExpectedDeltaPerPicOrderCntCycle is the sum of offset_for_ref_frame values (num_ref_frames_in_pic_order_cnt_cycle of these were coded in the sequence header).

Finally, the TopPicOrderCnt and /or BottomPicOrderCnt of th e picture are computed using the algorithm expressed as:

```
if( AbsFrameNum > 0 ){
        ExpectedPicOrderCnt =
            PicOrderCntCycleCnt * ExpectedDeltaPerPicOrderCntCycle
        for( i = 0; i <= FrameNumInPicOrderCntCycle; i++ )
            ExpectedPicOrderCnt = ExpectedPicOrderCnt + offset_for_ref_frame[ i ]
} else
        ExpectedPicOrderCnt = 0
if( nal_ref_idc == 0 )                                                    (8-9)
        ExpectedPicOrderCnt = ExpectedPicOrderCnt + offset_for_non_ref_pic
if( field_pic == 0 ) {
        TopPicOrderCnt = ExpectedPicOrderCnt + delta_pic_order_cnt[ 0 ]
        BottomPicOrderCnt = TopPicOrderCnt + offset_for_top_to_bottom_field
                    + delta_pic_order_cnt[ 1 ]
}else if ( bottom_field_flag == 0 )
        TopPicOrderCnt = ExpectedPicOrderCnt + delta_pic_order_cnt[ 0 ]
else if ( bottom_field_flag == 1 )
        BottomPicOrderCnt = ExpectedPicOrderCnt + offset_for_top_to_bottom_field
                    + delta_pic_order_cnt[ 0 ]
```

8.2.2.3 Examples for the decoding process for picture order count types 0 and 1 (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Type 0 can code the picture order counts quite efficiently when the encoder is reordering the pictures from display order to coding order in a regular pattern.

For a first example, assume there is a constant frame rate and frames are coded in display order as IPPPPPP... where the I frame is an IDR picture and all the P frames are reference pictures. Also assume that frames are not interlaced, so that TopPicOrderCnt and BottomPicOrderC nt are equal for each frame. In this case, mode 0 can be set up with offset_for_ref_frame[0] = 1 and and pic_order_present_flag = 0. In this case, the frame _num will increase by 1 with each picture, and OffsetPicOrderCnt will always correctly predict t he picture order count, so that delta_pic_order_cnt[0] will be zero for each frame. If delta_pic_order_always_zero_flag is set to 1, then no bits need be sent for delta_pic_order_cnt[0] or delta_pic_order_cnt[1]. The Table 8-1 illustrates how this works for the first few frames.

Table 8-1 – First example for picture order count type 0 [Ed. Note: Editorial issue with first column – Do we have frame types? What purpose does that column if any?]

Frame Type	frame_num	FramePicOrderCnt	TopPicOrderCnt	BottomPicOrderCnt	delta_pic_order_cnt[0]	delta_pic_order_cnt[1]
I	0	0	0	0	0 not sent	0 not sent
P	1	1	1	1	0 not sent	0 not sent
P	2	2	2	2	0 not sent	0 not sent
P	3	3	3	3	0 not sent	0 not sent
P	4	4	4	4	0 not sent	0 not sent
P	5	5	5	5	0 not sent	0 not sent
...	...	...	...	...	...	...

For a second example, again suppose that there is a constant frame rate with each frame needing distinct values for TopPicOrderCnt and BottomPicOrderCnt. Supp ose the frames are to be reordered from the display order IBBPBBP... to coding order IPBBPBB... with the first I frame an IDR frame, another I non -IDR frame every 15 frames, all P frames as references, and all B frames as non-references. In this case, mode 0 can be set up with offset_for_ref_frame[0] = 6, offset_for_non_ref_pic = -4, offset_for_top_to_bottom_field = 1, and pic_order_present_flag = 0. In this case,

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

OffsetPicOrderCnt will always correctly predict the picture order counts for the P frames an d half of the B frames. Table 8-2 illustrates how this works for the first few frames.

Table 8-2 – Second example for picture order count type 0

Frame Type	frame_num	FramePicOrderCnt	TopPicOrderCnt	BottomPicOrderCnt	delta_pic_order_cnt[0]	delta_pic_order_cnt[1]
I	0	0	0	1	0	0 not sent
P	1	6	6	7	0	0 not sent
B	2	2	2	3	0	0 not sent
B	2	4	4	5	2	0 not sent
P	2	12	12	13	0	0 not sent
B	3	8	8	9	0	0 not sent
B	3	10	10	11	2	0 not sent
...	...	...	...	...	...	...

Mode 0 can also code picture order counts when an encoder is reordering the pictures from display order to coding order in an irregular pattern. [Ed. Note: Consistency – Is this mode 0 or type 0?]

For an example of this, suppose tha t in the previous example some of the frames have duration 1.5 times the duration of the rest of the frames, and suppose that of the first seven frames the second B frame is the only longer duration frame. We can use the same setup as above except that pi c_order_present_flag = 1. Table 8-3 illustrates how this works for the first seven frames.

Table 8-3 – Third example for picture order count type 0 [Ed. Note: Consistency – Should this have a frame_num column?]

Frame Type	FramePicOrderCnt	TopPicOrderCnt	BottomPicOrderCnt	delta_pic_order_cnt[0]	delta_pic_order_cnt[1]
I	0	0	1	0	0
P	7	8	7	2	-2
B	2	2	3	0	0
B	4	4	5	2	0
P	13	14	13	0	-2
B	9	10	9	0	-2
B	11	12	11	2	-2
...	...	...	...	...	...

For an example of mode 1, suppose that there is a piecewise constant frame rate with a gap of one frame to be used perhaps by a systems layer for a frame repeat. Each frame needs distinct values for TopPicOrderCnt and BottomPicOrderCnt. Suppose the frames are to be reordered from the display order IBBPBBP... to coding order IPBBPBB... with the first I frame an IDR frame, and other I non -IDR frames every 15 frames directly following the one - frame gap, all P frames as references, and all B frames as non -references. In this case, mode 1 can be set up with num_ref_frames_in_pic_order_cnt_cycle = 5, offset_for_ref_frame = {6 ,6,6,6,8}, offset_for_non_ref_pic = -4, offset_for_top_to_bottom_field = 1, and pic_order_present_flag = 0 (i.e. Delta_pic_order_cnt[1] is always 0). Table 8-4 illustrates how this works for the first few frames. The mode 1 case is resilient to loss of non -IDR reference frames, while mode 0 is not. Both modes are resilient to loss of non -reference frames.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table 8-4 – First example for picture order count type 1

Frame Type	frame_num	FramePicOrderCnt	TopPicOrderCnt	BottomPicOrderCnt	ExpectedPicOrderCnt	Delta_pic_order_cnt[0]
I	0	0	0	1	0	0
P	1	6	6	7	6	0
B	2	2	2	3	2	0
B	2	4	4	5	2	2
P	2	12	12	13	12	0
B	3	8	8	9	8	0

B	6	28	28	28	28	0
...	...	...	...	...	...	...

For a second example of mode 1 where the predictions don't work out as smoothly, suppose that there is a constant frame rate with each frame using the same values for TopPicOrderCnt and BottomPicOrderCnt. Suppose the frames are to be reordered from the display order IBBPBBP... to coding order IPBBPBB... with the first I frame an IDR frame, another I non-IDR frame every 15 frames, all P frames as references, and all B frames as references also. In this case, mode 1 can be set up with num_ref_frames_in_pic_order_cnt_cycle = 3, offset_for_ref_frame = {4, -2, 1}, offset_for_top_to_bottom_field = 0, and pic_order_present_flag = 0 (i.e. Delta_pic_order_cnt[1] is always 0). Table 8-5 illustrates how this works for the first few frames.

Table 8-5 – Second example for picture order count type 1

Frame Type	frame_num	FramePicOrderCnt	TopPicOrderCnt	BottomPicOrderCnt	ExpectedPicOrderCnt	delta_pic_order_cnt[0]
I	0	0	0	0	0	0
P	1	3	3	3	4	-1

8.2.3 Decoding process for redundant slices

Input to this process is a coded slice.

Output of this process is a decoded approximation of the area of the primary picture represented in the redundant slice.

If the redundant_pic_cnt in the slice header of a coded slice is greater than 0, the decoder may discard the coded slice. If some of the samples in the decoded primary picture are incorrect and if the coded redundant slice can be correctly decoded, the decoder should replace the incorrect samples with the corresponding samples of the redundant decoded slice.

8.2.4 Decoding process for macroblock to slice group map

Input to this process are the active picture parameter set and the slice header of the slice to be decoded.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Output of this process is a macroblock to slice group map. [Ed.Note: Define variable ?]

Macroblock to slice group maps of mb_slice_group_map_type 0, 1, 2, and 6 are specified in the semantics of those types.

If decoding of a new picture is started as detected using the process in subclause 8.2.1 if num_slice_groups_minus1 is greater than 0 and if mb_slice_group_map_type is 3, 4, or 5, a macroblock to slice group map is generated. Slice group 0 has a growth order specified in subclauses 8.2.4.1-8.2.4.4. The number of macroblocks in slice group 0 is equal to slice_group_change_cycle × SliceGroupChangeRate. This number of macroblock locations in the specified growth order is allocated for slice group 0. The rest of the macroblocks of the picture are allocated for slice group 1.

8.2.4.1 Specification of allocation order for box-out for decoding process for macroblock to slice group map

Let H denote the number of coded macroblock rows of the picture and W denote the number of coded macroblocks columns of the picture. Macroblock locations are indicated with coordinates (x, y), where the top-left macroblock location of the picture has coordinates (0, 0) and the bottom-right macroblock location has coordinates (W − 1, H − 1). The mapping is created using a AllocationDirection variable that indicates the next macroblock location relative to the current one. AllocationDirection can have four values: (-1, 0), (1, 0), (0, -1) and (0, 1). Furthermore, the left-most and right-most macroblock columns in the mapping and the top-most and bottom-most macroblock rows in the mapping are stored in the variables Left, Right, Top, and Bottom respectively. For the box-out clockwise macroblock to slice group map type, the first macroblock location in the to slice group order is (x, y) = (W/2, H/2) and the initial AllocationDirection is (-1, 0). For the counter-clockwise macroblock to slice group map type, the first macroblock location in the mapping is (x, y) = ((W − 1)/2, (H − 1)/2) and the initial AllocationDirection is (0, 1). At the beginning, Left = Right = x, and Top = Bottom = y. A subsequent macroblock location (x, y) in the mapping is mapped by searching the first row from top to bottom in Table 8-6 for the same value of AllocationDirection and where the given condition is true. Then, the x, y, AllocationDirection, Left, Right, Top and Bottom variables are updated according to the refined macroblock to slice group map type. If Left >= 0, Right < W, Top >= 0 and Bottom < H, the next macroblock location (x, y) in the mapping is mapped as described above. Otherwise, all macroblock locations have been mapped to slice groups.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table 8-6 – Mapping for the box-out macroblock map to slice group type

AllocationDirection	Condition	Box-out clockwise	Box-out counter-clockwise
(-1, 0)	x > Left	x = x – 1	x = x – 1
(-1, 0)	x = = 0	y = Top – 1 Top = Top – 1 AllocationDirection = (1, 0)	y = Bottom + 1 Bottom = Bottom + 1 AllocationDirection = (1, 0)
(-1, 0)	x = = Left	x = x – 1 Left = Left – 1 AllocationDirection = (0, -1)	x = x –1 Left = Left – 1 AllocationDirection = (0, 1)
(1, 0)	x < Right	x = x + 1	x = x + 1
(1, 0)	x = = W – 1	y = Bottom + 1 Bottom = Bottom + 1 AllocationDirection = (-1, 0)	y = Top – 1 Top = Top – 1 AllocationDirection = (-1, 0)
(1, 0)	x = = Right	x = x + 1 Right = Right + 1 AllocationDirection = (0, 1)	x = x + 1 Right = Right + 1 AllocationDirection = (0, -1)
(0, -1)	y > Top	y = y – 1	y = y – 1
(0, -1)	y = = 0	x = Right + 1 Right = Right + 1 AllocationDirection = (0, 1)	x = Left – 1 Left = Left – 1 AllocationDirection = (0, 1)
(0, -1)	y = = Top	y = y – 1 Top = Top –1 AllocationDirection = (1, 0)	y = y –1 Top = Top –1 AllocationDirection = (-1, 0)
(0, 1)	y < Bottom	y = y + 1	y = y + 1
(0, 1)	y = = H – 1	x = Left – 1 Left = Left – 1 AllocationDirection = (0, -1)	x = Right + 1 Right = Right + 1 AllocationDirection = (0, -1)
(0, 1)	y = = Bottom	y = y + 1 Bottom = Bottom + 1 AllocationDirection = (-1 ,0)	y = y + 1 Bottom = Bottom + 1 AllocationDirection = (1 ,0)

8.2.4.2 Specification of the mapping for raster scan for decoding process for macroblock to slice group map

For the raster scan slice group macroblock to slice group map type, the first macroblock in the mapping is the top -left one of the picture, and the mapping follows the raster scan order.

For the reverse raster scan slice group macroblock to slice group map type, the first macroblock in the mapping is the bottom-right one of the picture, and the mapping follows the reverse raster scan order.

8.2.4.3 Specification of allocation order for wipe for decoding process for macroblock to slice group map

For the wipe right slice group macroblock to slice group map type, the first macroblock in the mapping is the top -left one of the picture. The mapping runs from top to bottom. The next macroblock after the b ottom macroblock of a column is the top macroblock of the column to the right of the previous column.

For the wipe left slice group macroblock to slice group map type, the first macroblock in the mapping is the bottom -right one of the picture. The mapping runs from bottom to top. The next macroblock after the top macroblock of a column is the bottom macroblock of the column to the left of the previous column.

8.2.4.4 Specification of allocation order for macroblock level adaptive frame and field coding for decoding process for macroblock to slice group map

[Ed. Note: Very large value in Format → Paragraph → Special → Hanging Indent for the above style.]

Mapping follows **Error! Reference source not found.** [Ed. Note: missing cross-reference]in subclause 6.3, instead of raster scan. [Ed.Note: more text need here !!!]

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

8.2.5 Decoding process for slice slice data partitioning

[Ed.Note: consider to move this to clause 7]

Input to this process are slice data partition A layer RBSP, slice data partition B layer RBSP, and slice data partition C layer RBSP that have the same slice_id and redundant_pic_cnt. Slice data partition B layer RBSP and slice data partition C layer RBSP may not be present.

Output of this process is a coded slice.

When slice slice data partitioning is not used, coded slices start with a slice header and are followed by all the entropy coded symbols of Categories 4, 5, and 6 (see Category column in clause 6.4) of the macroblock data for the macroblocks of the slice.

When slice data partitioning is used, the macroblock data of a slice is partitioned in three partitions contained in 3 or more NAL units [Ed. Note: More? I don't think so.]. Partition A contains a partition A header and all syntax elements of Category 4. Partition B contains a partition B header and all syntax elements of Category 5. Partition C contains a partition C header and all syntax elements of Category 6.

When slice data partitioning is used, each partition is parsed from a separate NAL unit, which may be empty if no symbols of the respective Category exist. The decoder shall process the three partitions of a coded slice equally to a corresponding slice layer RBSP by multiplexing between them depending on the partition assignment in the syntax tables in subclause 7.3. [Ed. Note: be more specific about how the decoder parses categories 5 and 6]

NOTE - Symbols of Category 5 are relevant to decoding of I and SI macroblock types. Symbols of Category 6 are relevant to the decoding of residual data of P and B macroblock types. Category 4 encompasses all other symbol types related to the decoding of macroblocks, and their information is often denoted as header information. The Partition A header contains all the symbols of the slice header, and additionally a slice number that is used to associate the partitions B and C with the partition A. The partition B and C headers contain only the slice number which allows their association with the partition A of the slice

8.2.6 Decoding process for reference picture reordering

Input to this process are the syntax elements for the reference index reordering as specified in subclause 7.3.3.1.

Output of this process are reference index list 0 and reference index list 1.

The decoded picture buffer contains frame stores. Each frame store may contain one field or a pair of complimentary fields. Complimentary fields have the same frame number but opposite parity. A frame store is in use when it contains at least one field. The decoder stores decoded pictures in the decoded picture buffer as indicated by the bitstream. Pictures are stored for prediction of pictures that are subsequent to the current picture in decoding order and/or because their decoded picture output time is later than their decode time. A picture that is stored for prediction, referred to as a reference picture, is marked as "used for reference", and is labelled as a short-term reference picture, in whicb case it is identified by its frame_number and parity. A short-term picture may be assigned a long-term reference frame index, in which case it is identified by its long-term index. A picture that is not stored for prediction is labelled as "unused for prediction". Eacb stored picture is associated with an output time indication. Pictures are removed from the decoded frame buffer when they are marked as "unused for reference" and their output time indication is earlier than or equal to the current time. Short-term reference pictures can remain marked for reference for a finite duration, given by MaxFrameNum. Long term reference pictures can remain marked "used for reference" until the next IDR picture. Memory_management_control_operation commands are used to modify the contents of the buffer.

Reference pictures are addressed through reference indices. A reference index is an index into a list of reference pictures stored in the decoded picture buffer. Wben decoding a P or SP slice there is a single list (list 0) of the reference picture indices. When decoding a B slice there is a second list (list 1) in addition to list 0 that lists the reference pictures in an order that is independent of the ordering of list 0. Prediction of a block in a B slice may be based on pictures from one or both lists.

At the beginning of decoding of each slice, the default index order is created using picture numbers and long-term indices. This default index order is mapped to an index order according to the remapping_of_pic_nums_idc, abs_diff_pic_num_minus1, and long_term_pic_idx fields. The decoder employs these (remapped) indices when referencing a picture for inter prediction on the macroblock layer. The total length of the remapped list is num_ref_idx_l0_active_minus1+1 for list 0 and is num_ref_idx_l1_active_minus1+1 for list 1. A given reference picture may appear at more than one index position in the remapped list 0 or list 1.

8.2.6.1 Decoding process for picture numbers

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Picture numbers are used to index reference pictures within the decoded picture buffer in the decoding process and for management and of the reference pictures for both changing the default indices and for controlling the contents of the

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

decoded picture buffer using memory management control operations. The construction of picture numbers depends upon the picture coding type of the picture being decoded. The picture numbers whe n decoding a coded frame are constructed for each entire short-term reference frame stored in the decoded picture buffer buffer. The picture number of a frame that has frame number FN is given by PN=FN.

The picture numbers when decoding a coded field are constructed for each short-term reference field stored in the decoded picture buffer. The picture number, PN, of a field that has frame number FN is given by PN=2 x FN if the field is a top field, and it is given by PN = 2 x FN+1 if the field is a bottom field.

Long-term picture indices are also used in the decoding process for management and use of the decoded frame buffer. Long-term picture indices are used for assigning a long-term index to a short-term reference picture, marking a long-term reference picture as "unused for reference", and for changing the default indices of pictures that have been assigned a long-term index.

If the current decoded picture is a frame, the long-term picture number, LTPN, of a frame that has long-term frame index LTFI, is given by LTPN = LTFI.

If the current decoded picture is a field, the long-term picture number, LTPN, of a field that has long-term frame index LTFI, is given by LTPN = 2 x LTFI if the field is a top field, and is given by LTPN = 2 x LTFI + 1 if the field is a bottom field. [Ed.Note: rewrite top and bottom field to parities]

If the current picture being decoded is a frame, the parameter MaxPicNum is specified to equal MaxFrameNum, and if the current picture being decoded is a field-structured picture, the parameter MaxPicNum is specified to equal 2 MaxFrameNum.

8.2.6.2 Decoding process for frame numbers

Input to this process are the frame number of the previous reference picture in decoding order and the frame number of the reference picture to be decoded.

Output of this process is decoded picture buffer management operations.

This process is performed when decoding of a new reference picture is started from the slice to be decoded.

Let PrevFrameNum be the frame number of the previous reference picture in decoding order and CurrFrameNum be the frame number of the slice to be decoded.

The decoder shall infer a gap in frame numbers if both of the following conditions are true:

1. The slice to be decoded does not belong to an IDR picture
2. (PrevFrameNum + 1) % MaxFrameNum != CurrFrameNum

If a gap in frame number is inferred, the set of missing frame numbers is calculated. If CurrFrameNum > PrevFrameNum, the set of missing frame numbers ranges from PrevFrameNum + 1 to CurrFrameNum – 1, inclusive. If CurrFrameNum <= PrevFrameNum, the set of missing frame numbers ranges from PrevFrameNum + 1 to MaxFrameNum – 1, inclusive, and from 0 to CurrFrameNum – 1, inclusive. [Ed.Note: this is normative ... what about weird cases ?]

If a gap in frame numbers is inferred and if required_frame _num_update_behaviour_flag equals 1, the decoder shall act as if reference frames corresponding to the set of missing frame numbers had been inserted into the decoded picture buffer using the sliding window reference picture buffering mode. [Ed. Note: Try to come up with more precise wording than "act as if..."] An index for a missing frame number in the decoded picture buffer is called an "invalid" index. The decoder should infer an unintentional picture loss if any "invalid" index is referred to in inter pr ediction or if an "invalid" index is re-mapped. The decoder should not infer an unintentional picture loss if a memory management control operation is applied to a frame having an "invalid" index. [Ed.Note: "invalid" ? change.]

If required_frame_num_update _behaviour_flag is equal to 0, the decoder should infer an unintentional picture loss if a gap in frame numbers is inferred or if a picture not stored in the decoded picture buffer is indicated in an abs_diff_pic_num_minus1 or long_term_pic_idx field.

NOTE - In case of an unintentional picture loss, the decoder may invoke some concealment process. If required_frame_num_update_behaviour_flag is equal to 1, the decoder may replace the picture corresponding to an "invalid" index with an error-concealed one and remove the "invalid" indication. Otherwise, the decoder may insert an error-concealed picture into the decoded picture buffer assuming the sliding window reference picture buffering mode. Concealment may be conducted by copying the previous decoded picture in decoding order into the position of the missing picture. In addition or instead, the decoder may send a forced intra update signal to the encoder by external means (for example, Recommendation H.245) if such external means is available, or the decoder may use external means or back-channel messages (for example, Recommendation H.245) to indicate the loss of pictures to the encoder if such external means is available.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

8.2.6.3 Initialization process for reference indices

This intitialization process is invoked when ... [Ed.Note: specify]

Output of this process is/are ??? [Ed.Note: specify output of this process]

A reference index is a relative index into a list of reference indices to indicate which reference picture out of the decoded picture buffer is used for inter prediction. When decoding a P or SP slice, there is one such list of reference indices, called the reference index list 0. When decoding a B slice, there may be two reference indices used per block each pointing into separate lists of reference indices which are called the reference index list 0 and reference index list 1.

Reference index list 0 and reference index list 1 have default mappings to the pictures numbers in the decoded picture buffer as specified below.

Default index order for P and SP slices

8.2.6.3.1 Initialization process for reference indices for P and SP slices in frames

This intitialization process is invoked when ... [Ed.Note: specify]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When decoding a frame, the default index order for list 0 prediction of P and SP slices in frames is for the short-term reference frames to precede the long-term reference frames in the reference indexing order. Within the set of short-term reference frames, the default order is for the frames to be ordered starting with the most recently-decoded frame and proceeding through to the reference frame in the decoded picture buffer that was decoded first (i.e., in decreasing order of frame_num in the absence of wrapping of the frame_num value). Within the set of long-term frames, the default order is for the frames to be ordered starting with the frame with the smallest long-term index and proceeding to the frame with largest long-term index.

A field that is stored in the decoded picture buffer and is marked as "used for reference" for which the opposite parity field is not stored in the decoded picture buffer or marked as "unused for reference" shall not be included in the default index order, shall not be remapped, and shall not be used for prediction in frames.

For example, assuming no wrap of the frame_num field, if the decoded picture buffer contains three short-term reference frames with frame_num equal to 300, 302, and 303 and two long-term reference frames with long-term frame indices 0 and 3, all being marked as "used for reference", the default index order is:

- default index 0 refers to the short-term reference frame with frame_num 303,
- default index 1 refers to the short-term reference frame with frame_num 302,
- default index 2 refers to the short-term reference frame with frame_num 300,
- default index 3 refers to the long-term reference frame with long-term frame index 0, and
- default index 4 refers to the long-term reference frame with long-term frame index 3.

8.2.6.3.2 Initialization process for reference indices for P and SP slices in fields

This intitialization process is invoked when ... [Ed.Note: specify]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When decoding a field, each field of the reference frames is identified as a separate reference picture with a unique index. Thus fields effectively have at least twice the number of pictures available for referencing.

The default index order for list 0 prediction of P and SP slices in fields is for the short-term reference fields to precede the long-term reference fields in the reference indexing order.

Within the set of short-term reference fields, the default order is calculated by following Step P_list0_1a and Step P_list0_1b.

Step P_list0_1a:

An ordered list of frames is created by ordering the short-term reference frames as in the case of creating the default index order for P and SP slices in frames, except that the current frame shall be included at the start of the list when the current field is the second of a frame and the first field of the frame is stored and marked "used for reference", and except that frames in which only one field is stored and marked "used for reference" are included in the list.

Step P_list0_1b:

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

The default index order is created by selecting reference fields from this ordered list of frames from step P_list0_1a by alternating between fields of the same parity and fields of the opposite parity, starting with fields that have the same parity as the current field. If one field of a reference frame was not decoded or not stored or stored but marked "unused for reference", the index order calculation shall ignore the missing field and instead index the next available stored reference field of the respective parity from the ordered list of frames. When there are no more short-term reference fields of the respective parity in the ordered list of frames, default indices shall be allocated to the not yet indexed fields of the other parity in the order in which they occur in the ordered list of frames.

Within the set of long-term fields, the default order is calculated by following Step P_list0_2a and Step P_list0_2b.

Step P_list0_2a:

An ordered list of frames is created by ordering the long-term reference frames starting with the frame with the smallest long-term index and proceeding to the frame with largest long-term index.

Step P_list0_2b:

The default index order is created by selecting reference fields from this ordered list of frames from step P_list0_2a using the procedure of Step P_list0_1b.

Figure 8-16 shows the case of the first field in a field-structured picture pair, while Figure 8-2 shows the case of the second field when no long-term fields are stored for reference.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

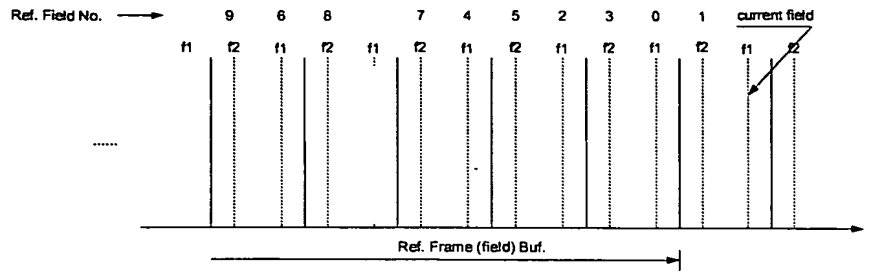

Figure 8-1 – Default reference field number assignment when the current picture is the first field coded in a frame [Ed. Note: Need to change f1/f2 to f0/f1 – always use zero-based indexing]

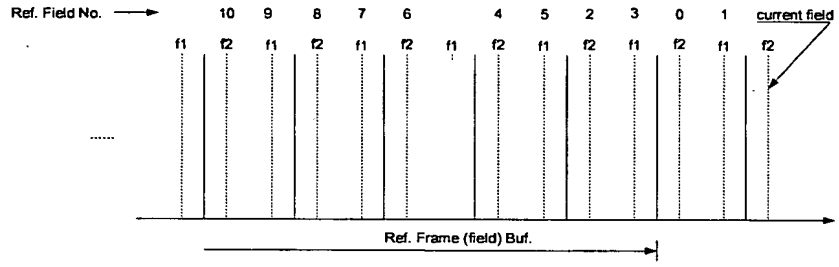

Figure 8-2 – Default reference field number assignment when the current picture is the second field coded in a frame [Ed. Note: Need to change f1/f2 to f0/f1 – always use zero-based indexing]

8.2.6.3.3 Initialization process for reference indices for B slices in frames

This intitialization process is invoked when … [Ed.Note: specify]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The organisation of short-term reference pictures in the default order for B slices depends on output order, as given by PicOrderCnt. In the case of a reference frame having being coded as two fields with different values of PicOrderCnt, the frame shall be considered to have the smaller of these two values of PicOrde rCnt for the purpose of constructing the default index order for B slices in frames.

When decoding a frame, the default index order for list 0 prediction of B slices is for the short -term reference frames (i.e., frames which have not been given a long -term index) to precede the long-term reference frames in the reference indexing order. Within the set of short-term reference frames, the default order is for the frames to be ordered starting with the frame with the largest value of PicOrderCnt less than the value of PicOrderCnt of the current frame and proceeding through to the short -term reference frame that has the smallest value of PicOrderCnt; and then the frame with the smallest value of PicOrderCnt greater than the value of PicOrderCnt of the current f rame and proceeding through to the short-term reference frame that has the largest value of PicOrderCnt. Within the set of long -term reference frames, the default order is for the frames to be ordered starting with the frame with the smallest long -term index and proceeding to the frame with the largest long-term index.

When decoding a frame, the default index order for list 1 prediction of B slices is for the short -term reference frames to precede the long-term reference frames in the reference indexing ord er. Within the set of short-term reference frames, the default order is for the frames to be ordered starting with the frame with the smallest value of PicOrderCnt greater than the value of PicOrderCnt of the current frame and proceeding through to the sh ort-term reference frame that has the

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

largest value of PicOrderCnt; and then the frame with the largest value of PicOrderCnt less than the value of PicOrderCnt of the current frame and proceeding through to the short -term reference frame that has the smallest value of PicOrderCnt . Within the set of long-term reference frames, the default order is for the frames to be ordered starting with the frame with the smallest long-term index and proceeding to the frame with the largest long -term index.

The ordinary default order specified in the previous paragraph shall be used as the default index order for list 1 prediction unless there is more than one reference picture in the set and the ordinary default index order for list 1 prediction is the same as the default index order for list 0 prediction. In this exceptional case, the default index order for list 1 prediction shall be the ordinary default index order with the order of the first two pictures switched.

A field that is stored in the decoded picture buffer and is marked as "used for reference" for which the opposite parity field is not stored in the decoded picture buffer or is stored but marked as "unused for reference" shall not be included in the default index order, shall not be remapped, and shall not b e used for prediction in frames.

8.2.6.3.4 Initialization process for reference indices for B slices in fields

This intitialization process is invoked when ... [Ed.Note: specify]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When decoding a field, each field of the stored reference frames is identified as a separate reference picture with a unique index. Thus field structured pictures effectively have at least twice the number of pictures available for referencing.

The default index order for list 0 prediction of B slices in fields is for the short -term reference fields to precede the long-term reference fields in the reference indexing order.

Within the set of short-term reference fields, the default order list 0 prediction is calculated b y following Step B_list0_1a and Step B_list0_1b.

Step B_list0_1a:

An ordered list of frames is created by ordering the short -term reference frames as in the case of creating the default list 0 index order for B slices in frames, except that the current fr ame shall be included at the start of the list when the current field is the second of a frame and the first field of the frame is stored and marked "used for reference", and except that frames in which only one field is stored and marked "used for referen ce" are included in the list.

Step B_list0_1b:

The default index order is created by selecting reference fields from this ordered list of frames from step B_list0_1a using the procedure of Step P_list0_1b.

Within the set of long-term fields, the default order is calculated by following Step B_list0_2a and Step B_list0_2b.

Step B_list0_2a:

An ordered list of frames is created by ordering the long -term reference frames starting with the frame with the smallest long-term index and proceeding to the frame with largest long-term index.

Step B_list0_2b:

The default index order is created by selecting reference fields from this ordered list of frames from step B_list0_2a using the procedure of Step P_list0_1b.

The default index order for list 1 prediction of B sli ces in fields is for the short-term reference fields to precede the long-term reference fields in the reference indexing order.

Within the set of short-term reference fields, the default order for list 1 prediction is calculated by following Step B_list1_1a and Step B_list1_1b.

Step B_list1_1a:

An ordered list of frames is created by ordering the short -term reference frames as in the case of creating the default list 1 index order for B slices in frames, except that the current frame shall be included imme diately before the frame with the largest value of PicOrderCnt less than the value of PicOrderCnt of the current frame when the current field is the second of a frame and the first field of the frame is stored and marked "used for reference", and except th at frames in which only one field is stored and marked "used for reference" are included in the list.

Step B_list1_1b:

The default index order is created by selecting reference fields from this ordered list of frames from step B_list1_1a using the procedu re of Step P_list0_1b.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Within the set of long-term fields, the default order is calculated by following Step B_list1_2a and Step B_list1_2b.

Step B_list1_2a:

An ordered list of frames is created by ordering the long -term reference frames starting with the frame with the smallest long-term index and proceeding to the frame with largest long -term index.

Step B_list1_2b:

The default index order is created by selecting reference fields from this ordered list of frames from step B_list1_2a using the procedure of Step P_list1_1b.

8.2.6.4 Assignment process for reference indices

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The syntax elements remapping_of_pic_nums_idc, abs_diff_pic_num_minus1, and long_term_pic_idx fields allow indexing into the decoded picture buffer to be temporarily altered from the default index order for the decoding of the current slice. A remapping_of_pic_nums_idc "end loop" indication indicates t he end of a list of reordering commands.

The indices are assigned starting at zero and increasing by one for each remapping_of_pic_nums_idc field. Pictures that are not re-mapped to a specific order by remapping_of_pic_nums_idc, shall follow after any pict ures having a re-mapped order in the indexing scheme, following the default order amongst these non -re-mapped pictures.

8.2.6.4.1 Assignment process for reference indices for short-term pictures

Input to this process is/are ??? [Ed.Note: specify input to this proces s]

Output of this process is/are ??? [Ed.Note: specify output of this process]

abs_diff_pic_num_minus1 plus one indicates the absolute difference between the picture number of the picture being re - mapped and the prediction value. For the first occurence of the abs_diff_pic_num_minus1 field in ref_idx_reordering( ), the prediction value is the picture number of the current picture. For subsequent occurences of the abs_diff_pic_num_minus1 field in ref_idx_reordering( ), the prediction value is the picture num ber of the picture that was re-mapped most recently using abs_diff_pic_num_minus1.

The decoder shall determine the picture number of the picture being re -mapped, PNQ, in a manner mathematically equivalent to the following, where the picture number predicti on is PNP.

```
if( remapping_of_pic_nums_idc = = 0 )     /* a negative difference */
  if( PNP - abs_diff_pic_num_minus1 < 0 )
    PNQ = PNP - abs_diff_pic_num_minus1 + MaxPicNum - 1;
  else
    PNQ = PNP - abs_diff_pic_num_minus1;
else   /* a positive difference */
  if( PNP + abs_diff_pic_num_minus1 > MaxPicNum-1 )
    PNQ  = PNP + abs_diff_pic_num_minus1 - MaxPicNum + 1;
  else
    PNQ  = PNP + abs_diff_pic_num_minus1 + 1;
```

The encoder shall control remapping_of_pic_nums_idc and abs_diff_pic_num_minus1 such that t he decoded value of abs_diff_pic_num_minus1 shall not be greater than or equal to MaxPicNum.

As an example implementation, the encoder may use the following process to determine values of abs_diff_pic_num_minus1 and remapping_of_pic_nums_idc to specify a r e-mapped picture number in question, PN:

```
DELTA = PNQ - PNP;
if( DELTA < 0 )
    if( DELTA < -MaxPicNum/2 - 1 )
        MDELTA = DELTA + MaxPicNum;
    else
        MDELTA = DELTA;
else
```

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

```
        if ( DELTA > MaxPicNum/2 )
            MDELTA = DELTA - MaxPicNum;
        else
            MDELTA = DELTA;
    abs_diff_pic_num_minus1 = Abs( MDELTA ) - 1;
```

remapping_of_pic_nums_idc is then determined by the sign of MDELTA.

The prediction value used by any subsequent abs_diff_pic_num_minus1 re -mappings is not affected by long_term_pic_idx.

8.2.6.4.2 Assignment process for reference indices for long-term pictures

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The long_term_pic_idx field indicates the index of the long -term reference picture being remapped.

8.2.7 Decoded picture buffer management process

Input to this process are syntax elements for the decoded picture buffer management 7.3.3.3 and the decoded picture buffer.

Output of this process is the possibl y modified decoded picture buffer.

A picture that is stored for prediction, referred to as a reference picture, is marked as "used for reference", and is labelled as either a short-term reference picture, in which case it is identified by its frame_number and parity, or is labelled as a long-term reference picture, in which case it is identified by its long -term index and parity. A picture that is not stored for prediction is labelled as "unused for reference".

The decoded frame buffer is initially empty, a nd the value of max_long_term_pic_idx_plus1 shall initially be zero.

When nal_ref_idc is not equal to zero, the current picture is stored in the decoded picture buffer and is marked "used for reference".

The decoded picture buffer is modified as indicated by adaptive_ref_pic_buffering_mode_flag, which indicates either "Sliding Window", a first-in, first-out mechanism, or "Adaptive Memory Control", a customised adaptive buffering operation specified with memory_management_control_operation commands. A pictur e that is stored in the decoded picture buffer and marked "used for reference" can be used as a reference for prediction until it is marked as "unused for reference" by either the "Sliding Window" or "Adaptive Memory Control" mechanism, after which it can not be used as a reference for prediction.

In frames, memory_management_control_operation commands apply to both fields of the frame indicated.

In fields, memory_management_control_operation commands apply to individual fields indicated.

The decoded picture buffer is a buffer that contains frames. Each frame in the buffer may contain a top field, a bottom field, or a top and bottom field, but in the latter case, both must have the same frame_num. When decoding a field, if a memory_management_control_operati on command assigns a long -term index to a field, another memory_management_control_operation command to assign the same long -term index to the other field of the same frame shall be present in the same dec_pic_buffer_management( ) if that field is stored and marked as "used for reference".

8.2.7.1 Sequence of operations for decoded picture buffer management process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The sequence of operations for the management of the decoded picture buffer is as follows.

Step 1:

The picture is decoded.

Step 2:

The decoded picture buffer is updated according to either the "Sliding Window" or "Adaptive Memory Control" mechanism as indicated by adaptive_ref_pic_buffering_mode_flag. In the case of "Adaptive Memory Control", the memory_management_control_operation commands are applied in the order in which they occur in the bitstream.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

If the picture is an IDR picture, all reference pictures are marked as "unused for reference" before performing the "Sliding Window" mechanism and before processing any memory_management_control_operation commands.

Step 3:

If nal_ref_idc indicates that the picture is to be stored for reference, the picture is s tored in the decoded picture buffer and is marked "used for reference". If the current picture is a frame or the first field of a frame marked "used for reference", there shall be a completely empty reference frame memory in the buffer into which the pictu re can be stored. If the current picture is the second stored reference field of a frame, it shall be stored in the same frame as the first field of the frame.

After adding a reference picture to the decoded picture buffer, the number of frames marked as " used for reference", including frames in which only one field is marked as "used for reference" shall not be greater than num_ref_frames.

8.2.7.2 Sliding window decoded picture buffer management process

Input to this process is/are ??? [Ed.Note: specify input to t his process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The sliding window reference picture buffering mode operates as specified in this paragraph, when nal_ref_idc indicates that the current picture is to be stored as a reference picture and the adaptive_ref_pic_buffering_mode_flag indicates "Sliding Window". The syntax element num_ref_frames of the sequence parameter set is used to define the operation of the sliding window reference picture buffering mode.

The sliding window reference picture buffering mode actions are only applied to the decoded picture buffer on processing of the first stored reference field of a frame. No action is taken when processing the second stored reference field of a frame.

Set S equal to the number of short-term reference frames in the decoded frame buffer that are marked as "used for reference", including short-term reference frames in which only one field is marked as "used for reference". Set L equal to the number of long-term reference frames in the decoded frame buffer that are marked as "used for reference", including long-term reference frames in which only one field is marked as "used for reference". Set N to the total number of frames stored in the decoded picture buffer.

If S + L equals num_ref_frames, S shall be greater than zero, and the short -term reference frame that was decoded first (i.e. in the absence of wrapping of the frame_num value, the frame with the smallest value of frame_num) is marked as "unused for reference".

If N equals DPBcapacity, S shall be greater than zero, and the short -term reference frame that was decoded first is marked as "unused for reference".

Otherwise no action is taken.

NOTE - num_ref_frames may be less than DPBcapacity to allow specific space in the decoded picture buffer for frames that are marked as "unused for reference". However, the number of frames that are marked as "unused for reference" may be greater than DPBcapacity - num_ref_frames, but in this case it should be noted that it may not be possible to discard non stored pictures without attempting to decode them, as they may interact with the operation of the sliding window.

8.2.7.3 Adaptive Memory Control decoded picture buffer management process

Input to this process is/are ??? [Ed.Note: specify inpu t to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The adaptive reference picture buffering mode allows all or specified pictures to be marked "unused for reference", allows specified pictures to be allocated a long-term frame index, allows the max_long_term_pic_idx_plus1 to be modified, and allows the whole buffer to be emptied, by use of memory_management_control_operation commands.

The element max_long_term_pic_idx_plus1 places a limit on the number of long -term frame indexes that may be used.

memory_management_control_operation commands are processed in the order they occur in the bitstream, and are processed after the whole picture has been decoded. When all commands have been processed, storage of the current picture is considered. When nal_ref_idc is not equal to 0, the current picture is marked "used for reference" and added to the decoded picture buffer initially as a short-term reference picture. memory_management_control_operation commands in the bitstre am shall be such that when nal_ref_idc indicates that the current picture is to be stored as a reference picture, there shall be sufficient capacity in the decoded picture buffer to store the current picture.

8.2.7.3.1 Assignment process for short-term pictures to "unused for reference"

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

If memory_management_control_operation equals 1 (Mark a Short -Term Reference Picture as "Unused for reference"), a specified short-term reference picture in the decoded picture buffer is marked as "unused for reference", if that picture has not already been marked as "unused for reference".

If the current decoded picture number is PNC, di fference_of_pic_nums_minus1 is used in an operation mathematically equivalent to the following equations, to calculate, PNQ, the picture number of the short -term reference picture to be marked as "unused for reference".

```
if(PNC < difference_of_pic_nums_minus1)
  PNQ = PNC - difference_of_pic_nums_minus1 - 1 + MaxPicNum;
else
  PNQ = PNC - difference_of_pic_nums_minus1 - 1;
```

Similarly, the encoder may compute the difference_of_pic_nums_minus1 value to encode using the following relation:

```
if(PNC < PNQ)
  difference_of_pic_nums_minus1 = PNC - PNQ - 1 + MaxPicNum;
else
  difference_of_pic_nums_minus1 = PNC - PNQ - 1;
```

8.2.7.3.2 Assignment process for long-term pictures to "unused for reference"

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If memory_management_control_operation equals 2 (Mark a Long -Term Reference Picture as "Unused for reference"), a specified long-term reference picture is marked as "unused for reference" , if that picture has not already been marked as "unused for reference".

The field long_term_pic_idx indicates the the long -term picture number, LTPN, of the picture to be marked as "unused for reference".

NOTE: this use of long_term_pic_idx is different t o its use when allocating a long-term index to a short-term reference picture.

8.2.7.3.3 Assignment process for a long-term index to a short-term reference picture

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If memory_management_control_operation equals 3 (Assign a Long -Term Index to a Picture), a specified short-term reference picture is allocated a specified long-term index, if that picture has not already been allocated a long-term index. If the picture specified in a long-term assignment operation is already associated with the required long_term_pic_idx, no action shall be taken by the decoder. The specified short -term reference picture is no longer considere d as a short-term reference picture following the processing of this command, and shall not be referenced at a later point in the bitstream by reference to its picture number, except for a repetition of the long -term index assignment.

If another picture is already assigned the same long-term index as the specified long-term index, the other picture is marked as "unused for reference".

The short-term reference picture to be assigned the long-term index is identified by its picture number, which is derived from difference_of_pic_nums_minus1 as in subclause 8.2.7.3.1.

When decoding a field, if a memory_management_control_operation command assigns a long -term index to a field, another memory_management_control_operation command to as sign the same long-term index to the other field of the same frame shall be present in the same dec_pic_buffer_management( ) if that field is stored in the decoded picture buffer and marked as "used for prediction". The long -term frame number of the frame into which the short-term picture is transferred is given by long_term_pic_idx.

long_term_pic_idx shall not be greater than max_long_term_pic_idx_plus1 −1.

The bitstream may contain the same long-term index assignment operation or max_long_term_pic_idx_plu s1 specification message repeatedly.

NOTE - If long_term_pic_idx does not satisfy this constraint, this condition should be treated by the decoder as an error. For error resilience, a repeated assignment of the long-term index or max_long_term_pic_idx_plus1 maybe desirable.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

A bitstream shall not assign a long-term index to a short-term reference picture that has been marked as "unused for reference" by the decoding process prior to the first such assignment message in the bitstream. A bitstream shall not assign a long-term index to a picture number that has not been included earlier in the bitstream.

Once a long-term picture index has been assigned to a picture, the only potential subsequent use of the long -term picture's picture number within the bitstream shall be in a repetition of the long-term index assignment. long_term_pic_idx becomes the unique ID for the life of a long -term picture.

8.2.7.3.4 Decoding process for maximum long-term index

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If memory_management_control_operation equals 4 (Specify the Maximum Long -Term Frame Index), max_long_term_pic_idx_plus1 indicates the maximum index allowed for long -term reference frames (until receipt of another value of max_long_term_pic_idx_plus1).

If max_long_term_pic_idx_plus1 is smaller than its previous value, all frames in the decoded picture buffer having indices greater than max_long_term_pic_idx_plus1 – 1 shall be marked "unused for reference".

If max_long_term_pic_idx_plus1 is greater than its previous value there are no immediate consequences on the decoded picture buffer.

NOTE - max_long_term_pic_idx_plus1 can therefore be used to mark long-term reference pictures as "unused for reference" but has no effect on short-term reference pictures. The frequency of transmitting max_long_term_pic_idx_plus1 is out of the scope of this Recommendation. However, the encoder should send a max_long_term_pic_idx_plus1 parameter upon receiving an error message, such as an intra request message.

8.2.7.3.5 Assignment process for all reference pictures to "unused for reference"

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If memory_management_control_operation equals 5 (reset all reference pictures), or the current picture is an IDR picture and the non_ref_pic_reset_flag is equal to 0, all reference pictures are removed from the decoded picture buf fer, and max_long_term_pic_idx_plus1 is set to zero. If memory_management_control_operation equals 5 (Reset all reference pictures), the picture shall be considered to have frame_num equal to 0 immediately after processing the memory_management_control_ope ration equal to 5.

8.2.7.3.6 Assignment process for all non-reference pictures to "unused"

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If memory_management_cont rol_operation equals 6 (reset all non -reference pictures) all non-reference pictures are removed from the decoded picture buffer.

8.2.7.3.7 Assignment process for all reference and non-reference pictures to "unused"

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If memory_management_control_operation equals 7 (reset all reference and non -reference pictures), or the current picture is an IDR picture and the non_ref_p ic_reset_flag is equal to 1, all reference and non-reference pictures are removed from the decoded picture buffer. If memory_management_control_operation equals 7 (reset all reference and non-reference pictures), the picture shall be considered to have fr ame_num equal to 0 immediately after processing the memory_management_control_operation equal to 7.

8.2.8 Decoding process for macroblock level frame/field adaptive coding

[Ed.Note: this should go somewhere else in the spec … to subclause 8.5.3]

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When mb_ frame_field_adaptive_flag is equal to 1, the decoded frame is scanned on a macroblock pair by macroblock pair basis, as shown in Figure 6-4. A macroblock pair can be decoded in either frame or field decoding mode. For frame decoding mode, a macroblock pair is decoded as two frame macroblocks, and each can be further divided into one of

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

block patterns shown in Figure 6-5. For field decoding mode, a macroblock pair is first split into one top -field macroblock and one bottom -field macroblock, as shown in Figure 8-3. The top-field macroblock and the bottom -field macroblock are further divided into block one of patterns shown in **Error! Reference source not found.**. Each macroblock in either frame or field decoding mode can have a different mb_type described in subclause 7.4.5.

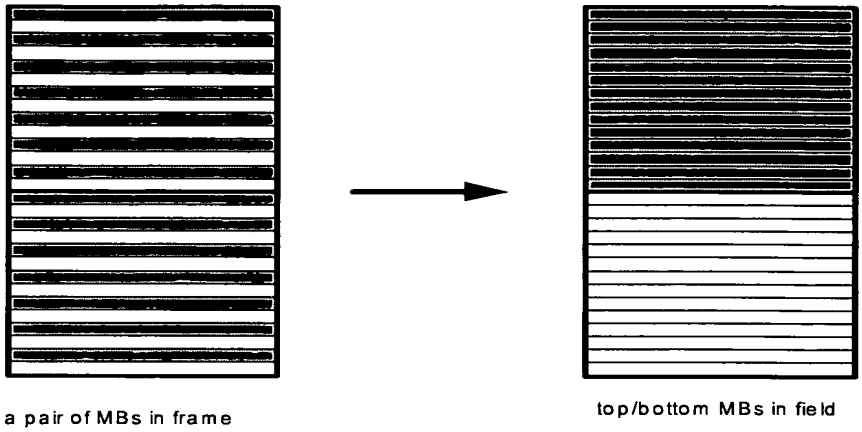

Figure 8-3 – Split of a pair of macroblocks into one top -field macroblock and one bottom -field macroblock. [Ed. Note: Should hae 16 lines per MB, not 14 as shown above]

When mb_field_decoding_flag is equal to 0, the top macroblock of a macroblock pair is decoded first, followed by the bottom macroblock. When mb_field_decoding_flag is equal to 1, the top-field macroblock is decoded first, followed by the bottom-field macroblock (see Figure 8-3).

When mb_frame_field_adaptive_flag is equal to 1, if only one macroblock of a macroblock pair is skipped, it shall be skipped in frame decoding mode if the other macroblock of the macroblock pair is coded in frame decoding mode otherwise it shall be skipped in field decoding mode. If both macroblocks in a macroblock pair are skipped, the process is described in subclause 8.2.8.1 for P and SP slices and in subclause 8.2.8.2 for B slices.

[Ed. Note: Need a precise description of macroblock numbering in MB -AFF case.]

8.2.8.1 Derivation process for frame or field decoding mode for a skipped macroblock pair in P or SP slices

[Ed.Note: this should go somewhere else in the spec ... to subclause 8.4]

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If both macroblocks in a macroblock pair are skipped in a P or SP slice, the macroblock pair will use the same frame or field decoding mode as its left neighbouring macroblock, if the left neighbouring macroblock exists and is in the same slice. If the left neighbouring macroblock is not available, the same frame or field decoding mode as the top neighbouring macroblock is used, if the top neighbouring macroblock exists and is in the same slice. Otherwise frame decoding mode is used.

8.2.8.2 Derivation process for frame or field decoding mode for skipped macroblock pair in B slice

[Ed.Note: this should go somewhere else in the spec ... to subclause 8.4]

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If both macroblocks in a macroblock pair are skipped in a B slice, th eir frame or field decoding mode is derived differently depending on the value of direct_spatial_mv_pred_flag. When direct_spatial_mv_pred_flag is equal to 1, the

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

frame or field decoding mode of the skipped macroblock pair is determined using the same meth od as for skipped macroblocks in P and SP slices, as described in subclause 8.2.8.1. When direct_spatial_mv_pred_flag is equal to 0, the frame or field decoding mode of the skipped macroblock pair shall follow the frame or field decoding mode of its co-located macroblock pair. The co-located macroblock is determined as described in subclause 8.4.1.4.2.1. [Ed. Note: Perhaps this should be moved later as co-located macroblock hasn't been defined yet.]

8.3 Intra prediction process

This process is invoked for I and SI macroblock types.

Input to this process are the macroblock type of the current macroblock (mb_type), prev_intra4x4_pred_mode_flag (if available), rem_intra4x4_pred_mode (if available), intra_chrom a_pred_mode (if available), and samples from neighbouring macroblocks or macroblock pairs.

Output of this process are Intra predicted samples of macroblocks or macroblock pairs.

The decoding process of Intra prediction modes is described. Samples used in the Intra prediction process shall be sample values prior to alteration by any deblocking filter operations.

8.3.1 Intra_4x4 prediction process

This process is invoked when mb_part_pred_mode(mb_type, 0) is equal to Intra_4x4. It is specified how the Intra predicted luma samples for the current macroblock are derived.

Input to this process are the syntax elements prev_intra4x4_pred_mode_flag, rem_intra4x4_pred_mode (if available), and decoded samples prior to the deblocking process from neighbouring luma blocks (if available).

Output of this process are Intra predicted luma samples for the current macroblock.

The luma component of a macroblock consists of 16 luma blocks of 4x4 samples. These luma blocks of 4x4 samples are scanned using the 4x4 luma block scanning process as specified in subclause 6.4.6.

For the each luma block of 4x4 samples, i.e., for 4x4LumaBlkIdx ranging from 0 to 15, the corresponding samples in adjacent blocks are derived in subclause 8.3.1.1 and the corresponding Intra4x4LumaPredMode[4x4LumaBlkIdx] is derived as specified in subclause 8.3.1.2. Then, given those values, the prediction values for each luma block are decoded as specified in subclause 8.3.1.3.

8.3.1.1 Derivation process for the available samples

8.3.1.1.1 Derivation process for the available samples for macroblocks

This process is invoked, when mb_adaptive_frame_field_flag is equal to 0. This process specifies the availabilty or non-availability and possible corresponding substitution for samples that are used for Intra prediction of a luma block of 4x4 samples.

Input to this process is the position of the luma block and prior (in decoding order) decoded samples prior to the deblocking filter process from adjacent luma blocks.

Output of this process are the values of samples labeled as A to M and their availability status.

Let 4x4LumaBlkLoc be the location of the upper left sample of the 4x4 luma block with index 4x4LumaBlkIdx.

The samples of a 4x4 luma block with index 4x4LumaBlkIdx containing samples a to p in Figure 8-4 are predicted using samples A to M in Figure 8-4 from adjacent blocks.

The sample a has the location 4x4LumaBlkLoc. T he sample d has the x-component of the location
4x4LumaBlkLoc[4x4LumaBlkIdx][0] + 4 and the y-component of the location
4x4LumaBlkLoc[4x4LumaBlkIdx][1].

Sample A is the sample with location 4x4LumaBlkLoc[4x4LumaBlkIdx][0] and
4x4LumaBlkLoc[4x4LumaBlkIdx][1] - 1.

[Ed.Note: Specify for samples B through M as for A or, better, change to description using P(x,y).]

[Ed.Note: not precise enough] Adjacent blocks containing samples A to D and I to M are the luma blocks to the left, above, and above-left to sample a. The adjacent block containing samples E to H is the luma block above -right to sample d.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

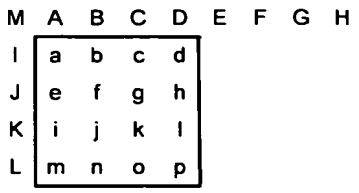

Figure 8-4 – Labelling of samples used for Intra_4x4 prediction

Samples A to M are marked as being "available for Intra prediction process" unless marked a "not available for prediction process" if one of the following conditions is true:

- if the sample is outside the picture or outside the current slice,
- if the sample is in a macroblock that is subsequent to the current macroblock in decoding order,
- if the sample is in a macroblock coded in Inter prediction mode and constrained_intra_pred_flag is equal to 1.

When samples E-H are not available, and the sample D is marked as being ava ilable for prediction, the sample value of D is substituted for sample values E-H and samples E-H are marked as being available.

8.3.1.1.2 Derivation process for the available samples for macroblock pairs

This process is invoked, when mb_adaptive_frame_field_flag is equal to 1 and field_pic_flag is equal to 0.

For samples a to p in Figure 8-4, the samples A to M in Figure 8-4 are derived as follows.

When the current macroblock pair is coded frame decoding mode, the sa me process as described in subclause 8.3.1.1.1 is invoked.

When the current macroblock pair is coded field decoding mode, for the current top -macroblock, samples A to M are derived by:

Sample A is the sample with location 4x4Lum aBlkLoc[4x4LumaBlkIdx][0] and 4x4LumaBlkLoc[4x4LumaBlkIdx][1] - 2.

Sample I is the sample with location 4x4LumaBlkLoc[4x4LumaBlkIdx][0] - 1 and 4x4LumaBlkLoc[4x4LumaBlkIdx][1].

[Ed.Note: Specify for samples B through M as for A or, better, change to description using P(x,y).]

When the current macroblock pair is coded field decoding mode, for the current bottom -macroblock, samples A to M are derived by:

Sample A is the sample with location 4x4LumaBlkLoc[4x4LumaBlkIdx][0] and 4x4LumaBlkLoc [4x4LumaBlkIdx][1] - 1.

Sample I is the sample with location 4x4LumaBlkLoc[4x4LumaBlkIdx][0] - 1 and 4x4LumaBlkLoc[4x4LumaBlkIdx][1].

NOTE – Each 4x4 luma block is assumed to be reconstructed as a frame prior to decoding the next 4x4 luma block.

8.3.1.2 Derivation process for the Intra4x4LumaPredMode

Input to this process are the syntax elements prev_intra4x4_pred_mode_flag, rem_intra4x4_pred_mode, and the location 4x4LumaBlkLoc[4x4LumaBlkIdx] of a 4x4 luma block with 4x4LumaBlkIdx.

Output of this pro cess is the variable Intra4x4LumaPredMode[4x4LumaBlkIdx].

Table 8-7 specifies the values for Intra4x4LumaPredMode[4x4LumaBlkIdx] and the associated names.

Table 8-7 – Specification of Intra4x4LumaPredMode[4x4LumaBlkIdx] and associated names

Intra4x4LumaPredMode[4x4LumaBlkIdx]	Name of Intra4x4LumaPredMode[4x4LumaBlkIdx]

6	Intra_4x4_Horizontal_Down (prediction mode)
7	Intra_4x4_Vertical_Left (prediction mode)
8	Intra_4x4_Horizontal_Up (prediction mode)

Intra4x4LumaPredMode[4x4LumaBlkIdx] labelled 0, 1, 3, 4, 5, 6, 7, and 8 represent directions of predictions as illustrated in Figure 8-5.

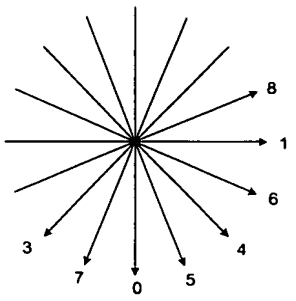

Figure 8-5 – Intra_4x4 prediction mode directions (informative)

The derivation process for the Intra4x4LumaPredMode for the current macroblock (pair) uses 3 steps:

Step 1: Derivation process for neighbouring macroblock (pair) indices and their availability.

Step 2: Derivation process for the Intra_4x4 prediction modes from neighboring macroblocks (pairs)

Step 3: Derivation process for Intra4x4LumaPredMode for the current macroblock (pair)

8.3.1.2.1 Derivation process for neighbouring macroblock addresses and their availability

This process is invoked, when mb_adaptive_frame_field is equal to 0 or field_pic_flag is equal to 1.

The input to this process is the address of the current macroblock (MbAddress).

The outputs of this process are the address of the macroblock to the left (Mb AddressA) of the current macroblock and the address of the macrolock above (MbAddressB) the current macroblock and their availability status.

The derivation process of the availability for neighbouring macroblocks in subclause 6.4.7 is invoked twice.

Input to the process in subclause 6.4.7 is MbAddressA = MbAddress – 1 and the output is whether the macroblock MbAddressA is available.

NOTE - MbAddressA is the address of the macroblock to the left of the current macroblock if it is available.

Input to the process in subclause 6.4.7 is MbAddressB = MbAddress – (frame_width_in_mbs_minus1 + 1) and the output is whether the macroblock MbAddressB is available.

NOTE - MbAddressB is the address of the macroblock above the current macroblock if it is available.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

8.3.1.2.2 Derivation process for neighbouring macroblock pair indices and their availability

This process is invoked, when mb_adaptive_frame_field is equal to 1 and field_pic_flag is equ al to 0.

The input to this process is the address of the current macroblock pair (MbPairAddress).

The outputs of this process are the address of the macroblock pair to the left (MbPairAddressA) of the current macroblock pair and the address of the macrolo ck above (MbPairAddressB) the current macroblock pair and their availability status.

The derivation process of the availability for neighbouring macroblock pairs in subclause 6.4.7 is invoked twice.

Input to the process in subclause 6.4.7 is MbPairAddressA = MbPairAddress – 1 and the output is whether the macroblock pair MbPairAddressA is available.

NOTE - MbPairAddressA is the address of the macroblock pair to the left of the current macroblock pair if it is available.

Input to the process in subclause 6.4.7 is MbPairAddressB = MbPairAddress – (frame_width_in_mbs_minus1 + 1) and the output is whether the macroblock pair MbPairAddressB is available.

NOTE - MbPairAddressB is the address of the macroblock pair above the current macroblock pair if it is available.

8.3.1.2.3 Derivation process for the Intra_4x4 prediction modes from neighboring macroblocks

This process is invoked, when mb_adaptive_frame_field is equal to 0 or field_pic_flag is equal to 1.

8.3.1.2.3.1 Derivation process for the Intra_4x4 prediction modes from left neighbouring macroblock

Input to this process is MbAddressA.

Output of this process are 4 values of the variable ExtIntra4x4LumaPredMode.

NOTE - ExtIntra4x4LumaPredMode is a 5x5 array that is used for the prediction of Intra4x4LumaPredMode, which is a 4x4 array. This process specifies 4 entries of the left column of ExtIntra4x4LumaPredMode.

When the macroblock MbAddressA is available and the mb_type of the macroblock MbAddress A is equal to I_4x4 or SI, the variable ExtIntra4x4LumaPredMode is derived in a process equivalent to:

```
for( i = 0, i < 4, i++ )
    ExtIntra4x4LumaPredMode[ (i+1)*5 ] = Intra4x4LumaPredMode[ 4x4LumaBlkScan( 3, i ) ]
```

where Intra4x4LumaPredMod is the variable assigned to the macroblock with index MbAddressA.

When macroblock MbAddressA is not available or the mb_type of the macroblock with index MbAddressA is not equal to I_4x4 or SI, the variable ExtIntra4x4LumaPredMode is derived in a process equivalent to:

```
for( i = 0, i < 4, i++ )
    ExtIntra4x4LumaPredMode[ (i+1)*5 ] = 2
```

8.3.1.2.3.2 Derivation process for the Intra_4x4 prediction modes from above neighbouring macroblock

Input to this process is MbAddressB.

Output of this process are 4 values of the variable ExtIntra4x4L umaPredMode.

NOTE - ExtIntra4x4LumaPredMode is a 5x5 array that is used for the prediction of Intra4x4LumaPredMode, which is a 4x4 array. This process specifies 4 entries of the top row of ExtIntra4x4LumaPredMode.

When the macroblock MbAddressB is availabl e and the mb_type of the macroblock MbAddressB is equal to I_4x4 or SI, the variable ExtIntra4x4LumaPredMode is derived in a process equivalent to:

```
for( i = 0, i < 4, i++ )
    ExtIntra4x4LumaPredMode[ i+1 ] = Intra4x4LumaPredMode[ 4x4LumaBlkScan( i, 3 ) ]
```

where Intra4x4LumaPredMode is the variable assigned to the macroblock MbAddressB.

When macroblock MbAddressA is not available or the mb_type of the macroblock MbAddressB is not equal to I_4x4 or SI, the variable ExtIntra4x4LumaPredMode is derived in a proc ess equivalent to:

```
for( i = 0, i < 4, i++ )
    ExtIntra4x4LumaPredMode[ i+1 ] = 2
```

8.3.1.2.4 Derivation process for the Intra_4x4 prediction modes from neighboring macroblock pairs

This process is invoked, when mb_adaptive_frame_field is equal to 1 and field_pic_flag is equal to 0.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

8.3.1.2.4.1 Derivation process for the Intra_4x4 prediction modes from neighboring macroblock pairs when current macroblock pair is coded in frame decoding mode

This process is invoked, when the current macroblock pair is coded in frame decoding mode.

Input to this process are MbPairAddress, MbPairAddressA, and MbPairAddressB.

Output of this process are 8 values of the variable ExtIntra4x4LumaPredModeTop for the top macroblock of the current macroblock pair and ExtIntra4x4LumaPredModeBottom for the bot tom macroblock of the current macroblock pair

The derivation processes as specified in subclause 8.3.1.2.3 are both invoked for both macroblocks of the current macroblock pair indexed as MbPairAddress.

For the derivation process in subclause 8.3.1.2.3.1, for the top macroblock of the current macroblock pair MbPairAddress, the top macroblock of the macroblock pair MbPairAddressA is assigned to MbAddressA as the input. The ouput is assigned to ExtIntra4x 4LumaPredModeTop.

For the derivation process in subclause 8.3.1.2.3.2, for the top macroblock of the current macroblock pair MbPairAddress, the bottom macroblock of the macroblock pair MbPairAddressB is assigned to MbAddressB as the input. The ouput is assigned to ExtIntra4x4LumaPredModeTop.

For the derivation process in subclause 8.3.1.2.3.1, for the bottom macroblock of the current macroblock pair MbPairAddress, the bo ttom macroblock of the macroblock pair MbPairAddressA is assigned to MbAddressA as the input. The ouput is assigned to ExtIntra4x4LumaPredModeBottom.

For the derivation process in subclause 8.3.1.2.3.1, for the bottom macroblock of the current macroblock pair MbPairAddress, the top macroblock of the current macroblock pair MbPairAddress is assigned to MbAddressB as the input. The ouput is assigned to ExtIntra4x4LumaPredModeBottom.

8.3.1.2.4.2 Derivation process for the Intra_4x4 prediction modes from neighboring macroblock pairs when current macroblock pair is coded in field decoding mode

This process is invoked, when the current macroblock pair is coded in frame decoding mode.

Input to this process are MbPairAddress, MbPairA ddressA, and MbPairAddressB.

Output of this process are 8 values of the variable ExtIntra4x4LumaPredModeTop for the top macroblock of the current macroblock pair and ExtIntra4x4LumaPredModeBottom for the bottom macroblock of the current macroblock pair.

The derivation processes as specified in subclause 8.3.1.2.3 are both invoked for both macroblocks of the current macroblock pair indexed as MbPairAddress.

For the derivation process in subclause 8.3.1.2.3.1, for the top macroblock of the current macroblock pair MbPairAddress, the top macroblock of the macroblock pair MbPairAddressA is assigned to MbAddressA as the input. The ouput is assigned to ExtIntra4x4LumaPredModeTop.

For the derivation process in subclause 8.3.1.2.3.1, for the bottom macroblock of the current macroblock pair MbPairAddress, the bottom macroblock of the macroblock pair MbPairAddressA is assigned to MbAddressA as the input. The ouput is assigned to ExtIntra4x4LumaPredModeBottom.

When the macroblock pair MbPairAddressB is coded in field decoding mode or when the macroblock with MbPairAddressB is not available, the following applies.

For the derivation process in subclause 8.3.1.2.3.2, for the top macroblock of the current macroblock pair MbPairAddress, the top macroblock of the macroblock pair MbPairAddressB is assigned to MbAddressB as the input. The ouput is assigned to ExtIntra4x4Lu maPredModeTop.

For the derivation process in subclause 8.3.1.2.3.2, for the bottom macroblock of the current macroblock pair MbPairAddress, the bottom macroblock of the macroblock pair MbPairAddressB is assigned to MbAddressB as the input. The ouput is assigned to ExtIntra4x4LumaPredModeBottom.

When the macroblock pair MbPairAddressB is coded in frame decoding mode, the following applies.

For the derivation process in subclause 8.3.1.2.3.2, for the top macroblock of the current macroblock pair MbPairAddress, the bottom macroblock of the macroblock pair MbPairAddressB is assigned to MbAddressB as the input. The ouput is assigned to ExtIntra4x4LumaPredModeTop.

For the derivation process in subclause 8.3.1.2.3.2, for the bottom macroblock of the current macroblock pair MbPairAddress, the bottom macroblock of the macroblock pair MbPairAddressB is assigned to MbAddressB as the input. The ouput is assigned to ExtIntra4x4LumaPredModeBottom.

Figure 8-6 illustrates the avove process when the current macroblock pair is coded in field decoding mode.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

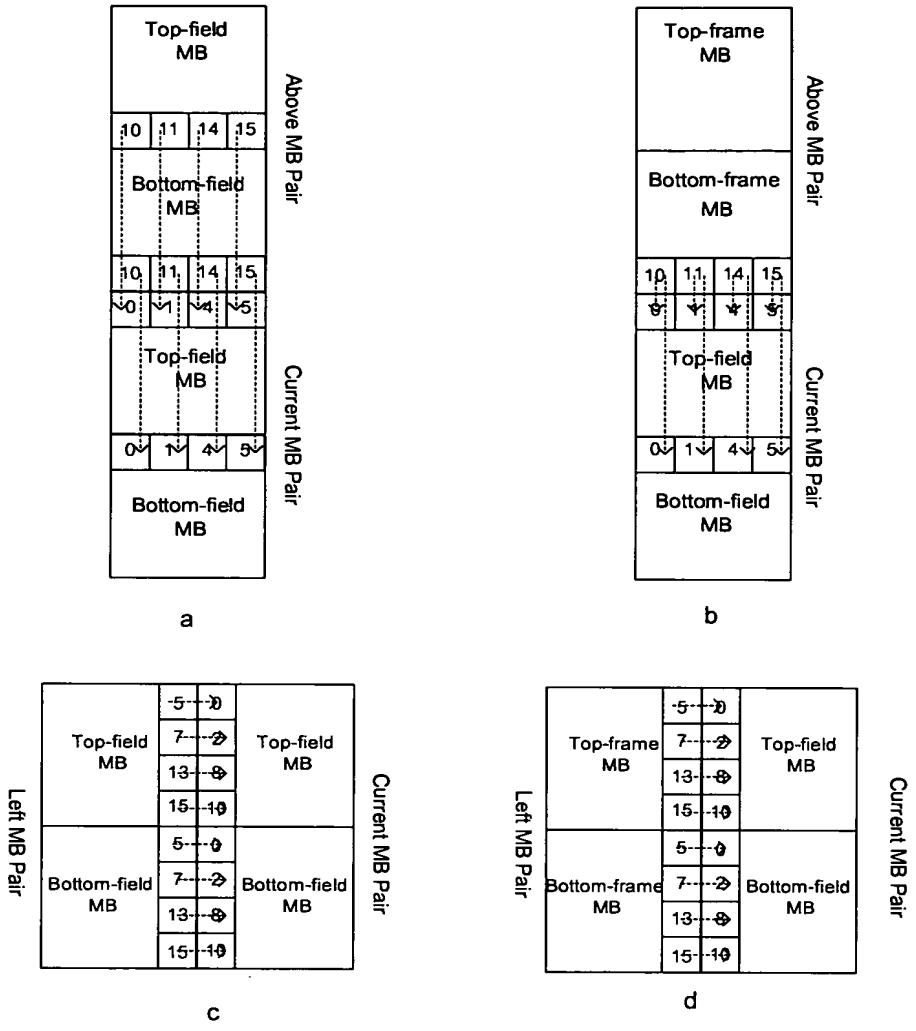

Figure 8-6 a) Definition of above neighbouring blocks when the above macroblock pair is in field mode b) Definition of above neighbouring blocks when the above macroblock pair is in frame mode c) Definition of left neighbouring blocks when the left macroblock pair is in field mode d) Definition of left neighbouring blocks when the left macroblock pair is in frame mode (informative)

8.3.1.2.5 Derivation process for Intra4x4LumaPredMode for the current macroblock

This process is invoked, when mb_adaptive _frame_field is equal to 0 or field_pic_flag is equal to 1.

The input to this process are prev_intra4x4_pred_mode_flag, rem_intra4x4_pred_mode, and ExtIntra4x4LumaPredMode.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

The variable Intra4x4LumaPredMode which is assigned to the current macroblock with index MbAddress is derived as follows.

```
for( 4x4LumaBlkIdx = 0, 4x4LumaBlkIdx < 16, 4x4LumaBlkIdx++ ) {
    i = 4x4LumaBlkIdx + RasterTo4x4LumaBlkOffset( 4x4LumaBlkIdx )
    Ext4x4LumaBlkIdx = 5 * ( i / 4 + 1 ) + ( i % 4 ) + 1
    PredIntra4x4LumaPredMode = Min( ExtIntra4x4LumaPredMode[ Ext4x4LumaBlkIdx - 1 ],
                                    ExtIntra4x4LumaPredMode[ Ext4x4LumaBlkIdx - 5 ] )
    if( prev_intra4x4_pred_mode_flag[ 4x4LumaBlkIdx ] )
        Intra4x4LumaPredMode[ 4x4LumaBlkIdx ] = PredIntra4x4LumaPredMode
    else {
        if( rem_intra4x4_pred_mode[ 4x4LumaBlkIdx ] < PredIntra4x4LumaPredMode )
            Intra4x4LumaPredMode[ 4x4LumaBlkIdx ] = rem_intra4x4_pred_mode[ 4x4LumaBlkIdx ]
        else
            Intra4x4LumaPredMode[ 4x4LumaBlkIdx ] = rem_intra4x4_pred_mode[ 4x4LumaBlkIdx ] + 1
    }
    ExtIntra4x4LumaPredMode[ Ext4x4LumaBlkIdx ] = Intra4x4LumaPredMode[ 4x4LumaBlkIdx ]
}
```

8.3.1.2.6 Derivation process for Intra4x4LumaPredMode for the current macroblock pair

This process is invoked, when mb_adaptive_frame_field is equal to 1 and field_pic_fla g is equal to 0.

The variable prev_intra4x4_pred_mode_flag, rem_intra4x4_pred_mode, and ExtIntra4x4LumaPredModeTop which are assigned to the top macroblock of the current macroblock pair are assigned as the input to the derivation process in subclause 8.3.1.2.5 with the output being Intra4x4LumaPredMode assigned to the top macroblock of the current macroblock pair.

The variable prev_intra4x4_pred_mode_flag, rem_intra4x4_pred_mode, and ExtIntra4x4LumaPredModeBottom which are assigned to the bottom macroblock of the current macroblock pair are assigned as the input to the derivation process in subclause 8.3.1.2.5 with the output being Intra4x4LumaPredMode assigned to the bottom macroblock of the current macroblock pair.

8.3.1.3 Decoding process for Intra_4x4 prediction modes

Input to this process are the samples A to M as specified in subclause 8.3.1.1 and Intra4x4LumaPredMode[4x4LumaBlkIdx] as specified in subcaluse 8.3.1.2.

Output of this process are the predicted samples for the 4x4 luma block with index 4x4LumaBlkIdx of the current macroblock.

Depending on Intra4x4LumaPredMode[4x4LumaBlkIdx], one of the Intra_4x4 prediction modes specified in subclauses 8.3.1.3.1 to 8.3.1.3.9 shall be used.

This process shall be invoked for each of the 4x4 luma blocks followed by the transform decoding process and picture construction process prior to deblocking f or each 4x4 luma block.

8.3.1.3.1 Specification of Intra_4x4_Vertical prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 0.

This mode shall be used only if A, B, C, D are available. The values of the predicted samples a to p are derived as follows:

- a, e, i, m are equal to A,
- b, f, j, n are equal to B,
- c, g, k, o are equal to C,
- d, h, l, p are equal to D.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

8.3.1.3.2 Specification of Intra_4x4_Horizontal prediction mode

This Intra_4x4 prediction mode sh all be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 1.

This mode shall be used only if I, J, K, L are available. The values of the predicted samples a to p are derived as follows:

- a, b, c, d are equal to I,
- e, f, g, h are equal to J,
- i, j, k, l are equal to K,
- m, n, o, p are equal to L.

8.3.1.3.3 Specification of Intra_4x4_DC prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 2.

The values of the predicted samples a to p are derived as follows:

If all samples A, B, C, D, I, J, K, L are available, all predicted samples are equal to (A+B+C+D+I+J+K+L+4)>>3.

If A, B, C, and D are not available and I, J, K, and L are available, all predicted samples are equal to (I+J+K+L+2)>>2.

If I, J, K, and L are not available and A, B, C, and D are available, all predicted samples are equal to (A+B+C+D+2)>>2.

If all samples A, B, C, D, I, J, K, L are not available, all predicted samples are equal to 128.

A block may therefore always be pre dicted in this mode.

8.3.1.3.4 Specification of Intra_4x4_Diagonal_Down_Left prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 3.

This mode shall be used only if all A, B, C, D, I, J, K, L, M are ava ilable. The values of the predicted samples a to p are derived as follows:

- a is equal to (A + 2B + C + 2) >> 2
- b, e are equal to (B + 2C + D + 2) >> 2
- c, f, i are equal to (C + 2D + E + 2) >> 2
- d, g, j, m are equal to (D + 2E + F + 2) >> 2
- h, k, n are equal to (E + 2F + G + 2) >> 2
- l, o are equal to (F + 2G + H + 2) >> 2
- p is equal to (G + 3H + 2) >> 2

8.3.1.3.5 Specification of Intra_4x4_Diagonal_Down_Right prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPred Mode[4x4LumaBlkIdx] is equal to 4.

This mode shall be used only if all A, B, C, D, I, J, K, L, M are available. The values of the predicted samples a to p are derived as follows:

- m is equal to (J + 2K + L + 2) >> 2
- i, n equal to (I + 2J + K + 2) >> 2
- e, j, o are equal to (M + 2I + J + 2) >> 2
- a, f, k, p are equal to (A + 2M + I + 2) >> 2
- b, g, l are equal to (M + 2A + B + 2) >> 2
- c, h are equal to (A + 2B + C + 2) >> 2
- d is equal to (B + 2C + D + 2) >> 2

8.3.1.3.6 Specification of Intra_4x4_V ertical_Right prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 5.

This mode shall be used only if all A, B, C, D, I, J, K, L, M are inside the slice. The values of the predicted samples a to p are derived as follows:

- a, j are equal to (M + A + 1) >> 1
- b, k are equal to (A + B + 1) >> 1

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- c, l are equal to (B + C + 1) >> 1
- d is are equal to (C + D + 1) >> 1
- e, n are equal to (I + 2M + A + 2) >> 2
- f, o are equal to (M + 2A + B + 2) >> 2
- g, p are equal to (A + 2B + C + 2) >> 2
- h is equal to (B + 2C + D + 2) >> 2
- i is equal to (M + 2I + J + 2) >> 2
- m is equal to (I + 2J + K + 2) >> 2

8.3.1.3.7 Specification of Intra_4x4_Horizontal_Down prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 6.

This mode shall be used only if all A, B, C, D, I, J, K, L, M are available. The values of the predicted samples a to p are derived as follows:

- a, g are equal to (M + I + 1) >> 1
- b, h are equal to (I + 2M + A+ 2) >> 2
- c is equal to (M + 2A + B+ 2) >> 2
- d is equal to (A + 2B + C+ 2) >> 2
- e, k are equal to (I + J + 1) >> 1
- f, l are equal to (M + 2I + J+ 2) >> 2
- i, o are equal to (J + K + 1) >> 1
- j, p are equal to (I + 2J + K+ 2) >> 2
- m is equal to (K + L + 1) >> 1
- n is equal to (J + 2K + L + 2) >> 2

8.3.1.3.8 Specification of Intra_4x4_Vertical_Left prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 7.

This mode shall be used only if all A, B, C, D, I, J, K, L, M are available. The values of the predicted samples a to p are derived as follows:

- a is equal to (A + B + 1) >> 1
- b, i are equal to (B + C + 1) >> 1
- c, j are equal to (C + D + 1) >> 1
- d, k are equal to (D + E + 1) >> 1
- l is equal to (E + F + 1) >> 1
- e is equal to (A + 2B + C + 2) >> 2
- f, m are equal to (B + 2C + D + 2) >> 2
- g, n are equal to (C + 2D + E + 2) >> 2
- h, o are equal to (D + 2E + F + 2) >> 2
- p is equal to (E + 2F + G + 2) >> 2

8.3.1.3.9 Specification of Intra_4x4_Horizontal_Up prediction mode

This Intra_4x4 prediction mode shall be used, when Intra4x4LumaPredMode[4x4LumaBlkIdx] is equal to 8.

This mode shall be used only if all A, B, C, D, I, J, K, L, M are available. The values of the predicted samples a to p are derived as follows:

- a is equal to (I + J + 1) >> 1
- b is equal to (I + 2J + K + 2) >> 2
- c, e are equal to (J + K + 1) >> 1
- d, f are equal to (J + 2K + L + 2) >> 2
- g, i are equal to (K + L + 1) >> 1

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- h, j are equal to (K + 3L + 2) >> 2
- k, l, m, n, o, p are equal to L

8.3.2 Intra_16x16 prediction process

This process is invoked when mb_part_pred_mode(mb_type, 0) is equal to Intra_16x16. It is specified how the Intra predicted luma samples for the current macroblock are derived.

Input to this process are the syntax elements mb_type, and decoded samples prior to the deblocking process from neighbouring luma blocks (if available).

Output of this process are Intra predicted luma samples for the current macroblock.

[Ed.Note: what about MB-AFF ???]

Let P(-1,y), with y=-1,0,...,15 and P(x,-1), with x=0,...,15 denote the 33 neighbouring samples immediately above and/or to the left of the 16x16 luma block. Let Pred(x,y) x,y = 0..15 denote the prediction for the 16x16 luma block samples. There are 4 different prediction modes as specified in subclauses **Error! Reference source not found.** to **Error! Reference source not found.**. Only Mode 3 uses P(-1,-1).

Samples P(x,-1) or P(-1,y) shall be considered not available if they are outside the picture or outside the current slice, or if they are in a non-intra macroblock and constrained_intra_pred is 1. If none of the neighbouring samples are available, Mode 2 (DC prediction) is the only possible 16x16 luma prediction mode.

8.3.2.1 Mode 0: vertical prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

This mode shall be used only if all neighbouring samples P(x, -1) , with x = 0..15 are available.

$$Pred(x, y) = P(x, -1), \text{ with } x, y = 0..15 \tag{8-10}$$

8.3.2.2 Mode 1: horizontal prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

This mode shall be used only if all neighbouring samples P(-1, y) , y=0..15 are available.

$$Pred(x, y) = P(-1, y), \text{ with } x, y = 0..15 \tag{8-11}$$

8.3.2.3 Mode 2: DC prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If all neighbouring samples P(x', -1) and P(-1, y') used in Equation 8-12 are available, the prediction for all luma samples in the macroblock is given by:

$$Pred(x, y) = [\sum_{x'=0}^{15} P(x',-1) + \sum_{y'=0}^{15} P(-1, y') + 16] >> 5 \quad \text{with } x, y = 0..15 \tag{8-12}$$

If the neighbouring samples P(x', -1) are not available and the neighbouring samples P(-1, y') are available, the prediction for all luma samples in the macroblock is given by:

$$Pred(x, y) = [\sum_{y'=0}^{15} P(-1, y') + 8] >> 4 \quad \text{with } x, y = 0..15, \tag{8-13}$$

If the neighbouring samples P(-1, y') are not available and the neighbouring samples P(x', -1) are available, the prediction for all luma samples in the macroblock is given by:

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$\text{Pred}(x, y) = [\sum_{x'=0}^{15} P(x',-1) + 8] >> 4 \quad \text{with } x, y = 0..15, \tag{8-14}$$

If none of the neighbouring samples P(x', -1) and P(-1,y') are available, the prediction for all luma samples in the macroblock shall be 128.

8.3.2.4 Mode 3: plane prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

This mode shall be used only if all neighbouring samples P(x, -1) with x = -1..15 and P(-1, y) with y = 0..15 are available:

$$\text{Pred}(x,y) = \text{Clip1}((a + b (x-7) + c (y-7) +16) >> 5), \tag{8-15}$$

where:

$$a = 16 (P(-1,15) + P(15,-1)) \tag{8-16}$$

$$b = (5*H+32)>>6 \tag{8-17}$$

$$c = (5*V+32)>>6 \tag{8-18}$$

and H and V are specified in Equations 8-19 and 8-20.

$$H = \sum_{x=1}^{8} x \cdot (P(7 + x,-1) - P(7 - x,-1)) \tag{8-19}$$

$$V = \sum_{y=1}^{8} y \cdot (P(-1,7 + y) - P(-1,7 - y)) \tag{8-20}$$

8.3.3 Intra prediction process for chroma blocks

This process is invoked for I and SI macroblock types. It is specified how the Intra predicted chroma samples for the current macroblock are derived.

Input to this process are the syntax elements intra_chroma_pred_mode and decoded samples prior to the deblocking process from neighboring luma blocks (if available).

Output of this process are Intra predicted chroma samples for the current macroblock.

[Ed.Note: what about MB-AFF ???]

The chroma in intra macroblocks is predicted in a manner very similar to the luma block in Intra_16x16 macroblock type (subclause **Error! Reference source not found.**), using one of four prediction modes. The same prediction mode is applied to both chroma blocks, but it is independent of the prediction mode used for the luma.

NOTE - If any portion of the luma macroblock is coded in intra mode, the entire chroma macroblock is coded intra.

Let P(-1,y), y=-1,0,...,7 and P(x,-1), with x=-1,0,...,7 denote the 17 neighbouring samples immediately above and/or to the left of the 8x8 chroma block. Let Pred(x,y) with x,y = 0..7 denote the prediction for the 8x8 chroma block samples. There are four different prediction modes as specified in subclauses **Error! Reference source not found.** to **Error! Reference source not found.**. Only Mode 3 uses P(-1,-1).

Samples P(x,-1) or P(-1,y) shall be considered not available if they are outside the picture or outside the current slice, or if they are in a non-intra macroblock and constrained_intra_pred is 1. If none of the neighbouring samples are available, Mode 2 (DC prediction) is the only possible 8x8 chroma prediction mode.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

8.3.3.1 Mode 0: DC prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If all samples P(-1,*n*) and P(*n*,-1) used in Equation 8-21 are available, the prediction is formed as:

$$\text{Pred}(x, y) = \left(\left(\sum_{n=0}^{7}\left(P(-1,n) + P(n,-1)\right)\right) + 8\right) >> 4 \quad \text{with } x, y = 0..7, \tag{8-21}$$

If the 8 samples P(-1,*n*) are not available but the 8 samples P(*n*,-1) are available, the prediction is formed as:

$$\text{Pred}(x,y) = \left[\left(\sum_{n=0}^{7} P(n,-1)\right) + 4\right] >> 3 \text{ with } x, y = 0..7, \tag{8-22}$$

If the 8 samples P(*n*,-1) are not available but the 8 samples P(-1, *n*) are available, the prediction is formed as:

$$\text{Pred}(x,y) = \left[\left(\sum_{n=0}^{7} P(-1,n)\right) + 4\right] >> 3 \text{ with } x, y = 0..7, \tag{8-23}$$

If none of the neighbouring samples P(x, -1) and P(-1,y) are available, the prediction for all chroma samples in the macroblock shall be 128.

8.3.3.2 Mode 1: horizontal prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

This mode shall be used only if all neighbouring samples P(-1, y), with y = 0..7 are available:

$$\text{Pred}(x, y) = P(-1, y), \text{ with } x, y = 0..7 \tag{8-24}$$

8.3.3.3 Mode 2: vertical prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

This mode shall be used only if all neighbouring samples P(x, -1), with x = 0..7 are available:

$$\text{Pred}(x, y) = P(x, -1), \text{ with } x, y = 0..7 \tag{8-25}$$

8.3.3.4 Mode 3: plane prediction

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

For the plane mode, the prediction is formed as:

$$\text{Pred}(x,y) = \text{Clip1}((a + b (x-3) + c (y-3) + 16) >> 5), \text{ with } x, y = 0,\ldots,7 \tag{8-26}$$

where:

$$a = 16 (P(-1,7) + P(7,-1)) \tag{8-27}$$

$$b = (17*H+16)>>5 \tag{8-28}$$

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$c = (17*V+16)>>5 \tag{8-29}$$

and H and V are specified as:

$$H = \sum_{x=1}^{4} x \cdot [P(3+x,-1) - P(3-x,-1)] \tag{8-30}$$

$$V = \sum_{y=1}^{4} y \cdot [P(-1,3+y) - P(-1,3-y)] \tag{8-31}$$

8.4 Inter prediction process

This process is invoked, when decoding P, SP, or B slices, and a macroblock is skipped or the macroblock type indicates Pred_L0, Pred_L1, Direct or BiPred prediction modes.

Input to this process are the skipped ma croblock indication (if available), the macroblock type mb_type (if available), the motion vector differences mvd_l0 and mvd_l1 (if available), the reference index list 0 and the reference index list 1 from subclause 8.2.6 and the reference pictures in the decoded picture buffer, the reference indices ref_idx_l0 and ref_idx_l1 (if available).

Output of this process are Inter prediction samples.

The Inter prediction process specifies a prediction of samples using reference picture s in the decoded picture buffer and syntax elements.

The inter prediction process for a macroblock or its partition consists of

- Calculation of variables for luma and chroma motion vector components and reference picture indices as specified in subclause 8.4.1.
- Calculation of luma and chroma inter prediction samples as specified in subclause 8.4.2.

In P and SP slices, inter prediction is only list 0 prediction. In B slices, inter prediction may be list 0 prediction only, list 1 prediction only, or bi -prediction using both list 0 and list 1 prediction.

8.4.1 Derivation process for motion vector components and reference picture indices

[Ed. Note: Perhaps this should be divided into separate sections for P and B slices. And perhaps all of the detail doesn't belong here, but in other sections.]

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The inter prediction process for each macroblock is specified by the syntax elements mb_type and, if present, sub_mb_type [i], with i indicating the sub -macroblock index.

Further, the inter prediction process for each macroblock is specified by several syntax elements, refere nce picture index for list 0 prediction ref_idx_l0 [i] and reference picture index for list 1 prediction ref_idx_l1 [i], with the macroblock type being given by the slice_type dependent value of mb_type and i being specified by num_mb_part(mb_type) in subclause 7.4.5.1.

Further, the inter prediction process for each macroblock is specified by the syntax elements motion vector difference for list 0 prediction mvd_l0[i][j][k] and motion vector difference for list 1 predic tion mvd_l1[i][j][k] with i being specified by num_mb_part(mb_type) in subclause 7.4.5.1, j being the sub -macroblock index in the 8x8 macroblock partition and is equal to 0 if the 8x8 partition is not sub -divided, and k equals to 0 corresponds to the x -component of the motion vector difference and k equals to 1 corresponds to the y -component of the motion vector difference.

MvL0[i][j][k] and MvL1[i][j][k] are the motion vectors used for inter prediction of the macroblock, for the list 0 and list 1 predictors, respectively. MvpL0[i][j][k] and MvpL1[i][j][k] are the motion vector predictors formed for the macroblock, for the list 0 and list 1 predictors, respectively. If list 0 prediction is not use d for the macroblock partition, MvL0[i][j][k] is set to zero. Otherwise, MvL0[i][j][k] is calculated by adding the motion vector predictor for the macroblock partition or sub -macroblock partition to mvd_l0[i][j][k]. For B slices, if list 1 prediction is not used for the macroblock partition, MvL1[i][j][k] is set to zero. Otherwise, MvL1[i][j][k] is calculated by

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

adding the motion vector predictor for the macroblock partition or sub -macroblock partition to mvd_l1[i][j][k].
MvL0[i][j][k] = MvpL0[i][j][k] + mvd_l0[i][j][k]

MvL1[i][j][k] = MvpL1[i][j][k] + mvd_l1[i][j][k]

When decoding a slice, it is assumed that for all neighbouring macroblocks, the syntax elements mb_type, RefIdxL0 [i], RefIdxL1[i], MvL0[i][j][k], and MvL1[i][j][k] ref_idx_l0[i], ref_idx_l1[i], mvd_l0[i][j][k], mvd_l1[i][j][k] are stored as necessary to calculate the luma motion vector prediction.

RefIdxL0[i] and RefIdxL1[i] are the reference picture indices used for inter prediction for the macroblock partition, for the list 0 and list 1 predictors, respectively. If list 0 prediction is not used for the macroblock partition , RefIdxL0[i] is set to zero. If the ref_idx_l0[i] field is present, RefIdxL0[i] is equal to ref_idx_l0[i]. If the ref_idx_l0[i] field is not present because num_ref_idx_l0_active_minus1 is equal to 0, RefIdxL0[i] is equal to 0. For skipped macroblocks in P or SP slices, RefIdxL0[i] is derived as described in subclause 8.4.1.4.2.2. In B slices, if list 1 prediction is not used for the macroblock partition, RefIdxL1[i] is set to zero. I f the ref_idx_l1[i] field is present, RefIdxL1[i] is equal to ref_idx_l1[i]. If the ref_idx_l1[i] field is not present because num_ref_idx_l1_active_minus1 is equal to 0, RefIdxL1[i] is equal to 0. For skipped macroblocks in B slices or direct macroblocks or macroblock partitions, RefIdxL0[i] RefIdxL1[i] are derived using one of two methods. If direct_ spatial_mv_pred_flag is equal to one, the motion vector prediction is formed using the spatial method, as defined in subclause 8.4.1.4.2.2. If direct_spatial_mv_pred_flag is equal to zero, the motion vector prediction is formed using the temporal method, as defined in subclause 8.4.1.4.2.3.

For decoding future B slices in decoding order, when the macroblock is part of a slice which is part of a picture "used for reference" in the decoded picture buffer, the syntax elements mb_type, ref_idx_l0 [i], ref_idx_l1[i], mvd_l0[i][j][k], and mvd_l1[i][j][k] are stored together with the decoded pictures. If list 0 prediction is used for the macroblock partition or sub -macroblock partition, MvL0[i][j][k] and RefIdxL0[i] are stored. If list 0 prediction is not used for the macroblock partition or sub -macroblock partition but list 1 prediction is used, MvL1[i][j][k] and RefIdxL1[i] are stored. If neither list 0 or list 1 prediction is used, i.e. for I and SI macroblock types, the value 0 is stored for both the motion vector and the reference index. [Ed. Note: Should this be described here, or in subclause 8.4.1.4.2.3 ?] When direct_temporal_constrained_flag is equal to 1, for each 8x8 sub-macroblock, only the motion vectors of the corner 4x4 blocks MvL0[i][j][k] and MvL1[i][j][k] need to be stored, as described in subclause 8.4.1.4.2.3.

This paragraph specifies how the variables RefIdxL0 [i], RefIdxL1[i], MvL0[i][j][k], and MvL1[i][j][k] are obtained from the syntax elements mb_type, ref_idx_l0 [i], ref_idx_l1[i], mvd_l0[i][j][k], and mvd_l1[i][j][k] in the current and in prior decoded macroblocks in decoding order.

The calculation of motion vector components is done separately for the list 0 and list 1 predictors, if used, and consists of the following steps

- Determination of the neighbouring luma blocks with associated luma motion vectors
- Determination of the values of the luma motion vectors in the neighbouring luma blocks dependent on ref_idx_l0 and ref_idx_l1, etc
- Determination of the luma motion vector prediction method depending on the macroblock partition
- Calculation of luma motion vector components from predictors and differential vectors
- Calculation of the chroma motion vector components

8.4.1.1 Derivation process for the neighbouring blocks for motion vector and reference index prediction

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

No motion vector component prediction takes place across macroblock boundaries of macroblocks that do not belong to the same slice. For the purpose of motion vector component prediction, macroblocks that do not belong to the same slice are treated as outside the picture.

The prediction of motion vector components, MvpL0[i][j][k] and MvpL0[i][j][k] , for a luma block E is calculated based on the motion vectors, MvL0[i][j][k] and MvL1[i][j][k], and reference picture indices, RefIdxL0[i] and RefIdxL0[i], of neighbouring blocks A, B, C, and D as shown in Figure 8-7.

A The block containing the sample to the left of the upper left sample in E

B The block containing the sample just above the upper left sample in E

C The block containing the sample above and to the right of the upper right sample in E

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

D The block containing the sample above and to the left of the upper left sample in E

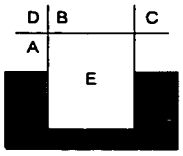

Figure 8-7 – Determination of the neighbouring luma blocks and associated motion vectors

The motion vector components of blocks A, B, C, and D are the input motion vector components for the prediction of the motion vector component of the current block E, unless they are modified by the rules in subclaus e 8.4.1.2.

[Ed. Note: Need a precise definition of the neighboring macroblocks in MB -AFF case. Some of the figures in VCEG-O37 might help.]

8.4.1.2 Derivation process for the luma motion vector predictors in the neighbouring blocks

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

8.4.1.2.1 Derivation process for the luma motion vector predictors in the neighbouring blocks in P and SP slices

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The following rules determine the predicted motion vector value resulting from the median prediction process f or block E:

- If block C is outside the current picture or slice or is not available due to the decoding order within a macroblock as specified in **Error! Reference source not found.**, its motion vector and reference picture index shall be considered equal to the motion vector and reference picture index for block D.
- If blocks B, C, and D are all outside the current picture or slice, their motion vector values and reference picture indices shall be considered as equal to the motion v ector value and reference picture index for block A.
- If any predictor not specified by the first or second rules above is coded as intra or is outside the current picture or slice, its motion vector value shall be considered equal to zero and it shall be considered to have a different reference picture than block E.
- If only one of the three blocks A, B and C has the same reference picture as block E, then the predicted motion vector for block E shall be equal to the motion vector of the A, B, or C block with the same reference picture as block E; otherwise, each component of the predicted motion vector value for block E shall be the median of the corresponding motion vector component values for blocks A, B, and C.

When mb_adaptive_frame_field_flag is equ al to 1, the following additional rules apply:

- If any of the blocks A, B, C, and D (indicated as X in the following) is coded in field decoding mode, such block is assigned, in addition to its own field MV, two frame MVs for the purpose of motion vector prediction. The first assigned frame MV is the field MV of the block with vertical motion vector component multiplied by 2. The second assigned frame MV is the field MV of the block in the same geometric location as block X in the second macroblock of the m acroblock pair with vertical motion vector component multiplied by 2. If any of the blocks A, B, C, and D (indicated as X in the following) is coded in frame mode, such block is assigned, in addition to its own frame MV, two field MVs for the purpose of motion vector prediction. The first assigned field MV is the frame MV of the block with vertical motion vector component divided by 2. The second assigned field MV is the frame MV of the

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

block in same geometric location as block X in the second macroblock of the macroblock pair with vertical motion vector component divided by 2.

- If any of the blocks A, B, C, and D (indicated as X in the following) is coded in field mode, such block is assigned, in addition to its own field reference number, two reference fram e numbers for the purpose of motion vector prediction. The first assigned reference frame number is the reference field number of the block divided by 2. The second assigned reference frame number is the reference field number, divided by 2, of the block in same geometric location as block X in the second macroblock of the macroblock pair. If any of the blocks A, B, C, and D (indicated as X in the following) is decoded in frame mode, such block is assigned, in addition to its own frame reference number, two reference field numbers for the purpose of motion vector prediction. The first assigned reference field number is the reference frame number of the block multiplied by 2. The second assigned reference field number is the reference frame number, multiplied by 2, of the block in same geometric location as block X in the second macroblock of the macroblock pair.
- If block E is in frame mode and block A, B, C or D is also in frame mode, the frame MVs and the reference frame number of block A, B, C or D shall be used in calculating the motion vector prediction of block E. If block A, B, C, or D is in field mode and its two assigned reference frame numbers are the same, its two assigned frame MVs shall be averaged for use in calculating the motion vector predictio nof block E. In this case, the assigned reference frame number shall be used as the reference frame number of the field mode block for use in calculating the motion vector prediction of block E. If block A, B, C, or D is decoded in field mode and its two assigned reference frame numbers are not the same, the particular block A, B, C, or D shall be treated as being out of picture/slice for the purpose of predicting the motion vectors of block E.
- If block E is in field mode and block A, B, C or D is also in field mode, the field MVs and the reference field number of block A, B, C or D shall be used in calculating the motion vector prediction of block E. If block A, B, C, or D is in frame mode and its two assigned reference field numbers are the same, its two assigned field MVs shall be averaged for use in calculating the motion vector prediction of block E. In this case, the assigned reference field number shall be used as the reference field number of the frame coded block for use in calculating the motion ve ctor prediction of block E. If block A, B, C, or D is in frame mode and its two assigned reference field numbers are not the same, the particular block A, B, C, or D shall be treated as being out of picture/slice for the purpose of predicting the motion v ectors of block E.

8.4.1.2.2 Derivation process for the luma motion vector predictors in the neighbouring blocks in B slices

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When decoding a B slice, the predictors of motion vector components for the list 0 and list 1 predictions are calculated as specified in subclause 8.4.1.2.1, with the following distinctions:

- the prediction for the motio n vector component in list i prediction which is referred to as MVC_i, where i = 0 or 1, is calculated only from neighbouring blocks A, B, C, and D that use reference pictures in the same temporal direction as the reference picture referred to by MV_i. If a neighbouring block does not have a motion vector referring to a reference picture in the same temporal direction, both components of the motion vector predictor for that block are set to zero and the neighbouring block shall be considered as belonging to a *different reference picture* for purposes of computing the median prediction of subclause 8.4.1.2.1.
- if a neighbouring block has two motion vectors both using the same reference picture as the reference picture associated with MV_i, then the list 0 motion vector from that block is used as a prediction. Otherwise, if a neighbouring block has both motion vectors using a reference picture in the same temporal direction as the reference picture associated with MV_i but they point to di fferent reference pictures, then the motion vector with the associated temporally closest reference picture is used.
- reconstructed motion vectors in direct mode neighbouring blocks, MvL0[i][j][k] and MvL1[i][j][k], shall be used as predictions for the current block motion vectors.
  - If a direct mode neighbouring block has two motion vectors, then this block is treated as if it were a bi - predictive neighbouring block.

If a direct mode neighbouring block has only one motion vector, then this blo ck is considered as a list 0 or list 1 block. (This occurs only when spatial direct mode is used.)

  - if both the list 0 and list 1 reference pictures are in the same temporal direction from the current picture and both are short term reference pictures, then the following process is followed for forming the predictor for the list 1 motion vector MV_{1_n} by scaling the list 0 motion vector, MV_0.

Formatted: Indent: Left: 0.25", Bulleted + Level: 1 + Aligned at: 0" + Tab after: 0.25" + Indent at: 0.25", Tabs: 0.5", List tab + Not at 0.25"

Formatted: Indent: Left: 0.25", Bulleted + Level: 1 + Aligned at: 0" + Tab after: 0.25" + Indent at: 0.25", Tabs: 0.5", List tab + Not at 0.25"

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- The motion vector predictor for motion vector MV_1 is the scaled motion vector (smv), which is calculated from the motion vector MV_0 as:

  $Z = (TD_1 \times 256) / TD_0 \qquad smv = (Z \times MV_0 + 128) >> 8$

- where TD_0 is the DiffPicOrderCount from the current picture to the reference picture indicated by ref_idx_l0, i.e. DiffPicOrderCount(current_pic, ref_idx_l0), and TD_1 is the DiffPicOrderCount from the current picture to the reference picture indicated by ref_idx_l1, DiffPicOrderCount(current_pic, ref_idx_l1).

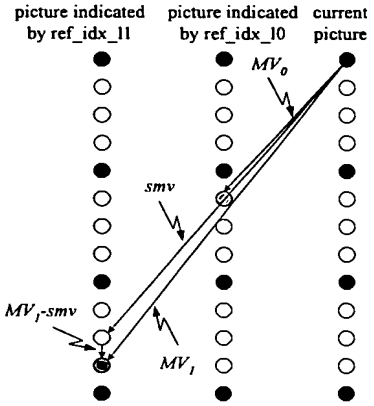

Figure 8-8 – Differential motion vector decoding with scaled motion vector

8.4.1.3 Derivation process for the luma motion vector prediction method

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

With exception of the 16x8 and 8x16 block shapes, "median prediction" (see subclause 8.4.1.3.1) is used. In case the macroblock may be classified to have directional segmentation the prediction is specified in subclause. The motion vector for a Skip mode macroblock shall be obtained as described in subclause 8.4.1.4.

8.4.1.3.1 Decoding process for median luma motion vector prediction

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Specify median prediction.

The reference picture index is given by ref_idx_l0 and ref_idx_l1.

8.4.1.3.2 Decoding process for directional segmentation luma motion vector prediction

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

If the macroblock where the block to be predicted is coded in 16x8 or 8x16 mode, the prediction is generated as follows (refer to Figure 8-9 and the definitions of A, B, C, E above):

a) Motion vector block size 8x16:

   1) Left block: A is used as prediction if it has the same reference picture as E, otherwise "median prediction" is used

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

2) Right block: C is used as prediction if it has the same reference picture as E, otherwise "median prediction" is used

b) Motion vector block size 16x8:

1) Upper block: B is used as prediction if it has the same reference picture as E, otherwise "median prediction" is used

2) Lower block: A is used as prediction if it has the same reference picture as E, otherwise "median prediction" is used

If the indicated prediction block is outside the picture, the same substitution rules are applied as in the case of me dian prediction.

For field-coded macroblocks, the directional segmentation follow the same conventions as the above, but the neighbouring blocks are constructed by using the rules mentioned in subclause 8.4.1.1??? [Ed. Note: ??].

The following additional considerations apply in the case of macroblock-adaptive frame/field coding When mb_field_decoding_flag == 1, block A, B, or C may be in different frame/field mode than block E. The reference picture of A, B or C used in determining if the individual block A, B or C is used as prediction or if median prediction is used is defined as follows.

1. Block E is in frame mode -- if any of the blocks A, B or C is in field mode and its two assigned reference frame numbers are the same, its two assigned frame motion vec tors are averaged for use in the motion vector prediction of block E. If the two assigned reference frame numbers are not the same, the block A, B or C is considered outside the picture.
2. Block E is in field mode -- if any of the blocks A, B or C is in fram e mode and its two assigned reference field numbers are the same, its two assigned field motion vectors are averaged for use in the motion vector prediction of block E. If the two assigned reference field numbers are not the same, the block A, B or C is co nsidered outside the picture.

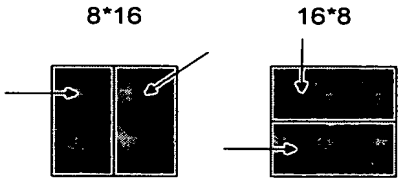

Figure 8-9 – Directional segmentation prediction

8.4.1.4 Derivation process for luma motion vectors for skipped and Direct prediction macroblocks

Input to this process is/are ??? [Ed.Note: speci fy input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

8.4.1.4.1 Derivation process for luma motion vectors for skipped macroblocks in P and SP slices

Input to this process is/are ??? [Ed.Note: specify input to this pro cess]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When decoding a P or SP slice, the motion vector for a skipped macroblock shall be equal to the prediction of the motion vector that would be computed for this macroblock whe n decoding a macroblock coded as Pred_L0_16x16 macroblock type, MvL0[i][j][k] = MvpL0[i][j][k], except if any of the conditions below hold. In that case, a motion vector with both components being equal to 0, MvL0[i][j][k] = 0, shall be used instead:

a) The macroblock immediately above or to the left is not available (that is, is outside of the picture or belongs to a different slice)

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

b) Either one of the motion vectors applying to samples A or B (as described in subclause 8.4.1.1 uses picture with ref_idx_l0 == 0 as reference and has zero magnitude.

The reference picture index is given by ref_idx_l0 and ref_idx_l1.

8.4.1.4.2 Derivation process for luma motion vectors for skipped, Direct_16x16 and Direct_8x8 in B slices

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When decoding a B slice, if the macroblock is skipped or coded as Direct_16x16 macroblock type or the sub -macroblock is coded as Direct_8x8 sub-macroblock type, the motion vectors for the corresponding partitions are derived in direct motion vector prediction mode. In direct motion vector prediction mode, the motion vector component differences are both set to zero; hence the motion vector components used for the inter prediction process are equal to the motion vector predictor components, MvL0[i][j][k] = MvpL0[i][j][k] and MvL1[i][j][k] = MvpL1[i][j][k]. Reference picture indices are also computed using the direct reference picture index prediction. When direct_spatial_mv_pred_flag is equal to 1, the spatial direct motion vector and reference picture index prediction mode specified in subclause 8.4.1.4.2.2 is used.

When direct_spatial_mv_pred_flag is equal to 0, the temporal direct motion vector and reference picture index prediction mode specified in subclause 8.4.1.4.2.3 is used, which utilizes the information stored in the co -located macroblock specified in subclause 8.4.1.4.2.1.

8.4.1.4.2.1 Derivation process for the co-located macroblock

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify ou tput of this process]

[Ed. Note: Limin's text needs harmonization: For a macroblock in B slice, the co -located macroblock is defined as the macroblock resided in the same geometric location of the first reference picture in list 1. A macroblock and its co -located shall have the same horizontal coordinates. The vertical coordinates may be different, depending upon whether macroblocks reside in frame or field picture. Let $y_{current}$ and $y_{co\text{-}located}$ be the vertical coordinates of a macroblock and its co-located macroblock. If the current macroblock and its co -located macroblock both reside in frame picture or field picture, $y_{co\text{-}located} = y_{current}$. If the current macroblock is in frame picture and its co -located macroblock in field picture, $y_{co\text{-}located} = y_{current} / 2$. If the current macroblock is in field picture and its col -located macrblock in frame picture, $y_{co\text{-}located} = 2 \times y_{current}$.] [Ed. Note: The harmonization of this section should be done in conjunction with more precise macroblock numbering in MB -AFF in section 8.3.7.]

[Ed. Note: Jill, Alexis, Limin ... please fill in] [Ed. Note: Jill's note – is this good enough?][Ed. Note: Alexis – It is probably necessary to make clarification here for cases 2 and 3 for interlace. Possibly these cases could also be moved here][Ed. Note: Jill – Also need to distinguish between frame pictures in MB -AFF mode and those not in MB -AFF mode, since macroblock numbering is different in those two cases. Can Limin trying writing these?]

8.4.1.4.2.2 Derivation process for spatial direct luma mo tion vector and reference picture index prediction mode

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When direct_spatial_mv_pred_flag is equal to 1, spatial direct mode is used to derive the luma motion vectors and reference picture indices for skipped macroblocks and macroblocks with mb_type Direct_16x16 or macroblock partitions with sub_mb_type Direct_8x8.

The first step in the Spatial direct luma moti on vector and reference picture index prediction mode is the determination of the reference picture index for each list (list 0 and list 1), RefIdxL0 [i] and RefIdxL0[i]. The same process is used for macroblocks coded using the Direct_16x16 macroblock type, and sub-macroblocks coded using the Direct_8x8 sub - macroblock type.

The reference picture indices for the neighbouring blocks A, B, C, and D within the current slice for the current luma macroblock E, for both Direct_16x16 macroblock and Direct_8x8 sub-macroblock types, as described in subclause 8.4.1.1 and shown in Figure 8-7, shall be used to determine the reference picture index for each list. As in 8.4.1.1, the reference index of block D is o nly used if block C is not available in the current slice. The reference picture index for each list (list 0 and list 1) shall be the minimum reference picture index among the reference picture indices used from the same list for the prediction or bi -prediction of the neighbouring blocks. If no neighbouring blocks are present within the current slice that use prediction from the same list, either for prediction or bi -prediction, the reference index for that list shall be inferred as not existing.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

If the reference index exists for either list, decision of the associated motion vector values for that list for each 4x4 block of the current macroblock depends on the coded parameters of the co-located 4x4 blocks in the first picture in list 1, if both pictures have been coded using the same picture type (frame or field). If the current picture is coded in field mode and the list 1 picture in frame mode, only the same parity lines and their associated motion parameters are considered. Otherwise, if current picture is in frame mode and the first list 1 picture in field mode, then the corresponding frame mode picture containing the first list 1 picture is considered, if such exists. If the reference index of either list for the current block is zero, the associated list 1 picture is a short-term picture, and if all lines of the co-located 4x4 block exist and were predicted using list 0 prediction, reference picture index 0 and motion vector components in the range of -1 to 1 in sub-pixel units, inclusive, then the motion vector for this 4x4 block is set to (0, 0). Otherwise, the associated candidate motion vector for each list shall be obtained, using the 16x16 block motion vector prediction, as described in subclause 8.4.1.2.2 by using the reference picture index of each list.

If both candidate reference picture indices exist, then the block is predicted as a bi-prediction block using the corresponding reference picture index and associated motion vector for each list. Otherwise, if a reference picture index exists for only one of the two lists, the block shall be predicted by single-list prediction using the reference picture index and associated motion vector for the existing list. Finally, if neither reference picture index exists, bi-prediction shall be used with reference picture index zero and associated motion vector (0, 0) for both lists.

8.4.1.4.2.3 Derivation process for temporal direct luma motion vector and reference picture index prediction mode

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When direct_spatial_mv_pred_flag is equal to 0, temporal direct mode is used to derive the luma motion vectors and reference picture indices for skipped macroblocks and macroblocks with mbtype Direct_16x16 or macroblock partitions with sub_mbtype Direct_8x8.

[Ed. Note: added the following paragraph and Figure from Lowell. Needs to be incorporated ...]

In the temporal direct mode, if the entire macroblock is skipped or coded using the Direct_16x16 macroblock type, then the same macroblock structure [Ed. Note: is "structure" defined? Should a different term be used?] as for the co-located macroblock defined in 8.4.1.4.2.1 is used. If direct_temporal_constrained_flag is equal to 0, then the same 8x8 sub-macroblock partitioning as in the co-located sub-macroblock is used, otherwise the 8x8 sub-macroblocks are constrained to not be subdivided. That is, if direct_temporal_constrained_flag is set to 0, then for each block of the current sub-macroblock, the list 0 and list 1 motion vectors are computed as scaled versions of the stored motion vector of the colocated block in the list 1 reference picture as described below. If direct_temporal_constrained_flag is set to 1, then for each 8x8 sub-macroblock of the current macroblock, only the motion vectors of the corner 4x4 block of the 8x8 sub-macroblock are stored.

[Ed. Note: The corner 4x4 block of an 8x8 submacroblock is defined to be the 4x4 block with the same relative decode number (see **Error! Reference source not found.**) as the 8x8 submacroblock in which it is contained (see Figure 8-10). For example, the lower-left 4x4 block within the lower-left 8x8 submacroblock is its corner 4x4 block. As a further example, the motion vectors of the lower-right 8x8 submacroblock are computed as scaled versions of the list 0 motion vectors of the lower-right 4x4 block that is contained within the co-located macroblock's lower-right 8x8 submacroblock.]

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

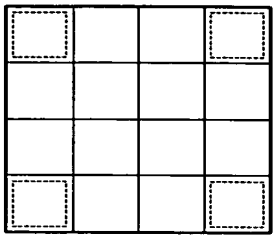

Figure 8-10 – Double-dashed border to indicate each 'corner' 4x4 block of each co-located 8x8 submacroblock, from which each temporal direct-mode 8x8 sub-macroblock derives its motion vectors if direct_temporal_constrained_flag is set to 1.

In temporal direct mode, the same frame or field decoding mode as for the co-located macroblock of the first picture (the picture at index 0) in list 1 is used. For each block of the current macroblock, the list 0 and list 1 motion vectors are computed as scaled versions of the stored motion vector of the co-located block in the list 1 reference picture as described below.

The list 0 reference picture for the direct mode current block is the same as the stored reference picture used for the co-located block. When temporal direct mode is used, the motion vector, frame or field decoding mode, and reference picture index must be stored for each sub macrobloc k. If a list 0 prediction is used, either alone or as part of bi-prediction, the list 0 motion vector and reference picture index are stored. If a list 0 prediction is not used, and a list 1 prediction is used, the list 1 motion vector and reference pict ure index are stored. If neither a list 0 or list 1 prediction is used, as is the case for an intra-coded block, a zero motion vector and ref_idx 0 of list 0 are stored. The list 0 and list 1 motion vectors for direct mode blocks are calculated differentl y depending on whether pic_struct and the reference indicate fields or frames. [Ed. Note: This was covered already in 8.4.1.]

If the co-located block is in a long-term reference picture or if the co-located block refers to a long-term picture, the list 0 and list 1 motion vectors for the direct mode current block are calculated by:

$$MV_0 = MV$$

$$MV_1 = 0$$

It is forbidden for direct mode to be used if the stored reference picture of the co-located block is not in the current picture's reference picture list.

[Ed. Note: Limin had provided some alternate text for the 3 cases that hasn't been integrated here.] [Ed. Note: I don't like using the word "forbidden". Should rephrase to something like "direct mode shall not be used...".]With possible adaptive switching of frame/field coding at the picture level and/or at the macroblock level, the current block or its co-located block can be coded in either frame structure or field structure. Hence, there are three cases that must be considered based on possible combinations of frame or field coding for a pair of a macroblocks in the current B slice and its co-located macroblock. Calculations of the two motion vectors in direct mode are slightly different for the three cases.

Case 1: The current macroblock and its co-located macroblock are either both in frame mode or both in field mode, as shown in Figure 8-11 and Figure 8-12. The list 0 reference for each block within the current macroblock is the same as the stored reference of the co-located block. Two motion vectors (MV_0, MV_1) are calculated by:

$$Z = (TD_B \times 256) / TD_D \qquad MV_0 = (Z \times MV + 128) >> 8$$

$$W = Z - 256 \qquad MV_1 = (W \times MV + 128) >> 8$$

where MV is the stored motion vector of the co-located block in list 1 reference picture. TD_B is the DiffPicOrderCount between the current picture and the list 0 reference picture, DiffPicOrderCount(ref_idx_l0, current_pic) and TD_D is the

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

DiffPicOrderCount between the list 1 reference picture and the list 0 reference picture (see **Error! Reference source not found.**), [Ed. Note: missing cross-reference]DiffPicOrderCount(ref_idx_l0, ref_idx_l1).

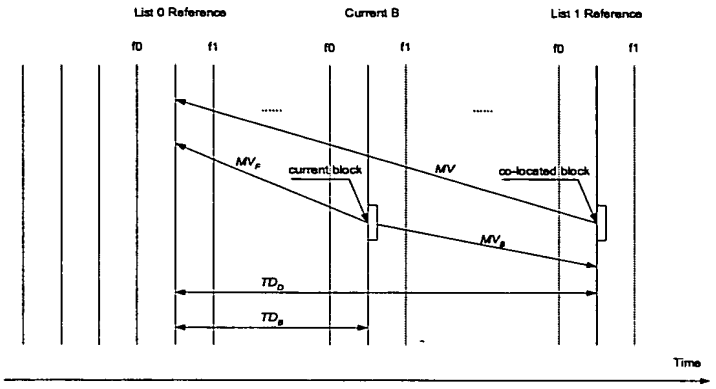

Figure 8-11 – Both the current block and its co-located block in the list 1 reference picture are in frame mode (f0 and f1 indicate the corresponding fields)

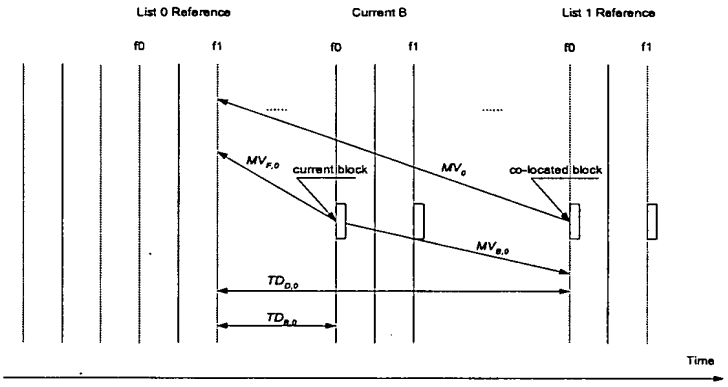

Figure 8-12 – Both the current macroblock and its co-located macroblock in the temporally subsequent picture are in field mode.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

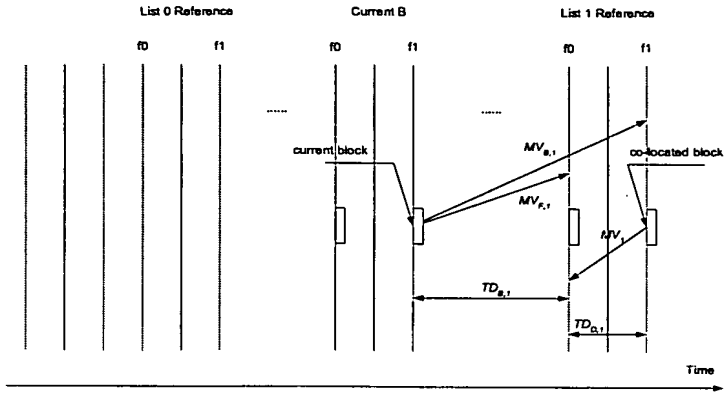

Figure 8-13 – The list 0 motion vector of the co-located block in field 1 of the list 1 reference frame may point to field 0 of the same frame.

Case 2: The current block is in field mode and its co-located block is in frame mode, as shown in Figure 8-14. Let $y_{current}$ and $y_{co\text{-}located}$ be the vertical indices of the blocks in the current macroblock within the field and in its co-located macroblock within the frame respectively. Then, $y_{co\text{-}located} = 2 \times y_{current}$. The blocks in the current macroblock and its co-located macroblock have the same horizontal indices. If the reference pictures are in their default order, and have not been reordered, the list 0 reference field is the same-parity field of the list 0 frame, and the list 1 reference field will be the same-parity field of the list 1 reference frame as shown in Figure 8-15.

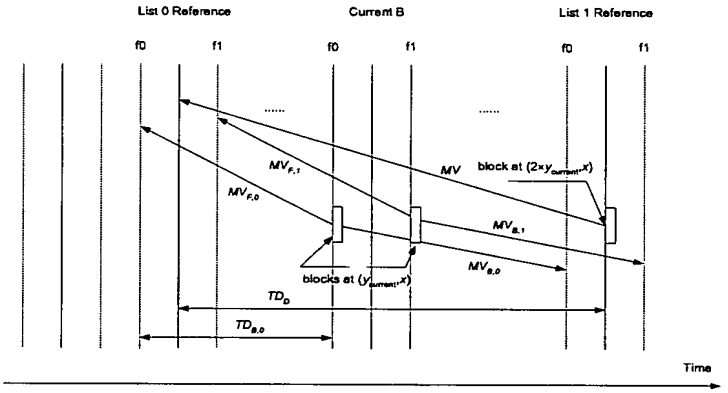

Figure 8-14 – The current macroblock is in field mode and its co-located macroblock in the list 1 reference picture is in frame mode

The motion vectors of a direct mode block are calculated from the list 0 motion vector of the co-located block in the list1 reference frame as follows:

$Z = (TD_B \times 256) / TD_D$ $\quad MV_0 = (Z \times MV + 128) >> 8$

$W = Z - 256$ $\quad MV_1 = (W \times MV + 128) >> 8$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

where MV is the list 0 motion vector of the co-located block in the list 1 reference picture with the vertical component shifted right by 1, because of the difference in vertical distance between fields and frames. TD_B is the DiffPicOrderCount between the current field and the list 0 reference frame, DiffPicOrderCount(ref_idx_l0, current_field) and TD_D is the DiffPicOrderCount between the list 1 reference frame and the list 0 reference field (see **Error! Reference source not found.**), [Ed. Note: missing cross-reference]DiffPicOrderCount(ref_idx_l0, ref_idx_l1).

Case 3: The current macroblock is in frame mode while its co-located macroblock in the list 1 reference picture is in field mode, as shown in Figure 8-15. Let $y_{current}$ and $y_{co\text{-}located}$ be the vertical indices of the blocks in the current macroblock within the frame and in its co-located macroblock within the field respectively. Then, $y_{co\text{-}located} = y_{current} / 2$. The blocks in the current macroblock and in its co-located macroblock have the same horizontal indices. The two fields of the co-located block in the list 1 reference may be coded in different modes. The default reference picture ordering is shown in Figure 8-15 [Ed. Note: I'm not too confident about this last sentence.].

The motion vectors of the direct mode block are calculated as follows:

$$Z = TD_B \times 256 / TD_D \qquad MV_0 = (Z \times MV + 128) >> 8$$

$$W = Z - 256 \qquad MV_1 = -(W \times MV + 128) >> 8$$

where MV is the list 0 motion vector of the co-located block in the list 1 reference picture with its vertical component shifted left by 1, because of the difference in vertical distance between fields and frames

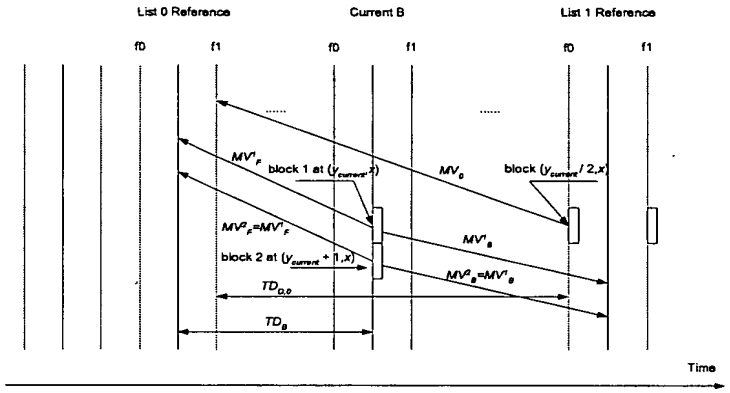

Figure 8-15 – The current macroblock is in frame mode while its co-located macroblock in the list 1 reference picture is in field mode.

8.4.1.5 Calculation of the resulting luma motion vector

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

[Ed. Note: This whole section's concepts are already addressed in other sections 8.4.1 and 8.3.7, and sbouldn't really be in both places. Which place should they be?]

For skipped macroblocks and for macroblocks coded in Direct_16x16 macroblock type or for sub-macroblocks coded in Direct_8x8 sub-macroblock type, the differential motion vector components are set to 0, so the motion vector used for inter prediction is equal to the motion vector predictor, MvL0[i][j][k] = MvpL0[i][j][k] and MvL1[i][j][k] = MvpL1[i][j][k]. [Ed. Note: This concept is already addressed in 8.4.1, and shouldn't really be in both places. Which place should it be?]

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

When decoding P and SP slices, the resulting motion vector components are obtained by adding the prediction of the motion vector components to the differential motion vector components.

MvL0[i][j][k] = MvpL0[i][j][k] + mvd_l0[i][j][k]

MvL1[i][j][k] = MvpL1[i][j][k] + mvd_l1[i][j][k]

[Ed. Note: This concept is already addressed in 8.4.1, a nd shouldn't really be in both places. Which place should it be?]

When decoding B slices, the motion vector predictor is formed using direct mode, using spatial direct mode if direct_spatial_mv_pred_flag equals 0 and temporal direct mode is direct_spatial _mv_pred_flag equals 1. No differential motion vector is decoded, so MvL0[i][j][k] = MvpL0[i][j][k] and MvL1[i][j][k] = MvpL1[i][j][k].

[Ed. Note: I think this whole paragraph was covered in 8.3.7]

8.4.1.6 [Ed, Note: This whole paragraph is covered in 8.4.1]Derivation process for chroma motion vectors

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Chroma motion vectors are derived from the luma motion vectors. Since the accuracy of luma motion vectors is 1/4 pel and chroma has half resolution compared to luma, the accuracy of chroma motion vectors is 1/8 pel. Due to the lower resolution of the chroma array relative to the luma array, a chroma motion vector applies to 1/4 as many samples as the luma motion vector.

NOTE - For example if the luma vector applies to 8x16 luma samples, the corresponding chroma vector applies to 4x8 chroma samples and if the luma vector applies to 4x4 luma samples, the corresponding chroma vector applies to 2x2 chroma samples.

In frame coding mode, the horizontal and vertical components of the chroma motion vector are obtained by dividing the corresponding components of luma motion vector by 2.

In field decoding mode, the horizontal component of the chroma motion vector is obtained by dividing the horizontal component of the corresponding luma motion vector by 2. The vertical component of the chroma motion vector is dependent on the parities of the current fie ld and the reference field where the corresponding luma motion vector is defined. The vertical component of chroma motion vector (MVCy) is calculated from the vertical component of the luma motion vector (MVy) according to the Table 8-8. Here, the units of MVy and MVCy represent full-sample vertical displacement units in luma and chroma respectively.

Table 8-8 – Calculation of vertical component of chroma vector in field coding mode

Parity conditions		Vertical component of chroma motion vector
Reference field	Current field	
Top field	Bottom field	$MVCy = \frac{MVy}{2} + \frac{1}{4}$
Bottom field	Top field	$MVCy = \frac{MVy}{2} - \frac{1}{4}$
Otherwise		$MVCy = \frac{MVy}{2}$

MVy: Vertical component of luma motion vector

MVCy: Vertical component of chroma motion vector

NOTE – Chroma motion vectors are exactly parallel to the corresponding luma motion vectors in both frame coding mode and field coding mode. In field coding mode, the locations of chroma samples in relative to luma samples in a top field is different from those in bottom field (see subclause 6.2 and Figure 6-2). From this reason, MVCy is shifted up/down by 1/4 pel from the MVy / 2 when vectors are defined between fields with different parity.

8.4.2 Decoding process for inter prediction samples

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Given the motion vectors, the prediction of the samples for the macroblock or its partitions is calculated. If weighted prediction is used, a weighting factor and/or offset are applied to the sample prediction.

If the mbtype of the macroblock or macroblock partition is Pred_L0 or Pred_L1, or for skippe d macroblocks in P or SP slices, a single predictor is formed. If the mbtype of the macroblock or macroblock partition is BiPred or Direct, or for skipped macroblocks in B slices, two predictors are formed, which are combined into a single predictor.

To obtain the prediction of the macroblock or partition sample values, the following steps are conducted

- reference picture selection
- interpolation process for fractional sample motion vectors to form a sample predictor
- possible weighting or combining of samp le predictors to form the final sample predictor

8.4.2.1 Reference picture selection process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

When mb_adaptive_fram e_field_flag is equal to 0, the reference picture selection is described in subclauses ??? [Ed. Note: ??]. If field_pic_flag indicates a field picture, only the reference field indicated by the ref_idx_l0 or ref_idx_l1 is used in the inter prediction. The motion vectors to be used are described in subclauses 7.3.5.1-7.3.5.2, 7.4.5, 7.4.6.1??? [Ed. Note: ??] and **Error! Reference source not found.** [Ed. Note: ??].

If the current macroblock pair is in frame decoding mode and one or more neighbouring blocks is in field mode, the reference frame index used in MV prediction from the field coded neighbours is obtained by dividing the reference field list index by 2 and truncation of any fractional result toward zero to obtain the effective frame index for prediction. If the macroblock pair is in frame mode, the reference field number for any frame coded neighbour is obtained by multiplying the reference frame index by 2. [Ed.Note: Some wording problems here] [Ed.Note: Limin: This paragraph is not correct, and does not belong here. For ref picture number selection for PMV, refer top 8.4.1.2.1.]

When a macroblock pair is in field mode, each field macroblock ma y refer to any (top or bottom) field in the decoded picture buffer.

[Ed.Note: Needs much more details]

8.4.2.2 Fractional sample interpolation process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed. Note: specify output of this process]

Quarter-sample interpolation with a 6-tap filter is applied to the luma samples in the block as described in subclauses 8.4.2.2.1. The interpolation process for fractional chroma samples in both cases is described in subclause 8.4.2.2.2.

If a sample referred to in the interpolation process (necessarily integer accuracy) is outside of the reference picture it shall be replaced by the nearest sample belonging to the picture (an edge or corner sample). Motion vectors are allowed to point to samples outside the reference picture. If a sample outside the reference picture is referred to in the prediction process, the nearest sample belonging to the picture (an edge or c orner sample) shall be used.

8.4.2.2.1 Luma sample interpolation process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

In Figure 8-16, the positions labelled with upper-case letters within shaded blocks represent reference picture samples at integer sample positions, and the positions labelled with lower -case letters within un-shaded blocks represent reference picture samples at fractional sample positions.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

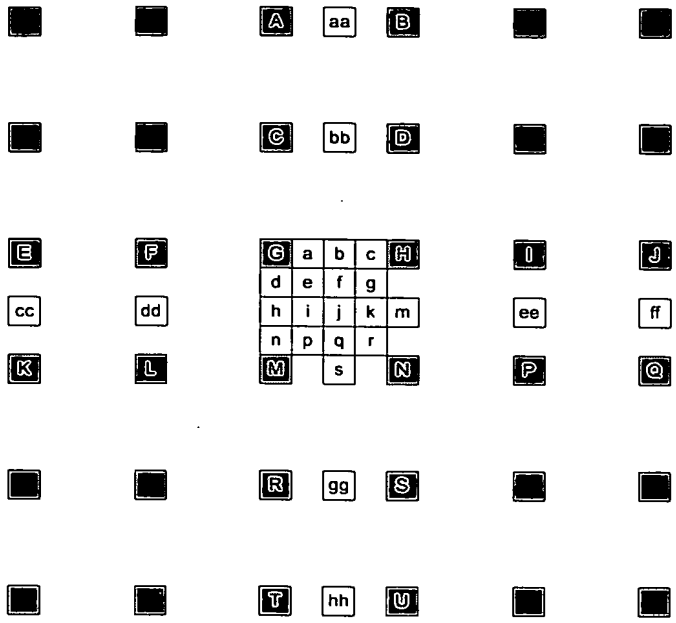

Figure 8-16 – Integer samples (shaded blocks with upper-case letters) and fractional sample positions (un-shaded blocks with lower-case letters) for quarter sample luma interpolation.

The luma prediction values at half sample positions shall be obtained by applying a 6 -tap filter with tap values (1, -5, 20, 20, -5, 1). The luma prediction values at quarter sample positions shall be obtained by averaging samples at integer and half sample positions. The process for each fractional position is described below.

- The samples at half sample positions labelled 'b' shall be obtained by first calculating intermediate values denoted as '*b*' by applying the 6-tap filter to the nearest integer position samples in the horizontal direction. The samples at half sample positions labelled 'h' shall be obtained by first calculating intermediate values denoted as '*h*' by applying the 6-tap filter to the nearest integer position samples in the vertical direction:

  b=(E-5F+20G+20H-5I+J),

  h=(A-5C+20G+20M-5R+T).

  The final prediction values shall be calculated using:

  b=Clip1((b+16)>>5),

  h= Clip1((h+16)>>5).

- The samples at half sample position labelled as 'j' shall be obtained by first calcul ating intermediate value denoted as '*j*' by applying the 6-tap filter to the intermediate values of the closest half sample positions in either the horizontal or vertical direction because these yield an equivalent result.

  j=*cc*-5*dd*+20h+20m-5*ee*+*ff*, or

  j=*aa*-5*bb*+20b+20s-5*gg*+*hh*,

  where intermediate values denoted as '*aa*', '*bb*', '*gg*', '*s*' and '*hh*' shall be obtained by applying the 6-tap filter horizontally in an equivalent manner to '*b*' and intermediate values denoted as '*cc*', '*dd*', '*ee*', '*m*' and '*ff*' shall be obtained by applying the 6-tap filter vertically in an equivalent manner to '*h*'. The final prediction value shall be calculated using: j=Clip1((j+512)>>10).

- The samples at quarter sample positions labelled as 'a', 'c', 'd', 'n', 'f', 'i', 'k' and 'q ' shall be obtained by averaging with truncation the two nearest samples at integer and half sample positions using:

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

a=(G+b)>>1, c=(H+b)>>1, d=(G+h)>>1, n=(M+h)>>1, f=(b+j)>>1, i=(h+j)>>1, k=(j+m)>>1 and q=(j+s)>>1.

- The samples at quarter sample positions labelled as 'e', 'g', 'p', and 'r' shall be obtained by averaging with truncation the two nearest samples at half sample positions in the diagonal direction using e=(b+h)>>1, g=(b+m)>>1, p=(h+s)>>1, and r=(m+s)>>1.

8.4.2.2.2 Chroma sample interpolation process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Inter chroma prediction values at fractional sample positions shall be obtained using:

$$v = ((8 - d_x) \cdot (8 - d_y) \cdot A + d_x \cdot (8 - d_y) \cdot B + (8 - d_x) \cdot d_y \cdot C + d_x \cdot d_y \cdot D + 32) >> 6 \qquad (8\text{-}32)$$

where A, B, C and D are the integer position reference picture samples surrounding the fractional sample location; d_x and d_y are the fractional parts of the sample position in units of one eighth samp le. The relationships between the variables in Equation 8-32 and reference picture positions are illustrated in Figure 8-17.

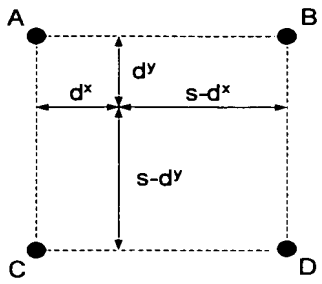

Figure 8-17 – Fractional sample position dependent variables in chroma interpolation and surrounding integer position samples A, B, C, and D. [Ed. Note: Edit to replace s with 8 and d^x and d^y with d_x and d_y]

8.4.2.3 Weighted sample prediction process

Input to this process is/are ??? [Ed.Note: specify inp ut to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

For P and SP slices, if weighted_pred_flag is equal to 0 the default weighted sample prediction process as described in subclause 8.4.2.3.1 is used for macroblocks or partitions coded using Pred_L0 and Pred_L1 prediction.

For P and SP slices, if weighted_pred_flag is equal to 1, explicit weighted prediction is applied to P and SP slices as described in subclause 8.4.2.3.2.

For B slices, if weighted_bipred_explicit flag is equal to 0 and weighted_bipred_implicit_flag is equal to 0, the default weighted sample prediction process as described in subclause 8.4.2.3.1 is used.

For B slices, if weighted_bipred_explicit flag is equal to 1, weighted sample prediction is used to form the final sample predictor, as described in subclause 8.4.2.3.2.

For B slices, if weighted_bipred_implicit_flag is equal to 1, the de fault weighted sample prediction process as described in subclause 8.4.2.3.1 is used for macroblocks or partitions coded using Pred_L0 and Pred_L1 prediction, and weighted sample prediction as described in subclause 8.4.2.3.2 is used for skipped macroblocks or macroblock or paritions coded using Bipred or Direct prediction.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

8.4.2.3.1 Default weighted sample prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

For macroblocks or partitions coded using Pred_L0 and Pred_L1 prediction, the default weighting applied to all interpolated luma and chroma samples is equal to 1.

For macroblocks or partitions coded using bi-prediction, including skipped macroblocks and direct mode macroblocks or partitions, if weighted_bipred_explicit_flag is equal to zero and weighted_bipred_implicit_flag is equal to zero, the two predictions are combined into a single predict or using the following formula.

$$P = (P_0 + P_1 + 1) >> 1$$

where

P_0 = list 0 reference prediction block [Ed. Note: Not a defined term. What does it mean?]

P_1 = list 1 reference prediction block

If either weighted_bipred_explicit_flag or weighted_bipred_imp licit_flag is equal to 1, a weighted prediction is formed as described in subclause 8.4.2.3.2.

8.4.2.3.2 Weighted sample prediction process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

In P slices when weighted_pred_flag is equal to 1, or in B slices, when weighted_bipred_explicit_flag is equal to one , weighted prediction is applied for all non-intra macroblocks and partitions, includin g those coded using Pred_L0, lPred_L1, Bipred, skipped and Direct prediction. When weighted_bipred_implicit_flag is equal to one, weighted prediction is applied to all bi-prediction macroblocks and partitions, including skipped macroblocks and those coded using Bipred, or Direct prediction.

For reference list 0 prediction, the luma prediction is generated as

$$P = \mathrm{Clip1}(((P_0 \cdot W_0 + 2^{LWD-1}) >> LWD) + O_0) \quad (8\text{-}33)$$

For reference list 1 prediction, the luma prediction block is generated as:

$$P = \mathrm{Clip1}(((P_1 \cdot W_1 + 2^{LWD-1}) >> LWD) + O_1) \quad (8\text{-}34)$$

where

P_0 = reference prediction block from list 0

P_1 = reference prediction block from list 1

LWD = luma_log_weight_denom

W_0 = luma_weight_l0[ref_idx_l0]

W_1 = luma_weight_l1[ref_idx_l1]

O_0 = luma_offset_l0[ref_idx _l0]

O_1 = luma_offset_l1[ref_idx_l1]

When bi-prediction is used, the luma prediction block is generated as:

$$P = \mathrm{Clip1}\ (((P_0\, W_0 + 2^{LWD-1}) >> LWD)\ + O_0 + ((P_1\, W_1 + 2^{LWD-1}) >> \mathrm{LWD}) + O_1 + 1) >> 1) \quad (8\text{-}35)$$

If weighted_bipred_implicit_flag is equal to one,

$LWD = 7$

$O0 = 0$

$O1 = 0$

$W0$ = *(128* DiffPicOrderCount(ref_idx_l1, current_pic) / DiffPicOrderCount (ref_idx_l1, ref_idx_l0) = W>>1 of subclause 8.4.1.2.2*

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$W1$ = (128* DiffPicOrderCount(current_pic,ref_idx_l0) / DiffPicOrderCount(ref_idx_l1 ,ref_idx_l0) = Z>>1 of subclause 8.4.1.2.2

except if DiffPicOrderCount(ref_idx_l1,ref_idx_l0) is equal to zero or if one or both reference pictures is a long term reference picture, in which case, $W_0 = W_1 = 128$.

Otherwise if weighted_bipred_explicit_flag is equal to one and use_implicit_weights_for_bipred_flag is equal to zero

LWD = luma_log_weight_denom

W_0 = luma_weight_l0[ref_idx_l0]

W_1 = luma_weight_l1 [ref_idx_l1]

O_0 = luma_offset_l0[ref_idx_l0]

O_1 = luma_offset_l1[ref_idx_l1]

For reference list 0 prediction, the chroma prediction block is generated as

$$P = \text{Clip1}(128 + (((CP_0 - 128) \cdot CW_0 + 2^{CWD-1}) >> CWD) + CO_0) \quad (8\text{-}36)$$

For reference list 1 prediction, the chroma prediction block is generated as:

$$P = \text{Clip1}(128 + (((CP_1 - 128) \cdot CW_1 + 2^{CWD-1}) >> CWD) + CO_1) \quad (8\text{-}37)$$

When bi-prediction is used, the chroma prediction block is generated as

$$P = \text{Clip1}(((((CP_0 - 128)\ CW_0 + 2^{CWD-1}) >> CWD) + CO_0 + (((CP_1 - 128)\ CW_1 + 2^{CWD-1}) >> CWD) + CO_1 + 1) >> 1) \quad (8\text{-}38)$$

where

j = 0 for Cb and 1 for Cr

CP_0 = chroma reference prediction block from list 0

CP_1 = chroma reference prediction block from list 1

If weighted_bipred_implicit_flag is equal to one,

$CWD = 7$

$CO0 = 0$

$CO1 = 0$

CW_0 = (128* DiffPicOrderCount(ref_idx_l1, current_pic) / DiffPicOrderCount (ref_idx_l1, ref_idx_l0) = W>>1 of subclause 8.4.1.2.2

CW_1 = (128* DiffPicOrderCount(current_pic,ref_idx_l0) / DiffPicOrderCount(ref_idx_ l1 ,ref_idx_l0) = Z>>1 of subclause 8.4.1.2.2

except if DiffPicOrderCount (ref_idx_l1, ref_idx_l0) is equal to zero or if one or both reference pictures is a long term reference, in which case, $CW_0 = CW_1 = 128$.

Otherwise if weighted_bipred_explicit_fla g is equal to one and use_implicit_weights_for_bipred_flag is equal to zero

CWD = chroma_log_weight_denom

CW_0 = chroma_weight_l0[ref_idx_l0][j]

CW_1 = chroma_weight_l1 [ref_idx_l1][j]

CO_0 = chroma_offset_l0[ref_idx _l0][j]

CO_1 = chroma_offset_l1[ref_idx_l1][j]

To limit the calculation to 16-bit precision, the following conditions shall be met:

$-128 \le W_0 \le 128$

$-128 \le W1 \le 128$

$-128 \le CW0 \le 128$

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$-128 \leq CW1 \leq 128$

8.5 Transform coefficient decoding process and picture construction process prior to deblocking filter process

Input to this process are mb_type, Intra16x16DCLevel (if available), Intra16x16ACLevel (if available), LumaLevel (if available), ChromaDCLevel, and ChromaACLevel. [Ed.Note: further specify the use of these variables.]

Output of this process are the residual samples of the macroblock.

This subclause specifies transform coefficient decoding and picture construction prior to the deblocking filter process.

8.5.1 Zig-zag scanning process and field scanning process

Input to this process is an 1-D array of levels.

Output of this process is a 2-D array of levels assigned to locations in the transform block.

[Ed.Note: we need to be more specific here. This is not easy ... esp. concerning Intra_16x16 ...]

The decoder maps the sequence of transform coefficient levels to the transform coefficient level positions. For this mapping, the two scanning pattern shown in Figure 8-18 are used. The zig-zag scan shall be used for blocks decoded in frame mode, and the field scan shall be used for blocks decoded in field mode.

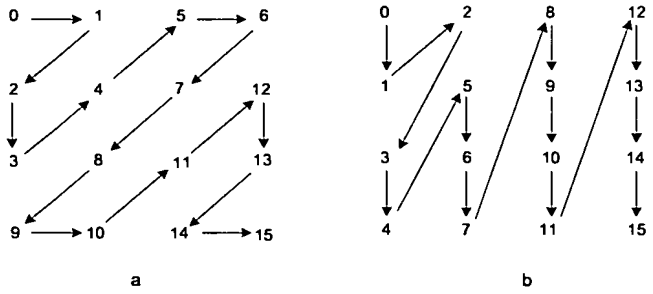

Figure 8-18 – a) Zig-zag scan. b) Field scan

When decoding a macroblock coded using Intra_16x16 macroblock prediction mode, the coefficients of the 4x4 luma DC transform are scanned in the same scan order as luma 4x4 coefficient blocks. Then for each 4x4 block of luma coefficients with AC coefficients to scan, the 15 remaining coefficients are scanned by starting the zig-zag scan in frame mode or field scan in field mode at its second position.

The coefficients of the 2x2 chroma DC transform are scanned in raster order. Then for each 4x4 block of chroma coefficients with AC coefficients to scan, the 15 remaining coefficients are scanned by starting the zig-zag scan in frame mode or the field scan in field mode at its second position.

8.5.2 Scaling and transformation process

Inputs to this process are

- QP_Y;
- QS;
- parsed transform coefficient level values;
- chroma_qp_index_offset.

Outputs of this process are:

- QP_C;
- QS_C.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- sample residual blocks X'';

QP scaling parameter values QP_Y, QP_C, QP_I, QS, and QS_C have a range from 0 to 51, inclusive. The value of QP_C for chroma is determined from the current value of QP_Y and the value of chroma_qp_index_offset. The sc aling equations are specified such that the equivalent scaling parameter doubles for every increment of 6 in QP. Thus, there is an increase in scaling magnitude of approximately 12% for each increase of 1 in the value of QP.

The value of QP_C shall be determined as specifed in Table 8-9 based on the indexing QP, denoted QP_I. The value of QP_I shall be calculated as specified by

$$QP_I = \text{Clip3}(0, 51, QP_Y + \text{chroma\_qp\_index\_offset}) \tag{8-39}$$

Table 8-9 – Specification of QP_C as a function of QP_I

QP_I	<30	30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51
QP_C	$=QP_I$	29	30	31	32	32	33	34	34	35	35	36	36	37	37	37	38	38	38	39	39	39	39

In the case of SP and SI slices, QS_C is calculated using the above process, substituting all QP values with equivalent QS values.

QP_Y shall be used as the QP to be applied for luma scaling and QP_C shall be used for chroma scaling.

The coefficients $R_{ij}^{(m)}$ specified as follows are used in Equations 8-43, 8-44, 8-46, 8-47, 8-48, 8-62, and 8-67:

$$R_{ij}^{(m)} = \begin{cases} V_{m0} & \text{for } (i,j) \in \{(0,0),(0,2),(2,0),(2,2)\}, \\ V_{m1} & \text{for } (i,j) \in \{(1,1),(1,3),(3,1),(3,3)\}, \\ V_{m2} & \text{otherwise;} \end{cases} \tag{8-40}$$

where the first and second subscripts of V are row and column indices, respectively, of the matrix specified as:

$$V = \begin{bmatrix} 10 & 16 & 13 \\ 11 & 18 & 14 \\ 13 & 20 & 16 \\ 14 & 23 & 18 \\ 16 & 25 & 20 \\ 18 & 29 & 23 \end{bmatrix}. \tag{8-41}$$

8.5.2.1 Scaling and transformation process for luma DC coefficients for Intra_16x16 macroblock type

Inputs to this process are

- QP_Y;
- parsed transform coefficient level values for luma DC coefficients of Intra_16x16 macroblocks;

Outputs of this process are:

- 16 scaled DC values for luma 4x4 blocks of Intra_16x16 macroblocks;

After decoding the coefficient levels for a 4x4 block of luma DC coefficients coded in 16x16 intra mode and assembling these into a 4x4 matrix C of elements c_{ij}, a transform process shall be applied in a manner mathematically equivalent to the following process. The process uses application of a transform before the scaling process.

The transform for the 4x4 luma DC coefficients in 16x16 intra macroblocks is specified by:

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$F = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00} & c_{01} & c_{02} & c_{03} \\ c_{10} & c_{11} & c_{12} & c_{13} \\ c_{20} & c_{21} & c_{22} & c_{23} \\ c_{30} & c_{31} & c_{32} & c_{33} \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{bmatrix}. \quad (8\text{-}42)$$

A bitstream conforming to this Recommendation | International Standard shall not contain data that results in any element of F that exceeds the range of integer values from -2^{15} to $2^{15}-1$, inclusive.

After the transform, scaling is performed according to the following:

a) If QP is greater than or equal to 12, then the scaled result shall be calculated as

$$DC_{ij} = [F_{ij} \cdot R_{00}^{(QP\%6)}] << (QP/6 - 2), \quad i,j = 0,\ldots,3. \quad (8\text{-}43)$$

b) If QP is less than 12, then the scaled results shall be ca lculated as

$$DC_{ij} = [F_{ij} \cdot R_{00}^{(QP\%6)} + 2^{1-QP/6}] >> (2 - QP/6), \quad i,j = 0,\ldots,3. \quad (8\text{-}44)$$

A bitstream conforming to this Recommendation | International Standard shall not contain data that results in element of DC_{ij} that exceeds the range of integer values from -2^{15} to $2^{15}-1$, inclusive.

8.5.2.2 Scaling and transformation process for chroma DC coefficients

Inputs to this process are

- QP_C;
- parsed transform coefficient level values for chroma DC coefficients of a macroblock;

Outputs of this process are:

- 4 scaled DC values for chroma 4 x4 blocks of a macroblock;

After decoding the coefficient levels for a 2x2 block of chroma DC coefficients and assembling these into a 2x2 matrix C of elements c_{ij}, the transform process is applied before the scaling process.

Definition of transform:

$$F = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}. \quad (8\text{-}45)$$

A bitstream conforming to this Recommendation | International Standard shall not contain data that results in any element of F that exceeds the range of integer values from -2^{15} to $2^{15}-1$, inclusive.

After the transform, scaling is performed according to the following.

a) If QP is greater than or equal to 6, then the scaling result shall be calculated as

$$DC_{ij} = [F_{ij} \cdot R_{00}^{(QP\%6)}] << (QP/6 - 1), \quad i,j = 0,1. \quad (8\text{-}46)$$

b) If QP is less than 6, then the scaling results shall be calculated by

$$DC_{ij} = [F_{ij} \cdot R_{00}^{(QP\%6)}] >> 1, \quad i,j = 0,1. \quad (8\text{-}47)$$

A bitstream conforming to this Recommendation | International Standard shall not contain data that results in any element of DC_{ij} that exceeds the range of integer values from -2^{15} to $2^{15}-1$, inclusive.

8.5.2.3 Scaling and transformation process for residual 4x4 blocks

Inputs to this process are

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- QP_Y if a luma 4x4 block;
- QP_C if a chroma 4x4 block;
- parsed transform coefficient level values for a 4x4 residual block;
- DC value if a luma 4x4 block of an Intra_16x16 macroblock;
- DC value if a chroma 4x4 block;

Outputs of this process are:

- reconstructed sample residual 4x4 blocks X'';

Scaling of 4x4 block coefficient levels c_{ij} other than those as specified in subclauses 8.5.2.1 and 8.5.2.2 shall be performed according to

$$w_{ij} = [c_{ij} \cdot R_{ij}^{(QP\%6)}] << (QP/6), \quad i,j = 0,...,3 . \tag{8-48}$$

A bitstream conforming to this Recommendation | International Standard shall not contain data that results in a value of w_{ij} that exceeds the range of integer values from -2^{15} to $2^{15}-1$, inclusive.

After constructing an entire 4x4 block of scaled transform coefficients and assembling these into a 4x4 matrix W of elements w_{ij} illustrated as

$$W = \begin{bmatrix} w_{00} & w_{01} & w_{02} & w_{03} \\ w_{10} & w_{11} & w_{12} & w_{13} \\ w_{20} & w_{21} & w_{22} & w_{23} \\ w_{30} & w_{31} & w_{32} & w_{33} \end{bmatrix} \tag{8-49}$$

in which the w_{00} element may be a result DC_{ij} from Equation 8-43, 8-44, 8-46, or 8-47; or may be from Equation 8-48, as appropriate, the transform process shall convert the block of reconstructed transform coefficients to a block of output samples in a manner mathematically equivalent to the following process:

a) First, each row of reconstructed transform coefficients is transformed using a one -dimensional transform, and

b) Second, each column of the resulting matrix is transformed using the same one -dimensional transform.

The one-dimensional transform is specified as follows for four input samples w_0, w_1, w_2, w_3.

a) First, a set of intermediate values is computed:

$$z_0 = w_0 + w_2 \tag{8-50}$$

$$z_1 = w_0 - w_2 \tag{8-51}$$

$$z_2 = (w_1 >> 1) - w_3 \tag{8-52}$$

$$z_3 = w_1 + (w_3 >> 1) \tag{8-53}$$

b) Then the transformed result is computed from these intermediate values

$$x_0 = z_0 + z_3 \tag{8-54}$$

$$x_1 = z_1 + z_2 \tag{8-55}$$

$$x_2 = z_1 - z_2 \tag{8-56}$$

$$x_3 = z_0 - z_3 \tag{8-57}$$

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

A bitstream conforming to this Recommendation | International Standard shall not contain data that results in a value of z_0, z_1, z_2, z_3, x_0, x_1, x_2, or x_3 that exceeds the range of integer values from -2^{15} to $2^{15}-1$, inclusive, in either the first (horizontal) or second (vertical) stage of application of this transformation process. A bitstream conforming to this Recommendation | International Standard shall not contain data that results in a value of x_0, x_1, x_2, or x_3 that exceeds the range of integer values from -2^{15} to $2^{15}-33$, inclusive, in the second (vertical) stage of application of this transformation process.

After performing the transform in both the horizontal and vertical directions to produce a block of transformed samples,

$$X' = \begin{bmatrix} x'_{00} & x'_{01} & x'_{02} & x'_{03} \\ x'_{10} & x'_{11} & x'_{12} & x'_{13} \\ x'_{20} & x'_{21} & x'_{22} & x'_{23} \\ x'_{30} & x'_{31} & x'_{32} & x'_{33} \end{bmatrix}, \tag{8-58}$$

the final reconstructed sample residual values shall be obtained as

$$X''_{ij} = [x'_{ij} + 2^5] >> 6 \tag{8-59}$$

8.5.3 Picture construction process prior to deblocking filter process

Inputs to this process are

- constructed sample residual 4x4 blocks X'';
- prediction 4x4 blocks P;

Outputs of this process are:

- constructed sample residual blocks S' prior to deblocking filter operation;

Finally, the reconstructed sample residual values X'' from Equation 8-59 are added to the prediction values P_{ij} from inter prediction or spatial prediction and clipped to the range of 0 to 255 to form the final decoded sample result prior to application of the deblocking filter:

$$S'_{ij} = \text{Clip1}(P_{ij} + X''_{ij}) \tag{8-60}$$

[Ed.Note: add MB-AFF picture construction process here. Not sure here is exactly where it goes]

8.6 Decoding process for SP and SI slices

This process is invoked when decoding P macroblock types in an SP slice type or an SI macroblock type in SI slices.

Input to this process are the prediction residual transform levels and the predicted luma samples for the current macroblock.

Output of this process are the decoded samples of the current mac roblock prior to deblocking.

This subclause specifies the transform coefficient decoding process and picture construction process for non -intra macroblock types in SP slices and SI macroblock type in SI slices.

SP slices make use of inter predictive coding to exploit temporal redundancy in the sequence, in a similar manner to P slices. Unlike P slices, however, SP slice coding allows identical reconstruction of a slice even when different reference pictures are being used.

SI slices make use of spatial prediction, in a similar manner to I slices. SI slice coding allows identical reconstruction to a corresponding SP slice.

NOTE - Above mentioned properties of SP and SI slices provide functionalities for bitstream switching, splicing, random access, VCR functionalities such as fast-forward, and error resilience/recovery.

An SP slice consists of macroblocks coded either as I macroblock types or P macroblock types. An SI slice consists of macroblocks coded either as I macroblock types or SI macroblock type.

The transform coefficient decoding process and picture construction process prior to deblocking filter process for I macroblock types in SI slices shall be invoked specified in subclause 8.5. SI macroblock type shall be decoded as described below.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

8.6.1 SP decoding process for non-switching pictures

This process is invoked, when decoding P macroblock types in SP slices in which sp_for_switch_flag is equal to 0.

Input to this process are inter predicted samples for the current macroblock f rom subclause 8.4 and the prediction residual coefficient levels.

Output of this process are the decoded samples of the current macroblock prior to the deblocking filter process.

This subclause applies to all macroblocks in SP s lices in which sp_for_switch_flag is equal to 0, except those with macroblock prediction mode equal to Intra_4x4 or Intra_16x16. It does not apply to SI slices.

Figure 8-19 depicts generic decoding for non-intra coded macroblocks in SP slices. The prediction P_{ij} for the current macroblock of the slice being decoded is formed by the inter prediction block as specified in subclause 8.4. After forming the predicted block P_{ij}, decoding is performed as follows.

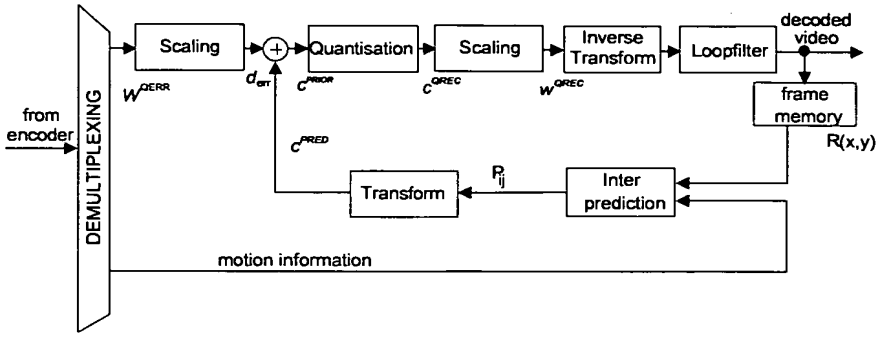

Figure 8-19 – A block diagram of a conceptual decoder for non-intra coded macroblocks in SP slices in which sp_for_switch_flag is equal to 0.

8.6.1.1 Luma transform coefficient decoding process

Input to this process are inter predicted luma samples for the current macroblock from subclause 8.4 and the prediction residual coefficient levels, LumaLevel.

Output of this process are the decoded luma samples of the c urrent macroblock prior to the deblocking filter process.

The predicted luma block, P_{ij}, where $P_{ij} = \{p_{00} \ldots p_{33}\}$, is transformed to produce transform coefficients c^{PRED} according to:

$$c^{PRED} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 2 & 1 & -1 & -2 \\ 1 & -1 & -1 & 1 \\ 1 & -2 & 2 & -1 \end{bmatrix} \begin{bmatrix} P_{00} & P_{01} & P_{02} & P_{03} \\ P_{10} & P_{11} & P_{12} & P_{13} \\ P_{20} & P_{21} & P_{22} & P_{23} \\ P_{30} & P_{31} & P_{32} & P_{33} \end{bmatrix} \begin{bmatrix} 1 & 2 & 1 & 1 \\ 1 & 1 & -1 & -2 \\ 1 & -1 & -1 & 2 \\ 1 & -2 & 1 & -1 \end{bmatrix} \quad (8\text{-}61)$$

The received prediction residual coefficients, w^{QERR}, are scaled using quantisation parameter QP, and added to the transform coefficients of the prediction block, as given by:

$$c_{ij}^{PRIOR} = c_{ij}^{PRED} + (((w_{ij}^{QERR} \; R_{ij}^{(QP\%6)} \; A_{ij}) << (QP/6)) >> 6) \;\; i, j = 0,\ldots,3 \quad (8\text{-}62)$$

where $R_{ij}^{(m)}$ is specified in Equation 8-40, and where A is specified as:

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$A_{ij} = \begin{cases} 16 & , \quad (i,j) = \{(0,0),(0,2),(2,0),(2,2)\}; \\ 25 & , \quad (i,j) = \{(1,1),(1,3),(3,1),(3,3)\}; \\ 20 & , \quad otherwise. \end{cases} \tag{8-63}$$

For luma, QP = QP_Y, as specified in Equation 7-8 and 7-12.

The coefficients $Q_{ij}^{(m)}$, used in the formulas below, are specified as:

$$Q_{ij}^{(m)} = \begin{cases} M_{m0} & , \quad (i,j) = \{(0,0),(0,2),(2,0),(2,2)\}; \\ M_{m1} & , \quad (i,j) = \{(1,1),(1,3),(3,1),(3,3)\}; \\ M_{m2} & , \quad otherwise. \end{cases} \tag{8-64}$$

where the first and second subscripts of M are row and column indices, respectively, of the matrix specified as:

$$M = \begin{bmatrix} 13107 & 5243 & 8066 \\ 11916 & 4660 & 7490 \\ 10082 & 4194 & 6554 \\ 9362 & 3647 & 5825 \\ 8192 & 3355 & 5243 \\ 7282 & 2893 & 4559 \end{bmatrix} \tag{8-65}$$

The resulting sum, c^{PRIOR}, is quantised with a quantisation parameter QS, as given by:

$$c_{ij}^{QREC} = (\mathrm{Sign}(c_{ij}^{PRIOR}) * [\mathrm{Abs}(c_{ij}^{PRIOR})\, Q_{ij}^{(QS\%6)} + (1 << (14+QS/6))]) >> (15+QS/6) \quad i,j = 0,\ldots,3 \tag{8-66}$$

For luma, QS = QS_Y, which is specified in Equation 7-9.

These quantised levels, c^{QREC}, are scaled as given by:

$$w_{ij}^{QREC} = (c_{ij}^{QREC}\ R_{ij}^{(QS\%6)}) << (QS/6) \quad i,j = 0,\ldots,3 \tag{8-67}$$

where $R_{ij}^{(m)}$ is specified in Equation 8-40.

The transform and reconstruction processes are performed for these scaled levels, as specified in Equations 8-49 through 8-59. Finally, after the reconstruction of a macroblock, filtering takes place as described in subclause 8.7.

8.6.1.2 Chroma transform coefficient decoding process

Input to this process are inter predicted chroma samples for the current macroblock from subclause 8.4 and the prediction residual coefficient levels, ChromaDCLevel and ChromaACLevel.

Output of this process are the decoded chroma samples of the current macroblock prior to the deblocking filter process.

The decoding of chroma components for non -intra coded macroblocks in SP slices is similar to the decoding of luma components in SP slices.

The predicted chroma block, P_{ij}, where $P_{ij} = \{p_{00} \ldots p_{33}\}$, is transformed according to Equation 8-61 to produce transform coefficients c^{PRED}. After calculating the coefficients of the 4 chroma blocks of a macroblock, D C coefficients of the 4 chroma blocks are assembled into a 2x2 matrix of elements DC_{ij} and an additional 2x2 transform is applied to the DC coefficients of these blocks. The 2 dimensional 2x2 transform procedure is specified by:

$$c^{PRED} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} DC_{00} & DC_{01} \\ DC_{10} & DC_{11} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \tag{8-68}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

The received DC prediction residual coefficients, w^{QERR}, are scaled using quantisation parameter QP, and added to the DC transform coefficients of the prediction block, as given by:

$$c_{ij}^{PRIOR} = c_{ij}^{PRED} + (((w_{ij}^{QERR} \quad R_{00}^{(QP\%6)} \quad A_{00}) << (QP/6)) >>5) \quad i, j = 0,1 \tag{8-69}$$

The resulting sum, c^{PRIOR}, is quantised with a quantisation parameter QS, as given by:

$$c_{ij}^{QREC} = \{Sign(c_{ij}^{PRIOR}) \quad [Abs(c_{ij}^{PRIOR}) \quad Q_{00}^{(QS\%6)} + (1<<(15+QS/6))]\}>>(16+QS/6) \quad i, j = 0, 1 \tag{8-70}$$

2x2 transform process as defined in Equation 8-45 is applied to these quantized levels where the output of the transform is denoted by F_{ij}. After the transform, scaling is performed according to the following:

a) If QS is greater than or equal to 6, then the scaling result shall be calculated as

$$DC_{ij}^{QREC} = (F_{ij} * R_{00}^{(QS\%6)}) << (QS/6-1) \quad i, j = 0,1 \tag{8-71}$$

b) If QS is less than 6, then the scaling results shall be calculated by

$$DC_{ij}^{QREC} = (F_{ij} * R_{00}^{(QS\%6)}) >> 1 \quad i, j = 0,1 \tag{8-72}$$

AC coefficients are decoded in an identical process to that u sed for luma, as specified by Equations 8-62 to 8-67.

The transform and reconstruction processes are performed for the scaled levels, as specified in Equations 8-49 through 8-59. Finally, after the reconstruction of a macroblock, filtering takes place as described in subclause 8.7.

The values of QP and QS, denoted QP_C and QS_C, respectively, shall be obtained using the process descri bed in subclause 8.5.2.

8.6.2 SP and SI slice decoding process for switching pictures

This process is invoked, when decoding P macroblock types in SP slices in which sp_for_switch_flag is equal to 1 or SI macroblock type in SI slices.

Input to this process are the prediction residual transform levels and the predicted samples for the current macroblock.

Output of this process are the decoded samples of the current macroblock prior to deblocking.

This subclause applies to P macroblock t ypes in SP slices in which sp_for_switch_flag is equal to 1, and to SI macroblock type in SI slices.

Figure 8-20 illustrates the decoding for macroblocks in SI and SP slices that are not of the Intra type (Intra_4x4 or Intra_16x16). When decoding P macroblock types in SP slices, the prediction P_{ij} for the current coded macroblock of the slice being decoded is formed by the inter prediction block using the process specified in subclause 8.4. When decoding SI macroblock type in SI slices, the prediction P_{ij} is formed by intra prediction block using the process as specified in subclause 8.3.1. After forming the predicted block P_{ij}, the decoding of SI macroblock type in SI slices an d P macroblock types in SP slices follows the same steps.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

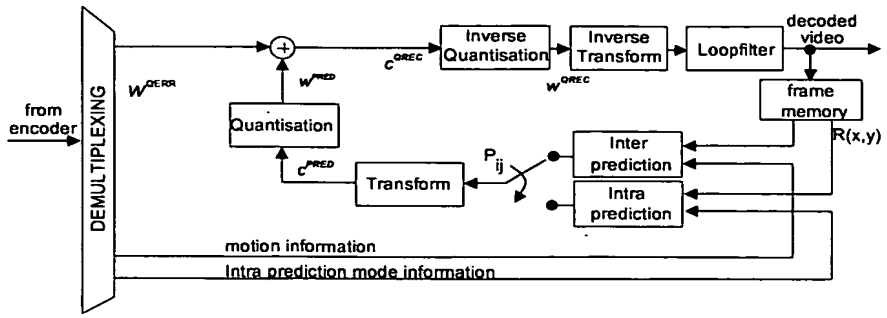

Figure 8-20– A block diagram of a conceptual decoder for non-intra macroblocks in SI slices; and for non-intra coded macroblocks in SP slices in which sp_for_switch_flag is equal to 1. (informative)

When decoding SI macroblocks, the intra prediction modes of the neighbouring SI and Intra_4x4 blocks are taken into account as described in subclause 8.3.1.

When decoding I_4x4 macroblocks, the intra prediction modes of the neighbouring Intra_4x4 blocks are taken into account as described in subclause 8.3.1, but the prediction mode of the neighbouring SI blocks are considered to be "mode 2: DC prediction", except in the case of constrained intra when the adjacent block is considered to be outside of the slice. [Ed.Note: read subclause 8.3.1 and be more specific here.]

8.6.2.1 Luma transform coefficient decoding process

Input to this process are predicted luma samples for the current macroblock from subclause 8.4 and the prediction residual coefficient levels, LumaLevel.

Output of this process are the decoded luma samples of the cur rent macroblock prior to the deblocking filter process.

The predicted luma block, P_{ij}, where $P_{ij} = \{p_{00} \ldots p_{33}\}$, is transformed according to Equation 8-61 to produce transform coefficients c^{PRED}. These transform coefficients are then quantised with a quantisation parameter QS, as given by:

$$w_{ij}^{PRED} = \{\text{Sign}(c_{ij}^{PRED})\,[\text{Abs}(c_{ij}^{PRED})\ Q_{ij}^{(QS\%6)} + (1<<(14+QS/6))]\}>>(15+QS/6) \qquad i, j = 0,\ldots, 3 \qquad (8\text{-}73)$$

NOTE - Equation 8-73 is the same as Equation 8-66 except for the change of name of input and output variables.

For luma, $QS = QS_Y$, which is specified in Equation 7-9.

The received prediction residual coefficients, w^{QERR}, are added to these quantised transform coefficients of the prediction block, as given by:

$$c_{ij}^{QREC} = w_{ij}^{PRED} + w_{ij}^{QERR} \qquad i, j = 0,\ldots, 3 \qquad (8\text{-}74)$$

These quantised levels, c^{QREC}, are scaled as in Equation 8-67 and the transform and reconstruction processes are performed for these scaled levels, as specified in Equations 8-49 through 8-59. Finally, after the reconstruction of a macroblock, filtering takes place as described in subclause 8.7.

8.6.2.2 Chroma transform coefficient decoding process

Input to this process are predicted chroma samples for the current macroblock from subclause 8.4 and the prediction residual coefficient levels, ChromaDCLevel and ChromaACLevel.

Output of this process are the decoded chroma samples of the current macroblock prior to the deblocking filter process.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

The decoding of chroma components for SP and SI non -intra macroblocks is similar to the decoding of luma components in SP slices.

The predicted chroma block, P_{ij}, where $P_{ij} = \{p_{00} \ldots p_{33}\}$, is transformed according to Equation 8-61 to produce transform coefficients c^{PRED}. After calculating the coefficients of the 4 chroma blocks of a macroblock, DC coefficients of the 4 chroma blocks are assembled into a 2x2 matrix of elements DC_{ij} and an additional 2x2 transform is applied to the DC coefficients as in Equation 8-68

The DC transform coefficients are then quantised with a quantisation parameter QS, as given by:

$$w_{ij}^{PRED} = \{\text{Sign}(c_{ij}^{PRED}) \ [\text{Abs}(c_{ij}^{PRED}) \ Q_{ij}^{(QS\%6)} + (1<<(15+QS/6))]\}>>(16+QS/6) \quad i, j = 0,1 \tag{8-75}$$

NOTE - Equation 8-75 is the same as Equation 8-70 except for the change of name of input and output variables.

The received prediction residual DC coefficients, w^{QERR}, are added to these quantised DC transform coefficients of the prediction block, as given by:

$$c_{ij}^{QREC} = w_{ij}^{PRED} + w_{ij}^{QERR} \qquad i, j = 0,1 \tag{8-76}$$

2x2 transform process as defined in Equation 8-45 is applied to these quantized levels c^{QREC} and scaling is performed according to Equation 8-71 and 8-72.

AC coefficients are decoded in an identical process to that used for luma, as specified in Equations 8-73 and 8-74.

The transform and reconstruction processes are performed for the scaled levels, as specified in Equations 8-49 through 8-59. Finally, after the reconstruction of a macroblock, filtering takes place as described in subclause 8.7.

The values of QP and QS, denoted QP_C and QS_C, respectively, shall be obtained using the process described in subclause 8.5.2.

8.7 Deblocking filter process

Input to this process are the decoded sample values of a picture, constructed as described in subclause 8.5.3; the prediction mode information (intra or inter) for each macroblock in a picture; informati on on which 4x4 luminance blocks in the picture were coded using non -zero coefficients; the motion vectors used for generating motion - compensated predictions in the picture; the quantization parameter values, QP, used for coding each macroblock; the deblocking filter control parameters disable_deblocking_filter_idc, FilterOffsetA, and FilterOffsetB; and, when mb_adaptive_frame_field_flag is equal to 1, the coding mode (frame/field) for each macroblock pair in a frame.

Output of this process are the filtered sample values for a picture that will be stored in the decoded picture buffer.

[Ed. Note: Operation with regard to PCM macroblock type needs to be specified.]

A conditional filtering shall be applied to all block edges of a slice, except edges at the bou ndary of the picture and any edges for which the deblocking filter is disabled as specified by disable_deblocking_filter_idc. This filtering is done on a macroblock basis, with macroblocks being processed in raster -scan order throughout the picture. For lu ma, as the first step, the 16 samples of the 4 vertical edges of the 4x4 raster shall be filtered beginning with the left edge, as shown on the left-hand side of Figure 8-21. Filtering of the 4 horizontal edges (vertical filtering) follows in the same manner, beginning with the top edge, as shown on the right -hand side of Figure 8-21. The same ordering applies for the filtering of each of the two chroma components, with the exception that 2 edges of 8 sample s each are filtered in each direction. [Ed. Note: The chroma filtering description here needs further clarification. Maybe we should do separate figures for chroma?] This process also affects the boundaries of the already reconstructed and filtered macrobl ocks above and to the left of the current macroblock. Picture edges are not filtered [Ed. Note: Is this redundant, based on the first sentence of the paragraph?].

For the deblocking filter process and the effect of the filter control parameters, the edges controlled by a macroblock are defined to be the block edges internal to the macroblock and the top and left edges between the current macroblock and its neighbouring macroblocks.

When mb_adaptive_frame_field_flag is equal to 1, all macroblock pairs are assumed to be reconstructed within the frame independent of the mb_field_decoding_flag.

When field_pic_flag is equal to 1, all decoding operations for the deblocking filter are based solely on samples within the current field.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

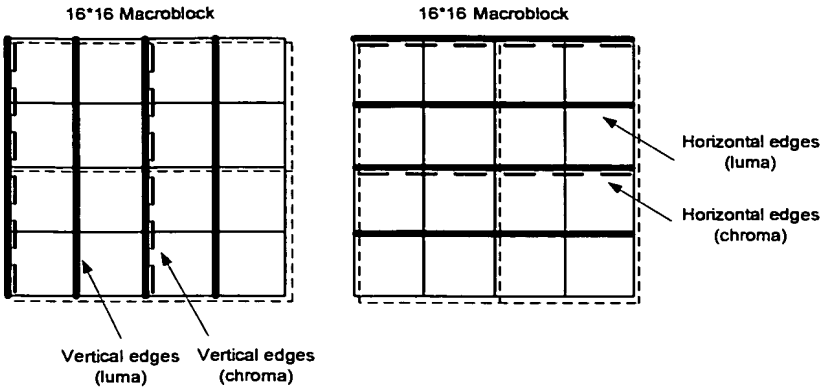

Figure 8-21 – Boundaries in a macroblock to be filtered (luma boundaries shown with solid lines and chroma boundaries shown with dashed lines)

Intra prediction of a macroblock shall be performed using the sample values prio r to the application of the deblocking filter process on the previously decoded and reconstructed neighbouring macroblocks.

NOTE - Depending on the implementation, the values necessary for intra prediction may need to be stored before filtering in order to be used in the intra prediction of the macroblocks to the right and below the current macroblock.

[Ed. Note: Does all of this really belong in the intra prediction section?]

8.7.1 Derivation process for the content dependent boundary filtering strength

Input to this process are the prediction mode information (intra or inter) for each macroblock in a picture; information on which 4x4 luminance blocks in the picture were coded using non -zero coefficients; the motion vectors used for generating motion-compensated predictions in the picture; and, when mb_adaptive_frame_field_flag is equal to 1 and field_pic_flag is equal to 0, the coding mode (frame/field) for each macroblock pair in a frame.

Output of this process are the Boundary Strength parameter, Bs, for each block boundary segment to be filtered.

For each boundary between neighbouring 4x4 luma blocks, a "Boundary Strength" Bs is assigned as shown in Figure 8-22. As indicated in Figure 8-21, every block boundary of a chroma block corresponds to a specific boundary of a luma block. Bs values for chroma are not calculated, but simply copied from the corresponding luma Bs. If Bs==0, filtering is skipped for that particular edge. In al l other cases filtering is dependent on the local sample properties and the value of Bs for this particular boundary segment.

For each edge, if any sample of the neighbouring macroblocks is coded using Intra macroblock prediction mode, selection between two relatively strong filtering modes is made based on whether the block boundary is also a macroblock boundary. If the block boundary is a macroblock boundary, a value of Bs=4 shall be assigned for this boundary segment. Otherwise, if Intra prediction is us ed in either block but the boundary is not a macroblock boundary, a value of Bs=3 shall be assigned.

If neither of the neighbouring macroblocks are coded using Intra macroblock prediction mode and at least one of them contains non-zero transform coefficient levels, a value of Bs=2 shall be assigned on this boundary segment, resulting in a medium filtering strength. If none of the previous conditions are satisfied, a value of Bs=1 shall be assigned if at least one of the following conditions is satisfied:

- one of the neigbouring macroblocks is coded in frame mode and the other is coded in field mode
- both macroblocks are coded in frame mode and the prediction of the two blocks is formed using different reference pictures or a different number [Ed.Note: ?] of re ference pictures
- both macroblocks are coded in field mode and the prediction of the same parity field of the two macroblocks is formed using different reference pictures or a different number of reference pictures.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

- any corresponding pair of motion vector s from the two neighbouring macroblocks is referencing the same picture and either component of this pair has a difference of more than one sample [Ed. Note: distance?].
- Otherwise, Bs shall be assigned the value 0, resulting in filtering being skipped fo r that particular boundary segment.

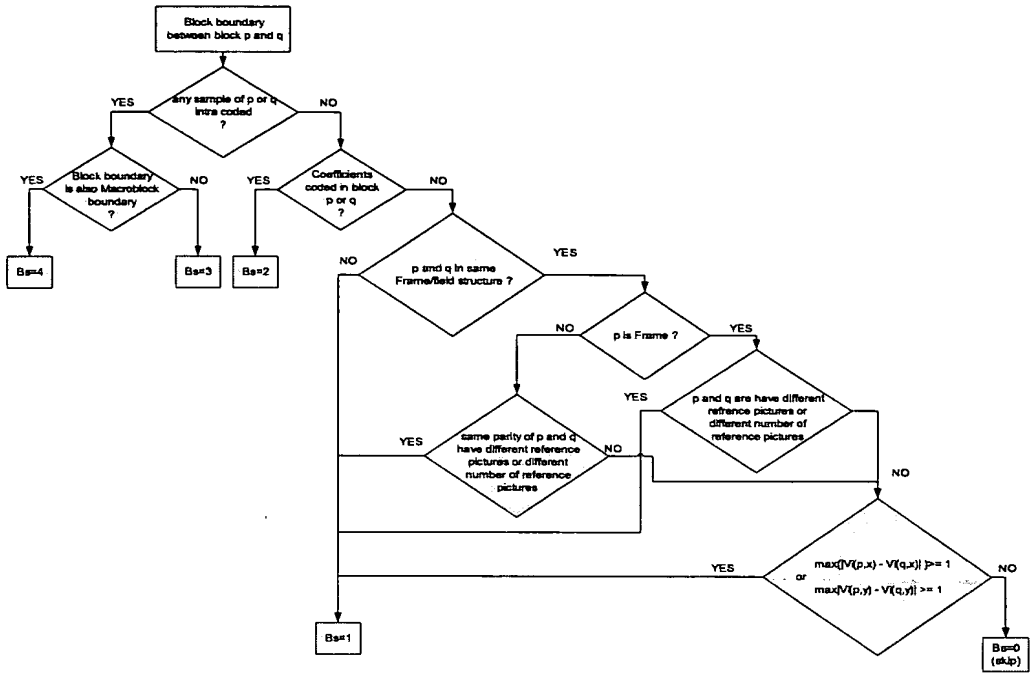

Figure 8-22 – Flow chart for determining the boundary strength (Bs), for the block boundary between two neighbouring 4x4 luma blocks [Ed.Note: ?] p and q , where $V_i(p,x)$ and $V_i(p, y)$ for i=1 to 1, 2 or 4, are the horizontal and vertical components of the motion vectors of block [Ed.Note: ?] p for the reference frame or the first and second reference fields.

8.7.2 Derivation process for the thresholds for each block boundary

Input to this process are the input sample values a single line of an edge segment to be filtered; the quantization parameter values, QP, used for coding each block that neighbours the edge segment; the deblocking filter control parameters FilterOffsetA and FilterOffsetB that apply to this edge segment; and the value of the Boundary Strength parameter, Bs, for the edge segment.

Output of this process is a Boolean decision as to wbether sample values will be modified on the input line of the edg e segment; and the value of Index $_A$, which is used to access the table of C0 values for filtering of edge segments with Bs smaller than 4, as specified in 8.7.3; the values of the threshold parameters (α and β), which are used for luma filtering of edge segments with Bs equal to 4, as specified in 8.7.4.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Figure 8-23 – Convention for describing samples across a 4x4 block horizontal or vertic al boundary

In the following description, the set of eight samples across a 4x4 block horizontal or vertical boundary is denoted as shown in Figure 8-23 with the actual boundary lying between p_0 and q_0. Uppercase letters indicate filtered samples and lower case letters indicate unfiltered samples with regard to the current edge filtering operation. However, p_1 and p_2 may indicate samples that have been modified by the filtering of a previous block edge.

Sets of samples across this edge are only filtered if the condition

$$Bs \neq 0 \;\&\&\; |p_0 - q_0| < \alpha \;\&\&\; |p_1 - p_0| < \beta \;\&\&\; |q_1 - q_0| < \beta \tag{8-77}$$

is true. The values of the thresholds α and β are dependent on the average value of QP for the two blocks as well as on a pair of index offsets "FilterOffsetA" and "FilterOffsetB" that may be transmitted in the slice header for the purpose of modifying the characteristics of the filter. The average QP value for the two blocks is computed as

$$QP_{av} = (QP_p + QP_q) >> 1. \tag{8-78}$$

For chroma, the corresponding QP_C values of the chroma blocks are used as input to to Equation 8-78 to compute QP_{av}.. When a macroblock pair is coded in field mode , the value used for QP_p or QP_q shall be the average of the QPs of the two macroblocks of the pair, which shall also be calculated using Equation 8-78, with QP_p and QP_q in this case being the QP values for the two macroblocks of the ma croblock pair. The index used to access the α table (Table 8-10), as well as the C0 table (Table 8-11) that is used in filtering of edges with Bs smaller than 4, is computed as:

$$Index_A = Clip3(0, 51, QP_{av} + FilterOffsetA) \tag{8-79}$$

NOTE - In SP and SI slices, QP_{av} is calculated in the same way as in other slice types. QS_Y from Equation 7-8 is not used in the deblocking filter.

The index used to access the β table (Table 8-10) is computed as:

$$Index_B = Clip3(0, 51, QP_{av} + FilterOffsetB) \tag{8-80}$$

The relationships between the indices computed using Equations 8-79 and 8-80 and the thresholds (α and β) are shown in Table 8-10.

8.7.3 Filtering process for edges with Bs smaller than 4

Input to this process are the input sample values for a single line of an edge segment that is to be filtered; the value of the Boundary Strength parameter, Bs; and the value of Index $_A$, as specified in **Error! Reference source not found.**.

Output of this process are the filtered result sample values for each line of input sample values.

Two types of filtering are specified. In the case of edge segments with $0 < Bs < 4$, the samples having values p_0 and q_0 shall be modified to filtered values P_0 and Q_0 as given by:

$$\Delta = \text{Clip3}(-C, C, (((q_0 - p_0) << 2 + (p_1 - q_1) + 4) >> 3)) \quad (8\text{-}81)$$

$$P_0 = \text{Clip1}(p_0 + \Delta) \quad (8\text{-}82)$$

$$Q_0 = \text{Clip1}(q_0 - \Delta) \quad (8\text{-}83)$$

where C is determined as specified below.

The two intermediate threshold variables

$$a_p = | p_2 - p_0 | \quad (8\text{-}84)$$

$$a_q = | q_2 - q_0 | \quad (8\text{-}85)$$

shall be used to determine whether filtering for the luma samples p_1 and q_1 is taking place at this position of the edge.

If $a_p < \beta$ for a luma edge, the sample having value p_0 shall be modified to a filtered value P_1 as specified by

$$P_1 = p_1 + \text{Clip3}(-C0, C0, (p_2 + ((p_0 + q_0) >> 1) - (p_1 << 1)) >> 1) \quad (8\text{-}86)$$

If $a_q < \beta$ for a luma edge, the sample having value q_1 shall be modified to a filtered value Q_1 as specified by

$$Q_1 = q_1 + \text{Clip3}(-C0, C0, (q_2 + ((p_0 + q_0) >> 1) - (q_1 << 1)) >> 1) \quad (8\text{-}87)$$

where C0 is specified in Table 8-11. Chroma samples p_1 and q_1 are never filtered.

For luma, C is determined by setting it equal to C0 and then incrementing it by one if $a_p < \beta$, and again by one if $a_q < \beta$. For chroma, C is equal to C0 + 1.

8.7.4 Filtering process for edges for Bs equal to 4

Inputs to this process are the input sample values for a single line of an edge segment that is to be filtered; the values of the threshold parameters α and β for the edge segment, as specified in subclause 8.7.2.

Outputs of this process are the filtered result sample values for each line of input sample values.

In this subclause, the intermediate variables a_p and a_q are computed as specified in Equations 8-84 and 8-85.

For luma samples, if the following condition holds:

$$a_p < \beta \;\&\&\; |p_0 - q_0| < ((\alpha >> 2) + 2) \tag{8-88}$$

filtering of the left/upper side of the block edge shall be applied by replacing the samples having values p_0, p_1, and p_2 with the filtered values P_0, P_1, and P_2 according to:

$$P_0 = (p_2 + 2*p_1 + 2*p_0 + 2*q_0 + q_1 + 4) >> 3 \tag{8-89}$$

$$P_1 = (p_2 + p_1 + p_0 + q_0 + 2) >> 2 \tag{8-90}$$

$$P_2 = (2*p_3 + 3*p_2 + p_1 + p_0 + q_0 + 4) >> 3 \tag{8-91}$$

For chroma samples, and for luma samples for which the condition described in Equation 8-88 does not hold, the filter shall be applied by replacing the sample having value p_0 with the filtered value P_0 according to:

$$P_0 = (2*p_1 + p_0 + q_1 + 2) >> 2 \tag{8-92}$$

Similarly, for filtering of luma samples on the right/lower side of the edge, if the following condition holds:

$$a_q < \beta \;\&\&\; |p_0 - q_0| < ((\alpha >> 2) + 2) \tag{8-93}$$

filtering shall be applied by replacing the samples having values q_0, q_1, and q_2 with the filtered values Q_0, Q_1, and Q_2 according to:

$$Q_0 = (p_1 + 2*p_0 + 2*q_0 + 2*q_1 + q_2 + 4) >> 3 \tag{8-94}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$$Q_1 = (p_0 + q_0 + q_1 + q_2 + 2) >> 2 \quad (8\text{-}95)$$

$$Q_2 = (2*q_3 + 3*q_2 + q_1 + q_0 + p_0 + 4) >> 3 \quad (8\text{-}96)$$

For chroma samples, and for luma samples for which the condition described in Equation 8-93 does not hold, the filter shall be applied by replacing the sample having value q_0 with the filtered value Q_0 according to:

$$Q_0 = (2*q_1 + q_0 + p_1 + 2) >> 2 \quad (8\text{-}97)$$

9 Parsing process

Input to this process are bits from the RBSP.

Output of this process are syntax elements.

This process is invoked when the descriptor of a syntax element in the syntax tables in subclause 7.3 is equal to ue(v), se(v), te(v) (see subclause 9.1), ce(v) (see subclause 9.2), or ae(v) (see subclause 9.3).

9.1 Parsing process for exp-Golomb codes

This process is invoked when the descriptor of a syntax element in the syntax tables in subclause 7.3 is equal to ue(v), se(v), or te(v). For syntax elements in subclauses 7.3.4 and 7.3.5, this process is invoked only if entropy_coding_mode is equal to 0.

Input to this process are bits from the RBSP.

Output of this process are syntax elements.

This subclause specifies the parsing process for the exp-Golomb coded or truncated exp-Golomb coded syntax elements.

Syntax elements coded as ue(v) or se(v) are exp-Golomb coded. The parsing process for these syntax elements begins with reading the bits starting at the current location in the bitstream up to and including the first non-zero bit, and counting the number of leading bits that are equal to zero. This process shall be equivalent to the following:

```
LeadingZeroBits = -1;
for( B=0; !B; LeadingZeroBits++ )
    B = read_bits( 1 )
```

A code number is then assigned as follows:

$$CodeNum = 2^{LeadingZeroBits} - 1 + read\_bits(LeadingZeroBits)$$

where the value returned from read_bits(LeadingZeroBits) is interpreted as a binary representation of an unsigned integer with most significant bit written first.

CodeNum is used to determine syntax elements coded as ue(v) as specified in subclause 9.1.1 and se(v) as specified in subclause 9.1.2.

Table 9-1 illustrates the structure of the exp-Golomb code by separating the bit string into "prefix" and "suffix" bits. The "prefix" bits are those bits which are parsed in the above pseudo-code for the computation of LeadingZeroBits, and are shown as either 0 or 1 in the bit string column of Table 9-1. The "suffix" bits are those bits which are parsed in the computation of CodeNum and are shown as x_i in Table 9-1, with i being in the range 0 to LeadingZeroBits-1, inclusive. Each x_i can take on values 0 or 1.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 9-1 – Bit strings with "prefix" and "suffix" bits and assignment to CodeNum ranges

Bit string form	Range of CodeNum
1	0
0 1 x_0	1-2
0 0 1 x_1 x_0	3-6
0 0 0 1 x_2 x_1 x_0	7-14
0 0 0 0 1 x_3 x_2 x_1 x_0	15-30
0 0 0 0 0 1 x_4 x_3 x_2 x_1 x_0	31-62
...	...

Table 9-2 illustrates explicitly the assignment of bit strings to CodeNum values.

Table 9-2 – Code number and Exp-Golomb codewords in explicit form and used as ue(v)

Bit string	CodeNum
1	0
0 1 0	1
0 1 1	2
0 0 1 0 0	3
0 0 1 0 1	4
0 0 1 1 0	5
0 0 1 1 1	6
0 0 0 1 0 0 0	7
0 0 0 1 0 0 1	8
0 0 0 1 0 1 0	9
...	...

For syntax elements coded as te(v) the range of the syntax element shall be determined first. The range of this syntax element may be between 0 and X, with X being greater than or equal to 1.

If X is greater than 1, then CodeNum for syntax elements coded as te(v) shall be parsed in the same way as syntax elements coded as ue(v) or se(v).

If X is equal to 1, the parsing process for CodeNum for syntax elements coded as te(v) is given by a process equivalent to:

```
B = read_bits( 1 )
CodeNum = !B
```

CodeNum is used to determine the syntax elements coded as te(v) as specified in subclause 9.1.1.

9.1.1 Mapping process for unsigned exp-Golomb and for truncated unsigned exp-Golomb codes

Input to this process is CodeNum as specified in subclause 9.1.

Output of this process is a syntax element coded as ue(v) and te(v), which is equal to CodeNum.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

9.1.2 Mapping process for signed Exp-Golomb codes

Input to this process is CodeNum as specified in subclause 9.1.

Output of this process is the syntax element coded as se(v).

The syntax elements is assigned to the C odeNum by ordering the syntax element by its absolute value in increasing order and representing the positive value for a given absolute value with the lower CodeNum. Table 9-3 provides the assignment rule.

Table 9-3 – Assignment of syntax element to CodeNum for signed exp-Golomb coded syntax elements se(v)

CodeNum	syntax element
0	0
1	1
2	-1
3	2
4	-2
5	3
6	-3
k	$(-1)^{k+1}$ Ceil(k÷2)

9.2 CAVLC parsing process for transform coefficients

This process is invoked when the descriptor of a syntax element in the syntax tables in subclause 7.3.5.3.1 is equal to ce(v) and entropy_coding_mode is equal to 0.

Input to this process are bits from a slice layer RBSP.

Output of this process are the syntax elements with descriptor ce(v), which are coeff_token, trailing_ones_sign, coeff_level, total_zeros, and run_before.

The following syntax elements are used: [Ed.Note: move to semantics ?]

1. The syntax element coeff_token gi ves the total number of coefficients (from now referred to as TotalCoeffs) and also contains the number of trailing ones (from now referred to as T1s).

NOTE - If there are non-zero coefficients, it is typically observed that there is a string of coefficients at the highest frequencies that are ±1.

2. For T1s, the sign is derived from the syntax element trailing_ones_sign and the level magnitude is equal to 1.
3. For levels other than zero-valued levels or T1s, the syntax element coeff_level is used to derive thei r value.
4. For levels equal to 0, two syntax elements total_zeros and run_before are used to determine their position. The syntax element total_zeros is used to derive the total number number of zeros before all coefficients and the syntax element run_before is used to derive the number before each non-zero coefficient. Since the number of coefficients is known from the syntax element coeff_token, the range for the syntax elements total_zeros and run_before is limited given that a known maximum of levels that can be decoded for a block.

9.2.1 Parsing process for total number of coefficients and trailing ones

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The syntax element coeff_token is decoded using the VLC specified in Table 9-4 to Table 9-7.

Four VLC tables are used for combined decoding of number of coefficients and T1s, i.e. one codeword signals both parameters. VLCs are listed in the tables below. T1s is clipped to 3. Any remaining trailing 1s are decoded as normal levels. The variable TotalCoeff is the value returned by the function total_coeff( ); the variable T1s is the value returned by the function tra iling_ones( ); and the variable NumCoeff is related to these quantities by TotalCoeff -T1s.

9.2.1.1 Table selection process

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

For all elements, except chroma DC, a choice between three tables and one FLC is made. N is a value used for table selection. Selection is done as follows: N is calculated using total_coeff( ) of the block above and to the left of the current block: N_U and N_L. In the Table 9-8, X means that the block is available in the same slice. The block's coding mode is not taken into account when determining availability. When finding the block above and to the left for a block of Intra16x16 DC coefficients, the location of the block is assumed to be (0,0), i.e. the upper left corner of the macroblock.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table 9-8 – Calculation of N for Num-VLCN

Upper block (N_U)	Left block (N_L)	N
X	X	$(N_L+N_U)/2$
X		N_U
	X	N_L
		0

0 <= N < 2 : Num-VLC0

2 <= N < 4 : Num-VLC1

4 <= N < 8 : Num-VLC2

N >= 8 : 6 bit FLC xxxxyy, as follows:

As a part of the coeff_token, TotalCoeff−1 is transmitted in the first 4 bits (xxxx) and T1s is transmitted as the last 2 bits (yy). There is one exception: the codeword 000011 represents T otalCoeff=0.

For chroma DC, Num-VLC_Chroma_DC is used.

9.2.2 Parsing process for level information

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

First, the sign of T1s are decoded from 1 bit each of trailing_ones_sign. A value of zero indicates a positive level and a value of 1 indicates a negative level. A maximum of 3 bits are read.

For the remaining level information, seven structured VLCs are used to decode levels. The structured level tables are explained in Table 9-9 to Table 9-15. Lev-VLC0 has its own structure while the other tables, **Lev-VLC*N*, *N* = 1 to 6**, share a common structure.

Table 9-9 – Level tables

Code	level_code
1	1
01	-1
001	2
0001	-2
..	..
00000000000001	-7
0000000000000001xxxs	±8 to ±15
0000000000000000001xxxxxxxxxxs	±16 ->

In the following descriptions of the level parsing process, Leadin gZeroBits specifies the number of zero-bits that occur before the first one-bit in the VLC codeword.

For Lev-VLC0, the following structure is used:

if (LeadingZeroBits < 14),

level_code is obtained directly from Table 9-9

else if (LeadingZeroBits < 15),

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

19-bit escape code: 0000 0000 0000 001x xxs,

where |level_code| = (value of x's) + 8,

and level_code is positive if s==0 and negative if s==1.

else,

28-bit escape code: 0000 0000 0000 0001 xxxx xxxx xxxs,

where |level_code| = (value of x's) + 16,

and level_code is positive if s==0 and negative if s==1.

For Lev-VLC*N*, *N* = 1 to 6, the following structure is used:

if (LeadingZeroBits < 15)

Code: 0....01x..xs,

where number of x's = *N*-1,

else,

28-bit escape code: 0000 0000 0000 0001 xxxx xxxx xxxs,

In either of these two cases:

|level_code| = (value of x's) + (LeadingZeroBits * $2^{(N-1)}$) + 1,

and level_code is positive if s==0 and negative if s==1.

Table 9-14 – Level VLC5

Code	level_code
1xxxxs	±1 to ±16
01xxxxs	±17 to ±32
..	..
0000000000000001xxxxs	±225 to ±240
00000000000000001xxxxxxxxxxxs	±241 ->

Table 9-15 – Level VLC6

Code	level_code
1xxxxxs	±1 to ±32
01xxxxxs	±33 to ±64
..	..
0000000000000001xxxxxs	±449 to ±480
00000000000000001xxxxxxxxxxxs	±481 ->

When T1s is less than 3, the level of the first coefficient (after T1s) is equal to the decoded level_code plus 1:

```
if( first_coefficient && trailing_ones( ) < 3 )
    coeff_level = ( | level_code | + 1 ) * Sign( level_code )
```

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

```
else
    coeff_level = level_code
```

Otherwise, coefficient levels (coeff_level) are equal to the decoded level_code value given in Table 9-9 to Table 9-15.

The last two entries in the Lev-VLC0 table are escape codes. The first escape code with 19 bits, four "x"'s, is used to decode the 8 levels above the last regularly coded level. The next escape code with 28 -bits, 12 "x"'s, is used to decode all remaining levels. For Lev-VLC1 to Lev-VLC6 tables, only the 28-bit escape code is used.

9.2.2.1 Table selection

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Selections of the tables are changed during the decoding process based on number of coefficients, number of trailing ones, and the previously decoded level value (coeff_level).

Let VLC denote the **Lev-VLC*N* (N=0-6) to be used.** After each level is decoded, the VLCN is updated according to the following method, where Level is the absolute value of the previously decoded level (coeff_level).

```
// VLC initialization for decoding first level
if (total_coeff(coeff_token) > 10 && trailing_ones(coeff_token)< 3)
   VLC = 1        // use Lev-VLC1 for first level
else
   VLC = 0        // use Lev-VLC0 for first level
// Assign FirstCoeff
// Decode level_code here and assign coeff_level and Level
// VLC update after decoding each level

vlc_inc table[6] = {0, 3, 6, 12, 24, 48}
if ((Level > vlc_inc[VLC]) && (VLC < 6))
   VLC++
if (FirstCoeff and Level > 3)
   VLC = 2
```

The first coefficient is always decoded with Lev-VLC0 or Lev-VLC1 while the rest of the coefficients are always decoded with Lev-VLC1 to Lev-VLC6.

The same procedure is used for chroma AC and DC coefficient levels.

9.2.3 Parsing process for run information

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

Run decoding is separated in total number of Zeros (i.e. the number of zeros located before the last non -zero coefficient in the zig-zag scan) and Run (of zeros) before each coefficient.

9.2.3.1 Parsing process for total number of zeros

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

The variable TotalZeros as given by total_zeros , is the sum of all zeros located before the last non -zero coefficient in a zig-zag scan. For example, given the string of coefficients 0 0 3 0 0 4 0 0 0 0 2 0 1 0 0 0, TotalZeros will be 2+2+4+1=9. Since TotalCoeff is already known, it determines the maximum possible value of TotalZeros. One out of 15 VLC tables is chosen based on TotalCoeff.

If TotalCoeff indicates that all coefficients are non-zero, TotalZeros is not decoded since it is known to be zero

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

9.2.3.2 Parsing process for run before each coefficient

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

At this stage it is known how many zeros are left to distribute (call this ZerosLeft). When decoding a run_before for the first time, ZerosLeft begins at TotalZeros, and decreases as more run_before elements are decoded.

For example, if there is only 1 zero left, the run before the next coefficient must be either of length 0 or 1, and only one bit is needed.

The number of preceding zeros before each non -zero coefficient (called RunBefore) needs to be decoded to properly locate that coefficient. Before decoding the next RunBefore, ZerosLeft is updated and used to select one out of 7 tables. RunBefore does not need to be decoded in the following two situations:

- If the total number of zeros has been reached (ZerosLeft = 0)
- For the last coefficient in the reverse zig-zag scan. Then the value is known to be ZerosLeft. This also means that the maximum value to be decoded is 14.

Table 9-18 – Tables for run_before

ZerosLeft Run Before	1	2	3	4	5	6	>6

9.3 CABAC parsing process for slice data

This process is invoked when parsing syntax elements with descriptor ae(v) in subclauses 7.3.4 and 7.3.5 and entropy_coding_mode is equal to 1.

Input to this process are bits from a slice layer RBSP and a request for a value of a syntax element .

Output of this process is the value of the syntax element.

When starting the parsing of the slice data of a slice in subclause 7.3.4, the initialisation process of the CABAC parsing process is invoked as specified in subclause 9.3.1.

The parsing of syntax elements proceeds as follows:

For each syntax element a binarization is derived as described in subclause 9.3.2.

The binarization for the syntax element and the sequence of parsed bins determines the decoding process flow as described in subcaluse 9.3.3.

For each bin of the binarization of the syntax element a context index Ctxldx is derived as specified in subclause 9.3.3.1.

For each Ctxldx the arithmetic decoding process is invoked as specified in subclause 9.3.3.2.

9.3.1 Initialisation process

Input to this process is the quantisation parameter QP_Y.

Output of this process are initialised CABAC internal variables.

The processes in subclauses 9.3.1.1 to 9.3.1.3 are invoked when starting the parsing of the slice data of a slice in subclause 7.3.4 and entropy_coding_ mode is equal to 1.

9.3.1.1 Initialisation process for contexts

Input to this process is the quantisation parameter QP_Y.

Output of this process are the initialised CABAC context models indexed by Ctxldx and the context identifier.

Each context model is initialised with an initial state, which consists of a state number and the meaning of the most probable symbol (MPS) as further described in subclause 9.3.3.2.2. The actual initial state of a context model depends linearly on the (initial) quantisation parameter QP_Y of the given slice, such that for each context model a pair of table entries {m, n} is given, from which the initial state is computed in the following way

1. Compute PreState = ((m*(QP_Y −12))>>4) + n;
2. Limit PreState to the range of [0,103], i.e.,
   PreState = min (103, max(0, PreState));
3. Map PreState to {State, MPS} pair according to the following rule:
   if (PreState <= 51) then {State = 51 -PreState, MPS = 0} else {State = PreState-52, MPS = 1}

For syntax elements specifically used for P- and B-slices only, there are always three tables defined. The index for addressing the used table is given by the indicator cabac_init_idc.

Table 9-19 – Table 9-29 contain the initialisation parameters {m, n} related to the context identifiers of all syntax elements except the end-of-slice flag.

For Ctxldx = 253 associated to the end_of_slice_flag and the bin of mb_type indicating the PCM mode, the initial state is given by State = 63 and MPS = 0.

NOTE – State=63 represents a non-adapted statewith fixed probability.

9.3.1.2 Initialisation process for the arithmetic decoding engine

Output of this process are the initialised decoding engine register CodeIntRange and CodeIntValOffset.

In the initialisation procedure of the decod er, as shown in Figure 9-1, CodeIntValOffset is first filled with nine bits of the compressed data using read_bits( ) and then CodeIntRange is set to 0x01FE.

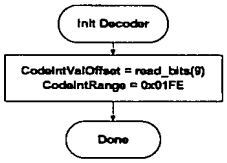

Figure 9-1 – Flowchart of initialisation of the decoding engine

9.3.1.3 Initialisation process for the arithmetic encoding engine (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

This process is invoked before encoding the first macroblock of a slice.

Output of this process are the values CodeIntLow and CodeIntRange of the arithmetic encoding engine.

In the initialisation procedure of the encoder, as illustrated in Figure 9-2, CodeIntLow is set to zero, and the range CodeIntRange is set to 0x01FE.

9.3.2 Binarization process

Input to this process is a request for a value of a syntax element.

Output of this process is the binarization of the syntax element and the associated context identifier.

The binarization process is a mapping process of a possibly non-binary valued syntax element onto a set of binary representations of values of the syntax element. The binary representation consists of a sequence of binary decisions, so-called bins.

Table 9-30 specifies the type of binarization process and context identifier associated to each syntax element. The specification of the unary (U) binarization process, the truncated unary (TU) binarization process, the concatenated unary / k^{th}-order Exp-Golomb (UEGk) binarization process, and the fixed-length (FL) binarization process is given in subclauses 9.3.2.1 to 9.3.2.4.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

coeff_absolute_value_minus1	CtxAbsLevel	UEG0, UCoff=14
coeff_sign_flag	CtxCoeffSignFlag	FL, C_{max}=1
end_of_slice_flag	CtxEosFlag	FL, C_{max}=1

9.3.2.1 Unary (U) binarization process

Input to this process is a request for a U binarization for a syntax element.

Output of this process is the U binarization of the syntax element.

Table 9-31 illustrates the unary binarization for a syntax element.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 9-31 – Unary binarization (informative)

syntax element	Binarization					
0	0					
1	1	0				
2	1	1	0			
3	1	1	1	0		
4	1	1	1	1	0	
5	1	1	1	1	1	0
...						
BinIdx	0	1	2	3	4	5

The binarization representation of a syntax element having value C is a bitstring of length C+1 indexed by BinIdx. The bins for BinIdx smaller than C are equal to 1. The bin with BinIdx equal to C is equal to 0.

9.3.2.2 Truncated unary (TU) binarization process

Input to this process is a request for a TU binarization for a syntax element and C_{max}.

Output of this process is the TU binarization of the syntax element .

For syntax element values smaller than C_{max} the unary binarization process as specified in subclause 9.3.2.1 is invoked. For the syntax element value equal to C_{max} the binary representation is a bitstring of length C_{max} +1 with all bins being equal to 1.

9.3.2.3 Concatenated unary/ k^{th}-order Exp-Golomb (UEGk) binarization process

Input to this process is a request for a UEGk binarization for a syntax element, parameter k and C_{max}.

Output of this process is the UEGk binarization of the syntax element.

Concatenated unary/k^{th}-order Exp-Golomb (UEGk) binarization consists of a concatenation of a prefix codeword and a suffix codeword. The prefix is formed by using a truncated unary binarization with C_{max} = UCoff, where UCoff denotes the cut-off parameter. For all syntax element values S with S < UCoff, the suffix codeword is void; for syntax element values S with S ≥ UCoff, the suffix consists of an Exp-Golomb code of order k for the symbol S – UCoff. For a given value S the Exp-Golomb code of order k is constructed as follows:

```
while( 1 ) {
    //first unary part of EGk
    if( S  >=  (unsigned int)( 1 << k ) )     {
       put( 1 );
       S = S - ( 1<<k );
       k++;
    } else {
       put( 0 );      //now terminating zero of unary part of EGk
       while( k-- )  //finally binary part of EGk
          put( ( S>>k )  &  0x01 );
       break;
    }
}
```

The indexing of bins is such that bin number BinIdx = 0 relates to the first binary decision in the unary prefix code with increasing indices towards the least significant bits of the binary part of the Exp-Golomb suffix.

9.3.2.4 Fixed-length (FL) binarization process

Input to this process is a request for a FL binarization for a syntax element and C_{max}.

Output of this process is the FL binarization of the syntax element.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Fixed-length (FL) binarization is constructed by using a L-bit binary representation of the syntax element value, where L = ceil($\log_2$(C_{max}+1)). The indexing of bins for the fixed-length binarization is such that the BinIdx = 0 relates to the least significant bit with increasing bin indices towards the most significant bit.

9.3.2.5 Binarization process for macroblock type and sub-macroblock type

Input to this process is a request for a binarization for syntax elements mb_type or sub_mb_type.

Output of this process is the binarization of the syntax element.

The binarization scheme for decoding of macroblock type in I slices is specified in Table 9-32. For macroblock types in SI slices the binarization consists of a prefix and a suffix part. The prefix consists of a single bit b_0 = ((mb_type == SI) ? 0 : 1). The suffix part for mb_type SI is void, while the suffix parts for all other macroblock types are given by the corresponding binarization pattern specified in Table 9-32.

The binarization schemes for P, SP, and B slices are specified in Table 9-33. The binarization for intra macroblock types in P and SP slices corresponding to mb_type values 7 to 32 consists of a prefix as specified in Table 9-33 and a suffix as specified in Table 9-32 for the corresponding intra mb_type. For intra macroblock types in B slices (mb_type values 23 to 48) the binarization consists of a prefix as specified in Table 9-33 and a suffix as specified in Table 9-32 for the corresponding intra mb_type.

For P, SP, and B slices the specification of the binarization for sub_mb_type is given in Table 9-34.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 9-32 – Binarization for macroblock types for I slices

9.3.2.6 Binarization process for motion vectors

Input to this process is a request for a binarization for the syntax element mvd_l0 or mvd_l1.

Output of this process is the binarization of the syntax element.

The binarization of the motion vector difference mvd_l0[i][j] or mvd_l 1[i][j] consists of a prefix and a suffix part. The prefix part of the binarization is given by the concatenated unary/3rd-order Exp-Golomb (UEG3) binarization of the absolute value of mvd_lx[i][j] (x = 0,1) with cut-off parameter UCoff = 9. The suffix part consists of the FL binarization of ½*(1-Sign(mvd_lx[i][j])) (x = 0,1) with C_{max} = 1.

9.3.2.7 Binarization process for coded block pattern

Input to this process is a request for a binarization for the syntax element coded_block_pattern.

Output of this process is the binarization of the syntax element.

The binarization of coded block pattern consists of a prefix and a suffix part. The prefix part of the binarization is given by the FL binarization of CodedBlockPatternLuma with C_{max} = 15 and L = 4. The suffix part consists of the TU binarization of CodedBlockPatternChroma with C_{max} = 2. The relationship between the value of the syntax element coded_block_pattern and the values of CodedBlockPatternLuma and CodedBlockPatternChroma is given as specified in subclause 7.4.5: coded_block_pattern = CodedBlockPatternLuma + 16 × CodedBlockPatternChroma.

9.3.2.8 Binarization process for mb_qp_delta

Input to this process is a request for a binarization for the syntax element mb_qp_delta.

Output of this process is the binarization of the syntax element.

The binary representation of mb_qp_delta is obtained by the U binarization of the mapped value of the syntax element mb_qp_delta, where the assignment rule between the signed value of mb_qp_delta and its m apped value is given as specified in Table 9-3.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

9.3.3 Decoding process flow

Input to this process is a binarization of the syntax element to be parsed and its context identifier as specified in subclause 9.3.2.

Output of this process is the value of the syntax element.

This process specifies how each bit of a bitstring is parsed for each syntax element.

After parsing each bit, the resulting bitstring is compared to one of the binary representations of the bin arization of the syntax element.

If the bitstring is equal to one of the binary representations, the corresponding value of the syntax element is returned. Otherwise, the next bit is parsed as described below.

While parsing each bin of the binarization, t he variable BinIdx is incremented by one starting with BinIdx=0 for the first bin. The variable BinIdx and the context identifier are used to determine the CtxIdx as specified in subclause 9.3.3.1.

The CtxIdx is used to parse th e value of the bin from the bitstream as specified in subclause 9.3.3.2.

9.3.3.1 Derivation process for the CtxIdx

Input to this process is the BinIdx and the context identifier.

Output of this process is the CtxIdx.

Table 9-35 shows the assignment of MaxCtxBinIdx and the ranges of CtxIdx to context identifiers.

All bins with BinIdx greater than MaxCtxBinIdx are parsed using the context assigned to MaxCtxBinIdx. If in Table 9-35 an entry for MaxCtxBinIdx is labeled as "na", no bins with BinIdx greater than MaxCtxBinIdx exist.

For all bins with BinIdx greater or equal to MinBinIdxEqProb the variable CtxEqPropFlag is set to 1. For bins with BinIdx smaller than MinBinIdxEqProb or for all bi ns of context identifiers, where in Table 9-35 an entry for MaxBinIdxEqProb is labeled as "na", CtxEqPropFlag is set to 0. CtxEqPropFlag is used to indicate that for parsing the value of the bin from the bitstream the arithmetic de coding process for decisions with uniform pdf as specified in subclause 9.3.3.2.2.3 shall be applied.

The context indices CtxIdx are labeled in a range from 0 to 253. The assignments of context identifier to ranges of CtxIdx is specified in Table 9-35. The lower value of the range of CtxIdx assigned to a syntax element specifies the offset for the CtxIdx (CtxIdxOffset).

NOTE – Some syntax elements can never occur together in a slice and therefore sometimes share the same CtxIdx.

CtxIdx=253 is assigned to the syntax element end_of_slice_flag and the bin of mb_type indicating the PCM mode. It represents a context, where the probabilities are fixed and not adapted. For parsing the value of the corresponding b ins from the bitstream, the arithmetic decoding process for decisions before termination as specified in subclause 9.3.3.2.2.4 shall be applied.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 9-37 shows the assignment of CtxIdx incremen ts (CtxIdxInc) to CtxCat for context identifiers CtxCodedBlock, CtxSigCoeff, CtxLastCoeff for BinIdx equal to 0. Depending on CtxCat, the range for the context identifiers CtxCodedBlock, CtxSigCoeff, CtxLastCoeff assigned to BinIdx is specified by CtxIdxOf fset + CtxIdxInc(CtxCat). Note that the specification of CtxCat is given in Table 9-41.

Table 9-37 – Assignment of CtxIdxInc to CtxCat for context identifiers CtxCodedBlock, CtxSigCoef f, and CtxLastCoeff

Context identifier	CtxCat (as specified in Table 9-41)				
	0	1	2	3	4
CtxCodedBlock	0 – 3	4 – 7	8 – 11	12 – 15	16 – 19
CtxSigCoeff	0 – 14	15 – 28	29 – 43	44 –46	47 – 60
CtxLastCoeff	0 – 14	15 – 28	29 – 43	44 –46	47 – 60

Table 9-38 shows the assignment of CtxIdx increments (CtxIdxInc) to BinIdx and CtxCat for context identifier CtxAhsLevel. Depending on CtxCat, the range for the context identifier CtxAbsLevel assigned to BinIdx is specified by CtxIdxOffset + CtxAbsLevelOffset(CtxCat) + CtxIdxInc(CtxCat).

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table 9-38 – Assignment of CtxAbsLevelOffset and CtxIdxInc to CtxCat for context identifier CtxAbsLevel

CtxCat	CtxAbsLevelOffset	BinIdx=0	BinIdx > 0
0	0	0,1,2,3,4	5,6,7,8,9
1	10	0,1,2,3,4	5,6,7,8,9
2	20	0,1,2,3,4	5,6,7,8,9
3	30	0,1,2,3,4	5,6,7,8
4	39	0,1,2,3,4	5,6,7,8,9

Further specification of CtxIdxInc for all context identifiers with the ranges of CtxIdx depending on BinIdx or CtxCat are given in subclauses 9.3.3.1.1 to 9.3.3.1.3.

For some BinIdx and context identifiers, CtxIdxInc is derived using context templates applied to prior in decoding order parsed syntax elements or parts thereof as specified in subclause 9.3.3.1.1.

For some BinIdx and context identifiers, CtxIdxInc is derived using context templates applied to prior in decoding order parsed bins as specified in subclause 9.3.3.1.2.

For the context identifiers CtxCodedBlock, CtxSigCoeff, CtxLastCoeff, and CtxAbsLevel, CtxIdxInc is derived as specified in subclause 9.3.3.1.3.

9.3.3.1.1 Assignment process of CtxIdxInc for context templates using two neighbouring syntax elements

Input to this process are a context identifier and a BinIdx.

Output of this process is a context index CtxIdxInc.

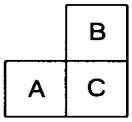

Figure 9-3 – Illustration of the generic context template using two neighbouring syntax elements A and B for conditional decoding of a current syntax element C

The generic design of this type of context template is shown in Figure 9-3. It involves two prior decoded syntax elements or prior decoded bins of the same syntax element that correspond to the spatially neighbouring blocks to the left (A) and on the top (B) of the regarded block C. The generic form of the equation specifying this type of context is given by

$$CtxVarSpat = CondTerm(A, B) \quad (9\text{-}1)$$

where the conditioning term CondTerm(A, B) describes the functional relationship between the spatially neigbbouring prior decoded syntax elements A and B, on the one hand, and CtxIdxInc, on the other hand. Three special cases of this template are specified as follows:

$$CtxVarSpat1 = CondTerm(A) + CondTerm(B) \quad (9\text{-}2)$$

$$CtxVarSpat2 = CondTerm(A) + 2*CondTerm(B) \quad (9\text{-}3)$$

$$CtxVarSpat3 = CondTerm(A). \quad (9\text{-}4)$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table 9-39 – Specification of CondTerm for context identifiers and BinIdx using context templates according to Equations (9-2) – (9-4)

Context identifier	BinIdx	Context template	CondTerm(X), semantics of X	CondTerm(X), if X not available
CtxMbSkip	0	CtxVarSpat1	(mb_skip_flag(X) == 0) ? 1 : 0 X: neighbouring macroblock	0
CtxMbTypeI	0	CtxVarSpat1	(mb_type(X) != I_4x4) ? 1: 0 X: neighbouring macroblock	0
CtxMbTypeSIPrefix	0	CtxVarSpat1	(mb_type(X) != SI) ? 1: 0 X: neighbouring macroblock	0
CtxMbTypeSISuffix	0	CtxVarSpat1	(mb_type(X) != I_4x4) ? 1: 0 X: neighbouring macroblock	0
CtxMbTypeB	0	CtxVarSpat1	((mb_type(X) != B_Direct_16x16) ? 1: 0) X: neighbouring macroblock	0
CtxIpredChroma	0	CtxVarSpat1	((intra_chroma_pred_mode(X) != 0) ? 1: 0) X: neighbouring macroblock	0
CtxRefIdx	0	CtxVarSpat2	(ref_idx_l0 != 0 bzw. ref_idx_l1(X) != 0) ? 1: 0 X: neighbouring block	0
CtxMbField	0	CtxVarSpat1	((mb_field_decoding_flag(X) != 0) ? 1: 0) X: neighbouring macroblock pair	0
CtxCbpLuma	i=0-3	CtxVarSpat2	i-th bit of CodedBlockPatternLuma(X) X: neighbouring 8x8 block of i-th block	0
CtxCbpChroma	0	CtxVarSpat2	(CodedBlockPatternChroma(X) != 0) ? 1: 0 X: neighbouring macroblock	0
CtxCbpChroma	1	CtxVarSpat2	4 + (CodedBlockPatternChroma(X) == 2) ? 1: 0 X: neighbouring macroblock	0
CtxCodedBlock	0	CtxVarSpat2	coded_block_flag(X) X: neighbouring block of same BlockType	1, if X is INTRA; 0, otherwise
CtxMbQpDelta	0	CtxVarSpat3	(mb_qp_delta(X) != 0) ? 1: 0 X: neighbouring macroblock	0

Table 9-39 contains the specification of CondTerm for context identifiers and BinIdx relying on templates using two neighbouring symbols. Note that the conditioning term CondTerm of the context identifier CtxCodedBlock depends on six block types as given in Table 9-41 (Luma-DC, Luma-AC, Chroma-U-DC, Chroma-V-DC, Chroma-U-AC, Chroma-V-AC). The interpretation of a neighbouring macroblock used for determination of CtxMbSkip has to be specified more precisely for the case of MB-adaptive frame/field coding. Since the decoder may not know the specific choice of frame or field mode when decoding the mb_skip_flag, it is always assumed that co -location of macroblocks for context determination has to be interpreted as co -location in the sense of pure frame coding. That means, for instance, that for context determination the macroblock on top of the current skipped macroblock in a (potential) top field position is always chosen as the bottom field MB of the MB pair above the current macroblock.

The specification of CtxIdxInc for the context identifiers CtxAbsMvdHoriz and CtxAbsMvdVert for BinIdx equal to 0 is given as follows.

$$CtxIdxInc(CtxAbsMvdComp) = \begin{cases} 0, (AbsMvdComp(A) + AbsMvdComp(B)) < 3, \\ 2, (AbsMvdComp(A) + AbsMvdComp(B)) > 32, \\ 1, otherwise, \end{cases} \quad (9\text{-}5)$$

where Comp denotes the horizontal component (Comp=Horiz) or vertical component (Comp=Vert) and A, B denote the neighbouring blocks of the current block to decode as shown in Figure 9-3. AbsMvdComp denote the absolute value of the corresponding component Comp of the motion vector difference. Since the neighbouring blocks A and B may belong to different macroblock partitions, the following principle for identifying the proper neighbouring blocks in Equation 9 -5 shall be applied. First, the motion vector difference is assumed to be given in oversampled form such that each 4x4 block

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

has its own motion vector difference (Mvd). That means, on the one hand, that in case of a neighbouring block having a coarser partition, the related 4x4 sub-blocks are assumed to inherit the Mvd from the corresponding parent block(s) in the quadtree partition. On the other hand, if the current block C represents a larger block than a 4x4 block, C shall be represented by the corresponding leftmost 4x4 sub-block in the top row of 4x4 sub-blocks. Then, given a block C, the neighbouring 4x4 sub-blocks B on top and A to the left of the representing 4x4 sub-block of C are chosen for evaluation of Equation 9-5. [Ed.Note: This paragraph should be re-written using the geometrical concepts]

9.3.3.1.2 Assignment process of CtxIdxInc for context templates using prior decoded bin values

Let $(b_0,b_1,b_2,\ldots, b_{k-1})$ denote the current bitstring of decoded bins related to a given syntax element C. Then, a generic type of context template associated to BinIdx = k of C is specified as

$$CtxVarBin = CondTerm(b_0,\ldots,b_{k-1}) \qquad (9\text{-}6)$$

where $k \geq 1$. Table 9-40 contains the specification of CondTerm for context identifiers and BinIdx using this type of context template.

Table 9-40 – Specification of CondTerm for context identifiers and BinIdx using the context template according to Equation 9-6

Context identifier	BinIdx	CondTerm($b_0,\ldots,b_{k-1}$)
CtxMbTypeI	4	(b_3 != 0) ? 5: 6
CtxMbTypeI	5	(b_3 != 0) ? 6: 7
CtxMbTypeI	6	7
CtxMbTypeSISuffix	4	(b_3 != 0) ? 5: 6
CtxMbTypeSISuffix	5	(b_3 != 0) ? 6: 7
CtxMbTypeSISuffix	6	7
CtxMbTypeP	2	(b_1 != 0) ? 2: 3
CtxMbTypePSuffix	3	(b_2 != 0) ? 2: 3
CtxMbTypeB	2	(b_1 != 1) ? 4: 5

9.3.3.1.3 Assignment process of CtxIdxInc for context identifiers used for transform coefficients

Three different additional context identifiers are used for conditioning of information related to transform coefficients. All these three types depend on context categories of different block types (BlockType) denoted by the variable CtxCat. The specification of these context categories is given in Table 9-41.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table 9-41 – Context categories for the different block types

BlockType	MaxNumCoeff	CtxCat
Luma DC block for INTRA16x16 mode	16	0:Luma-Intra16-DC
Luma AC block for INTRA16x16 mode	15	1:Luma-Intra16-AC
Luma block for INTRA 4x4 mode	16	2:Luma-4x4
Luma block for INTER 4x4 mode	16	
U-Chroma DC block for INTRA mode	4	3:Chroma-DC
V-Chroma DC block for INTRA mode	4	
U-Chroma DC block for INTER mode	4	
V-Chroma DC block for INTER mode	4	
U-Chroma AC block for INTRA mode	15	4:Chroma-AC
V-Chroma AC block for INTRA mode	15	
U-Chroma AC block for INTER mode	15	
V-Chroma AC block for INTER mode	15	

The context identifiers CtxSigCoeff and CtxLastCoeff are related to significant_coeff_flag and last_significant_coeff_flag, respectively; the CtxIdxInc of the related context identifiers depend on the scanning position ScanningPos within the regarded block:

$$\text{CtxIdxInc}(\text{CtxSigCoeff}, \text{ScanningPos}) = \text{ScanningPos} \tag{9-7}$$

$$\text{CtxIdxInc}(\text{CtxLastCoeff}, \text{ScanningPos}) = \text{ScanningPos} \tag{9-8}$$

For decoding of coeff_absolute_value_minus1, the CtxIdxInc for the context i dentifier CtxAbsLevel is specified depending on BinIdx as follows:

$$\text{CtxIdxInc}(\text{CtxAbsLevel}, \text{BinIdx}=0) = ((\text{NumDecodAbsLevelGt1} != 0)\ ?\ 4 :\ \min(3, \text{NumDecodAbsLevelEq1})) \tag{9-9}$$

$$\text{CtxIdxInc}(\text{CtxAbsLevel}, \text{BinIdx} > 0) = \min(4, \text{NumDecodAbsLevelGt1}) \tag{9-10}$$

where NumDecodAbsLevelEq1 denotes the accumulated number of decoded coefficients with absolute value equal to 1, and NumDecodAbsLevelGt1 denotes the accumulated number of d ecoded coefficients with absolute value greater than 1. Both numbers are related to the same transform coefficient block, where the current decoding takes place, which means that no additional information outside the regarded transform coefficient block is used for the context identifier CtxAbsLevel.

9.3.3.2 Arithmetic decoding process

Input to this process is CtxEqProbFlag and CtxIdx as derived in subclause 9.3.3.1.

Output of this process is the value of the bin.

NOTE - Arithmetic coding is based on the principle of recursive interval subdivision. Given a probability estimation p(0) and p(1)=1−p(0) of a binary decision (0, 1), an initially given code sub-interval with the range CodeIntRange will be subdivided into two sub-intervals having range p(0) × CodeIntRange and CodeIntRange −p(0) × CodeIntRange, respectively. Depending on the decision, which has been observed, the corresponding sub-interval will be chosen as the new code interval, and a binary code string pointing into that interval will represent the sequence of observed binary decisions. It is useful to distinguish between the most probable symbol (MPS) and the least probable symbol (LPS), so that binary decisions have to be identified as either MPS or LPS, rather than 0 or 1. Given this terminology, each context is specified by the probability p_{LPS} of the LPS and the value of MPS, which is either 0 or 1.

The arithmetic core engine in this Recommendation | International Standard has three distinct properties:

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

- The probability estimation is performed by means of a finite-state machine with a table-based transition process between 64 different representative probability states $\{P_k \mid 0 \le k < 64\}$ for the LPS probability p_{LPS}.
- The range CodeIntRange representing the state of the coding engine is quantized to a small set $\{Q_1,\ldots,Q_4\}$ of pre-set quantisation values prior to the calculation of the new interval range. Storing a table containing all 64×4 pre-computed product values of $Q_i \times P_k$ allows a multiplication-free approximation of the product CodeIntRange × P_k.
- For syntax elements or parts thereof with an approximately uniform probability distribution a separate simplified encoding and decoding path is used.

9.3.3.2.1 Probability estimation process

Input to this process are the current State and MPS values of CtxIdx.

Output of this process are the updated State and MPS of the context associated to CtxIdx.

The probability estimator is realized by a set of representative probabilities $\{ P_k \mid 0 \le k < 64 \}$ for the LPS together with some appropriately specified state transition rules. Table 9-42 shows the transition rules for adapting to a given MPS or LPS decision. For transition from one state to another each state is only addressed by its index State, which will be appropriately changed to a new index NextStateMPS(State) or NextStateLPS(State) after the decoding of a MPS or LPS symbol, respectively.

The numbering of the states is arranged in such a way that the state with index State=0 corresponds to a LPS probability value of 0.5, with decreasing LPS probability towards higher states.

After encoding or decoding a decision, an update of the probability estimate is obtained by switching the state index State to a new index:

```
if( decision  = =  MPS )
      State ← NextStateMPS(State)
else
      State ← NextStateLPS(State).
```

In the case, where the current state corresponds to a probability value of 0.5, which corresponds to the State index of 0, and a LPS symbol is observed, the sense of MPS and LPS has to be interchanged.

Table 9-42 – Probability transition

State	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
NextStateLPS	0	0	1	2	2	4	4	5	6	7	8	9	9	11	11	12

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

9.3.3.2.2 Table-based arithmetic decoding process

Input to this process are CtxIdx and BinIdx, for which the arithmetic decoding proce ss is invoked, CtxEqProbFlag, and the state variables CodeIntRange and CodeIntValOffset of the arithmetic decoding engine.

Output of this process is the value of the bin corresponding to BinIdx.

The status of the arithmetic decoding engine is represented b y the range of the code sub-interval (CodeIntRange) and the variable CodeIntValOffset specifiying the offset between a value pointing into the code sub -interval and the lower bound of the corresponding code sub-interval. Figure 9-4 illustrates the whole decoding process. By invoking the InitDecoder process before starting the parsing of the slice data, as specified in subclause 9.3.1.2, CodeIntRange and CodeIntValOffset are initialised. For decoding of th e value of a bin for a given BinIdx and CtxIdx, the context index CtxIdx is passed to the actual arithmetic decoding processes Decode(CtxIdx), Decode_eq_prob(CtxIdx) or Decode_terminate(CtxIdx). If CtxEqProbFlag is equal to 1, Decode_eq_prob( ) is invoked. If CtxEqProbFlag is equal to 0 and CtxIdx is equal to 253, Decode_eq_prob( ) is invoked; in all other cases Decode( ) as specified in subclause 9.3.3.2.2.1 shall be applied.

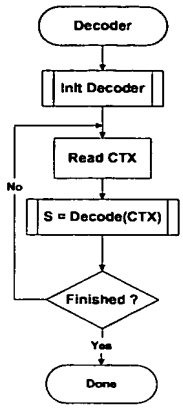

Figure 9-4 – Overview of the arithmetic decoding process (informative) [Ed.Note: Either Flowchart has to be updated or removed]

9.3.3.2.2.1 Decoding process for a decision

Input to this process are CtxIdx and the state variables CodeIntRange and CodeInt ValOffset.

Output of this process are the decoded value, and the updated state variables CodeIntRange and CodeIntValOffset.

Figure 9-5 shows the flowchart for decoding a single decision. In a first step, the estimation of the sub -interval ranges CodeIntRange(LPS) and CodeIntRange(MPS) = CodeIntRange – CodeIntRange(LPS) corresponding to the LPS and the MPS decision is performed as follows.

Given the interval range CodeIntRange, the CodeIntRange is first mapped to a quantized value Qu antCodeIntRange according to

$$\text{QuantCodeIntRange} = (\text{CodeIntRange} >> 6) - 4 \qquad (9\text{-}11)$$

such that the state index State and QuantCodeIntRange are used as an entry in the look-up table RTAB to determine CodeIntRange(LPS):

$$\text{CodeIntRange(LPS)} = \text{RTAB}[\text{State}][\text{QuantCodeIntRange}]. \qquad (9\text{-}12)$$

Table 9-43 specifies the corresponding values of RTAB.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

In a second step, the current value of CodeIntValOffset is compared to the size of the MPS sub-interval CodeIntRange ← CodeIntRange – CodeIntRange(LPS). If CodeIntValOffset is greater than or equal to CodeIntRange a LPS is decoded, CodeIntValOffset is decremented by CodeIntRange and the new range CodeIntRange is s et to CodeIntRange(LPS); otherwise a MPS is decoded. Given the decoded decision, the probability update is performed accordingly as specified in subclause 9.3.3.2.1. Depending on the current value of the new range CodeIntRange, renormalization will be performed as specified in subclause 9.3.3.2.2.2.

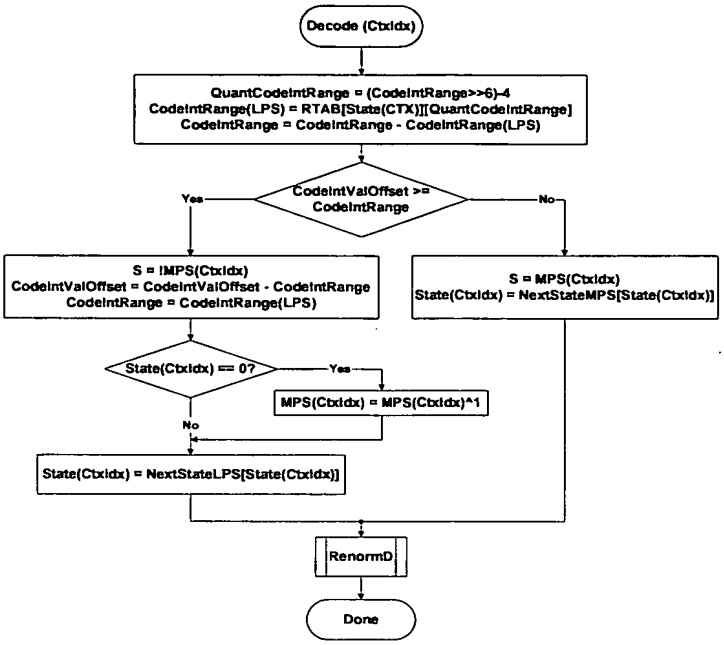

Figure 9-5 – Flowchart for decoding a decision

9.3.3.2.2.2 Renormalization process in the arithmetic decoding engine

Input to this process are bits from a slice layer RBSP and the state variables CodeIntRange and CodeIntValOffset.

Output of this process are the updated state variables CodeIntRange and CodeIntValOffset.

Renormalization is illustrated in Figure 9-6. The current range CodeIntRange is first logically compared to 0x0100: If it is greater than or equal to that value, no renormalization is needed and RenormD is finished; otherwise the renormalization loop is entered. Within this loop, the range CodeIntRange is doubled, i.e. left-shifted by 1 and a single bit is shifted into CodeIntValOffset by using read_bits(1).

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

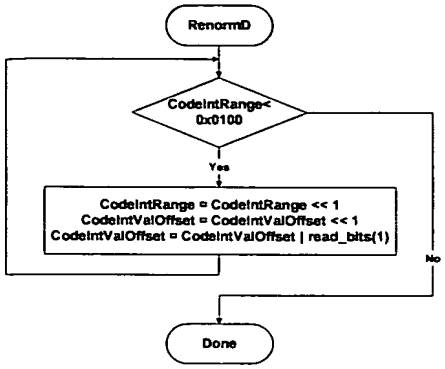

Figure 9-6 – Flowchart of renormalization

9.3.3.2.2.3 Arithmetic decoding process for decisions with uniform pdf using arithmetic decoder bypass

Input to this process are bits from a slice layer RBSP and the state variables CodeIntRange and CodeIntValOffset.

Output of this process are the updated state var iables CodeIntRange and CodeIntValOffset, and the decoded value.

This special decoding routine is invoked when CtxEqProbFlag is equal to 1. Figure 9-7 specifies the decoding process for this special case.

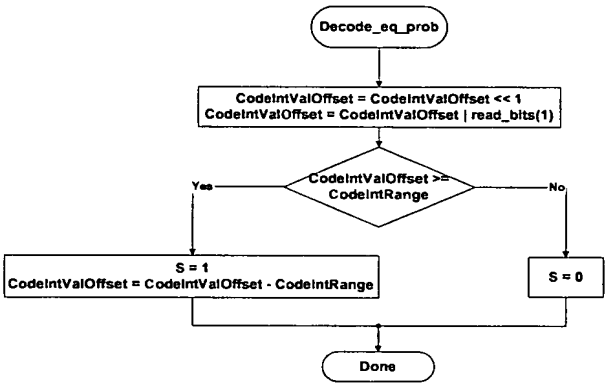

Figure 9-7 – Flowchart of decoding bypass

9.3.3.2.2.4 Decoding process for decisions before termination

Input to this process are bits from a slice layer RBSP and the state variables CodeIntRange and CodeIntValOffset.

Output of this process are the updated state variables CodeIntRange and CodeIntValOffset, and the decoded value.

This special decoding routine applies to decoding of end_of_slice_flag and of the bin indicating the PCM mode. Probabilities are fixed and not adapted. Figure 9-8 shows the flowchart of the corresponding decoding process. When the decision S is equal to 1 no renormalization is carried out and CABAC decoding is terminated. In such a case the last bit inserted in register CodeIntValOffset is the stop_bit.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

NOTE – This procedure may also be implemented using decode(CtxIdx) and setting State(CtxIdx) to 63 and MPS(CtxIdx) to 0. In the case where the result is S = 1, seven more bits would be read by decode(CtxIdx) and a decoder would have to adjust its bitstream pointer accordingly to properly decode following syntax elements.

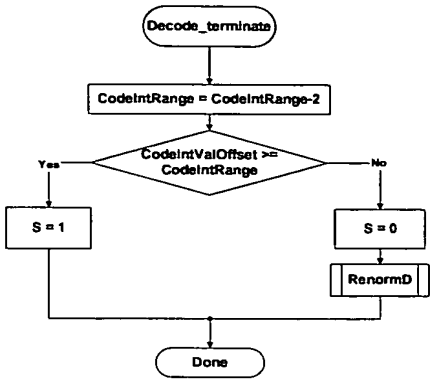

Figure 9-8 – Flowchart of decoding a decision before termination

9.3.3.2.3 Table-based arithmetic encoding process (informative)

[Ed.Note: This subclause needs to be revisited and updated according to the new terminology used in the arithmetic decoding spec.]

This subclause does not form an integral part of this Recommendation | International Standard.

Input to this process are decisions that are to be encoded and written, and the arithmetic encoding engine variables R and L.

Output of this process are bits that are written to the RBSP.

This informative subclause describes an arithmetic encoding engine that mach es the arithmetic decoding engine described in subclause 9.3.3.2.2. The status of the arithmetic encoding engine is represented by a value L pointing to the lower end of a sub-interval and the corresponding range R of that sub -interval. Figure 9-9 gives an illustration of the whole encoding process. Performing the InitEncoder procedure, which is further specified in subclause **Error! Reference source not found.**, L and R will be appropriately initialised. For encoding of each single decision S, the following two-step operation is employed: first, the related context model CTX is determined according to the rules specified in subclauses **Error! Reference source not found.**. Given the context model CTX and a symbol S the encoding operation Encode(CTX,S) then writes zero or more bits as described in subclause 9.3.3.2.3.1 to the current RBSP.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

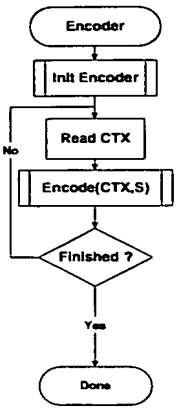

Figure 9-9 – Overview of the arithmetic encoding process

9.3.3.2.3.1 Encoding process for a decision (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Input to this process are the context variable (CTX), the decision to be encoded (S), and the arithmetic coding engine variables R and L.

Output of this process is the state of the arithmetic encoding engine State(CTX).

Figure 9-10 shows the flowchart for encoding a single decision. In a first step, the estimation of the sub-interval ranges R_{LPS} and $R_{MPS} = R - R_{LPS}$ corresponding to the LPS and the MPS decision is performed as follows.

Given the interval range R, we first map R to a quantized value Q using Equation 9-11 such that the state index State and Q are used as an entry in the look-up table RTAB to determine R_{LPS} as specified in Equation 9-12.

In a second step, the value of *S* is compared to the value of MPS(CTX). If S is different from MPS(CTX), R is added to L and then R is set to the value R_{LPS}. Given the encoded decision, the probability update is performed accordingly as specified in subclause 9.3.3.2.1. Depending on the current value of the new range R, renormalization will be performed as described in more detail in subclause 9.3.3.2.3.2.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

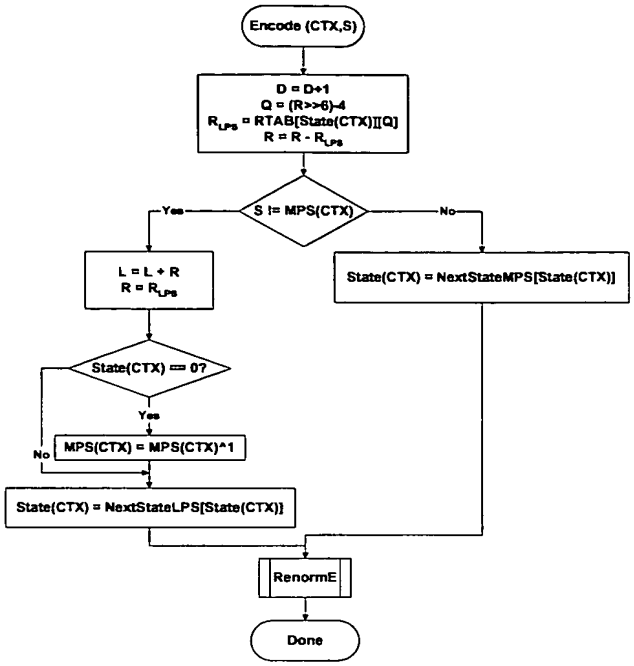

Figure 9-10 – Flowchart for encoding a decision

9.3.3.2.3.2 Renormalization process in the arithmetic encoding engine (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Input to this process are arithmetic coding engine variables R and L.

Output of this process are bits that are written to the RBSP.

Renormalization is illustrated in Figure 9-11. The current range *R* is first logically compared to 0x0100: If it is greater than or equal to that value, no renormalization is needed and RenormE is finished; otherwise the renormalizat ion loop is entered. Within this loop, it is first determined if a 0 or a 1 can safely be output, e.g. there is no possibility for a carry over in a future iteration. Otherwise the BO register is incremented by 1. Finally the values of L and R are doubled. The PutBit procedure described in Figure 9-12 provides carry over control.

9.3.3.2.3.3 Writing process for compressed bytes (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Input to this process is/are ??? [Ed.Note: spec ify input to this process]

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Output of this process is/are ??? [Ed.Note: specify output of this process]

Figure 9-13 shows how the output of compressed data is performed. First, a new byte of compressed data is written out to the RBSP bitstream C; then the index CL pointing to the current position of the bitstream C is incremented by 1 and the bit-counter is set to 7.

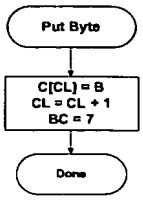

Figure 9-13 – Flowchart for output of compressed bytes

9.3.3.2.3.4 Arithmetic encoding process for decisions with uniform pdf using encoder bypass (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Input to this process is/are ??? [Ed.Note: specify input to th is process]

Output of this process is/are ??? [Ed.Note: specify output of this process]

This special encoding routine applies to encoding of the sign information of motion vector data and the sign of the levels of significant transform coefficients, which are assumed to have a uniform probability distribution. Renormalization is included in the Figure 9-14.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

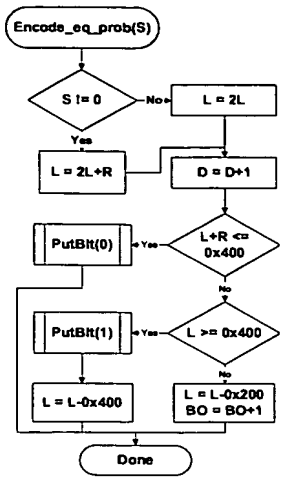

Figure 9-14 – Flowchart of encoding bypass

9.3.3.2.3.5 Encoding process for a decision before termination (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Input to this process is/are ??? [Ed.Note: specify input to this process]

Output of this process is/are ??? [Ed. Note: specify output of this process]

This encoding routine shown in Figure 9-15 applies to encoding of end_of_slice_flag and of the bin indicating the PCM mode. Probabilities are fixed and not adapted. When the symbol S is equal t o 1 CABAC encoding is terminated. In such a case the last byte B written by PutByte( ) contains the stop_bit as well as the alignment bits.

After terminating the arithmetic encoder at the end of a slice, the encapsulation procedure is invoked. Let N be th e number of bytes in the NAL unit after encapsulation and M the number of macroblocks in the slice. Furthermore let K be ceil((ceil((D-M)/32)-N)/3). If K is smaller than or equal to zero, no cabac_stuffing_bytes are appended to the NAL unit. Otherwise the 3-byte sequence 0x000003 is appended K times to the NAL unit after encapsulation, where the first two bytes 0x0000 represent a cabac_stuffing_word and the third byte 0x03 represents an emulation_prevention_byte.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Annex A
Profiles and levels

(This annex forms an integral part of this Recommendation | International Standard)

[Ed. Note:

1. Depending on final terminology, it may be necessary to change "picture" to "frame"; check terms. "Max picture size" is meant to refer to a complete picture (both fields) if interlaced. The same goes for other uses of the word "picture" in this annex.
2. Yellow highlighted text in this subclause re quires further consideration regarding proper terminology.
3. We need limits on slice sizes to properly bound slice_id]

Profiles and Levels specify the capabilities needed to decode the bitstream, and may be used to indicate interoperability points between individual decoder implementations.

NOTE - This Recommendation | International Standard does not include individually selectable "options" at the decoder, as this would increase interoperability difficulties.

Each Profile specifies a set of algorithmic featu res and limits which shall be supported by all decoders conforming to that Profile. Note that encoders are not required to make use of any particular set of features supported in a Profile.

Each Level specifies a set of limits on the values which may be t aken by the parameters of this Recommendation | International Standard. The same set of Level definitions is used with all Profiles, but individual implementations may support a different Level for each supported Profile. For any given Profile, Levels ge nerally correspond to decoder processing and memory capability, in units based on video decoding, rather than on specific implementation platforms.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

A.1 Requirements on video decoder capability

Capabilities of video decoders conforming to this Recommendation | International Standard are specified in terms of the ability to decode video streams conforming to constraints Profiles and Levels specified in this Annex. For each such Profile, the Level supported for that Profile shall also be expressed. Such expressi on may be in the form of coded values equivalent to a specific Profile and specific Level from this Annex.

Specific values are specified in this annex for the syntax elements profile_idc and level_idc. All other values of profile_idc and level_idc are reserved for future use by ITU-T | ISO/IEC.

NOTE: Decoders should not infer that if a reserved value of profile_idc or level_idc falls between the values specified in this Recommendation | International Standard this indicates intermediate capabilities between the specified profiles or levels, as there are no restrictions on the method to be chosen by ITU-T | ISO/IEC for the use of such future reserved values.

A.2 Profiles

A.2.1 Baseline profile

[Ed.Note: this subclause needs to be formalized s.t. the use of a feature i s indicated by a values of syntax elements.]

All decoders supporting the Baseline Profile shall be capable of decoding bitstreams which use the following features:

a) I and P slices types
b) Deblocking filter
c) Pictures with field_pic_flag equal to 0
d) Pictures with mb_adaptive_frame_field_flag equal to 0
e) Zig-zag scan
f) 1/4-sample inter prediction
g) Tree-structured motion segmentation down to 4x4 block size
h) VLC-based entropy coding
i) Arbitrary slice order (ASO): In Baseline profile, the decoding order of slices within a pi cture may not follow the constraint that first_mb_in_slice is monotonically increasing within the NAL unit stream for a picture.
j) Flexible macroblock ordering (FMO, maximum 8 slice groups): In Baseline profile, num_slice_groups_minus1<8.
k) Redundant slices
l) 4:2:0 chroma format

Conformance to the Baseline Profile is indicated by setting the syntax element profile_idc equal to 66.

A.2.2 Main profile

All decoders supporting the Main Profile shall be capable of decoding bitstreams which use the following features:

a) B slice types
b) CABAC
c) Weighted prediction
d) All features included in the Baseline Profile except:
    1. Arbitrary Slice Order (ASO): In Main profile, the decoding order of slices within a picture shall follow the constraint that first_mb_in_slice shall be monotonically i ncreasing within the NAL unit stream for a picture.
    2. Flexible Macroblock Order (FMO): In Main profile, num_slice_groups_minus1 shall be zero.
    3. Redundant Slices

Decoders supporting the Main Profile Level 2.1 and above shall also be capable of decoding bitstr eams using:

e) Pictures with field_pic_flag equal to 1
f) Pictures with mb_adaptive_frame_field_flag equal to 1

Conformance to the Main profile is indicated by setting the syntax element profile_idc equal to 77.

A.2.3 X profile

All decoders supporting the X Profile s hall be capable of decoding bitstreams which use the following features:

a) B slice types
b) SP and SI slice types
c) Slice slice data partitioning (nal_unit_type being equal to 2 through 4)
d) Weighted prediction
e) All features included in the Baseline Profile

Decoders supporting the X Profile Level 2.1 and above shall also be capable of decoding bitstreams using:

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

f) Pictures with field_pic_flag equal to 1
g) Pictures with mb_adaptive_frame_field_flag equal to 0 [Ed.Note: there was a 1 before in versions d16 to d36, my mistake, I believe]

All video decoders supporting the X Profile shall also support the Baseline Profile. The Level number supported for the Baseline Profile shall not be less than the Level number supported for the X Profile.

Conformance to the X Profile is indicated by setting the syntax element profile_idc equal to 88.

A.3 Levels

Level limits are expressed in units of whole luma macroblocks. If a particular picture height or width is not an exact multiple of a whole macroblock, that dimension shall be considered as rounded up to the next whole macroblock for the purposes of conformance with this subclause.

The definition of support for a given Level is that any picture size/frame rate combination shall be decoded where the:

a) sample processing rate (in whole macroblocks/second) is <= the Level limit given, and,

b) (frame_width_in_mbs_minus1+1) * (frame_height_in_mbs_minus1+1) <= MaxFS , and,

c) frame_width_in_mbs_minus1+1 <= sqrt(MaxFS * 8), and,

d) frame_height_in_mbs_minus1+1 <= sqrt(MaxFS * 8), and,

e) The the total number of bytes of NAL unit data (i.e., the total of the NumBytesInNALunit variables for the picture) that contain primary slices and slice data partitions for any coded frame is <= 128 * MaxFS * ChromaFormatParameter.

f) The the total number of bytes of NAL unit data (i.e., the total of the NumBytesInNALunit variables for the picture) that contain primary slices and slice data partitions for any coded field is <= 64 * MaxFS * ChromaFormatParameter

g) the HRD DPB verifier (subclause C.1.2) is satisfied with DPBcapacity as defined in subclause A.6.3, and,

h) maximum video bit rate of the bitstream is <= the Level limit given, and,

i) required CPB buffer size is <= the Level limit given, and,

j) vertical motion vector range does not exceed the Level limits given, and,

k) horizontal motion vector range does not exceed [-2048, 2047.75] in full-sample luma displacement units, and

l) luma direct and bi-predictive block size does not exceed the Level limits given, and

m) number of motion vectors per two consecutive macroblocks in decoding order (including from the last macroblock of a slice to the first macroblock of the next slice) does not exceed the Level limits given, and

n) picture rate is not greater than 172 frames per second (with each field picture counting as one half of a frame for purposes of this computation), and

o) number of reference frames is not greater than 15, and

p) number of sequence parameter sets is not greater than 32, and

q) number of picture parameter sets is not greater than 128, and

r) number of bits of macroblock_layer( ) data for any macroblock is not greater than 3200.

The definition of each Level includes the requirements of all lower numbered Levels in Table A-1. Decoders supporting a given Level shall also be capable of decoding bitstreams using all lower numbered Levels.

Note - display of decoded video is outside the scope of this Recommendation | International Standard; some decoder implementations may not include displays at all, and display limitations do not necessarily cause interoperability failures. [Ed. Note: why is this note here? This sort of thing is already covered elsewhere.]

"Picture size" means the total number of macroblocks in the complete picture (both even and odd fields if interlaced).

A.3.1 Level limits

Table A-1 below gives the parameter limits for each Level. Entries marked " -" in Table A-1 denote the absence of a corresponding limit.

Conformance to a particular Level shall be indicated by setting the syntax element level_idc equal to a value of ten times the level number specified in Table A-1.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table A-1 – Level Limits

Level #	Max Sample Processing Rate (MB/s)	Max Frame Size MaxFS (MBs)	Decoded picture buffer memory MaxKB (1024 bytes)	Max Video Bitrate (1000 bits/sec)	Max CPB Size (1000 bits)	Vertical MV Range (full samples)	Minimum luma Direct & Bi-predictive block size	Maximum number of MVs per two consecutive MBs
1	1 485	99	148.5	64	175	[-64,+63.75]	-	-
1.1	2 970	396	891.0	128	325	[-128,+127.75]	-	-
1.2	5 940	396	891.0	768	2 000	[-128,+127.75]	-	-
2	11 880	396	891.0	2 000	2 000	[-128,+127.75]	-	-
2.1	19 800	792	1 782.0	4 000	4 000	[-256,+255.75]	-	-
2.2	20 250	1 620	3 037.5	4 000	4 000	[-256,+255.75]	-	-
3	40 500	1 620	3 037.5	8 000	8 000	[-256,+255.75]	-	-
3.1	108 000	3 600	6 750.0	20 000	14 000	[-512,+511.75]	8x8	16
3.2	216 000	5 120	7 680.0	20 000	20 000	[-512,+511.75]	8x8	16
4	245 760	8 192	12 288.0	20 000	25 000	[-512,+511.75]	8x8	16
5	786 432	32 768	61 440.0	150 000	450 000	[-512,+511.75]	8x8	16

Levels with non-integer Level numbers in Table A-1 are refered to as "intermediate Levels". All Levels have the same status, but note that some applications may choose to use only the integer -numbered Levels.

The maximum video bitrate and maximum coded picture buffer (CPB) size in Table A-1 apply to VCL conformance. The equivalent limits for NAL conformance are 20% higher than these values. [Ed. Note: Do we have a clear definition of what distinguishes VCL from NAL?]

Informative subclause A.3.3 shows the effect of these limits on frame rates for several example picture formats.

A.3.2 Decoded picture buffer capacity

For verification by the HRD DPB verifier, the capacity of the DPB in frames for a given mode is defined. The memory availible for the DPB is defined in Table A-1. The capacity of the DPB is calculated by:

[Ed. Note (Karsten): Subclause 6.2 defines 4:2:0 as the only chroma format in H.264, so do why we need this ChromaFormatParameter?]

[Ed.Note: maybe we should add a syntax element (ue(v)) to make this future proof]

DPBcapacity = Min(max_dec_frame_buffering, 1024 * MaxKB / ((frame_width_in_mbs_minus1+1) * (frame_height_in_mbs_minus1+1) * (256*ChromaFormatParameter))).

The parameter DPBcapacity is in units of frames.

The parameter ChromaFormatParameter shall take values according to Table A-2:

Table A-2 – ChromaFormatParameter values

Chroma Format	ChromaFormatParameter
monochrome	1
4:2:0	1.5
4:2:2	2
4:4:4	3

A.3.3 Effect of level limits on frame rate (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Note 1 This is a variable-picture-size specification. The specific picture sizes in Table A-3 are illustrative examples only.

Note 2 As used in Table A-3, "525" refers to typical use for environments using 525 analogue scan lines (of which approximately 480 lines contain the visible picture region), and "625" refers to environments using 625 analogue scan lines (of which approximately 576 lines cont ain the visible picture region).

Note 3 XGA is also known as (aka) XVGA, 4SVGA aka UXGA, 16XGA aka 4Kx3K, CIF aka 625 SIF, 625 HHR aka 2CIF aka 1/2 625 D-1, aka 1/2 625 ITU-R BT.601, 525 SD aka 525 D-1 aka 525 ITU-R BT.601, 625 SD aka 625 D-1 aka 625 ITU-R BT.601.

Note 4 Frame rates given are correct for progressive scan modes, and for interlaced if "MB High" column value is even.

Annex B
Byte stream format

(This annex forms an integral part of this Recommendation | International Standard)

This annex specifies syntax and semantics of a byte stream format specified for use by systems that transmit some or all of the NAL unit stream as an ordered stream of bytes or bits within which the locations of NAL unit boundaries need to be identifiable from patterns in the data, such as ITU-T Recommendation H.222.0 | ISO/IEC 13818 -1 systems or ITU-T Recommendation H.320 systems. For bit-oriented transmission, the network bit order for the byte stream format is specified to start with the MSB of the first byte, proceed t o the LSB of the first byte, followed by the MSB of the second byte, etc.

The byte stream format consists of a sequence of byte_stream_nal_unit( ) structures. Each byte_stream_nal_unit( ) contains one start code prefix followed by one nal_unit( ). It may (and under some circumstances, it shall) also contain some additional zero_byte syntax elements.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

B.1 Byte stream NAL unit syntax and semantics

B.1.1 Byte stream NAL unit syntax

byte_stream_nal_unit( ) {	C	Mnemonic
while(next_bits(24) != 0x000001)		
zero_byte /* equal to 0x00 */		f(8)
if(more_data_in_byte_stream( )) {		
start_code_prefix /* equal to 0x000001 */		f(24)
nal_unit( )		
}		
}		

B.1.2 Byte stream NAL unit semantics

The order of byte stream NAL units in the byte stream shall follow th e decoding order of the NAL units contained in the byte stream NAL units.

zero_byte is a single byte equal to 0x00.

The minimum required number of zero_byte syntax elements preceding the start_code_prefix is 1 when either of the following conditions are fu lfilled:

- If the nal_unit_type within the nal_unit( ) is equal to 0x07 (sequence parameter set) or 0x08 (picture parameter set), or
- If the byte_stream_nal_unit( ) contains the first nal_unit( ) of a picture in decoding order, specifically defined as the first SEI message, picture delimiter, slice, or slice data partition nal_unit( ) specific to a particular picture in decoding order.

Any number of additional zero_byte syntax elements may immediately precede the start code prefix within the byte_stream_nal_unit( ).

[Ed. Note: Need to clarify scope of each SEI message to identify those that are considered "specific to a particular picture" – Note that this i salso needed for other purposes such as definition of decoding order for SEI messages.]

start_code_prefix is a fixed-value string of 3 bytes equal to 0x000001.

The use of the byte-aligned 3-byte sequence 0x000002 within the byte stream format is reserved for future use by ITU-T | ISO/IEC. [Ed. Note: What is the decoder supposed to do if it sees that valu e in a byte stream? My guess is that it should choke, so maybe we don't need to state that we reserve that byte string.]

B.2 Decoder byte-alignment recovery (informative)

This subclause does not form an integral part of this Recommendation | International Standard.

If the decoder does not have byte alignment with the encoder's byte stream, the decoder can examine the incoming bitstream for the binary pattern '00000000 00000000 00000000 00000001' (31 consecutive bits equal to 0 followed by bit equal to 1). The bit immediately following this pattern is the first bit of an aligned byte. Upon detecting this pattern, the decoder will be byte aligned with the encoder.

Once byte aligned with the encoder, the decoder can examine the incoming byte stream for the three -byte sequences 0x000001 and 0x000003.

If the three-byte sequence 0x000001 is detected, this represents a start code prefix.

If the three-byte sequence 0x000003 is detected, the decoder discards the third byte (0x03) as specified in subclause **Error! Reference source not found.**.

Many systems are inherently byte aligned, and thus have no need for the bit -oriented byte alignment detection procedure described in this subclause.

The byte alignment detection procedure described in this subclause is equivalent to searching a byte sequence for three consecutive zero-valued bytes (0x000000), starting at any alignment position. Detecting this pattern indicates that the next non-zero byte contains the end of a start code prefix, and the fir st non-zero bit in that next non-zero byte is the last bit of an aligned byte.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Annex C
Hypothetical Reference Decoder

(This annex forms an integral part of this Recommendation | International Standard)

This annex specifies ??? [Ed.Note: What ?]

C.1 Hypothetical reference decoder and buffering verifiers

The hypothetical reference decoder (HRD) represents a set of normative requirements on bitstreams. These constraints shall be enforced by an encoder, and can be assumed by a decoder or multiplexor to be true.

This subclause specifies the normative requirements of the HRD. Subclause C.2 provides additional information that is important for a full understanding of the HRD operation.

Two types of bitstreams are subject to the HRD requirements of this Recommendation | International Standard; a stream of VCL NAL units and a NAL bitstream (either a byte stream or a packet stream). Figure C-1 shows how each of these is constructed from the RBSP. In other words, a given set of HRD parameters may pertain to the VCL data only or to the multiplexed combination of VCL and NAL. This is signalled through video usability information (subclauses E.1 and E.2). Although the HRD may apply to the VCL, HRD information is not carried in the VCL, but only in the higher layer, whether a byte stream or a packet stream.

NOTE - When HRD information is contained within the bitstream, it is possible to verify the conformance of a bitstream to the requirements of this subclause based solely on information contained in the bitstream. If the HRD information is not present, as is the case for all stand-alone VCL streams, conformance can only be verified if the HRD data is supplied by external means.

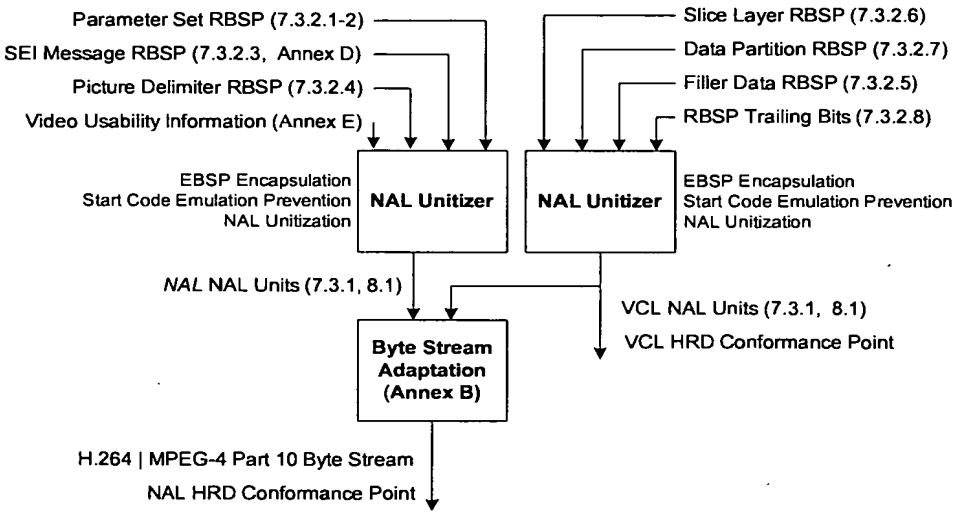

Figure C-1 – Structure of Byte streams and NAL unit streams and HRD Conformance Points

The HRD contains the following buffers, as shown in Figure C-2:

- one or more coded picture buffers (CPB), each of which is either variable bit rate (VBR) or constant bit rate (CBR), and
- one decoded picture buffer (DPB) attached to the output of one of the CPBs.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

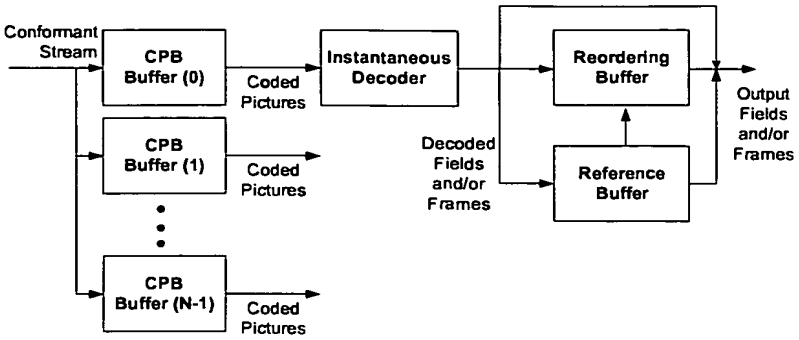

Figure C-2 – HRD Buffer Verifiers

The multiple CPBs exist because a bitstream may conform to multiple CPBs, as detailed in subclause C.2.2.

Considering the operation of a single CPB, data associated with coded pictures flow into the CPB according to a specified arrival schedule. Each coded picture is removed instantaneously and decoded by the decoder at CPB removal times. Decoded pictures are placed in the DPB at the CPB removal time. Finally, pictures are removed from the DPB at the later of the DPB output time and the time that they are no longer needed as reference for decoding. The conditions on a conformant bitstream are given below. The primary conditions are that the CPB neither underflow nor overflow and that the DPB does not overflow.

HRD syntax and semantics is contained in the following subclauses. High -level HRD information concerning the number of CPBs, their bitrates and buffer sizes is found in Annex E under subclauses E.1.1, E.1.2, E.2.1 and E.2.2. This information is part of the video usability information of the sequence parameter set. Timing information needed to initialize the HRD is contained in the buffering period SEI messages (subclauses D.1.1 and D.2.1). Timing information relating to the removal of pictures through the CPB and DPB is found in the picture timing SEI message (subclauses D.1.2 and D.2.2).

All the arithmetic in this annex is done with real values, so that no rounding errors can propagate. For example, the number of bits in a CPB just prior to or after removal of a transmitted picture is not nec essarily an integer. Furthermore, while conformance is guaranteed under the assumption that all frame -rates and clocks used to generate the bitstream match exactly the values signalled in the bitstream, in a real system each of these may vary from the sig nalled or specified value.

In the following description, let t_c = num_units_in_tick ÷ time_scale be defined as the *clock tick*. The clock tick is a time interval no larger than the shortest possible inter -picture capture interval in seconds. Also let $be[t]$ and $te[b]$ be the bit equivalent of a time t and the time equivalent of a number of bits b, with the conversion factor being the CPB arrival bit rate.

C.1.1 Operation of coded picture buffer

[Ed.Note: This description requires clear definition of a random access point.]

This specification applies independently to each set of CPB parameters wit hin the HRD VUI portion of the sequence parameter set. The bits associated with each picture include all NAL units associated with primary and redundant slices of the picture and all the data that follow the last NAL unit of the previous picture, includin g parameter sets, video usability information and SEI messages. This description applies to both NAL and VCL conformance, although for VCL conformance some of these data types will not be present.

C.1.1.1 Timing of bitstream arrival

The HRD may be initialized at the first picture following any random access point, defined by a random access point SEI message. The buffer is initially empty. The first bit of the first picture after the random access SEI message begins to enter the buffer at *initial arrival time* $t_{ai}(0)=0$ at the bit rate bit_rate[k] associated with the CPB (see subclauses E.2.2 and E.3.2). The last bit of the first transmitted picture finishes arriving at *final arrival time*

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$$t_{af}(0) = b(0) \div \text{bit\_rate}[k], \quad \text{(C-1)}$$

where $b(n)$ is the size in bits of the n-th picture in coded order. The final arrival time for each picture is always the sum of the initial arrival time and the time required for the bits associated with that picture to enter the CPB:

$$t_{af}(n) = t_{ai}(n) + b(n) \div \text{bit\_rate}[k]. \quad \text{(C-2)}$$

For each subsequent picture n, the initial arrival time is equal to the final arrival time of picture $n-1$, unless that time precedes the earliest arrival time, computed by

$$t_{ai,earliest}(n) = t_c \cdot \text{cpb\_removal\_delay}(n) - (\text{initial\_cpb\_removal\_delay\_offset} \div 90{,}000) \quad \text{(C-3)}$$

as indicated in:

$$t_{ai}(n) = \max\{ t_{af}(n-1), t_{ai,earliest}(n) \} \quad \text{(C-4)}$$

See subclauses D.2.1 and D.3.1 on the picture timing SEI Message for the syntax and semantics of cpb_removal_delay and initial_cpb_removal_delay_offset. When the encoder is producing a bit rate lower than the bit rate associated with a CPB, this rule may delay the entry of some pictures into the CPB, producing periods during which no data enters.

C.1.1.2 Timing of coded picture removal

For the first picture after receiving the buffering period SEI message associated with the random access point, the coded data associated with the picture is removed from the CPB at a *removal time* equal to the following:

$$t_r(0) = \text{initial\_cpb\_removal\_delay} \div 90000 \quad \text{(C-5)}$$

where initial_cpb_removal_delay is defined in the buffering period SEI message.

After the first picture is removed, the buffer is examined at subsequent points of time, each of which is delayed from the previous one by an integer multiple of the clock tick t_c.

The removal time $t_r(n)$ of coded data for picture n is delayed with respect to that of picture 0; the delay is equal to the time indicated in the cpb_removal_delay syntax element present in the picture t iming SEI Message.

$$t_r(n) = t_r(0) + t_c \cdot \text{cpb\_removal\_delay}(n) \quad \text{(C-6)}$$

At this time, the coded data for the next transmitted picture is removed from the CPB.

If low_delay_hrd_flag is equal to 1, and if the amount of coded data for picture n, $b(n)$, is so large that it prevents removal at the computed removal time, the coded data is removed at the *delayed removal time*, $t_{r,d}(n, m^*)$, given by

$$t_{r,d}(n,m^*) = t_r(0) + t_c \cdot m^*, \quad \text{(C-7)}$$

where m^* is such that $t_{r,d}(n, m^*-1) < t_{af}(n) \le t_{r,d}(n, m^*)$. This is an aspect of low-delay operation (see subclause C.2.1.2). This delayed removal time is the next time instant after the final arrival time $t_{af}(n)$ which is delayed with respect to $t_r(0)$ by an integer multiple of t_c.

C.1.1.3 Conformance constraints on coded bitstreams

A transmitted or stored stream of coded data conforming to this Recommendation | International Standard fulfils the following requirements.

- ***Removal time consistency.*** For each picture, the removal ti mes $t_r(n)$ computed using different buffering periods as starting points for conformance verification shall be consistent to within the precision of the clocks used (90 kHz clock used for initial removal time, t_c clock used for subsequent removal time calcu lations, and bit_rate[k] used for arrival times).

Note - This can be ensured at the encoder by computing the initial CPB removal delay for a buffering period SEI message from the arrival and removal times computed using Equations C-4 and C-6. That is, if the last picture before the random access point is picture $n-1$, then the initial CPB removal delay for the next buffering period SEI message could be computed by

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$initial\_cpb\_removal\_delay = 90000 \times (t_r(n) - t_r(n-1) + t_{ai}(n)) \quad \text{(C-8)}$$

- ***Underflow and Overflow Prevention.*** The buffer shall never overflow or underflow.

NOTE - In terms of the arrival and removal schedules, this means that, with the exception of some pictures in low-delay mode that are described below, all bits from a picture must be in the CPB at the picture's computed removal time $t_r(n)$. In other words, its final arrival time must be no later than its removal time: $t_{af}(n) \leq t_r(n)$. Further, the removal time $t_r(n)$ must be no later than the time-equivalent of the buffer size te[cpb_size[k]]. Note that this prevents both underflow and overflow.

- ***Big Picture Removal Time, Overflow Prevention and Resynchronisation of Underflow Prevention.*** If the final arrival time $t_{af}(n)$ of picture n exceeds its computed removal time $t_r(n)$, its size must be such that it can be removed from the buffer without overflow at $t_{r,d}(n,m)$ as specified above.

- ***Constant Bit Rate Constraint.*** If vbr_cbr_flag[k] = = 1, data shall arrive continuously at the input to the CPB. This is equivalent to ensuring that

$$t_{af}(n-1) \geq t_{ai,earliest}(n) \quad \text{(C-9)}$$

- ***Maximum Removal Rate.*** The difference between consecutive removal times, $t_r(n) - t_r(n-1)$, shall not be less than the ratio of the number of macroblocks in picture n to the maximum sample processing rate for the bitstream's level in macroblocks per second (see subclause A.3.1).

C.1.2 Operation of the decoded picture buffer (DPB) verifier

[Ed.Note:

- The description in Annex A should be much clearer about the relationship between the reference memory numbers in Table A-1 and the actual number of frames allowed for the Decoded Picture Buffer. And the term "reference memory" in Table A-1 should be changed to "Decoded Picture Buffer Memory."
- The DPB needs availiblity of DTS and OTS values and the operations of marking and unmarking defined in clause 8.
- Primary vs. redundant pictures (argh!)]

The decoded picture buffer contains frame stores. These frame stores may contain frames and/or fields that are to be used for reference in future decoding (reference pictures) and/or are held for future output (reordered and delayed pictures). At $t_r(0)$, the DPB fullness, measured in frames, is initialized to 0. The following four steps all happen instantaneously at $t_r(n)$, the CPB removal time of picture n, and in the sequence listed.

C.1.2.1 Removal of pictures from the DPB

[Ed.Note. Figure C-2 needs changed to reflect the new design.]

A picture's DPB output time $t_{o,dpb}(n)$ is computed by

$$t_{o,dpb}(n) = t_r(n) + t_c \cdot \text{dpb\_output\_delay}(n) \quad \text{(C-10)}$$

First, some pictures may be removed from the buffer. Picture m is removed if it satisfies both of the following rules:

- It has been marked as "unused for reference" during the decoding process of previously decoded pictures.
- Its DPB output time is less than or equal to the CPB removal time of the current picture; *i.e.* $t_{o,dpb}(m) \leq t_r(n)$

If picture n is an IDR picture additional pictures are removed from the DPB. If non_ref_pic_reset_flag is equal to 0, all reference pictures are removed from the DPB. If non_ref_pic_reset_flag is equal to 1, all pictures are removed from the DPB. Following the removal of any frame or the removal of the last field in a frame store, the fullness is decremented by one.

The ordering of DPB output times for the sequence of decoded pictures is required to be the same as the ordering of the picture order counts for the sequence of decoded pictures (subclause 8.2.2).

C.1.2.2 Picture decoding

After the removal step, picture n is decoded.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

C.1.2.2.1 Storage of Reference Pictures into the DPB

Picture *n* is added to the decoded picture buffer if it is marked as "used for reference" (through the nal_ref_idc). If the picture is a frame, it consumes an entire frame store. If it is a coded field and if there is no field of the opposite parity with the same frame number already in the DPB, it consumes an entire frame store. Otherwise, it consumes no additional memory.

C.1.2.2.2 Storage of Non-reference Pictures into the DPB

If the DPB output time of picture *n* exceeds its CPB removal time, it is stored in the DPB. If the picture is a frame, the fullness of the DPB is incremented by one. If it is a coded field and if there is no non -reference field of the opposite parity already in the DPB, the fullness of the DPB is incremented by one. Otherwise, it is paired with the non -reference field of the opposite parity which has the earliest DPB output time.

C.1.2.3 Unused picture marking

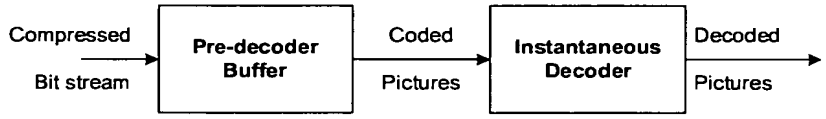
Next, mark each picture in the decoded picture buffer as "unused for reference" if it is no longer needed for reference. This may arise through an MMCO command associated with picture *n* (see subclauses 8.3.6.7.2, 8.3.6.7.3, 8.3.6.7.5, 8.3.6.7.6 and 8.3.6.7.7) or through sliding wi ndow operation (see subclause 8.3.6.6).

C.1.2.4 Conformance constraints

- ***Overflow Prevention.*** Immediately after any picture is added to the DPB, the fullness of the DPB shall be less than or equal to the level limit on the DPB pictures (see Annex A subclauses on Le vel Limits for each profile, and subclause A.3.1).
- ***Maximum Output Rate.*** The difference between the output time of a picture and that of the picture output immediately preceding it shall be larger than the ratio of the number of macroblocks in the picture to the maximum sample processing rate for the bitstream's level in macroblocks per second (see subclause A.3.1).

[Ed. Note: (ev) this output rate restriction only affects, and should only affect, the values of the dpb_output_delay, and does not relate to the number of pictures "output" by MMCO commands. (A single MMCO command might mark a large number of picture unused.)]

[Ed. Note: Note that this is an output rate restriction, distinct from the deco ding rate restriction. We intended to do both, right?]



[Ed. Note: A conforming stream can place reordered frames into space for sliding window as long as the sliding window is not using it. Non-reference frames can be dropped without impacting the operat ion of the sliding window remaining conforming.]

C.2 Informative description of the HRD

This subclause does not form an integral part of this Recommendation | International Standard.

Subclause 0 contains the normative requirements i mposed by a set of buffering verifiers. This subclause provides explanatory text describing in more detail the operation and capabilities of these buffers.

The HRD Coded Picture Buffer represents a means to communicate how the bit rate is controlled in th e process of compression. The HRD contains a CPB through which compressed data flows with a precisely specified arrival and removal timing, as shown in Figure C-2. An HRD may be designed for variable or constant bit rate operatio n, and for low-delay or delay-tolerant behavior. The HRD described in this document handles all cases.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Figure C-3 – A Hypothetical Reference Decoder

Compressed data representing a sequence of *coded pictures* flows into the CPB according to a specified *arrival schedule*. All compressed bits associated with a given coded picture are removed from the CPB by the instantaneous decoder at the specified *removal time* of the picture.

The CPB *overflows* if the buffer becomes full and more bits are arriving. The buffer *underflows* if the removal time for a picture occurs before all compressed bits representing the picture have arrived.

C.2.1 Constrained arrival time leaky bucket (CAT-LB) model

The hypothetical reference decoder (HRD) is a mathematical model of a decoder and its input buffer. The k-th CPB of the HRD is characterized by the pre-decoder peak rate bit_rate[k] (in bits per second), the buffer size cpb_size[k] (in bits), the sequence initial CPB removal delay (in seconds), as well as picture removal delays for each picture. The first three of these parameters represent levels of resources (transmission capacity, buffer capacity, and delay) used to decode a bitstream.

The term "leaky bucket" arises from the analogy of the encoder as a system that "dumps" water in discrete chunks into a bucket that has a hole in it. The departure of bits from the encoder buffer corresponds to water leaking out of the bucket. Here, the decoder buffer is described, which has an inverse behaviour where bits flow *in* at a constant rate, and are removed in chunks.

The leaky bucket described here is called a *constrained arrival time* leaky bucket because the arrival times of all pictures after the first are constrained to arrive at the buffer input no earlier than the difference in hypothetical encoder processing times between that picture and the first picture. Furthermore, the arrival of all pictures in the CPB can be adjusted with a flexible offset. In other words, if a picture is encoded exactly seven seconds after the first picture was encoded and the offset is 0.5 seconds, then its bits are guaranteed not to start arriving in the buffer prior to 6.5 seconds after the bits of the first picture started arriving. It is possible to know this encoding time difference because the inter-picture delay is sent in the bitstream as the CPB removal delay and the offset is sent as the CPB initial removal delay offset.

C.2.1.1 Operation of the CAT-LB HRD

The HRD input buffer has capacity cpb_size[k] bits. Initially, the buffer begins empty. The lifetime in the buffer of the coded bits associated with picture n is characterized by the *arrival interval* $\{t_{ai}(n), t_{af}(n)\}$ and the *removal time* $t_r(n)$. The end-points of the arrival interval are known as the *initial arrival time* and the *final arrival time*.

At time $t_{ai}(0) = 0$, the buffer begins to receive bits at the rate bit_rate[k]. The removal time $t_r(0)$ for the first picture is computed from the pre-decoder removal delay initial_cpb_removal_delay (see Buffering Period SEI Message) associated with the buffer by the following:

$$t_r(0) = \text{initial\_cpb\_removal\_delay} \div 90\,000. \quad \text{(C-11)}$$

Removal times $t_r(1)$, $t_r(2)$, $t_r(3)$, ..., for subsequent pictures (in transmitted order) are computed with respect to $t_r(0)$, as follows. Let the *clock tick* t_c be specified by

$$t_c = \text{num\_units\_in\_tick} \div \text{time\_scale} \quad \text{(C-12)}$$

For instance, if time_scale = 60 000 and num_units_in_tick = 1 001, then

$$t_c = 1\,001 \div 60\,000 = 16.68333\ldots \text{ milliseconds.} \quad \text{(C-13)}$$

In the picture piming SEI message for each picture, there is a cpb_removal_delay syntax element. This indicates the number of clock ticks to delay the removal of picture n after removing picture 0. Thus, the removal time is simply

$$t_r(n) = t_r(0) + t_c \times \text{cpb\_removal\_delay}(n) \quad \text{(C-14)}$$

The calculation of arrival times is more complex, because of the arrival time constraint. The initial arrival time of picture n is equal to the final arrival time of picture $n-1$, unless that time precedes the earliest arrival time, computed by

$$t_{ai,earliest}(n) = t_c \times \text{cpb\_removal\_delay}(n) - (\text{initial\_cpb\_removal\_delay\_offset} \div 90\,000) \quad \text{(C-15)}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Let $b(n)$ be the number of bits associated with picture n. The duration of the picture arrival interval is always the time - equivalent of the picture size in bit s, at the rate bit_rate[k].

$$t_{af}(n) - t_{ai}(n) \equiv te[b(n)] = b(n) \div \text{bit\_rate[k]} \quad \text{(C-16)}$$

Figure C-3 demonstrates a segment of the CPB fullness plot for a CAT-LB with the parameters given in Table C-1 and picture sizes given by the first column of Table C-2. Note that Table C-2 lists for each picture the values for many times of interest in the buffering process. In addition to quantiti es specified above, the second column of Table C-2 contains t_e, which represents a hypothetical encoding time equal to the earliest possible initial arrival time of the picture.

Table C-1 - Attributes of an example CAT-LB HRD

Attribute	Value	Units
time_scale	1	units per second

Figure C-4 – Buffer fullness plot for example HRD in Table C-2 with picture sizes given in Table C-3

As can be seen from Figure C-4, the initial picture is large, and is followed by five pictures at exactly the buffer arrival rate R. This is followed by twelve pictures at half the rate, four pictur es at three times the rate and one picture at twice the rate. Following this are two segments with pictures at 30% and 50% of the rate, respectively. In Figure C-4, the time interval from 10 seconds to 18 seconds illustrates the behaviour when the bit rate is constant and at or below the rate R. In fact, whenever the arrival bit rate remains less than R for a time, the lower points of the fullness curve will not change. It can be noted that data enters the buffer continuously at rate R until t=14.5 seconds. At that time, fifteen pictures have entered the buffer, and the sixteenth picture cannot enter because its earliest possible arrival time is t=15. Thus there is a 0.5 second flat spot from 14.5 to 15 seconds. The reason it t akes until t=14.5 for this to occur is that the initial picture took five picture periods to enter the buffer. Further, the fullness at the peak in such a segment will be proportional to the fraction of the peak rate being consumed by the pictures. From seconds 18 to 28, we see the temporary effect of an increase in arrival rate to above R. Once those large pictures start to exit the buffer, the bit rate of pictures leaving the buffer exceeds R, and the fullness decreases. This process terminates at sec ond 32, when the big pictures have exited and the series of smaller pictures starts entering the buffer. During seconds 36 -43, the 30% peak rate pictures are entering and leaving the buffer, and during seconds 43 -52, 30% peak rate pictures are leaving whi le 50% peal rate pictures are entering. Hence the buffer fullness rises. Once 50% peak rate pictures begin to leave, the fullness stabilizes at 50% full. Note that this CPB stabilizes at a fullness that is proportional to the ratio of the short -term average bit rate to the arrival bit rate, rather than at 100%.

In general, the curve of buffer fullness vs. time is given by the following expression:

$$BF(t) = \sum_{n} \left[I(t_{af}(n) \le t < t_r(n)) \times b(n) + I(t_{ai}(n) < t < t_{af}(n)) \times be(t - t_{ai}(n)) \right] \qquad \text{(C-17)}$$

This expression uses indicator functions $I(\,)$ with time-related logical assertions as arguments to sum only those pictures that are completely in the buffer at time t, plus the appropriate portion of the picture currently entering the buffer, if one is. The indicator function $I(x)$ is equal to 1 if x is true and equal to 0 otherwise.

C.2.1.2 Low-delay operation

Low-delay operation of the CPB is obtained by selecting a low value for the initial pre -decoder removal delay. This results in true low delay through the buffer because, under normal operation, no removal delay ($t_r(n)$-$t_{ai}(n)$) can exceed the initial removal delay minus the initial removal delay offset. To see this, consider that the maximum removal delay

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

for picture n occurs when the initial arrival time is equal to the earliest arrival time. Therefore, the maximum removal delay is given by $t_r(n) - t_{ai,earliest}(n)$. But,

$$t_r(n) = t_r(0) + t_c \times \text{cpb\_removal\_delay}(n), \quad \text{(C-18)}$$

and

$$t_{ai,earliest}(n) = t_c \times \text{cpb\_removal\_delay}(n) - (\text{initial\_cpb\_removal\_delay\_offset} \div 90\,000), \quad \text{(C-19)}$$

so

$$t_r(n) - t_{ai,earliest}(n) = t_r(0) + (\text{initial\_cpb\_removal\_delay\_offset} \div 90\,000). \quad \text{(C-20)}$$

Thus setting an initial low delay creates a steady-state low-delay condition. Note that the initial CPB removal delay is expected to be set to 0 or a very low value in the low delay mode.

However, in low-delay operation, it is useful to be able to process the occasional large picture whose size is so large than that it cannot be removed by its indicated removal time. Such a large picture can arise at a scene change, for example. This would ordinarily lead to an "underflow" condition. When a large picture is encountered, the rules for removal are relaxed to prevent this. The picture is removed at the *delayed removal time*, $t_{r,d}(n, m^*)$, given by

$$t_{r,d}(n,m^*) = t_r(0) + t_c \times m^* + (\text{initial\_cpb\_removal\_delay\_offset} \div 90\,000), \quad \text{(C-21)}$$

where m^* is such that $t_{r,d}(n, m^*-1) < t_{ai}(n) + te[b(n)] \le t_{r,d}(n, m^*)$. Note that the buffer must be large enough that this large picture can be accommodated without overflow. Immediately after such a picture is received the removal time of the next picture must be such that low-delay operation is resumed. An encoder can facilitate this by skipping a number of pictures immediately after the large picture, if necessary.

C.2.1.3 Bitstream / packet stream constraints

The buffer must not be allowed to underflow or overflow. Furthermore, all pictures except the isolated big pictures must be completely in the buffer before their computed removal times. Isolated big pictures are allowed to arrive later than their computed removal times, but must still obey the overflow constraint. In CBR mode, there must be no gaps in bit arrival.

C.2.1.3.1 Underflow

The underflow constraint, $BF(t) \ge 0$ for all t, is satisfied if the final arrival time of each picture precedes its removal time.

$$t_{af}(n) \le t_r(n) \quad \text{(C-22)}$$

This puts an upper bound on the size of picture n. The picture size can be no larger than the bit-equivalent of the time interval from the start of arrival to the removal time.

$$b(n) \le be[t_r(n) - t_{ai}(n)] \quad \text{(C-23)}$$

Since the initial arrival time $t_{ai}(n)$ is in general a function of the sizes and removal delays of previous pictures, the constraint on $b(n)$ will vary over time as well.

C.2.1.3.2 Overflow

Overflow is avoided provided the buffer fullness curve $BF(t)$ never exceeds the buffer size B.

The constraints that the initial pre-decoder removal delay must be no larger than the time-equivalent of the buffer size, $t_r(0) \le te(B)$, and that under normal operation no removal delay can exceed the initial one plus the initial offset guarantee that no overflow occurs in normal operation. To avoid overflow of an isolated big picture, the picture size is constrained by

$$b(n) \le be[B - t_{ai}(n)] \quad \text{(C-24)}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

C.2.1.3.3 Constant bitrate (CBR) operation

The CAT-LB model operates in constant bit rate mode if one further constraint is applied - that data must constantly arrive at the input of the buffer. This ensures that the average rate is equal to the buffer rate R. This model behaves like an ISO/IEC 11172-2 (MPEG-1) CBR model with variable frame rate. This condition is ensured if the final arrival time of picture $n-1$ is no earlier than the earliest initial arrival time of picture n.

$$t_{af}(n-1) \geq t_{ai,earliest}(n) \qquad \text{(C-25)}$$

This time constraint puts a lower bound on $b(n)$.

NOTE: A bitstream that satisfies an ISO/IEC 11172-2 or an ITU-T Recommendation H.262 | ISO/IEC 13818-2 CBR video buffering verifier at a given buffer size, initial delay and bitrate will also satisfy a CAT-LB with the same parameters.

C.2.1.4 Rate control considerations

An encoder employs rate control as a means to constrain the varying bit rate characteristics of the coded bitstream or packet stream in order to produce high quality coded pictures at the target bit rate(s). A rate control algorithm may target a variable bit rate (VBR) or a constant bit rate (CBR). It may even target both a high peak rate using a VBR scheme and an average rate using a CBR scheme. Further, as shown in subclause **Error! Reference source not found.**, multiple VBR rates can be targeted.

Rate control must ensure conformance with the CPB. This is related to the first goal of rate control, but is not necessarily the same. In this subclause, the way the CPB influences rate control is discussed. In a VBR CPB, the buffer must not overflow or underflow, but gaps may appear in the arrival rate. In order to meet these constraints, the encoder must ensure that for all t, the following inequalities remain true:

$$0 \leq BF(t) \leq B, \text{ for all } t. \qquad \text{(C-26)}$$

Using Equation D-14, this becomes:

$$0 \leq \sum_n \left[I(t_{af}(n) \leq t < t_r(n)) \times b(n) + I(t_{ai}(n) < t < t_{af}(n)) \times be(t - t_{ai}(n)) \right] \leq B, \text{ for all } t. \qquad \text{(C-27)}$$

The buffer fullness $B(t)$ is a piecewise non-decreasing function of time, with each non-decreasing interval bounded by two consecutive removal times. Therefore, it is sufficient to guarantee the conformance a t the interval endpoints; *i.e.* at the removal times. In particular, if underflow is prevented at the start of an interval (just after removal of a picture), it is completely prevented. The same holds for overflow at the end of the interval, just prior to picture removal. Therefore, the points of interest are the removal times. In the buffer at $t_r^-(n)$ and contributing to Equation C.-22 are picture n and possibly some additional pictures up to picture $m>n$ (with the last picture possibly only partially in the buffer). All pictures earlier than picture n have been removed. At $t_r^+(n)$, picture n has been removed.

Thus when encoding picture n, one rate control task is to allocate bits to picture n and the others in the immediate future in such a way that overflow is prevented at $t_r^-(n)$, and underflow is prevented at $t_r^+(n)$. Most immediately, as long as $b(n)$ is small enough so that $te[b(n)] \leq t_r(n) - t_{ai}(n)$, both overflow at $t_r^-(n)$ and underflow at $t_r^+(n)$ are prevented. This is usually a very high limit, and a rate control method will most likely further limit $b(n)$ through its bit allocation process.

C.2.2 Multiple leaky bucket description

C.2.2.1 Schedule of a bitstream

The sequence of removal time and picture size pairs $\{(t_r(n), b(n)), n=0,1,\ldots\}$ is called the schedule of a bitstream. The schedule of a bitstream is intrinsic to the bitstream, and completely characterizes the instantaneous coding rate of the bitstream over its lifetime. Although a bitstream may conform to CPBs with different peak bit rates and different p re-decoded buffer sizes, the schedule of the bitstream is independent of the CPB.

C.2.2.2 Containment in a leaky bucket

A leaky bucket with leak rate R_1, bucket size B_1, and initial bucket fullness B_1-F_1 is said to contain a bitstream with schedule $\{(t_r(n), b(n)), n=0,1,\ldots\}$ if the bucket does not overflow under the following conditions. At t_0, d_0 bits are inserted into the leaky bucket on top of the B_1-F_1 bits already in the bucket, and the bucket begins to drain at rate R1 bits per second. If the bucket empties, it remains empty until the next insertion. At time t_i, $i \geq 1$, d_i bits are inserted into the bucket, and the bucket continues to drain at rate R_1 bits per second. In other words, for $i \geq 0$, the state of the bucket just prior to time t_i is

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$b_0 = B_1 - F_1 \tag{C-28}$$

$$b_{i+1} = \max\{0, b_i + d_i - R_1(t_{i+1} - t_i)\}. \tag{C-29}$$

The leaky bucket does not overflow if $b_i + d_i \le B_1$ for all $i \ge 0$.

Equivalently, the leaky bucket contains the bitstream if the graph of the schedule o f the bitstream lies between two parallel lines with slope R_1, separated vertically by B_1 bits, possibly sheared horizontally, such that the upper line begins at F_1 at time t_0, as illustrated in Figure C-5. Note from Figure C-5 that the same bitstream is containable in more than one leaky bucket. Indeed, a bitstream is containable in an infinite number of leaky buckets.

Figure C-5 – Illustration of the leaky bucket concept
[Ed. Note: Something wrong with figure]

If a bitstream is contained in a leaky bucket with parameters (R_1,B_1,F_1), then when it is input with peak rate R_1 to a hypothetical reference decoder with parameters R=R_1, B=B_1, and F=F_1, then the HRD buffer does not overflow or underflow.

C.2.2.3 Minimum buffer size and minimum peak rate

If a bitstream is contained in two leaky buckets with parameters (R_1,B_1,F_1) and (R_2,B_2,F_2), then it is also contained in any leaky bucket with parameters (R,B,F) where a) $R_1 \le R \le R_2$, b) $B \ge B_{min}(R)$, and c) $F \ge F_{min}(R)$ and $B_{min}(R)$ and $F_{min}(R)$ are specified by

$$B_{min}(R) = \alpha B_n + (1 - \alpha)B_{n+1}, \tag{C-30}$$

$$F_{min}(R) = \alpha F_n + (1 - \alpha)F_{n+1}, \tag{C-31}$$

and

$$\alpha = (R_{n+1} - R) \div (R_{n+1} - R_n). \tag{C-32}$$

For $R \le R_1$,

$$B_{min}(R) = B_1 + (R_1 - R)T \tag{C-33}$$

$$F_{min}(R) = F_1, \tag{C-34}$$

where $T = t_{L-1} - t_0$ is the duration of the bitstream (i.e., the difference between the dec oding times for the first and last pictures in the bitstream). And for $R \ge R_N$,

$$B_{min}(R) = B_N \tag{C-35}$$

$$F_{min}(R) = F_N. \tag{C-36}$$

Thus, the leaky bucket parameters can be linearly interpolated and extrapolated.

Alternatively, when the bitstream is communicated to a decoder with bu ffer size B, it is decodable provided $\ge R_{min}(B)$ and $F \ge F_{min}(B)$, where for $B_n \ge B \ge B_{n+1}$,

$$R_{min}(B) = \alpha R_n + (1 - \alpha)R_{n+1} \tag{C-37}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$$F_{min}(B) = \alpha F_n + (1 - \alpha)F_{n+1} \quad \text{(C-38)}$$

$$\alpha = (B - B_{n+1}) \div (B_n - B_{n+1}). \quad \text{(C-39)}$$

For $B \geq B_1$,

$$R_{min}(B) = R_1 - (B - B_1) \div T \quad \text{(C-40)}$$

$$F_{min}(B) = F_1. \quad \text{(C-41)}$$

For $B \leq B_N$, the stream may not be decodable.

In summary, the bitstream is guaranteed to be decodable in the sense that the HRD buffer does not overflow or underflow, provided that the point (R,B) lies on or above the lower convex hull of the set of points (0, B_1+R_1T), (R_1,B_1), ..., (R_N,B_N), as illustrated in Figure C-6. The minimum start-up delay necessary to maintain this guarantee is $F_{min}(R) \div R$.

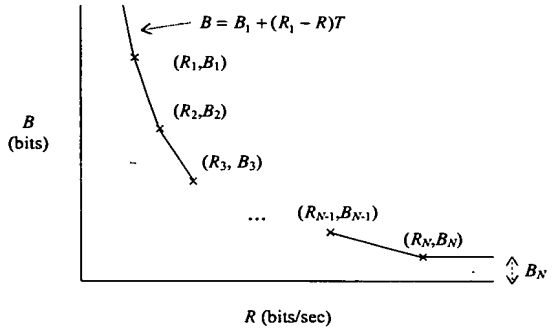

Figure C-6 – Further illustration of the leaky bucket concept

An HRD with buffer size B and initial decoder buffer fullness F with peak input rate R shall perform the tests $B \geq B_{min}(R)$ and $F \geq F_{min}(R)$, as specified above, for any conforming bitstream with LB parameters (R_1,B_1,F_1),...,(R_N,B_N,F_N), and shall decode the bitstream provided that $B \geq B_{min}(R)$ and $F \geq F_{min}(R)$.

C.2.2.4 Encoder considerations

The encoder can create a bitstream that is contained by some given N leaky buckets, or it can simply compute N sets of leaky bucket parameters after the bitstream is generated, or a combination of these. In the former, the encoder enforces the N leaky bucket constraints during rate control. Conventional rate control algorithm s enforce only a single leaky bucket constraint. A rate control algorithm that simultaneously enforces N leaky bucket constraints can be obtained by running a conventional rate control algorithm for each of the N leaky bucket constraints, and using as the current quantisation parameter (QP) the maximum of the QP's recommended by the N rate control algorithms.

Additional sets of leaky bucket parameters can always be computed after the fact (whether rate controlled or not), from the bitstream schedule for any given R_n, from the iteration specified in subclause C.2.2.2.

Annex D
Supplemental enhancement information

(This annex forms an integral part of this Recommendation | International Standard)

This annex specifies syntax and semantic for supplemental enhancement information that provides data constructs that are synchronous with the video data content. Each sei_payload( ) specifies PayloadType and PayloadSize parameters. This annex specifies supplemental enhancement information (SEI) that provides a data delivery mechanism construct that is delivered synchronous with the video data content. SEI assists in the processes related to decoding or display of video. SEI is not required for reconstructing the luma or chroma samples by a video decoder, and decoders are not required to process this information for conformance to this Recommendation | International Standard.

D.1.18 Progressive refinement segment end SEI message syntax

progressive_refinement_segment_end(PayloadSize) {	C	Descriptor
progressive_refinement_id	7	u(32)
}		

D.1.19 Reserved SEI message syntax

reserved_sei_message(PayloadSize) {	C	Descriptor
for(i=0; i<PayloadSize; i++)		
reserved_sei_message_payload_byte	7	b(8)
}		

D.2 SEI payload semantics

D.2.1 Buffering period SEI message semantics

A buffering period is specified as the set of pictures between two instances of the buffering period SEI message. The seq_parameter_set_id indicates the sequence p arameter set that contains the sequence HRD attributes.

seq_parameter_set_id indicates the sequence parameter set that contains the sequence HRD attributes.

initial_cpb_removal_delay: This syntax element represents the delay between the time of arrival i n the CPB of the first bit of the coded data associated with the first picture following the buffering period SEI message (including all NAL data in the case that the HRD pertains to the NAL) and the time of removal of the coded data associated with the sa me picture from the CPB. The syntax element is a fixed length code whose length in bits is given by initial_cpb_removal_delay_length_minus1+1. It is in units of a 90 kHz clock. The initial_cpb_removal_delay syntax element is used in conjunction with t he CPBs as specified in Annex C. initial_cpb_removal_delay shall not be equal to 0 and shall not exceed the time-equivalent of the CPB size.

initial_cpb_removal_delay_offset: This syntax element is used in combination with the cpb_removal_delay to comput e the initial arrival time of coded pictures in the CPB. It is in units of a 90 kHz clock. The initial_cpb_removal_delay_offset syntax element is a fixed length code whose length in bits is given by initial_cpb_removal_delay_length_minus1+1.

Over the entire sequence, the sum of initial_cpb_removal_delay and initial_cpb_removal_delay_offset shall be constant and shall not exceed the time-equivalent of the CPB size.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

D.2.2 Picture timing SEI message semantics

If the bitstream includes HRD data, then in the case that any HRD buffers are signalled in the sequence parameter set(s), the following statements are true.

1. At each random access point, a buffering period SEI message shall follow the random access point SEI message.
2. A picture timing SEI Message shall precede the first NAL Unit of each picture subsequent to the picture with the buffering period SEI message.

Each of these SEI messages pertains to the next picture that follows it in decoding order.

cpb_removal_delay: This syntax element indicates how many clock ticks (see Annex C) to wait after removal from the HRD CPB of the picture immediately following the most recent random access SEI message before removing from the buffer the picture data immediately following the SEI message which contains the element. This value is also used to calculate an earliest possible time of arrival of picture data into the CPB, as specified in Annex C. The syntax element is a fixed length code whose length in bits is given by cpb_removal_delay_length. The cpb_removal_delay is the remainder of a $2^{(cpb\_removal\_delay\_length\_minus1 + 1)}$ counter.

dpb_output_delay: This syntax element is used to compute the *DPB output time*. It indicates how many clock ticks to wait after removal of a picture from the CPB before it can be removed from the DPB (see Annex C).

NOTE - A picture is not removed from the DPB at its output time if it is still being used as a reference.

When field_pic_flag is equal to 1 and indicates multiple fields, the DPB output delay shall be interpreted to refer to the first field in time. [Ed. Note: needs improvement]

NOTE - The timing of other fields must be inferred from external information about the time interval between fields.

The size of the syntax element dpb_output_delay shall remain constant for the sequence and is given in bits by dpb_output_delay_length_minus1.

pic_structure_present_flag: If and only if this syntax element is equal to 1, the pic_structure syntax element is present and follows immediately.

pic_structure: This parameter indicates whether a picture should be displayed as a frame or one or more fields, according to Table D-1.

Table D-1 – Interpretation of pic_structure

Value	Indicated display of picture	Restrictions	NumClockTS
0	frame	field_pic_flag must be 0	1
1	top field	field_pic_flag must be 1, bottom_field_flag must be 0	1
2	bottom field	field_pic_flag must be 1, bottom_field_flag must be 1	1
3	top field, bottom field, in that order	field_pic_flag must be 0	2
4	bottom field, top field, in that order	field_pic_flag must be 0	2
5	top field, bottom field, top field repeated, in that order	field_pic_flag must be 0	3
6	bottom field, top field, bottom field repeated, in that order	field_pic_flag must be 0	3
7	reserved		

NumClockTS is determined by pic_structure as indicated in Table D-1. There are up to NumClockTS sets of clock timestamp information for a picture, as indicated by clock_timestamp[i] for each set. The sets of clock timestamp information apply to the field(s) or the frame associated with the picture by pic_structure. In the case of fields, the order of the timestamps is the same as the display order of the fields, as indicated by pic_structure. Two fields associated with a frame picture may have different values of ct_type. If EquivalentTimestamp is equal for two fields of opposite parity that are adjacent in display order, both with ct_type equal to 0 (progressive) or ct_type equalt to 2 (unknown), then the

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

two fields are indicated to have come fro m the same original frame. Two adjacent fields in display order shall have different values of EquivalentTimestamp if the value of ct_type for either field is 1 (interlaced).

The contents of the clock timestamp SEI message specify an ideal display time co mputed as

$$\text{EquivalentTimestamp} = ((HH * 60 + MM) * 60 + SS) * \text{time\_scale} + NF * (\text{num\_units\_in\_tick} * (1 + \text{nuit\_field\_based\_flag})) + TO, \quad \text{(D-1)}$$

in units of ticks of a clock with clock frequency equal to time_scale Hz. The E quivalentTimestamp is the ideal display time assuming a display that can display frames and fields at any time without regard to a frame or field rate. If two or more frames with pic_structure equal to 0 are adjacent in output order and have equal values of EquivalentTimestamp, the ideal display duration for all such frames except for the last frame in display order is 0, and ideally only the last frame is displayed. The EquivalentTimestamp is not used for HRD purposes. Note that nframes and NF are frame -based counts.

clock_timestamp_flag[i]: If this syntax element is equal to 1, a number of clock timestamp fields are present and follow immediately.

ct_type: This parameter indicates the type (interlaced or progressive) of the original material as follow s:

Table D-2 – Mapping of ct_type to original picture scan

Value	Original picture scan
0	progressive
1	interlaced
2	unknown
3	reserved

nuit_field_based_flag: Used in calculating EquivalentTimestamp, as specified in Equation D-1.

counting_type: Specifies the method of dropping values of the nframes parameter as specified in Table D-3.

Table D-3 – Definition of counting_type values

Value	Interpretation
0	no dropping of nframes count values and no use of time_offset
1	no dropping of nframes count values
2	dropping of individual zero values of nframes count
3	dropping of individual max_pps values of npictures count
4	dropping of the two lowest (value 0 and 1) nframes counts when seconds_value is zero and minutes_value is not an integer multiple of ten
5	dropping of unspecified individual nframes count values
6	dropping of unspecified numbers of unspecified nframes count values
7 - 31	reserved

full_timestamp_flag indicates whether the nframes parameter is followed by seconds_value or seconds_flag.

discontinuity_flag indicates whether the time difference between the current value of EquivalentTimestamp and the value of EquivalentTimestamp compu ted from the last previously clock timestamp in decoding order can be interpreted as a true time difference. A value of 0 indicates that the difference represents a true time difference.

cnt_dropped_flag indicates the skipping of one or more values of nfr ames using the counting method specified by counting_type.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

nframes indicates the value of *NF* used to compute the EquivalentTimestamp. nframes shall be less than

$$\text{MaxFPS} = \text{Ceil}\ (\ \text{time\_scale} \div \text{num\_units\_in\_tick}\ ) \qquad \text{(D- 2)}$$

If counting_type is equal to 2 and cnt_dropped_flag is equal to 1, nframes shall be equal to 1 and the value of nframes for the last previous picture in output order shall not be equal to 0 unless discontinuity_flag is equal to 1.

NOTE – When counting_type is equal to 2, the need for increasingly large magnitudes of *TO* in Equation D-1 when using fixed non-integer frame rates (e.g., 12.5 frames per second with time_scale equal to 25 and num_units_in_tick equal to 2 and nuit_field_based_flag equal to 0) can be avoided by occasionally skipping over the value nframes equal to 0 when counting (e.g., counting nframes from 0 to 12, then incrementing seconds_value and counting nframes from 1 to 12, then incrementing seconds_value and counting nframes from 0 to 12, etc.).

If counting_type is equal to 3 and cnt_dropped_flag is equal to 1, nframes shall be equal to 0 and the value of nframes for the last previous picture in output order shall not be equal to MaxFPS – 1 unless discontinuity_flag is equal to 1.

NOTE – When counting_type is equal to 3, the need for increasingly large magnitudes of *TO* in Equation D-1 when using fixed non-integer frame rates (e.g., 12.5 frames per second with time_scale equal to 25 and num_units_in_tick equal to 2 and nuit_field_based_flag equal to 0) can be avoided by occasionally skipping over the value nframes equal to MaxFPS when counting (e.g., counting nframes from 0 to 12, then incrementing seconds_value and counting nframes from 0 to 11, then incrementing seconds_value and counting nframes from 0 to 12, etc.).

If counting_type is equal to 4 and cnt_dropped_flag is equal to 1, nframes shall be equal to 2 and the indicated value of *SS* shall be zero and the indicated value of *MM* shall not be an integer multiple of ten and nframes for the last previous picture in output order shall not be equal to 0 or 1 unless discontinuity_flag is equal to 1.

NOTE – When counting_type is equal to 4, the need for increasingly large magnitudes of *TO* in Equation D-1 when using fixed non-integer frame rates (e.g., 30000÷1001 frames per second with time_scale equal to 60 000 and num_units_in_tick equal to 1 001 and nuit_field_based_flag equal to 1) can be reduced by occasionally skipping over the value nframes equal to MaxFPS when counting (e.g., counting nframes from 0 to 29, then incrementing seconds_value and counting nframes from 0 to 29, etc., until the seconds_value is zero and minutes_value is not an integer multiple of ten, then counting nframes from 2 to 29, then incrementing seconds_value and counting nframes from 0 to 29, etc.). This counting method is well known in industry and is often referred to as "NTSC drop-frame" counting.

If counting_type is equal to 5 or 6 and cnt_dropped_flag is equal to 1, nframes shall not be equal to 1 plus the value of nframes for the last previous picture in output order modulo MaxFPS unless discontinuity_flag is equal to 1.

NOTE – When counting_type is equal to 5 or 6, the need for increasingly large magnitudes of *TO* in Equation D-1 when using fixed non-integer frame rates can be avoided by occasionally skipping over some values of nframes when counting. The specific values of nframes that are skipped are not specified when counting_type is equal to 5 or 6.

seconds_flag indicates whether seconds_value is present when full_timestamp_flag is equal to 0.

seconds_value indicates the value of *SS* used to compute the EquivalentTimestamp. seconds_v alue shall not exceed 59. If not present, the last previous seconds_value in decoding order shall be used as *SS* to compute the EquivalentTimestamp.

minutes_flag indicates whether seconds_value is present when full_timestamp_flag is equal to 0 and seconds_ flag is equal to 1.

minutes_value indicates the value of *MM* used to compute the EquivalentTimestamp. minutes_value shall not exceed 59. If not present, the last previous minutes_value in decoding order shall be used as *MM* to compute the EquivalentTimesta mp.

hours_flag indicates whether seconds_value is present when full_timestamp_flag is equal to 0 and seconds_flag is equal to 1 and minutes_flag is equal to 1.

hours_value indicates the value of *HH* used to compute the EquivalentTimestamp. hours_value shal l not exceed 23. If not present, the last previousl hours_value in decoding order shall be used as *HH* to compute the EquivalentTimestamp.

bit_equal_to_one is a single bit which shall be equal to 1.

time_offset indicates the value of *TO* used to compute the EquivalentTimestamp. The number of bits used to represent time_offset shall be equal to time_offset_length. If time_offset is not present, the value 0 shall be used as *TO* to compute the EquivalentTimestamp.

D.2.3 Pan-scan rectangle SEI message semantics

The pan-scan rectangle SEI message parameters define the coordinates of a rectangle relative to the cropping rectangle of the picture parameter set. Each coordinate of this rectangle is specified in units of 1/16 th sample spacing relative to the luma sampling grid.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

pan_scan_rect_id contains an identifying number which may be used to identify the purpose of the pan -scan rectangle (for example, to identify the rectangle as the area to be shown on a particular display device or as the area that contains a particular actor in the scene). pan_scan_rect_id shall not exceed 0xFFFFFFFF.

Values of pan_scan_rect_id from 0 to 0xFF and from 0x200 to 0x7FFFFFFF may be used as specified externally. Values of pan_scan_rect_id from 0x100 to 0x1FF and from 0x80000000 to 0xFFFF FFFF are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of pan_scan_rect_id in the range of 0x100 to 0x1FF or in the range of 0x80000000 to 0xFFFFFFFF shall ignore (remove from the bitstream and discard) it.

pan_scan_rect_left_offset, pan_scan_rect_right_offset, pan_scan_rect_top_offset, and **pan_scan_rect_bottom_offset** specify, as signed integer quantities in units of $1/16^{th}$ sample spacing relative to the luma sampling grid, the location of the pan -scan rectangle. The values of each of these four syntax elements shall be inside the interval from -2^{31} to $2^{31}-1$, inclusive.

The pan-scan rectangle is specified, in units of $1/16^{th}$ sample spacing relative to the luma sampling grid, as the area of the rectangle with horizontal coordinates from 16 * cropping_rect_left + pan_scan_rect_left_offset to 16 * [16 * PicWidthInMbs – cropping_rect_right] + pan_scan_rect_right_offset – 1 and with vertical coordinates from 16 * cropping_rect_top + pan_scan_rect_top_offset to 16 * [16 * PicHeightInMb s – cropping_rect_bottom] + pan_scan_rect_bottom_offset – 1, inclusive. If this rectangular area includes samples outside of the cropping rectangle, the region outside of the cropping rectangle may be filled with synthesized content (such as black video c ontent or neutral grey video content) for display.

The value of 16 * cropping_rect_left + pan_scan_rect_left_offset shall be less than or equal to 16 * [16 * PicWidthInMbs – cropping_rect_right] + pan_scan_rect_right_offset – 1.

The value of 16 * cropping_ rect_top + pan_scan_rect_top_offset shall be less than or equal to 16 * [16 * PicHeightInMbs – cropping_rect_bottom] + pan_scan_rect_bottom_offset – 1.

D.2.4 Filler payload SEI message semantics

This message contains a series of PayloadSize bytes of value 0xFF, which can be discarded.

filler_byte shall be a byte having the value 0xFF.

D.2.5 User data registered by ITU-T Recommendation T.35 SEI message semantics

This message contains registered user data as specified by ITU -T Recommendation T.35.

itu_t_t35_country_code shall be a byte having a value specified as a country code by ITU -T Recommendation T.35.

itu_t_t35_country_code_extension_byte shall be a byte having a value specified as an extended country code by ITU -T Recommendation T.35.

itu_t_t35_payload_byte shall be a byte containing user data registered as specified by ITU -T Recommendation T.35.

D.2.6 User data unregistered SEI message semantics

This message contains unregistered arbitrary user data, the contents of which are not specified by this Recommendation | International Standard.

user_data_arbitrary_payload_byte is a byte having a value not specified by this Recommendation | International Standard.

NOTE - Users of this Recommendation | International Standard should exercise care in the use of the user data arbitrary SEI message to avoid the carriage of data content in a form likely to conflict with the data content format of other users (e.g., avoiding conflict by using a fixed multi-byte prefix identifier within the payload content).

D.2.7 Random access point SEI message semantics

The random access point SEI message assists a decoder to start decoding at a picture other than the first picture in the bitstream. All decoded pictures at or subsequent to the recovery point in output order are indicated to be correct or approximately correct in content, if decoding is started at the first picture in decoding order after the random access point SEI message. Decoded pictures produced by starting the decoding process at the random access point may not be correct in content until the indicated recovery point, and the decoding process starting at the random access point and ending at the recovery point may contain references to pictures not available in the decoded picture buffer.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

In addition, by use of the broken_link_flag, th e random access point SEI message can indicate to the decoder the location of a splice point in the bitstream that can result in serious visual artifacts even when the decoding process was begun at a previous IDR point in decoding order.

The recovery point is indicated as a count in units of coded pictures subsequent to the current picture at the position of the SEI message.

recovery_frame_cnt indicates the recovery point of output pictures in output order. All decoded pictures in output order are indicated to be correct or approximately correct in content starting at the output order position of the reference picture having the frame number equal to the frame number of the next slice incremented by recovery_frame_cnt in modulo MaxFrameNum arithmetic. recove ry_framepoint_count shall not exceed MaxFrameNum -1.

exact_match_flag indicates whether decoded pictures at and subsequent to the recovery point in output order obtained by starting the decoding process at the specified random access point shall be an exact match to the pictures that would be produced by a decoder starting at the last prior IDR point in the NAL unit stream. The value 0 indicates that the match may not be exact and the value 1 indicates that the match shall be exact.

If decoding starts from an random access point indicated in a random access point SEI message, all references to unavailable reference pictures shall be inferred as references to sample values given by Y=Cb=Cr=128 (mid -level grey) in intra macroblocks for purposes of determining the conformance of the value of exact_match_flag.

broken_link_flag indicates the presence or absence of a splicing point in the NAL unit stream at the location of the random access point SEI message. If broken_link_flag is equal to 1, pictures produced by starting the decoding process at the last previous IDR point may contain undesirable visual artifacts due to splicing operations and should not be displayed until the indicated random access recovery point in output order. If broken_link_flag is equal to 0, no indication is given regarding any potential presence of visual artifacts.

Regardless of the value of the broken_link_flag, pictures subsequent to the recovery point in output order are indicated to be correct or approximately correct in content.

If a sub-sequence information SEI message is transmitted in conjunction with a random access point SEI message in which broken_link_flag is equal to 1 and if subseq_layer_num is 0, subseq_id should be different from the latest subseq_id for subseq_layer_num e qual to 0 that was decoded prior to the random access point. If broken_link_flag is equal to 0, the subseq_id in sub -sequence layer 0 should remain unchanged.

If HRD information is present in the bitstream, a buffering period SEI message shall be transmit ted after the random access point SEI message and before any slice data in order to establish initialisation of the HRD buffer model.

D.2.8 Decoded picture buffer management Repetition SEI message semantics

The Decoded picture buffer management repetition SEI me ssage is used to repeat memory management control operation commands that were located earlier in decoding order.

original_frame_num identifies the picture were the repeated memory management control operation originally occurred.

dec_pic_buffer_managamen t( ) shall contain a copy of the decoded picture buffer management syntax elements of the picture whose frame_num was original_frame_num.

D.2.9 Spare picture SEI message semantics

The spare picture SEI message indicates that certain macroblocks, called spare dec oded macroblocks, in one or more decoded reference pictures resemble the co -located macroblocks in a certain decoded picture, called the target picture, so much that any of these spare decoded macroblocks can be used to replace a co -located incorrect decod ed macroblock in the target picture in the multi -frame buffer and in decoder output. Decoded pictures that contain spare macroblocks are called spare pictures.

target_frame_num identifies the target picture whose spare pictures and macroblocks are specifi ed later in the message. The target picture is the latest reference picture having frame_num equal to target_frame_num.

num_spare_pics_minus1 specifies the number of pictures which contain spare picture or macroblocks for the target picture. num_spare_pic s_minus1 shall not exceed 14.

delta_spare_frame_num specifies to which spare picture the following spare picture information in the current loop count belongs. For the first spare picture of the message, CandidateSpareFrameNum is set to target_frame_num -1, if target_frame_num is greater than 0 and MaxFrameNum – 1 otherwise. For later spare pictures, CandidateSpareFrameNum is the SpareFrameNum of the previous loop round minus 1 if SpareFrameNum is greater than 0 and MaxFrameNum – 1 otherwise. For each loop r ound, SpareFrameNum is calculated as follows:

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

```
SpareFrameNum = CandidateSpareFrameNum – delta_spare_frame_num
if( SpareFrameNum < 0 )
        SpareFrameNum = MaxFrameNum + SpareFrameNum                    (D-3)
```

ref_area_indicator specifies how the locations of spare macroblocks are coded. ref_area_indicator 0 indicates that all macroblocks of the spare picture are spare macroblocks.. ref_area_indicator 1 indicates an uncompressed spare macroblock map. ref_area_indicator 2 indicates a compressed spare macr oblock map. A spare macroblock map consists of flags for each macroblock location of a picture. ref_area_indicator shall not exceed 2.

If ref_area_indicator is 1, there is a **ref_mb_indicator** for each macroblock address of the spare macroblock map in raster scan order. ref_mb_indicator 0 indicates that the macroblock is a spare macroblock, and ref_mb_indicator 1 indicates that the macroblock is not a spare macroblock.

If ref_area_indicator is 2, a spare macroblock map between a spare picture and the target picture is compressed. The coded macroblock map for loop_count equal to 0 is the spare macroblock map between the target picture and the first spare picture. A coded macroblock map for loop_count greater than 0 is generated by applying an exclusive or oper ation between the previous spare macroblock map and the current spare macroblock map. The coded macroblock map is scanned in counter-clockwise box-out order as specified in subclause 8.2.4.1. The number of consecutive zeros in t he scanning order is indicated in **zero_run_length**. [Ed. Note: This paragraphs needs work. What is loop_count? What does compressed mean? What does it mean for something to be between a spare picture and the target picture?]

D.2.10 Scene information SEI message semantics

A scene is herein defined as a set of consecutive pictures in output order captured with one camera. Decoded pictures within one scene generally have similar pictorial contents and semantic meanings.

The scene information SEI message is used to label scenes with identifiers and to indicate scene changes. The message indicates how the uncoded source picture for the coded target picture was created. The decoder may use the information to select an appropriate algorithm to conceal transmission erro rs. For example, a specific algorithm may be used to conceal transmission errors that occurred in pictures belonging to a gradual scene transition. Furthermore, the scene information SEI message may be used for external purposes, such as for indexing the s cenes of a coded sequence.

scene_id identifies the scene which the target picture belongs to. Pictures in a scene shall share the same value of scene_id. Consecutive scenes in output order should not have the same value of scene_id. If the next slice or s lice data partition in decoding order belongs to a picture that includes contents from two scenes, scene_id is the scene identifier of the former scene in output order.

scene_transition_type indicates in which type of a scene transition, if any, the target picture is involved. The valid values of **scene_transition_type** are specified in Table D-4. scene_transition_type shall not exceed 6. If a value greater than 6 is received by the decoder, it shall be ignored (removed from the bit stream and discarded).

Table D-4 – Scene transition types.

Value	Description
0	No transition
1	Fade to black
2	Fade from black
3	Unspecified transition from or to constant color
4	Dissolve
5	Wipe
6	Unspecified mixture of two scenes
Other values	Reserved

If scene_transition_type is greater than 3, the next slice or slice data partition in decoding order belongs to a picture that includes contents from two scenes.

Scene transition types are specified as follows. The term "the former scene" is used to indicate the former scene involved in a scene transition in output order. The term "the latter scene" is used to indicate the latter scene involved in a scene transition in output order.

"**No transition**" indicates that the target picture does not belong to a gradual scene transition (all scene transiton types but scene cut). If two consecutive pictures in output order have scene_transition_type equal to zero and different scene IDs, a scene cut occurred between the two pictures.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

In "**Fade to black**" scene transition, the lightness of the scene monotonically reduces to zero (i.e., black picture).

In "**Fade from black**" scene transition, the lightness of the scene monotonically increases from zero to full intensity.

An uncompressed picture in "**Dissolve**" scene transition is generated by calculating a sum of co -located weighted sample values of a picture from the former scene and a picture from the latter scene. The weight of the former scene gradually decreases from full level to zero level, whereas the weight of the latter scene gradually increases from zero level to full level.

In "**Wipe**" scene transition, the latter scene covers the former scene in a spatially gradual manner, while the intensity of the scenes remains unchanged.

second_scene_id is present if the next slice or slice data partition in decoding order belongs to a picture that includes contents from two scenes, i.e., scene_transition_type is larger than 3. second_scene_id is the scene identifier of the latter scene in output order.

D.2.11 Sub-sequence information SEI message semantics

The sub-sequence information SEI message is used to indicate the position of a picture in data dependency hierarchy that consists of sub-sequence layers and sub-sequences.

A sub-sequence layer contains a subset of the coded pictures in a sequence. Sub -sequence layers are numbered with non - negative integers. A layer having a larger layer number is a higher layer than a layer having a smaller layer number. The layers are ordered hierarchically based on their dependency on each other so that a layer does not depend on any higher layer and may depend on lower layers. In other words, layer 0 is independently decodable, pictures in layer 1 may be predicted from layer 0, pictures in layer 2 may be predicted from la yers 0 and 1, etc.

NOTE: The subjective quality is expected to increase along with the number of decoded layers.

A sub-sequence is a set of coded pictures within a sub -sequence layer. A picture shall reside in one sub -sequence layer and in one sub-sequence only. A sub-sequence shall not depend on any other sub -sequence in the same or in a higher sub-sequence layer. A sub-sequence in layer 0 can be decoded independently of any other sub -sequences and previous long-term reference pictures.

The sub-sequence information SEI message concerns the picture containing the next slice or slice data partition in decoding order. The picture which the next slice or slice data partition belongs to is herein referred to as the current picture.

When a sub-sequence information SEI message is coded, the required_frame_num_update_behaviour_flag in the active sequence parameter set shall be equal to 1.

subseq_layer_num indicates the sub-sequence layer number of the current picture. If subseq_layer_num is greater than 0, memory management control operations shall not be used in any slice header of the current picture. subseq_layer_num shall be less than 256.

subseq_id identifies the sub-sequence within a layer. Consecutive sub -sequences within a particular layer in decoding order shall have a different subseq_id from each other. subseq_id shall be less than 65536.

first_ref_pic_flag equal to 1 signals that the current picture is the first reference picture of the sub -sequence in decoding order. Otherwise the first_ ref_pic_flag sh all be 0.

leading_non_ref_pic_flag equals to 1 if the current picture is a non -reference picture preceding any reference picture in decoding order within the sub -sequence. Otherwise the leading_non_ref_pic_flag shall be 0.

last_pic_flag equal to 1 signals that the current picture is the last picture of the sub -sequence (in decoding order), including all reference and non -reference pictures of the sub-sequence. For any other pictures, the last_pic_flag shall be 0.

subseq_frame_num shall be equal to 0 for the first reference picture of the sub -sequence and for any non -reference picture preceding the reference picture of the sub -sequence in decoding order. For each coded picture belonging to the sub-sequence in decoding order, subseq_frame_num shall be incremen ted by 1, in modulo MaxFrameNum operation, relative to the previous reference frame that belongs to the sub -sequence. Both fields of a frame, if present, shall have the same subseq_frame_num. subseq_frame_num shall be less than MaxFrameNum.

If the current picture is an IDR picture, it shall start a new sub -sequence in sub-sequence layer 0. Thus, the subseq_layer_num shall be 0, the subseq_id shall be different from the previous sub -sequence in sub-sequence layer 0, first_ref_pic_flag shall be 1, and leadin g_non_ref_pic_flag shall be 0.

D.2.12 Sub-sequence layer characteristics SEI message semantics

The sub-sequence layer characteristics SEI message indicates the characteristics of sub -sequence layers.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

A pair of average bit rate and average frame rate characterizes each sub-sequence layer. The first pair of average bit rate and average frame rate signals the characteristics of sub-sequence layer 0. The second pair, if present, signals the characteristics of sub-sequence layers 0 and 1 jointly. Each pair in decoding order signals the characteristics for a range of sub-sequence layers from layer number 0 to the layer number that is incremented by one from the previous upper limit of layer numbers. The values are in effect from the point they are decoded until an update of the values is decoded.

accurate_statistics_flag indicates how reliable the values of average_bit_rate and average_frame_rate are. accurate_statistics_flag equal to 1 indicates that the average_bit_rate and the average_frame_rate are rounded from statistically correct values. accurate_statistics_flag equal to 0 indicates that the average_bit_rate and the average_frame_rate are estimates and may deviate somewhat from the correct values.

average_bit_rate gives the average bit rate in units of 1000 bits per second. All NAL units in the range of sub-sequence layers specified above are taken into account in the calculation. The average bit rate is calculated according to the picture removal time specified in Annex C of the Recommendation | International Standard. In the following, B is the number of bits in all NAL units succeeding a sub-sequence layer characteristics SEI message (including the bits of the NAL units of the current picture) and preceding the next sub-sequence layer characteristics SEI message or the end of the stream. t_1 is the removal time (in seconds) of the current picture, and t_2 is the removal time (in seconds) of the latest picture before the next sub-sequence layer characteristics SEI message or the end of the stream. Then, the average_bit_rate is calculated as follows provided that $t_1 \neq t_2$:

$$\text{average\_bit\_rate} = \text{round}(B \div ((t_2 - t_1) * 1000)) \quad \text{(D-4)}$$

If t1 = t2, average_bit_rate shall be 0. Value zero indicates an unspecified bit rate.

average_frame_rate gives the average frame rate in units of frames/(256 seconds). All NAL units in the range of sub-sequence layers specified above are taken into account in the calculation. In the following, C is the number of frames between the current picture (inclusive) and the next sub-sequence layer characteristics SEI message or the end of the stream. t_1 is the removal time (in seconds) of the current picture, and t_2 is the removal time (in seconds) of the latest picture before the next sub-sequence layer characteristics SEI message or the end of the stream. Then, the average_frame_rate is calculated as follows provided that $t_1 \neq t_2$:

$$\text{average\_frame\_rate} = \text{round}(C * 256 \div (t_2 - t_1)) \quad \text{(D-5)}$$

If $t_1 = t_2$, average_frame_rate shall be 0. Value zero indicates an unspecified frame rate.

D.2.13 Sub-sequence characteristics SEI message semantics

The sub-sequence characteristics SEI message indicates the characteristics of a sub-sequence. It also indicates inter prediction dependencies between sub-sequences.

subseq_layer_num indicates the sub-sequence layer number to which the sub-sequence characteristics SEI message applies. subseq_layer_num shall be less than 256.

subseq_id indicates the sub-sequence within a layer to which the sub-sequence characteristics SEI message applies. subseq_id shall be less than 65536.

This message applies to the next sub-sequence in decoding order having the indicated subseq_layer_num and subseq_id. This sub-sequence is herein called the target sub-sequence.

duration_flag equal to 0 indicates that the duration of the target sub-sequence is not specified.

subseq_duration indicates the duration of the target sub-sequence in clock ticks of a 90-kHz clock.

average_rate_flag equal to 0 indicates that the average bit rate and the average frame rate of the target sub-sequence are unspecified.

accurate_statistics_flag indicates how reliable the values of average_bit_rate and average_frame_rate are. accurate_statistics_flag equal to 1, indicates that the average_bit_rate and the average_frame_rate are rounded from statistically correct values. accurate_statistics_flag equal to 0 indicates that the average_bit_rate and the average_frame_rate are estimates and may deviate from the statistically correct values.

average_bit_rate gives the average bit rate in (1000 bits)/second of the target sub-sequence. All NAL units of the target sub-sequence are taken into account in the calculation. The average bit rate is calculated according to the picture removal time specified in subclause C.1.1.2. In the following, B is the number of bits in all NAL units in the sub-sequence. t_1 is the removal time (in seconds) of the first picture of the sub-sequence (in decoding order), and t_2 is the removal time (in seconds) of the last picture of the sub-sequence (in decoding order). Then, the average_bit_rate is calculated as follows provided that $t_1 \neq t_2$:

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

$$average\_bit\_rate = round(B \div ((t_2 - t_1) * 1000)) \quad (D\text{-}6)$$

If $t_1 = t_2$, average_bit_rate shall be 0.

average_frame_rate gives the average frame rate in units of frames/(256 seconds) of the target sub-sequence. All NAL units of the target sub-sequence are taken into account in the calculation. The average frame rate is calculated according to the picture removal time specified in subclause C.1.1.2. In the following, C is the number of frames in the sub-sequence. t_1 is the removal time (in seconds) of the first picture of the sub-sequence (in decoding order), and t_2 is the removal time (in seconds) of the last picture of the sub-sequence (in decoding order). Then, the average_frame_rate is calculated as follows provided that $t_1 \neq t_2$:

$$average\_frame\_rate = round(C * 256 \div (t_2 - t_1)) \quad (D\text{-}7)$$

If t1 = t2, average_frame_rate shall be 0.

num_referenced_subseqs gives the number of sub-sequences which contain pictures that are used as reference pictures for inter prediction in the pictures of the target sub-sequence. num_referenced_subseqs shall be less than 256.

ref_subseq_layer_num and **ref_subseq_id** identify a sub-sequence that contains pictures that are used as reference pictures for inter prediction in the pictures of the target sub-sequence.

D.2.14 Full-frame freeze SEI message semantics

The full-frame freeze SEI message indicates that the contents of the entire prior displayed video frame in output order should be kept unchanged, without updating the display using the contents of the current decoded picture. The displayed frame should then remain unchanged until a full-frame freeze release SEI message is received, or until timeout occurs, whichever comes first. The full-frame freeze shall lapse due to timeout after five seconds or five pictures in output order, whichever is a longer period of time. The timeout can be prevented by the issuance of another full-frame freeze SEI message prior to or upon expiration of the timeout period.

D.2.15 Full-frame freeze release SEI message semantics

The full-frame freeze release SEI message indicates that the update of the displayed video frame should resume, starting with the contents of the current decoded picture and continuing for subsequent pictures in output order. The full-frame freeze release SEI message cancels the effect of any full-frame freeze SEI message sent with pictures that precede the current picture in output order.

D.2.16 Full-frame snapshot SEI message semantics

The full-frame snapshot SEI message indicates that the current frame is labeled for external use as a still-image snapshot of the video content.

snapshot_id specifies a snapshot identification number. snapshot_id shall not exceed 0xFFFFFFFF .

Values of snapshot_id from 0 to 0x7FFFFFFF may be used as specified externally. Values of snapshot_id from 0x80000000 to 0xFFFFFFFF are reserved for future use by ITU-T | ISO/IEC. Decoders encountering a value of snapshot_id from 0x80000000 to 0xFFFFFFF F shall ignore (remove from the bitstream and discard) it.

D.2.17 Progressive refinement segment start SEI message semantics

The progressive refinement segment start SEI message indicates the beginning of a specified set of consecutive coded pictures which is labeled as the current picture followed by a sequence of one or more pictures of refinement of the quality of the current picture, rather than as a representation of a continually moving scene.

The tagged set of consecutive coded pictures shall continue until one of following conditions is true. When a condition below becomes true, the next slice to be decoded does not belong to the tagged set of consecutive coded pictures.

1. The next slice to be decoded belongs to an IDR picture.
2. num_refinement_steps_minus1 is greater than 0 and the frame number of the next slice to be decoded is (CurrFrameNum + num_refinement_steps_minus1 + 1) % MaxFrameNum, where CurrFrameNum is the frame number of the next slice following this SEI message in decoding order.
3. num_refinement_steps_minus1 is 0 and a progressive refinement segment end SEI message with the same progressive_refinement_id as the one in this SEI message is decoded.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

4. num_refinement_steps_minus1 is 0 and a timeout of five seconds has elapsed since the decoding of this S EI message. The timeout can be prevented by the issuance of an identical progressive refinement segment start SEI message prior to or upon expiration of the timeout period.

The decoding order of picture within the tagged set of consecutive pictures should be the same as their output order. **progressive_refinement_id** specifies an identification number for the progressive refinement operation. progressive_refinement_id shall not exceed 0xFFFFFFFF.

Values of progressive_refinement_id from 0 to 0x7FFFFFFF may b e used as specified externally. Values of progressive_refinement_id from 0x80000000 to 0xFFFFFFFF are reserved for future use by ITU -T | ISO/IEC. Decoders encountering a value of progressive_refinement_id from 0x80000000 to 0xFFFFFFFF shall ignore (remove from the bitstream and discard) it.

num_refinement_steps_minus1 indicates the number of reference frames in the tagged set of consecutive coded pictures. num_refinement_steps equal to 0 indicates that number of reference frames in the tagged set of consec utive coded pictures is unknown. Otherwise, the number of reference frames in the tagged set of consecutive coded pictures is equal to num_refinement_steps_minus1 + 1. num_refinement_steps_minus1 shall not exceed MaxFrameNum -1.

D.2.18 Progressive refinement segment end SEI message semantics

The progressive refinement segment end SEI message indicates the end of a specified set of consecutive coded pictures which has been labeled by use of a progressive refinement segment start SEI message as an initial picture fol lowed by a sequence of one or more pictures of the refinement of the quality of the initial picture, and ending with the current picture.

progressive_refinement_id specifies an identification number for the progressive refinement operation. progressive_refinement_id shall not exceed 0xFFFFFFFF.

The progressive refinement segment end SEI message indicates the end of any progressive refinement segment previously started using a progressive refinement segment start SEI message with the same value of progressive_refinement_id.

Values of progressive_refinement_id from 0 to 0x7FFFFFFF may be used as specified externally. Values of progressive_refinement_id from 0x80000000 to 0xFFFFFFFF are reserved for future use by ITU -T | ISO/IEC. Decoders encountering a value of progressive_refinement_id from 0x80000000 to 0xFFFFFFFF shall ignore (remove from the bitstream and discard) it.

D.2.19 Reserved SEI message semantics

This message consists of data reserved for future backward -compatible use by ITU-T | ISO/IEC. Encoders conforming to this Recommendation | International Standard shall not send reserved SEI messages until and unless the use of such messages has been specified by ITU-T | ISO/IEC. Decoders conforming to this Recommendation | International Standard that encounter reserved SEI messages shall discard their content without effect on the decoding process, except as specified in future Recommendations | International Standards specified by ITU -T | ISO/IEC. reserved_sei_message_payload_byte is a byte reserved for future use by ITU-T | ISO/IEC.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Annex E
Video usability information

(This annex forms an integral part of this Recommendation | International Standard)

This Annex specifies syntax and semantics of those parts of the sequence parameter set and the picture param eter set that are not required for determining the decoded values of samples. The parameters specified in this annex can be used to facilitate the use of the decoded pictures or facilitate the resource allocation of a decoder by restricting certain video parameters beyond those limits specified by Annex A. Decoders are not required to process VUI sequence parameters for conformance to this Recommendation | International Standard.

For some of the parameters of this Annex, default values are specified in the semantics subclause. The syntax includes flags that allow avoiding the signalling of groups of parameters. If a specific group of parameters is not coded, the default values for these parameters become effective.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

E.2 VUI semantics

E.2.1 VUI sequence parameters semantics

aspect_ratio_info_present_flag : A flag that, when equal to 1, signals the presence of the aspect_ratio_idc. If the flag is 0, then the default value 0 shall apply to aspect_ratio_idc.

aspect_ratio_idc specifies the value of the sample aspect ratio. Table E-1 shows the meaning of the code. If aspect_ratio_idc indicates Extended_SAR, the sample aspect ratio is represented by sar_width and sar_height.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table E-1 – Meaning of sample aspect ratio indicator

aspect_ratio_idc	Sample aspect ratio	(informative) Examples of use
0	Unspecified or specified externally	
1	1:1 ("square")	1280x720 16:9 frame without overscan 1920x1080 16:9 frame without overscan (cropped from 1920x1088) 640x480 4:3 frame without overs can
2	12:11	720x576 4:3 frame with overscan 352x288 4:3 frame without overscan
3	10:11	720x480 4:3 frame with overscan 352x240 4:3 frame without overscan
4	16:11	720x576 16:9 frame with overscan 540x576 4:3 frame with overscan
5	40:33	720x480 16:9 fram e with overscan 540x480 4:3 frame with overscan
6	24:11	352x576 4:3 frame without overscan 540x576 16:9 frame with overscan
7	20:11	352x480 4:3 frame without overscan 480x480 16:9 frame with overscan
8	32:11	352x576 16:9 frame without overscan
9	80:33	352x480 16:9 frame without overscan
10	18:11	480x576 4:3 frame with overscan
11	15:11	480x480 4:3 frame with overscan
12	64:33	540x576 16:9 frame with overscan
13	160:99	540x480 16:9 frame with overscan
14-254	Reserved	
255	Extended_SAR	

sar_width indicates the horizontal size of the sample aspect ratio. A zero value is forbidden.

sar_height indicates the vertical size of the sample aspect ratio. A zero value is forbidden.

The sar_width and sar_height shall be relatively prime. If aspect_ratio_idc is zero or if either of sar_width or sar_height are zero, the sample aspect ratio shall be considered unspecified or specified externally.

overscan_info_present_flag: A flag that, when equal to 1, signals the presence of overscan_appropriate_flag. If overscan_info_present_flag is equal to 0 or is not present, the preferred display method for the video signal is unspecified.

overscan_appropriate_flag: A flag that, when equal to 1, indicates that the video signal is suitable for display using overscan. When overscan_appropriate_flag is equal to 0, this indicates that the video signal contains visually important information in the entire region out to the edges of the cropping rectangle of the picture, such that the video signal should not be displayed using overscan; instead it should be displayed using either an exact match between the display area and the cropping rectangle, or using underscan. For example, overscan_appropriate_flag equal to 1 might be used for entertainment television programming, or for a live view of people in a videoconference, and overscan_appropriate_flag equal to 0 might be used for computer screen capture or security camera content.

video_signal_type_present_flag: A flag that, when 1, signals the presence of video signal informatio n. If video_signal_type_present_flag is 0, then the following default values shall apply: video_format = 5, video_full_range_flag = 0, colour_description_present_flag = 0.

video_format: Indicates the representation of the pictures before being coded in accordance with this Recommendation | International Standard. Its meaning is specified in Table E-2.

Table E-2 – Meaning of video_format

video_format	Meaning
0	Component

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

1	PAL
2	NTSC
3	SECAM
4	MAC
5	Unspecified video format
6	Reserved
7	Reserved

video_full_range_flag indicates the nominal black level and range of the luma and chroma signals as derived from E'_Y, E'_{PB}, and E'_{PR} analogue component signals as follows:

If video_full_range_flag is equal to 0:

$$Y = \text{round}(219 * E'_Y + 16) \quad \text{(E-1)}$$

$$Cb = \text{round}(224 * E'_{PB} + 128) \quad \text{(E-2)}$$

$$Cr = \text{round}(224 * E'_{PR} + 128) \quad \text{(E-3)}$$

If video_full_range_flag is equal to 1:

$$Y = \text{round}(255 * E'_Y) \quad \text{(E-4)}$$

$$Cb = \text{round}(255 * E'_{PB} + 128) \quad \text{(E-5)}$$

$$Cr = \text{round}(255 * E'_{PR} + 128) \quad \text{(E-6)}$$

colour_description_present_flag indicates the presence of colour_primaries, transfer_characteristics and matrix_coefficients in the bitstream.

colour_primaries: This 8-bit integer describes the chromaticity coordinates of the source primaries, and is specified in Table E-3.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

Table E-3 – Colour Primaries

Value	Primaries		
0	Reserved		
1	ITU-R Recommendation BT.709		
	primary	x	y

8	Generic film (colour filters using Illuminant C)		
	primary	x	y
	green	0.243	0.692 (Wratten 58)
	blue	0.145	0.049 (Wratten 47)
	red	0.681	0.319 (Wratten 25)
9-255	Reserved		

If video_signal_type_present_flag is 0 or colour_description_present_flag is 0, colour_primaries shall have an inferred value equal to 2 (the chromaticity is unspecified or specified externally).

transfer_characteristics: This 8-bit integer describes the opto-electronic transfer characteristic of the source picture, and is specified in Table E-4.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

Table E-4 – Transfer Characteristics

Value	Transfer Characteristic
0	Reserved
1	ITU-R Recommendation BT.709 $V = 1.099\ L_C^{0.45} - 0.099$ for $1 \geq L_C \geq 0.018$ $V = 4.500\ L_C$ for $0.018 > L_C \geq 0$
2	Unspecified or externally-specified video Image characteristics are unknown or specified externally.
3	Reserved
4	ITU-R Recommendation BT.470-2 System M Assumed display gamma 2.2
5	ITU-R Recommendation BT.470-2 System B, G Assumed display gamma 2.8
6	Society of Motion Picture and Television Engineers 170M $V = 1.099\ L_C^{0.45} - 0.099$ for $1 \geq L_C \geq 0.018$ $V = 4.500\ L_C$ for $0.018 > L_C \geq 0$
7	Society of Motion Picture and Television Engineers 240M (1987) $V = 1.1115\ L_C^{0.45} - 0.1115$ for $L_C \geq 0.0228$ $V = 4.0\ L_C$ for $0.0228 > L_C$
8	Linear transfer characteristics i.e. $V = L_C$
9	Logarithmic transfer characteristic (100:1 range) $V = 1.0 - \log_{10}(L_C)/2$ for $1 = L_C = 0.01$ $V = 0.0$ for $0.01 > L_C$
10	Logarithmic transfer characteristic (316.22777:1 range) $V = 1.0 - \log_{10}(L_C)/2.5$ for $1 = L_C = 0.0031622777$ $V = 0.0$ for $0.0031622777 > L_C$
11-255	Reserved

If video_signal_type_present_flag is zero or colour_description_present_flag is 0, transfer_characteris tics shall have an inferred value equal to 2 (the transfer characteristics are unspecified or are specified externally).

matrix_coefficients: This 8-bit integer describes the matrix coefficients used in deriving luma and chroma signals from the green, blue, and red primaries, as specified in Table E-5.

Using the following definitions:

E'_R, E'_G, and E'_B are analogue with values between 0 and 1.

White is specified as $E'_R = E'_G = E'_B = 1$.

Then:

$$E'_Y = K_R * E'_R + (1 - K_R - K_B) * E'_G + K_B * E'_B \qquad \text{(E-7)}$$

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

$$E'_{PB} = 0.5 * (E'_R - E'_Y) \div (1-K_R) \quad \text{(E-8)}$$

$$E'_{PB} = 0.5 * (E'_B - E'_Y) \div (1-K_B) \quad \text{(E-9)}$$

Then E'_Y is analogue with values between 0 and 1, E'_{PB} and E'_{PR} are analogue with values between -0.5 and 0.5, and white is equivalently given by $E'_Y = 1$, $E'_{PB} = 0$, $E'_{PR} = 0$.

Table E-5 – Matrix Coefficients

Value	Matrix
0	Reserved
1	ITU-R Recommendation BT.709 $K_R = 0.2126$; $K_B = 0.0722$
2	Unspecified or externally-specified video Image characteristics are unknown or specified externally.
3	Reserved
4	Federal Communications Commission $K_R = 0.30$; $K_B = 0.11$
5	ITU-R Recommendation BT.470-2 System B, G: $K_R = 0.299$; $K_B = 0.114$
6	Society of Motion Picture and Television Engineers 170M $K_R = 0.299$; $K_B = 0.114$
7	Society of Motion Picture and Television Engineers 240M (1987) $K_R = 0.212$; $K_B = 0.087$
8-255	Reserved

If video_signal_type_present_flag is zero or colour_description_present_flag is 0, matrix_coeffi cients shall have an inferred value equal to 2 (the matrix coefficients shall be inferred to be unspecified or specified externally).

chroma_location_info_present_flag: A flag that, when 1, signals the presence of the chroma location information. If the flag is 0, then the following default values shall apply: chroma_location_frame = 0, chroma_location_field = 0; and the chroma locations in a frame shall be inferred to be the nominal locations shown in in Figure 6-1 and the chroma locations in a field shall be inferred to be the nominal locations shown in Figure 6-2.

chroma_location_frame specifies the 4:2:0 sampling structure for frame pictures according to Table E-6 and Figure E-1. The value of chroma_location_frame shall not exceed 3.

Table E-6 – Chroma Sampling Structure for Frame Pictures

Value of chroma_location_frame	Sampling Structure
0	unspecified
1	Frame according to Figure E-1 Chroma Sample Mode 1
2	Frame according to Figure E-1 Chroma Sample Mode 2
3	Frame according to Figure E-1 Chroma Sample Mode 3

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

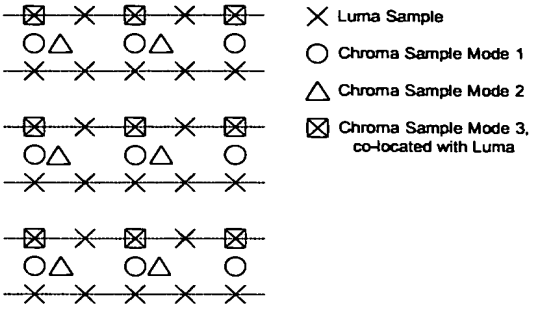

Figure E-1 – Luma and chroma sample types for frames

chroma_location_field specifies the 4:2:0 sampling structure for fields according to Table E-7 and Figure E-2. The value of chroma_location_field sh all not exceed 3.

Table E-7 – Chroma Sampling Structure for Fields

chroma_location_field	Sampling Structure
0	unspecified
1	Field according to Figure E-2 Chroma Sample Mode 1
2	Field according to Figure E-2 Chroma Sample Mode 2
3	Field according to Figure E-2 Chroma Sample Mode 3

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

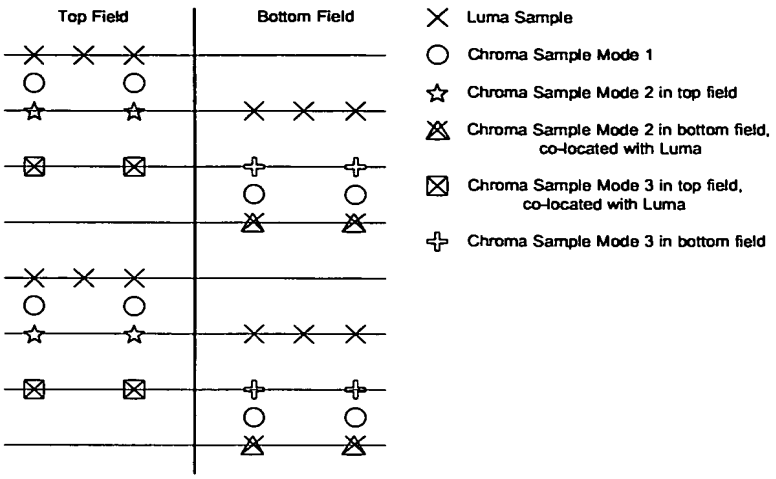

Figure E-2 – Luma and chroma association for fields

timing_info_ present_flag: A flag that, when equal to 1, signals the presence of time unit information. If timing_info_present_flag is equal to 0, then the following default values shall apply: num_units_in_tick = 0, time_scale = 0, fixed_frame_rate_flag = 0. [Ed. Note: These values make no sense, as it is not possible to create an HRD-conforming bitstream using these values.]

num_units_in_tick is the number of time units of a clock operating at the frequency time_scale Hz that corresponds to one increment of a clock tick counter. A clock tick is the minimum interval of time that can be represented in the coded data. For example, if the clock frequency of a video signal is (30 000) ÷ 1001 Hz, time_scale may be 30 000 and num_units_in_tick may be 1001. If num_units_in_tick is 0, the du ration of the clock tick is unspecified. [Ed. Note: This value makes no sense, as it is not possible to create an HRD -conforming bitstream without any specified clock tick.]

time_scale is the number of time units which pass in one second. For example, a ti me coordinate system that measures time using a 27 MHz clock has a time_scale of 27 000 000. If time_scale is 0, the duration of the clock tick specified above is unspecified. [Ed. Note: This value makes no sense, as it is not possible to create an HRD -conforming bitstream without any specified time scale.]

fixed_frame_rate_flag: A bit that, if equal to 1, indicates that the temporal distance between the HRD output times of any two consecutive frames or fields in output order as specified in Annex C is a co nstant. If equal to 0, the temporal distances between HRD output times of consecutive frames or fields in output order as specified in Annex C may not be constant.

nal_hrd_parameters_present_flag: If nal_hrd_parameters_present_flag is equal to 0, no HRD parameters pertaining to the multiplexed NAL and VCL bitstream are present in the bitstream. In this case, the multiplexed NAL and VCL bitstream conforms to an HRD whose buffer size and bit rate parameters are 20% higher than those given by the maxima specified in Table A-1 for the level specified by level_idc.

Note – when nal_hrd_parameters_present_flag is equal to 0, the conformance of the multiplexed NAL and VCL bitstream cannot be verified without external provision of all the NAL HRD parameters, including the NAL sequence HRD parameter information and all buffering period and picture timing SEI messages.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

If nal_hrd_parameters_present_flag is equal to 1, then NAL sequence HRD parameters (subclauses E.1.2 and E.2.2) immediately follow the flag. At least one of the NAL HRD coded picture buffers signalled in the sequence HRD parameters must have CPB bitrate and buffer size values that are both less than values 20% higher than the maxima specified in Table A-1 for the level specified by level_idc. Some of the NAL HRD coded picture buffers signalled may have values outside the level limits.

Furthermore, if nal_hrd_parameters_present_flag is equal to 1, then a buffering period SEI message (subclauses D.1.1 and D.2.1) immediately follows each random access point SEI message (subclauses D.1.7 and D.2.7), and a picture timing SEI message (subclauses D.1.1 and D.2.1) precedes each coded picture.

vcl_hrd_parameters_present_flag: If vcl_hrd_parameters_present_flag is equal to 0, no HRD parameters pertaining to the video coding layer are present in the bitstream. In this case, the bitstream conforms to an HRD whose buffer size and bit rate parameters are given by the maxima specified in Table A -1 for the level specified by level_idc.

Note – when vcl_hrd_parameters_present_flag is equal to 0, the conformance of the VCL bitstream cannot be verified without external provision of all the VCL HRD parameters, including the VCL sequence HRD parameter information and all buffering period and picture timing SEI messages.

If vcl_hrd_parameters_present_flag is equal to 1, then VCL sequence HRD parameters (subclauses E.1.2 and E.2.2) immediately follow the flag. At least one of the VCL HRD coded picture buffers signalled in the sequence HRD parameters must have CPB bitrate and buffer size values that are both less than the maxima specified in Table A -1 for the level specified by level_idc. Some of the HRD coded picture buffers signalled may have values outside the level limits.

Furthermore, if vcl_hrd_parameters_present_flag is equal to 1, then a buffering period SEI message (subclauses D.1.1 and D.2.1) immediately follows each random access point SEI message (subclauses D.1.7 and D.2.7), and a picture timing SEI message (subclauses D.1.1 and D.2.1) precedes each coded picture.

low_delay_hrd_flag: If low_delay_hrd_flag is equal to 0, the HRD operates in delay-tolerant mode. If low_delay_hrd_flag is equal to 1, the HRD operates in low-delay mode. In low-delay mode, only one HRD buffer may be selected and big pictures which violate the HRD removal time rules at the CPB are permitted.

NOTE - It is expected, but not required, that such big pictures occur only occasionally.

bitstream_restriction_flag: A flag that, when 1, signals the presence of bitstream restriction information. If bitstream_restriction_flag is set to 0, then the following default values shall apply: motion_vectors_over_pic_boundaries_flag = 1, max_bytes_per_pic_denom = 4, max_bits_per_mb_denom = 1, log2_max_mv_length_vertical = 16, log2_max_mv_length_horizontal = 16, max_dec_frame_buffering = 15, max_dec_frame_reordering = 15.

motion_vectors_over_pic_boundaries_flag equal to 0 indicates that no motion vector refers to samples outside the picture boundaries of the reference picture. motion_vectors_over_pic_boundaries_flag equal to 1 indicates that motion vectors may refer to samples outside the picture boundaries of a reference picture.

max_bytes_per_pic_denom indicates the maximum number of bytes that represent a picture.

The number of bytes that represent a picture in the NAL unit stream is defined for this purpose as the total number of bytes of NAL unit data (i.e., the total of the NumBytesInNALunit variables for the picture) that contain slices and slice data partitions for the picture. The value of max_bytes_per_pic_denom shall not exceed 16.

If max_bytes_per_pic_denom is equal to 0, no limit is indicated.

If max_bytes_per_pic_denom is not equal to 0, no coded frame shall be represented in the sequence by more than

(PicWidthInMbs*PicHeightInMbs)*(256*ChromaFormatParameter) ÷max_bytes_per_pic_denom

bytes.

If max_bytes_per_pic_denom is not equal to 0, no coded field shall be represented in the sequence by more than

(PicWidthInMbs*PicHeightInMbs)*(128*ChromaFormatParameter) ÷max_bytes_per_pic_denom

bytes.

[Ed. Note (Karsten): This references „ChromaFormatParameter" from table A -2. But there is no transmitted chroma format, so do we have to guess here? No – ChromaFormatParameter is always 4:2:0, as specified in Annex A]

max_bits_per_mb_denom indicates the maximum number of coded bits that represent a macroblock. The value of max_bits_per_mb_denom shall not exceed 16.

Deleted: DRAFT ITU-T Rec. H.264 (2002 E)

If max_bits_per_mb_denom is equal to 0, no limit is indicated. If max_bits_per_mb_denom is not equal to 0, no coded macroblock shall be represented in the bitstream by more than

(2048 * ChromaFormatParameter) ÷ max_bits_per_mb_denom

bits.

[Ed. Note: Insert reference to method of counting bits for a particular MB.]

[Ed. Note (Karsten): This references „ChromaFormatParameter" from table A-2. But there is no transmitted chroma format, so do we have to guess here? No – ChromaFormatParameter is always 4:2:0, as specified in Annex A]

log2_max_mv_length_vertical and **log2_max_mv_length_horizontal** indicate the maximum value of the absolute value of a decoded vertical or horizontal motion vector component, in ¼ luma sample unit s. A value of n asserts that no absolute value of a motion vector component is bigger than 2^n units of ¼ sample displacement. The value of log2_max_mv_length_vertical shall not exceed 16. The value of log2_max_mv_length_horizontal shall not exceed 16.

NOTE - The maximum absolute value of a decoded vertical or horizontal motion vector component is is also constrained by profile and level limits as specified in Annex A.

max_dec_frame_reordering specifies the maximum extent of reordering of frames from decod ing order to output order in the sequence. The sequence shall not require a decoded picture buffer with capacity of more than max_dec_frame_reordering frames to enable the output of decoded pictures in the output order indicated by the picture order count. The value of max_dec_frame_reordering shall not exceed the value of max_dec_frame_buffering.

For example, if max_dec_frame_reordering is equal to 0, then the output order of pictures in the bitstream shall be the same as the decoding order. If max_dec _frame_reordering is equal to 2, then no more than two pictures that follow any picture in decoding order may precede it in output order.

max_dec_frame_buffering specifies the maximum extent of buffering of frames from decoding time to output time in the sequence. The sequence shall not require a decoded picture buffer with capacity of more than max_dec_frame_buffering frames to enable the output of decoded pictures at the output times of the HRD. The value of max_dec_frame_reordering shall not exceed 15.

E.2.2 HRD parameters semantics

If multiple sequence parameter sets pertain to the bitstream, they shall contain consistent HRD information. [Ed. Note: What is the definition of consistent?]

cpb_cnt: This syntax element indicates the number of CPBs in the HRD. The value of cpb_cnt shall not be equal to 0 and shall not exceed 32. [Ed. Note: Should send cpb_cnt_minus1 rather than cpb_cnt.]

bit_rate_scale: Together with bit_rate_value[k], this syntax element specifies the maximum input bit rate of the k -th CPB in an HRD.

cpb_size_scale is used together with cpb_size_value[k] to define the CPB size of the k -th CPB in an HRD.

bit_rate_value[k]: Together with bit_rate_scale, this syntax element specifies the maximum input bit rate of the k -th CPB in an HRD. bit_rate_value[k] shall not exceed 2^{32}-1. The actual bit rate in bits per second is given by:

$$bit\_rate[\,k\,] = bit\_rate\_value[k] * 2^{(6 + bit\_rate\_scale)}. \quad \text{(E-1)}$$

cpb_size_value[k] is used together with cpb_size_scale to define the ma ximum input bit rate of the k-th CPB in an HRD. cpb_size_value[k] shall not exceed 2^{32}-1.

The actual buffer size in bits is given by

$$cpb\_size[k] = cpb\_size\_value[k] * 2^{(4 + cpb\_size\_scale)}. \quad \text{(E-2)}$$

For VCL HRD parameters, there shall be one value of k for which bit_rate[k] is within the maximum video bitrate, and cpb_size[k] is within the maximum CPB size specified in Table A-1. For NAL HRD parameters, there must be one value of k for which bit_rate[k] is within 120% of the maximum video bitrate, and cpb_size[k] is within 120% of the maximum CPB size.

vbr_cbr_flag: If equal to 0, this syntax element indicates that the CPB operates in variable bit rate (VBR) mode. If equal to 1, it indicates constant bit rate (CBR) operation.

Deleted: DRAFT ISO/IEC 14496-10 : 2002 (E)

initial_cpb_removal_delay_length_minus1 : Specifies the length in bits of the initial_cpb_removal_delay syntax element. The length of initial_cpb_removal_delay is initial_cpb_removal_delay_length_minus1+1..

cpb_removal_delay_length_minus1: Specifies the length in bits of the cpb_removal_delay syntax element. The length of cpb_removal_delay is cpb_removal_delay_length_minus1+1.

dpb_output_delay_length_minus1 : Specifies the length in bits of the dpb_output_delay syntax element. The lengt h of dpb_output_delay is dpb_output_delay_length_minus1+1.

time_offset_length: Specifies the length in bits of the time_offset syntax element.

E.2.3 VUI picture parameters semantics

frame_cropping_flag when equal to 1, signals the presence of frame cropping inf ormation. If frame_cropping_flag is set to 0, then the following default values shall apply frame_cropping_rect_left = 0, frame_cropping_rect_right = 0, frame_cropping_rect_top = 0, frame_cropping_rect_bottom = 0.

frame_cropping_rect_left, frame_cropping_ rect_right, frame_cropping_rect_top, frame_cropping_rect_bottom define the area of the luma frame internal array which shall contain the output region of the decoding process. The decoded values of these offsets consist of non -negative integer values, and the output region of the decoding process is specified as the area within the frame rectangle containing luma samples with horizontal coordinates from frame_cropping_rect_left to 16*PicWidthInMbs -(frame_cropping_rect_right + 1) and with vertical coordinates from frame_cropping_rect_top to 16*PicHeightInMbs -(frame_cropping_rect_bottom + 1), inclusive.

The value of frame_cropping_rect_left shall not exceed 16*PicWidthInMbs -(frame_cropping_rect_right – 1).

The value of frame_cropping_rect_top shall not exceed 16*PicHeightInMbs -(frame_cropping_rect_bottom – 1).

TITLE: Draft Text of Recommendation H.263 Version 2 ("H.263+") for Decision

---

(#20 Complete Text with No Change Marks Version)

1. Introduction

Attached is the draft text of Version 2 of Recommendation H.263, which is informally known as "H.263+". It is submitted for decision at the January-February 1998 meeting of Study Group 16, after having reached determination at the March 1997 meeting. It contains a number of optional feature enhancements which are added to the core syntax and semantics of the original Version 1 of H.263 (the current published Version 1 is dated 3/96). In the process of adding these new features, the precise definition and requirements of the original Version 1 syntax and semantics have not been changed — only optional new features have been added. A description of the editorial status of this draft is given in Section 2 of this preamble, and an overview of its new features is provided in Section 3.

2. Draft status relative to the determined output of the Geneva SG16 meeting of 3/97:

This document has undergone review at two interim Experts Group meetings, and has required some technical as well as editorial modifications. Although some technical aspects have needed changes as a result of small errors found during the interim technical review and testing, the overall set of feature enhancements remains the same. No drafted annexes have been added or removed or had a change of title or purpose. One new non-normative Appendix has been added to provide guidance for users of the standard, to encourage the adoption of the various new optional features in a unified and interoperable way across the full spectrum of terminal and network types.

3. Summary of New "H.263+" Extension Features

These revisions add optional features to Recommendation H.263 in order to broaden its range of useful application and to improve its compression performance. The additional optional feature set can be summarized in terms of the new types of pictures it can use, the new coding modes which can be applied to those pictures, and the definition of backward-compatible supplemental enhancement information which can be added into the video bitstream.

3.1. New types of pictures

3.1.1. Scalability pictures

Scalable video coding has potential for improving the delivery of video in error-prone, packet-loss-ridden, and heterogenous networks. It allows the video bitstream to be separated into multiple logical channels, so that some data can be lost or discarded without irreparable harm to the video representation. Three types of scalability pictures were added in this revision, one which provides temporal scalability and two which provide SNR or Spatial scalability:

1. B: A picture having two reference pictures, one of which temporally precedes the B picture and one of which is temporally subsequent to the B picture;
2. EI: A picture having a temporally simultaneous reference picture; and
3. EP: A picture having two reference pictures, one of which temporally precedes the EP picture and one of which is temporally simultaneous.

3.1.2. Improved PB frames

The existing Recommendation H.263 contains a special frame type called a "PB frame", which enables an increase in perceived frame rate with only a moderate increase in bit rate. However, recent investigations have indicated that the PB-frame as it exist is not sufficiently robust for continual use. Encoders wishing to use PB frames are limited in the types of prediction that a PB frame can use, which results in a lack of usefulness for PB frames in some situations. An improved, more robust type of PB frame has been added to enable heavier, higher-performance use of the PB frame design. It is a small modification of the existing PB frames mode.

3.1.3. Custom Source Formats

The existing Recommendation H.263 is very limited in the types of video input to which it can be applied. It allows only five video source formats defining the picture size, picture shape, and picture clock frequency. The new H.263+ feature set allows a wide range of optional custom source formats in order to make the standard apply to a much wider class of video scenes. These modifications help make the standard respond to the new world of resizable computer window-based displays, high refresh-rates, and wide format viewing screens.

3.2. New coding modes

This set of optional extensions of the H.263 video coding syntax also includes nine new coding modes that can be applied to the pictures in the bitstream:

1. Advanced INTRA Coding (AIC): A mode which improves the compression efficiency for INTRA macroblock encoding by using spatial prediction of DCT coefficient values;
2. Deblocking Filter (DF): A mode which reduces the amount of block artifacts in the final image by filtering across block boundaries using an adaptive filter;
3. Slice Structured (SS): A mode which allows a functional grouping of a number of macroblocks in the picture, enabling improved error resilience, improved transport over packet networks, and reduced delay;
4. Reference Picture Selection (RPS): A mode which improves error resilience by allowing a temporally previous reference picture to be selected which is not the most recent encoded picture that can be syntactically referenced;
5. Reference Picture Resampling (RPR): A mode which allows a resampling of a temporally previous reference picture prior to its use as a reference for encoding, enabling global motion compensation, predictive dynamic resolution conversion, predictive picture area alteration and registration, and special-effect warping;
6. Reduced-Resolution Update (RRU): A mode which allows an encoder to maintain a high frame rate during heavy motion by encoding a low-resolution update to a higher-resolution picture while maintaining high resolution in stationary areas;

7. Independent Segment Decoding (ISD): A mode which enhances error resilience by ensuring that corrupted data from some region of the picture cannot cause propagation of error into other regions;
8. Alternative INTER VLC (AIV): A mode which reduces the number of bits needed for encoding predictively-coded blocks when there are many large coefficients the block; and
9. Modified Quantization (MQ): A mode which improves the control of the bit rate by changing the method for controlling the quantizer step size on a macroblock basis, reduces the prevalence of chrominance artifacts by reducing the step size for chrominance quantization, increases the range of representable coefficient values for use with small quantizer step sizes, and increases error detection performance and reduces decoding complexity by prohibiting certain unreasonable coefficient representations.

3.3. Supplemental Enhancement Information

This revision also allows the addition of supplemental enhancement information to the video bitstream. Although this information does not affect the semantics for decoding the bitstream, it can enable enhanced features for systems which understand the optional additional information (while being discarded harmlessly by systems that do not understand it). This allows a variety of picture freeze and release commands, tagging information associated synchronously with the pictures in the bitstream for external use, and video transparency by use of chroma key information.

VIDEO CODING FOR LOW BIT RATE COMMUNICATION

ITU-T Recommendation H.263

(Previously "CCITT Recommendation")

FOREWORD

The ITU-T (Telecommunication Standardization Sector) is a permanent organ of the International Telecommunication Union (ITU). The ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Conference (WTSC), which meets every four years, establishes the topics for study by the ITU-T Study Groups which, in their turn, produce Recommendations on these topics.

The approval of Recommendations by the Members of the ITU-T is covered by the procedure laid down in WTSC Resolution No. 1 (Helsinki, March 1-12, 1993).

ITU-T Recommendation H.263 was prepared by ITU-T Study Group 16 (1997-2000) and was approved under the WTSC Resolution No. 1 procedure on the xx th of xx 1998.

NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

SUMMARY

This Recommendation specifies a coded representation that can be used for compressing the moving picture component of audio-visual services at low bit rates. The basic configuration of the video source coding algorithm is based on Recommendation H.261 and is a hybrid of inter-picture prediction to utilize temporal redundancy and transform coding of the remaining signal to reduce spatial redundancy. The source coder can operate on five standardised video source formats: sub-QCIF, QCIF, CIF, 4CIF and 16CIF, and can also operate using a broad range of custom video formats.

The decoder has motion compensation capability, allowing optional incorporation of this technique in the coder. Half pixel precision is used for the motion compensation, as opposed to Recommendation H.261 where full pixel precision and a loopfilter are used. Variable length coding is used for the symbols to be transmitted.

In addition to the basic video source coding algorithm, sixteen negotiable coding options are included for improved compression performance and the support of additional capabilities. Additional supplemental information may also be included in the bitstream for enhanced display capability and for external usage.

VIDEO CODING FOR LOW BIT RATE COMMUNICATION

(Geneva, 1998)

1 Scope

This Recommendation specifies a coded representation that can be used for compressing the moving picture component of audio-visual services at low bit rates. The basic configuration of the video source coding algorithm is based on Recommendation H.261. Sixteen negotiable coding options are included for improved performance and increased functionality. This Recommendation contains Version 2 of Recommendation H.263, which is fully compatible with the original Recommendation, adding only optional features to the original Version 1 content of the Recommendation.

2 References

The following Recommendations and other references contain provisions which, through reference in this text, constitute provisions of this Recommendation. At the time of publication, the editions indicated were valid. All Recommendations and other references are subject to revision; all users of this Recommendation are therefore encouraged to investigate the possibility of applying the most recent edition of the Recommendations and other references listed below. A list of the currently valid ITU-R Recommendations is regularly published.

[1] ITU-R Recommendation BT.601-4 (199x): *Encoding Parameters of Digital Television for Studios*

Reference [1] is referenced herein to define the (Y, C_B, C_R) color space and its 8-bit integer representation for pictures used by video codecs designed according to this Recommendation. (Reference [1] is not used to define any other aspects of this Recommendation.)

The following additional ITU-T Recommendations are mentioned for illustration purposes in this text, however they do not constitute provisions of this Recommendation. At the time of publication, the editions indicated were valid. All Recommendations and other references are subject to revision; all users of this Recommendation are therefore encouraged to investigate the possibility of applying the most recent edition of the Recommendations and other references listed below. A list of the currently valid ITU-T Recommendations is regularly published.

3 Brief specification

An outline block diagram of the codec is given in Figure 1.

3.1 Video input and output

To permit a single Recommendation to cover use in and between regions using 625- and 525-line television standards, the standardised source formats on which the source coder operates are based on a Common Intermediate Format (CIF). It is also possible using external negotiation (for example Recommendation H.245), to enable the use of a wide range of optional custom source formats. The standards of the input and output television signals, which may, for example, be composite or component, analogue or digital and the methods of performing any necessary conversion to and from the source coding format are not subject to recommendation.

3.2 Digital output and input

The video coder provides a self-contained digital bitstream which may be combined with other multi-facility signals (for example as defined in Recommendation H.223). The video decoder performs the reverse process.

3.3 Sampling frequency

Pictures are sampled at an integer multiple of the video line rate. This sampling clock and the digital network clock are asynchronous.

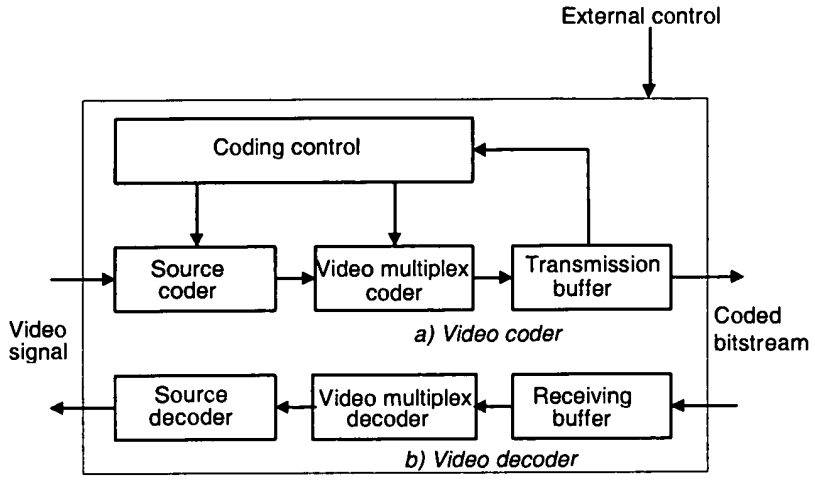

FIGURE 1/H.263

Outline block diagram of the video codec

3.4 Source coding algorithm

A hybrid of inter-picture prediction to utilize temporal redundancy and transform coding of the remaining signal to reduce spatial redundancy is adopted. The decoder has motion compensation capability, allowing optional incorporation of this technique in the coder. Half pixel precision is used for the motion compensation, as opposed to Recommendation H.261 where full pixel precision and a loopfilter are used. Variable length coding is used for the symbols to be transmitted.

In addition to the core H.263 coding algorithm, sixteen negotiable coding options can be used, either together or separately (subject to certain restrictions). Additional supplemental information may also be included in the bitstream for enhanced display capability and for external usage. A forward error correction method for application to the resulting video bitstream is provided for use when necessary. The negotiable coding options, forward error correction, and supplemental information usage are described in the subsequent subsections.

3.4.1 Continuous Presence Multipoint and Video Multiplex mode

In this optional mode up to four separate video "Sub-Bitstreams" can be sent within the same video channel. This feature is designed for use in continuous presence multipoint application or other situations in which separate logical channels are not available but the use of multiple video bitstreams is desired (see also Annex C).

3.4.2 Unrestricted Motion Vector mode

In this optional mode motion vectors are allowed to point outside the picture. The edge pixels are used as prediction for the "non-existing" pixels. With this mode a significant gain is achieved if there is movement across the edges of the picture, especially for the smaller picture formats (see also Annex D). Additionally, this mode includes an extension of the motion vector range so that larger motion vectors can be used. This is especially useful in case of camera movement and large picture formats.

3.4.3 Syntax-based Arithmetic Coding mode

In this optional mode arithmetic coding is used instead of variable length coding. The SNR and reconstructed pictures will be the same, but significantly fewer bits will be produced (see also Annex E).

3.4.4 Advanced Prediction mode

In this optional mode Overlapped Block Motion Compensation (OBMC) is used for the luminance part of P-pictures (see also Annex F). Four 8 × 8 vectors instead of one 16 × 16 vector are used for some of the macroblocks in the picture. The encoder has to decide which type of vectors to use. Four vectors use more bits, but give better prediction. The use of this mode generally gives a considerable improvement. A subjective gain is achieved because OBMC results in less blocking artifacts.

3.4.5 PB-frames mode

A PB-frame consists of two pictures being coded as one unit. The name PB comes from the name of picture types in Recommendation H.262 where there are P-pictures and B-pictures. Thus a PB-frame consists of one P-picture which is predicted from the previous decoded P-picture and one B-picture which is predicted from both the previous decoded P-picture and the P-picture currently being decoded. The name B-picture was chosen because parts of B-pictures may be bidirectionally predicted from the past and future pictures. With this coding option, the picture rate can be increased considerably without substantially increasing the bitrate (see also Annex G). However, an Improved PB frames mode is also provided (see also Annex M). The original PB frames mode is retained herein only for purposes of compatibility with systems made prior to the adoption of the Improved PB frames mode.

3.4.6 Forward Error Correction

A forward error correction method is specified for use when necessary for the protection of the video bitstream for use when appropriate. The method provided for forward error correction is the same BCH code method specified also in ITU-T Recommendation H.261 (see also Annex H).

3.4.7 Advanced INTRA Coding mode

In this optional mode, INTRA blocks are first predicted from neighboring INTRA blocks prior to coding (see also Annex I). Separate variable length code (VLC) tables are defined for the INTRA blocks. The technique is applied to INTRA-macroblocks within INTRA pictures and to INTRA-macroblocks within INTER pictures. This mode significantly improves the compression performance over the INTRA coding of the core H.263 syntax.

3.4.8 Deblocking Filter mode

In this optional mode, a filter is applied across the 8x8 block edge boundaries of decoded I- and P-pictures to reduce blocking artifacts (see also Annex J). The purpose of the filter is to mitigate the occurrence of block edge artifacts in the decoded picture. The filter affects the picture that is used for the prediction of subsequent pictures and thus lies within the motion prediction loop.

3.4.9 Slice Structured mode

In this optional mode, a "slice" layer is substituted for the GOB layer of the bitstream syntax (see also Annex K). The purposes of this mode are to provide enhanced error resilience capability, to make the bitstream more amenable to use with an underlying packet transport delivery, and to minimize video delay. A slice is similar to a GOB, in that it is a layer of the syntax that lies between the picture layer and the macroblock layer. However, the use of a slice layer allows a flexible partitioning of the picture, in contrast with the fixed partitioning and fixed transmission order required by the GOB structure.

3.4.10 Supplemental Enhancement Information

Additional supplemental information may be included in the bitstream to signal enhanced display capability or to provide information for external usage (see also Annex L). This supplemental information can be used to signal a full-picture or partial-picture freeze or freeze-release request with or without resizing, can also be used to tag particular pictures or sequences of pictures within the video stream for external usage, and can be used to convey chroma key information for video compositing. The supplemental information may be present in the bitstream even though the decoder may not be capable of providing the enhanced capability to use it, or even to properly interpret it — simply discarding the supplemental information is allowable by decoders unless a requirement to provide the requested capability has been negotiated by external means.

3.4.11 Improved PB-frames mode

This optional mode represents an improvement compared to the PB-frames mode option (see also annexes G and M). The main difference between the two modes is that in the Improved PB-frames mode, each B-block may be forward predicted using a separate motion vector or backward predicted with a zero vector. This significantly improves coding efficiency in situations in which downscaled P-vectors are not good candidates for B-prediction. The backward prediction is particularly useful when there is a scene cut between the previous P-frame and the BPB-frame.

3.4.12 Reference Picture Selection mode

An optional mode is provided which improves the performance of real-time video communication over error-prone channel by allowing temporal prediction from pictures other than the most recently-sent reference picture (see also Annex N). This mode can be used with back-channel status messages which are sent back to the encoder to inform it about whether its bitstream is being properly received. In error-prone channel environments, this mode allows the encoder to optimize its video encoding for the conditions of the channel.

3.4.13 Temporal, SNR and Spatial Scalability mode

In this optional mode there is support for temporal, SNR, and spatial scalability (see also Annex O). Scalability implies that a bitstream is composed of a base layer and one or more associated enhancement layers. The base layer is a separately decodable bitstream. The enhancement layers can be decoded in conjunction with the base layer to increase perceived quality by either increasing the picture rate, increasing the picture quality, or increasing the picture size. SNR scalability refers to enhancement information to increase the picture quality without increasing picture resolution. Spatial scalability refers to enhancement information to increase the picture quality by increasing picture resolution either horizontally, vertically, or both. There is also support for temporal scalability by the use of B pictures. A B picture is a scalability enhancement containing pictures that can be bi-directionally predicted from two pictures in a reference layer, one temporally previous to the current picture and one temporally subsequent. B pictures allows enhancement layer information to be used to increase perceived quality by increasing the picture rate of the displayed enhanced video sequence. This mode can be useful for heterogenous networks with varying bandwidth capacity and also in conjunction with error correction schemes.

3.4.14 Reference Picture Resampling mode

A syntax is provided for supporting an optional mode for which the reference picture used for video image prediction is processed by a resampling operation prior to its use in forming a predictor for the current input picture (see also Annex P). This allows efficient dynamic selection of an appropriate image resolution for video encoding, and can also support picture warping for use as a global motion compensator or special-effect generator.

3.4.15 Reduced-Resolution Update mode

An optional mode is provided which allows reduced resolution updates to a reference picture having a higher resolution (see also Annex Q). This mode is expected to be used when encoding a highly active scene, and allows an encoder to increase the picture rate at which moving parts of a scene can be represented, while maintaining a higher resolution representation in more static areas of the scene.

3.4.16 Independent Segment Decoding mode

An optional mode is provided which allows a picture to be constructed without any data dependencies which cross GOB or multi-GOB video picture segments or slice boundaries (see also Annex R). This mode provides error robustness by preventing the propagation of erroneous data across the boundaries of the video picture segment areas.

3.4.17 Alternative INTER VLC mode

An optional mode is provided which improves the efficiency of INTER picture coding when significant changes are evident in the picture (see also Annex S). This efficiency improvement is obtained by allowing a VLC code originally designed for INTRA pictures to be used for some INTER picture coefficients as well.

3.4.18 Modified Quantization mode

An optional mode is provided which improves the bit-rate control ability for encoding, reduces chrominance quantization error, expands the range of representable DCT coefficients, and places certain restrictions on coefficient values (see also Annex T). This mode modifies the semantics of the differential quantization step size parameter of the bitstream by broadening the range of step size changes that can be specified. It also reduces the quantization step size used for chrominance data. The range of DCT coefficient levels is broadened to ensure that any possible coefficient value can be encoded to within the accuracy allowed by the step size. Certain restrictions

are also placed on coefficients in this mode to increase error detection performance and minimize decoder complexity.

3.5 Bit rate

The transmission clock is provided externally. The video bit rate may be variable. In this Recommendation no constraints on the video bit rate are given; constraints will be given by the terminal or the network.

3.6 Buffering

The encoder shall control its output bitstream to comply with the requirements of the hypothetical reference decoder defined in Annex B. Video data shall be provided on every valid clock cycle. This can be ensured by MCBPC stuffing (see Tables 7 and 8) or, when forward error correction is used, also by forward error correction stuffing frames (see Annex H).

The number of bits created by coding any single picture shall not exceed a maximum value specified by the parameter BPPmaxKb which is measured in units of 1024 bits. The minimum allowable value of the BPPmaxKb parameter depends on the largest picture size that has been negotiated for use in the bitstream (see Table 1). The picture size is measured as the picture width times height for the luminance (Y) component, measured in pixels. An encoder may use a larger value for BPPmaxKb than as specified in Table 1, provided the larger value is first negotiated by external means, for example Recommendation H.245.

When the Temporal, SNR, and Spatial Scalability mode (Annex O) is employed, the number of bits sent for each picture in each enhancement layer shall not exceed the maximum value specified by BPPmaxKb.

TABLE 1/H.263

Minimum BPPmaxKb for different source picture formats

Y Picture Size in Pixels	Minimum BPPmaxKb
up to 25,344 (or QCIF)	64
25,360 to 101,376 (or CIF)	256
101,392 to 405,504 (or 4CIF)	512
405,520 and above	1024

3.7 Symmetry of transmission

The codec may be used for bidirectional or unidirectional visual communication.

3.8 Error handling

Error handling should be provided by external means (for example Recommendation H.223). If it is not provided by external means (for example in Recommendation H.221) the optional error correction code and framing as described in Annex H can be used.

A decoder can send a command to encode one or more GOBs (or slices if Annex K is employed) of its next picture in INTRA mode with coding parameters such as to avoid buffer overflow. A decoder can also send a command to transmit only non-empty GOB headers if the Slice Structured mode (see Annex K) is not in use. The transmission method for these signals is by external means (for example Recommendation H.245).

3.9 Multipoint operation

Features necessary to support switched multipoint operation are included in Annex C.

4 Source coder

4.1 Source format

The source coder operates on non-interlaced pictures having a source format which is defined in terms of 1) the picture format, as determined by the number of pixels per line, the number of lines per picture, and the pixel aspect ratio, and 2) the timing between pictures, as determined by the picture clock frequency (PCF). For example, the common intermediate format (CIF) has 352 pixels per line, 288 lines, a pixel aspect ratio of 12:11, and a picture clock frequency of 30 000/1001 pictures per second.

The source coder operates on non-interlaced pictures occurring at a picture clock frequency (PCF) of 30 000/1001 (approximately 29.97) times per second, termed the CIF PCF. It is also possible to negotiate the use of an optional custom PCF by external means. A custom PCF is given by 1 800 000 / (clock divisor * clock conversion factor) where clock divisor can have values of 1 through 127 and clock conversion factor can either be 1000 or 1001.□The tolerance on the picture clock frequency is ± 50 ppm.

Pictures are coded as luminance and two colour difference components (Y, C_B and C_R). These components and the codes representing their sampled values are as defined in ITU-R Recommendation BT.601-4.

- Black = 16;
- White = 235;
- Zero colour difference = 128;
- Peak colour difference = 16 and 240.

These values are nominal ones and the coding algorithm functions with input values of 1 through to 254.

There are five standardised picture formats: sub-QCIF, QCIF, CIF, 4CIF and 16CIF. It is also possible to negotiate a custom picture format. For all of these picture formats, the luminance sampling structure is dx pixels per line, dy lines per picture in an orthogonal arrangement. Sampling of each of the two colour difference components is at dx/2 pixels per line, dy/2 lines per picture, orthogonal. The values of dx, dy, dx/2 and dy/2 are given in Table 2 for each of the standardised picture formats.

TABLE 2/H.263

Number of pixels per line and number of lines for each of the standardised H.263 picture formats

Picture Format	number of pixels for luminance (dx)	number of lines for luminance (dy)	number of pixels for chrominance (dx/2)	number of lines for chrominance (dy/2)
sub-QCIF	128	96	64	48
QCIF	176	144	88	72
CIF	352	288	176	144
4CIF	704	576	352	288
16CIF	1408	1152	704	576

For all picture formats, colour difference samples are sited such that their block boundaries coincide with luminance block boundaries as shown in Figure 2. The pixel aspect ratio is the same for each of the standardised picture formats and is the same as defined for QCIF and CIF in Recommendation H.261: (288/3):(352/4), which simplifies to 12:11 in relatively prime numbers. The picture area covered by all of the standardised picture formats except the sub-QCIF picture format has an aspect ratio of 4:3.

Custom picture formats can have a custom pixel aspect ratio as described in Table 3, if the custom pixel aspect ratio use is first negotiated by external means. Custom picture formats can have any number of lines and any number of pixels per line, provided that the number of lines is divisible by four and is in the range [4,...,1152], and provided that the number of pixels per line is also divisible by four and is in the range [4,...2048]. For picture formats having a width or height that is not divisible by 16, the picture is decoded in the same manner as if the width or height had the next larger size that would be divisible by 16 and then the picture is cropped at the right and the bottom to the proper width and height for display purposes only.

TABLE 3/H.263

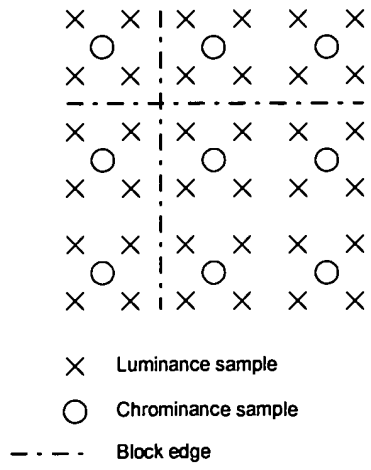
Custom Pixel Aspect Ratios

Pixel Aspect Ratio	Pixel Width : Pixel Height
Square	1:1
CIF	12:11
525-type for 4:3 picture	10:11
CIF for 16:9 picture	16:11
525-type for 16:9 picture	40:33
Extended PAR	m:n, m and n are relatively prime

All decoders and encoders shall be able to operate using the CIF picture clock frequency. Some decoders and encoders may also support custom picture clock frequencies. All decoders shall be able to operate using the sub-QCIF picture format. All decoders shall also be able to operate using the QCIF picture format. Some decoders may also operate with CIF, 4CIF or 16CIF, or custom picture formats. Encoders shall be able to operate with one of the picture formats sub-QCIF and QCIF. The encoders determine which of these two formats are used, and are not obliged to be able to operate with both. Some encoders can also operate with CIF, 4CIF, 16CIF, or custom picture formats. Which optional formats and which picture clock frequencies can be handled by the decoder is signalled by external means, for example Recommendation H.245. For a complete overview of possible picture formats and video coding algorithms, refer to the terminal description, for example Recommendation H.324.

NOTE – For CIF, the number of pixels per line is compatible for practical purposes with sampling the active portions of the luminance and colour difference signals from 525- or 625-line sources at 6.75 and 3.375 MHz respectively. These frequencies have a simple relationship to those in ITU-R Recommendation BT.601-4.

Means shall be provided to restrict the maximum picture rate of encoders by having a minimum number of non-transmitted pictures between transmitted ones. Selection of this minimum number shall be by external means (for example, Recommendation H.245). For the calculation of the minimum number of non-transmitted pictures in PB-frames mode, the P-picture and the B-picture of a PB-frames unit are taken as two separate pictures.



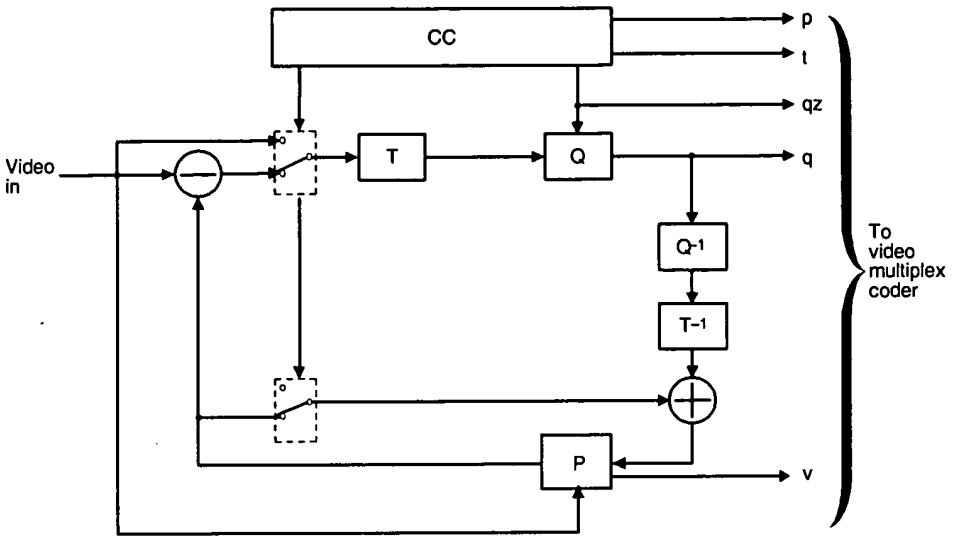


FIGURE 2/H.263

Positioning of luminance and chrominance samples

4.2 Video source coding algorithm

The source coder is shown in generalized form in Figure 3. The main elements are prediction, block transformation and quantization.

T Transform
Q Quantizer
P Picture Memory with motion compensated variable delay

CC Coding control
p Flag for INTRA/INTER
t Flag for transmitted or not
qz Quantizer indication
q Quantizing index for transform coefficients
v Motion vector

FIGURE 3/H.263

Source coder

4.2.1 GOBs, slices, macroblocks and blocks

Each picture is divided either into groups of blocks (GOBs) or into slices.

A group of blocks (GOB) comprises of up to k*16 lines, where k depends on the number of lines in the picture format and depends on whether the optional Reduced-Resolution Update mode is in use (see Annex Q). The dependencies are shown in Table 4. If the number of lines is less than or equal to 400 and the optional Reduced-Resolution Update mode is not in use, then k = 1. If the number of lines is less than or equal to 800 and the optional Reduced-Resolution Update mode is in use or the number of lines is more than 400, then k=2. If the number of lines is more than 800, then k=4. When using custom picture sizes, the number of lines in the last (bottom-most) GOB may be less than k*16 if the number of lines in the picture is not divisible by k*16. However, every GOB in each of the standardized picture formats has k*16 lines, as the number of lines in each standardized picture format is an integer multiple of k*16. Thus, for example, if the optional Reduced-Resolution mode is not in use, the number of GOBs per picture is 6 for sub-QCIF, 9 for QCIF, and 18 for CIF, 4CIF and 16CIF. The GOB numbering is done by use of vertical scan of the GOBs, starting with the upper GOB (number 0) and ending with the bottom-most GOB. An example of the arrangement of GOBs in a picture is given for the CIF picture format in Figure 4. Data for each GOB consists of a GOB header (may be empty) followed by data for macroblocks. Data for GOBs is transmitted per GOB in increasing GOB number.

TABLE 4/H.263

Parameter k for GOB size definition

Number of Lines dy	Value of k when not in RRU mode	Value of k when in RRU mode
4,...,400	1	2
404,...,800	2	2
804,...,1152	4	4

The Slice Structured mode is described in Annex K. Slices are similar to GOBs in that they are a multi-macroblock layer of the syntax, but slices have a more flexible shape and usage than GOBs, and slices may appear in the bitstream in any order, under certain conditions.

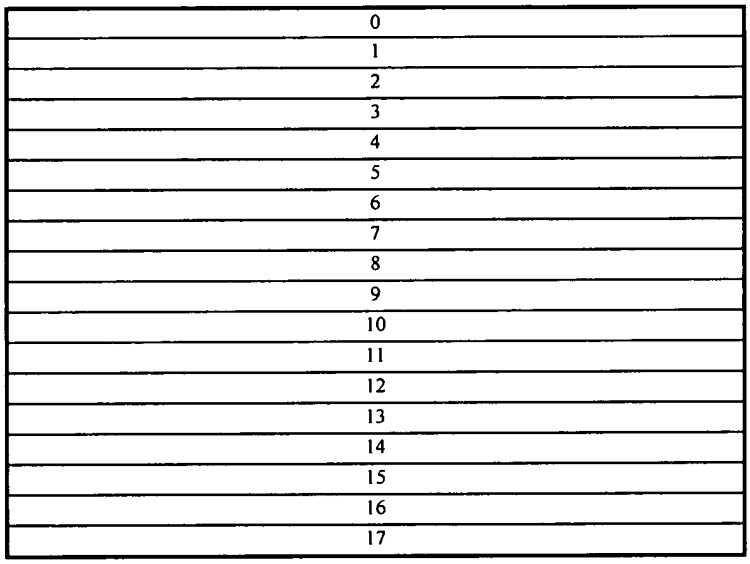

FIGURE 4/H.263

Arrangement of Groups of Blocks in a CIF picture

Each GOB is divided into macroblocks. The macroblock structure depends on whether the optional Reduced-Resolution Update (RRU) mode is in use (see Annex Q). Unless in RRU mode, each macroblock relates to 16 pixels by 16 lines of Y and the spatially corresponding 8 pixels by 8 lines of C_B and C_R. Further, a macroblock consists of four luminance blocks and the two spatially corresponding colour difference blocks as shown in Figure 5. Each luminance or chrominance block thus relates to 8 pixels by 8 lines of Y, C_B or C_R. Unless in RRU mode, a GOB comprises one macroblock row for sub-QCIF, QCIF and CIF, two macroblock rows for 4CIF and four macroblock rows for 16CIF.

When in RRU mode, a macroblock relates to 32 pixels by 32 lines of Y and the spatially corresponding 16 pixels by 16 lines of C_B and C_R, and each luminance or chrominance block relates to 16 pixels by 16 lines of Y, C_B or C_R. Furthermore, a GOB comprises one macroblock row for CIF and 4CIF, and two macroblock rows for 16CIF.

The macroblock numbering is done by use of horizontal scan of the macroblock rows from left to right, starting with the upper macroblock row and ending with the lower macroblock row. Data for the macroblocks is transmitted per macroblock in increasing macroblock number. Data for the blocks is transmitted per block in increasing block number (see Figure 5).

The criteria for choice of mode and transmitting a block are not subject to recommendation and may be varied dynamically as part of the coding control strategy. Transmitted blocks are transformed and resulting coefficients are quantized and entropy coded.

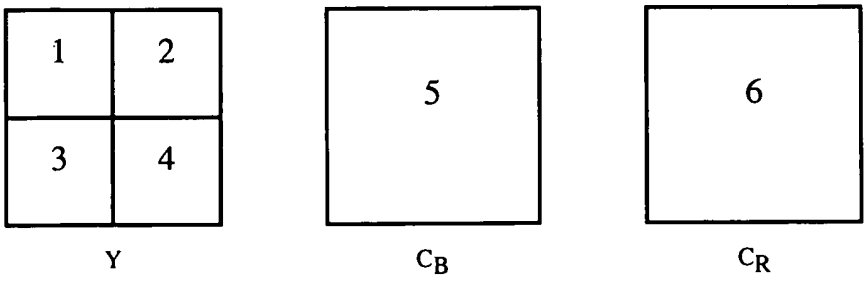

FIGURE 5/H.263

Arrangement of blocks in a macroblock

4.2.2 Prediction

The primary form of prediction is inter-picture and may be augmented by motion compensation (see 4.2.3). The coding mode in which temporal prediction is applied is called INTER; the coding mode is called INTRA if no temporal prediction is applied. The INTRA coding mode can be signalled at the picture level (INTRA for I-pictures or INTER for P-pictures) or at the macroblock level in P-pictures. In the optional PB-frames mode, B-pictures are always coded in INTER mode. The B-pictures are partly predicted bidirectionally (refer to Annex G).

In total, H.263 has seven basic picture types (of which only the first two are mandatory) which are defined primarily in terms of their prediction structure:

1. INTRA: A picture having no reference picture(s) for prediction (also called an I picture);
2. INTER: A picture using a temporally-previous reference picture (also called a P picture);
3. PB: A frame representing two pictures and having a temporally-previous reference picture (see Annex G);
4. Improved PB: A frame functionally similar but normally better than a PB frame (see Annex M);
5. B: A picture having two reference pictures, one of which temporally precedes the B picture and one of which temporally succeeds the B picture and has the same picture size (see Annex O);
6. EI: A picture having a temporally simultaneous reference picture which has either the same or a smaller picture size (see Annex O); and
7. EP: A picture having two reference pictures, one of which temporally precedes the EP picture and one of which is temporally simultaneous and has either the same or a smaller picture size (see Annex O).

As used herein, a "reference" or "anchor" picture is a picture that contains data which can be used by reference as a basis for the decoding of another picture. This use by reference is also known as "prediction", although it sometimes may actually indicate use in a reverse-temporal direction.

4.2.3 Motion compensation

The decoder will accept one vector per macroblock or, if the Advanced Prediction mode or the Deblocking Filter mode is used, one or four vectors per macroblock (see Annexes F and J). If the PB-frames mode is used, one additional delta vector can be transmitted per macroblock for adaptation of the motion vectors for prediction of the B-macroblock. Similarly, an Improved PB-frame macroblock (see Annex M) can include an additional forward motion vector. B-picture macroblocks (see Annex O) can be transmitted together with a forward and a backward motion vector, and EP-pictures can be transmitted with a forward motion vector.

Both horizontal and vertical components of the motion vectors have integer or half integer values. In the default prediction mode, these values are restricted to the range [–16, 15.5] (this is also valid for the forward and backward motion vector components for B-pictures).

In the Unrestricted Motion Vector mode however, the maximum range for vector components is increased. If PLUSPTYPE is absent, the range is [–31.5, 31.5], with the restriction that only values that are within a range of [–16, 15.5] around the predictor for each motion vector component can be reached if the predictor is in the range [–15.5, 16]. If PLUSPTYPE is absent and the predictor is outside [–15.5, 16], all values within the range [–31.5, 31.5] with the same sign as the predictor plus the zero value can be reached. If PLUSPTYPE is present, the motion vector values are less restricted (see also Annex D).

In the Reduced-Resolution Update mode, the motion vector range is enlarged to approximately double size, and each vector component is restricted to have only a half-integer or zero value. Therefore the range of each motion vector component is [-31.5, 30.5] in the default Reduced-Resolution Update mode (see Annex Q) and a larger range if the Unrestricted Motion Vector mode is also used (see also Annex D).

A positive value of the horizontal or vertical component of the motion vector signifies that the prediction is formed from pixels in the referenced picture which are spatially to the right or below the pixels being predicted.

Motion vectors are restricted such that all pixels referenced by them are within the coded picture area, except when the Unrestricted Motion Vector mode, the Advanced Prediction mode, the Advanced Prediction mode, or the Deblocking Filter mode is used (see Annexes D, F, and J), or in B and EP pictures of the Temporal, SNR, and Spatial Scalability mode (see Annex O).

4.2.4 Quantization

Unless the optional Advanced INTRA Coding mode or Modified Quantization mode is in use, the number of quantizers is 1 for the first coefficient of INTRA blocks and 31 for all other coefficients. Within a macroblock the same quantizer is used for all coefficients except the first one of INTRA blocks. The decision levels are not defined. The first coefficient of INTRA blocks is nominally the transform dc value uniformly quantized with a step size of 8. Each of the other 31 quantizers use equally spaced reconstruction levels with a central dead-zone around zero and with a step size of an even value in the range 2 to 62. For the exact formulas, refer to 6.2. For quantization using the Advanced INTRA Coding mode, refer to Annex I. For quantization using the Modified Quantization mode, refer to Annex T.

NOTE – For the smaller quantization step sizes, the full dynamic range of the transform coefficients cannot be represented unless the optional Modified Quantization mode is in use.

4.3 Coding control

Several parameters may be varied to control the rate of generation of coded video data. These include processing prior to the source coder, the quantizer, block significance criterion and temporal subsampling. The proportions of such measures in the overall control strategy are not subject to recommendation.

When invoked, temporal subsampling is performed by discarding complete pictures.

A decoder can signal its preference for a certain tradeoff between spatial and temporal resolution of the video signal. The encoder shall signal its default tradeoff at the beginning of the call and shall indicate whether it is capable of responding to decoder requests to change this tradeoff. The transmission method for these signals is by external means (for example, Recommendation H.245).

4.4 Forced updating

This function is achieved by forcing the use of the INTRA mode of the coding algorithm. The update pattern is not defined. To control the accumulation of inverse transform mismatch error, each macroblock shall be coded in INTRA mode at least once every 132 times when coefficients are transmitted for this macroblock in P-pictures. A similar requirement applies when using optional EP pictures (see Annex O), for which each macroblock shall be coded in an INTRA or upward mode at least once every 132 times when coefficients are transmitted for the macroblock.

4.5 Byte alignment of start codes

Byte alignment of start codes is achieved by inserting a stuffing codeword consisting of less than 8 zero-bits before the start code such that the first bit of the start code is the first (most significant) bit of a byte. A start code is therefore byte aligned if the position of its most significant bit is a multiple of 8-bits from the first bit in the H.263 bitstream. All picture, slice, and EOSBS start codes shall be byte aligned, and GOB and EOS start codes may be byte aligned.

NOTES

1 The number of bits spent for a certain picture is variable but always a multiple of 8 bits.

2 H.324 requires H.263 encoders to align picture start codes with the start of logical information units passed to the Adaptation Layer (AL_SDU's).

5 Syntax and semantics

The video syntax is arranged in a hierarchical structure with four primary layers. From top to bottom the layers are:

- Picture;
- Group of Blocks, or slice, or video picture segment;
- Macroblock;
- Block.

The syntax diagram is shown in Figure 6. A guide for interpretation of the diagram consists of the following:

1. Arrow paths show the possible flows of syntax elements. Any syntax element which has zero length is considered absent for arrow path diagramming purposes (thus, for example, there is an arrow path bypassing PSTUF despite the mandatory nature the PSTUF field since the length of the PSTUF field may be zero).
2. Abbreviations and semantics for each syntax element are as defined in later clauses.
3. The set of syntax elements and arrow paths shown using thick solid lines denotes the syntax flow of the "baseline" mode of operation, without the use of any optional enhancements. (This syntax was also present in the Version 1 of this Recommendation, and remains unchanged in any way.)
4. The set of syntax elements and arrow paths shown using thick dotted lines denotes the additional elements in the syntax flow of the optional enhancements which have been present in both Version 1 and Version 2 of this Recommendation. (This syntax remains unchanged in any way.)
5. The set of syntax elements and arrow paths shown using thin solid lines denotes the additional new elements in the syntax flow of the optional enhancements which are specific to the additional optional features added in Version 2. (This syntax was not present in Version 1.)
6. Syntax element fields shown with square-edged boundaries indicate fixed-length fields, and those with rounded boundaries indicate variable-length fields. One syntax element (DQUANT) is shown with both types of boundaries, because can have either a variable or fixed length.
7. A fixed-length field is defined to be a field for which the length of the field is not dependent on the data in the content of the field itself. The length of this field is either always the same, or is determined by the prior data in the syntax flow.
8. The term "layer" is used to refer to any part of the syntax which can be understood and diagrammed as a distinct entity.

Unless specified otherwise, the most significant bit is transmitted first. This is bit 1 and is the left most bit in the code tables in this Recommendation. Unless specified otherwise, all unused or spare bits are set to "1". Spare bits shall not be used until their functions are specified by the ITU.

5.1 Picture layer

Data for each picture consists of a picture header followed by data for Group of Blocks or for slices, eventually followed by an optional end-of-sequence code and stuffing bits. The structure is shown in Figure 7 for pictures that do not include the optional PLUSPTYPE data field. PSBI is only present if indicated by CPM. TR_B and DBQUANT are only present if PTYPE indicates use of the 'PB-frame' mode (unless the PLUSPTYPE field is present and the use of DBQUANT is indicated therein).

The optional PLUSPTYPE data field is present when so indicated in bits 6-8 of PTYPE. When present, an additional set of data is included in the bitstream, which immediately follows PTYPE and precedes PQUANT. In addition, the CPM and PSBI fields are moved forward in the picture header when PLUSPTYPE is present, so that they appear immediately after PLUSPTYPE rather than being located after PQUANT. The format for the additional data following PLUSPTYPE is shown in Figure 8. All fields in this additional picture header data after PLUSPTYPE are optional, depending on whether their presence is indicated in PLUSPTYPE. When the Slice Structured mode (see Annex K) is in use, slices are substituted for GOBs in the location shown in Figure 7.

Combinations of PSUPP and PEI may not be present, and may be repeated when present. EOS and EOSBS+ESBI may not be present, while ESTUF may be present only if EOS or EOSBS is present. EOS shall not be repeated unless at least one picture start code appears between each pair of EOS codes. Picture headers for dropped pictures are not transmitted.

FIGURE 7/H.263

Structure of picture layer
(without optional PLUSPTYPE-related fields)

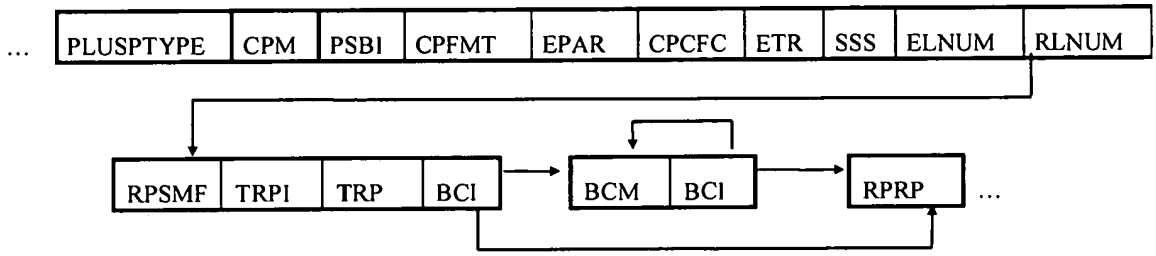

FIGURE 8/H.263

Structure of optional PLUSPTYPE-related fields
(located immediately after PTYPE when present)

5.1.1 Picture Start Code (PSC) (22 bits)

PSC is a word of 22 bits. Its value is 0000 0000 0000 0000 1 00000. All picture start codes shall be byte aligned. This shall be achieved by inserting PSTUF bits as necessary before the start code such that the first bit of the start code is the first (most significant) bit of a byte.

5.1.2 Temporal Reference (TR) (8 bits)

The value of TR is formed by incrementing its value in the temporally-previous reference picture header by one plus the number of skipped or non-reference pictures at the picture clock frequency since the previously transmitted one. The interpretation of TR depends on the active picture clock frequency. Under the standard CIF picture clock frequency, TR is a 8-bit number which can have 256 possible values. The arithmetic is performed with only the eight LSBs. If a custom picture clock frequency is signalled in use, Extended TR in section 5.1.8 and TR form a 10-bit number where TR stores the eight least significant bits (LSBs) and ETR stores the 2 most significant bits (MSBs). The arithmetic in this case is performed with the ten LSBs. In the optional PB-frames or Improved PB-frames mode, TR only addresses P-pictures; for the temporal reference for the B-picture part of PB or Improved PB frames refer to section 5.1.22.

5.1.3 Type Information (PTYPE) (Variable Length)

Information about the complete picture:

- Bit 1: Always "1", in order to avoid start code emulation.
- Bit 2: Always "0", for distinction with Recommendation H.261.
- Bit 3: Split screen indicator, "0" off, "1" on.
- Bit 4: Document camera indicator, "0" off, "1" on.
- Bit 5: Full Picture Freeze Release, "0" off, "1" on.

– Bits 6-8: Source Format, "000" forbidden, "001" sub-QCIF, "010" QCIF, "011" CIF, "100" 4CIF, "101" 16CIF, "110" reserved, "111" extended PTYPE,

If bits 6-8 are not equal to "111", which indicates an extended PTYPE (PLUSPTYPE) the following five bits are also present in PTYPE:

– Bit 9: Picture Coding Type, "0" INTRA (I-picture), "1" INTER (P-picture),

– Bit 10: Optional Unrestricted Motion Vector mode (see Annex D), "0" off, "1" on.

– Bit 11: Optional Syntax-based Arithmetic Coding mode (see Annex E), "0" off, "1" on.

– Bit 12: Optional Advanced Prediction mode (see Annex F), "0" off, "1" on.

– Bit 13: Optional PB-frames mode (see Annex G), "0" normal I- or P-picture, "1" PB-frame.

Split screen indicator is a signal that indicates that the upper and lower half of the decoded picture could be displayed side by side. This bit has no direct effect on the encoding or decoding of the picture.

Full Picture Freeze Release is a signal from an encoder which responds to a request for packet retransmission (if not acknowledged) or fast update request (see also Annex C) or picture freeze request (see also Annex L) and allows a decoder to exit from its freeze picture mode and display the decoded picture in the normal manner.

If bits 6-8 indicate a different source format than in the previous picture header, the current picture shall be an I-picture, unless an extended PTYPE is indicated in bits 6-8 and the capability to use the optional Reference Picture Resampling mode (see Annex P) has been negotiated externally (for example Recommendation H.245).

Bits 10-13 refer to optional modes that are only used after negotiation between encoder and decoder (see also the Annexes D, E, F and G, respectively). If bit 9 is set to "0", bit 13 shall be set to "0" as well.

Bits 6-8 shall not have a value of '111' which indicates the presence of an extended PTYPE (PLUSPTYPE) unless the capability has been negotiated externally (for example Recommendation H.245) to allow the use of a custom source format or one or more of the other optional modes available only by the use of an extended PTYPE (see Annexes I through K and M through T). Whenever bit 6-8 do not have a value of '111', all of the additional modes available only by the use of an extended PTYPE shall be considered to have been set to an "off" state and shall be inferred to remain "off" unless explicitly switched on later in the bitstream.

5.1.4 Plus PTYPE (PLUSPTYPE) (Variable Length)

A codeword of 12 or 30 bits which is present only if the presence of extended PTYPE is indicated in bits 6-8 of PTYPE.

PLUSPTYPE is comprised of up to three subfields, UFEP, OPPTYPE, and MPPTYPE. OPPTYPE is present only if UFEP has a particular value.

5.1.4.1 Update Full Extended PTYPE (UFEP) (3 bits)

A fixed length codeword of 3 bits which is present only if "extended PTYPE" is indicated in PTYPE bits 6-8. When set to "000", it indicates that only those extended PTYPE fields which need to be signaled in every picture header (MPPTYPE) are included in the current picture header. When set to "001", indicates that all extended PTYPE fields are included in the current picture header. If the picture type is INTRA or EI, this field shall be set to "001".

In addition, if PLUSPTYPE is present in each of a continuing sequence of pictures, this field shall be set to "001" at least as often as specified by a five second or five picture timeout period, whichever allows a larger interval of time. More specifically, the timeout period requires UFEP="001" to appear in the PLUSPTYPE field (if PLUSPTYPE is present in every intervening picture) of the first picture header with temporal reference indicating a time interval greater than or equal to five seconds since the last occurrence of UFEP="001", or of the fifth picture after the last occurrence of UFEP="001" (whichever requirement allows a longer period of time as measured by temporal reference).

Encoders should set UFEP to "001" more often in error-prone environments. Values of UFEP other than '000' and '001' are reserved.

5.1.4.2 The optional part of PLUSPTYPE (OPPTYPE) (18 bits)

If UFEP is "001", then the following bits are present in PLUSPTYPE:

Bit 1-3 Source Format, "000" reserved, "001" sub-QCIF, "010" QCIF, "011" CIF, "100" 4CIF, "101" 16CIF, "110" custom source format, "111" reserved,

Bit 4 Optional Custom PCF, "0" CIF PCF, "1" custom PCF.,

Bit 5 Optional Unrestricted Motion Vector (UMV) mode (see Annex D), "0" off, "1" on,

Bit 6 Optional Syntax-based Arithmetic Coding (SAC) mode (see Annex E), "0" off, "1" on,

Bit 7 Optional Advanced Prediction (AP) mode (see Annex F), "0" off, "1" on,

Bit 8 Optional Advanced INTRA Coding (AIC) mode (see Annex I), "0" off, "1" on,

Bit 9 Optional Deblocking Filter (DF) mode (see Annex J), "0" off, "1" on,

Bit 10 Optional Slice Structured (SS) mode (see Annex K), "0" off, "1" on,

Bit 11 Optional Reference Picture Selection (RPS) mode (see Annex N), "0" off, "1" on,

Bit 12 Optional Independent Segment Decoding (ISD) mode (see Annex R),"0" off, "1" on,

Bit 13 Optional Alternative INTER VLC (AIV) mode (see Annex S), "0" off, "1" on,

Bit 14 Optional Modified Quantization (MQ) mode (see Annex T), "0" off, "1" on,

Bit 15 Equal to "1" to prevent start code emulation,

Bit 16 Reserved, shall be equal to "0",

Bit 17 Reserved, shall be equal to "0".

Bit 18 Reserved, shall be equal to "0".

5.1.4.3. The mandatory part of PLUSPTYPE when PLUSPTYPE present (MPPTYPE) (9 bits)

Regardless of the value of UFEP, the following 9 bits are also present in PLUSPTYPE:

Bit 1-3 Picture Type Code:
"000" I-picture (INTRA),
"001" P-picture (INTER),
"010" Improved PB frame (see Annex M),
"011" B-picture (see Annex O),
"100" EI-picture (see Annex O),
"101" EP-picture (see Annex O),
"110" reserved,
"111" reserved

Bit 4 Optional Reference Picture Resampling (RPR) mode (see Annex P), "0" off, "1" on,

Bit 5 Optional Reduced-Resolution Update (RRU) mode (see Annex Q), "0" off, "1" on,

Bit 6 Rounding Type (RTYPE) (see section 6.1.2),

Bit 7 Reserved, shall be equal to "0",

Bit 8 Reserved, shall be equal to "0",

Bit 9 Equal to "1" to prevent start code emulation.

The encoder should control the rounding type so that P pictures, Improved PB frames, and EP pictures have different values for Bit 6 (Rounding Type for P-Pictures) from their reference pictures for motion compensation. Bit 6 can have an arbitrary value if the reference picture is an I or an EI picture. Bit 6 can be set to "1" only when Bits 1-3 indicate a P Picture, Improved PB frame, or EP Picture. For other types of pictures, this bit shall always be set to "0".

5.1.4.4 The semantics of PLUSPTYPE

The mandatory part of PLUSPTYPE consists of features which are likely to be changed on a picture-by-picture basis. Primarily, these are the bits that indicate the picture type among I, P, Improved PB, B, EI, and EP. (Note that the PB-frames mode of Annex G cannot be used with PLUSPTYPE present—the Improved PB frames mode of Annex M should be used instead.) However, they also include indications for the use of the RPR and RRU modes, as these may change from picture to picture as well.

Features that are likely to remain in use rather than being changed from one picture to another (except in obvious ways as discussed in section 5.4.4.5), have been placed in the optional part of PLUSPTYPE. When UFEP is 000,

the missing mode information is inferred from the type of picture and from the mode information sent in a previous PLUSPTYPE with UFEP equal to 001.

If PLUSPTYPE is present but UFEP is 000, then

1. For a P picture or Improved PB frame (see Annex M), the pixel aspect ratio, picture width, and picture height are unchanged from those of the reference picture.

2. For a temporal-scalability B picture (see Annex O) in an enhancement layer, the reference layer number (RLNUM) is the same as the enhancement layer number (ELNUM) if the last picture sent in the enhancement layer was an EI or EP picture. If the last picture sent in the enhancement layer was a B picture, the reference layer number is the same as the reference layer number of the last B picture. The pixel aspect ratio, picture width and picture height are unchanged from those of the temporally subsequent reference layer picture.

   Note that if temporally surrounding EI or EP pictures exist in the same enhancement layer as the B picture, RLNUM (explicit or implied) shall always be equal to ELNUM. Note also that the pixel aspect ratio, picture width and picture height of a B picture (explicit or implied) shall always be equal to those of its temporally subsequent reference layer picture.

3. For a SNR/Spatial scalability EP picture (see Annex O), the pixel aspect ratio, picture width and picture height are unchanged from those of the temporally previous reference picture in the same enhancement layer.

5.1.4.5 Mode restrictions for certain picture types and mode inference rules

Certain modes do not apply to certain types of pictures. Particularly, these restrictions apply:

1. The following modes do not apply within I (INTRA) pictures: Unrestricted Motion Vector (see Annex D), Advanced Prediction (see Annex F), Alternative INTER VLC (see Annex S), Reference Picture Resampling (see Annex P), and Reduced Resolution Update (see Annex Q).

2. The following modes do not apply within B pictures (see Annex O): Syntax-based Arithmetic Coding (see Annex E), Deblocking Filter (see Annex J), and Advanced Prediction (see Annex F).

3. The following modes do not apply within EI pictures (see Annex O): Unrestricted Motion Vector (see Annex D), Syntax-based Arithmetic Coding (see Annex E), Advanced Prediction (see Annex F), Reference Picture Resampling (see Annex P), Reduced Resolution Update (see Annex Q), and Alternative INTER VLC (see Annex S).

4. The following modes do not apply within EP pictures (see Annex O): Syntax-based Arithmetic Coding (see Annex E) and Advanced Prediction (see Annex F).

One or more of the modes listed in the above four-item list may have a mode flag having a value "1" in the optional part of PLUSPTYPE within a picture of a type that is prohibited for that mode (types I, B, EI, or EP). This condition is allowed and shall be interpreted subject to the mode inference rules which follow in the next paragraph.

Mode states are subject to the following mode inference rules:

1. Once a mode flag has been set to "1" in the optional part of PLUSPTYPE, the current picture and each subsequent picture in the bitstream shall be assigned a state of "on" for that mode.

2. An inferred state of "off" shall be assigned to any mode which does not apply within a picture having the current picture type code. However, each subsequent picture in the bitstream shall have an inferred state of "on" for that mode (unless this too results in an obvious conflict—which shall be resolved in the same way). In the case of layered scalable bitstreams (see Annex O), the mode state shall be inferred only from within the same layer of the bitstream.

3. The inference of state shall continue until another picture containing the optional part of PLUSPTYPE is sent or until a picture which does not contain PLUSPTYPE at all is sent, whichever comes first. If a new picture containing the optional part of PLUSPTYPE is sent, the state sent in the new message shall override the old state. If a picture is sent which does not contain PLUSPTYPE (a picture in which bit 6-8 of PTYPE is not '111'), a state of "off" shall be assigned to all modes not explicitly set to "on" in the PTYPE field, and all modes shall continue to have an inferred state of "off" until a new picture containing the optional part of PLUSPTYPE is sent.

4. Two modes do not require mode state inference, since the mode flags for these modes appear in the mandatory part of PLUSPTYPE. These are the Reference Picture Resampling mode (Annex P) and the Reduced Resolution Update mode (Annex Q). The mode flag for either these modes shall not be set unless the current picture allows the use of the mode. For example, the Reduced Resolution Update mode bit shall not be set in an INTRA picture.

5.1.4.6 Mode interaction restrictions

Certain modes cannot be used in combination with certain other modes.

1. The Syntax-based Arithmetic Coding mode (see Annex E) shall not be used with the Alternative INTER VLC mode (see Annex S) or the Modified Quantization mode (see Annex T).
2. If PLUSPTYPE is present, the Unrestricted Motion Vector mode (see Annex D) shall not be used with the Syntax-based Arithmetic Coding mode (see Annex E).
3. The Independent Segment Decoding mode (see Annex R) shall not be used with the Reference Picture Resampling mode (see Annex P).
4. The Independent Segment Decoding mode (see Annex R) shall not be used with the Slice Structured mode without the simultaneous use of the Rectangular Slice submode of the Slice Structured mode (see Annex K).

5.1.4.7 The picture header location of CPM (1 bit) and PSBI (2 bits)

The location of the CPM and PSBI fields in the picture header depends on whether or not PLUSPTYPE is present (see sections 5.1.20 and 5.1.21). If PLUSPTYPE is present, then CPM follows immediately after PLUSPTYPE in the picture header. If PLUSPTYPE is not present, then CPM follows immediately after PQUANT in the picture header. PSBI always follows immediately after CPM (if CPM="1").

5.1.5 Custom Picture Format (CPFMT) (23 bits)

A fixed length codeword of 23 bits that is present only if the use of a custom picture format is signaled in PLUSPTYPE and UFEP is '001'. When present, CPFMT consists of:

Bit 1-4 Pixel Aspect Ratio Code: A 4-bit index to the PAR value in Table 5. For extended PAR, the exact pixel aspect ratio shall be specified in EPAR (section 5.1.6).,

Bit 5-13 Picture Width Indication: Range [0,...,511]; Number of pixels per line = (PWI+1)*4,

Bit 14 Equal to "1" to prevent start code emulation,

Bit 15-23 Picture Height Indication: Range [1,...,288]; Number of lines = PHI*4.

TABLE 5/H.263

PAR Code Definition

PAR Code	Pixel Aspect Ratios
0000	forbidden
0001	1:1 (Square)
0010	12:11 (CIF for 4:3 picture)
0011	10:11 (525-type for 4:3 picture)
0100	16:11 (CIF stretched for 16:9 picture)
0101	40:33 (525-type stretched for 16:9 picture)
0110-1110	reserved
1111	extended PAR

5.1.6 Extended Pixel Aspect Ratio (EPAR) (16 bits)

A fixed length codeword of 16 bits that is present only if CPFMT is present and extended PAR is indicated therein. When present, EPAR consists of:

Bit 1-8 PAR Width: "0" is forbidden. The natural binary representation of the PAR width,
Bit 9-16 PAR Height: "0" is forbidden. The natural binary representation of the PAR height.

The PAR Width and PAR Height shall be relatively prime.

5.1.7 Custom Picture Clock Frequency Code (CPCFC) (8 bits)

A fixed length codeword of 8 bits that is present only if PLUSPTYPE is present and UFEP is 001 and a custom picture clock frequency is signalled in PLUSPTYPE. When present, CPCFC consists of:

Bit 1 Clock Conversion Code: "0" indicates a clock conversion factor of 1000 and "1" indicates 1001.

Bit 2-8 Clock Divisor: "0" is forbidden. The natural binary representation of the value of the clock divisor.

The custom picture clock frequency is given by 1 800 000/(clock divisor * clock conversion factor) Hz.

The temporal reference counter shall count in units of the inverse of the picture clock frequency, in seconds. When the PCF changes from that specified for the previous picture, the temporal reference for the current picture is measured in terms of the prior PCF, so that the new PCF takes effect only for the temporal reference interpretation of future pictures.

5.1.8 Extended Temporal Reference (ETR) (2 bits)

A fixed length codeword of 2 bits which is present only if a custom picture clock frequency is in use (regardless of the value of UFEP). It is the two MSBs of the 10-bit number defined in section 5.1.2.

5.1.9 Unlimited Unrestricted Motion Vectors Indicator (UUI) (Variable Length)

A variable length codeword of 1 or 2 bits that is present only if the optional Unrestricted Motion Vector mode is indicated in PLUSPTYPE and UFEP is 001. When UUI is present it indicates the effective limitation of the range of the motion vectors being used.

UUI = "1" : The motion vector range is limited according to Tables D.1 and D.2.

UUI = "01" : The motion vector range is not limited except by the picture size.

5.1.10 Slice Structured submode bits (SSS) (2 bits)

A fixed length codeword of 2 bits which is present only if the optional Slice Structured mode (see Annex K) is indicated in PLUSPTYPE and UFEP is 001. If the Slice Structured mode is in use but UFEP is not 001, the last values sent for SSS shall remain in effect.

Bit 1 Rectangular Slices, "0" indicates free-running slices, "1" indicates rectangular slices.

Bit 2 Arbitrary Slice Ordering, "0" indicates sequential order, "1" indicates arbitrary order.

5.1.11 Enhancement layer number (ELNUM) (4 bits)

A fixed length codeword of 4 bits which is present only if the optional Temporal, SNR, and Spatial Scalability mode is in use (regardless of the value of UFEP). The particular enhancement layer is identified by an enhancement layer number, ELNUM. Picture correspondence between layers is achieved via the temporal reference. Picture size is either indicated within each enhancement layer using the existing source format fields or is inferred by the relationship to the reference layer. The first enhancement layer above the base layer is designated as Enhancement Layer Number 2, and the base layer has number 1.

5.1.12 Reference layer number (RLNUM) (4 bits)

A fixed length codeword of 4 bits which is present only if the optional Temporal, SNR, and Spatial Scalability mode is in use (see Annex O) and UFEP is 001. The layer number for the pictures used as reference anchors is identified by a reference layer number (RLNUM). Time correspondence between layers is achieved via the temporal reference.

Note that for B pictures in an enhancement layer having temporally surrounding EI or EP pictures which are present in the same enhancement layer, RLNUM shall be equal to ELNUM (see Annex O).

5.1.13 Reference Picture Selection Mode Flags (RPSMF) (3 bits)

A fixed length codeword of 3 bits that is present only if the Reference Picture Selection mode is in use and UFEP is 001. When present, RPSMF indicates which type of back-channel messages are needed by the encoder. If the Reference Picture Selection mode is in use but RPSMF is not present, the last value of RPSMF that was sent shall remain in effect.

100: neither ACK nor NACK signals needed
101: need ACK signals to be returned

110: need NACK signals to be returned
111: need both ACK and NACK signals to be returned
000-011: reserved

5.1.14 Temporal reference for prediction indication (TRPI) (1 bit)

A fixed length codeword of 1 bit that is present only if the optional Reference Picture Selection mode is in use (regardless of the value of UFEP). When present, TRPI indicates the presence of the following TRP field.

0: TRP field is not present.
1: TRP field is present.

TRPI shall be 0 whenever the picture header indicates an I or EI picture.

5.1.15 Temporal Reference for Prediction (TRP) (10 bits)

When present (as indicated in TRPI), TRP indicates the Temporal Reference which is used for prediction of the encoding, except for in the case of B pictures. For B pictures, the picture having the temporal reference TRP is used for the prediction in the forward direction. (Prediction in the reverse-temporal direction always uses the immediately temporally-subsequent picture.) TRP is a ten bit number. If a custom picture clock frequency was not in use for the reference picture, the two MSBs of TR are zero and the LSBs contain the eight bit TR found in the picture header of the reference picture. If a custom picture clock frequency was in use for the reference picture, TR is a ten bit number consisting of the concatenation of ETR and TR from the reference picture header.

5.1.16 Back-Channel message Indication (BCI) (Variable Length)

A variable length field of one or two bits that is present only if the optional Reference Picture Selection mode is in use. When set to "1", this signals the presence of the following optional video back-channel message (BCM) field. "01" indicates the absence or the end of the video back-channel message field. Combinations of BCM and BCI may not be present, and may be repeated when present. BCI shall be set to "01" if the videomux submode of the optional Reference Picture Selection mode is not in use.

5.1.17 Back-Channel Message (BCM) (Variable Length)

The Back-Channel message with syntax as specified in section N.4.2, which is present only if the preceding BCI field is present and is set to "1".

5.1.18 Reference Picture Resampling Parameters (RPRP) (Variable Length)

A variable length field that is present only if the optional Reference Picture Resampling mode bit is set in PLUSPTYPE. This field carries the parameters of the Reference Picture Resampling mode (see Annex P). Note that the Reference Picture Resampling mode can also be invoked implicitly by the occurrence of a picture header for an INTER coded picture having a picture size which differs from that of the previous encoded picture, in which case the RPRP field is not present and the Reference Picture Resampling mode bit is not set.

5.1.19 Quantizer Information (PQUANT) (5 bits)

A fixed length codeword of 5 bits which indicates the quantizer QUANT to be used for the picture until updated by any subsequent GQUANT or DQUANT. The codewords are the natural binary representations of the values of QUANT which, being half the step sizes, range from 1 to 31.

5.1.20 Continuous Presence Multipoint and Video Multiplex (CPM) (1 bit)

A codeword of 1 bit that signals the use of the optional Continuous Presence Multipoint and Video Multiplex mode (CPM); "0" is off, "1" is on. For the use of CPM, refer to Annex C. CPM follows immediately after PLUSPTYPE if PLUSPTYPE is present, but follows PQUANT in the picture header if PLUSPTYPE is not present.

5.1.21 Picture Sub-Bitstream Indicator (PSBI) (2 bits)

A fixed length codeword of 2 bits that is only present if Continuous Presence Multipoint and Video Multiplex mode is indicated by CPM. The codewords are the natural binary representation of the sub-bitstream number for the picture header and all following information until the next Picture or GOB start code (see also Annex C). PSBI follows immediately after CPM if CPM is "1" (the location of CPM and PSBI in the picture header depend on whether PLUSPTYPE is present).

5.1.22 Temporal Reference for B-pictures in PB-frames (TR_B) (3/5 bits)

TR_B is present if PTYPE or PLUSPTYPE indicates 'PB-frame' or 'Improved PB-frame' (see also Annexes G and M) and indicates the number of non-transmitted or non-reference pictures (at 29.97 Hz or the custom picture clock frequency indicated in CPCFC) since the last P- or I-picture or P part of a PB or Improved PB frame and before the B-picture part of the PB- or Improved PB-frame. The codeword is the natural binary representation of the number of non-transmitted pictures plus one. It is 3-bits long for standard CIF picture clock frequency and is extended to five bits when a custom picture clock frequency is in use. The maximum number of non-transmitted pictures is 6 for the standard CIF picture clock frequency and 30 when a custom picture clock frequency is used.

5.1.23 Quantization information for B-pictures in PB frames (DBQUANT) (2 bits)

DBQUANT is present if PTYPE or PLUSPTYPE indicates 'PB-frame' or 'Improved PB-frame' (see also Annexes G and M). In the decoding process a quantization parameter QUANT is obtained for each macroblock. With PB-frames QUANT is used for the P-block, while for the B-block a different quantization parameter BQUANT is used. QUANT ranges from 1 to 31. DBQUANT indicates the relation between QUANT and BQUANT as defined in Table 6. In this table, "/" means division by truncation. BQUANT ranges from 1 to 31; if the value for BQUANT resulting from Table 6 is greater than 31, it is clipped to 31.

TABLE 6/H.263

DBQUANT codes and relation between QUANT and BQUANT

DBQUANT	BQUANT
00	(5xQUANT)/4
01	(6xQUANT)/4
10	(7xQUANT)/4
11	(8xQUANT)/4

5.1.24 Extra Insertion Information (PEI) (1 bit)

A bit which when set to "1" signals the presence of the following optional data field.

5.1.25 Supplemental Enhancement Information (PSUPP) (0/8/16 ... bits)

If PEI is set to "1", then 9 bits follow consisting of 8 bits of data (PSUPP) and then another PEI bit to indicate if a further 9 bits follow and so on. Encoders shall use PSUPP as specified in Annex L. Decoders which do not support the extended capabilities described in Annex L shall be designed to discard PSUPP if PEI is set to 1. This enables backward compatibility for the extended capabilities of Annex L so that a bitstream which makes use of the extended capabilities can also be used without alteration by decoders which do not support those capabilities.

5.1.26 Stuffing (ESTUF) (Variable length)

A codeword of variable length consisting of less than 8 zero-bits. Encoders may insert this codeword directly before an EOS codeword. Encoders shall insert this codeword as necessary to attain mandatory byte alignment directly before an EOSBS codeword. If ESTUF is present, the last bit of ESTUF shall be the last (least significant) bit of a byte, so that the start of the EOS or EOSBS codeword is byte aligned. Decoders shall be designed to discard ESTUF. See Annex C for a description of EOSBS and its use.

5.1.27 End Of Sequence (EOS) (22 bits)

A codeword of 22 bits. Its value is 0000 0000 0000 0000 1 11111. It is up to the encoder to insert this codeword or not. EOS may be byte aligned. This can be achieved by inserting ESTUF before the start code such that the first bit of the start code is the first (most significant) bit of a byte. EOS shall not be repeated unless at least one picture start code appears between each pair of EOS codes.

5.1.28 Stuffing (PSTUF) (Variable length)

A codeword of variable length consisting of less than 8 zero-bits. Encoders shall insert this codeword for byte alignment of the next PSC. The last bit of PSTUF shall be the last (least significant) bit of a byte, so that the video bitstream including PSTUF is a multiple of 8 bits from the first bit in the H.263 bitstream. Decoders shall be designed to discard PSTUF.

If for some reason the encoder stops encoding pictures for a certain time-period and resumes encoding later, PSTUF shall be transmitted before the encoder stops, to prevent that the last up to 7 bits of the previous picture are not sent until the coder resumes coding.

5.2 Group of Blocks Layer

Data for each Group of Blocks (GOB) consists of a GOB header followed by data for macroblocks. The structure is shown in Figure 9. Each GOB contains one or more rows of macroblocks. For the first GOB in each picture (with number 0), no GOB header shall be transmitted. For all other GOBs, the GOB header may be empty, depending on the encoder strategy. A decoder can signal the remote encoder to transmit only non-empty GOB headers by external means, for example Recommendation H.245. GSTUF may be present when GBSC is present. GN, GFID and GQUANT are present when GBSC is present. GSBI is present when CPM is "1" in the Picture header.

FIGURE 9/H.263

Structure of GOB layer

5.2.1 Stuffing (GSTUF) (Variable length)

A codeword of variable length consisting of less than 8 zero-bits. Encoders may insert this codeword directly before a GBSC codeword. If GSTUF is present, the last bit of GSTUF shall be the last (least significant) bit of a byte, so that the start of the GBSC codeword is byte aligned. Decoders shall be designed to discard GSTUF.

5.2.2 Group of Block Start Code (GBSC) (17 bits)

A word of 17 bits. Its value is 0000 0000 0000 0000 1. GOB start codes may be byte aligned. This can be achieved by inserting GSTUF before the start code such that the first bit of the start code is the first (most significant) bit of a byte.

5.2.3 Group Number (GN) (5 bits)

A fixed length codeword of 5 bits. The bits are the binary representation of the number of the Group of Blocks. For the GOB with number 0, the GOB header including GSTUF, GBSC, GN, GSBI, GFID and GQUANT is empty; as group number 0 is used in the PSC. Group numbers 1 through 17 are used in GOB headers of the standard picture formats. Group numbers 1 through 24 are used in GOB headers of custom picture formats. Group numbers 16 through 28 are emulated in the slice header (see Annex K) when CPM='0', and Group Numbers 25-27 and 29 are emulated in the slice header (see Annex K) when CPM='1'. Group number 31 is used in the EOS code, and group number 30 is used in the EOSBS code.

5.2.4 GOB Sub-Bitstream Indicator (GSBI) (2 bits)

A fixed length codeword of 2 bits that is only present if CPM is "1" in the picture header. The codewords are the natural binary representation of the sub-bitstream number for the GOB header and all following information until the next Picture or GOB start code (see also Annex C).

5.2.5 GOB Frame ID (GFID) (2 bits)

A fixed length codeword of 2 bits. GFID shall have the same value in every GOB (or slice) header of a given picture. Moreover, if PTYPE as indicated in a picture header is the same as for the previous transmitted picture, GFID shall have the same value as in that previous picture, provided PLUSPTYPE is not present. However, if PTYPE in a certain picture header differs from the PTYPE in the previous transmitted picture header, the value for GFID in that picture shall differ from the value in the previous picture.

If PLUSPTYPE is present, the value of GFID shall be the same as that for the previous picture (in the same layer) if the PTYPE, and PLUSPTYPE, and all of the present fields among CPFMT, EPAR, CPCFC, SSS, ELNUM, RLNUM, UUI, RPSMF, and RPRP remain in effect as for the previous picture; otherwise, GFID shall be different than that for the previous picture.

5.2.6 Quantizer Information (GQUANT) (5 bits)

A fixed length codeword of 5 bits which indicates the quantizer QUANT to be used for the remaining part of the picture until updated by any subsequent GQUANT or DQUANT. The codewords are the natural binary representations of the values of QUANT which, being half the step sizes, range from 1 to 31.

5.3 Macroblock Layer

Data for each macroblock consists of a macroblock header followed by data for blocks. The structure is shown in Figure 10. COD is only present in pictures that are not of type 'INTRA', for each macroblock in these pictures. MCBPC is present when indicated by COD or when the picture is of type 'INTRA'. MODB is present for MB-type 0-4 if PTYPE indicates "PB-frame". CBPY, DQUANT, MVD and MVD_{2-4} are present when indicated by MCBPC. CBPB and MVDB are only present if indicated by MODB. Block Data is present when indicated by MCBPC and CBPY. MVD_{2-4} are only present when in Advanced Prediction mode (refer to Annex F) or Deblocking Filter mode (refer to Annex J). MODB, CBPB and MVDB are only present in PB-frames mode (refer to Annex G). For coding of the symbols in the Syntax-based Arithmetic Coding mode, refer to Annex E. For coding of the macroblock layer in B, EI, and EP pictures, see Annex O.

COD	MCBPC	MODB	CBPB	CBPY	DQUANT	MVD	MVD_2	MVD_3	MVD_4	MVDB	Block Data

FIGURE 10/H.263

Structure of macroblock layer

5.3.1 Coded macroblock indication (COD) (1 bit)

A bit which when set to "0" signals that the macroblock is coded. If set to "1", no further information is transmitted for this macroblock; in that case the decoder shall treat the macroblock as an INTER macroblock with motion vector for the whole block equal to zero and with no coefficient data. COD is only present in pictures that are not of type 'INTRA', for each macroblock in these pictures.

NOTE – In Advanced Prediction mode (see Annex F), overlapped block motion compensation is also performed if COD is set to "1"; and in Deblocking Filter mode (see Annex J), the deblocking filter is also performed if COD is set to "1".

5.3.2 Macroblock type & Coded block pattern for chrominance (MCBPC) (Variable length)

MCBPC is a variable length codeword giving information about the macroblock type and the coded block pattern for chrominance. The codewords for MCBPC are given in Tables 7 and 8. MCBPC is always included in coded macroblocks.

An extra codeword is available in the tables for bit stuffing. This codeword should be discarded by decoders. If an Improved PB-frame is indicated by MPPTYPE Bits 1-3 and Custom Source Format is indicated in OPPTYPE Bits 1-3, then MBA shall not indicate Stuffing before the first macroblock of the picture (in order to prevent start code emulation).

The macroblock type gives information about the macroblock and which data elements are present. Macroblock types and included elements are listed in Tables 9 and 10. Macroblock type 5 (indices 21-24 in Table 8) shall not be present unless an extended PTYPE (PLUSPTYPE) is present in the picture header and either the Advanced Prediction mode (see Annex F) or the Deblocking Filter mode (see Annex J) is in use, and shall not be present for the first macroblock of a picture. Also, encoders shall not allow an MCBPC code for macroblock type 5 to immediately follow seven consecutive zeros in the bitstream (as can be caused by particular INTRADC codes followed by COD=0), in order to prevent start code emulation. Codes for macroblock type 5 can be preceded by stuffing when necessary to fulfill this requirement (for macroblocks other than the first of a picture).

TABLE 7/H.263

VLC table for MCBPC (for I-pictures)

Index	MB type	CBPC (56)	Number of bits	Code
0	3	00	1	1
1	3	01	3	001
2	3	10	3	010
3	3	11	3	011
4	4	00	4	0001
5	4	01	6	0000 01
6	4	10	6	0000 10
7	4	11	6	0000 11
8	Stuffing	--	9	0000 0000 1

The coded block pattern for chrominance signifies C_B and/or C_R blocks when at least one non-INTRADC transform coefficient is transmitted (INTRADC is the dc-coefficient for INTRA blocks, see 5.4.1), unless the optional Advanced INTRA Coding mode is in use. $CBPC_N$ = 1 if any non-INTRADC coefficient is present for block N, else 0, for $CBPC_5$ and $CBPC_6$ in the coded block pattern. If Advanced INTRA Coding is in use, the usage is similar, but the INTRADC coefficient is indicated in the same way as the other coefficients (see Annex I). Block numbering is given in Figure 5. When MCBPC = Stuffing, the remaining part of the macroblock layer is skipped. In this case, the preceding COD = 0 is not related to any coded or not-coded macroblock and therefore the macroblock number is not incremented. For P-pictures, multiple stuffings are accomplished by multiple sets of COD=0 and MCBPC=Stuffing. See Tables 7 and 8.

TABLE 8/H.263

VLC table for MCBPC (for P-pictures)

Index	MB type	CBPC (56)	Number of bits	Code
0	0	00	1	1
1	0	01	4	0011

INTER	3	INTRA	X	X	X	X	(X)		X	(X)	
INTER	4	INTRA+Q	X	X	X	X	(X)	X	X	(X)	
INTER	5	INTER4V+Q	X	X	X	X	(X)	X	X	(X)	X
INTER	stuffing	-	X	X							

Note 1: "x" means that the item is present in the macroblock

Note 2: CBPB and MVDB are only present if indicated by MODB

Note 3: B-blocks are always coded in INTER mode, even if the macroblock type of the PB-macroblock indicates INTRA

5.3.3 Macroblock mode for B-blocks (MODB) (Variable length)

MODB is present for MB-type 0-4 if PTYPE indicates 'PB-frame' and is a variable length codeword indicating whether CBPB is present (indicates that B-coefficients are transmitted for this macroblock) and/or MVDB is present. In Table 11 the codewords for MODB are defined. MODB is coded differently for Improved PB frames, as specified in Annex M.

TABLE 11/H.263

VLC table for MODB

Index	CBPB	MVDB	Number of bits	Code
0			1	0
1		X	2	10
2	X	X	2	11

Note: "X" means that the item is present in the macroblock

5.3.4 Coded block pattern for B-blocks (CBPB) (6 bits)

CBPB is only present in PB-frames mode if indicated by MODB. $CBPB_N$ = 1 if any coefficient is present for B-block N, else 0, for each bit $CBPB_N$ in the coded block pattern. Block numbering is given in Figure 5, the utmost left bit of CBPB corresponding with block number 1.

5.3.5 Coded block pattern for luminance (CBPY) (Variable length)

Variable length codeword giving a pattern number signifying those Y blocks in the macroblock for which at least one non-INTRADC transform coefficient is transmitted (INTRADC is the dc-coefficient for INTRA blocks, see section 5.4.1), unless the Advanced INTRA Coding mode is in use. If Advanced INTRA Coding is in use, INTRADC is indicated in the same manner as the other coefficients (see Annex I).

$CBPY_N$ = 1 if any non-INTRADC coefficient is present for block N, else 0, for each bit $CBPY_N$ in the coded block pattern. Block numbering is given in Figure 5, the utmost left bit of CBPY corresponding with block number 1. For a certain pattern $CBPY_N$, different codewords are used for INTER and INTRA macroblocks as defined in Table 13.

5.3.6 Quantizer Information (DQUANT) (2 bits/Variable Length)

If the Modified Quantization mode is not in use, DQUANT is a two bit code to define a change in QUANT. In Table 12 the differential values for the different codewords are given. QUANT ranges from 1 to 31; if the value for QUANT after adding the differential value is less than 1 or greater than 31, it is clipped to 1 and 31 respectively. If the Modified Quantization mode is in use, DQUANT is a variable length codeword as specified in Annex T.

TABLE 12/H.263

DQUANT codes and differential values for QUANT

Index	Differential value	DQUANT
0	-1	00
1	-2	01
2	1	10
3	2	11

14	11 10	00 01	4	0110
15	11 11	00 00	2	11

5.3.7 Motion Vector Data (MVD) (Variable length)

MVD is included for all INTER macroblocks (in PB-frames mode also for INTRA macroblocks) and consists of a variable length codeword for the horizontal component followed by a variable length codeword for the vertical component. Variable length codes are given in Table 14. If the Unrestricted Motion Vector mode is used and PLUSPTYPE is present, motion vectors are coded using Table D.3 instead of Table 14 (see Annex D).

TABLE 14/H.263

VLC table for MVD

Index	Vector differences		Bit number	Codes
0	-16	16	13	0000 0000 0010 1

63	15.5	-16.5	13	0000 0000 0011 0

5.3.8 Motion Vector Data (MVD_{2-4}) (Variable length)

The three codewords MVD_{2-4} are included if indicated by PTYPE and by MCBPC, and consist each of a variable length codeword for the horizontal component followed by a variable length codeword for the vertical component of each vector. Variable length codes are given in Table 14. MVD_{2-4} are only present when in Advanced Prediction mode (see Annex F) or Deblocking Filter mode (see Annex J).

5.3.9 Motion vector data for B-macroblock (MVDB) (Variable length)

MVDB is only present in PB-frames or Improved PB-frames mode if indicated by MODB, and consists of a variable length codeword for the horizontal component followed by a variable length codeword for the vertical component of each vector. Variable length codes are given in Table 14. For the use of MVDB, refer to Annex G and Annex M.

5.4 Block Layer

If not in PB-frames mode, a macroblock comprises four luminance blocks and one of each of the two colour difference blocks (see Figure 5). The structure of the block layer is shown in Figure 11. INTRADC is present for every block of the macroblock if MCBPC indicates macroblock type 3 or 4 (see Tables 7 and 8). TCOEF is present if indicated by MCBPC or CBPY.

In PB-frames mode, a macroblock comprises twelve blocks. First the data for the six P-blocks is transmitted as in the default H.263 mode, then the data for the six B-blocks. INTRADC is present for every P-block of the macroblock if MCBPC indicates macroblock type 3 or 4 (see Tables 7 and 8). INTRADC is not present for B-blocks. TCOEF is present for P-blocks if indicated by MCBPC or CBPY; TCOEF is present for B-blocks if indicated by CBPB.

For coding of the symbols in the Syntax-based Arithmetic Coding mode, refer to Annex E.

5.4.2 Transform coefficient (TCOEF) (Variable length)

The most commonly occurring EVENTs are coded with the variable length codes given in Table 16. The last bit "s" denotes the sign of the level, "0" for positive and "1" for negative.

An EVENT is a combination of a last non-zero coefficient indication (LAST; "0": there are more non-zero coefficients in this block, "1": this is the last non-zero coefficient in this block), the number of successive zeros preceding the coded coefficient (RUN), and the non-zero value of the coded coefficient (LEVEL).

The remaining combinations of (LAST, RUN, LEVEL) are coded with a 22 bit word consisting of 7 bits ESCAPE, 1 bit LAST, 6 bits RUN and 8 bits LEVEL. Use of this 22-bit word for encoding the combinations listed in Table 16 is not prohibited. For the 8-bit word for LEVEL, the code 0000 0000 is forbidden, and the code 1000 0000 is forbidden unless the Modified Quantization mode is in use (see Annex T). The codes for RUN and for LEVEL are given in Table 17.

6 Decoding process

6.1 Motion compensation

In this clause, the motion compensation for the default H.263 prediction mode is described. For a description of motion compensation in the Unrestricted Motion Vector mode, refer to Annex D. For a description of motion compensation in the Advanced Prediction mode, refer to Annex F. For a description of motion compensation in the Reduced-Resolution Update mode refer to Annex Q.

6.1.1 Differential motion vectors

The macroblock vector is obtained by adding predictors to the vector differences indicated by MVD (see Table 14 and Table D.3). For differential coding with four vectors per macroblock refer to Annex F. In case of one vector per macroblock, the candidate predictors for the differential coding are taken from three surrounding macroblocks as indicated in Figure 12. The predictors are calculated separately for the horizontal and vertical components.

In the special cases at the borders of the current GOB, slice, or picture, the following decision rules are applied in increasing order:

1) When the corresponding macroblock was coded in INTRA mode (if not in PB-frames mode with bidirectional prediction) or was not coded (COD = 1), the candidate predictor is set to zero.

2) The candidate predictor MV1 is set to zero if the corresponding macroblock is outside the picture or the slice (at the left side).

3) Then, the candidate predictors MV2 and MV3 are set to MV1 if the corresponding macroblocks are outside the picture (at the top) or outside the GOB (at the top) if the GOB header of the current GOB is non-empty; or outside the slice when in Slice Structured mode,

4) Then, the candidate predictor MV3 is set to zero if the corresponding macroblock is outside the picture (at the right side).

For each component, the predictor is the median value of the three candidate predictors for this component.

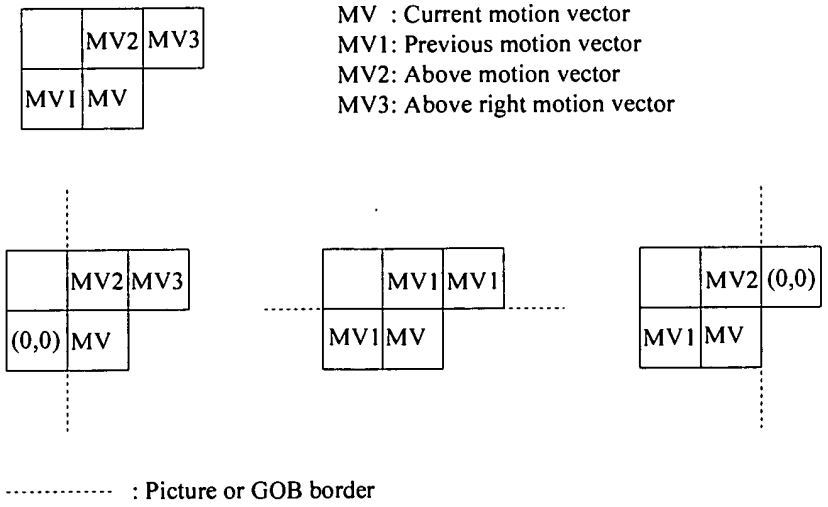

FIGURE 12/H.263

Motion vector prediction

Advantage is taken of the fact that the range of motion vector component values is constrained. Each VLC word for MVD represents a pair of difference values. Only one of the pair will yield a macroblock vector component falling within the permitted range [–16, 15.5]. A positive value of the horizontal or vertical component of the motion vector signifies that the prediction is formed from pixels in the previous picture which are spatially to the right or

below the pixels being predicted. If the unrestricted motion vector mode (see Annex D) is used, the decoding of motion vectors shall be performed as specified in section D.2.

The motion vector is used for all pixels in all four luminance blocks in the macroblock. Motion vectors for both chrominance blocks are derived by dividing the component values of the macroblock vector by two, due to the lower chrominance format. The component values of the resulting quarter pixel resolution vectors are modified towards the nearest half pixel position as indicated in Table 18.

TABLE 18/H.263

Modification of quarter pixel resolution chrominance vector components

quarter pixel position	0	1/4	1/2	3/4	1
resulting position	0	1/2	1/2	1/2	1

6.1.2 Interpolation for subpixel prediction

Half pixel values are found using bilinear interpolation as described in Figure 13. "/" indicates division by truncation.

The value of RCONTROL is equal to the value of the rounding type (RTYPE) bit (bit 6) in MPPTYPE (see section 5.1.4.3), when the Source Format field (bits 6-8) in PTYPE indicates "extended PTYPE". Otherwise RCONTROL has an implied value of 0. Regardless of the RTYPE bit, the value of RCONTROL is set to 0 for the B-part of Improved PB frames (see Annex M).

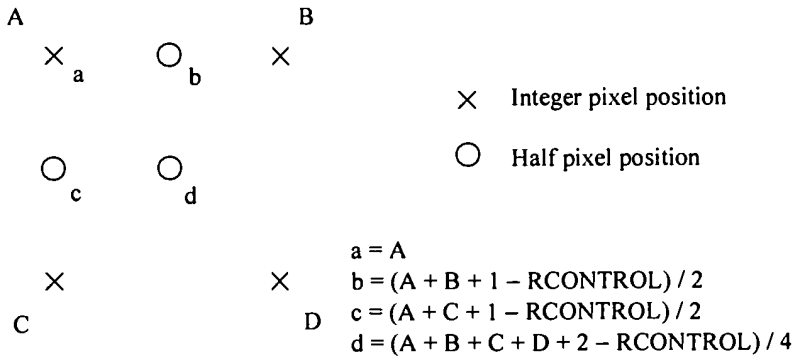

FIGURE 13/H.263

Halfpixel prediction by bilinear interpolation

6.2. Coefficients decoding

6.2.1. Inverse Quantization

The inverse quantization process is described in this section, except for when the optional Advanced INTRA Coding mode is in use (see Annex I). If LEVEL = "0", the reconstruction level REC = "0". The reconstruction level of INTRADC is given by Table 15. The reconstruction levels of all non-zero coefficients other than the INTRADC one are given by the following formulas:

$$|REC| = QUANT \cdot (2 \cdot |LEVEL| + 1) \qquad \text{if QUANT = "odd"}$$

$$|REC| = QUANT \cdot (2 \cdot |LEVEL| + 1) - 1 \qquad \text{if QUANT = "even"}$$

Note that this process disallows even valued numbers. This has been found to prevent accumulation of IDCT mismatch errors. After calculation of |REC|, the sign is added to obtain REC: REC = sign(LEVEL) · |REC|

Sign(LEVEL) is given by the last bit of the TCOEF code (see Table 16) or by Table 17.

6.2.2 Clipping of reconstruction levels

After inverse quantization, the reconstruction levels of all coefficients other than the INTRADC one are clipped to the range –2048 to 2047.

6.2.3 Zig-zag positioning

The quantized transform coefficients are placed into an 8 × 8 block according to the sequence given in Figure 14, unless the optional Advanced INTRA Coding mode is in use (see Annex I). Coefficient 1 is the dc-coefficient.

1	2	6	7	15	16	28	29
3	5	8	14	17	27	30	43
4	9	13	18	26	31	42	44

11	20	24	33	40	46	53	55
21	23	34	39	47	52	56	61
22	35	38	48	51	57	60	62
36	37	49	50	58	59	63	64

FIGURE 14/H.263

Zig-zag positioning of quantized transform coefficients

6.2.4 Inverse transform

After inverse quantization and zig-zag of coefficients, the resulting 8 × 8 blocks are processed by a separable two-dimensional inverse discrete cosine transform of size 8 by 8. The output from the inverse transform ranges from –256 to +255 after clipping to be represented with 9 bits. The transfer function of the inverse transform is given by:

$$f(x,y) = 1/4 \sum_{u=0}^{7} \sum_{v=0}^{7} C(u)C(v)F(u,v)\cos[\pi(2x+1)u/16]\cos[\pi(2y+1)v/16]$$

with $u, v, x, y = 0, 1, 2, \ldots, 7$

where x,y = spatial coordinates in the pixel domain,

u,v = coordinates in the transform domain,

$C(u) = 1/\sqrt{2}$ for $u = 0$, otherwise 1,

$C(v) = 1/\sqrt{2}$ for $v = 0$, otherwise 1.

NOTE – Within the block being transformed, $x = 0$ and $y = 0$ refer to the pixel nearest the left and top edges of the picture respectively.

The arithmetic procedures for computing the inverse transform are not defined, but should meet the error tolerance specified in Annex A.

6.3 Reconstruction of blocks

6.3.1 Summation

After motion compensation and coefficients decoding (inverse transform included), a reconstruction is formed for each luminance and chrominance block. For INTRA blocks, the reconstruction is equal to the result of the inverse

transformation. For INTER blocks, the reconstruction is formed by summing the prediction and the result of the inverse transformation. The summation is performed on a pixel basis. For the summation in the Reduced-Resolution Update mode refer to Annex Q.

6.3.2 Clipping

To prevent quantization distortion of transform coefficient amplitudes causing arithmetic overflow in the encoder and decoder loops, clipping functions are inserted. The clipper operates after the summation of prediction and reconstructed prediction error on resulting pixel values less than 0 or greater than 255, changing them to 0 and 255 respectively.

Annex A

Inverse transform accuracy specification

(This annex forms an integral part of this Recommendation)

A.1 Generate random integer pixel data values in the range –L to +H according to the random number generator given below ("C" version). Arrange into 8 by 8 blocks. Data set of 10 000 blocks should each be generated for (L = 256, H = 255), (L = H = 5) and (L = H = 300).

A.2 For each 8 by 8 block, perform a separable, orthonormal, matrix multiply, forward discrete cosine transform using at least 64-bit floating point accuracy.

$$F(u,v) = 1/4C(u)C(v)\sum_{x=0}^{7}\sum_{y=0}^{7} f(x,y)\cos[\pi(2x+1)u/16]\cos[\pi(2y+1)v/16]$$

with $u, v, x, y = 0, 1, 2, \ldots, 7$

x, y = spatial coordinates in the pixel domain;

u, v = coordinates in the transform domain;

$C(u) = 1/\sqrt{2}$ for $u = 0$, otherwise 1;

$C(v) = 1/\sqrt{2}$ for $v = 0$, otherwise 1.

A.3 For each block, round the 64 resulting transformed coefficients to the nearest integer values. Then clip them to the range –2048 to +2047. This is the 12-bit input data to the inverse transform.

A.4 For each 8 by 8 block of 12-bit data produced by A.3, perform a separable, orthonormal, matrix multiply, inverse discrete transform (IDCT) using at least 64-bit floating point accuracy. Round the resulting pixels to the nearest integer and clip to the range –256 to +255. These blocks of 8 × 8 pixels are the reference IDCT output data.

A.5 For each 8 by 8 block produced by A.3, apply the IDCT under test and clip the output to the range –256 to +255. These blocks of 8 × 8 pixels are the test IDCT output data.

A.6 For each of the 64 IDCT output pixels, and for each of the 10 000 block data sets generated above, measure the peak, mean and mean square error between the reference and the test data.

A.7
- For any pixel, the peak error should not exceed 1 in magnitude.
- For any pixel, the mean square error should not exceed 0.06.
- Overall, the mean square error should not exceed 0.02.
- For any pixel, the mean error should not exceed 0.015 in magnitude.
- Overall, the mean error should not exceed 0.0015 in magnitude.

A.8 All zeros in shall produce all zeros out.

A.9 Re-run the measurements using exactly the same data values of A.1, but change the sign on each pixel.

"C" program for random number generation

```
/* L and H shall be long, that is 32 bits */
long rand   (L,H)
long        L,H;
{
```

```
    static long randx = 1;                  /* long is 32 bits          */
    static double z = (double) 0x7fffffff;

    long        i,j;
    double      x;                          /* double is 64 bits        */

    randx = (randx * 1103515245) + 12345;
    i = randx & 0x7ffffffe;                 /* keep 30 bits             */
    x = ( (double)i ) /  z;                 /* range 0 to 0.99999 ...   */
    x *= (L+H+1);                           /* range 0 to < L+H+1       */
    j = x;                                  /* truncate to integer      */
    return(j – L);                          /* range –L to H            */
}
```

Annex B

Hypothetical Reference Decoder

(This annex forms an integral part of this Recommendation)

The Hypothetical Reference Decoder (HRD) is defined as follows:

B.1 The HRD and the encoder have the same clock frequency as well as the same picture clock frequency, and are operated synchronously.

B.2 The HRD receiving buffer size is (B + BPPmaxKb * 1024 bits) where (BPPmaxKb * 1024) is the maximum number of bits per picture that has been negotiated for use in the bitstream (see 3.6). The value of B is defined as follows:

$$B = 4 \cdot R_{max} / PCF$$

where PCF is the effective picture clock frequency, and R_{max} is the maximum video bit rate during the connection in bits per second. The effective picture clock frequency is the standard CIF picture clock frequency unless a custom PCF is specified in the CPCFC field of the picture header. This value for B is a minimum. An encoder may use a larger value for B, provided the larger number is first negotiated by external means, for example Recommendation H.245.

The value for R_{max} depends on the system configuration (for example GSTN or ISDN, single or multi-link) and may be equal to the maximum bit rate supported by the physical link. Negotiation of R_{max} is done by external means, for example Recommendation H.245.

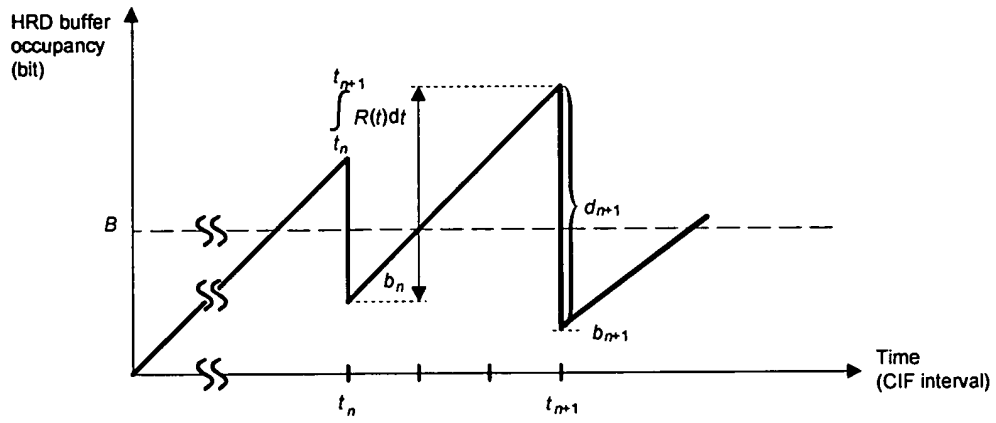
B.3 The HRD is initially empty.

B.4 The HRD buffer is examined at picture clock intervals (1000 / PCF ms). If at least one complete coded picture is in the buffer then all the data for the earliest picture in bitstream order is instantaneously removed (e.g. at t_{n+1} in Figure B.1). Immediately after removing the above data the buffer occupancy must be less than B. This is a requirement on the coder output bitstream including coded picture data and MCBPC and STUF stuffing but not error correction framing bits, fill indicator (Fi), fill bits or error correction parity information described in Annex H.

For the purposes of this definition, unless the optional Temporal, SNR, and Spatial Scalability mode is in use, a complete coded picture is one normal I- or P-picture, or a PB-frame or Improved PB-frame.

When the Temporal, SNR, and Spatial Scalability mode is in use (see Annex O), each enhancement layer is given an additional HRD, for which a complete coded picture is one EI, EP, or B picture. The base layer buffer shall hold the bits of the picture header as they arrive, until a sufficient amount of the picture header has arrived to determine whether the picture is a base layer or enhancement layer picture, and the number of the enhancement layer. When it can be determined that the arriving picture belongs to an enhancement layer, all bits for that picture shall be instantly transferred to the appropriate enhancement layer HRD, and any later bits which arrive continue to be placed into the enhancement layer HRD until a sufficient amount of some new picture header has arrived to determine that the bistream should again be re-routed into another HRD buffer. The process of enhancement layer identification is instantaneous and asynchronous, independent of the picture clock interval checking times.

To meet this requirement the number of bits for the $(n+1)$th coded picture d_{n+1} must satisfy:



$$d_{n+1} \geq b_n + \int_{t_n}^{t_{n+1}} R(t)dt - B$$

where

b_n is the buffer occupancy just after time t_n;

t_n is the time the nth coded picture is removed from the HRD buffer;

$R(t)$ is the video bitrate at time t.

NOTE – Time $(t_{n+1} - t_n)$ is an integer number of CIF picture periods (1/29.97, 2/29.97, 3/29.97, ...).

FIGURE B.1/H.263

HRD buffer occupancy

Annex C

Considerations for Multipoint

(This annex forms an integral part of this Recommendation)

The following facilities are provided to support switched multipoint operation.

C.1 Freeze picture request

Causes the decoder to freeze its displayed picture until a freeze picture release signal is received or a time-out period of at least six seconds has expired. The transmission of this signal is by external means (for example Recommendation H.245). Note that a similar command may also be sent using supplemental enhancement information within the picture header of the video bitstream (see Annex L, section L.4).

C.2 Fast update request

Causes the encoder to encode its next picture in INTRA mode with coding parameters such as to avoid buffer overflow. The transmission method for this signal is by external means (for example Recommendation H.245).

C.3 Freeze picture release

A signal from an encoder which has responded to a fast update request and allows a decoder to exit from its freeze picture mode and display decoded pictures in the normal manner. This signal is transmitted by PTYPE (see 5.1.3) in the picture header of the first picture coded in response to the fast update request.

C.4 Continuous Presence Multipoint and Video Multiplexing (CPM)

(NOTE: Not used for H.324.)

In this Recommendation a negotiable Continuous Presence Multipoint and Video Multiplexing mode is provided in which up to four independent H.263 bitstreams can be multiplexed as independent "Sub-Bitstreams" in one new video bitstream with use of the PSBI, GSBI, SSBI, and ESBI fields. Capability exchange for this mode is done by external means (for example Recommendation H.242). Reference Picture Selection back-channel data for responding to independent Sub-Bitstreams is supported using the BCPM and BSBI fields.

When in CPM mode, the CPM field shall be set to "1" in each of the independent H.263 Sub-Bitstreams. Sub-Bitstreams are identified by a stream identifier number using the Sub-Bitstream indicators (SBIs) in the Picture and GOB or slice and EOSBS headers of each H.263 bitstream. The SBI indicates the number of the H.263 bitstream to which that header and all following information until the next Picture or GOB header or slice header in the composed video bitstream belongs.

Each Sub-Bitstream is considered as a normal H.263 bitstream and shall therefore comply to the capabilities that are exchanged by external means. The information for the different H.263 bitstreams is not transmitted in any special predefined order, an SBI can have any value independent from preceding SBIs and the picture rates for the different H.263 bitstreams may be different. The information in each individual bitstream is also completely independent from the information in the other bitstreams. For example, the GFID codewords in one Sub-Bitstream are not influenced by GFID or PTYPE codewords in other Sub-Bitstreams. Similarly, the mode state inference rules when using an extended picture type (PLUSPTYPE) in the picture header and all other aspects of the video bitstream operation shall operate independently and separately for each Sub-Bitstream.

As a matter of convention, the Sub-Bitstream with the lowest Sub-Bitstream identifier number (sent in SBI) is considered to have the highest priority in situations in which some conflict of resource requirements may necessitate a choice of priority (unless a different priority convention is established by external means).

In order to mark the end of each Sub-Bitstream of the CPM mode, a syntax is provided as shown in Figure C.1, provided the ability to send this added syntax is first negotiated by external means (while CPM operation was defined in Version 1 of this Recommendation, the end of Sub-Bitstream syntax was added in Version 2 and thus is not considered a part of Version 1 CPM operation). The end of Sub-Bitstream syntax (ESTUF+EOSBS+ESBI) marks the end of each Sub-Bitstream, rather than the end of the entire stream as done by an EOS code.

Note — No ability to negotiate CPM Sub-Bitstream operation as defined herein for Recommendation H.263 was adopted into any ITU-T Recommendations for terminals (such as Recommendation H.324) prior to the creation of Version 2 of this Recommendation. Thus any external negotiation of CPM operation adopted into a future H-series terminal Recommendation shall imply support for the end of Sub-Bitstream syntax unless otherwise specified in the H-series terminal Recommendation.

There are three parts to the end of Sub-Bitstream syntax. Following mandatory byte alignment using ESTUF, an EOSBS codeword of 23 bits is sent (corresponding to a GOB header with GN=30, which is otherwise unused in the syntax, followed by a single zero-valued bit which is reserved for future use). The EOSBS codeword is then followed by a two bit ESBI codeword indicating which Sub-Bitstream is affected. This pair of codewords signifies that the sending of data for the associated Sub-Bitstream has ended and that any subsequent data sent for the same Sub-Bitstream shall be entirely independent from that which came before the EOSBS. In particular, the next picture for the Sub-Bitstream after the EOSBS code shall not be an INTER picture or any other picture type which can use forward temporal prediction (an I or EI picture is allowed, but a P picture, PB-frame, Improved PB frame, B picture, or EP picture is not).

The syntax of EOSBS and ESBI is described in the following subsections. ESTUF is described in section 5.1.26.

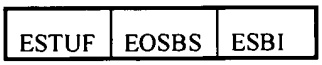


FIGURE C.1/H.263

Syntax diagram for End of Sub-Bitstream Indicators

C.4.1. End Of Sub-Bitstream code (EOSBS) (23 bits)

The EOSBS code is a codeword of 23 bits. Its value is 0000 0000 0000 0000 1 11110 0. It is up to the encoder whether to insert this codeword or not. EOSBS should not be sent unless at least one picture header has previously been sent for the same Sub-Bitstream indicated in the following ESBI field, and shall not be sent unless the capability to send EOSBS has been negotiated by external means. EOSBS codes shall be byte aligned. This is achieved by inserting ESTUF before the EOSBS start code such that the first bit of the EOSBS start code is the first (most significant) bit of a byte (see section 5.1.26).

The EOSBS code indicates that the sending of data for the indicated Sub-Bitstream has stopped and the Sub-Bitstream has been declared over, until re-started by issuance of another picture start code for that Sub-Bitstream. Subsequent pictures with the same Sub-Bitstream identifier number (ESBI) shall be completely independent of and shall not depend in any way on the pictures which were sent prior to the EOSBS code.

Control and other information associated with the video bitstream in general without specification of which Sub-Bitstreams these codes are meant to apply (such as a Freeze Picture Request or a Fast Update Request sent in H.242) should be presumed to apply to all of the *active* Sub-Bitstreams only. A Sub-Bitstream is considered active if at least one picture start code has been received for the Sub-Bitstream and the last data sent which was applicable to that Sub-Bitstream was not an EOS or EOSBS+ESBI.

C.4.2. Ending Sub-Bitstream Indicator (ESBI) (2 bits)

ESBI is a fixed length codeword of two bits which follows immediately after EOSBS. It indicates the Sub-Bitstream number of the ending Sub-Bitstream. Its value is the natural two bit binary representation of the Sub-Bitstream number.

Annex D

Unrestricted Motion Vector mode

(This annex forms an integral part of this Recommendation)

This annex describes the optional Unrestricted Motion Vector mode of H.263. The capability of this mode of H.263 is signalled by external means (for example Recommendation H.245). The use of this mode is indicated in PTYPE or PLUSPTYPE.

The range of motion vectors and the VLC table used for coding the motion vector differences for the Unrestricted Motion Vector mode depend on whether the PLUSPTYPE field of the picture header is present. When PLUSPTYPE is present, the range of motion vectors also depends on the picture size and the value of the UUI field in the picture header.

D.1 Motion vectors over picture boundaries

In the default prediction mode of H.263, motion vectors are restricted such that all pixels referenced by them are within the coded picture area (see 4.2.3). In the Unrestricted Motion Vector mode however this restriction is removed and therefore motion vectors *are* allowed to point outside the picture. When a pixel referenced by a motion vector is outside the coded picture area, an edge pixel is used instead. This edge pixel is found by limiting the motion vector to the last full pixel position inside the coded picture area. Limitation of the motion vector is performed on a pixel basis and separately for each component of the motion vector.

For example, if the Unrestricted Motion Vector mode is used for a QCIF picture, the referenced pixel value for the luminance component is given by the following formula:

$$Rumv(x, y) = R(x', y')$$

where:

x, y, x', y' = spatial coordinates in the pixel domain;

$Rumv(x, y)$ = pixel value of the referenced picture at (x, y) when in Unrestricted Motion Vector mode;

$R(x', y')$ = pixel value of the referenced picture at (x', y') when in Unrestricted Motion Vector mode;

$x' = 0$ if $x < 0$;

$= 175$ if $x > 175$;

$= x$ otherwise;

$y' = 0$ if $y < 0$;

$= 143$ if $y > 143$;

$= y$ otherwise;

and the coded picture area of R(x', y') is $0 <= x' <= 175$, $0 <= y' <= 143$. The given boundaries are integer pixel positions; however, (x', y') can also be a half pixel position within these boundaries.

D.1.1. Restrictions for motion vector values

If PLUSPTYPE is present in the picture header, the motion vector values are restricted such that no element of the 16×16 (or 8×8) region that is selected shall have a horizontal or vertical distance more than 15 pixels outside the coded picture area. Note that this is a smaller extrapolation range than when PLUSPTYPE is not present.

Note — When PLUSPTYPE is absent, the extrapolation range is a maximum of 31.5 pixels outside the coded picture area when the Unrestricted Motion Vector mode is used, and 16 pixels outside the coded picture area when the Advanced Prediction mode (see Annex F) is used without the Unrestricted Motion Vector mode.

D.2 Extension of the motion vector range

In the default prediction mode, the values for both horizontal and vertical components of the motion vectors are restricted to the range [–16, 15.5] (this is also valid for the forward and backward motion vector components for

B-pictures). In the Unrestricted Motion Vector mode however, the maximum range for vector components is extended.

If the PLUSPTYPE field is not present in the picture header, the motion vector range is extended to [–31.5, 31.5], with the restriction that only values that are within a range of [–16, 15.5] around the predictor for each motion vector component can be reached if the predictor is in the range [–15.5, 16]. If the predictor is outside [–15.5, 16], all values within the range [–31.5, 31.5] with the same sign as the predictor plus the zero value can be reached. So, if MV_C is the motion vector component and P_C is the predictor for it, then:

$$-31.5 \leq MV_C \leq 0 \qquad if -31.5 \leq P_C \leq -16$$

$$-16 + P_C \leq MV_C \leq 15.5 + P_C \qquad if -15.5 \leq P_C \leq 16$$

$$0 \leq MV_C \leq 31.5 \qquad if\ 16.5 \leq P_C \leq 31.5$$

In the Unrestricted Motion Vector mode, the interpretation of Table 14 for MVD, $MVD_{2\text{-}4}$ and MVDB is as follows:

- if the predictor for the motion vector component is in the range [–15.5, 16], only the first column of vector differences applies;
- if the predictor for the motion vector component is outside the range [–15.5, 16], the vector difference from Table 14 shall be used that results in a vector component inside the range [–31.5, 31.5] with the same sign as the predictor (including zero).

The predictor for MV_D and $MVD_{2\text{-}4}$ is defined as the median value of the vector components MV1, MV2 and MV3 as defined in 6.1.1 and F.2. For MVDB the predictor $P_C = (TR_B \times MV)/TR_D$ where MV represents a vector component for an 8 * 8 luminance block in a P-picture (see also G.4).

If PLUSPTYPE is present, the motion vector range does not depend on the motion vector prediction value. If the UUI field is set to "1" the motion vector range depends on the picture format. For standardized picture formats up to CIF the range is [-32,31.5], for those up to 4CIF the range is [-64,63.5], and for those up to 16CIF the range is [-128,127.5], and for even larger custom picture formats the range is [-256,255.5]. The horizontal and vertical motion vector ranges may be different for custom picture formats. The horizontal and vertical ranges are specified in Tables D.1 and D.2.

TABLE D.1/H.263

Horizontal Motion Vector Range when PLUSPTYPE present and UUI = 1

Picture width	Horizontal motion vector range
4, ..., 352	[-32, 31.5]
356, ..., 704	[-64, 63.5]
708, ..., 1408	[-128, 127.5]
1412,..., 2048	[-256, 255.5]

TABLE D.2/H.263

Vertical Motion Vector Range when PLUSPTYPE present and UUI = 1

Picture height	Vertical motion vector range
4, ..., 288	[-32, 31.5]
292, ..., 576	[-64, 63.5]
580, ..., 1152	[-128, 127.5]

In the Reduced-Resolution Update mode, the specified range applies to the pseudo motion vectors. This implies that the resulting actual motion vector range is enlarged to approximately double size (see also Annex Q).

If UUI is set to "01", the motion vectors are not limited except by their distance to the coded area border as explained in section D.1.1. The same limitation applies to the actual motion vectors (not just the pseudo motion vectors) in the Reduced-Resolution Update mode.

To encode the motion vectors when PLUSPTYPE is present, Table D.3 is used to encode the difference between the motion vector and the motion vector prediction. Every entry in Table D.3 has a single value (in contrast to Table 14). The motion vector range and the use of Table D.3 to encode motion vector data apply to all picture types when PLUSPTYPE is present.

Motion vectors differences are always coded as a pair of a horizontal and a vertical component. If a pair equals (0.5,0.5) six consecutive zeros are produced. To prevent start code emulation, this occurrence shall be followed by one bit set to "1". This corresponds to sending one additional zero motion vector component.

TABLE D.3/H.263

Motion Vector Table used when PLUSPTYPE present

Absolute value of vector difference in half-pixel units	number of bits	Codes
0	1	1
1	3	0s0

"$x_4x_3x_2x_1x_0$"+32 (32:63)	13	0$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0
"$x_5x_4x_3x_2x_1x_0$"+64 (64:127)	15	0$x_5$1$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0
"$x_6x_5x_4x_3x_2x_1x_0$"+128 (128:255)	17	0$x_6$1$x_5$1$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0
"$x_7x_6x_5x_4x_3x_2x_1x_0$"+256 (256:511)	19	0$x_7$1$x_6$1$x_5$1$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0
"$x_8x_7x_6x_5x_4x_3x_2x_1x_0$"+512 (512:1023)	21	0$x_8$1$x_7$1$x_6$1$x_5$1$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0
"$x_9x_8x_7x_6x_5x_4x_3x_2x_1x_0$"+1024 (1024:2047)	23	0$x_9$1$x_8$1$x_7$1$x_6$1$x_5$1$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0
"$x_{10}x_9x_8x_7x_6x_5x_4x_3x_2x_1x_0$"+2048 (2048:4095)	25	0x_{10}1$x_9$1$x_8$1$x_7$1$x_6$1$x_5$1$x_4$1$x_3$1$x_2$1$x_1$1$x_0$1s0

Table D.3 is a regularly constructed reversible table. Each row represents an interval of motion vector differences in half-pixel units. The bits "...x_1x_0" denote all bits following the leading "1" in the binary representation of the absolute value of the motion vector difference. The bit "s" denotes the sign of the motion vector difference, "0" for

positive and "1" for negative. The binary representation of the motion vector difference is interleaved with bits that indicate if the code continues or ends. For example, the motion vector difference −13 has sign s=1 and binary representation $1x_2x_1x_0 = 1101$. It is encoded as 0 $x_2$1 $x_1$1 $x_0$1 s0 = 0 11 11 01 10. The 0 in the second position of the last group of two bits indicates the end of the code.

Annex E

Syntax-based Arithmetic Coding mode

(This annex forms an integral part of this Recommendation)

E.1 Introduction

In the Variable Length Coding/Decoding (VLC/VLD) as described in clause 5, a symbol is VLC encoded using a specific table based on the syntax of the coder. This table typically stores lengths and values of the VLC code words. The symbol is mapped to an entry of the table in a table look-up operation, and then the binary code word specified by the entry is sent out normally to a buffer for transmitting to the receiver. In VLD decoding, the received bitstream is matched entry by entry in a specific table based on the syntax of the coder. This table must be the same as the one used in the encoder for encoding the current symbol. The matched entry in the table is then mapped back to the corresponding symbol which is the end result of the VLD decoder and is then used for recovering the video pictures. This VLC/VLD process implies that each symbol must be encoded into a fixed integral number of bits. Removing this restriction of fixed integral number of bits for symbols can lead to reductions of resulting bitrates, which can be achieved by arithmetic coding.

This annex describes the optional Syntax-based Arithmetic Coding (SAC) mode of H.263. In this mode, all the corresponding variable length coding/decoding operations of H.263 are replaced with arithmetic coding/decoding operations. The capability of this mode of H.263 is signalled by external means (for example Recommendation H.245). The use of this mode is indicated in PTYPE.

E.2 Specification of SAC encoder

In SAC mode, a symbol is encoded by using a specific array of integers (or a model) based on the syntax of the coder and by calling the following procedure which is specified in C language.

```
#define   q1    16384
#define   q2    32768
#define   q3    49152
#define   top   65535

static long      low, high, opposite_bits, length;

void   encode_a_symbol(int index, int cumul_freq[ ])

{
       length = high - low + 1;
       high = low - 1 + (length * cumul_freq[index]) / cumul_freq[0];
       low += (length * cumul_freq[index+1]) / cumul_freq[0];
       for ( ; ; ) {
          if (high < q2) {
             send out a bit "0" to PSC_FIFO;
             while (opposite_bits > 0) {
                send out a bit "1" to PSC_FIFO;
                opposite_bits--;
             }
          }
          else if (low >= q2) {
             send out a bit "1" to PSC_FIFO;
             while (opposite_bits > 0) {
                send out a bit "0" to PSC_FIFO;
                opposite_bits--;
             }
             low-= q2;
             high -= q2;
          }
```

```
            else if (low >= q1 && high < q3) {
                opposite_bits += 1;
                low -= q1;
                high -= q1;
            }
            else break;

            low *= 2;
            high = 2*high+1;
        }
}
```

The values of low, high and opposite_bits are initialized to 0, top and 0, respectively. PSC_FIFO is a FIFO for buffering the output bits from the arithmetic encoder. The model is specified through cumul_freq[ ], and the symbol is specified using its index in the model.

E.3 Specification of SAC decoder

In SAC decoder, a symbol is decoded by using a specific model based on the syntax and by calling the following procedure which is specified in C language.

```
static long      low, high, code_value, bit, length, index, cum;

int     decode_a_symbol(int cumul_freq[ ])

{
        length = high - low + 1;
        cum = (-1 + (code_value - low + 1) * cumul_freq[0]) / length;
        for (index = 1; cumul_freq[index] > cum; index++);
        high = low - 1 + (length * cumul_freq[index-1]) / cumul_freq[0];
        low += (length * cumul_freq[index]) / cumul_freq[0];
        for ( ; ; ) {
            if (high < q2);
            else if (low >= q2) {
                code_value -= q2;
                low -= q2;
                high -= q2;
            }
            else if (low >= q1 && high < q3) {
                code_value -= q1;
                low -= q1;
                high -= q1;
            }
            else break;

            low *= 2;
            high = 2 * high + 1;
            get bit from PSC_FIFO;
            code_value = 2 * code_value + bit;
        }
        return (index-1);
}
```

Again the model is specified through cumul_freq[ ]. The decoded symbol is returned through its index in the model. PSC_FIFO is a FIFO for buffering the incoming bitstream. The decoder is initialized to start decoding an arithmetic coded bitstream by calling the following procedure.

```
void    decoder_reset( )
{
        code_value = 0;
        low = 0;
        high = top;
        for (int i = 1;   i <= 16;   i++) {
            get bit from PSC_FIFO;
            code_value = 2 * code_value + bit;
        }
}
```

E.4 Syntax

As in VLC table mode of H.263, the syntax of the symbols is partitioned into four layers: Picture, Group of Blocks, Macroblock and Block. The syntax of the top three layers remain exactly the same. The syntax of the Block layer also remains quite similar, but is illustrated in Figure E.1.

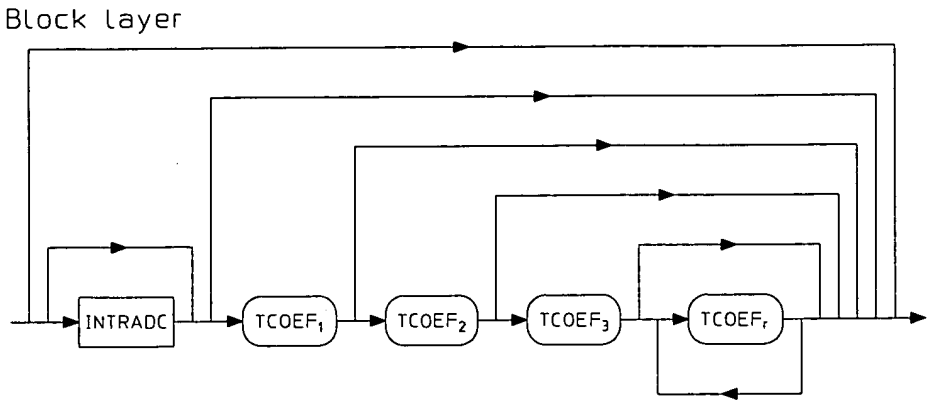

FIGURE E.1/H.263

Structure of SAC Block layer

In Figure E.1, TCOEF1, TCOEF2, TCOEF3 and TCOEFr are Last-Run-Level symbols as defined in 5.4.2, and are the possible 1st, 2nd, 3rd and rest of the symbols, respectively. TCOEF1, TCOEF2, TCOEF3 and TCOEFr are only present when one, two, three or more coefficients are present in the block layer, respectively.

E.5 PSC_FIFO

PSC_FIFO in encoder or decoder is a FIFO of size > 17 bits. In PSC_FIFO of encoder, illegal emulations of PSC and GBSC are located and are avoided by stuffing a "1" after each successive appearance of 14 "0"s (which are not part of PSC or GBSC). In PSC_FIFO of the decoder, the first "1" after each string of 14 "0"s is deleted; if instead a string of 14 "0"s is followed by a "0", it indicates that a legal PSC or GBSC is detected. The exact location of the PSC or GBSC is determined by the next "1" following the string of zeros.

E.6 Header layer symbols

The header layers of the syntax are considered to be those syntactical elements above the block and macroblock layers (see Figure 6 and the syntax specification in the text). The header levels of the basic Version 1 syntax can form three possible strings, (PSTUF)--PSC--TR--PTYPE--PQUANT--CPM--(PSBI)--(TRB-DBQUANT)--PEI--(PSUPP--PEI--...), (GSTUF)--GBSC--GN--(GSBI)--GFID--GQUANT, and (ESTUF)--(EOS)--(PSTUF). In the revised syntax of Version 2, the header levels of the syntax can have other structures (see Figure 6 and the syntax specification in the text). The header level syntax strings are directly sent to PSC_FIFO as in the normal VLC table mode of H.263 at encoder side, and are directly sent out from PSC_FIFO in the decoder after a legal PSC, GBSC, SSC, EOS, or EOSBS is detected.

If a header is not the first in a video session, the arithmetic encoder needs to be reset before sending the header by calling the following procedure. This procedure shall also be called at the end of a video session if (ESTUF)--EOS (or (ESTUF)--EOSBS for the Sub-Bitstream for which the last header was sent) is not sent.

```
void    encoder_flush( )

{
        opposite_bits++;
        if (low < q1) {
            send out a bit "0" to PSC_FIFO;
            while (opposite_bits > 0) {
                send out a bit "1" to PSC_FIFO;
                opposite_bits--;
            }
        }
        else {
            send out a bit "1" to PSC_FIFO;
            while (opposite_bits > 0) {
                send out a bit "0" to PSC_FIFO;
                opposite_bits--;
            }
        }
        low = 0;
        high = top;
}
```

In the decoder, after each fixed length symbol string, procedure **decoder_reset** is called.

E.7 Macroblock and Block layer symbols

Models for the macroblock and block layer symbols are included in E..8. The indices as given in the VLC tables of clause 5 are used for the indexing of the integers in the models.

The model for COD in P-pictures is named cumf_COD.. The index for COD being "0" is 0, and is 1 for COD being "1". The model for MCBPC in P pictures is named cumf_MCBPC_no4MVQ unless PLUSPTYPE is present in the picture header and either the Advanced Prediction mode (Annex F) or the Deblocking Filter mode (Annex J) is in use, in which case the model is named cumf_MCBPC_4MVQ The indexes for MCBPC are defined in Table 7 for I-pictures and Table 8 for P-pictures. The model for MCBPC in I-pictures is named by cumf_MCBPC_intra.

The model for MODB is cumf_MODB_G if Annex G is used or cumf_MODB_M if Annex M is used. The indexes for MODB are defined in Table 11 or Table M.I, respectively. The model for CBPBn, n=1,2,...,4, is cumf_YCBPB, and the model for CBPBn, n=5,6, is cumf_UVCBPB, with index 0 for CBPBn=0 and index 1 for CBPBn=1.

The model for CBPY is cumf_CBPY in INTER macroblocks and cumf_CBPY_intra in INTRA macroblocks. The model for DQUANT is cumf_DQUANT. The indexing for CBPY and DQUANT is defined in Tables 13 and 12, respectively.

The model for MVD, $MVD_{2\text{-}4}$ and MVDB is cumf_MVD and the model for INTRADC is cumf_INTRADC. The indexing is defined in Tables 14 and 15, respectively.

A non-escaped TCOEF consists of a symbol for TCOEF1/2/3/r followed by a symbol, SIGN, for the sign of the TCOEF. The models for TCOEF1, TCOEF2, TCOEF3 and TCOEFr in INTER blocks are cumf_TCOEF1, cumf_TCOEF2, cumf_TCOEF3, cumf_TCOEFr. The models for INTRA blocks are cumf_TCOEF1_intra, cumf_TCOEF2_intra, cumf_TCOEF3_intra, cumf_TCOEFr_intra. For all TCOEFs the indexing is defined in Table 16. The model for SIGN is cumf_SIGN. The indexing for SIGN is 0 for positive sign and 1 for negative sign.

The models for LAST, RUN, LEVEL after ESCAPE are cumf_LAST (cumf_LAST_intra), cumf_RUN (cumf_RUN_intra), cumf_LEVEL (cumf_LEVEL_intra) for INTER (INTRA) blocks. The indexing for LAST is 0 for LAST=0 and 1 for LAST=1, while the indexing for RUN and LEVEL is defined in Table 17.

The model for INTRA_MODE is cumf_INTRA_AC_DC. The indexing is defined in Table I.1.

Annex F
Advanced Prediction mode

(This annex forms an integral part of this Recommendation)

F.1 Introduction

This annex describes the optional Advanced Prediction mode of H.263, including overlapped block motion compensation and the possibility of four motion vectors per macroblock. The capability of this mode is signalled by external means (for example Recommendation H.245). The use of this mode is indicated in PTYPE. In the Advanced Prediction mode, motion vectors are allowed to cross picture boundaries as is the case in the Unrestricted Motion Vector mode (for the description of this technique refer to D.1). The extended motion vector range feature of the Unrestricted Motion Vector mode is not automatically included in the Advanced Prediction mode, and only is active if the Unrestricted Motion Vector mode is selected. If the Advanced Prediction mode is used in combination with the PB-frames mode, overlapped motion compensation is only used for prediction of the P-pictures, not for the B-pictures.

F.2 Four motion vectors per macroblock

In this Recommendation, one motion vector per macroblock is used except when in Advanced Prediction mode or Deblocking Filter mode. In this mode, the one/four vectors decision is indicated by the MCBPC codeword for each macroblock. If only one motion vector is transmitted for a certain macroblock, this is defined as four vectors with the same value. If MCBPC indicates that four motion vectors are transmitted for the current macroblock, the information for the first motion vector is transmitted as the codeword MVD and the information for the three additional motion vectors is transmitted as the codewords MVD_{2-4} (see also 5.3.7 and 5.3.8).

The vectors are obtained by adding predictors to the vector differences indicated by MVD and MVD_{2-4} in a similar way as when only one motion vector per macroblock is present, according to the decision rules given in 6.1.1. Again the predictors are calculated separately for the horizontal and vertical components. However, the candidate predictors MV1, MV2 and MV3 are redefined as indicated in Figure F.1. If only one vector per macroblock is present, MV1, MV2 and MV3 are defined as for the 8 * 8 block numbered 1 in Figure 5 (this definition is given in the upper left of the four sub-figures of Figure F.1).

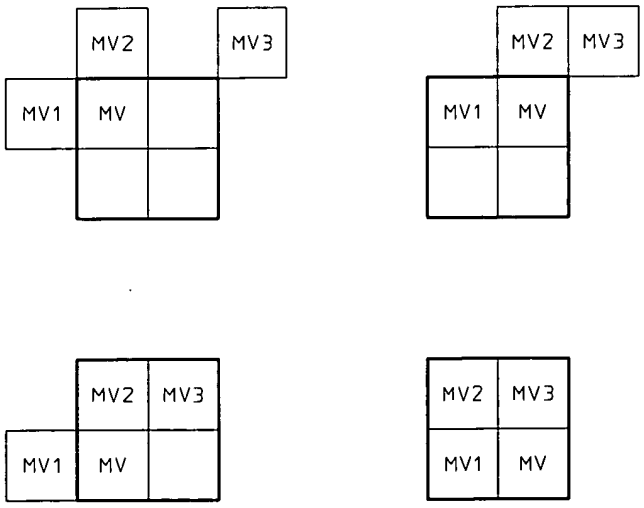

FIGURE F.1/H.263

Redefinition of the candidate predictors MV1, MV2 and MV3

for each of the luminance blocks in a macroblock

If four vectors are used, each of the motion vectors is used for all pixels in one of the four luminance blocks in the macroblock. The numbering of the motion vectors is equivalent to the numbering of the four luminance blocks as given in Figure 5. Motion vector MVD_{CHR} for both chrominance blocks is derived by calculating the sum of the four luminance vectors and dividing this sum by 8; the component values of the resulting sixteenth pixel resolution vectors are modified towards the nearest half pixel position as indicated in Table F.1.

TABLE F.1/H.263

Modification of sixteenth pixel resolution chrominance vector components

sixteenth pixel position	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	/16
resulting position	0	0	0	1	1	1	1	1	1	1	1	1	1	1	2	2	/2

Half pixel values are found using bilinear interpolation as described in 6.1.2. In Advanced Prediction mode, the prediction for luminance is obtained by overlapped motion compensation as described in Section F.3. The prediction for chrominance is obtained by applying the motion vector MVD_{CHR} to all pixels in the two chrominance blocks (as it is done in the default prediction mode).

F.3 Overlapped motion compensation for luminance

Each pixel in an 8 * 8 luminance prediction block is a weighted sum of three prediction values, divided by 8 (with rounding). In order to obtain the three prediction values, three motion vectors are used: the motion vector of the current luminance block, and two out of four "remote" vectors:

- the motion vector of the block at the left or right side of the current luminance block;
- the motion vector of the block above or below the current luminance block.

For each pixel, the remote motion vectors of the blocks at the two nearest block borders are used. This means that for the upper half of the block the motion vector corresponding to the block above the current block is used, while for the lower half of the block the motion vector corresponding to the block below the current block is used (see Figure F.3). Similarly, for the left half of the block the motion vector corresponding to the block at the left side of the current block is used, while for the right half of the block the motion vector corresponding to the block at the right side of the current block is used (see Figure F.4).

Let (x,y) be a position in a picture measured in integer pixel units.

Let (m,n) be an integer block index in a picture, as given by

$$m = x / 8 \quad \text{and} \quad n = y / 8,$$

where "/" denotes division with truncation.

Let (i,j) be an integer pixel location in an 8×8 block, given by

$$i = x - m \cdot 8 \quad \text{and} \quad j = y - n \cdot 8,$$

resulting in

$$(x,y) = (m \cdot 8 + i, n \cdot 8 + j).$$

Let (MV^k_x, MV^k_y) be a motion vector, which may contain full-pixel or half pixel offsets, with $k = 0$, 1, or 2. For example, (MV^k_x, MV^k_y) can be equal to (-7.0, 13.5). Here, (MV^0_x, MV^0_y) denotes the motion vector for the current block (m,n), (MV^1_x, MV^1_y) denotes the motion vector of the block either above or below, and (MV^2_x, MV^2_y) denotes the motion vector either to the left or right of the current block (m,n) as defined above.

Then the creation of each pixel, $P(x,y)$, in an 8×8 luminance prediction block with block index (m,n) is governed by the following equation:

$$P(x,y) = (q(x,y) \cdot H_0(i,j) + r(x,y) \cdot H_1(i,j) + s(x,y) \cdot H_2(i,j) + 4)/8,$$

where $q(x,y)$, $r(x,y)$ and $s(x,y)$ are the prediction values taken from the referenced picture as defined by

$q(x,y) = p(x + MV^0_x, y + MV^0_y)$,

$r(x,y) = p(x + MV^1_x, y + MV^1_y)$,

$s(x,y) = p(x + MV^2_x, y + MV^2_y)$,

where $p(x+MV^k_x, y+MV^k_y)$ is the prediction value at position $(x+MV^k_x, y+MV^k_y)$ in the referenced picture. Note that $(x+MV^k_x, y+MV^k_y)$ may be outside the picture and can be at a full or half pixel position. In cases using half pixel motion vectors, $p(x+MV^k_x, y+MV^k_y)$ refers to the value obtained after the interpolation process described in section 6.1.2 is applied.

The matrices $H_0(i,j)$, $H_1(i,j)$ and $H_2(i,j)$ are defined in Figures F.2, F.3 and F.4, where (i, j) denotes the column and row, respectively, of the matrix.

When neither the Slice Structured mode (see Annex K) nor the Independent Segment Decoding mode (see Annex R) are in use, remote motion vectors from other video picture segments are used in the same way as remote motion vectors inside the current GOB. If either the Slice Structured mode or the Independent Segment Decoding mode are in use, the remote motion vectors corresponding to blocks from other video picture segments are set to the motion vector of the current block, regardless of the other conditions described in the next paragraph. (See Annex R for the definition of a video picture segment.)

If one of the surrounding macroblocks was not coded, the corresponding remote motion vector is set to zero. If one of the surrounding blocks was INTRA coded, the corresponding remote motion vector is replaced by the motion vector for the current block except when in PB-frames mode. In this case (INTRA block in PB-frame mode), the INTRA block's motion vector is used (also see Annex G). If the current block is at the border of the picture and therefore a surrounding block is not present, the corresponding remote motion vector is replaced by the current motion vector. In all cases, if the current block is at the bottom of the macroblock (for block number 3 or 4, see Figure 5), the remote motion vector corresponding with an 8 * 8 luminance block in the macroblock below the current macroblock is replaced by the motion vector for the current block.

The weighting values for the prediction are given in Figures F.2, F.3 and F.4.

Annex G

PB-frames mode

(This annex forms an integral part of this Recommendation)

G.1 Introduction

This annex describes the optional PB-frames mode of H.263. The capability of this mode is signalled by external means (for example Recommendation H.245). The use of this mode is indicated in PTYPE.

A PB-frame consists of two pictures being coded as one unit. The name PB comes from the name of picture types in Recommendation H.262 where there are P-pictures and B-pictures. Thus a PB-frame consists of one P-picture which is predicted from the previous decoded P-picture and one B-picture which is predicted both from the previous decoded P-picture and the P-picture currently being decoded. The name B-picture was chosen because parts of B-pictures may be bidirectionally predicted from the past and future pictures. The prediction process is illustrated in Figure G.1.

An improved version of the PB frames mode, termed the "Improved PB frames mode," is described in Annex M. The PB frames mode as described in this annex is retained herein only for purposes of compatibility with systems designed prior to the adoption of the Improved PB frames mode. For this reason, the PB frames mode as described in this annex cannot be used with the additional features of the syntax which require the use of PLUSPTYPE.

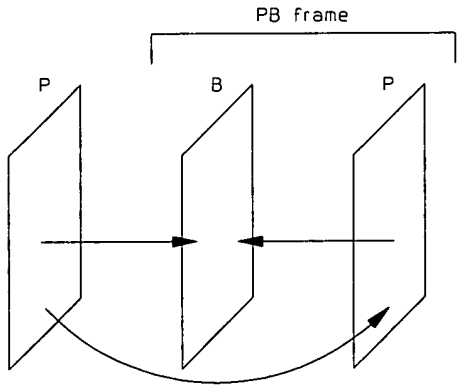

FIGURE G.1/H.263

Prediction in PB-frames mode

G.2 PB-frames and INTRA blocks

When PB-frames are used the coding mode INTRA has the following meaning (see also 5.3.2):

- The P-blocks are INTRA coded.
- The B-blocks are INTER coded with prediction as for an INTER block.

If PB-frames are used, Motion Vector Data (MVD) is included also for INTRA macroblocks in pictures for which PTYPE indicates "INTER". In this case the vector is used for the B-blocks only. The codewords MVD_{2-4} are never used for INTRA (see also Table 10). When in both the Advanced Prediction mode and the PB-frames mode, and

one of the surrounding blocks was coded in INTRA mode, the corresponding remote motion vector is not replaced by the motion vector for the current block. Instead, the remote "INTRA" motion vector is used.

G.3 Block Layer

In a PB-frame, a macroblock comprises twelve blocks. First the data for the six P-blocks is transmitted as in the default H.263 mode, then the data for the six B-blocks (see also 5.4). The structure of the block layer is shown in Figure 11. INTRADC is present for every P-block of the macroblock if MCBPC indicates macroblock type 3 or 4 (see Tables 7 and 8). INTRADC is not present for B-blocks. TCOEF is present for P-blocks if indicated by MCBPC or CBPY; TCOEF is present for B-blocks if indicated by CBPB.

G.4 Calculation of vectors for the B-picture in a PB-frame

The vectors for the B-picture are calculated as follows (see also 6.1.1). Assume we have a vector component MV in half pixel units to be used in the P-picture (MV represents a vector component for an 8 * 8 luminance block; if only one vector per macroblock is transmitted, MV has the same value for each of the four 8 * 8 luminance blocks). For prediction of the B-picture we need both forward and backward vector components MV_F and MV_B. These forward and backward vector components are derived from MV and eventually enhanced by a delta vector given by MVDB.

- TR_D The increment of the temporal reference TR (or the combined extended temporal reference ETR and temporal reference TR in an Improved PB frame when a custom picture clock frequency is in use) from the last picture header (see 5.1.2). If TR_D is negative then $TR_D = TR_D + d$ where d = 256 for CIF picture frequency and 1024 for any custom picture clock frequency
- TR_B See 5.1.21.

Assume that MV_D is the delta vector component given by MVDB and corresponding with vector component MV. If MVDB is not present, MV_D is set to zero. If MVDB is present, the same MV_D given by MVDB is used for each of the four luminance B-blocks within the macroblock.

Now MV_F and MV_B are given in half pixel units by the following formulas:

$$MV_F = (TR_B \times MV) / TR_D + MV_D$$

$$MV_B = ((TR_B - TR_D) \times MV) / TR_D \quad \text{if } MV_D \text{ is equal to 0}$$

$$MV_B = MV_F - MV \quad \text{if } MV_D \text{ is unequal to 0}$$

where "/" means division by truncation. It is assumed that the scaling reflects the actual position in time of P- and B-pictures. Advantage is taken of the fact that the range of values for MV_F is constrained. Each VLC word for MVDB represents a pair of difference values. Only one of the pair will yield a value for MV_F falling within the permitted range (default [–16, 15.5]; in Unrestricted Motion Vector mode [–31.5, 31.5]). The formulas for MV_F and MV_B are also used in the case of INTRA blocks where the vector data is used only for predicting B-blocks.

For chrominance blocks, MV_F is derived by calculating the sum of the four corresponding luminance MV_F vectors and dividing this sum by 8; the resulting sixteenth pixel resolution vector components are modified towards the nearest half pixel position as indicated in Table F.1. MV_B for chrominance is derived by calculating the sum of the four corresponding luminance MV_B vectors and dividing this sum by 8; the resulting sixteenth pixel resolution vector components are modified towards the nearest half pixel position as indicated in Table F.1.

A positive value of the horizontal or vertical component of the motion vector signifies that the prediction is formed from pixels in the referenced picture which are spatially to the right or below the pixels being predicted.

G.5 Prediction of a B-block in a PB-frame

In this subclause a block means an 8 × 8 block. The following procedure applies for luminance as well as chrominance blocks. First, the forward and backward vectors are calculated. It is assumed that the P-macroblock (luminance and chrominance) is first decoded, reconstructed and clipped (see 6.3.2). This macroblock is called P_{REC}. Based on P_{REC} and the prediction for P_{REC}, the prediction for the B-block is calculated.

The prediction of the B-block has two modes that are used for different parts of the block:

- For pixels where the backward vector – MV_B – points inside P_{REC}, use bidirectional prediction. This is obtained as the average of the forward prediction using MV_F relative to the previous decoded picture, and the backward prediction using MV_B relative to P_{REC}. The average is calculated by dividing the sum of the two predictions by two (division by truncation).
- For all other pixels, forward prediction using MV_F relative to the previous decoded picture is used.

Figure G.2 indicates which part of a block is predicted bidirectionally (shaded part of the B-block) and which part with forward prediction only (rest of the B-block).

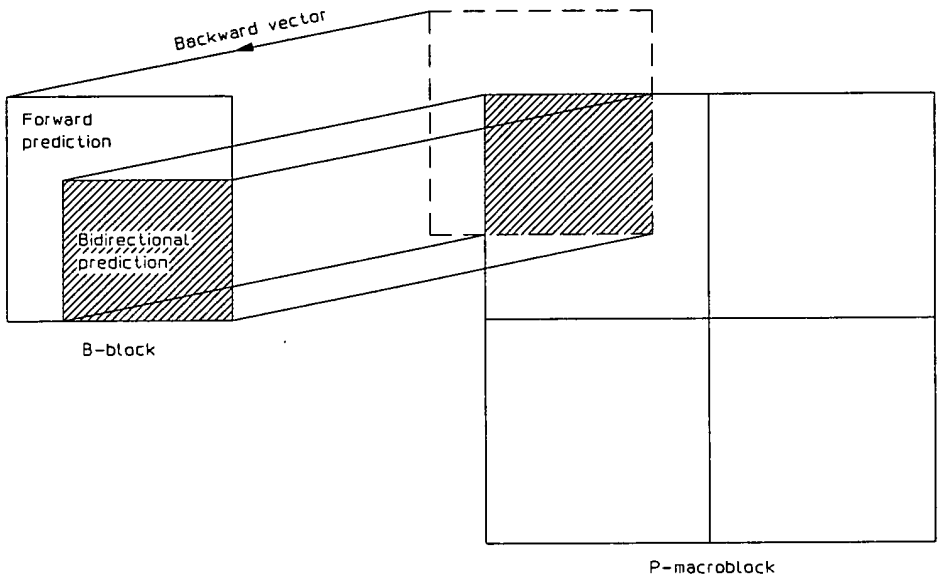

FIGURE G.2/H.263

Forward and bidirectional prediction for a B-block

Bi-directional prediction is used for pixels where the backward vector – MV_B – points inside P_{REC}. These pixels are defined by the following procedures which are specified in C language.

Definitions:

nh	Horizontal position of block within a macroblock (0 or 1).
nv	Vertical position of block within a macroblock (0 or 1).
mh(nh,nv)	Horizontal vector component of block (nh,nv) in half pixel units.
mv(nh,nv)	Vertical vector component of block (nh,nv) in half pixel units.
mhc	Horizontal chrominance vector component.
mvc	Vertical chrominance vector component.

Procedure for luminance

```
for (nh = 0; nh <= 1; nh++) {
   for (nv = 0; nv <= 1; nv++) {
      for (i = nh * 8 + max(0,(–mh(nh,nv)+1)/2 – nh * 8);
            i <= nh * 8 + min(7,15–(mh(nh,nv)+1)/2 – nh * 8); i++) {
         for (j = nv * 8 + max(0,(–mv(nh,nv)+1)/2 – nv * 8);
            j <= nv * 8 + min(7,15–(mv(nh,nv)+1)/2 – nv * 8); j++) {
            predict pixel (i,j) bidirectionally
         }
      }
   }
}
```

Procedure for chrominance

```
for (i = max(0, (–mhc+1)/2); i <= min(7,7–(mhc+1)/2); i++) {
   for (j = max(0, (–mvc+1)/2); j <= min(7,7–(mvc+1)/2); j++) {
      predict pixel (i,j) bidirectionally;
   }
}
```

Pixels not predicted bidirectionally are predicted with forward prediction only.

Annex H

Forward Error Correction for coded video signal

(This annex forms an integral part of this Recommendation)

H.1 Introduction

This annex describes an optional forward error correction method (code and framing) for transmission of H.263 encoded video data. This forward error correction may be used in situations where no forward error correction is provided by external means, for example at the multiplex or system level. It is not used for Recommendation H.324. Both the framing and the forward error correction code are the same as in Recommendation H.261.

H.2 Error correction framing

To allow the video data and error correction parity information to be identified by a decoder an error correction framing pattern is included. This pattern consists of multiframes of eight frames, each frame comprising 1 bit framing, 1 bit fill indicator (Fi), 492 bits of coded data (or fill all 1s) and 18 bits parity (see Figure H.1). For each multiframe the frame alignment pattern formed by the framing bits of the eight individual frames is:

$$(S_1S_2S_3S_4S_5S_6S_7S_8) = (00011011)$$

The fill indicator (Fi) can be set to zero by an encoder. In this case 492 consecutive fill bits (fill all 1s) are used instead of 492 bits of coded data. This may be used for stuffing data (see 3.6).

H.3 Error correcting code

The error correction code is a BCH (511,493) forward error correction code. Use of this by the decoder is optional. The parity is calculated against a code of 493 bits, comprising 1 bit fill indicator (Fi) and 492 bits of coded video data.

The generator polynomial is:

$$g(x) = (x9 + x4 + 1)(x9 + x6 + x4 + x3 + 1)$$

Example: for the input data of "01111 . . . 11" (493 bits) the resulting correction parity bits are "011011010100011011" (18 bits).

H.4 Relock time for error corrector framing

Three consecutive error correction frame alignment patterns (24 bits) should be received before frame lock is deemed to have been achieved. The decoder should be designed such that frame lock will be re-established within 34 000 bits after an error corrector framing phase change.

NOTE – This assumes that the video data does not contain three correctly phased emulations of the error correction framing sequence during the relocking period.

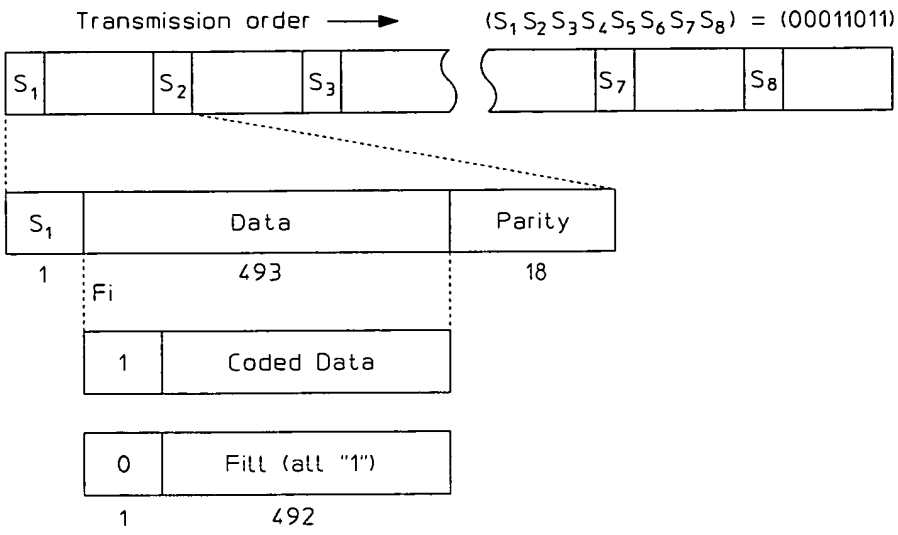

FIGURE H.1/H.263

Error correcting frame

Annex I
Advanced INTRA Coding mode

(This annex forms an integral part of this Recommendation.)

This annex describes the optional Advanced INTRA Coding mode of H.263. The capability of this mode of H.263 is signaled by external means (for example Recommendation H.245). The use of this mode is indicated in the PLUSPTYPE field of the picture header.

I.1 Introduction

This optional mode alters the decoding of macroblocks of type 'INTRA' (macroblocks of other types are not affected). The coding efficiency of INTRA macroblocks is improved by using

1. INTRA-block prediction using neighboring INTRA blocks for the same component (Y, C_B, or C_R),
2. Modified inverse quantization for INTRA coefficients, and
3. A separate VLC for INTRA coefficients.

A particular INTRA-coded block may be predicted from the block above the current block being decoded, from the block to the left of the current block being decoded, or from both. Special cases exist for situations in which the neighboring blocks are not INTRA coded or are not in the same video picture segment. Block prediction always uses data from the same luminance or color difference component (Y, C_B, or C_R) as the block being decoded. In prediction, DC coefficients are always predicted in some manner. The first row of AC coefficients may be predicted from those in the block above, or the first column of AC coefficients may be predicted from those in the block to the left, or only the DC coefficient may be predicted as an average from the block above and the block to the left, as signaled on a macroblock-by-macroblock basis. The remaining AC coefficients are never predicted. Inverse quantization of the INTRADC coefficient is modified to allow a varying quantization step size, unlike in the main text of this Recommendation where a fixed step size of 8 is used for INTRADC coefficients. Inverse quantization of all INTRA coefficients is performed without a "dead-zone" in the quantizer reconstruction spacing.

I.2 Syntax

When using the Advanced INTRA Coding mode, the macroblock layer syntax is altered as specified in Figure I.1. The syntax as shown in Figure I.1 is the same as that defined in section 5.3 except for the insertion of an additional INTRA_MODE field for INTRA macroblocks. INTRA_MODE is present only when MCBPC indicates a macroblock of type INTRA (macroblock type 3 or 4). The prediction mode is coded using the variable length code shown in Table I.1. One prediction mode is transmitted per INTRA macroblock.

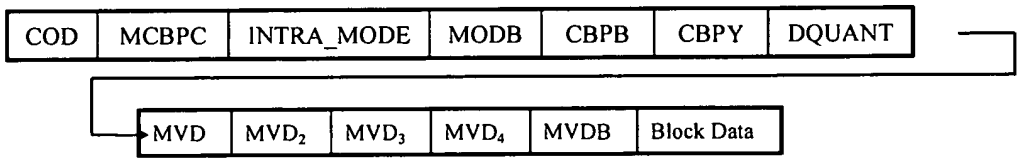

FIGURE I.1/H.263

Structure of macroblock layer

TABLE I.1/H.263

VLC for INTRA_MODE

Index	Prediction Mode	VLC
0	0 (DC Only)	0
1	1 (Vertical DC & AC)	10
2	2 (Horizontal DC & AC)	11

I.3 Decoding Process

Two scans in addition to the zigzag scan are employed. The two added scans are shown in Figure I.2 parts (a) and (b), and the zigzag scan is shown in Figure 14.

For INTRA coded blocks, if Prediction Mode=0, the zigzag scan shown in Figure 14 is selected for all blocks in the macroblock, otherwise, the prediction direction is used to select a scan for the macroblock.

Prediction Mode=1 uses the vertically adjacent block in forming a prediction. This prediction mode is designed for INTRA blocks which are dominated by stronger horizontal frequency content, so the vertically adjacent block is used to predict the horizontal frequency content of the current block, with a prediction of zero for all coefficients representing vertical AC content. Then the scanning pattern is chosen to scan the stronger horizontal frequencies prior to the vertical ones, using the Alternate-Horizontal scan.

Prediction Mode=2 uses the horizontally adjacent block in forming a prediction. This prediction mode is designed for INTRA blocks which are dominated by stronger vertical frequency content, so the horizontally adjacent block is used to predict the vertical frequency content of the current block, with a prediction of zero for all coefficients representing horizontal AC content. Then the scanning pattern is chosen to scan the stronger vertical frequencies prior to the horizontal ones, using the Alternate-Vertical scan.

For non INTRA blocks, the 8x8 blocks of transform coefficients are scanned with "zigzag" scanning as shown in Figure 14.

(b) Alternate-Vertical scan (as in Recommendation H.262)

FIGURE I.2/H.263

Alternate DCT Scanning patterns for Advanced INTRA Coding

A separate VLC table is used for all INTRADC and INTRA AC coefficients. This table is specified in Table I.2. Note that the VLC codeword entries used in Table I.2 are the same as those used in the normal TCOEF table (Table 16) used when Advanced INTRA Coding is not in use, but with a different interpretation of LEVEL and RUN (without altering LAST).

Depending on the value of INTRA_MODE either one or eight coefficients are prediction residuals that must be added to a predictor as described below. Figure I.3 shows three 8×8 blocks of final reconstructed DCT levels for the same component (Y, C_B, or C_R), labeled RecA'(u,v), RecB'(u,v) and RecC'(u,v), where u and v are column (horizontal) and row (vertical) indices, respectively. The reconstruction process differs from the processing

described in section 6.2.1. INTRADC residuals are reconstructed differently by use of a variable step size, as opposed to using Table 15, and then a predictor is added to the residual values to obtain the final coefficient reconstruction value. INTRA coefficients other than INTRADC are also reconstructed differently than in section 6.2.1, using a reconstruction spacing without a "dead-zone" and then in some cases adding a predictor to obtain the final coefficient reconstruction value. The block may contain both DC and AC prediction residuals.

The definitions of MCPBC and CBPY are changed when Advanced INTRA Coding is in use. When Advanced INTRA Coding is in use, INTRADC transform coefficients are no longer handled as a separate case, but are instead treated in the same way as the AC coefficients in regard to MCPBC and CBPY. This means that a zero INTRADC will not be coded as a LEVEL, but will simply increase the run for the following AC coefficients.

The inverse quantization process for the B part of an Improved PB frame (see Annex M) is not altered by the use of the Advanced INTRA Coding mode.

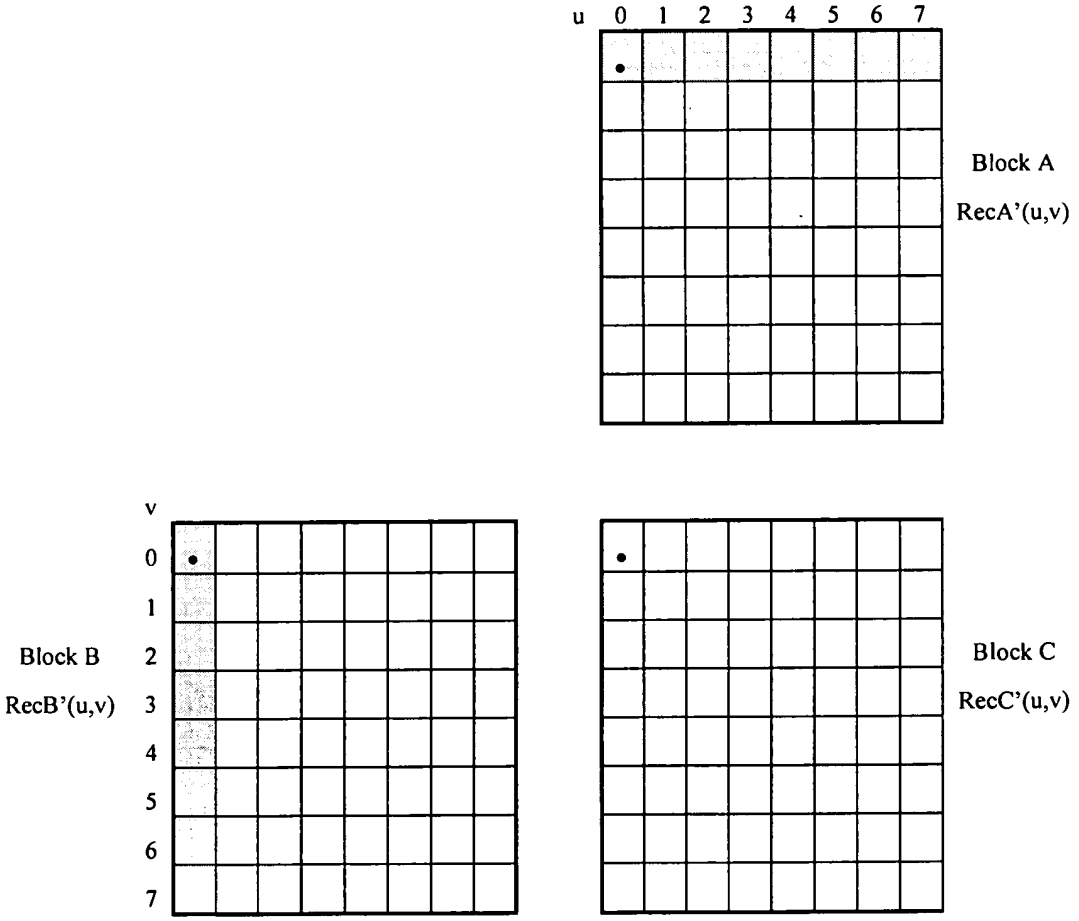

FIGURE I.3/H.263

Three Neighboring blocks in the DCT domain

Define RecC(u,v) to be the reconstructed coefficient *residuals* of the current block. For all INTRA coefficients, the reconstructed residual value is obtained by

$$RecC(u,v) = 2 * QUANT * LEVEL(u,v) \qquad u=0, \ldots, 7, v=0, \ldots, 7.$$

(Note that LEVEL(u,v) denotes a quantity having both a magnitude and a sign in the above equation.)

Define RecC'(u,v) to be the *final* reconstructed coefficient values of the current block (after adjustments for prediction, oddification as described below, and clipping). The final reconstructed coefficient values RecC'(u,v) are

recovered by adding RecC(u,v) to the appropriate prediction as signaled in the INTRA_MODE field, altering the least-significant bit if needed for oddification of the DC coefficient, and clipping.

RecA'(u,v) denotes the *final* reconstructed coefficient values for the block immediately above the current block. RecB'(u,v) denotes the *final* reconstructed coefficient values of the block immediately to the left of the current block.

The ability to use the reconstructed coefficient values for blocks A and B in the prediction of the coefficient values for block C depends on whether blocks A and B are in the same video picture segment as block C. A block is defined to be "in the same video picture segment" as another block only if the following conditions are fulfilled:

1. The relevant block is within the boundary of the picture, and
2. If not in Slice Structured mode (see Annex K), the relevant block is either within the same GOB or no GOB header is present for the current GOB, and
3. If in Slice Structured mode, the relevant block is within the same slice.

The block C to be decoded is predicted only from INTRA blocks within the same video picture segment as block C, as shown below.

If Prediction Mode = 0 is used (DC prediction only) and blocks A and B are both INTRA blocks within the same video picture segment as block C, then the DC coefficient of block C is predicted from the average (with truncation) of the DC coefficients of blocks A and B. If only one of the two blocks A and B is an INTRA block within the same video picture segment as block C, then the DC coefficient of only this one of the two blocks is used as the predictor for Prediction Mode = 0. If neither of the two blocks A and B are INTRA blocks within the same video picture segment as block C, then the prediction uses the value of 1024 as the predictor for the DC coefficient.

If Prediction Mode = 1 or 2 (vertical DC & AC or horizontal DC & AC prediction) and the referenced block (block A or block B) is not an INTRA block within the same video picture segment as block C, then the prediction uses the value of 1024 as the predictor for the DC coefficient and the value of 0 as the predictor for the AC coefficients of block C.

A process of "oddification" is applied to the DC coefficient in order to minimize the impact of IDCT mismatch errors. Certain values of coefficients can cause a round-off error mismatch between different IDCT implementations, especially certain values of the (0,0), (0,4), (4,0), and (4,4) coefficients. For example, a DC coefficient of 8k+4 for some integer k results in an inverse-transformed block having a constant value k+0.5, for which slight errors can cause rounding in different directions on different implementations.

Define the clipAC() function to indicate clipping to the range -2048 to 2047. Define the clipDC() function to indicate clipping to the range 0 to 2047. Define the oddifyclipDC(x) function as

```
If (x is even) {
    result = clipDC(x+1)
} else {
    result = clipDC(x)
}
```

The reconstruction for each INTRA prediction mode is then specified as follows, in which the operator "/" is defined as division by truncation:

mode 0: DC prediction only.

```
RecC'(u,v) = clipAC( RecC(u,v) )                    (u,v) ≠ (0,0), u = 0, ..., 7, v = 0, ..., 7.
If (block A and block B are both INTRA coded and are both in the same video picture segment as block C) {
  tempDC = RecC(0,0) + ( RecA'(0,0) + RecB'(0,0) ) / 2
} else {
  If (block A is INTRA coded and is in the same video picture segment as block C) {
    tempDC = RecC(0,0) + RecA'(0,0)
  } else {
    If (block B is INTRA coded and is in the same video picture segment as block C) {
      tempDC = RecC(0,0) + RecB'(0,0)
    } else {
      tempDC = RecC(0,0) + 1024
    }
  }
}
```

RecC'(0,0) = oddifyclipDC(tempDC)

mode 1: DC and AC prediction from the block above.

If (block A is INTRA coded and is in the same video picture segment as block C) {
  tempDC = RecC(0,0) + RecA'(0,0)
  RecC'(u,0) = clipAC(RecC(u,0) + RecA'(u,0)) u = 1, ..., 7,
  RecC'(u,v) = clipAC(RecC(u,v)) u = 0, ..., 7, v = 1, ..., 7.
} else {
  tempDC = RecC(0,0) + 1024
  RecC'(u,v) = clipAC(RecC(u,v)) (u,v) ≠ (0,0), u = 0, ...,7, v = 0, ..., 7
}
RecC'(0,0) = oddifyclipDC(tempDC)

mode 2: DC and AC prediction from the block to the left.

If (block B is INTRA coded and is in the same video picture segment as block C) {
  tempDC = RecC(0,0) + RecB'(0,0)
  RecC'(0,v) = clipAC(RecC(0,v) + RecB'(0,v)) v = 1, ..., 7,
  RecC'(u,v) = clipAC(RecC(u,v)) u = 1, ..., 7, v = 0, ..., 7.
} else {
  tempDC = RecC(0,0) + 1024
  RecC'(u,v) = clipAC(RecC(u,v)) (u,v) ≠ (0,0), u = 0, ..., 7, v = 0, ..., 7
}
RecC'(0,0) = oddifyclipDC(tempDC)

Annex J
Deblocking Filter mode

(This annex forms an integral part of this Recommendation.)

J.1 Introduction

This annex describes the use of an optional block edge filter within the coding loop. The main purpose of the block edge filter is to reduce blocking artifacts. The filtering is performed on 8x8 block edges. Motion vectors may have either 8x8 or 16x16 resolution (see section J.2). The processing described in this annex applies only for the P, I, EP, or EI pictures or the P picture part of an Improved PB frame. (Possible filtering of B-pictures or the B-picture part of an Improved PB frame is not a matter for standardization, however some type of filtering is recommended for improved picture quality.) The capability of this mode is signaled by external means (for example Recommendation H.245). The use of this mode is indicated in the PLUSPTYPE field of the picture header.

J.2 Relation to UMV and AP modes (Annexes D and F)

The use of the deblocking filter mode has similar effects on picture quality as overlapped block motion compensation (OBMC) as defined in Annex F when used alone. When both techniques are used together, a further improvement in picture quality can be obtained. The Advanced Prediction mode (see also Annex F) consists of three elements:

1. Four motion vectors per macroblock as defined in section F.2
2. Overlapped motion compensation for luminance as defined in section F.3
3. Motion vectors over picture boundaries as defined in section D.1

In order for the Deblocking Filter mode to be able to provide maximum performance when complexity considerations may prevent use of the OBMC part of the Advanced Prediction mode, the Deblocking Filter mode includes the ability to use four motion vectors per macroblock and motion vectors over picture boundaries.

In summary, the three options defined in annexes D, F and J contain the following five coding elements:

1. Motion vectors over picture boundaries (D.1)
2. Extension of motion vector range (D.2)
3. Four motion vectors per macroblock (F.2)
4. Overlapped motion compensation for luminance (F.3)
5. Deblocking edge filter (J.3)

Table J.1 indicates which of the five elements are turned on depending on which of the three options defined in annexes D, F and J are turned on.

TABLE J.1/H.263

Feature Elements for UMV, AP, and DF modes

ON	ON	OFF	ON	ON	ON	ON	OFF
ON	ON	ON	ON	ON	ON	ON	ON

J.3 Definition of the deblocking edge filter

The filter operations are performed across 8x8 block edges at the encoder as well as on the decoder side. The reconstructed image data (the sum of the prediction and reconstructed prediction error) are clipped to the range of 0 to 255 as described in section 6.3.2. Then the filtering is applied, which alters the picture that is to be stored in the picture store for future prediction. The filtering operations include an additional clipping to ensure that resulting pixel values stay in the range 0...255. No filtering is performed across a picture edge, and when the Independent Segment Decoding mode is in use, no filtering is performed across slice edges when the Slice Structured mode is in use (see Annexes K and R) or across the top boundary of GOBs having GOB headers present when the Slice Structured mode is not in use (see Annex R). Chrominance as well as luminance data are filtered.

When the mode described in this Annex is used together with the Improved PB-frames mode of Annex M, the backward prediction of the B-macroblock is based on the reconstructed P-macroblock (named P_{REC} in section G.5) after the clipping operation but before the deblocking edge filter operations. The forward prediction of the B-macroblock is based on the filtered version of the previous decoded picture (the same picture data that are used for prediction of the P-macroblock).

The deblocking filter operates using a set of four (clipped) pixel values on a horizontal or vertical line of the reconstructed picture, denoted as A, B, C and D, of which A and B belong to one block called block1 and C and D belong to a neighboring block called block2 which is to the right of or below block1. Figure J.1 shows examples for the position of these pixels.

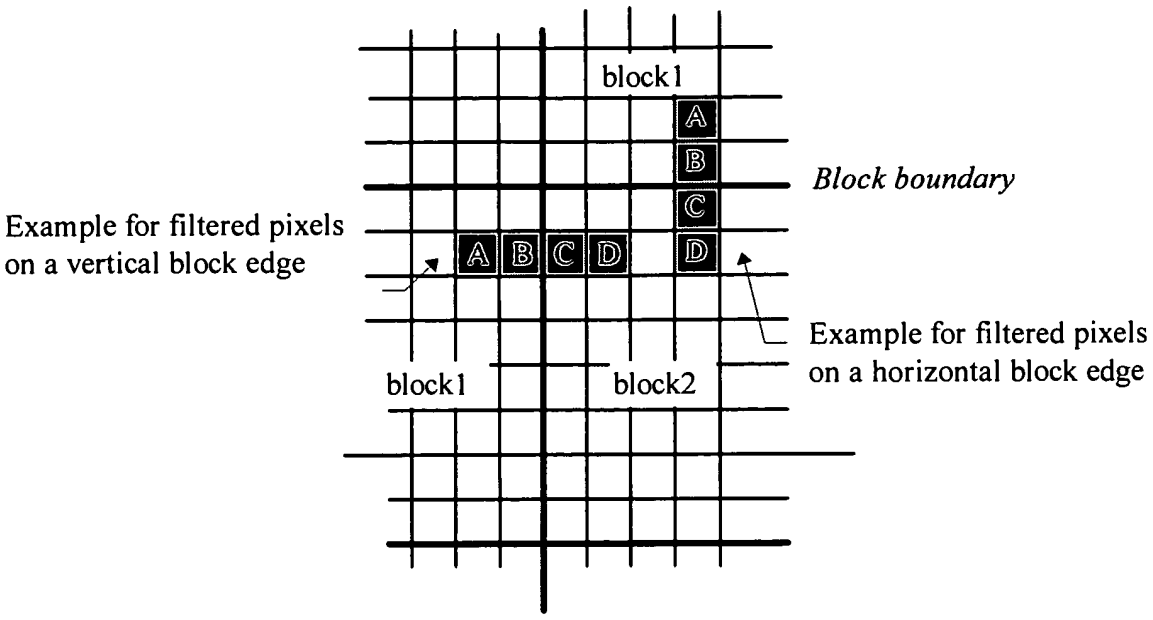

FIGURE J.1/H.263

Examples of positions of filtered pixels

One or both of the following conditions must be fulfilled in order to apply the filter across a particular edge:

Condition 1: block1 belongs to a coded macroblock (COD==0 || MB-type == INTRA), or

Condition 2: block2 belongs to a coded macroblock (COD==0 || MB-type == INTRA)

If filtering is to be applied across the edge, A, B, C, and D shall be replaced by A1, B1, C1, D1 where:

B1 = clip(B + d1)

C1 = clip(C – d1)

A1 = A – d2

D1 = D + d2

d = (A–4B+4C–D) / 8

d1 = UpDownRamp(d, STRENGTH)

d2 = clipd1((A – D) / 4, d1/2)

UpDownRamp(x, STRENGTH) = SIGN(x) * (MAX(0, abs(x)–MAX(0, 2*(abs(x) – STRENGTH))))

STRENGTH depends on QUANT and determines the amount of filtering.
The relation between STRENGTH and QUANT is given in Table J.2.

QUANT = quantization parameter used for block2 if block2 belongs to a coded macroblock, or

QUANT = quantization parameter used for block1 if block2 does not belong to a coded macroblock (but block1 does)

The function clip(x) is defined according to section 6.3.2, and the function clipd1(x, lim) clips x to the range ± abs(lim). The symbol "/" denotes division by truncation toward zero.

Figure J.2 shows how the value of d1 varies as a function of d. As a result, the filter has an effect only if d is smaller than 2*STRENGTH (and different from zero). This is to prevent the filtering of strong true edges in the

picture content. . However, if the Reduced-Resolution Update mode is in use, STRENGTH is set to infinity, and as a result, the value of d1 is always equal to the value of d (see section Q.7.2 in Annex Q).

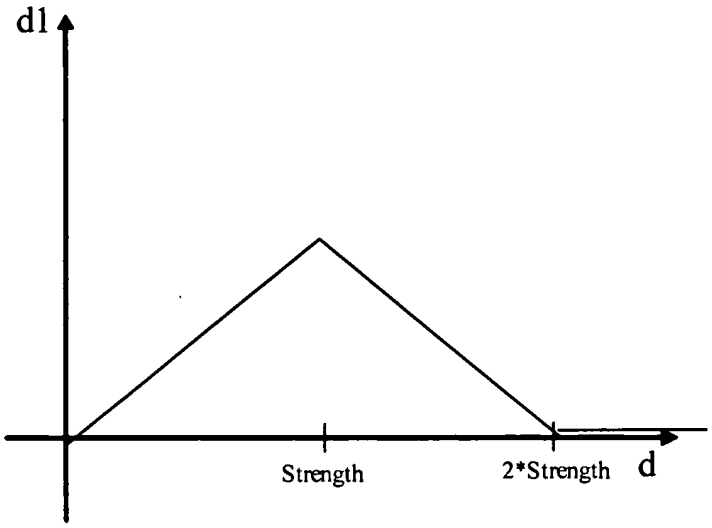

FIGURE J.2/H.263

Parameter d1 as a function of parameter d for deblocking filter mode

TABLE J.2/H.263

Relationship between QUANT and STRENGTH of Filter

QUANT	STRENGTH	QUANT	STRENGTH
1	1	17	8
2	1	18	8
3	2	19	8
4	2	20	9
5	3	21	9
6	3	22	9
7	4	23	10
8	4	24	10
9	4	25	10
10	5	26	11
11	5	27	11
12	6	28	11
13	6	29	12
14	7	30	12
15	7	31	12
16	7		

The definition of d1 is designed to ensure that small mismatches between the encoder and decoder will remain small and will not build up over multiple pictures of a video sequence. This would be a problem, for example, with a condition that simply switches the filter on or off, because a mismatch of only ±1 for d could then cause the filter to be switched on at the encoder side and off at the decoder side, or vice versa.

Due to rounding effects, the order of edges where filtering is performed must be specified.

Filtering across horizontal edges:

Basically this process is assumed to take place first. More precisely, the pixels $\begin{pmatrix} A \\ B \\ C \\ D \end{pmatrix}$ that are used in filtering across a horizontal edge shall not have been influenced by previous filtering across a vertical edge.

Filtering across vertical edges:

Before filtering across a vertical edge using pixels (A,B,C,D), all modifications of pixels (A,B,C,D) resulting from filtering across a horizontal edge shall have taken place.

Note that if one or more of the pixels (A,B,C,D) taking part in a filtering process are outside of a picture, no filtering takes place. Also, if the Independent Segment Decoding Mode is in use (see Annex R) and one or more of the pixels (A,B,C,D) taking part in a filtering process are in different video picture segments (see Annex I, section I.3 concerning when a block is considered to be in the same video picture segment), no filtering is performed.

Annex K
Slice Structured mode

(This annex forms an integral part of this Recommendation.)

K.1 Introduction

This annex describes the optional Slice Structured mode of H.263. The capability of this mode of H.263 is signaled by external means (for example Recommendation H.245). The use of this mode is indicated in the PLUSPTYPE field of the picture header. In order to facilitate optimal usage in a number of environments, this mode contains two submodes which are also capable of being signalled by external means (for example Recommendation H.245). These two submodes are used to indicate whether or not rectangular slices will be used and/or whether the slices will be transmitted in sequential order or sent in an arbitrary order.

A slice is defined as a slice header followed by consecutive macroblocks in scanning order. An exception is for the slice that immediately follows the picture start code in the bitstream for a picture (which is not necessarily the slice starting with macroblock 0). In this case only part of the slice header is transmitted as described in section K.2. The slice layer defines a video picture segment, and is used in place of the GOB layer in this optional mode. A slice video picture segment starts at a macroblock boundary in the picture and contains a number of macroblocks. Different slices within the same picture shall not overlap with each other, and every macroblock shall belong to one and only one slice.

This mode contains two submodes, which are signaled in the SSS field of the picture header:

1. The Rectangular Slice submode (RS). When RS is in use, the slice shall occupy a rectangular region of width specified by the SWI parameter of the slice header in units of macroblocks, and contains a number of macroblocks in scanning order within the rectangular region. When the Rectangular Slice submode is not in use, the SWI field is not present in the slice header and a slice contains a number of macroblocks in scanning order within the picture as a whole.
2. The Arbitrary Slice Ordering submode (ASO). When ASO is in use, the slices may appear in any order within the bitstream. When ASO is not in use, the slices must be sent in the (unique) order for which the MBA field of the slice header is strictly increasing from each slice to each subsequent slice in the picture.

Slice boundaries are treated differently than simple macroblock boundaries in order to allow slice header locations within the bitstream to act as resynchronization points for bit error and packet loss recovery and in order to allow out-of-order slice decoding within a picture. Thus, no data dependencies can cross the slice boundaries within the current picture, except for the Deblocking Filter mode which, when in use without the Independent Segment Decoding mode, filters across the boundaries of the blocks in the picture. However, motion vectors within a slice can cause data dependencies which cross the slice boundaries in the reference picture used for prediction purposes, unless the optional Independent Segment Decoding mode is in use.

The following rules are adopted to ensure that slice boundary locations can act as resynchronization points and to ensure that slices can be sent out of order without causing additional decoding delays:

1. The prediction of motion vector values are the same as if a GOB header were present (see section 6.1.1), preventing the use of motion vectors of blocks outside the current slice for the prediction of the values of motion vectors within the slice.
2. The Advanced INTRA Coding mode (see Annex I) treats the slice boundary as if it were a picture boundary with respect to the prediction of INTRA block DCT coefficient values.
3. The assignment of remote motion vectors for use in overlapped block motion compensation within the Advanced Prediction mode also prevents the use of motion vectors of blocks outside the current slice for use as remote motion vectors (see section F.3).

K.2 Structure of slice layer

The structure of the slice layer of the syntax is shown in Figure K.1 for all slices except the slice that immediately follows the picture start code in the bitstream for a picture. For the slice following the picture start code, only the emulation prevention bits (SEPB1, SEPB3, and conditionally SEPB2 as specified below), the MBA field and, when in the RS submode, also the SWI field are included.

SSTUF	SSC	SEPB1	SSBI	MBA	SEPB2	SQUANT	SWI	SEPB3	GFID	Macroblock Data

FIGURE K.1/H.263

Structure of slice layer

Refer to section 5.2.5 for GFID, and section 5.3 for description of Macroblock layer.

K.2.1 Stuffing (SSTUF) (Variable Length)

A codeword of variable length consisting of less than 8 bits. Encoders shall insert this codeword directly before an SSC codeword whenever needed to ensure that SSC is byte-aligned. If SSTUF is present, the last bit of SSTUF shall be the last (least significant) bit of a byte, so that the start of the SSC codeword is byte aligned. Decoders shall be designed to discard SSTUF. Notice that 0 is used for stuffing within SSTUF.

K.2.2 Slice Start Code (SSC) (17 bits)

A word of 17 bits. Its value is 0000 0000 0000 0000 1. Slice start codes shall be byte aligned. This can be achieved by inserting SSTUF before the start code such that the first bit of the start code is the first (most significant) bit of a byte. The slice start code is not present for the slice which follows the picture start code.

K.2.3 Slice Emulation Prevention Bit 1 (SEPB1) (1 bit)

A single bit always having the value of "1", which is included to prevent start code emulation.

K.2.4 Slice Sub-Bitstream Indicator (SSBI) (4 bits)

A codeword of length four bits which is present only when CPM = '1' in the picture header. SSBI indicates the Sub-Bitstream number for the slice for Continuous Presence Multipoint and Video Multiplex operation, as described in Annex C. The mapping from the value of SSBI to the Sub-Bitstream number is shown in Table K.1. SSBI is not present for the slice which follows the picture start code.

K.2.5 Macroblock Address (MBA) (5/6/7/9/11/12/13/14 bits)

A codeword having a length that is dependent on the current picture size and whether the Reduced Resolution Update mode is in effect (see Annex Q). The bits are the binary representation of the macroblock number of the first macroblock in the current slice as counted from the beginning of the picture in scanning order, starting with macroblock number 0 at the upper left corner. MBA uniquely identifies which macroblock in the picture the current slice starts with. Codeword lengths for this codeword are provided in Table K.2. For custom picture sizes, the field width is given by the first entry in the table that has an equal or larger number of macroblocks, and the maximum value is the number of macroblocks in the current picture minus one. When in the Reduced Resolution Update mode, the relevant picture size is the lower resolution update picture size rather than the picture size indicated in the picture header (see Annex Q).

K.2.6 Slice Emulation Prevention Bit 2 (SEPB2) (1 bit)

A single bit always having the value "1", which is included under certain conditions to prevent start code emulation. For slices other than the one following the picture start code, SEPB2 is included only if the MBA field width is greater than 11 bits and CPM = '0' in the picture header, or if the MBA field width is greater than 9 bits and CPM = '1' in the picture header. For the slice following the picture start code, SEPB2 is included only if the Rectangular Slice submode is in use.

K.2.7 Quantizer Information (SQUANT) (5 bits)

A fixed length codeword of 5 bits which indicates the quantizer QUANT to be used for that slice until updated by any subsequent DQUANT. The codewords are the natural binary representations of the values of QUANT which, being half the step sizes, range from 1 to 31. SQUANT is not present for the slice which follows the picture start code.

K.2.8 Slice Width Indication in Macroblocks (SWI) (3/4/5/6/7 bits)

A codeword which is present only if the Rectangular Slice submode is active, and having a length which depends on the current picture size and whether the Reduced Resolution Update mode is active, as specified in Table K.3. For custom picture sizes, the field width is given by the next standard format size which is equal or larger in width (QCIF, CIF, ...), and the maximum value is the total number of macroblocks across the picture minus one. The last row of the table indicates the field width for picture sizes wider than 16CIF. SWI refers to the width of the current

rectangular slice having its first macroblock (upper left) specified by MBA. The calculation of the actual slice width is given by

Actual Slice Width = SWI + 1

When in the Reduced Resolution Update mode, the relevant picture size is that of the lower resolution picture size for the update information, rather than the picture size indicated in the picture header.

K.2.9 Slice Emulation Prevention Bit 3 (SEPB3) (1 bit)

A single bit always having the value of "1" in order to prevent start code emulation.

TABLE K.1/H.263

Values of SSBI and associated Sub-Bitstream Numbers

Annex L
Supplemental Enhancement Information Specification

(This annex forms an integral part of this Recommendation.)

L.1 Introduction

This annex describes the format of the supplemental enhancement information sent in the PSUPP field of the picture layer of H.263. The capability of a decoder to provide any or all of the enhanced capabilities described in this annex may be signaled by external means (for example Recommendation H.245). Decoders which do not provide the enhanced capabilities may simply discard any PSUPP information bits that appear in the bitstream. The presence of this supplemental enhancement information is indicated in PEI, and an additional PEI bit is inserted between every octet of PSUPP data, as described in sections 5.1.24 and 5.1.25.

In this annex, a distinction is made between the "decoded picture" and the "displayed picture". For purposes of this annex, the "displayed picture" is a picture having the same picture format as specified for the current picture by the picture layer of the video bitstream syntax. The "displayed picture" is constructed as described in this annex from the decoded picture, the prior displayed picture, the supplementary enhancement information described herein, and in some cases partly from a background picture which is externally controlled.

L.2 PSUPP Format

The PSUPP data consists of a four-bit function type indication FTYPE, followed by a four-bit parameter data size specification DSIZE, followed by DSIZE octets of function parameter data, optionally followed by another function type indication, and so on. One function type indication value is defined as an escape code to provide for future extensibility to allow definition of more than fifteen different functions. A decoder which receives a function type indication which it does not support can discard the function parameter data for that function and then check for a subsequent function type indication which may be supported. The defined FTYPE values are shown in Table L.1.

TABLE L.1/H.263

FTYPE Function Type Values

0	Reserved
1	Do Nothing
2	Full-Picture Freeze Request
3	Partial-Picture Freeze Request
4	Resizing Partial-Picture Freeze Request

6	Full-Picture Snapshot Tag
7	Partial-Picture Snapshot Tag
8	Video Time Segment Start Tag
9	Video Time Segment End Tag
10	Progressive Refinement Segment Start Tag
11	Progressive Refinement Segment End Tag
12	Chroma Key Information
13	Reserved
14	Reserved
15	Extended Function Type

L.3 Do Nothing

No action is requested by the Do Nothing function. This function is used to prevent start code emulation. Whenever the last five or more bits of the final octet of the previous PSUPP octet are all zero and no additional PSUPP function requests are to be sent, the Do Nothing function shall be inserted into PSUPP to prevent the possibility of start code emulation. The Do Nothing function may also be sent when it is not required by rule expressed in the previous sentence. DSIZE shall be zero for the Do Nothing function.

L.4 Full-Picture Freeze Request

The full-picture freeze request function indicates that the contents of the entire prior displayed video picture shall be kept unchanged, without updating the displayed picture using the contents of the current decoded picture. The displayed picture shall then remain unchanged until the freeze picture release bit in the current PTYPE or in a subsequent PTYPE is set to 1, or until timeout occurs, whichever comes first. The request shall lapse due to timeout after five seconds or five pictures, whichever is a longer period of time. The timeout can be prevented by the issuance of another full-picture freeze request prior to or upon expiration of the timeout period (e.g., repeating the request in the header of the first picture with temporal reference indicating a time interval greater than or equal to five seconds since issuance, or in the header of the fifth picture after issuance). DSIZE shall be zero for the full-picture freeze request function.

L.5 Partial-Picture Freeze Request

The partial-picture freeze request function indicates that the contents of a specified rectangular area of the prior displayed video picture should be kept unchanged, without updating the specified area of the displayed picture using the contents of the current decoded picture. The specified area of the displayed picture shall then remain unchanged until the freeze picture release bit in the current PTYPE or in a subsequent PTYPE is set to 1, until a partial-picture freeze-release request affecting the specified area is received, until the source format specified in a picture header differs from that of previous picture headers, or until timeout occurs, whichever comes first. Any change in the picture source format shall act as a freeze release for all active partial-picture freeze requests. The request shall lapse due to timeout after five seconds or five pictures, whichever is a longer period of time. The timeout can be prevented by the issuance of an identical partial-picture freeze request prior to or upon expiration of the timeout period (e.g., repeating the request in the header of the first picture with temporal reference indicating a time interval greater than or equal to five seconds since issuance, or in the header of the fifth picture after issuance). DSIZE shall be equal to 4 for the partial-picture freeze request. The four octets of PSUPP that follow contain the horizontal and vertical location of the upper left corner of the frozen picture rectangle, and the width and height of the rectangle, respectively, using eight bits each and expressed in units of eight pixels. For example, a 24-pixel wide and 16 pixel tall area in the upper left corner of the video display is specified by the four parameters (0, 0, 3, 2).

L.6 Resizing Partial-Picture Freeze Request

The resizing partial-picture freeze request function indicates that the contents of a specified rectangular area of the prior displayed video picture should be resized to fit into a smaller part of the displayed video picture, which should then be kept unchanged, without updating the specified area of the displayed picture using the contents of the current decoded picture. The specified area of the displayed picture shall then remain unchanged until the freeze release bit in the current PTYPE or in a subsequent PTYPE is set to 1, until a partial-picture freeze-release request affecting the specified area is received, until the source format specified in a picture header differs from that of previous picture headers, or until timeout occurs, whichever comes first. Any change in the picture source format shall act as a freeze release for all active resizing partial-picture freeze requests. The request shall lapse due to timeout after five seconds or five pictures, whichever is a longer period of time. The timeout can be prevented by the issuance of a partial-picture freeze request for the affected area of the displayed picture prior to or upon expiration of the timeout period (e.g., issuing a partial-picture freeze request in the header of the first picture with temporal reference indicating a time interval greater than or equal to five seconds since issuance, or in the header of the fifth picture after issuance). DSIZE shall be equal to 8 for the resizing partial-picture freeze request. The eight octets of PSUPP data that follow contain 32 bits used to specify the rectangular region of the affected area of the displayed picture, and then 32 bits used to specify the corresponding rectangular region of the affected area of the decoded picture. The width and height of the rectangular region in the decoded picture shall both be equal to 2^i times the width and height specified for the rectangular region in the displayed picture, where i is an integer in the range of 1 to 8. The location and size of each of these two rectangular regions is specified using the same format as such a region is specified in the partial-picture freeze request function.

L.7 Partial-Picture Freeze-Release Request

The partial-picture freeze-release request function indicates that the contents of a specified rectangular area of the displayed video picture shall be updated by the current and subsequent decoded pictures. DSIZE shall be equal to 4 for the partial-picture freeze-release request. The four octets of PSUPP data that follow specify a rectangular region of the displayed picture in the same format as such a region is specified in the partial-picture freeze request function.

L.8 Full-Picture Snapshot Tag

The full-picture snapshot tag function indicates that the current picture is labeled for external use as a still-image snapshot of the video content. DSIZE shall be equal to 4 for the full-picture snapshot tag function. The four octets of PSUPP data that follow specify a snapshot identification number for external use.

L.9 Partial-Picture Snapshot Tag

The partial-picture snapshot tag function indicates that a specified rectangular area of the current picture is labeled for external use as a still-image snapshot of the video content. DSIZE shall be equal to 8 for the partial-picture snapshot tag function. The first four octets of PSUPP data that follow specify a snapshot identification number for external use, and the remaining four octets of PSUPP data that follow specify a rectangular region of the decoded picture in the same format as such a region is specified in the partial-picture freeze request function.

L.10 Video Time Segment Start Tag

The video time segment start tag function indicates that the beginning of a specified sub-sequence of video data is labeled as a useful section of video content for external use, starting with the current picture. The tagged sub-sequence of video data shall continue until stopped by the receipt of a matching video time segment end tag function or until timeout, whichever comes first. The tagged sub-sequence shall end due to timeout after five seconds or five pictures, whichever is a longer period of time. The timeout can be prevented by the issuance of an identical video time segment start tag function prior to or upon expiration of the timeout period (e.g., repeating the video time segment start tag function in the header of the first picture with temporal reference indicating a time interval greater than or equal to five seconds since issuance, or in the header of the fifth picture after issuance). DSIZE shall be equal to 4 for the video time segment start tag function. The four octets of PSUPP data that follow specify a video time segment identification number for external use.

L.11 Video Time Segment End Tag

The video time segment end tag function indicates that the end of a specified sub-sequence of video data is labeled as a useful section of video content for external use, ending with the previous picture. DSIZE shall be equal to 4 for the video time segment start tag function. The four octets of PSUPP data that follow specify a video time segment identification number for external use.

L.12 Progressive Refinement Segment Start Tag

The progressive refinement segment start tag function indicates the beginning of a specified sub-sequence of video data which is labeled as the current picture followed by a sequence of zero or more pictures of refinement of the quality of the current picture, rather than as a representation of a continually moving scene. The tagged sub-sequence of video data shall continue until stopped by the receipt of a matching progressive refinement segment end tag function or until timeout, whichever comes first. The tagged sub-sequence shall end due to timeout after five seconds or five pictures, whichever is a longer period of time. The timeout can be prevented by the issuance of an identical progressive refinement segment start tag function prior to or upon expiration of the timeout period (e.g., repeating the progressive refinement start tag function in the header of the first picture with temporal reference indicating a time interval greater than or equal to five seconds since issuance, or in the header of the fifth picture after issuance). DSIZE shall be equal to 4 for the video time segment start tag function. The four octets of PSUPP data that follow specify a progressive refinement segment identification number for external use.

L.13 Progressive Refinement Segment End Tag

The progressive refinement segment end tag function indicates the end of a specified sub-sequence of video data which is labeled as an initial picture followed by a sequence of zero or more pictures of the refinement of the quality of the initial picture, and ending with the previous picture. DSIZE shall be equal to 4 for the video time segment start tag function. The four octets of PSUPP data that follow specify a progressive refinement identification number for external use.

L.14 Chroma Keying Information

The Chroma Keying Information Function (CKIF) indicates that the "chroma keying" technique is used to represent "transparent" and "semi-transparent" pixels in the decoded video pictures. When being presented on the display, "transparent" pixels are not displayed. Instead, a background picture which is either a prior reference picture or is an externally controlled picture is revealed. Semi-transparent pixels are displayed by blending the pixel value in

the current picture with the corresponding value in the background picture. One octet is used to indicate the keying color value for each component (Y, C_B, or C_R) which is used for chroma keying. To represent pixels that are to be "semi-transparent," two threshold values, denoted as T_1 and T_2, are used. Let α denote the transparency of a pixel; $\alpha = 255$ indicates that the pixel is opaque, and $\alpha = 0$ indicates that the pixel is transparent. For other values of α, the resulting value for a pixel should be a weighted combination of the pixel value in the current picture and the pixel value from the background picture (which is specified externally). The values of α may be used to form an image that is called an "alpha map." Thus the resulting value for each component may be

$$[\alpha \cdot X + (255-\alpha) \cdot Z] / 255$$

where X is the decoded pixel component value (for Y, C_B, or C_R), and Z is the corresponding pixel component value from the background picture.

The α value can be calculated as follows. First, the distance of the pixel color from the key color value is calculated:

$$d = A_Y(X_Y - K_Y)^2 + A_B(X_B - K_B)^2 + A_R(X_R - K_R)^2$$

in which X_Y, X_B, and X_R are the Y, C_B, and C_R values of the decoded pixel color, K_Y, K_B, and K_R are the corresponding key color parameters, and A_Y, A_B, and A_R. are keying flag bits which indicate which color components are used as keys. Once the distance d is calculated, the α value may be computed as specified in the following pseudo-code:

```
for each pixel
   if      (d<T1) then α = 0;
   else if (d>T2) then α = 255;
   else α = [255·(d-T1)]/(T2-T1)
```

However, the precise method for performing the chroma keying operation in the decoder is not specified herein, since normative specification of the method is not needed for interoperability. The process described here is provided for illustration purposes in order to convey the intended interpretation of the data parameters.

Since the derived α value is simply a function of X_Y, X_B, and X_R, a look-up table (LUT) can be built to achieve the above operation. Such an LUT has 2^{8xN} entries corresponding to all pixel values, where N is the number of color components used as keys. Each entry in the LUT would then contain the corresponding α value.

DSIZE shall be in the range of 1 to 9 (inclusive) for chroma keying information, according to the amount of data sent with the CKIF. No more than one CKIF shall be sent with a picture.

The first octet following the DSIZE octet shall contain the representation order of the current picture—streams having a lower representation order are assumed to form the background picture for streams having a higher representation order.

If DSIZE is greater than one, the next octet after the representation order octet shall be used to send six flag bits defined as:

bit 1 : A_Y : A flag bit indicating the presence of a K_Y key parameter for luminance Y values
bit 2 : A_B : A flag bit indicating the presence of a K_B key parameter for chroma C_B values
bit 3 : A_R : A flag bit indicating the presence of a K_R key parameter for chroma C_R values
bit 4 : A_1 : A flag bit indicating the presence of a T_1 threshold parameter for transparency
bit 5 : A_2 : A flag bit indicating the presence of a T_2 threshold parameter for opacity
bit 6 : RPB: A flag bit indicating the use of the reference picture as a background picture
bit 7 : reserved
bit 8 : reserved

DSIZE shall be equal to 1 or shall be equal to 2 plus the number of flag bits among A_Y, A_B, and A_R which are set to 1, plus 2 times the number of bits among A_1 and A_2 which are set to 1. If DSIZE is greater than 1, then an additional octet shall be sent to specify the value of each color component for each of the flag bits A_Y, A_B, and A_R which are set to one and two additional octets shall be sent to specify each of the flagged threshold values among T_1 and T_2. These octets shall follow in the same order as the flag bits.

If DSIZE is equal to 1, or if all three keying color flag bits A_Y, A_B, and A_R, are zero, the keying flag bits A_Y, A_B, and A_R and keying colors K_Y, K_B, and K_R which were used for the previous keyed picture should also be used for the current picture. If no previous values have been sent for the video sequence, the default keying flag bits $A_Y = 1$, $A_B = 1$, and $A_R = 1$ and the default key colors $K_Y = 50$, $K_B = 220$, and $K_R = 100$ should be used as the previous values.

If DSIZE is equal to 1, or if both of the keying threshold flag bits A_1 and A_2 are zero, the keying threshold values T_1 and T_2 which were used for the previous keyed picture should also be used for the current picture. If no previous values have been sent for the video sequence, the default threshold values $T_1 = 48$ and $T_2 = 75$ should be used as the previous values.

In the portion where the pixels are "semi-transparent" (i.e., when $T_1 < d < T_2$), the decoded pixels typically contain the chroma key color in components where chroma keys are used. This may result in certain color artifacts. To address this problem, these pixel values may be adjusted before they are blended with the background color. Such a correction process may be applied to color components being used in the chroma key operation as indicated by the flag bits. The process is as follows:

$$X' = K + (T_2/d)\,(X-K)$$

where X is the original decoded pixel component value, and X' is the corrected value.

Since the adusted pixel values X'_Y, X'_B, and X'_R are functions of X_Y, X_B, and X_R, the color correction can be achieved by using an LUT. This LUT would have 2^{8N} entries corresponding to all pixel values, where N is the number of color components used as keys. Each entry would then contain the corresponding corrected values.

If the reference picture background (RPB) flag bit is set to '1', this indicates that the temporally-previous reference picture (prior to any Annex P resampling performed for the current picture) should be held as the (opaque) background of the current picture and of all subsequent chroma keyed pictures, until replaced by the arrival of another picture having an RPB flag set to '1'. If the current picture has no temporally-previous reference picture (i.e., if the current picture is a picture of type INTRA or EI), the picture to which the RPB flag bit refers is the picture which would normally have been the reference picture if the current picture were of type INTER or EP as appropriate. If the RPB flag bit is set to '0', this indicates that background should remain as previously controlled (either under external control or using a reference picture which was previously stored upon receipt of a prior picture having RPB set to '1').

The use of the chroma keying which is invoked by the issuance of the chroma keying information function shall start with the current picture and shall continue until a subsequent picture of type INTRA or EI occurs or until a timeout period expires, whichever comes first. The use of chroma keying shall end due to timeout after five seconds or five pictures, whichever is a longer period of time. The timeout can be prevented by the issuance of an identical chroma keying information function prior to or upon expiration of the timeout period (e.g., repeating the chroma keying information function in the header of the first picture with temporal reference indicating a time interval greater than or equal to five seconds since issuance, or in the header of the fifth picture after issuance). The encoder shall send sufficient information with the chroma keying information function for complete resynchronization to occur with each picture of type INTRA or EI and within each timeout interval (it shall not rely on using stored or default values of the key colors or thresholds).

L.15 Extended Function Type

The extended function type indication is used to signal that the following PSUPP octet contains an extended function. The usage of extended functions is reserved for the ITU to have a later ability to define a larger number of backward-compatible PSUPP data functions. DSIZE shall be equal to zero for the extended function type indication. In order to allow backward compatibility of future use of the extended function type indication, decoders shall treat the second set of four bits in the octet which follows the extended function type indication as a DSIZE value indicating the number of subsequent octets of PSUPP that are to be skipped for extended function parameter data, which may be followed by additional FTYPE indications.

Annex M
Improved PB-frames mode

(This annex forms an integral part of this Recommendation.)

M.1 Introduction

This annex describes an optional Improved PB-frames mode of H.263. It is therefore considered to be advantageous to use the present Improved PB-frames mode instead of the PB-frames mode defined in Annex G. The capability of this mode is signaled by external means (for example Recommendation H.245). The use of this mode is indicated in the PLUSPTYPE field of the picture header.

Most parts of this option are similar to the PB-frame option defined in Annex G.

To avoid confusion with B pictures as defined in Annex O, the terms B-picture, B-macroblock, and B-block will not be used in this annex. Instead, we will use the notation B_{PB} to mean the "B-part" of an Improved PB frame. When reference is made to Annex G, B-picture and B-block shall be read as B_{PB}-picture and B_{PB}-block.

The main difference between the PB frames mode and the Improved PB frames mode is that in the Improved PB frames mode, the B_{PB}-macroblock has available a forward and a backward prediction mode in addition to the bi-directional prediction mode. In this Annex, MVDB (when present) refers to a forward motion vector. (Note that in Annex G MVDB was used to refer to an enhancement of the downscaled forward and backward vectors for bidirectional prediction, rather than a distinct forward motion vector.)

All the differences from Annex G are identified in this annex. When nothing is indicated, it means that the same procedure as described in Annex G is used.

M.2 B_{PB}-macroblock prediction modes

There are three different ways of coding a B_{PB}-macroblock. The different coding modes are signaled by the parameter MODB. The B_{PB}-macroblock coding modes are:

M.2.1 Bidirectional prediction

In the bidirectional prediction mode, prediction uses the reference pictures before and after the B_{PB}-picture (in the case of a sequence of Improved PB frames, this means the P-picture part of the temporally previous Improved PB frame and the P-picture part of the current Improved PB frame). This prediction is equivalent to the prediction defined in Annex G when MV_D =0. Notice that in this mode (and only in this mode), motion vector data (MVD) of the PB-macroblock must be included even if the P-macroblock is INTRA coded. (Notice the difference between MVD - motion vector data - and MV_D - delta vector - defined in Annex G).

M.2.2 Forward prediction

In the forward prediction mode the vector data contained in MVDB are used for forward prediction from the previous reference picture (an INTRA or INTER picture, or the P-picture part of a PB or Improved PB frame). This means that there is always only one 16x16 vector for the B_{PB}-macroblock in this prediction mode.

A simple predictor is used for coding of the forward motion vector. The rule for this predictor is that if the current macroblock is not at the far left edge of the picture or slice and the macroblock to the left has a forward motion vector, then the predictor of the forward motion vector for the current macroblock is set to the value of the forward motion vector of the block to the left; otherwise the predictor is set to zero. The difference between the predictor and the desired motion vector is then VLC coded in the same way as vector data to be used for the P-picture (MVD).

Concerning motion vectors over picture boundaries defined in section D.1, the described technique also applies for the forward B_{PB}-vector if this feature is in use (this applies for forward as well as for bidirectional prediction mode).

M.2.3 Backward prediction

In the backward prediction mode the prediction of the B_{PB} macroblock is identical to P_{REC} (defined in section G.5). No motion vector data is used for the backward prediction.

M.3 Calculation of vectors for bidirectional prediction of a the B-macroblock

In case bidirectional prediction is used, the scaled forward and backward vectors are calculated as described in Annex G when $MV_D = 0$.

M.4 MODB table

A new definition for MODB (replacing Table 11) is shown in Table M.1. It indicates the possible coding modes for a B_{PB}-block.

TABLE M.1/H.263

MODB table for Improved PB-frames mode

Index	CBPB	MVDB	Number of bits	Code	Coding Mode
0			1	0	Bidirectional prediction
1	x		2	10	Bidirectional prediction
2		x	3	110	Forward prediction
3	x	x	4	1110	Forward prediction
4			5	11110	Backward prediction
5	x		5	11111	Backward prediction

Note — The symbol "x" in the table above indicates that the associated syntax element is present.

Annex N
Reference Picture Selection mode

(This annex forms an integral part of this Recommendation.)

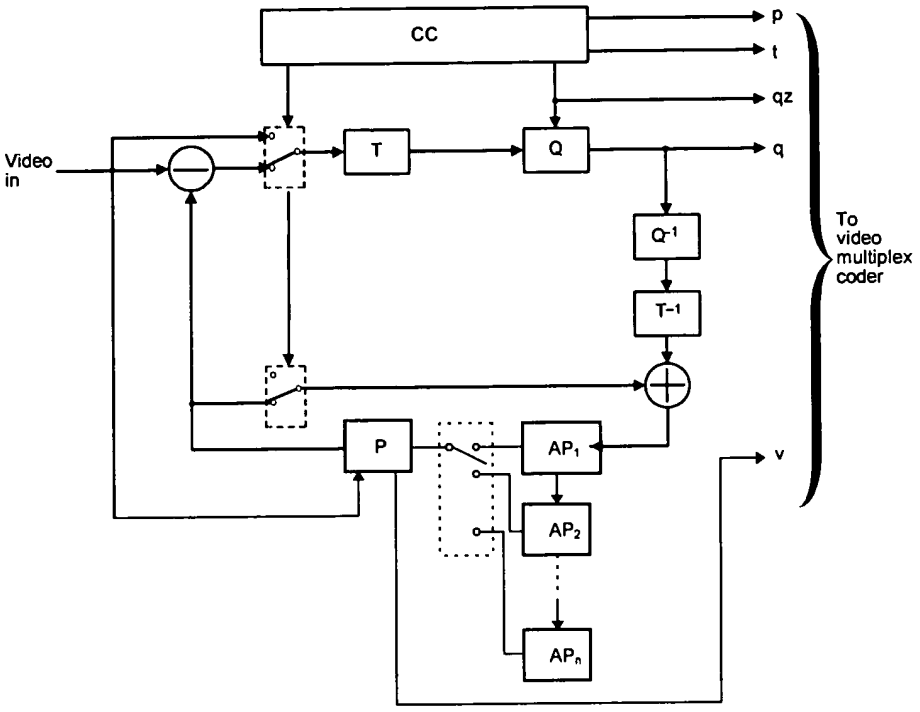
N.1 Introduction

This annex describes the optional Reference Picture Selection mode of H.263, which operates using a modified interframe prediction method called "NEWPRED." The capability of this mode of H.263 is signaled by external means (for example Recommendation H.245). The amount of additional picture memory accommodated in the decoder may also be signaled by external means to help the memory management at the encoder. This mode can use backward channel messages sent from a decoder to an encoder to inform the encoder which part of which pictures have been correctly decoded at the decoder. The use of this mode is indicated in the PLUSPTYPE field of the picture header. This mode has two back-channel mode switches which define whether a backward channel is used and what kind of messages are returned on that backward channel from the decoder, and has another submode defined in terms of the channel for the backward channel messages.

The two back-channel mode switches of this mode determine the type of messages sent on the back-channel, specifying whether ACK (acknowledgment messages), or NACK (non-acknowledgment messages) are sent. Together, the two switches define four basic methods of operation:

1. NEITHER: In which no back-channel data is returned from the decoder to the encoder,
2. ACK: In which the decoder returns only acknowledgment messages,
3. NACK: In which the decoder returns only non-acknowledgment messages, and
4. ACK+NACK: In which the decoder returns both acknowledgment and non-acknowledgment messages.

The specific type of messages to be sent as outlined above is indicated in the picture header.



There are also two methods of operation in terms of the channel for backward channel messages:

1. Separate Logical Channel mode: This method of operation delivers back-channel data through a separate logical channel in the multiplex layer of the system, and
2. VideoMux mode: This method of operation delivers back-channel data for received video within the forward video data of a video stream of encoded data.

This annex specifies a syntax for the backward channel messages as well as for forward channel data.

N.2 Video source coding algorithm

The source coder of this mode is shown in generalized form in Figure N.1. This figure shows a structure which uses a number of picture memories. The source coder may select one of the picture memories to suppress the temporal error propagation due to the inter-frame coding. The Independent Segment Decoding mode (see Annex R), which treats boundaries of GOBs with non-empty headers or slices as picture boundaries, can be used to avoid error propagation due to motion compensation across the boundaries of the GOBs or slices when this mode is applied to a smaller unit than a picture, such as a GOB or slice. The information to signal which picture is selected for prediction is included in the encoded bitstream. The strategy used by the encoder to select the picture to be used for prediction is out of the scope of this Recommendation.

T Transform
Q Quantizer
P Picture Memory with motion compensated variable delay
AP Additional Picture Memory
CC Coding control
p Flag for INTRA/INTER
t Flag for transmitted or not
qz Quantizer indication
q Quantizing index for transform coefficients
v Motion vector

FIGURE N.1/H.263

Source coder for NEWPRED

N.3 Channel for Back-Channel messages

This mode has two methods of operation in terms of the type of channel for back-channel messages. One is the separate logical channel mode and the other is the videomux mode. The separate logical channel mode is a preferred mode and delivers the back-channel message defined in N.4.2 through the dedicated logical channel. The videomux mode is prepared for the system which cannot set up the separate extra channel for the back-channel messages due to the restriction of the number of channels' combinations. The videomux mode delivers the back-channel messages through the same logical channel with the forward video data in the opposite direction.

N.3.1 Separate Logical Channel Mode

The separate logical channel mode delivers back-channel messages through a dedicated logical channel opened only for the purpose of the back-channel messages. The association mechanism with the forward channel which delivers video data is provided by external means (for example Recommendation H.245). Separate logical channel operation requires an external framing mechanism for synchronization of the messages within the back channel, as the back-channel syntax defined herein contains no synchronization flag words.

N.3.2 VideoMux Mode

The videomux mode delivers the back-channel messages through the same logical channel with the forward video data in the opposite direction. The syntax of the multiplexed bitstream is described in the section N.4.1. The back-

channel messages may be inserted by using the Back-Channel message Indication (BCI) in the GOB or slice header.

N.4 Syntax

N.4.1 Forward Channel

The syntax for the forward channel data which conveys the compressed video signal is altered only in the Group of Blocks (GOB) or slice layer.

The syntax of the GOB layer is illustrated in Figure N.2. The fields of TRI, TR, TRPI, TRP, BCI, and BCM are added to Figure 9.

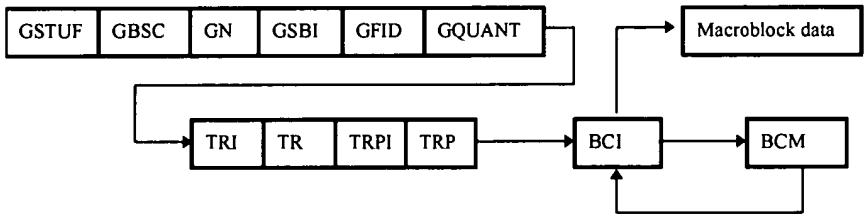


FIGURE N.2/H.263

Structure of GOB layer for NEWPRED

When the optional Slice Structured mode (see Annex K) is in use, the syntax of the slice layer is modified in the same way as the GOB layer. The syntax is illustrated Figure N.3.

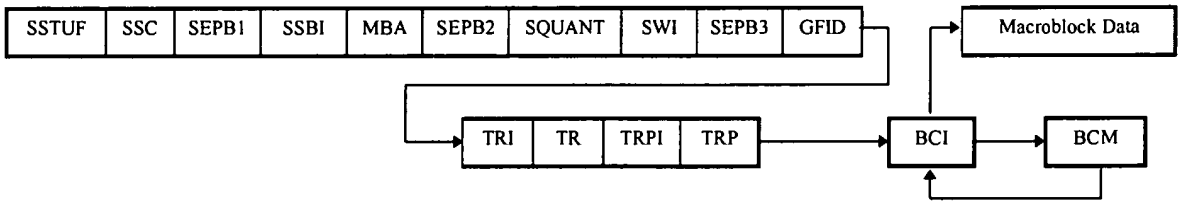

FIGURE N.3/H.263

Structure of Slice layer for NEWPRED

N.4.1.1 TRI (Temporal Reference Indicator) (1 bit)

TRI indicates whether or not the following TR field is present.

0: TR field is not present.
1: TR field is present.

N.4.1.2 Temporal Reference (TR) (8/10 bits)

When present, TR is an eight bit number unless a custom picture clock frequency is in use, in which case it is a ten bit number consisting of the concatenation of ETR and TR of the picture header.

N.4.1.3 TRPI (Temporal Reference for Prediction Indicator) (1 bit)

TRPI indicates whether or not the following TRP field is present.

0: TRP field is not present.
1: TRP field is present.

TRPI shall be equal to zero whenever the picture is an I or EI picture.

N.4.1.4 Temporal Reference for Prediction (TRP) (10 bits)

When present (as indicated in TRPI), TRP indicates the Temporal Reference which is used for prediction of the encoding, except in the case of B pictures and the B-picture part of an Improved PB frame. For B pictures or the B-picture part of an Improved PB frame, the picture having the temporal reference TRP is used for the prediction in the forward direction. (Prediction in the reverse-temporal direction always uses the immediately temporally-subsequent picture.) TRP is a ten bit number. If a custom picture clock frequency was not in use for the reference picture, the two MSBs of TR are zero and the LSBs contain the eight bit TR found in the picture header of the reference picture. If a custom picture clock frequency was in use for the reference picture, TR is a ten bit number consisting of the concatenation of ETR and TR from the reference picture header.

N.4.1.5 Back-Channel message Indication (BCI) (Variable Length)

This field contains one or two bits, when set to "1", it signals the presence of the following video Back-Channel Message (BCM) field. Otherwise, the field value is "01", which indicates the absence or the end of the video back-channel message field. Combinations of BCM and BCI may not be present, and may be repeated when present. BCI shall always be set to "01" if the videomux mode is not in use.

N.4.1.6 Back-Channel Message (BCM) (Variable Length)

The Back-Channel Message having syntax as defined in the section N.4.2, which is present only if the preceding BCI field is set to "1".

N.4.2 Back-Channel Message (BCM) Syntax

The syntax for the back-channel which conveys the acknowledgment/non-acknowledgment messages is illustrated in Figure N.4. This message is returned from a decoder to an encoder in order to tell whether a forward channel data was correctly decoded or not.

BT	URF	TR	ELNUM1	ELNUM	BCPM	BSB1	BEPB1	GN/MBA	BEPB2	RTR	BSTUF

FIGURE N.4/H.263

Structure of back-channel message (BCM) syntax for NEWPRED

N.4.2.1 Back-channel message Type (BT) (2 bits)

Back-channel message type indicates if the corresponding part of the encoded message is correctly decoded or not. Which type of message is required for the encoder is indicated in the picture header of the forward channel.

00: reserved for future use
01: reserved for future use
10: NACK. This indicates the erroneous decoding of the corresponding part of the forward channel data.
11: ACK. This indicates the correct decoding of the corresponding part of the forward channel data.

N.4.2.2 Unreliable Flag (URF) (1 bit)

The Unreliable Flag is set to 1 when a reliable value for TR or GN/MBA is not available to the decoder. (When BT is NACK, a reliable TR may not be available at the decoder.)

0: reliable
1: unreliable

N.4.2.3 Temporal Reference (TR) (10 bits)

Temporal reference contains the TR information of the video picture segment for which the ACK/NACK is indicated in the back-channel message. Note: The meaning of the term "video picture segment" as used herein is defined in Annex R. If a custom picture clock frequency was not in use for the reference picture, the two MSBs of TR are zero and the LSBs contain the eight bit TR found in the picture header of the reference picture. If a custom

picture clock frequency was in use for the reference picture, TR is a ten bit number consisting of the concatenation of ETR and TR from the reference picture header.

N.4.2.4 Enhancement Layer Number Indication (ELNUMI) (1 bit)

The enhancement layer number indication is "0" unless the optional Temporal, SNR and Spatial Scalability mode (Annex O) is used in the forward channel data and some enhancement layers of the forward channel are combined on one logical channel and the back-channel message refers to an enhancement layer (rather than the base layer), in which case the enhancement layer number indication shall be "1".

N.4.2.5 Enhancement Layer Number (ELNUM) (4 bits)

Enhancement layer number is present if and only if ELNUMI is "1", in which case it contains the layer number of the enhancement layer referred to in the back-channel message.

N.4.2.6 BCPM (1 bit)

BCPM is "0" unless the CPM mode is used in the forward channel data, in which case it is "1". If BCPM is "1", this indicates that BSBI is present.

N.4.2.7 Back-channel Sub Bitstream Indicator (BSBI) (2 bits)

A fixed length codeword of 2 bits that is only present if BCPM is "1". The BSBI is the natural binary representation of the appropriate Sub-Bitstream number in the forward channel data for which the ACK/NACK message is indicated in the back-channel message as described in section 5.2.4 and Annex C.

N.4.2.8 Back-channel Emulation Prevention Bit 1 (BEPB1) (1 bit)

A field which is present if and only if the videomux mode is in use. This field is always set to "1" to prevent a start code emulation.

N.4.2.9 GOB Number/Macroblock Address (GN/MBA) (5/6/7/9/11/12/13/14 bits):

A GOB number or Macroblock address is present in this field. If the optional Slice Structured mode (see Annex K) is not in use, this field contains the GOB number of the beginning of the video picture segment for which the NACK/ACK message is indicated in the back-channel message. If the optional Slice Structured mode is in use, this field contains the macroblock address of the beginning of the slice for which the NACK/ACK message is indicated in the back-channel message. The length of this field is the length specified elsewhere in this Recommendation for GN or MBA.

N.4.2.10 Back-channel Emulation Prevention Bit 2 (BEPB2) (1 bit)

A field which is present if and only if the videomux mode is in use. This field is always set to "1" to prevent a start code emulation.

N.4.2.11 Requested Temporal Reference (RTR) (10 bits)

Requested temporal reference is present only if BT is NACK. RTR indicates the requested temporal reference of the GOB or slice associated with the NACK. Typically it is the TR of the last correctly decoded video picture segment of the corresponding position at the decoder. If a custom picture clock frequency was not in use for the requested reference picture, the two MSBs of RTR are zero and the LSBs contain the eight bit TR found in the picture header of the requested reference picture. If a custom picture clock frequency was in use for the requested reference picture, RTR is a ten bit number consisting of the concatenation of ETR and TR from the requested reference picture header.

N.4.2.12 Stuffing (BSTUF) (Variable Length)

This field is present if and only if the separate logical channel mode is in use and the back channel message is the last in an external frame. BSTUF consists of a codeword of variable length consisting of zero or more bits of value "0". This field is only present at the end of an external frame.

N.5 Decoder Process

The decoder of this mode may need an additional number of picture memories to store the correctly decoded video signals and their Temporal Reference (TR) information. The decoder uses the stored picture for which the TR is TRP as the reference picture for inter-frame decoding instead of the last decoded picture, if the TRP field exists in the forward channel data. When the picture for which the TR is TRP is not available at the decoder, the decoder may send a forced INTRA update signal to the encoder by external means (for example Recommendation H.245).

Unless a different frame storage policy is negotiated by external means, correctly decoded video picture segments shall be stored into memory for use as later reference pictures on a first-in, first-out basis as shown in Figure N.1 (except for B pictures, which are not used as reference pictures), and video picture segments which are detected as having been incorrectly decoded should not replace correctly decoded ones in this memory area.

An acknowledgment message (ACK) and a non-acknowledgment message (NACK) are defined as back-channel messages. An ACK may be returned when the decoder decodes a video picture segment successfully. NACKs may be returned when the decoder fails to decode a video picture segment, and may continue to be returned until the decoder gets the expected forward channel data which includes the requested TRP or an INTRA update. Which types of message shall be sent is indicated in the RPSMF field of the picture header of the forward channel data.

In a usage scenario known as "Video Redundancy Coding", the Reference Picture Selection mode may be used by some encoders in a manner in which more than one representation is sent for the pictured scene at the same temporal instant (usually using different reference pictures). In such a case in which the Reference Picture Selection mode is in use and in which adjacent pictures in the bitstream have the same temporal reference, the decoder shall regard this occurrence as an indication that redundant copies have been sent of approximately the same pictured scene content, and shall decode and use the first such received picture while discarding the subsequent redundant picture(s).

Annex O
Temporal, SNR, and Spatial Scalability mode

(This annex forms an integral part of this Recommendation.)

This annex describes the optional mode of H.263 in support of Temporal, SNR, and Spatial Scalability. This mode may also be used in conjunction with error control schemes. The capability of this mode and the extent to which its features are supported is signaled by external means (for example Recommendation H.245). The use of this mode is indicated in PLUSPTYPE.

O.1 Overview

Scalability allows for the decoding of a sequence at more than one quality level. This is done by using a hierarchy of pictures and enhancement pictures partitioned into one or more layers. There are three types of pictures used for scalability: B, EI, and EP pictures, as explained below. Each of these has an enhancement layer number ELNUM that indicates to which layer it belongs, and a reference layer number RLNUM that indicates which layer is used for its prediction. The lowest layer is called the base layer, and has layer number 1.

Scalability is achieved by three basic methods: temporal, SNR, and spatial enhancement.

O.1.1 Temporal scalability

Temporal scalability is achieved using bi-directionally predicted pictures, or B-pictures. B-pictures allow prediction from either or both a previous and subsequent reconstructed picture in the reference layer. This property generally results in improved compression efficiency as compared to that of P pictures. These B-pictures differ from the B-picture part of a PB (or Improved PB) frame (see Annexes G and M) in that they are separate entities in the bitstream: they are not syntactically intermixed with a subsequent P (or EP) picture.

B pictures (and the B part of PB or Improved PB frames) are not used as reference pictures for the prediction of any other pictures. This property allows for B-pictures to be discarded if necessary without adversely affecting any subsequent pictures, thus providing temporal scalability. Figure O.1 illustrates the predictive structure of P and B pictures.

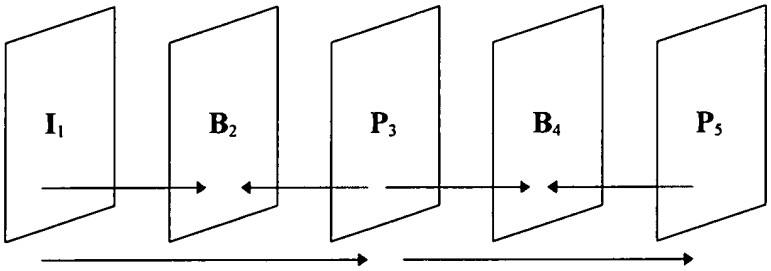

FIGURE O.1/H.263

Illustration of B picture prediction dependencies

The location of B pictures in the bitstream is in a data-dependence order rather than in strict temporal order. (This rule is consistent with the ordering of other pictures in the bitstream, but for all picture types other than the B picture, no such conflict arises between the data-dependence order and the temporal order.) For example, if the pictures of a video sequence were numbered 1, 2, 3, ..., then the bitstream order of the encoded pictures would be $I_1, P_3, B_2, P_5, B_4, \ldots$, where the subscript refers to the original picture number (as illustrated in Figure O.1).

There is no limit to the number of B pictures that may be inserted between pairs of reference pictures in the reference layer (other than what is necessary to prevent temporal ambiguity from overflows of the temporal reference field in the picture header). However, a maximum number of such pictures may be signaled by external means (for example Recommendation H.245).

The picture height, width, and pixel aspect ratio of a B picture shall always be equal to those of its temporally-subsequent reference layer picture.

Motion vectors are allowed to extend beyond the picture boundaries of B pictures.

O.1.2 SNR scalability

The other basic method to achieve scalability is through spatial/SNR enhancement. Spatial scalability and SNR scalability are equivalent except for the use of interpolation as is described shortly. Because compression introduces artifacts and distortions, the difference between a reconstructed picture and its original in the encoder is (nearly always) a nonzero-valued picture, containing what can be called the coding error. Normally, this coding error is lost at the encoder and never recovered. With SNR scalability, these coding error pictures can also be encoded and sent to the decoder, producing an enhancement to the decoded picture. The extra data serves to increase the signal-to-noise ratio of the video picture, and hence the term SNR scalability. Figure O.2 illustrates the data flow for SNR scalability. The vertical arrows from the lower layer illustrate that the picture in the enhancement layer is predicted from a reconstructed approximation of that picture in the reference (lower) layer.

If prediction is only formed from the lower layer, then the enhancement layer picture is referred to as an EI picture. It is possible, however, to create a modified bi-directionally predicted picture using both a prior enhancement layer picture and a temporally simultaneous lower layer reference picture. This type of picture is referred to as an EP picture or "Enhancement" P-picture. The prediction flow for EI and EP pictures is shown in Figure O.2. (Although not specifically shown in Figure O.2, an EI picture in an enhancement layer may have a P picture as its lower layer reference picture, and an EP picture may have an I picture as its lower-layer enhancement picture.)

For both EI and EP pictures, the prediction from the reference layer uses no motion vectors. However, as with normal P pictures, EP pictures use motion vectors when predicting from their temporally-prior reference picture in the same layer.

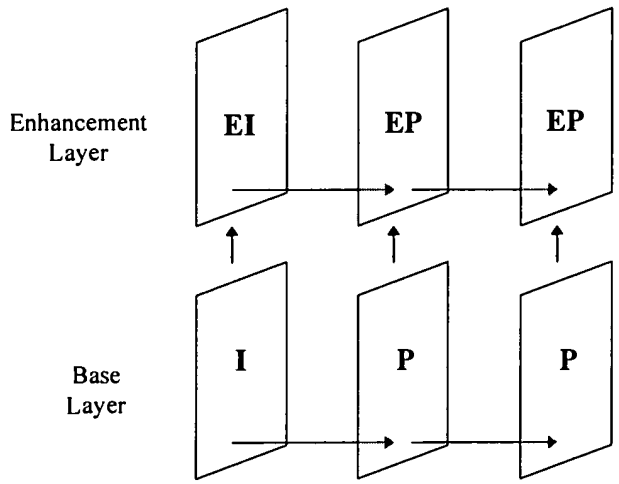

FIGURE O.2/H.263

Illustration of SNR scalability

O.1.3 Spatial scalability

The third and final scalability method in the Temporal, SNR, and Spatial Scalability mode is spatial scalability, which is closely related to SNR scalability. The only difference is that before the picture in the reference layer is used to predict the picture in the spatial enhancement layer, it is interpolated by a factor of two either horizontally or vertically (1-D spatial scalability), or both horizontally and vertically (2-D spatial scalability). The interpolation filters for this operation are defined in section O.6. For a decoder to be capable of some forms of spatial

scalability, it may also need to be capable of custom picture formats. For example, if the base layer is sub-QCIF (128x96), the 2-D spatial enhancement layer picture would be 256x192, which does not correspond to a standard picture format. Another example would be if the base layer were QCIF (176x144), with the standard pixel aspect ratio of 12:11. A 1-D horizontal spatial enhancement layer would then correspond to a picture format of 352x144 with a pixel aspect ratio of 24:11. Thus a custom picture format would have to be used for the enhancement layer in these cases. An example which does not require a custom picture format would be the use of a QCIF base layer with a CIF 2-D spatial enhancement layer. Spatial scalability is illustrated in Figure O.3.

Other than requiring an upsampling process to increase the size of the reference layer picture prior to its use as a reference for the encoding process, the processing and syntax for a spatial scalability picture is functionally identical to that for an SNR scalability picture.

Since there is very little syntactical distinction between pictures using SNR scalability and pictures using spatial scalability, the pictures used for either purpose are called EI and EP pictures.

The picture in the base layer which is used for upward prediction in an EI or EP picture may be an I picture, a P picture, or the P part of a PB or Improved PB frame (but shall not be a B picture or the B part of a PB or Improved PB frame).

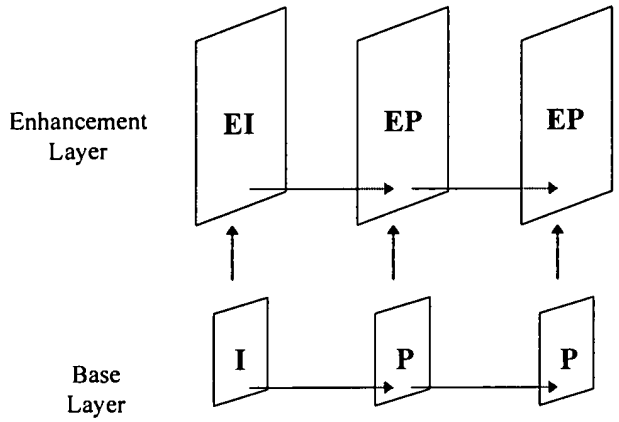

FIGURE O.3/H.263

Illustration of Spatial Scalability

O.1.4 Multilayer scalability

It is possible not only for B pictures to be temporally inserted between pictures of types I, P, PB, and Improved PB, but also between pictures of types EI and EP, whether these consist of SNR or spatial enhancement pictures. It is also possible to have more than one SNR or spatial enhancement layer in conjunction with a base layer. Thus a multilayer scalable bitstream can be a combination of SNR layers, spatial layers, and B pictures. The size of a picture cannot decrease, however, with increasing layer number. It can only stay the same or increase by a factor of two in one or both dimensions. Figure O.4 illustrates a multilayer scalable bitstream.

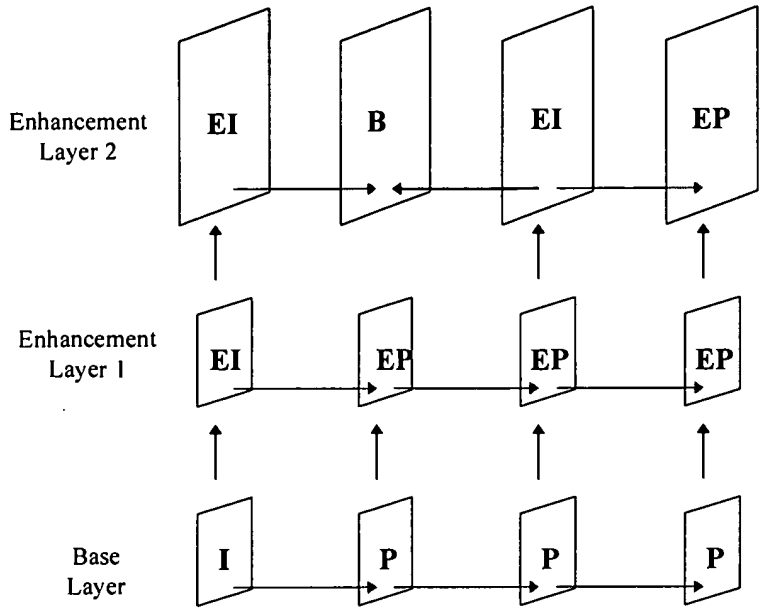

FIGURE O.4/H.263

Illustration of multilayer scalability

In the case of multilayer scalability, the picture in a reference layer which is used for upward prediction in an EI or EP picture may be a I, P, EI, or EP picture, or may be the P part of a PB or Improved PB frame in the base layer (but shall not be a B picture or the B part of a PB or Improved PB frame).

As with the two layer case, B pictures may occur in any layer. However, any picture in an enhancement layer which is temporally simultaneous with a B picture in its reference layer must be a B picture or the B picture part of an PB or Improved PB frame. This is to preserve the disposable nature of B pictures. Note, however, that B pictures may occur in layers that have no corresponding picture in lower layers. This allows an encoder to send enhancement video with a higher picture rate than the lower layers.

The enhancement layer number and the reference layer number for each enhancement picture (B, EI, or EP) are indicated in the ELNUM and RLNUM fields, respectively, of the picture header (when present). See the inference rules described in section 5.1.4.4 for when these fields are not present. If a B picture appears in an enhancement layer in which temporally-surrounding SNR or Spatial Scalability pictures also appear, the reference layer number (RLNUM) of the B picture shall be the same as the enhancement layer number (ELNUM).

The picture height, width, and pixel aspect ratio of a B picture shall always be equal to those of its temporally-subsequent reference layer picture.

O.2 Transmission order of pictures

Pictures which are dependent on other pictures shall be located in the bitstream after the pictures on which they depend.

The bitstream syntax order is specified such that for reference pictures (i.e., picture having types I, P, EI, or EP, or the P part of PB or Improved PB), the following two rules shall be obeyed:

1. All reference pictures with the same temporal reference shall appear in the bitstream in increasing enhancement layer order (since each lower layer reference picture is needed to decode the next higher layer reference picture).

2. All temporally simultaneous reference pictures as discussed in item 1 above shall appear in the bitstream prior to any B pictures for which any of these reference pictures is the first temporally subsequent reference picture in the reference layer of the B picture (in order to reduce the delay of decoding all reference pictures which may be needed as references for B pictures).

Then, the B-pictures with earlier temporal references shall follow (temporally ordered within each enhancement layer).

The bitstream location of each B picture shall comply with the following rules:

1. Its bitstream location shall be after that of its first temporally subsequent reference picture in the reference layer (since the decoding of the B picture generally depends on the prior decoding of that reference picture).
2. Its bitstream location shall be after that of all reference pictures that are temporally simultaneous with the first temporally subsequent reference picture in the reference layer (in order to reduce the delay of decoding all reference pictures which may be needed as references for B pictures)
3. Its bitstream location shall precede the location of any additional temporally subsequent pictures other than B pictures in its reference layer (since to allow otherwise would increase picture-storage memory requirements for the reference layer pictures).
4. Its bitstream location shall be after that of all EI and EP pictures that are temporally simultaneous with the first temporally subsequent reference picture.
5. Its bitstream location shall precede the location of all temporally subsequent pictures within its same enhancement layer (since to allow otherwise would introduce needless delay and increase picture-storage memory requirements for the enhancement layer).

Figure O.5 illustrates two allowable picture transmission orders given by the rules above for the layering structure shown therein (with numbers in dotted-line boxes indicating the bitstream order, separated by commas for the two alternatives).

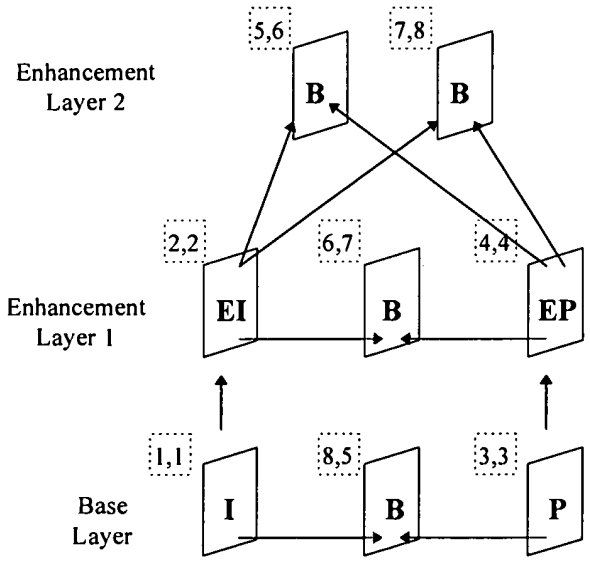

FIGURE O.5/H.263

Example of picture transmission order

O.3 Picture Layer Syntax

The Enhancement Layer Number (ELNUM, section 5.1.11) is always present in any enhancement (B, EI, or EP) picture and shall not be present in I or P pictures, or in PB or Improved PB frames. The Reference Layer Number (RLNUM, section 5.1.12) is present for some enhancement pictures and is inferred for others, as described in section 5.1.12.

There is exactly one base layer and it has ELNUM and RLNUM equal to 1. The RLNUM gives the enhancement layer number of the forward and backward reference pictures for B-pictures, for the upward reference picture for EI and EP-pictures. The reference pictures of the base layer may consist of I, PB, Improved PB, and P pictures, none of which include ELNUM or RLNUM in the picture header (their implied values are 1).

For B-pictures, RLNUM must be less or equal to ELNUM, while for EI and EP-pictures, RLNUM must be smaller than ELNUM.

ELNUM may be different from the layer number used at the system level. Since B-pictures have no other pictures dependent on themselves, they may even be put in a separate enhancement layer by system components external to H.263 (for example Recommendations H.245 and H.223). Moreover, it is up to the implementor as to whether the enhancement pictures are sent in separate video channels or remain multiplexed together with the base layer pictures.

As stated in section 5.1.4.5, the Deblocking Filter mode (see Annex J) does not apply within B pictures. This is because B pictures are not used for the prediction of any other pictures, and thus the application of a deblocking filter to these pictures is entirely a post-processing technique which is outside the scope of this Recommendation. However, the use of some type of deblocking filter for B pictures is encouraged, and a filter such as that described in Annex J may in fact be a good design to use for that purpose.

The Temporal Reference (TR) (see section 5.1.2) is defined exactly as for I and P pictures.

There shall be no TR_B (see section 5.1.22) or DBQUANT (see section 5.1.23) fields in the picture header of B, EI or EP-pictures.

O.4 Macroblock Layer Syntax

The macroblock layer syntax for B and EP-pictures is the same, since each uses two reference pictures in a similar way. However, the interpretation varies slightly depending on the picture type. Figure O.6 indicates the B and EP syntax. The MBTYPE field indicates whether there is direct-mode prediction, forward prediction, backward/upward prediction, or bi-directional prediction. The MBTYPE is defined differently for B and EP-pictures as described below.

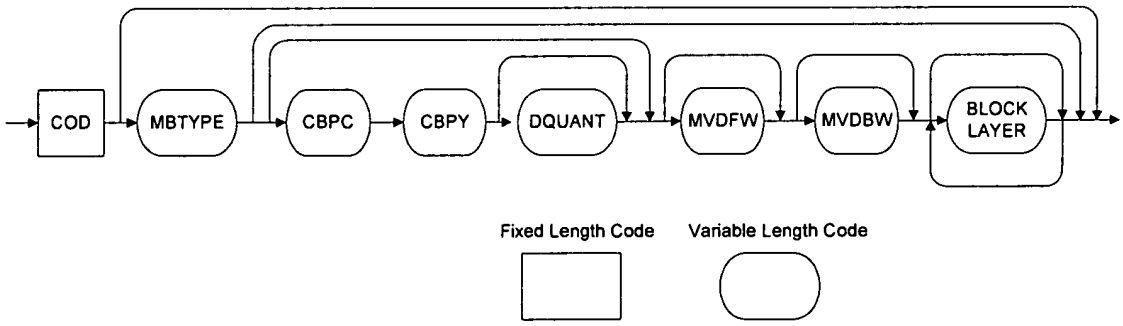

FIGURE O.6/H.263

Macroblock syntax for EP and B pictures

The direct prediction mode is only available for B-pictures. It is a bi-directional prediction mode similar to the bi-directional mode in Improved PB-frames mode (Annex M). The only difference is that there is no restriction on which pixels can be backward predicted since the complete backward prediction image is known at the decoder. Bi-directional mode uses separate motion vectors for forward and backward prediction. In both direct and bi-directional mode, the prediction pixel values are calculated by averaging the forward and backward prediction pixels. The average is calculated by dividing the sum of the two predictions by two (division by truncation). In direct mode, when there are four motion vectors in the reference macroblock, then all four motion vectors are used as in Improved PB-frames mode (Annex M).

For B pictures, forward prediction means prediction from a previous reference picture in the reference layer. Backward prediction means prediction from a temporally subsequent reference picture in the reference layer.

For EP-pictures, forward prediction means prediction from a previous EI or EP picture in the same layer, while upward prediction is used to mean prediction from the temporally simultaneous (possibly interpolated) reference picture in the reference layer. No motion vector is used for the upward prediction (which is syntactically in the same place as backward prediction for B pictures), although one can be used for the forward prediction.

The macroblock syntax for EI-pictures is slightly different. As shown in Figure O.7, the MBTYPE and CBPC are combined into an MCBPC field. No forward prediction is used, only upward prediction from the temporally simultaneous reference picture in the reference layer. No motion vector is used.

In B and EP pictures, motion vectors over picture boundaries may be used as described in section D.1 of Annex D (although extension of the motion vector range as described in section D.2 is only active if the Unrestricted Motion Vector mode is also in use).

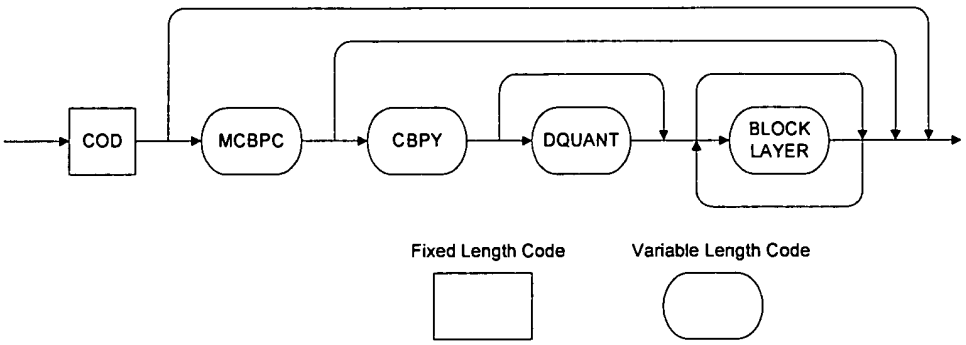

FIGURE O.7/H.263

Macroblock syntax for EI pictures

O.4.1 Coded macroblock indication (COD) (1 bit)

A bit which when set to "0" signals that the macroblock is coded. If set to "1", no further information is transmitted for this macroblock and the macroblock is handled as "skipped" as described below.

O.4.2 MBTYPE/MCBPC (VLC)

There are different MBTYPE tables for B and EP pictures. For EI pictures, there is instead a MCBPC table. Table O.1 is the MBTYPE table for B-pictures. Table O.2 is the MBTYPE table for EP pictures. Table O.3 is the MCBPC table for EI pictures.

For B pictures, the "Direct (skipped)" prediction type indicates that neither MBTYPE, nor any data is transmitted in the macroblock and that the decoder derives forward and backward motion vectors and the corresponding bi-directional prediction. This is signaled by the COD bit. The "Forward (no texture)", the "Backward (no texture)", and the "Bi-dir (no texture)" prediction types for a B picture indicate forward, backward, and bi-directional prediction with no coefficients, and with one transmitted motion vector for forward and backward prediction, and two transmitted motion vectors for bi-directional prediction.

For EP pictures, the "Forward (skipped)" prediction type indicates that no additional data is sent for the macroblock, so that the decoder should use forward prediction with a zero motion vector and no coefficients. The "Upward (no texture)" and "Bi-dir (no texture)" prediction types for an EP picture indicate upward and bi-directional prediction with no coefficients, and with zero motion vector(s).

For EI pictures, the "Upward (skipped)" prediction type indicates that no additional data is sent for the macroblock, so that the decoder should use upward prediction with a zero motion vector and no coefficients.

O.4.3 Coded Block Pattern for Chrominance (CBPC) (Variable Length)

When present, CBPC indicates the coded block pattern for chrominance blocks as described in Table O.4. CBPC is present only for EP and B pictures, when its presence is indicated by MBTYPE (see Tables O.1 and O.2).

TABLE O.4/H.263

CBPC VLC codes

Index	Code block pattern (56)	CBPC	Bits
0	00	0	1
1	01	10	2
2	10	111	3
3	11	110	3

O.4.4 Coded Block Pattern for Luminance(CBPY) (Variable Length)

When present, CBPY indicates which blocks in the luminance portion of the macro block are present. CBPY is present only when its presence is indicated by MBTYPE (see Tables O.1, O.2 and O.3). CBPY is coded as described in section 5.3.5 and Table 13. Upward predicted macroblocks in EI and EP pictures, bi-directional predicted macroblocks in EP pictures, and INTRA macroblocks in EI, EP, and B pictures use the CBPY definition for INTRA macroblocks, and other macroblock types in EI, EP, and B pictures use the CBPY definition for INTER macroblocks.

O.4.5 Quantizer Information (DQUANT) (2 bits/Variable Length)

DQUANT is used as in other picture macroblock types. See section 5.3.6 and Annex T.

O.4.6 Motion vector data (MVDFW, MVDBW) (Variable Length)

MVDFW is the motion vector data for the forward vector, if present. MVDBW is the motion vector data for the backward vector, if present (allowed only in B pictures). The variable length codewords are given in Table 14, or Table D.3 if the Unrestricted Motion Vector mode is used (see Annex D).

O.5 Motion vector decoding

O.5.1 Differential Motion Vectors

Motion vectors for forward, backward or bi-directionally predicted blocks are differentially encoded. To recover the macroblock motion vectors, a prediction is added to the motion vector differences. The predictions are formed in a similar manner to that described in section 6.1.1, except that forward motion vectors are predicted only from forward motion vectors in surrounding macroblocks, and backward motion vectors are predicted only from backward motion vectors in surrounding macroblocks. The same decision rules apply for the special cases at picture, GOB or slice borders as described in section 6.1.1. If a neighboring macroblock does not have a motion vector of the same type (forward or backward), the candidate predictor for that macroblock is zero for that motion vector type.

O.5.2 Motion vectors in direct mode

For macroblocks coded in direct mode, no vector differences are transmitted. Instead, the forward and backward motion vectors are directly computed from the temporally consecutive P-vector as described in G.4 with the restriction that MV_D is always zero. These derived vectors are not used for prediction of other motion vectors.

O.6 Interpolation filters

The method by which a picture is interpolated for 2-D spatial scalability is shown in Figures O.8 and O.9. The first figure shows the interpolation for interior pixels, while the second one shows the interpolation close to picture boundaries. This is the same technique used in Annex Q and in some cases in Annex P. The method by which a picture is interpolated for 1-D spatial scalability is shown in Figures O.10 and O.11. Figure O.10 shows the interpolation for interior pixels in the horizontal direction. The interpolation for the vertical direction is analogous. Figure O.11 shows the interpolation for pixels at picture boundaries. Again, the interpolation for the vertical direction is analogous. Again, this is the same technique use in some cases in Annex P.

Annex P
Reference Picture Resampling

(This annex forms an integral part of this Recommendation.)

P.1 Introduction

This annex describes the use and syntax of a resampling process which can be applied to the previous decoded reference picture in order to generate a "warped" picture for use in predicting the current picture. This resampling syntax can specify the relationship of the current picture to a prior picture having a different source format, and can also specify a "global motion" warping alteration of the shape, size, and location of the prior picture with respect to the current picture. In particular, the Reference Picture Resampling mode can be used to adaptively alter the resolution of pictures during encoding. A fast algorithm is used to generate bilinear interpolation coefficients. The capability to use this mode and the extent to which its features are supported is negotiated externally (for example Recommendation H.245). This mode may be used in restricted scenarios that may be defined during capability negotiation (e.g., to support only factor-of-four picture resizing, to support only half-pixel resolution picture warping, or to support arbitrary image size resizing and displacements).

Note: The default image transformation between pictures of differing resolutions is defined to maintain the spatial alignment of the edges of the picture area and of the relative locations of the luminance and chrominance samples. This may have implications on the design of any resampling operations used for generating pictures of various resolutions at the encoder and for displaying pictures of various resolutions after decoding (particularly regarding shifts in spatial location caused by phase shifts induced in resampling). Also, since this mode can be used for dynamic adaptive picture resolution changes, operation with this mode may benefit from external negotiation to display the decoded picture at a higher resolution than its encoded picture size, in order to allow switching between encoded picture sizes without resizing the picture display.

If the Reference Picture Resampling bit in the PLUSPTYPE field is not set, but PLUSPTYPE is present and the picture is an INTER, B, or EP picture or an Improved PB frame, and the picture size differs from that of the temporally previous encoded picture, this condition invokes Reference Picture Resampling with warping parameters (see section P.2.2) set equal to zero, fill mode (see section P.2.3) set to *clip*, and displacement accuracy (see section P.2.1) set to $\frac{1}{16}$-pixel accuracy. This causes the resampling process to easily act as a predictively-encoded change in picture resolution. In simple factor-of-four resolution change cases such as transitions between CIF and 4CIF, the resampling process reduces to the same simple filter used for Spatial Scalability (Annex O) or for Reduced Resolution Update (Annex Q), except for the application of rounding control.

If the picture is an EP picture and the Reference Picture Resampling bit is set in the PLUSPTYPE field of the picture header of the reference layer, this bit shall also be set in the picture header of the EP picture in the enhancement layer.

If a B-picture uses the Reference Picture Resampling mode, the resampling process shall be applied to the temporally previous anchor picture and not to the temporally subsequent one. The temporally previous anchor picture to which the resampling process is applied shall be the decoded picture (i.e., prior to any resampling applied by Reference Picture Resampling if this mode is also invoked for the subsequent reference picture). The temporally subsequent anchor picture shall have the same picture size as the B picture.

If the Reference Picture Resampling mode is invoked for an Improved PB frame, one set of warping parameters is sent and the resampled reference picture is used as the reference for both the B and P part of the Improved PB frame.

The Reference Picture Resampling is defined in terms of the displacement of the four corners of the current picture area. For the luminance field of the current picture with horizontal size H and vertical size V, four conceptual motion vectors $\underline{v}^{00}$, $\underline{v}^{H0}$, $\underline{v}^{0V}$, and $\underline{v}^{HV}$ are defined for the upper left, upper right, lower left, and lower right corners of the picture, respectively. These vectors describe how to move the corners of the current picture to map them onto the corresponding corners of the previous decoded picture, as shown in Figure P.1. The units of these vectors are the same as those in the reference picture grid. To generate a vector $\underline{v}(x,y)$ at some real-valued location (x, y) in the interior of the current picture, an approximation to bilinear interpolation is used, *i.e.*, as in

$$\underline{v}(x,y) = \left(1-\frac{y}{V}\right)\left[\left(1-\frac{x}{H}\right)\underline{v}^{00} + \left(\frac{x}{H}\right)\underline{v}^{H0}\right] + \left(\frac{y}{V}\right)\left[\left(1-\frac{x}{H}\right)\underline{v}^{0V} + \left(\frac{x}{H}\right)\underline{v}^{HV}\right].$$

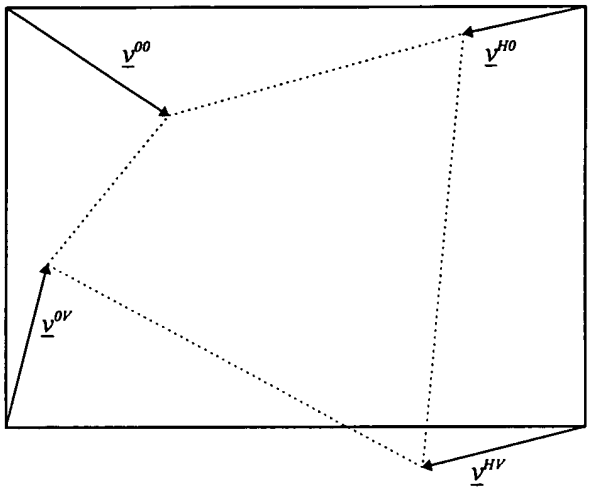

FIGURE P.1/H.263

Example of conceptual motion vectors used for warping

The horizontal size H and vertical size V of the current picture, and the horizontal size H_R and vertical size V_R of the reference picture are those indicated by the picture header, regardless of whether these values are divisible by 16 or not. If the picture width or height is not divisible by 16, the additional area shall be generated by adding pixels to the resampled picture using the same fill mode as used in the resampling process.

For the simplicity of description, the resampling vectors $\underline{r}^0$, $\underline{r}^x$, $\underline{r}^y$, and $\underline{r}^{xy}$ are defined as

$$\underline{r}^0 = \underline{v}^{00}$$

$$\underline{r}^x = \underline{v}^{H0} - \underline{v}^{00}$$

$$\underline{r}^y = \underline{v}^{0V} - \underline{v}^{00}$$

$$\underline{r}^{xy} = \underline{v}^{00} - \underline{v}^{H0} - \underline{v}^{0V} + \underline{v}^{HV} .$$

Using this definition, the equation for bilinear interpolation is rewritten as

$$\underline{v}(x,y) = \underline{r}^0 + \left(\frac{x}{H}\right)\underline{r}^x + \left(\frac{y}{V}\right)\underline{r}^y + \left(\frac{x}{H}\right)\left(\frac{y}{V}\right)\underline{r}^{xy}$$

For warping purposes, it is assumed that the coordinates of the upper left corner of the picture area are $(x, y)=(0,0)$ and that each pixel has unit height and width, so that the centers of the pixels lie at the points $(x, y)=(i_L + \frac{1}{2}, j_L + \frac{1}{2})$ for $i_L = 0, \ldots, H-1$ and $j_L = 0, \ldots, V-1$, where the L subscript indicates that i_L and j_L pertain to the luminance field. (As the pixel aspect ratio is usually constant or the conversion of the aspect ratio is performed by this resampling, there is no need to consider the actual pixel aspect ratio for these purposes.) Using this convention, the x- and y-displacements at the locations of interest in the luminance field of the reference picture are

$$v_x(i_L, j_L) = \frac{1}{HV}\left[HVr_x^0 + \left(i_L + \tfrac{1}{2}\right)Vr_x^x + \left(j_L + \tfrac{1}{2}\right)Hr_x^y + \left(i_L + \tfrac{1}{2}\right)\left(j_L + \tfrac{1}{2}\right)r_x^{xy}\right]$$

$$v_y(i_L, j_L) = \frac{1}{HV}\left[HVr_y^0 + \left(i_L + \tfrac{1}{2}\right)Vr_y^x + \left(j_L + \tfrac{1}{2}\right)Hr_y^y + \left(i_L + \tfrac{1}{2}\right)\left(j_L + \tfrac{1}{2}\right)r_y^{xy}\right]$$

Because all positions and phases must be computed relative to the center of the upper-left corner pixel, which has the coordinate $(x, y)=(\frac{1}{2},\frac{1}{2})$, the quantities of primary interest are

$$x_R(i_L,j_L)-\frac{1}{2}=\left(i_L+\frac{1}{2}\right)+v_x(i_L,j_L)-\frac{1}{2}$$

$$=\frac{1}{HV}\left[HVr_x^0+\left(i_L+\frac{1}{2}\right)(HV+Vr_x^x)+\left(j_L+\frac{1}{2}\right)Hr_x^y+\left(i_L+\frac{1}{2}\right)\left(j_L+\frac{1}{2}\right)r_x^{xy}\right]-\frac{1}{2}$$

$$y_R(i_L,j_L)-\frac{1}{2}=\left(j_L+\frac{1}{2}\right)+v_y(i_L,j_L)-\frac{1}{2}$$

$$=\frac{1}{HV}\left[HVr_y^0+\left(j_L+\frac{1}{2}\right)Vr_y^x+\left(j_L+\frac{1}{2}\right)(HV+Hr_y^y)+\left(i_L+\frac{1}{2}\right)\left(j_L+\frac{1}{2}\right)r_y^{xy}\right]-\frac{1}{2}$$

Once a location has been determined in the prior decoded reference picture using an approximation of these equations, bilinear interpolation as specified later in this annex shall be used to generate a value for the resampled pixel.

Each resampling vector can be decomposed into two components, with the first component describing the geometrical warping and the second component accounting for any difference in size between the predicted picture (horizontal size H and vertical size V) and the reference picture (horizontal size H_R and vertical size V_R). This decomposition is as follows:

$$\begin{aligned}
\underline{v}^{00} &= \underline{v}^{00}_{warp}+\underline{v}^{00}_{size} = \underline{v}^{00}_{warp}+(0,0)\\
\underline{v}^{H0} &= \underline{v}^{H0}_{warp}+\underline{v}^{H0}_{size} = \underline{v}^{H0}_{warp}+(H_R-H,0)\\
\underline{v}^{0V} &= \underline{v}^{0V}_{warp}+\underline{v}^{0V}_{size} = \underline{v}^{0V}_{warp}+(0,V_R-V)\\
\underline{v}^{HV} &= \underline{v}^{HV}_{warp}+\underline{v}^{HV}_{size} = \underline{v}^{HV}_{warp}+(H_R-H,V_R-V)
\end{aligned}$$

P.2 Syntax

Whenever the reference picture resampling bit is set in the PLUSTPYPE field of the picture header, the RPRP field of the picture header includes parameters which control the Reference Picture Resampling process. This includes a two-bit warping displacement accuracy (WDA) field, may include eight warping parameters or one-bit warping parameter refinements, and includes a fill mode, as described in this section.

P.2.1 Warping Displacement Accuracy (WDA) (2 bits)

A two bit warping displacement accuracy field WDA appears first in the RPRP field of the bitstream, and indicates the accuracy of the displacements for each pixel. A value of "10" indicates that the x- and y-displacements for each pixel are quantized to half-pixel accuracy. A value of "11" indicates that the displacements are quantized to $\frac{1}{16}$-pixel accuracy. The use of other values is reserved.

P.2.2 Warping Parameters (Variable Length)

When the Reference Picture Resampling parameters are sent for an INTER or B picture, or an Improved PB frame, eight warping parameters are included in the picture header using the variable length code (VLC) shown in Table D.3. For an EP picture using SNR scalability, the warping parameters of the lower layer are used and no warping parameters are transmitted. If the Reference Picture Resampling bit is set in the PLUSPTYPE field of the picture header for an EP picture using spatial scalability, the warping parameters of the lower layer are refined to the accuracy needed for the current layer by multiplying the warping parameter for each up-sampled dimension (warping parameters with subscript x and/or y) of the lower layer by two and adding the value of one additional bit that is sent in place of the associated warping parameter to define the least significant bit of the warping parameter.

The eight integer warping parameters (or their one-bit refinements) are sent in the following order:

$$w_x^0, w_y^0, w_x^x, w_y^x, w_x^y, w_y^y, w_x^{xy}, \text{ and } w_y^{xy}.$$

When not a one-bit refinement, these parameters are sent in a similar manner as motion vector differences in the Unrestricted Motion Vector mode when PLUSPTYPE is present, using Table D.3 with no restriction on the range of the parameters (i.e., a range of −4095 to +4095). As when encoding motion vector difference pairs, an emulation prevention bit shall be added as needed after each pair of warping parameters is sent, such that if the all-zero codeword (the value +1 in half-pixel units) of Table D.3 is used for both warping parameters in the pair (w_x^0 and w_y^0, w_x^x and w_y^y, or w_x^{xy} and w_y^{xy}), the pair of codewords is followed by a single bit equal to 1 to prevent start code emulation.

These eight warping parameters are interpreted as picture corner displacements relative to the displacements that would be induced by removing the resizing component of the resampling vectors. The warping parameters are scaled to represent half-pixel offsets in the luminance field of the current picture, and the range for the values of these paramenters is −4095 to +4095. The warping parameters are defined using the resampling vectors by the relations

$$w_x^0 = 2r_x^0 \qquad w_y^0 = 2r_y^0$$

$$w_x^x = 2\left(r_x^x - (H_R - H)\right) \qquad w_y^x = 2r_y^x$$

$$w_x^y = 2r_x^y \qquad w_y^y = 2\left(r_y^y - (V_R - V)\right)$$

$$w_x^{xy} = 2r_x^{xy} \qquad w_y^{xy} = 2r_y^{xy}$$

P.2.3 Fill Mode (FILL_MODE) (2 bits)

For an INTER or B picture or an Improved PB frame, immediately following the VLC-coded warping parameters in the picture header are two bits which define the fill-mode action to be taken for the values of pixels for which the calculated location in the reference picture lies outside of the reference picture area. The meaning of these two bits is shown in Table P.1 and their location is shown in Figure P.2. For an EP picture, the fill-mode action is the same as that for the reference layer, and the two fill-mode bits are not sent.

TABLE P.1/H.263

Fill mode bits/action

fill-mode bits	fill action
0 0	*color*
0 1	*black*
1 0	*gray*
1 1	*clip*

If the fill mode is *clip*, the coordinates of locations in the prior reference picture are independently limited as in the Unrestricted Motion Vector mode so that pixel values outside of the prior reference picture area are estimated by extrapolation from the values of pixels at the image border. If the fill mode is *black*, luminance samples outside of the prior reference picture area are assigned a value of $Y = 16$ and chrominance samples are assigned a value of $C_B = C_R = 128$. If the fill mode is *gray*, luminance and chrominance values are assigned a value of $Y = C_B = C_R = 128$. If the fill mode is *color*, then additional fields are sent to specify a fill color, as described in the next section.

P.2.4 Fill Color Specification (Y_FILL, C_B_EPB, C_B_FILL, C_R_EPB, C_R_FILL) (26 bits)

If the fill mode is *color* and the picture is not an EP picture, then the fill-mode bits are followed in the bitstream by three eight-bit integers, *Y_fill*, C_B*_fill*, and C_R*_fill*, which specify a fill color precisely. Between these three eight-

bit integers are two emulation prevention bits (C_B_EPB and C_R_EPB) each of which is equal to 1. The format of this color specification, which is present only when the fill mode is *color*, is shown in Figure P.2. Each eight-bit integer field is sent using its natural representation. For an EP picture, the fill-mode action (and fill color) is the same as that for the reference layer, and the fill color specification is not sent.

FIGURE P.2/H.263

Format of fill mode and fill color specification data

P.3 Resampling algorithm

The method described in this section shall be mathematically equal in result to that used to generate the samples of the resampled reference picture. Using the integer warping parameters $w_x^0, w_y^0, w_x^x, w_y^x, w_x^y, w_y^y, w_x^{xy}$, and w_y^{xy}, integer parameters $u_x^{00}, u_y^{00}, u_x^{H0}, u_y^{H0}, u_x^{0V}, u_y^{0V}, u_x^{HV}$, and u_y^{HV} which denote the x- and y-displacements at the corners of the luminance field in $\frac{1}{32}$-pixel accuracy (the actual displacements are obtained by dividing these values by 32) are defined as

$$u_x^{00} = 16w_x^0 \qquad u_y^{00} = 16w_y^0$$
$$u_x^{H0} = 16\left(w_x^0 + w_x^x + 2(H_R - H)\right) \qquad u_y^{H0} = 16\left(w_y^0 + w_y^x\right)$$
$$u_x^{0V} = 16\left(w_x^0 + w_x^y\right) \qquad u_y^{0V} = 16\left(w_y^0 + w_y^y + 2(V_R - V)\right)$$
$$u_x^{HV} = 16\left(w_x^0 + w_x^x + w_x^y + w_x^{xy} + 2(H_R - H)\right) \qquad u_y^{HV} = 16\left(w_y^0 + w_y^x + w_y^y + w_y^{xy} + 2(V_R - V)\right)$$

Next, H' and V', which denote the horizontal and vertical size of the *virtual frame*, are defined as the smallest integers that satisfy the following condition

$$H' \geq H,\ V' \geq V,\ H' = 2^m,\ V' = 2^n,\ m \text{ and } n \text{ are positive integers.}$$

By applying bilinear extrapolation to the corner vectors of the luminance field, the integer parameters $u_x^{LT}, u_y^{LT}, u_x^{RT}, u_y^{RT}, u_x^{LB}, u_y^{LB}, u_x^{RB}$, and u_y^{RB} which denote the x- and y-displacements of the luminance field at the *virtual points* $(x, y) = (0, 0)$, $(H', 0)$, $(0, V')$, and (H', V') in $\frac{1}{32}$-pixel accuracy (the actual displacements are obtained by dividing these values by 32) are defined as

$$u_x^{LT} = u_x^{00} \qquad u_y^{LT} = u_y^{00}$$
$$u_x^{RT} = \left((H - H')u_x^{00} + H'u_x^{H0}\right) // H \qquad u_y^{RT} = \left((H - H')u_y^{00} + H'u_y^{H0}\right) // H$$
$$u_x^{LB} = \left((V - V')u_x^{00} + V'u_x^{0V}\right) // V \qquad u_y^{LB} = \left((V - V')u_y^{00} + V'u_y^{0V}\right) // V$$
$$u_x^{RB} = \left((V - V')\left((H - H')u_x^{00} + H'u_x^{H0}\right) + V'\left((H - H')u_x^{0V} + H'u_x^{HV}\right)\right) // (HV)$$
$$u_y^{RB} = \left((V - V')\left((H - H')u_y^{00} + H'u_y^{H0}\right) + V'\left((H - H')u_y^{0V} + H'u_y^{HV}\right)\right) // (HV)$$

where "//" denotes integer division that rounds the quotient to the nearest integer, and rounds half integer values away from 0.

In the remainder of this annex, it is assumed that the centers of the pixels lie at the points $(x, y)=(i + \frac{1}{2}, j + \frac{1}{2})$ for both the luminance and chrominance fields. Integer parameters i, j are defined as

- $i = 0, \ldots, H - 1$ and $j = 0, \ldots, V - 1$ for luminance, and
- $i = 0, \ldots, \frac{H}{2} - 1$ and $j = 0, \ldots, \frac{V}{2} - 1$ for chrominance.

This implies that different coordinate systems are used for luminance and chrominance as shown in Figure P.3. Using the coordinate system for chrominance, the integer parameters $u_x^{LT}, u_y^{LT}, u_x^{RT}, u_y^{RT}, u_x^{LB}, u_y^{LB}, u_x^{RB}$, and u_y^{RB} defined above can also be regarded as the x- and y-displacements of the chrominance field at virtual points (x, y)=(0, 0), ($H'/2$, 0), (0, $V'/2$), and ($H'/2$, $V'/2$) in $\frac{1}{64}$-pixel accuracy (the actual displacements are obtained by dividing these values by 64). Using these parameters and a an additional parameter S, which is defined as 2 for luminance and as 1 for chrominance, the resampling algorithm for the luminance and chrominance fields are defined using common equations.

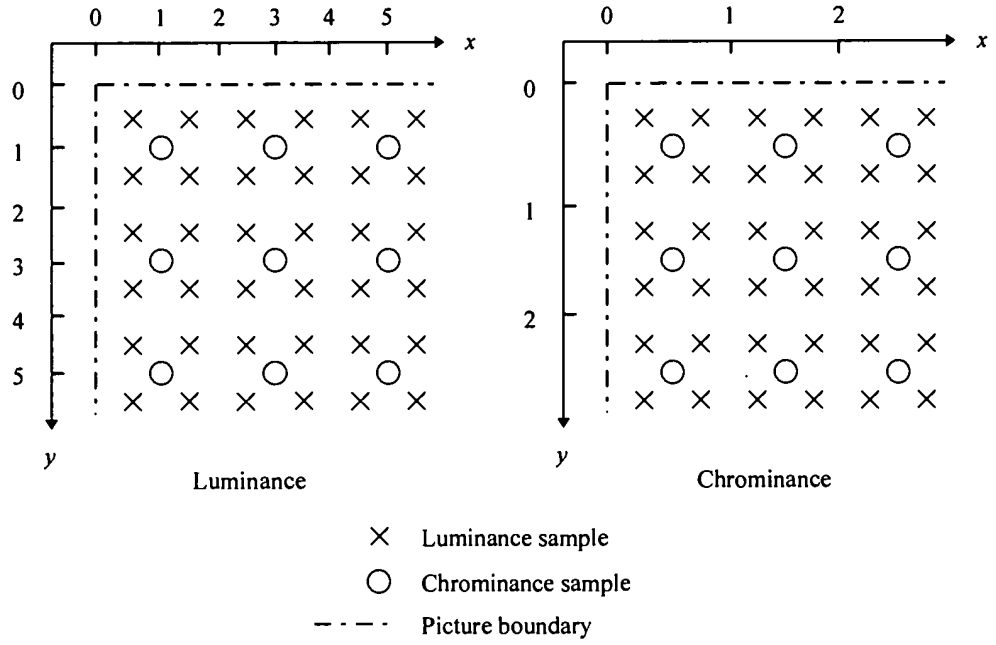

FIGURE P.3/H.263

Coordinate systems for luminance and chrominance fields

The integer parameters $u_x^L(j), u_y^L(j), u_x^R(j)$, and $u_y^R(j)$ which denote the x- and y-displacements of the picture field at (x, y)=$(0, j+\frac{1}{2})$ and $(SH'/2, j+\frac{1}{2})$ in $\frac{S}{64}$-pixel accuracy (the actual displacements are obtained by dividing these values by 64/S) are defined using one dimensional linear interpolation as

$$u_x^L(j) = \left((SV'-2j-1)u_x^{LT} + (2j+1)u_x^{LB}\right) /\!/ (SV') \qquad u_y^L(j) = \left((SV'-2j-1)u_y^{LT} + (2j+1)u_y^{LB}\right) /\!/ (SV')$$

$$u_x^R(j) = \left((SV'-2j-1)u_x^{RT} + (2j+1)u_x^{RB}\right) /\!/ (SV') \qquad u_y^R(j) = \left((SV'-2j-1)u_y^{RT} + (2j+1)u_y^{RB}\right) /\!/ (SV')$$

where "//" denotes integer division that rounds the quotient to the nearest integer, and rounds half integer values away from 0.

Finally, the parameters that specify the transformed position in the reference picture become

$$I_R(i,j) = Pi + \left((SH'-2i-1)u_x^L(j) + (2i+1)u_x^R(j) + 32H'/P\right) /\!/\!/ (64H'/P)$$

$$J_R(i,j) = Pj + \left((SH'-2i-1)u_y^L(j) + (2i+1)u_y^R(j) + 32H'/P\right) /\!/\!/ (64H'/P)$$

$$i_R(i,j) = I_R(i,j) /\!/\!/ P \qquad j_R(i,j) = J_R(i,j) /\!/\!/ P$$

$$\varnothing_x = I_R(i,j) - (I_R(i,j) /\!/\!/ P)P \qquad \varnothing_y = J_R(i,j) - (J_R(i,j) /\!/\!/ P)P$$

where

"///": integer division with truncation towards the negative infinity,

"/": integer division (in this case resulting in no loss of accuracy),

P: accuracy of x- and y-displacements (P=2 when WDA="10" and P=16 when WDA="11" or is absent, see section P.2.1 for the definition of WDA),

$(\frac{I_R(i,j)}{P}+\frac{1}{2},\frac{J_R(i,j)}{P}+\frac{1}{2})$: (x, y) location of the transformed position (both $I_R(i,j)$ and $J_R(i,j)$ are integers),

$(i_R(i,j)+\frac{1}{2}, j_R(i,j)+\frac{1}{2})$: (x, y) location of the sampling point near the transformed position (both $i_R(i,j)$ and $j_R(i,j)$ are integers),

$(\varnothing_x,\varnothing_y)$: bilinear interpolation coefficients of the transformed position (both $\varnothing_x$ and $\varnothing_y$ are integers).

The computation of this equation can be simplified by replacing the divisions by shift operations, since $64H'/P = 2^{m+2}$ when P=16 and $64H'/P = 2^{m+5}$ when P=2.

Using these parameters, the sample value, $E_P(i, j)$, of the pixel located at $(x, y)=(i+\frac{1}{2}, j+\frac{1}{2})$ in the resampled picture is obtained using bilinear interpolation by

$$E_P(i,j) = \Big((P-\varnothing_y)\big((P-\varnothing_x)E_R(i_R,j_R)+\varnothing_x E_R(i_R+1,j_R)\big) + \varnothing_y\big((P-\varnothing_x)E_R(i_R,j_R+1)+\varnothing_x E_R(i_R+1,j_R+1)\big)+P^2/2-1+RCRPR\Big)/P^2$$

where "/" denotes division by truncation. i_R and j_R are simplified notations for $i_R(i, j)$ and $j_R(i, j)$, and $E_R(i_R, j_R)$ denotes the sample value of the pixel located at $(x, y)=(i_R+\frac{1}{2}, j_R+\frac{1}{2})$ in the reference picture after extrapolation using the proper fill mode if necessary. The value of parameter RCRPR is defined as follows:

- For a B-picture (or the B-part of an Improved PB frame) which has a P-picture as its temporally subsequent anchor picture, RCRPR is equal to the rounding type (RTYPE) bit in MPPTYPE (see section 5.1.4.3) of this temporally subsequent P-picture. This implies that for Improved PB frames, RCRPR has the same value for the P-part and the B-part.
- For other types of pictures, RCRPR is equal to the RTYPE bit of the current picture.

P.4 Example of implementation

In this section, an implementation example of the algorithm described in the previous section is provided as pseudo-code.

P.4.1 Displacements of virtual points

When a large picture is coded, a straightforward implementation of the equation for obtaining parameters u_x^{RB} and u_y^{RB} shown in section P.3 may necessitate the usage of variables requiring more that 32 bits for their binary representation. For systems which cannot easily use 64 bit integer or floating point registers, an example of an algorithm which does not require variables with more than 32 bits for the calculation of u_x^{RB} and u_y^{RB} is shown below.

Since H, V, H', and V' are divisible by 4, the definition of u_x^{RB} can be rewritten as

$$u_x^{RB} = \Big((V_Q - V_Q')\big((H_Q - H_Q')u_x^{00} + H_Q' u_x^{H0}\big) + V_Q'\big((H_Q - H_Q')u_x^{0V} + H_Q' u_x^{HV}\big)\Big) // A$$

where $H_Q=H/4$, $V_Q=V/4$, $H_Q'=H'/4$, $V_Q'=V'/4$, $A=H_QV_Q$, and "//" denotes integer division that rounds the quotient to the nearest integer, and rounds half integer values away from 0. Next, parameters T_T and T_B are defined as

$$T_T = (H_Q - H_Q')u_x^{00} + H_Q' u_x^{H0}$$
$$T_B = (H_Q - H_Q')u_x^{0V} + H_Q' u_x^{HV}$$

for simplicity of description. Using operator "///" which denotes integer division with truncation towards the negative infinity, and operator "%" which is defined as $a \% b = a - (a /// b)\, b$, the value of u_x^{RB} can be obtained via the following pseudo-code:

```
q = (VQ - VQ')*(TT ///A) + VQ'*(TB ///A) + ((VQ - VQ')*(TT %A) + VQ'*(TB % A)) ///A;
r = ((VQ - VQ')*(TT %A) + VQ'*(TB % A)) %A;
if (q < 0)
  u_x^RB = q+(r+(A-1)/2)/A;
else
  u_x^RB = q+(r+A/2)/A;
```

The value of u_y^{RB} can also be calculated using this algorithm.

P.4.2 Resampling algorithm

To simplify the description of the algorithm, a function `prior_sample` is defined. Its purpose is to generate a pixel value for any integer location (i_p, j_p) relative to the prior reference picture sampling grid:

```
clip(xmin, x, xmax) {
  if (x < xmin) {
    return xmin;
  } else if (x > xmax) {
    return xmax;
  } else {
    return x;
  }
}

prior_sample(ip, jp) {
  if (FILL_MODE = clip) {
    ic = clip(0, ip, S*HR/2-1);
    jc = clip(0, jp, S*VR/2-1);
    return prior_ref[ic, jc];
  } else {
    if ((ip < 0) OR (ip > S*HR/2-1) OR (jp < 0) OR (jp > S*VR/2-1)) {
      return fill_value;
    } else {
      return prior_ref[ip, jp];
    }
  }
}
```

In the pseudo-code, `prior_ref[i, j]` indicates the sample in column i and row j in the temporally previous reference picture.

Next, a filter function that implements the bilinear interpolation described in section P.3 is defined. It is assumed that all arguments of the following function are integers and that the bilinear interpolation coefficients, $\varnothing_x$ and $\varnothing_y$, are quantized in the range 0,...,P–1 (inclusive).

```
filter(x0, y0, Øx, Øy) {
  return /((P-Øy)·((P-Øx)·prior_sample(x0, y0)+Øx·prior_sample(x0+1, y0))+
           Øy·((P-Øx)·prior_sample(x0, y0+1)+Øx·prior_sample(x0+1, y0+1))+
         P²/2-1+RCRPRJ/P²;.
}
```

Finally, the method for warping the reference picture to generate a prediction for the current picture can be specified in terms of these functions. The pixels of the prediction picture can be generated in a raster scan order. It

is assumed that the values $u_x^L(j), u_y^L(j), u_x^R(j)$, and $u_y^R(j)$ are already calculated and loaded into variables u_x^L, u_y^L, u_x^R, and u_y^R. Defining parameter D as $D = 64H'/P$ and noting that $H'=2^m$, the sample values of the pixels in the j th line of the resampled field (the topmost line is defined as the 0th line) is obtained by the following pseudo-code:

```
a_x^i = D * P + 2 * (u_x^R - u_x^L);
a_y^i = 2 * (u_y^R - u_y^L);
a_x = u_x^L * S * 2^m + (u_x^R - u_x^L) + D / 2;
a_y = j * D * P + u_y^L * S * 2^m + (u_y^R - u_y^L) + D / 2;
for (i = 0; i < S * H / 2; i++) {
    I_R = a_x /// D;
    J_R = a_y /// D;
    i_R = I_R /// P;
    j_R = J_R /// P;
    Ø_x = I_R - (i_R * P);
    Ø_y = J_R - (j_R * P);
    new_ref[i, j] = filter(i_R, j_R, Ø_x, Ø_y);
    a_x += a_x^i;
    a_y += a_y^i;
}
```

where all the variables used in this code are integer variables and `new_ref[i, j]` indicates the sample generated for column i and row j in the resampled reference picture. According to the definition of the parameters, all the divisions in this code can be replaced by binary shift operations. For example, when P=16,

```
I_R = a_x /// D;
J_R = a_y /// D;
i_R = I_R /// P;
j_R = J_R /// P;
Ø_x = I_R - (i_R * P);
Ø_y = J_R - (j_R * P);
```

can be rewritten, assuming that a_x, a_y, I_R, and J_R are binary-coded integer variables in two's complement representation, as

```
I_R = a_x >> (m+2);
J_R = a_y >> (m+2);
i_R = I_R >> 4;
j_R = J_R >> 4;
Ø_x = I_R & 15;
Ø_y = J_R & 15;
```

where "$>> N_{shift}$" denotes a right arithmetic binary shift by N_{shift} bits (N_{shift} is a positive integer), and "&" denotes a bit-wise AND operation.

P.5 Factor-of-4 resampling

Factor-of-4 resampling, which converts both the horizontal and vertical size of the picture by a factor of 2 or $\frac{1}{2}$, is a special case of the resampling algorithm described in section P.3. The simplified description of the resampling algorithm for this special case is provided in this section.

The value of the parameter RCRPR used in the following figures is determined by the rounding type (RTYPE) bit in MPPTYPE (see section 5.1.4.3) as described in section P.3. Additionally, "/" in the following figures indicates division by truncation.

P.5.1 Factor-of-4 upsampling

The pixel value interpolation method used in factor-of-4 upsampling for internal pixels are shown in Figure P.4 By assuming the existence of pixels outside the picture according to the selected fill mode (see sections P.2.3 and P.2.4), the same interpolation method is applied for boundary pixels The interpolation method for boundary pixels when *clip* is selected as the fill mode is shown in Figure P.5. Since precise factor-of-4 upsampling requires x- and y- displacements with at least $\frac{1}{4}$-pixel accuracy, the warping displacement accuracy (WDA) field specified in section P.2.1 must be set to "11" or the resampling must be implicitly invoked in order to use this upsampling method .

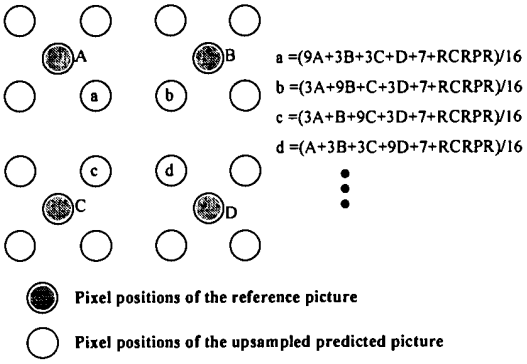

FIGURE P.4/H.263

Factor-of-4 upsampling for pixels inside the picture

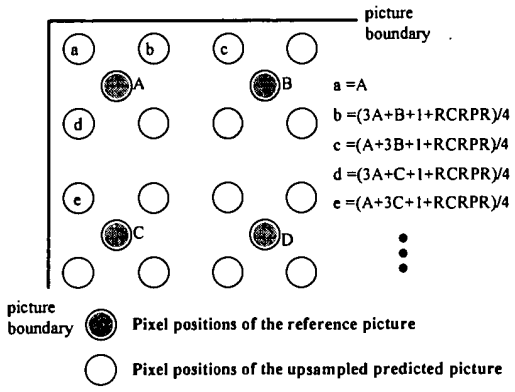

FIGURE P.5/H.263

Factor-of-4 upsampling for pixels at the picture boundary (fill mode = *clip*)

P.5.2 Factor-of-4 downsampling

The pixel value interpolation method for factor-of-4 downsampling is shown in Figure P.6. Since x- and y-displacements with $\frac{1}{2}$-pixel accuracy is sufficient for precise factor-of-4 downsampling, both "10" and "11" are allowed as the value of the displacement accuracy (WDA) field (if present) specified in section P.2.1.

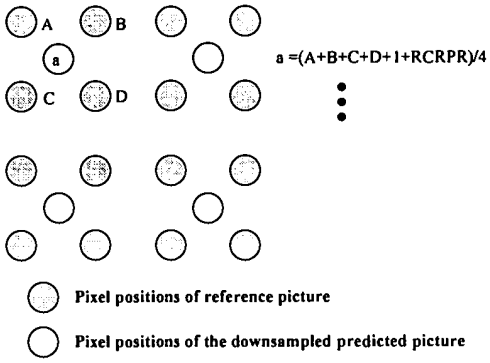

FIGURE P.6/H.263

Factor-of-4 downsampling

Annex Q
Reduced-Resolution Update mode

(This annex forms an integral part of this Recommendation.)

Q.1 Introduction

This annex describes an optional Reduced-Resolution Update mode of H.263. The capability of this mode is signaled by external means (for example Recommendation H.245). The use of this mode is indicated in the PLUSPTYPE field of the picture header.

The Reduced-Resolution Update mode is expected to be used when encoding a highly active scene, and provides the opportunity to increase the coding picture rate while maintaining sufficient subjective quality. This mode allows the encoder to send update information for a picture that is encoded at a reduced resolution, while preserving the detail in a higher resolution reference image to create a final image at the higher resolution.

The syntax of the bitstream in this mode is identical to the syntax for coding without the mode, but the semantics, or interpretation of the bitstream is somewhat different. In this mode, the portion of the picture covered by a macroblock is twice as wide and twice as high. Thus, there is approximately one-quarter the number of macroblocks as there would be without this mode. Motion vector data also refers to blocks of twice the normal height and width, or 32x32 and 16x16 instead of the normal 16x16 and 8x8. On the other hand, the DCT or texture data should be thought of as describing 8x8 blocks on a reduced resolution version of the picture. To produce the final picture, the texture data is decoded at a reduced resolution and then up-sampled to the full resolution of the picture. After upsampling, the full resolution texture image is added to the (already full resolution) motion compensated image to create the image for display and further reference.

In this mode, a picture which has the horizontal size H and vertical size V as indicated in the picture header is created as a final image for display.

In this mode, a referenced picture used for prediction and created for further decoding has a horizontal size H_R and a vertical size V_R which are the same as in the default mode as defined in section 4.1. That is, the H_R and V_R are,

$$H_R = ((H + 15) / 16) * 16$$

$$V_R = ((V + 15) / 16) * 16$$

where H and V are the horizontal size and the vertical size as indicated in the picture header and "/" is defined as division by truncation.

Then in this annex, the texture is coded at a reduced resolution with height and width of H_C and V_C where

$$H_C = ((H_R + 31) / 32) * 32$$

$$V_C = ((V_R + 31) / 32) * 32$$

and "/" is defined as division by truncation.

If H_C and H_R, or V_C and V_R are not identical to each other, such as in the QCIF format, an extension of the referenced picture is performed , and the picture is decoded in the same manner as if the width and height are H_C and V_C. Then the resulting picture which is tiled by 32*32 macroblocks is cropped at the right and the bottom to the width H_R and height V_R, and this cropped picture is stored as a reference picture for further decoding.

If both H and V are the same as those of a resulting picture having the width H_C and the height V_C, this resulting picture is used for display. Otherwise, this resulting picture is further cropped to the size H*V, and the cropped picture here is used for display purpose only.

If the Temporal, SNR, and Spatial Scalability mode (Annex O) or Reference Picture Resampling mode (Annex P) is also used with this option, the source format of the current picture might be different from that of the reference picture. In this case, the resampling of the reference picture shall be performed before decoding.

Note: This mode can be used with the Reference Picture Selection mode (see Annex N) without modification, since the reference picture (after possible resampling by the Reference Picture Resampling mode) has the same size as indicated in the current picture header when this option is used.

Q.2 Decoding Procedure

Figure Q.1 shows the block diagram of the block decoding in the Reduced-Resolution Update mode.

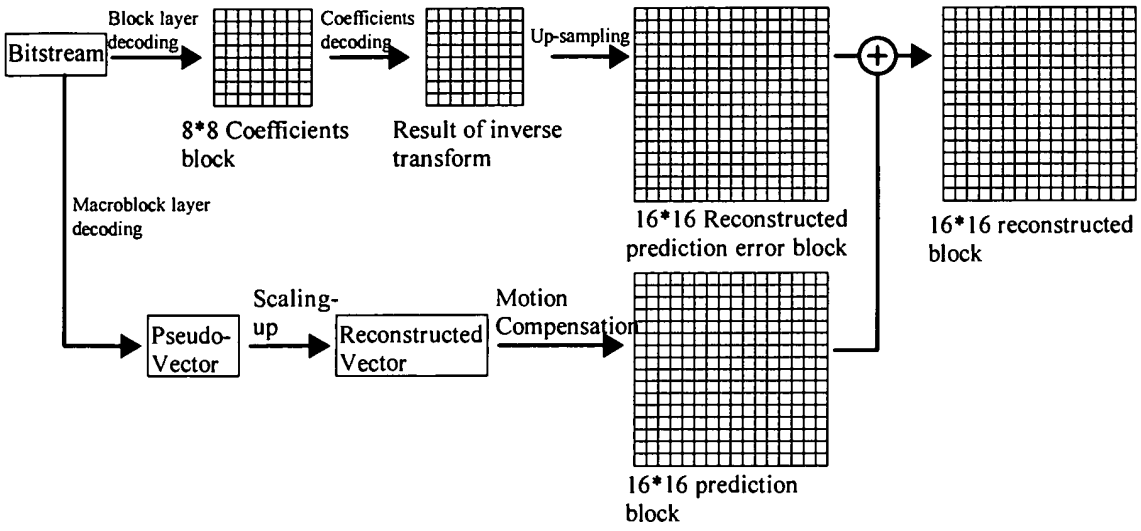

FIGURE Q.1/H.263

Block diagram of block decoding in Reduced-Resolution Update mode

The decoding procedure is given in the following sections:

Q.2.1 Reference Preparation

In some cases, the available reference picture has different size from H_C and V_C. Then the reference picture shall be converted before decoding procedure according to Q.2.1.1 or Q.2.1.2.

Q.2.1.1 Reference Picture Resampling

If the Temporal, SNR, and Spatial Scalability mode (Annex O) or Reference Picture Resampling mode (Annex P) is also used with this option, the source format of the current picture might be different from that of the reference picture. In this case, the resampling of the reference picture according to each Annex shall be performed first.

Q.2.1.2 Extension of Reference Picture

If H_R or V_R is not divisible by 32, such as with the QCIF format, the reference picture is extended. The detailed procedure for this extension is defined in section Q.3.

Q.2.2 Macroblock layer decoding

Decoding can be thought of as operating on "enlarged" blocks of size 32x32 in luminance and 16x16 in chrominance. The texture and motion data for each enlarged block is decoded to create a 32x32 motion block and a 32x32 texture block, as described in Q.2.2.1. and Q.2.2.2. respectively. These motion and texture blocks are then added as described in Q.2.2.3.

Q.2.2.1 Motion Compensation

First, Each component of the macroblock motion vector (or four macroblock motion vectors) is formed from MVD (and possibly MVD_{2-4}). If in Improved PB-Frames mode, MV_F and MV_B for B-Picture is also formed from

MVDB. The detailed procedure for this motion vector formation is defined in section Q.4. If the current picture mode is a B picture or EP-picture, the motion vector for forward and backward are also obtained according to section Q.4.

The motion vector for the two chrominance blocks of the macroblock is obtained from the macroblock motion vector according to section 6.1.1. If either the Advanced Prediction mode or the Deblocking Filter mode is in use and thus four motion vectors are defined for the macroblock, the motion vector for both chrominance blocks is obtained from the four motion vectors according to section F.2. If in the Improved PB-frames mode the creation of the chrominance vector is specified in Annex M. If a B picture or EP-picture is used, the creation of the chrominance vector is specified in Annex O.

Then, a prediction is formed from the motion vector for a INTER Macroblock. Four 16×16 luminance prediction blocks are obtained from the macroblock motion vector, and two 16×16 chrominance prediction blocks are obtained from the chrominance motion vector. For interpolation for subpixel prediction refer to section 6.1.2. If Advanced Prediction mode is also used, an enlarged overlapped motion compensation is performed to obtain four 16×16 luminance prediction blocks using enlarged weighting matrices, for which a detailed procedure is defined in section Q.5. If the current picture mode is an Improved PB-frame, B-picture, or EP-picture, the prediction is obtained according to the other relevant Annexes, except that the size of the predicted blocks is 16×16 instead of 8×8.

Q.2.2.2 Texture decoding

First, the bitstream of the block layer is decoded according to section 5.4. Then coefficients are decoded and the 8×8 reduced-resolution reconstructed prediction error blocks are obtained as the result of inverse transform according to section 6.2.

Then the 16×16 reconstructed prediction error blocks are obtained by upsampling the 8×8 reduced-resolution reconstructed prediction error blocks. For the creation of the edge pixels in each 16×16 reconstructed prediction error block, only the pixels which belong to the corresponding block are used. The detailed procedure is defined in section Q.6.

Q.2.2.3 Reconstruction of block

For each luminance and chrominance block, a summation of the prediction and prediction error is performed. The procedure is identical to section 6.3.1, except that the size of blocks is 16×16 instead of 8×8. Then the clipping is performed according to the section 6.3.2.

Then a block boundary filter is applied to the boundary pixels of the 16×16 reconstructed blocks. The detailed procedure is described in section Q.7.

Q.2. 3 Picture Store

If both H_R and V_R are divisible by 32, such as with the CIF format, the resulting picture reconstructed as described in section Q.2.2 is stored as a reference picture as it is for further decoding. Otherwise, such as the QCIF format, the reconstructed picture which is just covered with 32×32 macroblocks is cropped at the right and the bottom to the width H_R and height V_R, and this cropped picture is stored as a reference picture for further decoding.

Q.2.4 Display

If both H and V are the same as H_C and V_C, the resulting picture in section Q.2.2 is used for display purposes as it is. Otherwise, this resulting picture is further cropped to the size H×V, and the cropped picture is used for display purpose only.

Q.3 Extension of Referenced Picture

If H_R or V_R is not divisible by 32, such as with the QCIF format, the extension of the referenced picture is performed before decoding macroblock/block layer. The width and the height of the extended reference picture for luminance are the next larger size that would be divisible by 32, and those for chrominance are the next larger size that would be divisible by 16.

Note: The width and height of the referenced picture in the default mode are always extended to be divisible by 16 even if picture formats has a width or height that is not divisible by 16, because the picture shall be decoded as if the width or height had the next larger size that would be divisible by 16. See section 4.1/H.263.

If neither Unrestricted Motion Vector mode, Advanced Prediction mode nor Deblocking Filter mode is used with this option, the extended pixels can be arbitrary values, because the extended pixels will be never used as a reference pixels of the decoded picture to be reconstructed and displayed.

If either Unrestricted Motion Vector mode, Advanced Prediction mode or Deblocking Filter mode is also used with this option, the extension of the referenced picture is performed by duplicating the edge pixel of the referenced picture, in order to ensure the decoding when motion vectors point outside the right and bottom edge of the picture.

For example, if the Reduced-Resolution Update mode is used for a QCIF, the width of the referenced picture is 176 and the height is 144, which are not divisible by 32. In order to cover a QCIF picture with 32×32 sized macroblocks, the number of macroblock row should be 6, and the number of macroblock column should be 5. Therefore the width of the extended referenced picture is 192 and the height is 160.

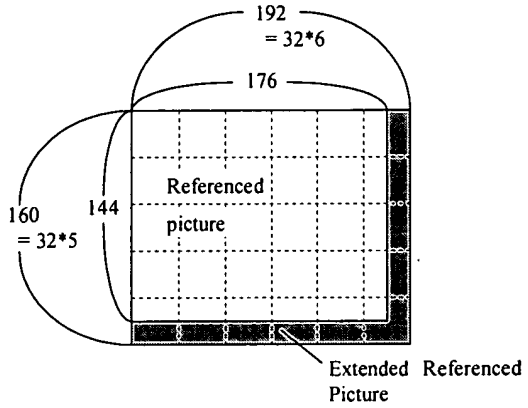

FIGURE Q.2/H.263

Extension of referenced picture for QCIF picture size

The extension of the referenced picture in QCIF is illustrated in Figure Q.2. The extended referenced picture for luminance is given by the following formula:

$R_{RRU}(x, y) = R(x', y')$,
where
x, y = spatial coordinates of the extended referenced picture in the Pixel domain,
x', y' = spatial coordinates of the referenced picture in the pixel domain,
$R_{RRU}(x, y)$ = pixel value of the extended referenced picture at (x, y),
R(x', y') = pixel value of the referenced picture at (x', y'),

x' = 175 if x > 175 and x < 192
= x otherwise,

y' = 143 if y > 143 and y < 160
= y otherwise,

The referenced pictures for chrominance is also extended in the same manner.

Q.4 Reconstruction of motion vectors

In Reduced-Resolution Update mode, the motion vector range is enlarged to approximately double size in both the horizontal and vertical directions. In order to realize an enlarged range using the VLC for MVD defined in Table

14, each vector component is restricted to be only half-pel or zero value. Therefore the range of each motion vector component is [-31.5,30.5] in the default Reduced-Resolution Update mode. If the Unrestricted Motion Vector mode is used, the vector range [-limit,limit] as defined in section D.2 applies to the pseudo-motion vectors and translates into [-(2*limit-0.5),2*limit-1.5] for the motion vectors. For CIF this means that the pseudo-motion vector range is [-32,31.5] and the motion vector range is [-63.5,62.5]. If the UUI field is set to "01", the motion vectors are unlimited. However, the motion vectors (not just the pseudo-motion vectors) are always limited to point not more than 15 pixels outside the coded area as described in section D.1.1. Figure Q.3 illustrates the possible positions of macroblock motion vector or four motion vector predictions around the (0, 0) vector value. The dashed lines indicate the integer coordinates.

For the macroblock using differential motion vectors in a B picture, the motion vector for forward and backward prediction are obtained independently. In the Reduced-Resolution Update mode, the motion vector component MVc for a luminance block is reconstructed from MVD and MVD_{2-4} as follows;

1. Pseudo- prediction vector component **pseudo-P_C** is created from the prediction vector component P_C.

   pseudo-P_C = 0 if P_C = 0

   pseudo-P_C = sign(P_C) * (|P_C| + 0.5) / 2.0 if $P_C \neq 0$

   "/" indicates floating-point division (without loss of accuracy). The prediction vector component P_C is defined as the median value of the vector components MV1, MV2 and MV3 as defined in section 6.1.1/H.263 and F.2/H.263.

2. Pseudo- macroblock vector component **pseudo-MV_C** is obtained by adding the motion vector differences MVD (and MVD_{2-4}) from Table 14 to the pseudo-P_C.

   In the default Reduced-Resolution Update mode, the value of **pseudo-MV_C** is restricted to the range [-16, 15.5]. Only one of the pair will yield a pseudo-MV_C falling within the permitted range. The procedure is performed in the similar way as defined in section 6.1.1/H.263.

   If the Unrestricted Motion Vector mode is also used with the Reduced-Resolution Update mode, **pseudo-MV_C** is obtained by adding the motion vector differences MVD (and MVD_{2-4}) from Table D.3.

   If four motion vectors are present, the procedure is performed in the similar way as defined in section F.2/H.263

3. Motion vector component **MV_C** is obtained from pseudo-MV_C in the following formula:

   $MV_C = 0$ if pseudo-$MV_C = 0$

   MV_C = sign(pseudo-MV_C) * (2.0 * |pseudo-MV_C| - 0.5) if pseudo-$MV_C \neq 0$

   As a result, each vector component is restricted to have a half-integer or zero value, and the range of each motion vector component is enlarged to approximately twice the pseudo-motion vector range.

4. If the current picture mode is an Improved PB frame, or when the MBTYPE indicates the direct mode in a B picture, the motion vector components **MV_F** and/or **MV_B** for forward and backward prediction are created.

   First, pseudo motion vector components **pseudo-MV_F** and/or **pseudo-MV_B** are calculated based on the rules for the prediction modes defined in Annex O or Annex M.

   In the case of the Bidirectional prediction in the Improved PB-frames mode (section M.2.1) or when the MBTYPE indicates the direct mode in a B picture (section O.5.2), pseudo-MV_F and pseudo-MV_B are calculated from **pseudo-MV_D** and **pseudo-MV_C** assuming that pseudo-MV_D is zero and pseudo-MV_C is MV, as defined in Annex G and Annex M.

   In the case of forward prediction in the Improved PB-frames mode (section M.2.2), **pseudo-MV_{DB}** is obtained by decoding the variable length code MVDB according to Table 13. Then pseudo-MV_F is obtained by adding the pseudo-MV_{DB} to the **pseudo-Predictor**. In order to form the pseudo-Predictor, the predictor obtained according to the procedure defined in section M.2.2 of Annex M is converted to the pseudo-Predictor vector according to the formula defined in item 1 of this section.

In the case of Backward prediction in the Improved PB-frames mode (section M.2.3), pseudo-MV_B is set to zero.

Then the motion vectors MV_F and/or MV_B for forward and backward prediction are obtained from pseudo-MV_F and/or pseudo-MV_B according to the formula defined in item 3 of this section.

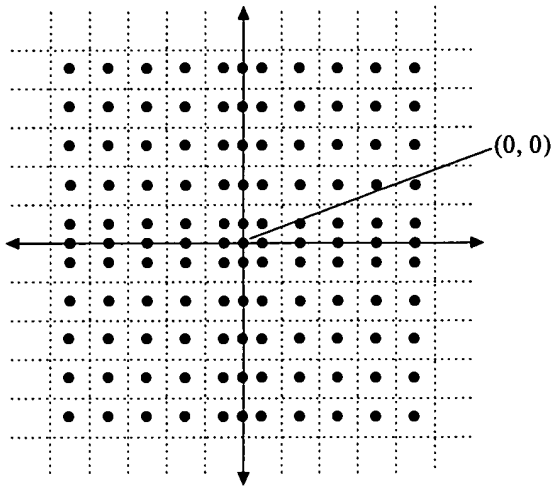

FIGURE Q.3/H.263

Reconstruction of motion vector

Q.5 Enlarged overlapped motion compensation for luminance

If Advanced Prediction mode is also used with Reduced-Resolution Update mode, enlarged matrices of weighting values are used to perform the overlapped motion compensation. Except that the size of each block and weighting matrices is 16×16, the procedure of the creation of each prediction block is identical to the description of F.3 in Annex F.

The enlarged matrices of weighting values for the16×16 luminance prediction are given in Figures Q.4, Q.5, and Q.6.

Weighting values, H_2, for prediction with motion vector of 16×16 luminance blocks to the left or right of current 16×16 luminance block

Q.6 Upsampling of the reduced-resolution reconstructed prediction error

The 16×16 reconstructed prediction error block is obtained by upsampling the 8×8 reduced-resolution reconstructed prediction error block. In order to realize a simple implementation, filtering is closed within a block which enables to perform an individual upsampling on block basis. Figure Q.7 shows the positioning of samples. The upsampling procedure for the luminance and chrominance pixels which are inside the 16×16 reconstructed prediction error blocks is defined in section Q.6.1. For the creation of the luminance and chrominance pixels which are at the boundary of 16×16 reconstructed prediction error block, the procedure is defined in section Q.6.2. Chrominance blocks as well as luminance blocks are up-sampled. The symbol "/" in Figures Q.8 and Q.9 indicates division by truncation.

The creation of reconstructed prediction error for pixels of a 16x16 block is shown in Figure Q.9.

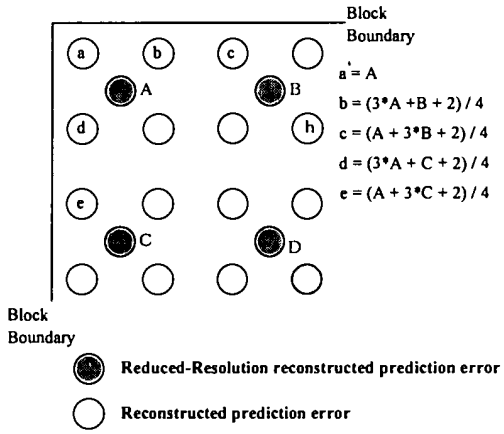

FIGURE Q.9/H.263

Creation of reconstructed prediction error for pixels at the block boundary

Q.7 Block boundary filter

The filter operations are performed along the edges of the 16×16 reconstructed blocks at the encoder as well as on the decoder side. There are two alternative of filtering, depending on whether Deblocking Filter mode is used or not.

The default filtering in Reduced-Resolution Update mode is performed according to section Q.7.1.

If Deblocking Filter mode is also used with Reduced-Resolution Update mode, the filtering is performed according to section Q.7.2.

In both cases, filtering is performed on the complete reconstructed image data before storing the data in the picture store for future prediction. No filtering is performed across picture edges, slice edges in Slice Structured mode (see Annex K), or GOB boundaries having GOB headers present in Independent Segment Decoding mode (see Annex R). Chrominance as well as luminance data is filtered.

Q.7.1 Definition of the default block boundary filter

In the Reduced-Resolution Update mode, the default filtering is performed according to this section.

If A and B are two pixel values on a line — horizontal or vertical — of the reconstructed picture, and A belongs to one 16×16 block called block1 whereas B belongs to a neighboring 16×16 block called block2 which is to the right or below of block1. Figure Q.10 shows examples for the position of these pixels.

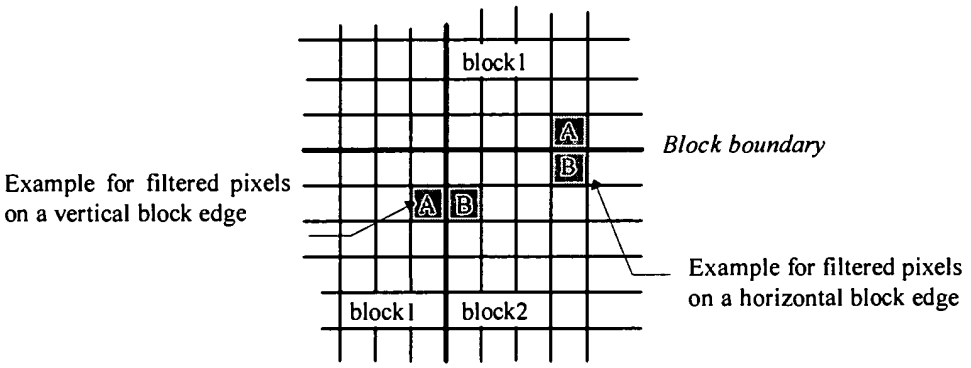

FIGURE Q.10/H.263

Default block boundary filter

One of the following conditions must be fulfilled in order to turn the filter on for a particular edge:

- block1 belongs to a coded macroblock (COD==0 || MB-type == INTRA) **or**
- block2 belongs to a coded macroblock (COD==0 || MB-type == INTRA)

A shall be replaced by A1 and B shall be replaced by B1. "/" indicates division by truncation.

A1 = (3*A + B + 2) / 4

B1 = (A + 3*B + 2) / 4

The order of edges where filtering is performed is identical to the description provided in section J.3 of Annex J.

Q.7.2 Definition of the block boundary filter when Deblocking Filter mode is used

If the Deblocking Filter mode (see Annex J) is used with the Reduced-Resolution Update mode, the filtering which is defined in Annex J with one modification is performed on the boundary pixels of 16×16 luminance and chrominance blocks, in place of the filtering described in section Q.7.1. The one modification of the filtering in Annex J is that the parameter STRENGTH is given the value of positive infinity. This implies that the function UpDownRamp(x, STRENGTH) defined in section J.3 becomes a linear function of x.

As a result, the procedure of the deblocking filter described in section J.3 is redefined in the following manner;

B1 = clip(B + d1)
C1 = clip(C – d1)
A1 = A – d2
D1 = D + d2
d1 = (A–4B+4C–D) / 8
d2 = clipd1((A – D) / 4, d1/2)

Annex R
Independent Segment Decoding mode

(This annex forms an integral part of this Recommendation.)

R.1 Introduction

This annex describes the optional Independent Segment Decoding mode of H.263, which allows a picture to be decoded without the presence of any data dependencies across slice boundaries or across GOB boundaries having non-empty GOB headers. The use of this mode is indicated in the PLUSPTYPE field of the picture header. The capability to use this optional mode is negotiated by external means (for example Recommendation H.245).

When the use of this mode is indicated, the video picture segment boundaries (as defined by the boundaries of the slices or the upper boundaries of the GOBs for which GOB headers are sent, or the boundaries of the picture, whichever bounds a region in the smallest way) are treated as picture boundaries when decoding, including the treatment of motion vectors which cross those boundaries (which result in boundary extrapolation when the Unrestricted Motion Vector mode, the Advanced Prediction mode, the Deblocking Filter mode, or the Temporal, SNR, and Spatial Scalability mode are in use, and which are prohibited when none of those optional modes are in use).

R.2 Mode Operation

A video picture segment is defined by the following:

If the Slice Structured mode (see Annex K) is not in use, then one GOB or a plural number of consecutive GOBs forms one video picture segment. The location of the top of each video picture segment is indicated by the presence of a non-empty GOB header for which the border of the video picture segment lies just above the macroblocks in the GOB for which a header is present, or the top of the picture, whichever is lower. The location of the bottom of each video picture segment is defined by the top of the next video picture segment, or the bottom of the picture, whichever is uppermost.

If the Slice Structured mode (see Annex K) is in use, then each slice forms one video picture segment.

In the Independent Segment Decoding mode, each video picture segment is decoded with complete independence from all other video picture segments, and is also independent of all data outside the same video picture segment location in the reference picture(s). This includes:

1. No use of motion vectors outside of the current video picture segment for motion vector prediction (as in section 6.1.1)
2. No use of motion vectors outside of the current video picture segment as remote motion vectors for overlapped block motion compensation when the Advanced Prediction mode is in use (see section F.3)
3. No deblocking filter operation across video picture segment boundaries (see section J.3)
4. No use of motion vectors which reference data outside the current video picture segment unless the Unrestricted Motion Vector mode (see Annex D), the Advanced Prediction mode (see Annex F), the Deblocking Filter mode (see Annex J) or the Temporal, SNR, and Spatial Scalability mode (see Annex O) are in use; in which case the borders of the current video picture segment in the prior picture are extrapolated as described in Annex D to form predictions of the pixels which reference the out-of-bounds region.
5. No bilinear interpolation across the boundaries of the ¼-size or ½-size region corresponding to the current video picture segment for upward prediction in spatial scalability EI and EP pictures (as defined in Annex O).
6. When the Reduced Resolution Update mode (see Annex Q) is in use, no block boundary filter operation across video picture segment boundaries.
7. No use of the Reference Picture Resampling mode with the Independent Segment Decoding mode.

R.3 Constraints on Usage

Certain restrictions are placed on the use of other aspects of the video coding syntax when the Independent Segment Decoding mode is in use. These restrictions are made to prevent two pathological cases which otherwise would make operation of the Independent Segment Decoding mode difficult.

R.3.1 Constraint on segment shapes

In the use of the Slice Structured mode (Annex K) without the use of the Rectangular Slice submode (section K.1), there can arise cases in which the shape of a video picture segment may be non-convex (having "inside corners", or even comprising two distinct and separated regions of the picture).

Therefore, the Independent Segment Decoding mode shall not be used with the Slice Structured mode without the simultaneous use of the Rectangular Slice submode of the Slice Structured mode (see Annex K). This constraint is mandated to prevent the need for difficult special-case treatment in order to determine how and when to perform extrapolation of each video picture segment.

R.3.2 Constraint on changes of segment shapes

If the shape of the video picture segments were allowed to change in any way from picture to picture in the bitstream, there could arise cases in which the bitstream would be difficult to decode. This is because in such cases the bitstream content is not sufficient to determine the shape of each video picture segment prior to the possible appearance of motion vectors in the bitstream which require knowledge of the video picture segment shape for proper interpretation.

Therefore, when the Independent Segment Decoding mode is in use, the video picture segmentation for all pictures and frames allowing temporal prediction (i.e., all P, B, and EP pictures and all Improved PB frames) shall be the same as that used in its temporal reference picture. Also, when the Independent Segment Decoding mode is in use, the video picture segmentation for all EI pictures shall either be the same or shall differ only by sub-dividing the video picture segmentation used in its reference picture. Also, the Independent Segment Decoding mode shall not be used in any picture or frame which uses reference pictures (all picture types except INTRA) unless the Independent Segment Decoding mode is also used in all of the reference picture(s) for the current picture. As a result of this constraint, the shape of the video picture segments in the Independent Segment Decoding mode shall never change from picture to picture except as changed in I and EI pictures (and the manner in which EI pictures can change segmentation is itself also somewhat constrained).

Annex S
Alternative INTER VLC mode

(This annex forms an integral part of this Recommendation.)

S.1 Introduction

This annex describes an optional Alternative INTER VLC mode of H.263, which improves the efficiency of inter-picture coding when significant changes are evident in the picture. This efficiency improvement is obtained by allowing some VLC codes originally designed for INTRA pictures to be used for some INTER picture coefficients and CBPY data as well. The use of this mode is indicated in the PLUSPTYPE field of the picture header. The capability to use this optional mode is negotiated by external means (for example Recommendation H.245). The mode contains two syntax alterations, one for the encoding of INTER coefficients and another for the encoding of the INTER CBPY values.

S.2 Alternative INTER VLC for coefficients

The concept behind the design of the INTRA VLC table of Annex I is to use the same codewords as in the original INTER VLC but with a different interpretation of LEVEL and RUN. The INTRA VLC is better suited in cases where there are many and/or large-valued coefficients.

The INTRA VLC is constructed so that codewords have the same value for LAST (0 or 1) in both the INTER and INTRA tables. The INTRA table is therefore produced by "reshuffling" the meaning of the codewords with the same value of LAST. Furthermore, for events with large |LEVEL| the INTRA table uses a codeword which in the INTER table has a large RUN. In INTER blocks having a large number of large-magnitude coefficients, it can sometimes be more efficient to use the INTRA table than the INTER table, and in some such cases the choice of the VLC table can be apparent to the decoder since decoding using the INTER table would result in RUN values so large as to indicate the presence of more than 64 coefficients for a block. Under these circumstances, the INTRA table can be used to improve the efficiency of INTER coding.

S.2.1 Encoder action.

The encoder may use the INTRA VLC table for coding an INTER block whenever the decoder can detect its use—in other words, whenever decoding using the INTER VLC table would cause coefficients outside the 64 coefficients of a block to be addressed.

The encoder would normally choose to use the INTRA VLC table for coding an INTER block only when the above condition is satisfied and also when the INTRA VLC usage results in fewer bits than the INTER VLC for the same coefficient values. This will often be the case when there are many large coefficients, due to the way the INTRA VLC was produced (since the ordinary INTER VLC table contains long run-lengths for the same codewords in which the INTRA VLC table contains large coefficient amplitudes).

S.2.2 Decoder action

The decoding process is as follows:

1. The decoder first receives all coefficient codes of a block.
2. The codewords are then interpreted assuming that INTER VLC is used. If the addressing of coefficients stays inside the 64 coefficients of a block, the VLC decoding is finished.
3. If coefficients outside the block are addressed, the codewords shall be interpreted according to the INTRA VLC.

S.3 Alternative INTER VLC for CBPY

The INTER CBPY codewords (Table 13) are designed with the assumption that there are more Y blocks with all zero coefficients than there are with at least one non-zero coefficient. When both C_B and C_R blocks have at least one non-zero coefficient, i.e., $CBPC_5 = CBPC_6 = 1$, this assumption no longer holds. For this reason, when the Alternative INTER VLC mode is in use, the CBPY codewords as defined in Table 13 for INTRA macroblocks shall also be used for INTER macroblocks whenever $CBPC_5 = CBPC_6 = 1$.

Annex T
Modified Quantization mode

(This annex forms an integral part of this Recommendation.)

T.1 Introduction

This annex describes an optional Modified Quantization mode of H.263, which modifies quantizer operation. The use of this mode is indicated in the PLUSPTYPE field of the picture header. The capability to use this optional mode is negotiated by external means (for example Recommendation H.245).

This mode includes four key features:

1. The bit-rate control ability for encoding is improved by altering the syntax for the DQUANT field,
2. Chrominance fidelity is improved by specifying a smaller step size for chrominance than that for luminance data,
3. The range of representable coefficient values is extended to allow the representation of any possible true coefficient value to within the accuracy allowed by the quantization step size,
4. The range of quantized coefficient levels is restricted to those which can reasonably occur, to improve the detectability of errors and minimize decoding complexity.

T.2 Modified DQUANT Update

This mode modifies the semantics of the DQUANT field. With this mode, it is possible to use DQUANT either to modify QUANT by plus or minus a small amount, or to signal any specific new value for QUANT. The size of the small amount of modification depends on the current value of QUANT. By use of this mode, more flexible control of the quantizer step size can be specified in the DQUANT field.

The codeword for DQUANT in this mode is no longer a two bit fixed length field. It is a variable length field which can either be two bits or six bits in length. Whether it is two or six bits depends on the first bit of the code. The description below is therefore split into two sections, depending on the first bit.

T.2.1 Small-step QUANT alteration

When the first bit of the DQUANT field is 1, only one additional bit is sent in DQUANT. The single additional bit is used to modify QUANT by a differential value. The change in the value of QUANT is dependent on the second bit of DQUANT and on the prior value of QUANT, as shown in Table T.1.

Example: If the previous value of QUANT is 29 and DQUANT is signalled with the codeword '11', then the differential value is +2, and thus the resulting new QUANT value is 31.

TABLE T.1/H.263

Semantics of small-step QUANT alteration

	Change of QUANT	
Prior QUANT	DQUANT = 10	DQUANT = 11
1	+2	+1
2–10	–1	+1
11–20	–2	+2
21–28	–3	+3
29	–3	+2
30	–3	+1
31	–3	–5

T.2.2 Arbitrary QUANT selection

When the first bit of the DQUANT field is 0, five additional bits are sent in DQUANT. The following five bits represent a new QUANT as defined in section 5.1.19.

Example: Regardless of the current value of QUANT, if DQUANT is signaled with the code word '001111', then the new value of QUANT is 15.

T.3 Altered quantization step size for chrominance coefficients

When the modified quantization mode is in use, the quantization parameter of the chrominance coefficients is different from the quantization parameter of the luminance. The luminance quantization parameter is signaled in the bitstream. It is called QUANT. When this mode is in use, a different quantization parameter termed QUANT_C is used for the inverse quantization of chrominance coefficients. The relation between QUANT and QUANT_C is given in Table T.2. If the deblocking filter mode (see Annex J) is in use, QUANT_C shall also be used for the application of the deblocking filter to the chrominance data. Whenever QUANT is discussed herein in any other context, it shall mean the quantization step size of the luminance.

TABLE T.2/H.263

Relationship between QUANT and QUANT_C

Range of QUANT	Value of QUANT_C
1–6	QUANT_C = QUANT
7–9	QUANT_C = QUANT – 1
10–11	9
12–13	10
14–15	11
16–18	12
19–21	13
22–26	14
27–31	15

T.4 Modified coefficient range

When the Modified Quantization mode is in use, quantized DCT coefficients having quantization level magnitudes greater than 127 can be represented in the bitstream. This has two advantages:

1. Encoder performance is improved by allowing the true full range of possible coefficient values to be represented, and
2. Encoder complexity is reduced by eliminating the need to increase the quantization step size upon encountering certain large coefficient values which would otherwise be unrepresentable.

It is possible that the correct value of a DCT coefficient prior to quantization in the encoder will have a magnitude as high as 2040. Thus, a range of –127 to +127 for LEVEL is insufficient to cover the entire range of possible coefficient values whenever the quantization parameter QUANT or QUANT_C is less than 8. The expanded coefficient range broadens the range of LEVEL to allow any true coefficient value to be more properly encoded.

When the Modified Quantization mode is in use, the meaning of the LEVEL field following an ESCAPE code (0000 011, as per section 5.4.2) is altered. In this mode, rather than being forbidden, the bit sequence 1000 0000 is used to represent an EXTENDED-ESCAPE code. An AC coefficient of magnitude greater than 127 is represented by sending an EXTENDED-ESCAPE code, immediately followed by a fixed-length EXTENDED-LEVEL field of 11 bits. An extended coefficient value is encoded into the EXTENDED-LEVEL field by taking the least significant 11 bits of the two's-complement binary representation of LEVEL and cyclically rotating them to the right by 5 bit

positions. This rotation is necessary to prevent start code emulation. The cyclic rotation is illustrated in Figure T.1.

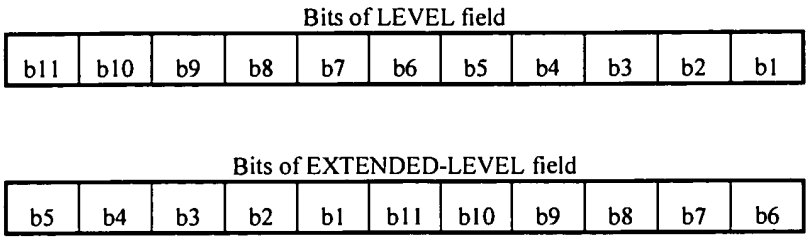

FIGURE T.1/H.263

Cyclic rotation of coefficient representation

T.5 Usage Restrictions

When the Modified Quantization mode is in use, certain restrictions are placed on the encoded coefficient values. This has several benefits:

1. The detectability of bit errors is improved by prohibiting certain unreasonable coefficient values, thus allowing these values to be recognized as bit errors by the decoder; and
2. Decoder complexity is reduced by reducing the wordlength necessary for inverse quantization prior to clipping.
3. Start-code emulation is prevented for coefficients encoded using the EXTENDED-ESCAPE mechanism described in section T.4.

These restrictions are as follows. When the Modified Quantization mode is in use:

1. For any coefficient, the reconstruction level magnitude |REC| produced by the inverse quantization process described in section 6.2.1 using the current value of QUANT or QUANT_C as appropriate, and the encoded value of LEVEL, shall be less than 4096. This additional restriction applies to all coefficients, regardless of whether the coefficient is sent using the EXTENDED-ESCAPE mechanism or not.
2. The bitstream shall not use either the normal ESCAPE code or the EXTENDED-ESCAPE code to encode a combination of LAST, RUN, and LEVEL for which there exists a codeword entry in the applicable VLC table, which is either Table 16 (section 5.4.2) or Table I.2 (section I.3).
3. The EXTENDED-ESCAPE code shall be used only when the quantization parameter for the coefficient (QUANT or QUANT_C) is less than eight (8).
4. The EXTENDED-ESCAPE code shall be used only when it is followed by an EXTENDED-LEVEL field representing a value of LEVEL which is outside of the range –127 to +127.

Appendix I
List of patent holders

(This appendix does not form an integral part of this Recommendation)

[Ed. Note: Appendix I should be kept the same as in the existing published Recommendation H.263 Version 1, provided it exists, and should be updated as appropriate. If Appendix I does not exist, then the content shown below as Appendix III should be adopted as Appendix I.]

Appendix II
Error Tracking

(This appendix does not form an integral part of this Recommendation)

[Ed. Note: Appendix II should be kept the same as in the existing published Recommendation H.263 Version 1. (It does exist, but it is not found in the published Recommendation on the ITU site as of the time of the preparation of this draft.)]

Appendix III
Recommended Optional Enhancement

(This appendix does not form an integral part of this Recommendation)

III.1 Introduction

With the variety of optional modes available in this Recommendation (H.263 Version 2), it is crucial that several preferred mode combinations for operation be defined, so that option-enhanced terminals will have a high probability of connecting to each other using some syntax better than the "baseline." This appendix contains a list of preferred mode combinations, structured into three "levels" of support. Each level includes support for the levels below it, creating an "onion peel" structure of capabilities. The primary objective of this appendix is to describe the order in which modes should be supported in decoders, rather than to enforce a particular small set of mode combinations upon encoders.

In determining which modes would be placed into this level structure, the primary criteria used were performance-related: improvement in subjective quality, impact on delay, and impact on complexity (this includes computational burden, data dependencies, and ease of implementation). However, because this appendix seeks to address a wide variety of applications and transport layers, features addressing error resilience and ease of packetization were also incorporated into the same level structure. In keeping with these objectives, the levels of support described in this appendix are intended to be *universal*, so that the means of transport will not be an issue and the need for application-specific "profiles" will be minimized. This universality is seen as a key to promoting good interoperability across different types of terminals and networks. To maintain universality, several optional features have not been included in the level structure described herein. The absence of these features is not meant to be a condemnation of their usage; instead, their absence reflects only a collective opinion about the likelihood of widespread adoption of these features across a full spectrum of terminals, networks, and applications.

III.2 Levels of Preferred Mode Support

Each optional mode described in this appendix has been categorized into one of three levels of support. While the ratio of performance improvement to computational complexity was a major criterion used in this categorization, utility for packetization and error resilience were also considered. Decoder support for a given level implies support for all lower levels. Furthermore, decoder support for a given level implies support for all subset combinations of the constituent modes of that level and all lower levels. This last requirement exists so that the limitations placed upon an encoder's choice of mode combinations is minimized. This is in keeping with the primary objective of this appendix, which is to describe the order in which modes should be supported at the decoder, rather than to enforce a particular small set of mode combinations upon the encoder.

Backward compatibility is also an important issue to consider. For this reason, a preferred mode combination including only the Advanced Prediction mode (Annex F) is also recommended (although this recommendation falls outside the level structure defined below), since Advanced Prediction is regarded as the most beneficial of the optional modes in the original edition (Version 1) of this Recommendation.

III.2.1 Level 1 Preferred Modes

The first level of support is composed of the following modes:

1. **Advanced INTRA Coding (Annex I).** Use of this mode improves the coding efficiency for INTRA macroblocks (whether within INTRA pictures or predictively-coded pictures). The additional computational requirements of this mode are minimal at both the encoder and decoder (as low as a maximum of 8 additions/subtractions per 8×8 block in the decoding process plus the use of a different but very similar VLC table in order to obtain a significant improvement in coding efficiency). For these reasons, Advanced INTRA Coding is included at this lowest level of support.

2. **Deblocking Filter (Annex J).** Because of the significant subjective quality improvement that may be realized with a deblocking filter, these filters are already widely in use as a method of post-processing in video communication terminals. Annex J represents the preferred mode of operation for a deblocking filter because it places the filter within the coding loop. This placement eases the implementation of the filter (by reducing the memory requirement) and somewhat improves the coding performance over a post-procesing implementation. As with the Advanced Prediction mode, this mode also includes the four-motion-vector-per-macroblock feature and picture boundary extrapolation for motion compensation, both of which can further improve coding efficiency. The computational requirements of the deblocking filter are several hundred

operatons per coded macroblock, but memory accesses and computational dependencies are uncomplicated. This last point is what makes the Deblocking Filter preferable to Advanced Prediction. Also, the benefits of Advanced Prediction are not as substantial when the Deblocking Filter is used as well. Thus, the Deblocking Filter is included at this lowest level of support while Advanced Prediction is deferred to Level 3.

3. **Supplemental Enhancement Information (Full-Frame Freeze Only) (Annex L Section L.4).** The full-frame freeze is very simple to implement, requiring only that the decoder be able to stop the transfer of data from its output buffer to the video display. This sub-mode is useful for preventing the display of low-fidelity pictures while the encoder is building up a higher fidelity picture.

4. **Modified Quantization (Annex T).** This mode includes an extended DCT coefficient range, modified DQUANT syntax, and a modified step size for chrominance. The first two features allow for more flexibility at the encoder and may actually decrease the encoder's computational load (by eliminating the need re-encode macroblocks when coefficient level saturation occurs). The third feature noticeably improves chrominance fidelity, typically with little added bit-rate cost and with virtually no increase in computation. At the decoder, the only significant computational burden is the ability to parse several new bitstream symbols.

III.2.2 Level 2 Preferred Modes

The second level of support is composed of the following modes:

1. **Unrestricted Motion Vectors (With UUI = "1" Sufficient) (Annex D).** Annex D has two primary features: (1) picture boundary extrapolation, and (2) longer motion vector support. The first is already supported by the inclusion of Annex J in the first level of support. The longer motion vector support can provide a significant improvement in coding efficiency, especially for large picture sizes, rapid motion, camera movement, and low picture rates. When used with PLUSPTYPE present, this mode also allows for longer motion vector differences, which can significantly simplify encoder operation. The longer motion vectors do present a potential problem for the decoder in terms of memory access, but frame-size-dependent limits on the maximum motion vector size prevent this problem from becoming an appreciable obstacle to implementation.

2. **Slice Structured Mode (Annex K).** For compatibility with packet-based transport layers, the Slice Structured mode is included here. All submodes of Annex K are to be supported, including the Rectangular Slice submode and the Arbitrary Slice Ordering submode. The additional computational burden imposed by the Slice Structured mode is minimal, limited primarily to bitstream generation and parsing.

3. **Reference Picture Resampling (Implicit Factor-of-4 Mode Only) (Annex P).** The implicit factor-of-4 mode of Reference Picture Resampling allows for automatic reference picture resampling only when the size of the new frame is changed, as indicated in the picture header. No bitstream overhead is required for this mode of operation. Predictive dynamic resolution changes allow an encoder to make intelligent trade-offs between temporal and spatial resolution. Furthermore, this simplest mode of operation for Annex P (factor of 4 upsampling or downsampling only) adds only a modest amount of computational complexity to both the encoder or decoder, since the factor of 4 case uses a simple fixed FIR filter (requiring roughly 4 operations per pixel, at most).

III.2.3 Level 3 Preferred Modes

The third and final level of support is composed of the following modes:

1. **Advanced Prediction (Annex F).** From a coding efficiency standpoint, this mode is the most important of the modes available in the prior version (Version 1) of this Recommendation. It includes overlapped block motion compensation, the four-motion-vector-per-macroblock feature, and it allows for motion vectors to point outside of the picture boundaries. The use of Advanced Prediction results in significant improvements in both subjective and objective performance. It does, however, require an appreciable increase in computation. More importantly, the data dependencies introduced by Advanced Prediction result in a complicated order of processing at the decoder. Coupled with the fact that the quality improvements are not as obvious when the Deblocking Filter is also in use, these complexity considerations are the reason this mode is part of the third support level, rather than the first. However, since implementations of Recommendation H.263 that were designed prior to the adoption of the other modes in this list might have implemented Advanced Prediction by itself, Advanced Prediction-only operation is also recommended for maximal backward compatibility.

2. **Improved PB-frames (Annex M).** The Improved PB-frames mode represents a substantial improvement over the basic PB-frames mode (Annex G) and has been demonstrated to significantly improve the coding efficiency for video sequences with a low degree of motion. While the basic version of PB-frames had problems in handling scene cuts and irregular motion, the Improved PB-frames mode may be used effectively at all times. In terms of computational burden, this mode is roughly neutral (especially for macroblock-pipelined architectures). However, because the Improved PB-frames mode can have a negative impact on delay and

because it requires an additional frame store to implement (at both the encoder and decoder), it is placed in a higher layer.

3. **Independent Segment Decoding (Annex R).** While the Independent Segment Decoding mode does introduce a significant amount of complexity (in terms of ease of implementation), it also significantly improves the error robustness of a video decoder, particularly in the presence of packet losses. For this reason, it is likely that many applications in which data can be lost in transmission (whether through packet loss or channel interference) will make use of the Independent Segment Decoding mode, especially in combination with the Slice Structured mode.

4. **Alternate INTER VLC (Annex S).** This mode has been demonstrated to improve coding efficiency especially for pictures with heavy motion which are coded with high fidelity. This mode uses the same VLC table as the Advanced INTRA Coding mode and is also simple from a computational standpoint (for each block, it requires at most one additional pass over the parsed symbols to decode them into DCT coefficients). However, it is possible that this mode could lead to some difficulty in implementation (especially on highly pipelined architectures), which is why it is not included at the lower levels of support.

III.3 Picture Formats and Picture Clock Frequencies

To ensure a high quality level of interoperability, encoders and decoders supporting a large standard picture format (QCIF, CIF, 4CIF, 16CIF) should support all smaller standard picture formats. (As specified elsewhere in this Recommendation, decoders shall support Sub-QCIF and QCIF, and encoders shall support Sub-QCIF or QCIF.) Decoders should be capable of operation with a smaller picture format at maximum frame rates no lower than the maximum frame rate for which it is capable of operation with a larger standard picture format. For example, a decoder capable of decoding 4CIF pictures at 15 pictures per second (actually 15*(1000/1001) pictures per second) should also be able to decode CIF, QCIF and SQCIF pictures at least at 15 pictures per second.

Encoders and decoders supporting custom picture formats and/or custom picture clock frequencies are recommended to follow the guidelines below:

1. An encoder or decoder which supports a custom picture format should support all standard picture formats equal or smaller in both height and width than those of any supported custom picture format. For example, an encoder supporting a custom picture format of 256×256 should support QCIF and SQCIF picture encoding.

2. An encoder or decoder which supports a custom picture clock frequency for a standard picture format should support a higher or equal frame rate (in pictures per second) at the standard picture clock frequency of 30 Hz (actually 30*(1000/1001) Hz) for the same picture format. For example, if a decoder supports QCIF pictures at 12.5 pictures per second with a 25 Hz picture clock, it should at least be able to decode QCIF pictures at 15 pictures per second at 30 Hz. If a custom picture format is used, all supported smaller or equal standard picture formats should be capable of operating at frame rates for the standard picture clock frequency no lower than the maximum frame rate of the custom picture format.

With TML-8 Changes edited by Thomas Wiegand

Title: H.26L Test Model Long Term Number 8 (TML-8) draft0.

Purpose: Test model

This d0 version of TML-8 includes the following changes from TML-6 (adopted in Austin and Porto Seguro):

- Run coding of coded MBs M29,M57
- 1/8 pixel prediction accuracy M45
- DQUANT on MB level M31
- Vectors pointing outside picture M34
- Dropping RDquant M72
- Drop of isolated chroma AC coefficients M32
- New sections7,8 for data partitioning and NAL(input not received yet) M52
- Some bug fixes
- New section for entropy coding including the description of UVLC and CABAC. (D. Marpe)
- Section "Motion Estimation and Mode Decision" with new High-complexity mode (H. Schwarz)

1 Scope

This document is a description of a reference coding method to be used for the development of a new compression method ITU-T recommendation- H.26L. The basic configuration of the algorithm is similar to H.263.

Some of the differences from H.263 are:

- Only one regular VLC is used for symbol coding
- 1/4 pixel positions are used for motion prediction
- A number of different blocksizes are used for motion prediction
- Residual coding is based on 4x4 blocks and a integer transform is used
- Multiple reference frames may be used for prediction and this is considered to replace any use of B-frames

The first part of the document describes the coding method by mainly defining the decoder actions. Towards the end, 'test model issues' relevant for the encoder to be used as reference for the development of the standard will be covered. This split should make it easy at a later stage to split the document into what is relevant for the standard and a test model. However, at the moment we find it preferable to have one combined document.

2 Organization of source- and compressed data

2.1 Picture formats

At the moment only the QCIF and CIF formats are included in the model [Not true of the software anymore – the document needs to be updated about this (but not relevant to testing at QCIF and CIF resolutions)].

2.2 Subdivision of a picture into macroblocks

A CIF picture is divided into 18x22 = 396 macroblocks. Similarly a QCIF picture is divided into 99 macroblocks as indicated in Figure 1. At the moment there are no other layers in the described model. [Slice layers are supported in the software, but not fully reflected in this document.]

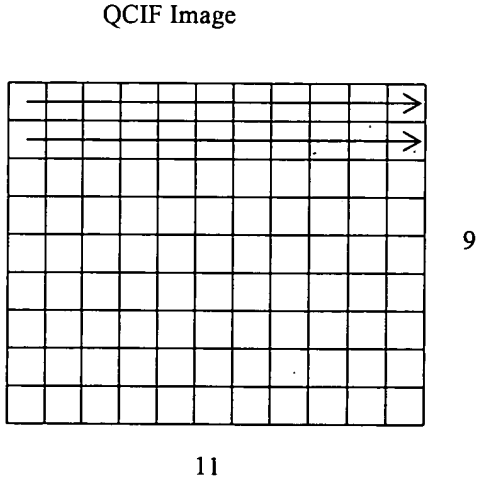

Figure 1 Subdivision of a QCIF picture into 16x16 macroblocks

2.3 *Order of the bitstream within a macroblock*

Figure 2 and Figure 3 indicates how a macroblock is divided and the order of the different syntax elements resulting from coding a macroblock.

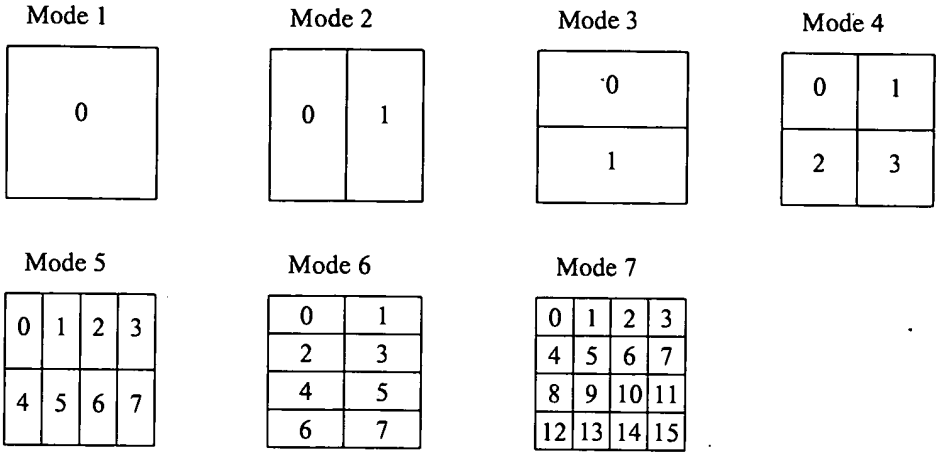

Figure 2 Numbering of the vectors for the different blocks depending on the inter mode. For each block the horizontal component comes first followed by the vertical component

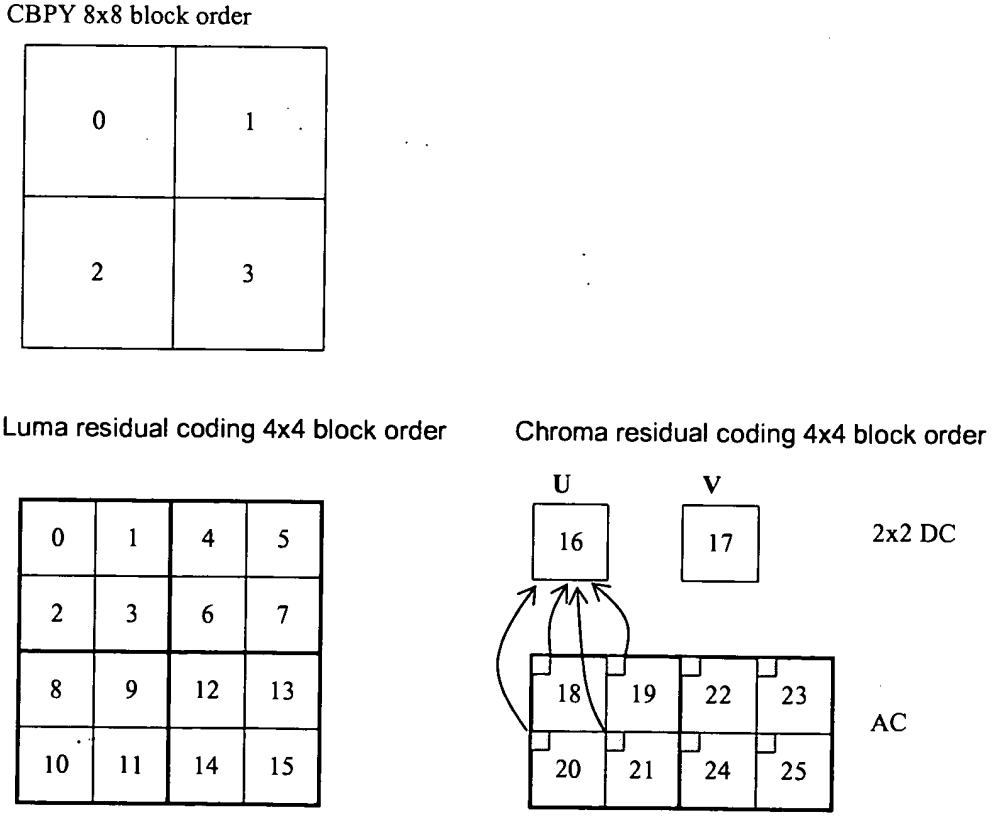

Figure 3 Ordering of blocks for CBPY and residual coding of 4x4 blocks

2.4 *Syntax*

2.4.1 Syntax diagram

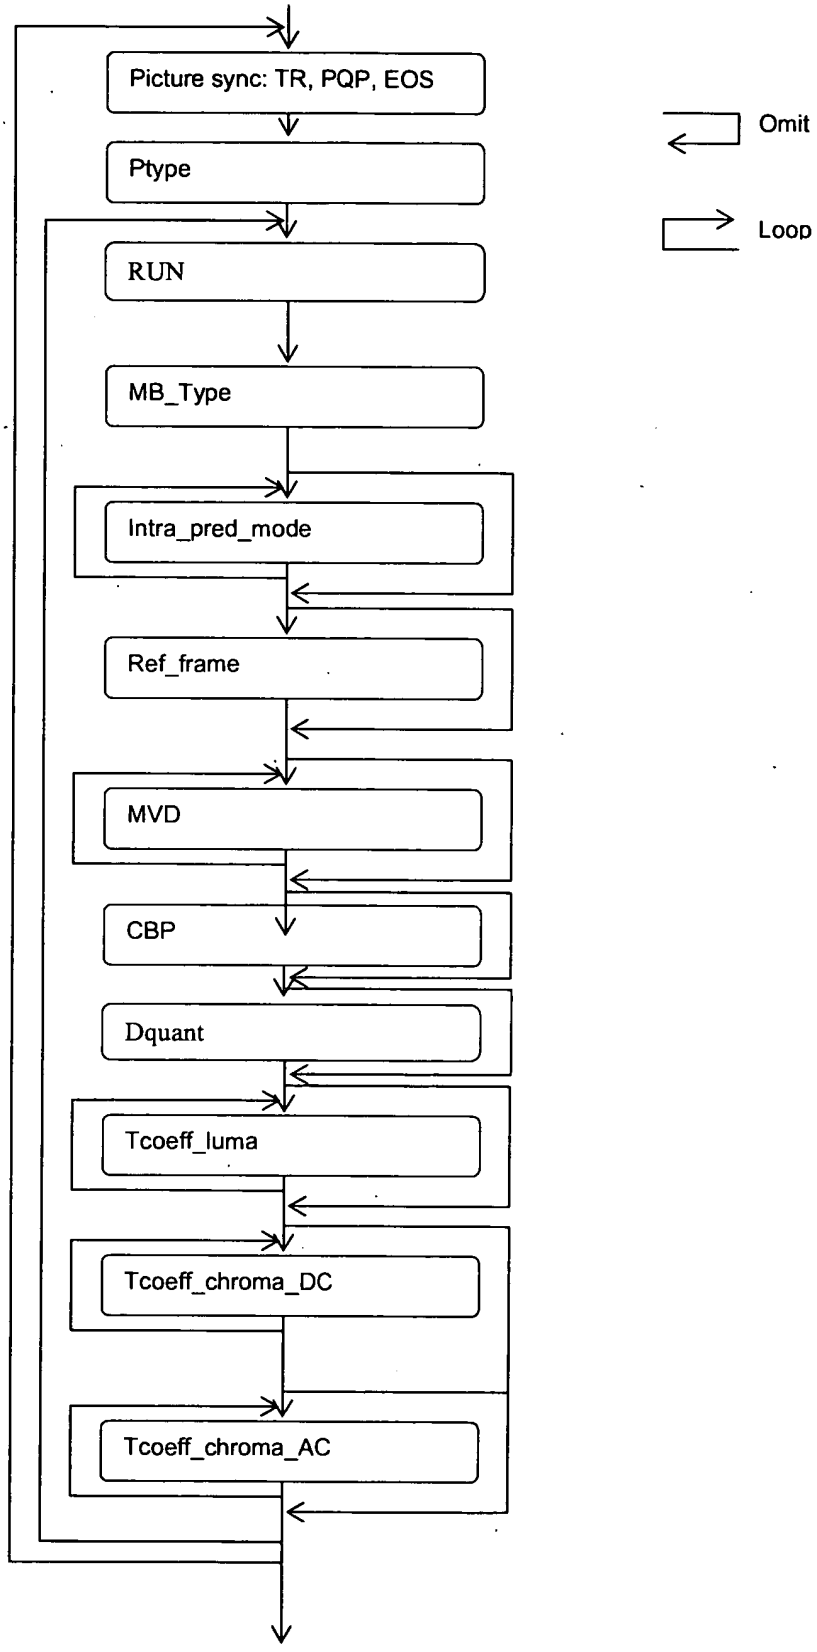

Figure 4 Syntax diagram for all the elements in the video bitstream

3 Description of syntax elements

3.1 Picture sync

The first codeword in a picture is 31 bits long (L = 31). It works as a picture sync, but it also contains an INFO part that has 15 bits. These bits are used for:

TR(8 bits) Temporal reference. The value of TR is formed by incrementing its value in the temporally-previous reference picture header by one plus the number of skipped or non-reference pictures at the picture clock frequency since the previously transmitted one.

PQP(5 bits) Picture QP: Information about the quantizer QUANT to be used for luma for the picture. (See under Quantization concerning QUANT for chroma). The 5 bit representation is the natural binary representations of the values of QP which range from 0 to 31. QP is a pointer to the actual quantization parameter QUANT to be used. (See below under quantization). The range of quantization value is still about the same as for H.263, 1-31. An approximate relation between the QUANT in H.263 and QP is: $QUANT_{H.263}(QP) \approx QP_0(QP) = 2^{QP/6}$. $QP_0()$ will be used later for scaling purposes when selecting prediction modes.

Formats 0 indicates QCIF, 1 indicates CIF

EOS 0 for picture header. 1 indicates End Of Sequence

The sketch below indicates where the different bits are located within INFO.

8b: TR	5b: PQP	1b: Formats	1b: EOS

3.2 Picture type (Ptype)

Code_number =0: Inter picture with prediction from the most recent decoded picture only.

Code_number =1: Inter picture with possibility of prediction from more than one previous decoded picture. For this mode information reference picture for prediction must be signalled for each macroblock.

Code_number =2: Intra picture.

Code_number =3: B picture with prediction from the most recent previous decoded and subsequent decoded pictures only.

Code_number =4: B picture with possibility of prediction from more than one previous decoded picture and subsequent decoded picture. When using this mode, information reference frame for prediction must be signaled for each macroblock.

3.3 RUN

A macroblock is called skipped if no information is sent. In that case the reconstruction of a n inter macroblock is made by copying the colocated picture material from the laset decoded frame. (See separate definition for B-pictures). RUN indicates the number of skipped macroblocks in an inter- or B-picture before a coded picture. If the last MB of the frame is not coded an additional codeword is added which points to a MB outside the picture.

3.4 Macro block type (MB_Type)

Refer to **Error! Reference source not found.**. There are different MB-Type tables for Intra and Inter frames.

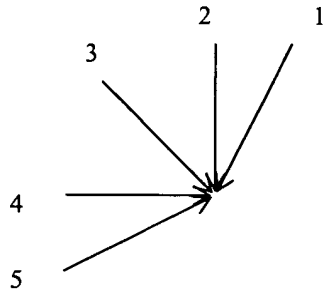
3.4.1 Intra

Intra 4x4 Intra coding as defined in sections 3.5.1 to 3.5.8.

Imode, nc, AC	See definition in section 3.5.9.3. These modes refer to 16x16 intra coding.

3.4.2 Inter

Skip	No further information about the macroblock is transmitted. A copy of the colocated macroblock in the most recent decoded picture is used as reconstruction for the present macroblock.
NxM (eg. 8x4)	The macroblock is predicted from a past picture with block size NxM. For each NxM block motion vector data is provided. Depending on N and M there may be 1 to 16 sets of motion vector data for a macroblock.
Intra 4x4	4x4 intra coding.



Code numbers from 9 and upwards represent 16x16 intra coding.

3.5 Intra prediction mode (Intra_pred_mode)

Even in Intra mode, prediction is always used for each sub block in a macroblock. A 4x4 block is to be coded (pixels labelled a to p below). The pixels A to I from neighbouring blocks are already decoded and may be used for prediction.

I	A	B	C	D
E	a	b	c	d
F	e	f	g	h
G	i	j	k	l
H	m	n	o	p

There are 6 intra prediction modes labelled 0 to 5. Mode 0 is 'DC-prediction' (see below). The other modes represent directions of predictions as indicated below.

3.5.1 Mode 0: DC prediction

Generally all pixels are predicted by (A+B+C+D+E+F+G+H)//8. If four of the pixels are outside the picture, the average of the remaining four is used for prediction. If all 8 pixels are outside the picture the prediction for all pixels in the block is 128. A block may therefore always be predicted in this mode.

3.5.2 Mode 1:

This mode is used only if all A,B,C,D are inside the picture.

a is predicted by:	(A+B)/2
e is predicted by	B
b,i are predicted by	(B+C)/2
f,m are predicted by	C
c,j are predicted by	(C+D)/2
d,g,h,k,l,n,o,p are predicted by	D

3.5.3 Mode 2: Vertical prediction

If A,B,C,D are inside the picture, a,e,i,m are predicted by A, b,f,j,n by B etc.

3.5.4 Mode 3: Diagonal prediction

This mode is used only if all A,B,C,D,E,F,G,H,I are inside the picture. This is a 'diagonal' prediction.

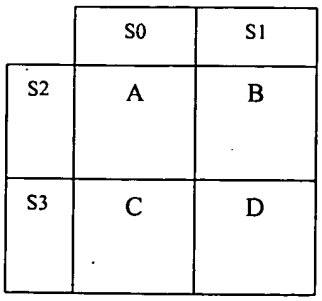
m is predicted by:	(H+2G+F)//4
i,n are predicted by	(G+2F+E)//4
e,j,o are predicted by	(F+2E+I)//4
a,f,k,p are predicted by	(E+2I+A)//4
b,g,l are predicted by	(I+2A+B)//4
c,h are predicted by	(A+2B+C)//4
d is predicted by	(B+2C+D)//4

3.5.5 Mode 4:Horizontal prediction

If E,F,G,H are inside the picture, a,b,c,d are predicted by E, e,f,g,h by F etc.

3.5.6 Mode 5:

This mode is used only if all E,F,G,H are inside the picture.



a is predicted by:	(E+F)/2
b is predicted by	F
c,e are predicted by	(F+G)/2
f,d are predicted by	G
i,g are predicted by	(G+H)/2
h,j,k,l,m,n,o,p are predicted by	H

3.5.7 Prediction of chroma blocks

For chroma prediction there is only one mode. No information is therefore needed to be transmitted. The prediction is indicated in the figure below. The 8x8 chroma block consists of 4 4x4 blocks A,B,C,D. S0,1,2,3 are the sums of 4 neighbouring pixels.

If S0, S1, S2, S3 are all inside the frame:
A = (S0 + S2 + 4)/8
B = (S1 + 2)/4
C = (S3 + 2)/4
D = (S1 + S3 + 4)/8

If only S0 and S1 are inside the frame:
A = (S0 + 2)/4
B = (S1 + 2)/4
C = (S0 + 2)/4
D = (S1 + 2)/4

If only S2 and S3 are inside the frame:
A = (S2 + 2)/4
B = (S2 + 2)/4
C = (S3 + 2)/4
D = (S3 + 2)/4
If S0, S1, S2, S3 are all outside the frame: A = B = C = D = 128
(Note: This prediction should be considered changed)

3.5.8 Coding of Intra prediction modes

Since each of the 4x4 luma blocks shall be assigned a prediction mode, this will require a considerable number of bits if coded directly. We have therefore tried to find more efficient ways of coding mode information. First of all we observe that the chosen prediction of a block is highly correlated with the prediction modes of adjacent blocks. This is illustrated in Figure 5 a. When the prediction modes of A and B are known (including the case that A or B or both are outside the picture) an ordering of the most probable, next most probable etc. of C is given. This ordering is listed in Table 1. For each prediction mode of A and B a list of 5 numbers is given. Example: Prediction mode for A and B is 2. The string 2 1 0 3 4 5 indicates that mode 2 is also the most probable mode for block C. Mode 1 is the next most probable one etc. In the bitstream there will for instance be information that Prob0 = 1 (see **Error! Reference source not found.**) indicating that the next most probable mode shall be used for block C. In our example this means Intra prediction mode 1. Use of '–' in the table indicates that this instance can not occur because A or B or both are outside the picture.
For more efficient coding, information on intra prediction of two 4x4 luma blocks are coded in one codeword (Prob0 and Prob1 in **Error! Reference source not found.**). The order of the resulting 8 codewords is indicated in Figure 5 b.

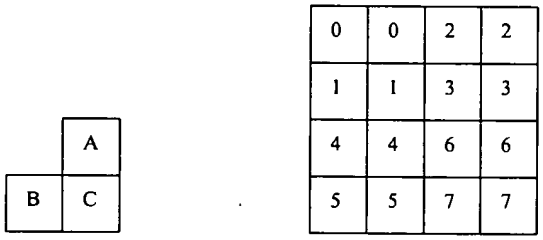


Figure 5 a) Prediction mode of block C shall be established. A and B are adjacent blocks. b) order of intra prediction information in the bitstream

Table 1 Prediction mode as a function of ordering signalled in the bitstream (see text)

B\A	outside	0	1	2	3	4	5
outside	0 -----	021 ---	102 ---	201 ---	012 ---	012 ---	012 ---
0	045 ---	041352	104325	230415	304215	043152	043512
1	045 ---	014325	102435	203145	032145	041325	014352
2	045 ---	012345	102345	210345	302145	042135	013245
3	045 ---	304152	310425	231054	304215	403512	305412
4	405 ---	403512	401532	240351	430512	403512	405312
5	504 ---	540312	015432	201453	530412	450312	504132

3.5.9 Intra mode based on 16x16 macroblocks (16x16 intra mode)

This intra mode is particularly suitable for regions with little details, also referred to as 'flat' regions.

3.5.9.1 Prediction modes

Assume that the block to be predicted has pixel locations 0 to 15 horizontally and 0 to 15 vertically. We use the notation P(i,j) where i,j = 0..15. P(i,-1), i=0..15 are the neighboring pixels above the block and P(-1,j), j=0..15 are the neighboring pixels to the left of the block. Pred(i,j) i,j = 0..15 is the prediction for the whole luma macroblock. We have 4 different prediction modes:

IMODE = 0 (vertical)

Pred(i,j) = P(i,-1), i,j=0..15

IMODE = 1 (horizontal)

Pred(i,j) = P(-1,j), i,j=0..15

IMODE = 2 (DC prediction)

$$\text{Pred(i,j)} = (\sum_{i=0}^{15}(P(-1,i)+P(i,-1)))/32 \quad \text{i,j=0..15}$$

IMODE = 3 (Plane prediction)

Pred(i,j) = (a + bx(i-7) + cx(j-7) +16)/32

Where:

a = 16x(P(-1,15) + P(15,-1))

b = 5x(*H*/4)/16

c = 5x(*V*/4)/16

$$H = \sum_{i=1}^{8} ix(P(7+i,-1)+P(7-i,-1))$$

$$V = \sum_{j=1}^{8} jx(P(-1,7+j)+P(-1,7-j))$$

3.5.9.2 Residual coding

The residual coding is based on 4x4 transform. But similar to coding of chroma coefficients, another 4x4 transform to the 16 DC coefficients in the macroblock are added. In that way we end up with an overall DC for the whole MB which works well in flat areas.

Since we use the same integer transform to DC coefficients, we have to perform additional normalization to those coefficients, which implies a division by 676. To avoid the division we performed normalization by $49/2^{15}$ on the encoder side and $48/2^{15}$ on the decoder side, which gives sufficient accuracy.

Only single scan is used for 16x16 intra coding.

To produce the bitstream, we first scan through the 16 'DC transform' coefficients. There is no 'CBP' information to indicate no coefficients on this level. If AC = 1 (see below) ac coefficients of the 16 4x4 blocks are scanned. There are 15 coefficients in each block since the DC coefficients are included in the level above.

3.5.9.3 Signalling of mode information for 16x16 intra coding

See **Error! Reference source not found.**. Three parameters have to be signaled. They are all included in MB-type.

Imode: 0,1,2,3

AC: 0 means there are no ac coefficients in the 16x16 block. 1 means that there is at least one ac coefficient and all 16 blocks are scanned.

nc: CBP for chroma (see 3.8)

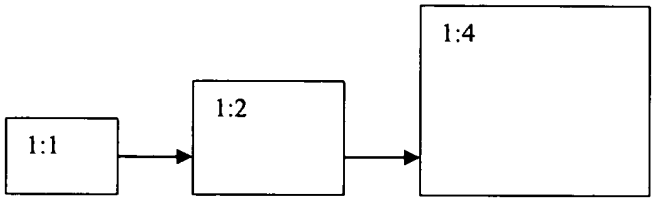
3.6 Reference frame (Ref_frame)

If PTYPE indicates possibility of prediction from more than one previous decoded picture, the exact frame to be used must be signalled. This is done according to the following table.

Code_number	Reference frame
0	The last decoded frame (1 frame back)
1	2 frames back
2	3 frames back
..	..

3.7 *Motion Vector Data (MVD)*

If so indicated by MB_type, vector data for 1-16 blocks are transmitted. For every block a prediction is formed for the horizontal and vertical components of the motion vector. MVD signals the difference between the vector component to be used and this prediction. The order in which vector data is sent is indicated in Figure 2. Motion vectors are allowed to point to pixels outside the reference frame. If a pixel outside the reference frame is referred to in the prediction process the nearest pixel belonging to the frame (an edge or corner pixel) shall be used. This process is performed on a pixel bases..



3.7.1 Fractional pixel accuracy

3.7.1.1 1/4 pixel accuracy

Note: It has been adopted to use direct interpolation to produce 1/4 pixel values (see VCEG-L20) at the decoder. However, this also has implications on the encoder which must use extra effort to avoid encoder/decoder mismatch. This issue will be further clarified in an ad.hoc. group and a solution presented at the next meeting. The text will then be updated.

In the baseline coding mode, 1/4 pixel accuracy is used to define motion vectors. To avoid encoder/decoder mismatch, the interpolation procedure has to be defined in detail.

The figure below indicates that interpolation for luminance may be defined as taking place in two steps.

Interpolation: 6H, 6V bilinear

Step I: Generation of ½ pixel positions

The 'x' - es below represent integer pixel positions. First the '+' - es (horizontal ½ pixel positions) are produced by using a 6 tap filter: (1,-5,20,20,-5,1)/32. The result is rounded to the nearest integer and clipped to the range 0 to 255. Then all the '*' – es are produced by using the same 6 tap. The result is rounded to the nearest integer and clipped to the range 0 to 255. If the filtering process refer to a pixel outside the picture, it is replaced by the nearest picture edge pixel.

```
x + x + x + x + x
* * * * * * * * *
x + x + x + x + x
* * * * * * * * *
x + x + x + x + x
* * * * * * * * *
```

Step II: Generation of ¼ pixel positions

The 'x' - es below represent ½ pixel positions (from above). First the '+' - es are produced by linear interpolation (average of the neighbouring ½ pixel positions). The result is truncated to the nearest integer. Then all the '*' – es are produced by vertical linear interpolation with truncation to the nearest integer.

```
x + x + x + x + x
* * * * * * * * *
x + x + x + x + x
* * * * * * * * *
x + x + x + x + x
* * * * * * * * *
```

Interpolation position with more low pass filtering

The figure below indicate a grid with interpolated positions where capital letters represent integer positions, numbers represent ½ pixel positions and lower case letters represent 1/4 pixel positions.

```
A a 1 b B
c d e f g
2 h 3 i 4
j k l m n
C o 5 p D
```

Relative to integer positions, the position m is chosen to represent a position with more low pass filtering. According to the definition above, m ≈ ('3' + '4' + '5' + 'D')/4. (≈ is used due to possible rounding effects). Instead we define:

m = ('A' + 'B' + 'C' + 'D' + 2)/4

3.7.1.2 1/8 pixel accuracy

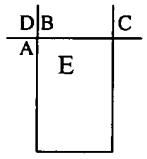
For a higher complexity or higher coding efficiency profile (not yet defined) 1/8 pixel accuracy prediction using 8-tap filters may be used. The interpolation process is assumed to be performed in a separable manner - first in the horizontal direction and then in the vertical direction. Hence the filter operation is fully specified by the one-dimensional filter taps. The filter taps are given below:

Position								
Integer				1				
1/8	(-3	12	-37	485	71	-21	6	-1)/512
2/8	(-3	12	-37	229	71	-21	6	-1)/256
3/8	(-6	24	-76	387	229	-60	18	-4)/512
4/8	(-3	12	-39	158	158	-39	12	-3)/256
5/8	(-4	18	-60	229	387	-76	24	-6)/512
6/8	(-1	6	-21	71	229	-37	12	-3)/256
7/8	(-1	6	-21	71	485	-37	12	-3)/512

3.7.2 Prediction of vector components

In all macroblocks with square motion vector blocks (16x16, 8x8, 4x4) "median prediction" (see 3.7.2.1) is used. In case the macroblock may be classified to have directional segmentation the prediction is defined in 3.7.2.2.

3.7.2.1 Median prediction



In the figure below the vector component E of the indicated block shall be predicted. The prediction is normally formed as the median of A, B and C. However, the prediction may be modified as described below. Notice that it is still referred to as "median prediction"

A The component applying to the pixel to the left of the upper left pixel in E

B The component applying to the pixel just above the upper left pixel in E

C The component applying to the pixel above and to the right of the upper right pixel in E

D The component applying to the pixel above and to the left of the upper left pixel in E

A, B, C, D and E may represent motion vectors from different reference pictures. As an example we may be seeking prediction for a motion vector for E from the last decoded picture. A, B, C and D may represent vectors from 2, 3, 4 and 5 pictures back. The following substitutions may be made prior to median filtering.

- If A and D are outside the picture, their values are assumed to be zero and they are considered to have "different reference picture than E".
- If D, B, C are outside the picture, the prediction is equal to A (equivalent to replacing B and C with A before median filtering).

- If C is outside the picture or still not available due to the order of vector data (see Figure 2), C is replaced by D.

If any of the blocks A, B, C, D are intra coded they count as having "different reference frame. If one and only one of the vector components used in the median calculation (A, B, C) refer to the same reference picture as the vector component E, this one vector component is used to predict E.

3.7.2.2 Directional segmentation prediction

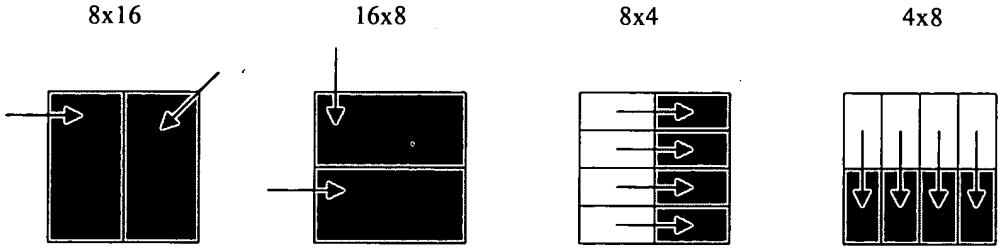
If the macroblock where the block to be predicted belongs to has a directional segmentation (vector block size of 8x16, 16x8, 8x4 or 4x8) the prediction is generated as follows (refer to figure below and the definitions of A, B, C, E above):

Vector block size 8x16:

Left block:	A is used as prediction if it has the same reference picture as E, otherwise "Median prediction" is used
Right block:	C is used as prediction if it has the same reference picture as E, otherwise "Median prediction" is used

Vector block size 16x8:

Upper block:	B is used as prediction if it has the same reference picture as E, otherwise "Median prediction" is used
Lower block:	A is used as prediction if it has the same reference picture as E, otherwise "Median prediction" is used



Vector block size 8x4:

For white blocks:	"Median prediction" is used
For shaded blocks:	A is used as prediction

Vector block size 4x8:

For white blocks:	"Median prediction" is used
For shaded blocks:	B is used as prediction

If the indicated prediction block is outside the picture, the same substitution rules are applied as in the case of median prediction.

3.7.3 Chroma vectors

Chroma vectors are derived from the luma vectors. Since chroma has half resolution compared to luma, the chroma vectors are obtained by a division of two:

Croma_vector = Luma_vector/2 - which means that the chroma vectors have a resolution of 1/8 pixel.

Due to the half resolution, a chroma vector applies to 1/4 as many pixels as the luma vector. For example if the luma vector applies to 8x16 luma pixels, the corresponding chroma vector applies to 4x8 chroma pixels and if the luma vector applies to 4x4 luma pixels, the corresponding chroma vector applies to 2x2 chroma pixel.

For fractional pixel interpolation for chroma prediction, bilinear interpolation is used. The result is rounded to the nearest integer.

3.8 Coded Block Pattern (CBP)

The CBP contains information of which 8x8 blocks - luma and chroma - contain transform coefficients. Notice that an 8x8 block contains 4 4x4 blocks meaning that the statement '8x8 block contains coefficients' means that 'one or more of the 4 4x4 blocks contain coefficients'. The 4 least significant bits of CBP contain information on which of 4 8x8 luma blocks in a macroblock contains nonzero coefficients. Let us call these 4 bits CBPY. The ordering of 8x8 blocks is indicated in Figure 3. A 0 in position n of CBP (binary representation) means that the corresponding 8x8 block has no coefficients whereas a 1 means that the 8x8 block has one or more non-zero coefficients.

For chroma we define 3 possibilities:

nc=0: no chroma coefficients at all.

nc=1 There are nonzero 2x2 transform coefficients. All chroma AC coefficients = 0. Therefore we do not send any EOB for chroma AC coefficients.

nc=2 There may be 2x2 nonzero coefficients and there is at least one nonzero chroma AC coefficient present. In this case we need to send 10 EOBs (2 for DC coefficients and 2x4=8 for the 8 4x4 blocks) for chroma in a macroblock.

The total CBP for a macroblock is: **CBP = CBPY + 16xnc**

The CBP is signalled with a different codeword for Inter macroblocks and Intra macroblocks since the statistics of CBP values are different in the two cases.

3.9 Dquant

Dquant contains the possibility of changing QUANT on the macroblock level. It does not need to be present for macroblocks without nonzero transform coefficients. More specifically Dquant is present for non-skipped macroblocks:

- If CBP indicates that there are nonzero transform coefficients in the MB

or

- If the MB is 16x16 based intra coded

Tha value of Dquant shall be interpreted in the same way as Motion Vecor Data (**Error! Reference source not found.**). Its value may range from -16 to +16 which enables the QP to be changed to any value in the range 0-31.

$QUANT_{new} = modulo_{32}(QUANT_{old} + Dquant + 32)$ (also known as "arithmetic wrap")

4 Transform and inverse transform

This section defines all elements related to transform coding and decoding. It is therefore relevant to all the syntax elements 'Tcoeff' in the syntax diagram.

4.1 4x4 block size

Instead of DCT, an integer transform with basically the same coding property as a 4x4 DCT is used. The transformation of the pixels a,b,c,d into 4 transform coefficients A,B,C,D is defined by:

```
A =  13a + 13b + 13c + 13d
B =  17a +  7b -  7c - 17d
C =  13a - 13b - 13c + 13d
D =   7a - 17b + 17c -  7d
```

The inverse transformation of transform coefficients A,B,C,D into 4 pixels a',b',c',d' is defined by:

```
a' = 13A + 17B + 13C +  7D
b' = 13A +  7B - 13C - 17D
```

```
c' = 13A -  7B - 13C + 17D
d' = 13A - 17B + 13C -  7D
```

The relation between a and a' is: a' = 676a. This is because the expressions defined above contain no normalisation. Normalisation will be performed in the quantization/dequantisation process and a final shift after inverse quantization.

The transform/inverse is performed both vertically and horizontally in the same manner as in H.263. By the above exact definition of inverse transform, the same operations will be performed on coder and decoder side which means that we have no 'inverse transform mismatch'.

4.2 2x2 transform/inverse transform of chroma DC coefficients

With the low resolution of chroma it seems to be preferable to have larger blocksize than 4x4. Specifically the 8x8 DC coefficient seems very useful for better definition of low resolution chroma. The 2 dimensional 2x2 transform procedure is illustrated below. DC0,1,2,3 are the DC coefficients of 2x2 chroma blocks.

DC0	DC1	**Two dimensional 2x2 transform** ⇒	DDC(0,0)	DDC(1,0)
DC2	DC3		DDC(0,1)	DDC(1,1)

Definition of transform:

DCC(0,0) = (DC0+DC1+DC2+DC3)/2

DCC(1,0) = (DC0-DC1+DC2-DC3)/2

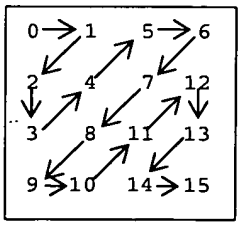
DCC(0,1) = (DC0+DC1-DC2-DC3)/2

DCC(1,1) = (DC0-DC1-DC2+DC3)/2

Definition of inverse transform:

DC0 = (DCC(0,0)+ DCC(1,0)+ DCC(0,1)+ DCC(1,1))/2

DC1 = (DCC(0,0)- DCC(1,0)+ DCC(0,1)- DCC(1,1))/2

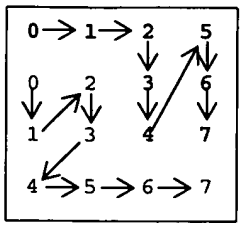


DC2 = (DCC(0,0)+ DCC(1,0)- DCC(0,1)- DCC(1,1))/2

DC3 = (DCC(0,0)- DCC(1,0)- DCC(0,1)+ DCC(1,1))/2

4.3 Scanning and quantization

4.3.1 Simple scan



Except for Intra coding of luma with QP<24, simple scan is used. This is basically zig-zag scanning similar to the one used in H.263. The scanning pattern is:

4.3.2 Double scan

When using the VLC defined above, we use a one bit code for EOB. For Inter blocks and Intra with high QP the probability of EOB is typically 50% which is well matched with the VLC. In other words this means

that we on average have one non-zero coefficient per 4x4 block in addition to the EOB code (remember that a lot of 4x4 blocks only have EOB). On the other hand, for Intra coding we typically have more than one non-zero coefficient per 4x4 block. This means that the 1 bit EOB becomes inefficient. To improve on this the 4x4 block is subdivided into two parts that are scanned separately and with one EOB each. The two scanning parts are shown below – one of them in bold.

4.3.3 Quantization

The quantization/dequantization process shall perform 'normal' quantization/dequantization as well as take care of the fact that transform operations are kept very simple and therefore do not contain normalization of transform coefficients. 32 different QP values are used. They are arranged so that there is an increase of step size of about 12% from one QP to the next. Increase of QP by 6 means that the step size is about doubled. There is no 'dead zone' in the quantization process and the total range of step size from smallest to largest is about the same as for H.263.

The QP signalled in the bitstream applies for luma quantization/dequantization. This could be called QP_{luma}. For chroma quantization/dequantization a different value - QP_{chroma} - is used. The relation between the two is:

QP_{luma}	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
QP_{chroma}	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	17	18	19	20	20	21	22	22	23	23	24	24	25	25

When QP is used in the following we mean QP_{luma} or QP_{chroma} depending on what is appropriate.

Two arrays of numbers are used for quantization/dequantization.

A(QP=0,..,31)
620,553,492,439,391,348,310,276,246,219,195,174,155,138,123,110,98,87,78,69,62,55,49,44,39,35,
31,27,24,22,19,17

B(QP=0,..,31)

3881,4351,4890,5481,6154,6914,7761,8718,9781,10987,12339,13828,15523,17435,19561,21873,24552,27656,308
47,34870,38807,43747,49103,54683,61694,68745,77615,89113,100253,109366,126635,141533

The relation between A() and B() is: $A(QP) \times B(QP) \times 676^2 = 2^{40}$.

It is assumed that a coefficient K is quantized in the following way:

$LEVEL = (KxA(QP) + fx2^{20})/2^{20}$ $|f|$ is in the range (0-0.5) and f has the same sign as K.

Dequantization:

K' = LEVELxB(QP)

After inverse transform this results in pixel values that are 2^{20} too high. A shift of 20 bits (with rounding) is therefore needed on the reconstruction side. The definition of transform and quantization is designed so that no overflow will occur with use of 32 bit arithmetic.

4.3.4 Scanning and quantization of 2x2 chroma DC coefficients

DDC() is quantized (and dequantized) separately resulting in LEVEL, RUN and EOB. The scanning order is: DCC(0,0), DCC(1,0), DCC(0,1), DCC(1,1). Inverse 2x2 transform as defined above is then performed after dequantization resulting in dequantized 4x4 DC coefficients: DC0' DC1' DC2' DC3'.

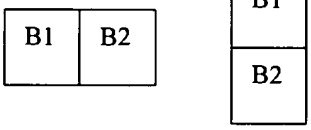
Chroma AC coefficients (4x4 based) are then quantized similarly to before. Notice that there are only 15 AC coefficients. The maximum size of RUN is therefore 14. However, for simplicity we use the same relation between LEVEL, RUN and Code no. As defined for 'Simple scan' in **Error! Reference source not found.**.

4.4 Use of 2-dimensional model for coefficient coding.

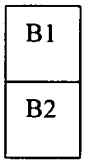
In the 3D model for coefficient coding (see H.263) there is no good use of a short codeword of 1 bit. On the other hand, with the use of 2D VLC plus End Of Block (EOB) (as used in H.261, H.262) and with the small block size, 1 bit for EOB is usually well matched to the VLC.

Furthermore, with the fewer non-zero coefficients per block, the advantage of using 3D VLC is reduced.

As a result we use a 2D model plus End Of Block (EOB) in the present model. This means that an event to be coded (RUN, LEVEL) consists of:



RUN which is the number of zero coefficients since the last nonzero coefficient.

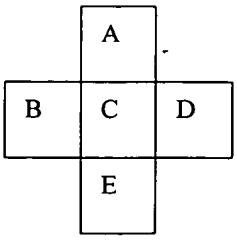


LEVEL the size of the nonzero coefficient

EOB signals that there are no more nonzero coefficients in the block

4.5 Deblocking filter

The deblocking filter process takes place both across vertical block edges and horizontal block edges. The filtering is performed first across vertical edges. The filtered pixels are then used when performing filtering across horizontal block edges. As a result block1 and block2 (see below) may be located in one of the positions:



The filtering may be based on 4x4 block boundaries or macroblock boundaries if one or both adjacent macroblocks are intra coded (see 4.5.3)

4.5.1 Block strength

Here we consider filteringbased on a 4x4 block structure. Each 4x4 block in a reconstructed picture is assigned a **Strength** value ranging from 0 to 3. This value is assigned based on different criteria. The maximum value is chosen. Assume that one criterion results in **value** to be assigned. The new assignment is: **Strength = max(Strength,value),** so that we always keep the maximum value. In the figure below A, B, C, D and E are 4x4 blocks. Blocks may be luma or chroma. Different strenght is used for luma and chroma. This difference is introduced by $\mathbf{St_0}$ which is 0 for chroma and 1 for luma.

The procedure for assignment is as follows:

- Initially each 4x4 block of a picture is assigned **Strength = 0**
- If C is intra coded: $\mathbf{Strength_C = St_0 + 2}$, $\mathbf{Strength_A = max(Strength_A, St_0 + 1)}$, $\mathbf{Strength_B = max(Strength_B, St_0 + 1)}$, $\mathbf{Strength_D = max(Strength_D, St_0 + 1)}$, $\mathbf{Strength_E = max(Strength_E, St_0 + 1)}$
- If C has nonzero transform coefficients: $\mathbf{Strength_C = max(Strength_C,2)}$, $\mathbf{Strength_A = max(Strength_A,1)}$, $\mathbf{Strength_B = max(Strength_B,1)}$, $\mathbf{Strength_D = max(Strength_D,1)}$, $\mathbf{Strength_E = max(Strength_E,1)}$

- For luma blocks: If the absolute difference between one of the vector components of block A and block C is at least one integer pixel (four ¼ pixels) then: **$Strength_A$ = max($Strength_A$,1), $Strength_C$ = max($Strength_C$,1)**. The same procedure is applied to vector differences between blocks (B and C), (C and D) and (C and E)
- For chroma blocks: Since chroma has half the resolution of luma, there may be different vectors also inside the chroma block C. This is illustrated by the horizontal broken line i block C. The procedure for a chroma block is that if the absolute difference between one of the vector components on each side of the boundary between A and C or across the dotted line inside C is at least one integer pixel (four ¼ pixels) then: **$Strength_A$ = max($Strength_A$,1), $Strength_C$ = max($Strength_C$,1)**. A similar procedure is applied to vector differences between blocks (B and C), (C and D) and (C and E) *(Note: This description for chroma may seem strange. It is written to reflect what happens in the software. A simpler rule should be sought and reflected in a later version of TML as well as in the software)*

4.5.2 Filtering of pixels on both sides of a 4x4 block boundary

In the following description it is assumed that a vertical 4x4 grid boundary is to be filtered (that is, horizontal filtering takes place). Horizontal grid boundaries are filtered utilizing the same algorithm, but 'left' pixels should be substituted for 'above' pixels and 'right' pixels for 'below' pixels. Let us denote the set of eight pixels across a 4x4 block boundary as l_4, l_3, l_2, l_1, r_1, r_2, r_3, r_4.
Up to two pixels can be updated as a result of the filtering process on both sides of the boundary (that is at most l_2, l_1, r_1, r_2). The number of updated pixels on both sides of the boundary depends on corresponding right and left activity parameters a_r and a_l. Both activity parameters are limited by the so called overall activity parameter *n*:

$$n = \begin{cases} 1 & \alpha + \alpha/2 \le 2\Delta \\ 2 & \alpha \le 2\Delta < \alpha + \alpha/2 \\ 3 & 2\Delta < \alpha \end{cases}$$

where $\Delta = |r_1 - l_1|$ is a positive integer representing gray level difference across the boundary, and α is a QP dependent threshold specified in Table 1.

QP	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
α	0	0	0	0	0	0	0	0	3	3	3	7	7	7	12	17	17	22	28	34	40	47	60	67	82	89	112	137	153	187	213	249
β	0	0	0	0	0	0	0	0	3	3	3	4	4	4	6	6	6	7	8	8	9	9	10	10	11	11	12	12	13	13	14	14

Table 1. QP dependent threshold parameters α and β.

The right filter activity parameter a_r is equal to the smallest integer i>0 not larger than *n* for which the inequality $|r_1 - r_{i+1}| * i > \beta$ holds. The QP dependent threshold β is given in Table 1. If no $i < n$ satisfies the condition, a_r is set to *n*. The left filter activity parameter a_l is obtained using the same set of rules substituting pixels on the right of the boundary r_i with pixels l_i on the left of the boundary. Once a_r and a_l are calculated, the pixels to be updated and their filtering support windows are determined by using Table 2. The same table applies for both right and left pixel although only right pixels are listed in the table. Information on how to filter the left pixels is obtained by swapping a_r and a_l and substituting r_1, r_2 with l_1, l_2.

a_r (only if a_l>1)	pixel r_1	pixel r_2
1	no filtering	no filtering
2	filtered	no filtering
3	filtered	filtered

Table 2. Pixels to be updated as a function of a_r.

When filtering within P frames, the left (right) activity parameter is upper bounded by 2 if *strength* of the left (right) 4x4 block is no larger than 1. Selected pixels are filtered as follows:

$$L_1 = (21*l_2 + 22*l_1 + 21*r_1 + 32)/64$$
$$L_2 = (21*l_3 + 22*l_2 + 21*L_1 + 32)/64$$
$$R_1 = (21*l_1 + 22*r_1 + 21*r_2 + 32)/64$$
$$R_2 = (21*R_1 + 22*r_2 + 21*r_3 + 32)/64$$

When either of pixels r_1, l_1 are updated by filtering then the difference between filtered and nonfiltered value is clipped to the range [-C, C] where C = (Clip(QP,strength$_{left}$) + Clip(QP,strength$_{right}$) + a_r + a_l) / 2. When pixel r_2 is updated by filtering then the difference is clipped to the range [-C_{right}, C_{right}] with C_{right} = Clip(QP,strength$_{right}$). Similarly for pixel l_2.

Definition of the table Clip(QP,strength):

QP	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	29	30	31
Clip(qp,1)	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	2	2	2	2	2	3	3
Clip(qp,2)	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	2	2	2	2	3	3	3	3	4	5	5
Clip(qp,3)	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	2	2	2	2	3	3	3	4	4	5	5	5	7	8	9

The filter is applied on a 4x4 grid for both luminance and chrominace, first for all the vertical then for all the horizontal block boundaries.

4.5.3 Filtering across macroblock boundaries connected to intra coding

In case of intra coding and areas in the picture with little texture the subjective quality may be improved by stronger filtering across macroblock boundaries. This stronger filtering across a macroblock boundary is performed if:

One or both of the adjacent macroblocks are intra coded

and

a_r and a_l are equal to 3

and

Δ is in the range [2-qp/4]

In case these conditions are fulfilled, the pixels l_3 to r_3 when filtering luminance frames and l_2 to r_2 when filtering chrominance frames are modified in the following way:

$$L_1 = (25*l_3 + 26*l_2 + 26*l_1 + 26*r_1 + 25*r_2 + 64)/128$$
$$L_2 = (25*l_4 + 26*l_3 + 26*l_2 + 26*L_1 + 25*r_1 + 64)/128$$
$$L_3 = (\quad 26*l_4 + 51*l_3 + 26*L_2 + 25*L_1 + 64)/128$$
$$R_1 = (25*l_2 + 26*l_1 + 26*r_1 + 26*r_2 + 25*r_3 + 64)/128$$
$$R_2 = (25*l_1 + 26*R_1 + 26*r_2 + 26*r_3 + 25*r_4 + 64)/128$$
$$R_3 = (25*R_1 + 26*R_2 + 51*r_3 + 26*r_4 \quad + 64)/128$$

Notice that when filtering across the next 4x4 block boundary, pixel r_3 may get overwritten. To compensate the effect R_3 is stored and used as l_2 when filtering across the next 4x4 block boundary.

Otherwise filtering is done as described in the section above.

5 Entropy Coding

5.1 *Universal Variable Length Coding (UVLC)*

In the default entropy coding mode, a universal VLC is used to code all syntax. The table of codewords may be written in the following compressed form.

$$
\begin{array}{c}
1 \\
0\ x_0\ 1 \\
0\ x_1\ 0\ x_0\ 1 \\
0\ x_2\ 0\ x_1\ 0\ x_0\ 1 \\
0\ x_3\ 0\ x_2\ 0\ x_1\ 0\ x_0\ 1 \\
\cdots\cdots\cdots\cdots\cdots
\end{array}
$$

where x_n take values 0 or 1. We will sometimes refer to a codeword with its length in bits (L) and INFO = x_n .. x_1 x_0 . Notice that the number of bits in INFO is L/2 (division by truncation). The codewords are numbered from 0 and upwards. The definition of the numbering is:

Code_number = $2^{L/2}$ + INFO -1 (L/2 use division with truncation. INFO = 0 when L = 1)

Some of the first code numbers and codewords are written explicitly in the table below. As an example, for the code number 5, L = 5 and INFO = 10 (binary) = 2 (decimal)

Code number	Codewords in explicit form
0	1
1	0 0 1
2	0 1 1
3	0 0 0 0 1
4	0 0 0 1 1
5	0 1 0 0 1
6	0 1 0 1 1
7	0 0 0 0 0 0 1
8	0 0 0 0 0 1 1
9	0 0 0 1 0 0 1
10	0 0 0 1 0 1 1
11	0 1 0 0 0 0 1
.....	. . . .

When L and INFO is known, the regular structure of the table makes it easy to create a codeword bit by bit. Similarly, a decoder may easily read bit by bit until the last "1" which gives the end of the codeword. L and INFO is then readily available. For each parameter to be coded, there is a conversion rule from the parameter value to the code number (or L and INFO). **Error! Reference source not found.** lists the connection between code number and most of the parameters used in the present coding method.

Table 2: Connection between codeword number and parameter values.

Code_ number	RUN	MB_Type		Intra_pred_mode[1]		MVD	CBP		Tcoeff_chroma_DC[2]		Tcoeff_chroma_AC[2] Tcoeff_luma[2] Simple scan		Tcoeff_luma[2] Double scan

[1] Prob0 and Prob1 defines the Intra prediction modes of two blocks relative to the prediction of prediction modes (see details in the section for Intra coding).

[2] For the entries above the horizontal line, the table is needed for relation between code number and Level/Run/EOB. For the remaining Level/Run combination there is a simple rule. The Level/Run combinations are assigned a code number according to the following priority: 1) sign of Level (+ -) 2) Run (ascending) 3) absolute value of Level (ascending).

[3] 16x16 based intra mode. The 3 numbers refer to values for (Imode,AC,nc) - see 3.5.9.3.

5.2 *Context-based Adaptive Binary Arithmetic Coding (CABAC)*

5.2.1 Overview

The entropy coding method of context-based adaptive binary arithmetic coding (CABAC) has three distinct elements compared to the default entropy coding method using a fixed, universal table of variable length codes (UVLC):

1. *Context modeling* provides estimates of conditional probabilities of the coding symbols. Utilizing suitable context models, given inter-symbol redundancy can be exploited by switching between different probability models according to already coded symbols in the neighborhood of the current symbol to encode.
2. *Arithmetic codes* permit non-integer number of bits to be assigned to each symbol of the alphabet. Thus the symbols can be coded almost at their entropy rate. This is extremely beneficial for symbol probabilities much greater than 0.5, which often occur with efficient context modeling. In this case, a variable length code has to spend at least one bit in contrast to arithmetic codes, which may use a fraction of one bit.
3. *Adaptive* arithmetic codes permit the entropy coder to adapt itself to non-stationary symbol statistics. For instance, the statistics of motion vector magnitudes vary over space and time as well as for different sequences and bit-rates. Hence, an adaptive model taking into account the cumulative probabilities of already coded motion vectors leads to a better fit of the arithmetic codes to the current symbol statistics.

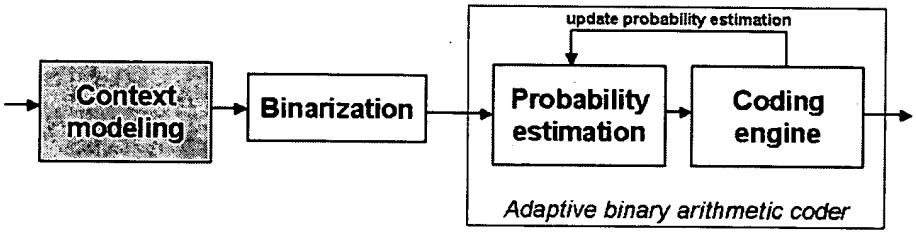

Figure 6: Generic block diagram of CABAC entropy coding scheme

Next we give a short overview of the main coding elements of the CABAC entropy coding scheme as depicted in Figure 6. Suppose a symbol related to an arbitrary syntax element is given, then, in a first step, a suitable model is chosen according to a set of past observations. This process of constructing a model conditioned on neighboring symbols is commonly referred to as *context modeling* and is the first step in the entropy coding scheme. The particular context models that are designed for each given syntax model are described in detail in Section 5.2.2 and Section 5.2.3. If a given symbol is non-binary valued, it will be mapped onto a sequence of binary decisions, so-called *bins*, in a second step. The actual *binarization* is done according to a given binary tree, as specified in Section 5.2.4. Finally, each binary decision is encoded with the *adaptive binary arithmetic coding* (AC) engine using the *probability estimates*, which have been provided either by the context modeling stage or by the binarization process itself. The provided models serve as a probability estimation of the related bins. After encoding of each bin, the related model will be updated with the encoded binary symbol. Hence, the model keeps track of the actual statistics.

5.2.2 Context Modeling for Coding of Motion and Mode Information

In this section we describe in detail the context modeling of our adaptive coding method for the syntax elements macroblock type (MB_type), motion vector data (MVD) and reference frame parameter (Ref_frame).

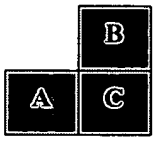
5.2.2.1 Context Models for Macroblock Type

We distinguish between MB_type for intra and inter frames. In the following, we give a description of the context models which have been designed for coding of the MB_type information in both cases. The subsequent process of mapping a non-binary valued MB_type symbol to a binary sequence in the case of inter frames will be given in detail in section 5.2.4.

5.2.2.1.1 Intra Pictures

For intra pictures, there are two possible modes for each macroblock, i.e. Intra4x4 and Intra16x16, so that signalling the mode information is reduced to transmitting a binary decision. Coding of this binary decision for a given macroblock is performed by means of context-based arithmetic coding, where the context of a current MB_type C is build by using the MB_types A and B[1] of neighboring macroblocks (as depicted in Figure 7) which are located in the causal past of the current coding event C. Since A and B are binary decisions, we define the actual context number *ctx_mb_type_intra(C)* of C by *ctx_mb_type_intra(C) = A + 2*B*, which results in four different contexts according to the 4 possible combinations of MB_type states for A and B.

In the case of MB_type Intra16x16, there are three additional parameters related to the chosen intra prediction mode, the occurrence of significant AC-coefficients and the coded block pattern for the chrominance coefficients, which have to be signaled. In contrast to the current test model, this information is not included in the mode information, but is coded separately by using distinct models as described in Section 5.2.3.



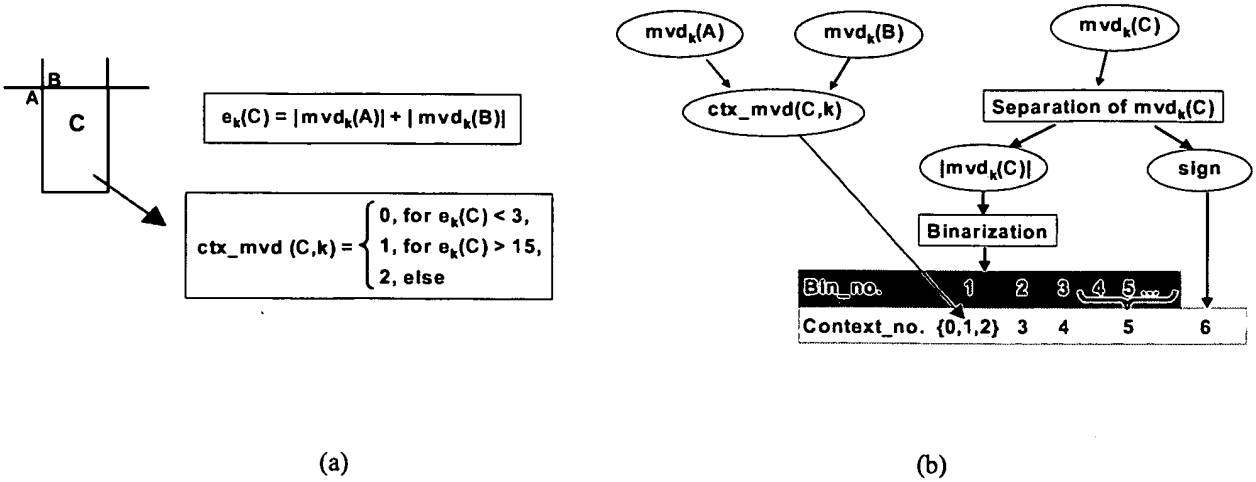


Figure 7: Neighboring symbols A and B used for conditional coding of a current symbol C.

5.2.2.1.2 P- and B-Pictures

Currently there a 10 different macroblock types for P-frames and 18 different macroblock types for B-frames, provided that the additional information of the 16x16 Intra mode is not considered as part of the mode information. Coding of a given MB_type information C is done similar to the case of intra frames by using a context model which involves the MB_type information A and B of previously encoded (or decoded) macroblocks (cp. Figure 7). However, here we only use the information whether the neighboring macroblocks of the given macroblock are of type Skip (P-frame) or Direct (B-frame), such that the actual context number *ctx_mb_type_inter(C)* is given in C-style notation for P-frame coding by *ctx_mb_type_inter(C) = ((A==Skip)?0:1) + 2*((B==Skip)?0:1)* and by *ctx_mb_type_inter(C) = ((A==Direct)?0:1) + 2*((B==Direct)?0:1)* for B-frame coding. Thus, we obtain 4 different contexts, which, however, are only used for coding of the first bin of the binarization ***b(C)*** of C, where the actual binarization of C will be performed as outlined in Section 5.2.4. For coding the second bin, a separate model is provided and for all remaining bins of ***b(C)*** two additional models are used as further explained in Sect. 5.2.3. Thus, a total number of 7 different models are supplied for coding of macroblock type information relating to P-and B-frames.

[1] For mathematical convenience the meaning of the variables A, B and C is context dependent.

(a) (b)

Figure 8: Illustration of the encoding process for a given residual motion vector component mvdk(C) of a block C: (a) Context selection rule. (b) Separation of mvdk(C) into sign and magnitude, binarization of the magnitude and assignment of context models to bin_nos.

5.2.2.2 Context Models for Motion Vector Data

Motion vector data consists of residual vectors obtained by applying motion vector prediction. Thus, it is a reasonable approach to build a model conditioned on the local prediction error. A simple measure of the local prediction error at a given block C is given by evaluating the L1-norm $e_k(A,B) = |mvd_k(A)| + |mvd_k(B)|$ of two neighboring motion vector prediction residues $mvd_k(A)$ and $mvd_k(B)$ for each component of a motion vector residue $mvd_k(C)$ of a given block, where A and B are neighboring blocks of block C, as shown in Figure 8 (a). If one of the neighboring blocks belongs to an adjacent macroblock, we take the residual vector component of the leftmost neighboring block in the case of the upper block B, and in the case of the left neighboring block A we use the topmost neighboring block. If one of the neighboring blocks is not available, because, for instance, the current block is at the picture boundary, we discard the corresponding part of e_k. By using e_k, we now define a context model *ctx_mvd(C,k)* for the residual motion vector component $mvd_k(C)$ consisting of three different context models:

$$ctx\_mvd(C,k) = \begin{cases} 0, e_k(C) < 3, \\ 1, e_k(C) > 15, \\ 2, else. \end{cases}$$

For the actual coding process, we separate $mvd_k(C)$ in sign and modulus, where only the first bin of the binarization of the modulus $|mvd_k(C)|$ is coded using the context models *ctx_mvd(C,k)*. For the remaining bins, we have three additional models: two for the second and the third bin and a third model for all remaining bins. In addition, the sign coding routine is provided with a separate model. This results in a total sum of 7 different models for each vector component (see Figure 8).

In the case of B-frame coding, an additional syntax element has to be signaled when the bi-directional mode is chosen. This element represents the block size (Blk_size), which is chosen for forward or backward motion prediction. The related code number value ranges between 0 and 6 according to the 7 possible block shapes **Error! Reference source not found.**. Coding of Blk_size is done by using the binarization of the P_MB_type as described in Section 5.2.3.

5.2.2.3 Context Models for Reference Frame Parameter

If the option of temporal prediction from more than one reference frame is enabled, the chosen reference frame for each macroblock must be signaled. Given a macroblock and its reference frame parameter as a symbol C according to the definition in Sect. 3, a context model is built by using symbols A and B of the reference frame parameter belonging to the two neighboring macroblocks (cp. Figure 7). The actual context number of C is then defined by *ctx_ref_frame(C) = ((A==0)?0:1) + 2*((B==0)?0:1)*, such that *ctx_ref_frame(C)* indicates one of four models used for coding of the first bin of the binary equivalent

b(C) of C. Two additional models are given for the second bin and all remaining bins of *b(C)*, which sums up to a total number of six different models for the reference frame information.

5.2.3 Context Modeling for Coding of Texture Information

This section provides detailed information about the context models used for the syntax elements of coded block pattern (CBP), intra prediction mode (IPRED) and (RUN, LEVEL) information.

5.2.3.1 Context Models for Coded Block Pattern

Except for MB_type Intra16x16, the context modeling for the coded block pattern is treated as follows. There are 4 luminance CBP bits belonging to 4 8x8 blocks in a given macroblock. Let C denote such a Y-CBP bit, then we define *ctx_cbp_luma(C) = A + 2*B,* where A and B are Y-CBP bits of the neighboring 8x8 blocks, as depicted in Figure 7. The remaining 2 bits of CBP are related to the chrominance coefficients. In our coding approach, these bits are translated into two dependant binary decisions, such that, in a first step, we send a bit *cbp_chroma_sig* which signals whether there are significant chrominance coefficients at all. The related context model is of the same kind as that of the Y-CBP bits, i.e. *ctx_cbp_chroma_sig(C) = A + 2*B,* where A and B are now notations for the corresponding *cbp_chroma_sig* bits of neighboring macroblocks. If *cbp_chroma_sig = 1* (non-zero chroma coefficients exist), a second bit *cbp_chroma_ac* related to the significance of AC chrominance coefficients has to be signalled. This is done by using a context model conditioned on the *cbp_chroma_ac* decisions A and B of neighboring macroblocks, such that *ctx_cbp_chroma_AC(C) = A + 2*B.* Note, that due to the different statistics there are different models for Intra and Inter macroblocks, so that the total number of different models for CBP amounts to 2*3*4=24. For the case of MB_type Intra16x16, there are three additional models, one for the binary AC decision and two models for each of the two chrominance CBP bits.

5.2.3.2 Context Models for Intra Prediction Mode

In Intra4x4 mode, coding of the intra prediction mode C of a given block is conditioned on the intra prediction mode of the previous block A to the left of C (cp. Figure 7). In fact, it is not the prediction mode number itself which is signaled and which is used for conditioning but rather its predicted order similar as it is desribed in Sect. 3.5.8. There are 6 different prediction modes and for each mode, two different models are supplied: one for the first bin of the binary equivalent of C and the other for all remaining bins. Together with two additional models for the two bits of the prediction modes of MB_type Intra16x16 (in binary representation), a total number of 14 different models for coding of intra prediction modes is given.

5.2.3.3 Context Models for Run/Level

Coding of (RUN, LEVEL) pairs is conditioned on the scanning mode, the DC/AC block type, the luminance/chrominance, and the intra/inter macroblock decision. Thus, a total number of 9 different block types are given according to Table 3, which, in turn, results in 9 different contexts. In contrast to the current test model, RUN and LEVEL are coded separately in our coding approach, as described in the following two subsections.

Ctx_run_level	Block Type
0	Double Scan
1	Single Scan, Inter
2	Single Scan, Intra
3	Intra16x16, DC
4	Intra16x16, AC
5	Chroma, DC, Inter
6	Chroma, DC, Intra
7	Chroma, AC, Inter
8	Chroma, AC, Intra

Table 3: Numbering of the different context models used for coding of RUN and LEVEL

5.2.3.3.1 Context-based Coding of LEVEL Information

For a given block C, the LEVEL information is first separated into sign and magnitude. According to its context *ctx_run_level(C)* four different models are chosen, where one model is used for coding of the sign information and the remaining 3 models are used for the first, the second and all remaining bins of the binarization of LEVEL. If LEVEL≠0 (EOB), the corresponding RUN is coded in a subsequent coding routine, as described in the following section.

5.2.3.3.2 Context-based Coding of RUN Information

For each context *ctx_run_level(C)* two separate models are provided for the coding of RUN; one model for the first bin and the second model for all remaining bins of the binary sequence related to RUN.

Code symbol	Binarization							
0	1							
1	0	1						
2	0	0	1					
3	0	0	0	1				
4	0	0	0	0	1			
5	0	0	0	0	0	1

. . .	.	.	.	.	.	.	.	.
Bin_no.	**1**	**2**	**3**	**4**	**5**	**6**	**7**	..

Table 4: Binarization by means of the unary code tree

5.2.4 Binarization of Non-Binary Valued Symbols

A non-binary valued symbol will be decomposed into a sequence of binary decisions. Except for the MB_type syntax element we use the binarization given by the unary code tree in Table 4.

P_MB_type	Binarization
0	0
1	1 0 0
2	1 0 1
3	1 1 0 0 0
4	1 1 0 0 1
5	1 1 0 1 0
6	1 1 0 1 1
7	1 1 1 0 0
8	1 1 1 0 1
9	1 1 1 1 0
Bin_no	**1 2 3 4 5**

(a)

B_MB_type	Binarization
0	0
1	1 0 0
2	1 0 1
3	1 1 0 0 0
4	1 1 0 0 1
5	1 1 0 1 0
6	1 1 0 1 1
7	1 1 1 0 0 0 0
.	.
17	1 1 1 1 0 1 0
Bin_no	**1 2 3 4 5 6 7**

(b)

Table 5: (a) Binarization for P-frame MB_type and (b) for B-frame MB_type

For the binary decomposition of the MB_type symbols of P- or B-frames, which are of limited range (0 ... 9) or (0 ... 17) respectively, an alternative binarization is used, which is shown in Table 5.

5.2.5 Adaptive Binary Arithmetic Coding

At the beginning of the overall encoding of a given frame the probability models associated with all 126 different contexts are initialized with a pre-computed start distribution. For each symbol to encode the frequency count of the related binary decision is updated, thus providing a new probability estimate for the next coding decision. However, when the total number of occurrences of a given model exceeds a pre-defined threshold, the frequency counts will be scaled down. This periodical rescaling exponentially weighs down past observations and helps to adapt to the non-stationarity of a source. The binary arithmetic coding engine used in our presented approach is a straightforward implementation similar to that given in Witten et al., "Arithmetic Coding for Data Compression", *Comm. of the ACM*, 30 (6), 1987, pp.520-541.

6 Test model issues

6.1 Motion Estimation and Mode Decision

6.1.1 Low-complexity mode

6.1.1.1 Finding optimum prediction mode

Both for intra prediction and motion compensated prediction, a similar loop as indicated in Figure 9 is run through. The different elements will be described below.

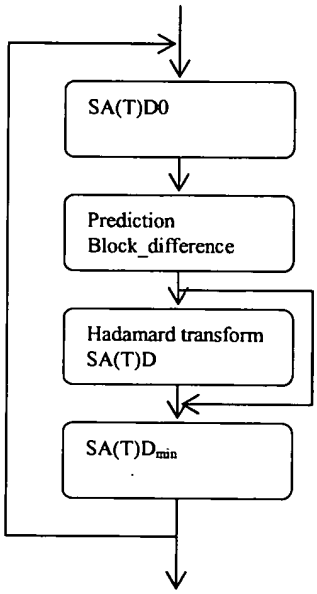

Figure 9 Loop for prediction mode decision

6.1.1.1.1 SA(T)D0

The SA(T)D to be minimised is given a 'bias' value initially in order to favour prediction modes that need few bits to be signalled. This bias is basically a parameter representing bit usage times $QP_0(QP)$

Intra mode decision: SA(T)D0 = $QP_0(QP)$xOrder_of_prediction_mode (see above)

Motion vector search: SA(T)D0 = $QP_0(QP)$x(Bits_to_code_vector + 2xcode_number_of_ref_frame)

In addition there are two special cases:

- For motion prediction of a 16x16 block with 0 vector components, 16x$QP_0(QP)$ is subtracted from SA(T)D to favour the skip mode.
- For the whole intra macroblock, 24x$QP_0(QP)$ is added to the SA(T)D before comparison with the best SA(T)D for inter prediction. This is an empirical value to prevent using too many intra blocks.

6.1.1.1.2 Block_difference

For the whole block the difference between the original and prediction is produced

Diff(i,j) = Original(i,j) - Prediction(i,j)

6.1.1.1.3 Hadamard transform

For integer pixel search (see below) we use SAD based on Diff(i,j) for decision. Hence no Hadamard is done and we use SAD instead of SATD.

$$SAD = \sum_{i,j} |Diff(i,j)|$$

However, since we will do a transform of Diff(i,j) before transmission, we will do a better optimisation if a transform is done before producing SAD. Therefore a two dimensional transform is performed in the decision loop for selecting intra modes and for fractional pixel search (see below). To simplify implementation, the Hadamard transform is chosen in this mode decision loop. The relation between pixels and basis vectors (BV) in a 4 point Hadamard transform is illustrated below (not normalized):

	Pixels →			
B	1	1	1	1
V	1	1	-1	-1
↓	1	-1	-1	1
	1	-1	1	-1

This transformation is performed horizontally and vertically and result in DiffT(i,j). Finally SATD for the block and for the present prediction mode is produced.

$$SATD = (\sum_{i,j} |DiffT(i,j)|)/2$$

Choose the prediction mode that results in the minimum $SA(T)D_{min}$.

6.1.1.2 Encoding on macroblock level

6.1.1.2.1 Intra coding

When starting to code a macroblock, intra mode is checked first. For each 4x4 block, full coding indicated in Figure 9 is performed. At the end of this loop the complete macroblock is intra coded and a $SATD_{intra}$ is calculated.

6.1.1.2.2 Table for intra prediction modes to be used at the encoder side

Table 6 gives the table of intra prediction modes according to probability of each mode to be used on the decoder side. On the encoder side we need a sort of inverse table. Prediction modes for A and B are known as in Table 1. For the encoder we have found a Mode that we want to signal with an ordering number in the bitstream (whereas on the decoder we receive the order in the bitstream and want to convert this to a mode). Table 6 is therefore the relevant table for the encoder. Example: Prediction mode for A and B is 2. The string in Table 6 is 2 1 0 3 4 5. This indicates that prediction mode 0 has order 2 (third most probable). Prediction mode 1 is second most probable and prediction mode 2 has order 0 (most probable) etc. As in Table 1 '–' indicates that this instance can not occur because A or B or both are outside the picture.

Table 6 Prediction ordering to be used in the bitstream as a function of prediction mode (see text).

B\A	outside	0	1	2	3	4	5
outside	0-----	021---	102---	120---	012---	012---	012---
0	0---12	025314	104325	240135	143025	035214	045213
1	0---12	014325	102435	13 0245	032145	024315	015324
2	0---12	012345	102345	210345	132045	032415	013245
3	0---12	135024	214035	320154	143025	145203	145032
4	1---02	145203	125403	250314	245103	145203	145302
5	1---20	245310	015432	120534	245130	245301	135420

6.1.1.2.3 Inter mode selection

Next motion vector search is performed for motion compensated prediction. A search is made for all 7 possible block structures for prediction as well as from the 5 past decoded pictures. This result in 35 combinations of blocksizes and reference frames.

6.1.1.2.4 Integer pixel search

The search positions are organised in a 'spiral' structure around the predicted vector (see vector prediction). The numbering from 0 and upwords for the first positions are listed below:

```
. .  .  .  .  .
.15  9 11 13 16
.17  3  1  4 18
.19  5  0  6 20
.21  7  2  8 22
.23 10 12 14 24
```

A parameter MC_range is used as input for each sequence. To speed up the search process, the search range is further reduced:

- Search range is reduced to: Range = MC_range/2 for all block sizes except 16x16 in prediction from the most recent decoded picture.
- The range is further reduced to: Range = Range/2 for search relative to all older pictures.

After Range has been found, the centre for the spiral search is adjusted so that:

- No vector position is outside the picture.
- The (0,0) vector position is within the search range. This is done by clipping the horizontal and vertical positions of the search centre to ±Range.

6.1.1.2.5 Fractional pixel search

Fractional pixel search is performed in two steps. This is illustrated below where capital letters represent integer positions, numbers represent ½ pixel positions and lower case letters represent ¼ pixel positions.

```
A       B       C

    1   2   3

D   4   E   5   F
      a b c
    6 d 7 e 8
      f g h
G       H       I
```

Assume that the integer search points to position E. Then ½ pixel positions 1,2,3,4,5,6,7,8 are searched. Assume that 7 is the best position. Then the ¼ pixel positions a,b,c,d,e,f,g,h are searched. (Notice that by this procedure a position with 'more low pass filtering' – see 3.7.1 - is automatically checked).

After fractional pixel search has been performed for the complete macroblock, the SATD for the whole macroblock is computed: $SATD_{inter}$.

6.1.1.2.6 Decision between intra and inter

If $SATD_{intra} < SATD_{inter}$ intra coding is used. Otherwise inter coding is used.

6.1.2 High-complexity mode

6.1.2.1 Motion Estimation

For each block or macroblock the motion vector is determined by full search on integer-pixel positions followed by sub-pixel refinement.

6.1.2.1.1 Integer-pixel search

As in low-complexity mode, the search positions are organized in a spiral structure around a prediction vector. The full search range given by MC_range is used for all INTER-modes and reference frames. To

speed up the search process , the prediction vector of the 16x16 block is used as center of the spiral search for all INTER-modes. Thus the SAD values for 4x4 blocks can be pre-calculated for all motion vectors of the search range and than used for fast SAD calculation of all larger blocks. The search range is not forced to contain the (0,0)-vector.

6.1.2.1.2 Fractional pixel search

The fractional pixel search is performed as in the low-complexity case.

6.1.2.1.3 Finding the best motion vector

The integer-pixel motion search as well as the sub-pixel refinement returns the motion vector that minimizes

$$J(\mathbf{m}, \lambda_{MOTION}) = SA(T)D(s, c(\mathbf{m})) + \lambda_{MOTION} \cdot R(\mathbf{m} - \mathbf{p})$$

with $\mathbf{m} = (m_x, m_y)^T$ being the motion vector, $\mathbf{p} = (p_x, p_y)^T$ being the prediction for the motion vector, and λ_{MOTION} being the Lagrange multiplier. The rate term $R(\mathbf{m} - \mathbf{p})$ represents the motion information only and is computed by a table-lookup. The rate is estimated by using the universal variable length code (UVLC) table, even if CABAC is used as entropy coding method. For integer-pixel search, SAD is used as distortion measure. It is computed as

$$SAD(s,\ c(\mathbf{m})) = \sum_{x=1,\ y=1}^{B,\ B} \left| s[x, y] - c[x - m_x, y - m_y] \right|, \quad B = 16, 8 \text{ or } 4 .$$

with *s* being the original video signal and *c* being the coded video signal. In the sub-pixel refinement search, the distortion measure SATD is calculated after a Hadamard transform (see section 6.1.1.1.3). The Lagrangian multiplier λ_{MOTION} is given by

$$\lambda_{MOTION,P} = \sqrt{5} \cdot e^{QP/20} \cdot \sqrt{\frac{QP+5}{34-QP}}$$

P-frames and

$$\lambda_{MOTION,B} = 2 \cdot \sqrt{5} \cdot e^{QP/20} \cdot \sqrt{\frac{QP+5}{34-QP}}$$

for B-frames, where QP is the macroblock quantization parameter.

6.1.2.1.4 Finding the best reference frame

The determination of the reference frame *REF* and the associated motion vectors for the *NxM* inter modes in P-frames and the *FWD NxM* modes in B-frames is done after motion estimation by minimizing

$$J(REF \mid \lambda_{MOTION}) = SATD(s, c(REF, \mathbf{m}(REF))) + \lambda_{MOTION} \cdot (R(\mathbf{m}(REF) - \mathbf{p}(REF)) + R(REF)) ;$$

The rate term $R(REF)$ represents the number of bits associated with choosing REF and is computed by table-lookup using UVLC. The reference frame and block sizes for the bi-directional mode are chosen as combination of the "best" forward and backward mode.

6.1.2.2 Mode decision

6.1.2.2.1 Macroblock mode decision

The macroblock mode decision is done by minimizing the Lagrangian functional

$$J(s,c,MODE \mid QP,\lambda_{MODE}) = SSD(s,c,MODE \mid QP) + \lambda_{MODE} \cdot R(s,c,MODE \mid QP)$$

where QP is the macroblock quantizer, λ_{MODE} is the Lagrange multiplier for mode decision, and $MODE$ indicates a mode chosen from the set of potential prediction:

I-frame: $MODE \in \{INTRA4x4,\ INTRA16x16\}$,

P-frame: $MODE \in \begin{Bmatrix} INTRA4x4,\ INTRA16x16,\ SKIP, \\ 16x16,\ 16x8,\ 8x16,\ 8x8,\ 8x4,\ 4x8,\ 4x4 \end{Bmatrix}$,

B-frame: $MODE \in \begin{Bmatrix} INTRA4x4,\ INTRA16x16,\ BIDIRECT,\ DIRECT, \\ FWD16x16,\ FWD16x8,\ FWD8x16,\ FWD8x8,\ FWD8x4, \\ FWD4x8,\ FWD4x4,\ BAK16x16,\ BAK16x8,\ BAK8x16, \\ BAK8x8,\ BAK8x4,\ BAK4x8,\ BAK4x4 \end{Bmatrix}$.

Note that the $SKIP$ mode refers to the 16x16 mode where no motion and residual information is encoded. SSD is the sum of the squared differences between the original block s and its reconstruction c being given as

$$SSD(s,c,MODE \mid QP) = \sum_{x=1,y=1}^{16,16} \left(s_Y[x,y] - c_Y[x,y,MODE \mid QP]\right)^2 + \sum_{x=1,y=1}^{8,8} \left(s_U[x,y] - c_U[x,y,MODE \mid QP]\right)^2 + \sum_{x=1,y=1}^{8,8} \left(s_V[x,y] - c_V[x,y,MODE \mid QP]\right)^2,$$

and $R(s,c,MODE \mid QP)$ is the number of bits associated with choosing $MODE$ and QP including the bits for the macroblock header, the motion, and all DCT blocks. $c_Y[x,y,MODE \mid QP]$ and $s_Y[x,y]$ represent the reconstructed and original luminance values; c_U, c_V and s_U, s_V the corresponding chrominance values.

The Lagrangian multiplier λ_{MODE} is given by

$$\lambda_{MODE,P} = 5 \cdot e^{QP/10} \cdot \left(\frac{QP+5}{34-QP}\right)$$

for I- and P-frames and

$$\lambda_{MODE,B} = 20 \cdot e^{QP/10} \cdot \left(\frac{QP+5}{34-QP}\right)$$

for B-frames, where QP is the macroblock quantization parameter.

6.1.2.2.2 INTER 16x16 mode decision

The *INTER16x16* mode decision is performed by choosing the INTER16x16 mode which results in the minimum SATD value.

6.1.2.2.3 INTER 4x4 mode decision

For the *INTRA4x4* prediction, the mode decision for each 4x4 block is performed similar to the macroblock mode decision by minimizing

$$J(s,c,IMODE \mid QP,\lambda_{MODE}) = SSD(s,c,IMODE \mid QP) + \lambda_{MODE} \cdot R(s,c,IMODE \mid QP)$$

where QP is the macroblock quantizer, λ_{MODE} is the Lagrange multiplier for mode decision, and $IMODE$ indicates an intra prediction mode:

$$IMODE \in \{DC, HOR, VERT, DIAG, DIAG\_RL, DIAG\_LR\}.$$

SSD is the sum of the squared differences between the original 4x4 block luminance signal$s$ and its reconstruction *c*, and $R(s,c,IMODE \mid QP)$ represents the number of bits associated with choosing *IMODE*. It includes the bits for the intra prediction mode and the DCT-coefficients for the 4x4 luminance block. The rate term is computed using the UVLC entropy coding, even if CABAC is used for entropy coding.

6.1.2.3 Algorithm for motion estimation and mode decision

The procedure to encode one macroblock s in a I-, P- or B-frame in the high-complexity mode is summarized as follows.

1. Given the last decoded frames, λ_{MODE}, λ_{MOTION}, and the macroblock quantizer QP
2. Choose intra prediction modes for the *INTRA 4x4* macroblock mode by minimizing

$$J(s,c,IMODE \mid QP,\lambda_{MODE}) = SSD(s,c,IMODE \mid QP) + \lambda_{MODE} \cdot R(s,c,IMODE \mid QP)$$

   with $IMODE \in \{DC, HOR, VERT, DIAG, DIAG\_RL, DIAG\_LR\}$.

3. Determine the best $INTRA16x16$ prediction mode by choosing the mode which results in the minimum SATD.

4. Perform motion estimation and reference frame selection by minimizing

$$J(REF, \mathbf{m}(REF) \mid \lambda_{MOTION}) = SA(T)D(s, c(REF, \mathbf{m}(REF))) + \lambda_{MOTION} \cdot (R(\mathbf{m}(REF) - \mathbf{p}(REF)) + R(REF))$$

for each reference frame and motion vector of a possible macroblock mode.

5. Choose the macroblock prediction mode by minimizing

$$J(s, c, MODE \mid QP, \lambda_{MODE}) = SSD(s, c, MODE \mid QP) + \lambda_{MODE} \cdot R(s, c, MODE \mid QP),$$

given QP and λ_{MODE} when varying $MODE$. $MODE$ indicates a mode out of the set of potential macroblock modes:

I-frame: $MODE \in \{INTRA4x4, INTRA16x16\}$,

P-frame: $MODE \in \begin{Bmatrix} INTRA4x4, INTRA16x16, SKIP, \\ 16x16, 16x8, 8x16, 8x8, 8x4, 4x8, 4x4 \end{Bmatrix}$,

B-frame: $MODE \in \begin{Bmatrix} INTRA4x4, INTRA16x16, BIDIRECT, DIRECT, \\ FWD16x16, FWD16x8, FWD8x16, FWD8x8, FWD8x4, \\ FWD4x8, FWD4x4, BAK16x16, BAK16x8, BAK8x16, \\ BAK8x8, BAK8x4, BAK4x8, BAK4x4 \end{Bmatrix}$.

The computation of $J(s, c, SKIP \mid QP, \lambda_{MODE})$ and $J(s, c, DIRECT \mid QP, \lambda_{MODE})$ is simple. The costs for the other macroblock modes are computed using the intra prediction modes or motion vectors and reference frames, which have been estimated in steps 2- 4.

6.2 Quantization

For each transform coefficient K the quantized LEVEL is produced in the following way:

LEVEL = (KxA(QP) + fx2^{20})/2^{20} |f| is 1/3 for intra and 1/6 for inter blocks and f has the same sign as K.

6.3 Elimination of single coefficients in inter macroblocks

6.3.1 Luma

With the small 4x4 blocks, it may happen that for instance a macroblock has only one nonzero coefficient with |Level| =1. This will probably be a very expensive coefficient and it could have been better to set it to zero. For that reason a procedure to check single coefficients have been implemented for inter luma blocks. During the quantization process, a parameter **Single_ctr** is accumulated depending on Run and Level according to the following rule:

If Level = 0 or (|Level| = 1 and Run > 5) nothing is added to **Single_ctr**.

If |Level| > 1, 9 is added to **Single_ctr**.

If |Level| = 1 and Run < 6, a value T(Run) is added to **Single_ctr**. where T(0:5) =(3,2,2,1,1,1)

If the accumulated **Single_ctr** for a 8x8 block is less than 4, all coefficients of that luma block are set to zero. Similarly, if the accumulated **Single_ctr** for the whole macroblock is less than 6, all coefficients of that luma macroblock are set to zero.

6.3.2 Chroma

A similar method to the one for luma is used. **Single_ctr** is calculated similarly for each chroma component, but for AC coefficients only and for the whole macroblock.

If the accumulated **Single_ctr** for each chroma component of a macroblock is less than 7, all the AC chroma coefficients of that component for the whole macroblock are set to zero.

7 B-pictures

7.1 Introduction

This is a first definition of B pictures to be used in TML. It is mainly intended to get started on work of testing relevant coding tools. Due to the early stage of definition, a separate description and definition of syntax elements is included in this section. In a later version of TML it is foreseen that B-frames will be fully incorporated in the remaining definition. The use of B pictures is indicated in PTYPE.

Temporal scalability is achieved using bi-directionally predicted pictures, or B pictures. The B pictures are predicted from either or both the previous and subsequent reconstructed pictures to achieve improved coding efficiency as compared to that of P pictures. The B pictures are disposable, since the B pictures are not used as reference pictures for the prediction of any other pictures. This property allows B pictures to be discarded without destroying the ability to decode the sequence and adversely affecting the quality of any subsequent pictures, thus providing temporal scalability. Figure A.1 illustrates the predictive structure with two B pictures inserted between I/P pictures.

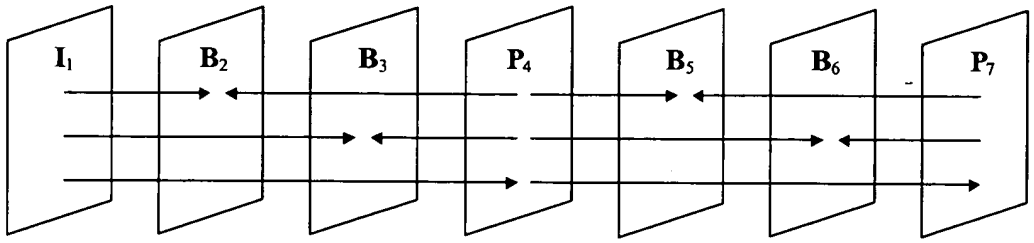

FIGURE A.1/H.26L

The location of B pictures in the bitstream is in a data-dependence order rather than in temporal order. Pictures that are dependent on other pictures shall be located in the bitstream after the pictures on which they depend. For example, as illustrated in Figure A.1, B_2 and B_3 are dependent on I_1 and P_4, and B_5 and B_6 are dependent on P_4 and P_7. Therefore the bitstream syntax order of the encoded pictures would be I_1, P_4, B_2, B_3, P_7, B_5, B_6, ... However, the display order of the decoded pictures should be I_1, B_2, B_3, P_4, B_5, B_6, P_7, ... The difference between the bitstream order of encoded pictures and the display order of decoded pictures will increase latency and memory to buffer the P pictures.

There is no limit to the number of B pictures that may be inserted between each I/P picture pair. The maximum number of such pictures may be signaled by external means (for example Recommendation H.245). The picture height, width, and pixel aspect ratio of a B picture shall always be equal to those of its temporally subsequent reference picture.

The B pictures described in this section support multiple reference frame prediction. The maximum number of previous reference frames that may be used for prediction in B pictures must be less than or equal to the number of reference frames used in the immediately following P frame, and it may be signaled by external means (for example Recommendation H.245). The use of this mode is indicated by PTYPE.

7.2 Five Prediction modes

There are five different prediction modes supported by B pictures. They are direct, forward, backward, bi-directional and the intra prediction modes. Both direct mode and bi-directional mode are bi-directional prediction. The only difference is that the bi-directional mode uses separate motion vectors for forward and backward prediction, whereas the forward and backward motion vectors of the direct mode are derived from the motion vectors used in the corresponding macroblocks of the subsequent reference frame. In the direct mode, the same number of motion vectors are used as are used in the reference macroblock for prediction. To calculate prediction blocks for the direct and bi-directional prediction mode, the forward and backward motion vectors are used to obtain appropriate blocks from reference frames and then these blocks are averaged by dividing the sum of the two prediction blocks by two.

Forward prediction means prediction from a previous reference picture, and backward prediction means prediction from a temporally subsequent reference picture.

The intra prediction means to encode the macroblock by using intra coding.

7.3 Finding optimum prediction mode

SA(T)D is initialized by a bias value to favor a prediction mode that needs few bits to be transmitted. This bias value is bit usage times $QP_0(QP)$ for the given coding mode.

For flat regions having zero motion, B pictures basically fail to make effective use of zero motion and instead are penalized in performance by selecting 16x16 intra mode. Therefore, in order to prevent assigning 16x16 intra mode to a region with little details and zero motion, SA(T)D of direct mode is subtracted by $16xQP_0(QP)$ to bias the decision toward selecting the direct mode.

And SA(T)D of 4x4 intra mode employs the same manner as section 5.1.

The calculation of SA(T)D at each mode is as follows.

- Forward prediction mode :

  $SA(T)D0 = QP_0(QP) \times (2 \times code\_number\_of\_Ref\_frame + Bits\_to\_code\_MVDFW)$

- Backward prediction mode :

  $SA(T)D0 = QP_0(QP) \times Bits\_to\_code\_MVDBW$

- Bi-directional prediction mode :

  $SA(T)D0 = QP_0(QP) \times (2 \times code\_number\_of\_Ref\_frame + Bits\_to\_code\_forward\_Blk\_size + Bits\_to\_code\_backward\_Blk\_size + Bits\_to\_code\_MVDFW + Bits\_to\_code\_MVDBW)$

- Direct prediction mode :

  $SA(T)D = SA(T)D - 16 \times QP_0(QP)$

- 4x4 Intra mode :

  $SA(T)D0 = QP_0(QP) \times Order\_of\_prediction\_mode$

  $SA(T)D = SA(T)D + 24 \times QP_0(QP)$

Finally the mode with the minimum $SA(T)D_{min}$ is selected as an optimum prediction mode.

7.4 Syntax

Some additional syntax elements are needed for B pictures. The structure of B picture related fields is shown in Figure A.2. On the Ptype, two picture types shall be added to include B pictures with and without multiple reference frame prediction. On the MB_type, different macroblock types shall be defined to indicate the different prediction types for B pictures. The fields of Blk_size, MVDFW, and MVDBW shall be inserted to enable bi-directional prediction.

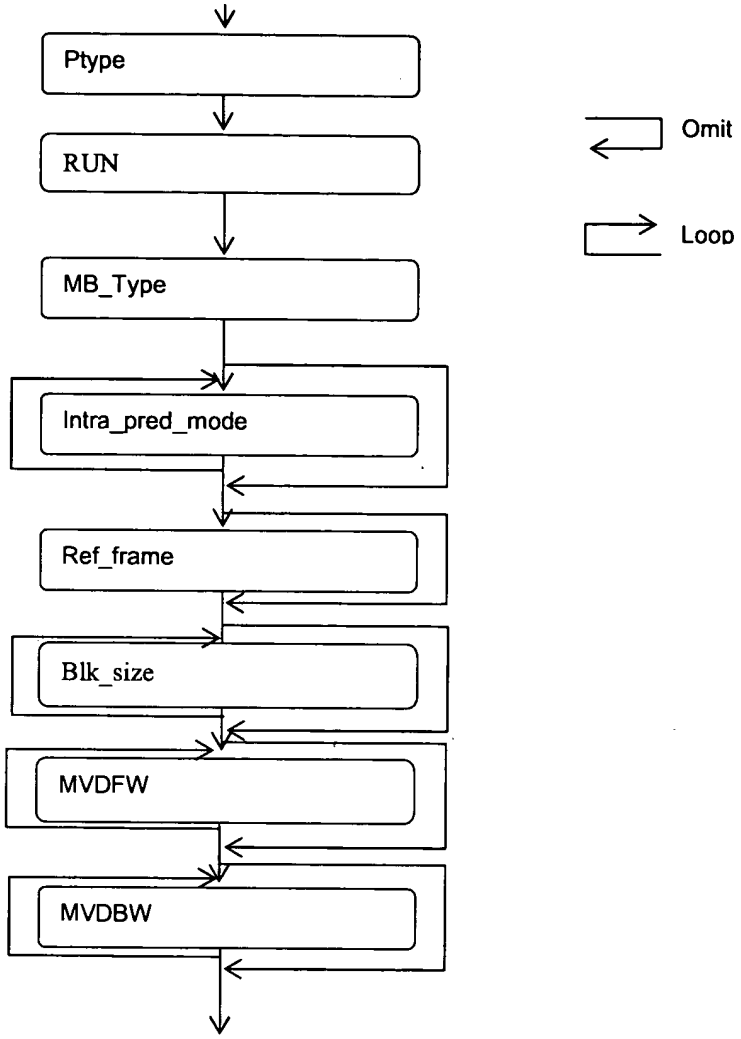

FIGURE A.2/H.26L

7.4.1 Picture type (Ptype) and RUN

See sections 3.2 and 3.3 for definitions.

7.4.2 Macro block type (MB_type)

The MB_type indicates the prediction mode and block size used to encode each macroblock. As mentioned earlier, five different prediction modes are supported by B pictures. For the forward, backward and bi-directional prediction modes, a macroblock is predicted from either or both of the previous and subsequent pictures with block size NxM. Table A.1 shows the macroblock types and the included data elements for B pictures.

In "Direct" prediction type, no motion vector data is transmitted.

The "Forward_NxM" indicates that the macroblock is prediction from a previous picture with block size NxM. The "backward_NxM" indicates that the macroblock is prediction from a subsequent picture with block size NxM. For each NxM block, motion vector data is provided. Therefore, depending on N and M, up to 16 sets of motion vector data have to be transmitted for a macroblock.

For the "Bi-directional" prediction type, the parameter Blk_size is used to indicate the block size used for forward and backward motion prediction (the Blk_size field is described in detail below). Both forward and backward motion vector data sets are transmitted. Depending on the block size indicated in Blk_size, up to 16 fields of motion vector data is transmitted for each of forward and backward prediction for a macroblock.

The "Intra_4x4" and "Intra_16x16" prediction type indicates that the macroblock is encoded by intra coding with different intra prediction modes which are defined in the same manner as section 3.4. No transmitted motion vector data is needed for intra mode.

7.4.3 Intra prediction mode (Intra_pred_mode)

As present, Intra_pred_mode indicates which intra prediction mode is used for a macroblock. Intra_pred_mode is present when Intra_4x4 prediction type is indicated in the MB_type. The code_number is same as that described in the Intra_pred_mode entry of Table 1.

7.4.4 Reference Frame (Ref_frame)

At present, Ref_frame indicates the position of the reference frame in the reference frame buffer to be used for forward motion compensated for current macroblock. Ref_frame is present only when the Ptype signals the use of multiple reference frames and only when the present MB_type indicates Forward_NxM or Bi-directional prediction type. Decoded I/P pictures are stored in the reference frame buffer in first-in-first-out manner and the most recently decoded I/P frame is always stored at position 0 in the reference frame buffer. The code_number for Ref_frame is described in Table A.2.

TABLE A.1/H.26L

MB_Type and related data elements for B pictures

0	Direct					
Code_number	Prediction Type	Intra_pred _mode	Ref_frame[1]	Blk_size	MVDFW	MVDBW
1	Forward_16x16		X		X	
2	Backward_16x16					X
3	Bi-directional		X	X	X	X
4	Forward_16x8		X		X	
5	Backward_16x8					X
6	Forward_8x16		X		X	
7	Backward_8x16					X
8	Forward_8x8		X		X	
9	Backward_8x8					X
10	Forward_8x4		X		X	
11	Backward_8x4					X
12	Forward_4x8		X		X	
13	Backward_4x8					X
14	Forward_4x4		X		X	
15	Backward_4x4					X
16	Intra_4x4	X				
17	Intra_16x16[2]					
...	...					

[1] Ref_frame is a valid field only when the usage of multiple reference frames is present in Ptype, e.g., when Ptype=4 the Ref_frame field is present.

[2] Intra_16x16 indicates 16x16 based intra mode and should represent 24 different prediction modes as defined in section 3.4.9 in Q15-J-28. For code_number greater than 16 in Table A.1, please see the code numbers from 9 and upwards in the field of inter MB_type of Table 1 in Q15-J-28 for reference.

TABLE A.2/H.26L

Code_number for ref_frame

Code_number	Reference frame
0	The most recent previous frame (1 frame back)
1	2 frames back
2	3 frames back
...	...

7.4.5 Block Size (Blk_size)

If present, Blk_size indicates which block size is used for forward and backward motion prediction in a macroblock as described in Table A.3. Blk_size is present only when Bi-directional prediction type is indicated in the MB_type. There are two sets of Blk_size data, one for forward motion vector data, and another for backward motion vector data.

TABLE A.3/H.26L

Code_number for Blk_size

Code_number	Block Size
0	1 16x16 block
1	4 8x8 blocks
2	2 16x8 blocks
3	2 8x16 blocks
4	2 8x4 blocks
5	8 4x8 blocks
6	16 4x4 blocks

7.4.6 Motion vector data (MVDFW, MVDBW)

MVDFW is the motion vector data for the forward vector, if present. MVDBW is the motion vector data for the backward vector, if present. If so indicated by MB_type or Blk_size (bi-directional prediction type only), vector data for 1-16 blocks are transmitted. The order of transmitted motion vector data is the same as that indicated in Figure2. For the code_number of motion vector data, please refer to Table 1.

7.5 Decoder Process for motion vector

7.5.1 Differential motion vectors

Motion vectors for forward, backward, or bi-directionally predicted macroblock are differentially encoded. A prediction has to be added to the motion vector differences to get the motion vectors for the macroblock. The predictions are formed in way similar to that described in section 3.6.2. The only difference is that forward motion vectors are predicted only from forward motion vectors in surrounding macroblocks, and backward motion vectors are predicted only from backward motion vectors in surrounding macroblocks.

If a neighboring macroblock does not have a motion vector of the same type or does not use the same reference frame for multiple reference frame prediction, the candidate predictor for that macroblock is set to zero for that motion vector type.

7.5.2 Motion vectors in direct mode

In direct mode the same block structure as for the macroblock in the temporally subsequent picture is assumed. For each of the subblocks the forward and backward motion vectors are computed as scaled versions of the corresponding vector components of the macroblock in the temporally subsequent picture as described below.

As the multiple reference frame prediction is used, the forward reference frame for the direct mode is the same as the one used for the corresponding macroblock in the temporally subsequent reference picture. The forward and backward motion vectors for direct mode macroblocks are calculated as follows.

$$MV_F = (TR_B * MV) / TR_D$$

$$MV_B = (TR_B - TR_D) * MV / TR_D$$

Where the vector component MV_F is the forward motion vectors, MV_B is the backward motion vector, and MV represents the motion vectors in the corresponding macroblock in the subsequent reference picture. Note that if the subsequent reference is an intra-coded frame or the reference macroblock is an intra-coded block, the motion vectors are set to zero. TR_D is the temporal distance between the temporally previous and next reference frame, and TR_B is the temporal distance between the current frame and previous reference frame.

It should be noted that when multiple reference frame prediction is used, the reference frame for the motion vector predictions is treated as though it were the most recent previous decoded frame. Thus, instead of using the temporal reference of the exact reference frame to compute the temporal distances TR_D and TR_B, the temporal reference in most recent previous reference frame is used to compute the temporal distances TR_D and TR_B.

8 Data Partitioning and Interim File Format

The traditional TML bit stream syntax simply concatenates the VLC coded symbols to form a bit stream, with the exception of the possible byte alignment of the picture (ans slice?) header. Data Partitioning re-arranges the symbols in such a way that all symbols of one data type (e.g. DC coefficients, macrobloc headers, motion vectors) that belong to a single slice are collected in one VLC coded bitstream that starts byte aligned. Decoders can process such a partitioned data streams by fetching symbols from the correct patition. The partition to fetch from is determined through the decoder's state machine, according to the syntax diagram discussed in section 2.4
In order to cleanly divide the concept of data partitioning (which is useful in all error prone environments) from network specifica, an interim file format is used that stores the compressed, VLC coded bits of each partition along with easy-to-process, uncompressed header information. It should be emphasized that this file format is not intended to be transmitted – it rather forms a clean interface between network specific and network unspecific syntax elements. Adaptation layers for IP and highly bit error prone H.223-based networks are discussed later in this document.

8.1 Data Partitioning

Data Partitioning is implemented by concatenating all VLC coded symbols of one data type and one slice (or full picture if slices are not used). At the moment, for a few partitions as indicated below contain data of more than one

data type that are so closely related that a finer diversion seems to be fruitless. The following data types are currently defined:

0	TYPE_HEADER	Picture or Slice Headers (Note 1)
1	TYPE_MBHEADER	Macroblock header information (Note 2)
2	TYPE_MVD	Motion Vector Data
3	TYPE_CBP	Coded Block Pattern
4	TYPE_2x2DC	2x2 DC Coefficients
5	TYPE_COEFF_Y	Luma AC Coefficients
6	TYPE_COEFF_C	Chroma AC Coefficients
7	TYPE_EOS	End-of-Stream Symbol

Note 1: TYPE_HEADER encompasses all Picture/Slice header information
Note 2: TYPE_MBHEADER encompasses The MB-Type, Intra-Prediction mode and Reference Frame ID.

8.2 Interim File Format

The Interim File Format consists of variable length records that include a fixed length header and the initially byte aligned, concatenated, VLC coded symbols. The fixed length header has the following structure:

int32	BitCount	Number of VLC coded bits following the fixed length header
int32	DataType	Data Type of symbols
int32	PicID	Picture ID, currently a copy of the TR
int32	SliceID	Slice ID, an integer value indicating that the informatuion belongs to the n'th slice of PicID
int32	StartMB	The starting MB (in scan order, starting at 0 ???) of that slice
int32	QP	The Quantizer Parameter (copy of the picture/slice header's QP, non-VLC coded
int32	Format	Picture Format, non-VLC coded copy of the picture header's Format field
[]byte	Data	Bitcount # of bits, padded with 0 bits in the last byte

The ordering of partitions is by picture, slice, data-type. If no symbols are coded for a given data type (which is frequently the case for Intra pictures) then that record is not present. Decoders should be designed to accept out-of-order data type records for a give Slice/Picture. Any other syntax violation in particular missing partitions, can be used to trigger syntax-based repair and/or error concealment.

9 Network Adaptation Layer for IP networks

This section covers the Network Adaptation Layer for non-managed, best effort IP networks using RTP [RFC1889] as the transport. The section will likely end up in the form of a standard's track RFC covering an RTP packetization for H.26L.

The NAL takes the information of the Interim File Format as discussed in section 8.2 and converts it into packets that can conveyed directly over RTP. It is designed to be able to take advantage of more than one virtual transport stream (either within one RTP stream by unequal packet content protection currently discussed in the IETF and as Annex I of H.323, or by using several RTP streams with network or application layer unequal error protection).

In doing so, it has to

- arrange partitions in an intelligent way into packets
- eventually split/recombine partitions to match MTU size constraints
- avoid the redundancy of (mandatory) RTP header information and information in the video stream
- define receiver/decoder reactions to packet losses. Note: the IETF tends more and more to do this in a normative way, whereas in the ITU and in MPEG this is typically left to implementers. Issue has to be discussed one day. Current document provides information without makeing any assumptions about that.

9.1 Assumptions

Any packetization scheme has to make some assumptions on typical network conditions and constraints. The following set of assumptions have been used in earlier Q.15 research on packetization and are deemed to be still valid:

- MTU size: around 1500 bytes per packet for anything but dial-up links, 500 bytes for dial-up links.

- Packet loss characteistic: non-bursty (due to drop-tail router implementations, and assuming reasonable pacing algorithms (e.g. no bursting occurs at the sender).
- Packet loss rate: up to 20%

9.2 Combining of Partitions according to Priorities

In order to allow uneqal protection of more important bits of the bitstream, exactly two packets per slice are generated (see Q15-J-53 for a detailed discussion). Slices should be used to ensure that both packets meet the MTU size constraints to avoid network splitting/recombining processes.

The 'First' packet contains the following partitions:
- TYPE_HEADER
- TYPE_MBHEADER
- TYPE_MVD
- TYPE_EOS

The 'Second' packet is assembled using the rest of the partitions
- TYPE_CBP Coded Block Patterm
- TYPE_2x2DC 2x2 DC Coefficients
- TYPE_COEFF_Y Luma AC Coefficients
- TYPE_COEFF_C Chroma AC Coefficients

This configuration allows decoding the first packet independently from the second (although not vice versa). As the first packet is more important both because motion information is important for struction [for what?] and because the 'First' packet is necessary to decode the 'Second', UEP should be used to protect the 'First' packet s higher.

9.3 Packet Structure

Each packet consists of a fixed 32 bit header a series of Part-of-Partition structures (POPs).

The packet header contains information

Bit 31	1 == This packet contains a picture header
Bit 30	1 == This packet contains a slice header
Bits 25..29	Reserved
Bits 10-24	StartMB. It is assumed that no picture has more than 2**14 Macroblocks
Bits 0..9	SliceID. It is assumed that a picture does not have more than 1024 slices

Note: The PictureID (TR) can be easily reconstructed from the RTP Timestamp and is therefore not coded again.
Note: The current software reconstructs QP and Format out of the VLC coded Picture/Slice header symbols. This is architecturally not nice and should be changed, probably by deleting these two values from the interim File Format.
Note: This header is likely to change once bigger picture formats etc. come into play.

Each Part-of-Partition structure contains a header of 16 bits whose format is as follows

Bits 15..12	Data Type
Bits 11..0	Length of VLC-coded POP payload (in bits, starting byte-aligned, 0 indicates 4096 bits of paylaod)

Th reasoning behind the introduction of POP packets lies in avoiding large fixed length headers for (typically) small partitions. See Q15-J-53.

9.4 Packetization Process

The packetization process converts the Interim File Format (or, in a real world system, data partitioned symbols arriving through a software interface) into packets. The following RTP header fields are used (see RFC1889 for exact semantics):
- Timestamp: is calculated according to the rules of RFC1889 and RFC2429 based on a 90 KHz timestamp.
- Marker Bit: set for the very last packet of a picture ('Second' packet of the last Slice), otherwise cleared.
- Sequence Number is increased by one for every generated packet, and starts with 0 for easier debugging (this in contrast to RFC1889, where a random initialization is mandatory for security purposes).
- Version (V): 2
- Padding (P): 0
- Extension (X): 0

- Csourcecount (CC): 0
- Payload Type (PT): 0 (This in contrast to RFC1889 where 0 is forbidden)

The RTP header is followed by the payload, which follows the packet structure of section 9.3.

The RTP packet file, used as the input to packet loss simulators and similar tools (note that this format is identical to the ones used for IP-related testing during the H.263++ project, so that the loss simulators, error paytterns etc, can be re-used):

- Int32 size of the following packet in bytes
- []byte packet content, starting with the RTP header.

9.5 De-packetization

The De-packetization process reconstructs a file in the Interim File Format from an RTP packet file (that is possible subject to packet losses). This task is straightforwad and reverse to the packetization process. (Note that the QP and Format fields curretly have to be reconstructed using the VLC-coded symbols in the TYPE_HEADER partition. This bug in the Interim File Format spec should be fixed some time).

9.6 Repair and Error Concealment

In order to take advantage of potential UEP for the 'First' packet and the ability of the decoder to reconstruct data where CBP/coefficient information was lost, a very simple error concealment strategy is used. This strategy repairs the bitstream by replacing a lost CBP partition with CBPs that indicate no coded coefficients. Unfortunately, the CBP codewords for Intra and Inter blocks are different, so that such a repair cannot be done context-insensitive. Instead of (partly) VLC-decoding the CBP partition in the NAL module in order to insert the correct type of CBP symbol in the (lost) partition, the decoder itself can be changed to report the appropriate CBP symbols saying "No coefficients" whenever the symbol fetch for a CBP symbol returns with the indication of a lost/empty partition.

Question: 15/16

STUDY GROUP 16 – CONTRIBUTION ___

SOURCE*: RAPPORTEUR FOR Q.15/16 (Gary SULLIVAN)

TITLE: DRAFT FOR "H.263++" ANNEXES U, V, AND W TO RECOMMENDATION H.263

This contribution contains a draft for three new annexes to be added to ITU-T Recommendation H.263 (*Video Coding for Low Bit Rate Communication*):

Annex U, specifying an optional *Enhanced Reference Picture Selection* (ERPS) mode,
Annex V, specifying an optional *Data Partitioned Slice* (DPS) mode, and
Annex W, specifying optional *Additional Supplemental Enhancement Information.*

Drafts of these annexes were determined by ITU-T SG16 in February, 2000. It is proposed that this draft of these annexes be decided at the SG 16 meeting in November 2000.

SUMMARY

This document contains three additional annexes to Recommendation H.263:

Annex U: An optional *Enhanced Reference Picture Selection* (ERPS) mode capable of providing enhanced coding efficiency and enhanced error resilience (particularly against loss of data packets). The ERPS mode operates by managing a multi-picture buffer of stored pictures.

Annex V: An optional *Data Partitioned Slice* (DPS) mode capable of providing enhanced error resilience (particularly against localized corruption of bitstream contents during transmission). The DPS mode operates by separating header and motion vector data from DCT coefficient data in the bitstream and by protecting motion vector data using a reversible representation.

Annex W: Optional *Additional Supplemental Enhancement Information* which can be added to an H.263 bitstream to provide backward-compatible enhancements, including:

- Indication of use of a specific fixed-point IDCT
- Picture Messages, including the message types of:
  - Arbitrary Binary Data,
  - Text (Arbitrary, Copyright, Caption, Video Description, or Uniform Resource Identifier),
  - Picture Header Repetition (Current, Previous, Next with Reliable Temporal Reference, or Next with Unreliable Temporal Reference),
  - Interlaced Field Indications (Top or Bottom), and
  - Spare Reference Picture Identification.

Annex U
Enhanced Reference Picture Selection mode

(This annex forms an integral part of this Recommendation.)

U.1 Introduction

This annex describes the optional Enhanced Reference Picture Selection (ERPS) mode of this Recommendation. The capability to use this optional mode is negotiated by external means (for example, Recommendation H.245). The amount of picture memory accommodated in the decoder for ERPS operation should also be signaled by external means. The use of this mode shall be indicated by setting the formerly-reserved bit 16 of the optional part of the PLUSPTYPE (OPPTYPE) to "1". The mode provides benefits for both error resilience and coding efficiency by using a memory buffer of reference pictures.

A sub-mode of the ERPS mode is specified for Sub-Picture Removal. The purpose of Sub-Picture Removal is to reduce the amount of memory required to store multiple reference pictures. The memory reduction is accomplished by specifying the partitioning of each reference picture into smaller rectangular units called sub-pictures. The encoder can then indicate to the decoder that specific sub-picture areas of specific reference pictures will not be used as a reference for the prediction of subsequent pictures, thus allowing the memory allocated in the decoder for storing these areas to be used to store data from other reference pictures. The support for this sub-mode and the allowed fragmentation of the picture memory into minimum picture units (MPUs) for Sub-Picture Removal as defined herein is also negotiated by external means (for example, Recommendation H.245).

A sub-mode of the ERPS mode is specified for enabling two-picture backward prediction in B pictures. This sub-mode can enhance performance by providing encoders for B pictures not only with an ability to use multiple references for forward prediction, but also to use more than one reference picture for backward prediction. The support for this sub-mode is negotiated by external means (for example, Recommendation H.245).

For error resilience, the ERPS mode can use backward channel messages, which are signaled by external means (for example, Recommendation H.245) sent from a decoder to an encoder to inform the encoder which pictures or parts of pictures have been incorrectly decoded. The ERPS mode provides enhanced performance compared to the Reference Picture Selection (RPS) mode defined in Annex N. It shall not be used simultaneously with the RPS mode. (It can be used in such a way as to provide essentially the same functionality as the RPS mode.)

For coding efficiency, motion compensation can be extended to prediction from multiple pictures. The extension of motion compensation to multi-picture prediction is achieved by extending each motion vector by a picture reference parameter that is used to address a macroblock or block prediction region for motion compensation in any of the multiple reference pictures. The picture reference parameter is a variable length code specifying a relative buffer index. The reference pictures are assembled in a buffering scheme that is controlled by the encoder.

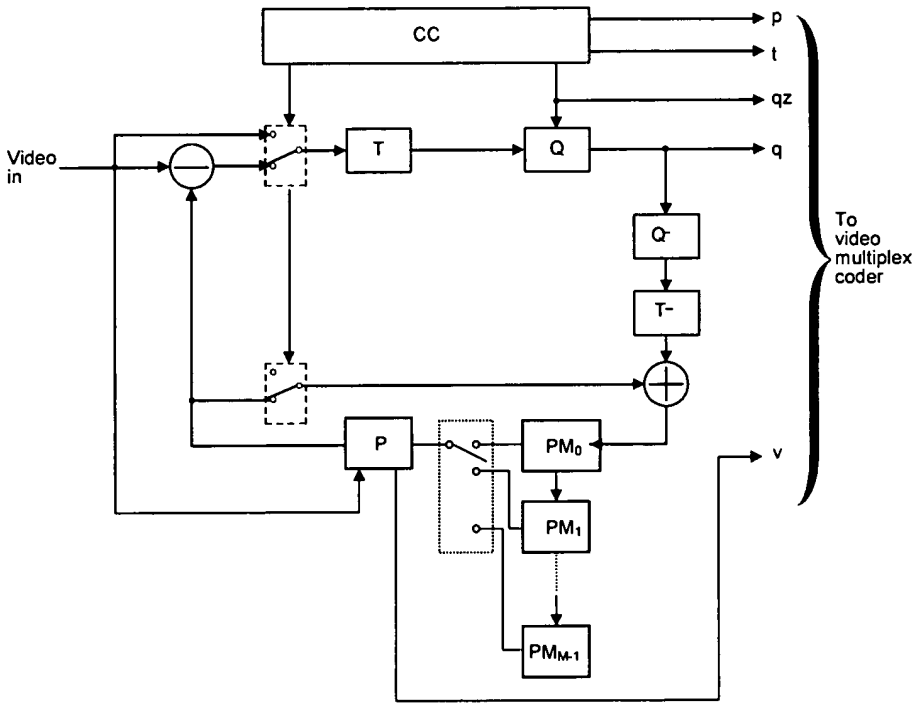
The ERPS mode shall not be used with the Syntax-based Arithmetic Coding mode (see Annex E) or the Data Partitioned Slice mode (see Annex V).

Once activated, the ERPS mode shall not be inactivated in subsequent pictures in the bitstream unless the initial inactivation occurs in an I or EI picture and any reactivation is also in an I or EI picture and is accompanied by a buffer reset (RESET equal to "1"). If inactivated, the entire contents of the ERPS multi-picture buffer shall be set to "unused" status.

U.2 Video source coding algorithm

The source coder of this mode is shown in generalized form in Figure U.1. This figure shows a structure that uses a number of picture memories.

The video source coding algorithm can be extended to multi-picture motion compensation. Enhanced coding efficiency may be achieved by allowing reference picture selection on the macroblock level. A picture buffering scheme with relative indexing is employed for efficient addressing of pictures in the multi-picture buffer. The multi-picture buffer control may work in two distinct types of operation.



In the first of these two types of operation, a "Sliding Window" over time can be accommodated by the buffer control unit. In such a buffering scheme using M picture memories $PM_0 ... PM_{M-1}$, the most recent preceding (up to M) decoded and reconstructed pictures are stored in the picture memories and can be used as references for decoding. If the number of pictures maximally accommodated by the multi-picture buffer corresponds to M, the motion estimation when coding a picture m, if $0 \leq m \leq M-1$, can utilize m pictures. When coding a picture $m \geq M$, the maximum number of pictures M can be used. Alternatively, a

second "Adaptive Memory Control" type of operation can be used for a more flexible and specific control of the picture memories than with the simple "Sliding Window" scheme.

The operation of the ERPS mode results in the assignment of "unused" status to some pictures or sub-picture areas of pictures that have been sent to the decoder. Once some picture or area of a picture has been assigned to "unused" status, the bitstream shall not contain any data that causes a reference to any "unused" area for the prediction of subsequent pictures. By managing the assignment of "unused" status to previous pictures, the encoder shall ensure that sufficient memory is available in the decoder to store all data needed for the representation of subsequent pictures. The overall buffer size and structure is conveyed to the decoder in the bitstream, and the encoder shall control the buffer such that the specified total capacity is not exceeded by stored picture data that has not been assigned to "unused" status.

The source coder may select one or several of the picture memories to suppress temporal error propagation caused by inter-picture coding. The Independent Segment Decoding mode (see Annex R), which treats boundaries of GOBs with non-empty headers or slices as picture boundaries, can be used to avoid spatial error propagation due to motion compensation across the boundaries of the GOBs or slices when this mode is applied to a smaller unit than a picture, such as a GOB or slice. The information to signal which picture is selected for prediction is included in the encoded bitstream.

The strategy used by the encoder to select the picture or pictures to be used for prediction is out of the scope of this Recommendation.

T Transform
Q Quantizer
P Picture Memory with motion compensated variable delay
PM Picture Memory
CC Coding control
p Flag for INTRA/INTER
t Flag for transmitted or not
qz Quantizer indication
q Quantizing index for transform coefficients
v Motion vector

FIGURE U.1/H.263

Source coder for Enhanced Reference Picture Selection mode

U.3 Forward-Channel Syntax

The syntax is altered in the picture, Group of Blocks (GOB), and slice layers. When indicated by a parameter MRPA being equal to "1", the syntax is also altered in the macroblock layer. In the picture, GOB, and slice layers, an Enhanced Reference

Picture Selection layer (ERPS layer) is inserted. In the macroblock layer, picture reference parameters are inserted under certain conditions to enable multi-picture motion compensation.

U.3.1 Syntax of the Picture, GOB, and Slice layer

The Enhanced Reference Picture Selection syntax for the PLUS header (otherwise as shown in Figure 8) is shown in Figure U.2. The fields of RPSMF, PN, and the ERPS layer are inserted into the PLUS header. The fields of TRPI, TRP, BCI, and BCM are not present (since they are only needed for the RPS mode of Annex N, which is not allowed when the ERPS mode is active).

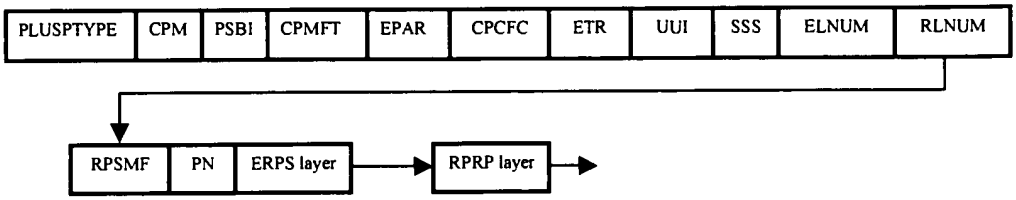


FIGURE U.2/H.263

Structure of PLUS Header for the ERPS mode

The syntax for the GOB layer is shown in Figure U.3. The fields of PNI, PN, NOERPSL, and the ERPS layer are added to the syntax (otherwise defined as in Figure 9).

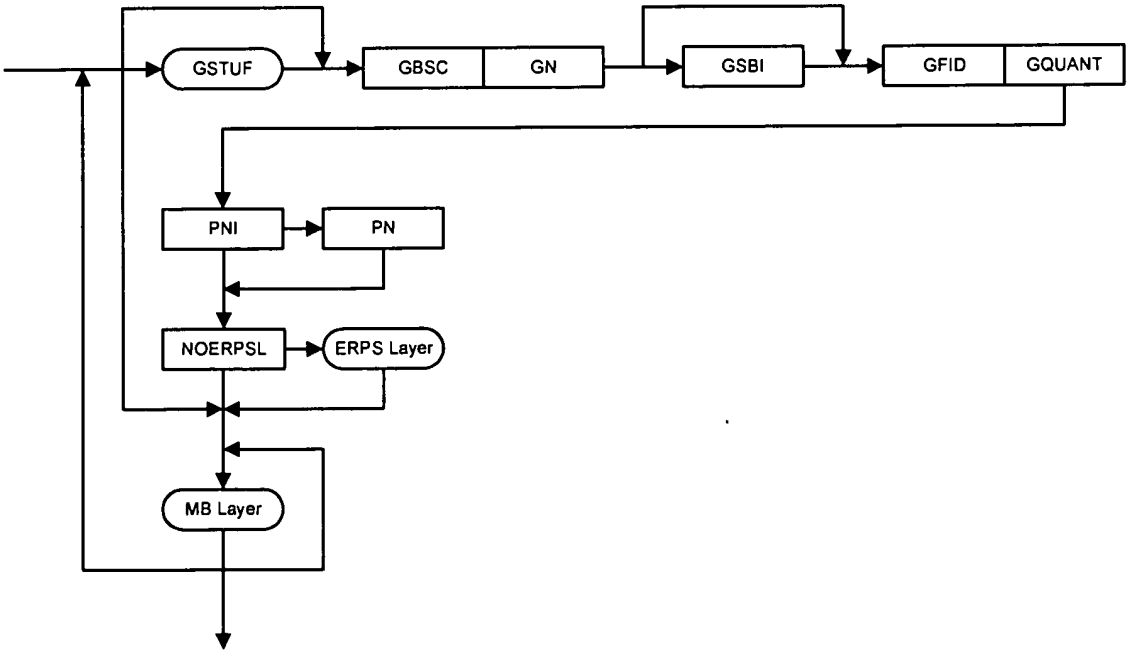

FIGURE U.3/H.263

Structure of GOB layer for the ERPS mode

When the optional Slice Structured mode (see Annex K) is in use, the syntax of the slice layer is modified in the same way as the GOB layer. The syntax for the slice layer is shown in Figure U.4. The slice that immediately follows the picture start code in the bitstream also includes all of the added fields PNI, PN, NOERPSL, and the ERPS layer.

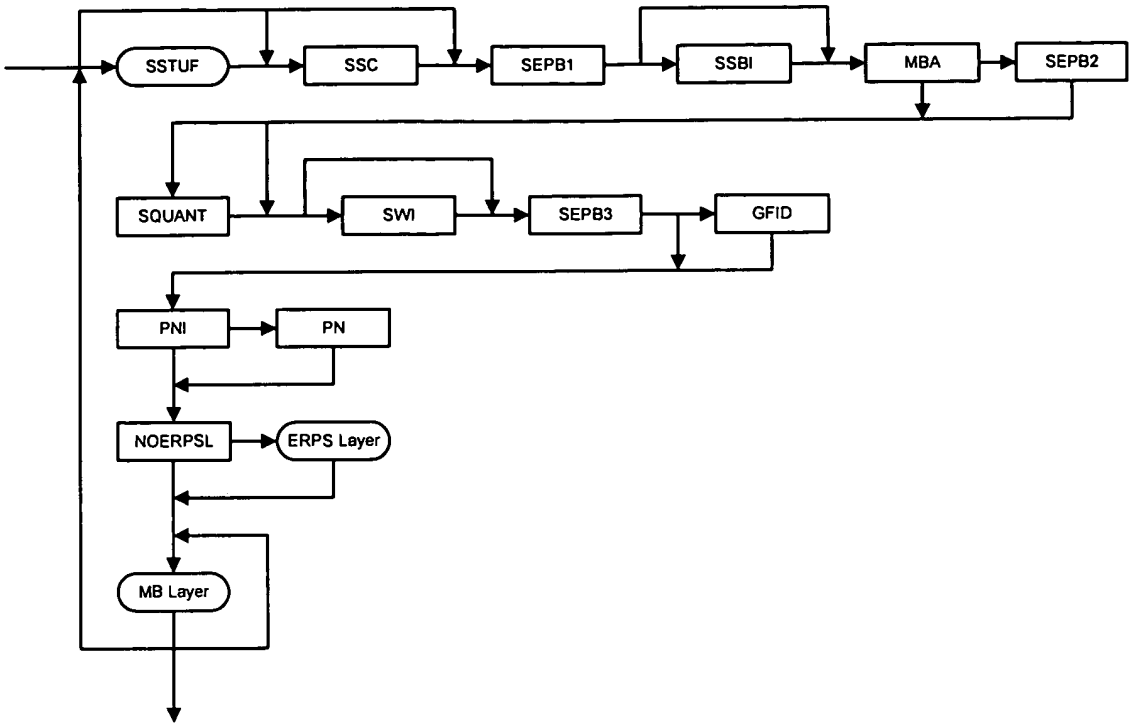

FIGURE U.4/H.263

Structure of Slice layer for the ERPS mode

The ERPS layer is shown in Figure U.5.

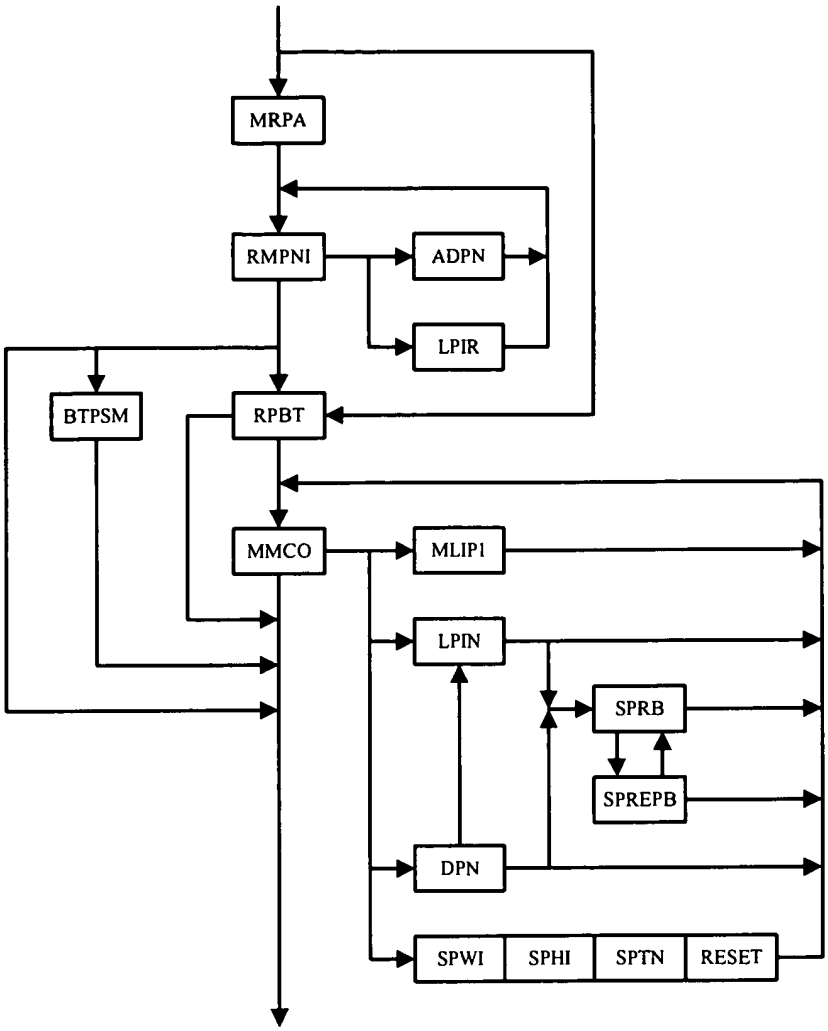

FIGURE U.5/H.263

Structure of the ERPS layer

Variable length codes for the ADPN, LPIR, MLIP1, DPN, LPIN, SPTN, PR, PR_0, PR_2, PR_3, PR_4, PRB, and PRFW fields are given in Table U.1.

Table U.1/H.263

Variable length codes for ADPN, LPIR, MLIP1, DPN, LPIN, SPTN, PR, PR_0, PR_2, PR_3, PR_4, PRB, and PRFW

Absolute position	Number of bits	Codes
0	1	1
"x_0"+1 (1:2)	3	$0x_00$
"x_1x_0"+3 (3:6)	5	$0x_11x_00$
"$x_2x_1x_0$"+7 (7:14)	7	$0x_21x_11x_00$
"$x_3x_2x_1x_0$"+15 (15:30)	9	$0x_31x_21x_11x_00$
"$x_4x_3x_2x_1x_0$"+31 (31:62)	11	$0x_41x_31x_21x_11x_00$
"$x_5x_4x_3x_2x_1x_0$"+63 (63:126)	13	$0x_51x_41x_31x_21x_11x_00$
"$x_6x_5x_4x_3x_2x_1x_0$"+127 (127:254)	15	$0x_61x_51x_41x_31x_21x_11x_00$
"$x_7x_6x_5x_4x_3x_2x_1x_0$"+255 (255:510)	17	$0x_71x_61x_51x_41x_31x_21x_11x_00$

"$x_9x_8x_7x_6x_5x_4x_3x_2x_1x_0$"+1023 (1023:2046)	21	$0x_91x_81x_71x_61x_51x_41x_31x_21x_11x_00$
"$x_{10}x_9x_8x_7x_6x_5x_4x_3x_2x_1x_0$"+2047 (2047:4094)	23	$0x_{10}1x_91x_81x_71x_61x_51x_41x_31x_21x_11x_00$

U.3.1.1 Reference Picture Selection Mode Flags (RPSMF) (3 bits)
RPSMF is a 3 bit fixed length codeword that is present in the PLUS header whenever the ERPS mode is in use (regardless of the value of UFEP). RPSMF shall not be present in the GOB or slice layer. When present, RPSMF indicates which type of back-channel messages are needed by the encoder. The values of RPSMF shall be as defined in subclause 5.1.13.

U.3.1.2 Picture Number Indicator (PNI) (1 bit)
PNI is a single bit fixed length codeword that is always present at the GOB or slice layer and is not present in the PLUS header. When present, PNI indicates whether or not the following PN field is also present.

"0": PN field is not present.
"1": PN field is present.

U.3.1.3 Picture Number (PN) (10 bits)
PN is a 10 bit fixed length codeword that is always present in the PLUS header when the ERPS mode is in use, and is present at the GOB or slice layer only when indicated by PNI.

PN shall be incremented by 1 for each coded and transmitted picture, in a 10-bit modulo operation, relative to the PN of the previous stored picture. The term "stored picture" is defined in subclause U.3.1.5.7. For EI and EP pictures, PN shall be incremented from the value in the last stored EI or EP picture within the same scalability enhancement layer. For B pictures, PN shall be incremented from the value in the most temporally-recent stored non-B picture in the reference layer of the B picture which precedes the B picture in bitstream order (a picture which is temporally subsequent to the B picture). B pictures are not stored in the multi-picture buffer, as they are not used as references for subsequent pictures. Thus a picture immediately following a B picture in the reference layer of the B picture or another B picture which immediately follows a B picture in the same enhancement layer shall have the same PN as the B picture. Similarly, if a non-B picture is present in the bitstream which is not stored, the picture following this non-B picture (in the same enhancement layer, in the case of Annex O operation) shall have the same PN as the non-stored non-B picture.

In a usage scenario known as "Video Redundancy Coding", the ERPS mode may be used by some encoders in a manner in which more than one representation is sent for the pictured scene at the same temporal instant (usually using different reference pictures). In such a case in which the ERPS mode is in use and in which adjacent pictures in the bitstream have the same temporal reference and the same picture number, the decoder shall regard this occurrence as an indication that redundant copies have been sent of approximately the same pictured scene content, and shall decode and use the first such received picture while discarding the subsequent redundant picture(s).

The PN serves as a unique ID for each picture stored in the multi-picture buffer (for a given enhancement layer, in the case of Annex O operation) within 1024 coded and stored pictures. Therefore, a picture cannot be kept in the buffer after more than 1023 subsequent coded and stored pictures (in the same enhancement layer, in the case of Annex O operation) unless it has

been assigned a long-term picture index as specified below. The encoder shall ensure that the bitstream shall not specify retaining any short-term picture after more than 1023 subsequent stored pictures. A decoder which encounters a picture number on a current picture having a value equal to the picture number of some other short-term stored picture in the multi-picture buffer (in the same enhancement layer, in the case of Annex O operation, and excluding the video redundancy coding case described in the previous paragraph) should treat this condition as an error.

U.3.1.4 No Enhanced Reference Picture Selection Layer (NOERPSL) (1 bit)

NOERPSL is a single bit fixed length codeword that is present at the GOB or slice level whenever the ERPS mode is in use. It is not present in the PLUS header. The values of NOERPSL shall be as follows:

"0": The ERPS layer is sent,
"1": The ERPS layer is not sent.

If NOERPSL is "1", all ERPS settings and re-mappings in effect for the picture shall be applied also for the relevant GOB or slice. ERPS layer information sent at the GOB or slice level does not affect the decoding process of any other GOB or slice.

U.3.1.5 Enhanced Reference Picture Selection layer (ERPS) (variable length)

The ERPS layer is always present at the picture level when the ERPS mode is in use, and is present at the GOB or slice level if NOERPSL is "0". It specifies the buffer indexing used to decode the current picture, GOB, or slice, and manages the contents of the picture buffer.

U.3.1.5.1 Multiple Reference Pictures Active (MRPA) (1 bit)

MRPA is a single bit fixed length codeword that is present only if the picture coding type indicates a P-picture, an EP-picture, an Improved PB frame, or B-picture. MRPA is the first element in the ERPS layer if present. MRPA specifies whether the number of active reference pictures for forward-prediction or backward-prediction decoding of the current picture, GOB, or slice may be larger than one. The value of MRPA shall be as follows:

"1": More than one reference picture may be used for forward or backward motion compensation.
"0": Only one reference picture is used for forward or backward motion compensation. In this case, the extensions of the macroblock layer syntax in subclause U.3.2 do not apply.

MRPA may be changed from GOB to GOB or slice to slice so that different GOBs or slices may address different numbers of reference pictures.

MRPA shall be "0" in any picture which invokes the Reference Picture Resampling mode (see Annex P), and the same picture shall be indicated as the forward reference picture to be used at both the picture and GOB or slice levels for any such current picture. If the current picture is a B picture, the backward reference picture shall have the same size as the current picture, and any reference picture resampling process shall be applied only to the forward reference picture. Reference picture resampling shall be invoked only if the multi-picture buffer contains sufficient "unused" capacity to store the resampled forward reference picture, but after the resampled reference picture is used for the decoding of the current picture, the resampled forward reference picture shall not be stored in the multi-picture buffer.

U.3.1.5.2 Re-Mapping of Picture Numbers Indicator (RMPNI) (variable length)

RMPNI is a variable length codeword that is present in the ERPS layer if the picture is a P, EP, Improved PB, or B picture. RMPNI indicates whether any default picture indices are to be re-mapped for motion compensation of the current picture, GOB, or slice – and how the re-mapping of the relative indices into the multi-picture buffer is to be specified if indicated. RMPNI is transmitted using Table U.2. If RMPNI indicates the presence of an ADPN or LPIR field, an additional RMPNI field immediately follows the ADPN or LPIR field.

A picture reference parameter is a relative index into the ordered set of pictures. The RMPNI, ADPN, and LPIR fields allow the order of that relative indexing into the multi-picture buffer to be temporarily altered from the default index order for the decoding of a particular picture, GOB, or slice. The default index order is for the short-term pictures (i.e., pictures which have not been given a long-term index) to precede the long-term pictures in the reference indexing order. Within the set of short-term pictures, the default order is for the pictures to be ordered starting with the most recent buffered reference picture and proceeding through to the oldest reference picture (i.e., in decreasing order of picture number in the absence of wrapping of the ten-bit picture number field). Within the set of long-term pictures, the default order is for the pictures to be ordered starting with the picture with the smallest long-term index and proceeding up to the picture with long-term index equal to the most recent value of MLIP1–1.

For example, if the buffer contains three short-term pictures with short-term picture numbers 300, 302, and 303 (which were transmitted in increasing picture-number order) and two long-term pictures with long-term picture indices 0 and 3, the default index order is:

- default relative index 0 refers to the short-term picture with picture number 303,
- default relative index 1 refers to the short-term picture with picture number 302,
- default relative index 2 refers to the short-term picture with picture number 300,
- default relative index 3 refers to the long-term picture with long-term picture index 0, and
- default relative index 4 refers to the long-term picture with long-term picture index 3.

The first ADPN or LPIR field that is received (if any) moves a specified picture out of the default order to the relative index of zero. The second such field moves a specified picture to the relative index of one, etc. The set of remaining pictures not moved to the front of the relative indexing order in this manner shall retain their default order amongst themselves and shall follow the pictures that have been moved to the front of the buffer in relative indexing order.

If MRPA is "0", no more than one ADPN or LPIR field shall be present in the same ERPS layer unless the current picture is a B picture. If the current picture is a B picture and MRPA is "0", no more than two ADPN or LPIR fields shall be present in the same ERPS layer.

Any re-mapping of picture numbers specified for some picture shall not affect the decoding process for any other picture. Any re-mapping of picture numbers specified for some GOB or slice shall not affect the decoding process for any other GOB or slice. A re-mapping of picture numbers specified for a picture shall only affect the decoding process for any GOB or slice within that picture in two ways:

- If NOERPSL is "1" at the GOB or slice level, then the re-mapping specified at the picture level is also used at the GOB or slice level.
- If the picture is a B picture, the re-mapping specified at the picture level shall specify the calculation of the value of TR_B and TR_D for direct bidirectional prediction.

An RMPNI "end loop" indication is the last element of the ERPS layer for a B picture if MRPA is "0". In a B picture with MRPA equal to "1", an RMPNI "end loop" indication is followed by BTPSM. In a P or EP picture or Improved PB frame, an RMPNI "end loop" indication is followed by RPBT.

Within one ERPS layer, RMPNI shall not specify the placement of any individual reference picture into more than one re-mapped position in relative index order.

Table U.2/H.263

RMPNI operations for re-mapping of reference pictures

Value	Re-mapping Specified
'1'	ADPN field is present and corresponds to a negative difference to add to a picture number prediction value
'010'	ADPN field is present and corresponds to a positive difference to add to a picture number prediction value
'011'	LPIR field is present and specifies the long-term index for a reference picture
'001'	End loop for re-mapping of picture relative indexing default order

U.3.1.5.3 Absolute Difference of Picture Numbers (ADPN) (variable length)

ADPN is a variable length codeword that is present only if indicated by RMPNI. ADPN follows RMPNI when present. ADPN is transmitted using Table U.1, where the index into the table corresponds to ADPN – 1. ADPN represents the absolute difference between the picture number of the currently re-mapped picture and the prediction value for that picture number. If no previous ADPN fields have been sent within the current ERPS layer, the prediction value shall be the picture number of the current picture. If some previous ADPN field has been sent, the prediction value shall be the picture number of the last picture that was re-mapped using ADPN.

If the picture number prediction is denoted PNP, and the picture number in question is denoted PNQ, the decoder shall determine PNQ from PNP and ADPN in a manner mathematically equivalent to the following:

```
if (RMPNI == '1') {// a negative difference
  if (PNP – ADPN < 0)
```

```
  PNQ = PNP – ADPN +1024;
 else
  PNQ = PNP – ADPN;
}else{              // a positive difference
 if (PNP + ADPN > 1023)
  PNQ  = PNP + ADPN – 1024;
 else
  PNQ  = PNP + ADPN;
}
```

The encoder shall control RMPNI and ADPN such that the decoded value of ADPN shall not be greater than or equal to 1024.

As an example implementation, the encoder may use the following process to determine values of ADPN and RMPNI to specify a re-mapped picture number in question, PNQ:

```
DELTA = PNQ – PNP;
if (DELTA < 0) {
 if (DELTA < –511)
  MDELTA = DELTA + 1024;
 else
  MDELTA = DELTA;
}else{
 if(DELTA > 512)
  MDELTA = DELTA – 1024;
 else
  MDELTA = DELTA;
}

ADPN = abs(MDELTA);
```

where abs() indicates an absolute value operation. Note that the index into Table U.1 corresponds to the value of ADPN – 1, rather than the value of ADPN itself.

RMPNI would then be determined by the sign of MDELTA.

U.3.1.5.4 Long-term Picture Index for Re-Mapping (LPIR) (variable length)

LPIR is a variable length codeword that is present only if indicated by RMPNI. LPIR follows RMPNI when present. LPIR is transmitted using Table U.1. It represents the the long-term picture index to be re-mapped. The prediction value used by any subsequent ADPN re-mappings is not affected by LPIR.

U.3.1.5.5 B-Picture Two-Picture Prediction Sub-Mode (BTPSM) (1 bit)

BTPSM is a single bit fixed length codeword that is present only in a B picture (see Annex O) and only when MRPA is "1". It follows an RMPNI "end loop" indication and is the last element of the ERPS layer for the B picture when present. It indicates whether the two-picture backward prediction sub-mode is in use for the picture as follows:

"0" : Single-picture backward prediction
"1" : Two-picture backward prediction

BTPSM has an implied value of "0" if not present (when MRPA is "0").

The set of pictures available for use as forward prediction references is the set of pictures in the multi-picture buffer other than the set of backward reference pictures. The set of backward reference pictures is determined by the value of BTPSM. If single-picture backward prediction is specified by BTPSM, the first picture in (possibly re-mapped) relative index order is the only backward reference picture. If two-picture backward prediction is specified by BTPSM, the first two pictures in (possibly re-mapped) relative index order are the two backward reference pictures. The relative index for forward prediction then becomes a relative index into the set of forward reference pictures.

The contents of the multi-picture buffer are not affected by the presence of a B picture. The B picture is not stored in the multi-picture buffer and is not used as a reference for the coding of subsequent pictures.

U.3.1.5.6 Reference Picture Buffering Type (RPBT) (1 bit)

RPBT is a single bit fixed length codeword that specifies the buffering type of the currently decoded picture. It follows an RMPNI "end loop" indication when the picture is not an I, EI, or B picture. It is the first element of the ERPS layer if the picture is an I or EI picture. It is not present if the picture is a B picture. The values for RPBT are defined as follows:

"1" : Sliding Window,
"0" : Adaptive Memory Control.

In the "Sliding Window" buffering type, the current decoded picture shall be added to the buffer with default relative index 0, and any marking of pictures as "unused" in the buffer is performed automatically in a first-in-first-out fashion among the set of short-term pictures. In this case, if the buffer has sufficient "unused" capacity to store the current picture, no additional pictures shall be marked as "unused" in the buffer. If the buffer does not have sufficient "unused" capacity to store the current picture, the picture (or pictures as necessary to free the needed amount of memory in the case of sub-picture removal) with the largest default relative index (or indices as necessary in the case of sub-picture removal) among the short-term pictures in the buffer shall be marked as "unused". In the sliding window buffering type, no additional information is transmitted to control the buffer contents.

In the "Adaptive Memory Control" buffering type, the encoder explicitly specifies any addition to the buffer or marking of data as "unused" in the buffer, and may also assign long-term indices to short-term pictures. The current picture and other pictures may be explicitly marked as "unused" in the buffer, as specified by the encoder. This buffering type requires further information that is controlled by memory management control operation (MMCO) parameters.

RPBT, if present in GOB or slice layers, shall be the same as in the picture layer. Any MMCO command present in GOB or slice layers shall convey the same operation as some MMCO command in the picture layer.

If the picture is a B picture, RPBT shall not be present and the decoded picture shall not be stored in the multi-picture buffer. This ensures that a B picture shall not affect the contents of the multi-picture buffer.

Similarly, the B-picture part of an Improved PB frame shall not be stored in the buffer. All control fields associated with controlling the storage of an Improved PB frame shall be considered to be associated with controlling the storage of only the P-picture part of the Improved PB frame.

U.3.1.5.7 Memory Management Control Operation (MMCO) (variable length)

MMCO is a variable length codeword that is present only when RPBT indicates "Adaptive Memory Control", and may occur multiple times if present. It specifies a control operation to be applied to manage the multi-picture buffer memory. The MMCO parameter is followed by data necessary for the operation specified by the value of MMCO, and then an additional MMCO parameter follows – until the MMCO value indicates the end of the list of such operations. MMCO commands do not affect the buffer contents or the decoding process for the decoding of the current picture – rather, they specify the necessary buffer status for the decoding of subsequent pictures in the bitstream. The values and control operations associated with MMCO are defined in Table U.3.

All memory management control operations specified using MMCO shall be specified in the picture layer. Some or all of the same operations as are specified at the picture layer may also be specified at the GOB or slice layer (with the same associated data). MMCO shall not specify memory operations at the GOB or slice layer that are not also specified with the same associated data at the picture layer.

A buffer size and structure specification MMCO command shall be the first MMCO command if present. No more than one buffer size and structure specification MMCO command shall be present in a given ERPS layer. A buffer size and structure specification MMCO command with RESET equal to "1" shall be present in the first picture in which the ERPS mode is activated in any series of ERPS mode pictures in the bitstream. A buffer size and structure specification MMCO command with RESET equal to "1" shall precede any use of MMCO to indicate marking sub-picture areas of any short-term or long-term pictures as "unused". The sub-picture width and height specified in a buffer size and structure specification MMCO command shall not differ from the value of these parameters in a prior buffer size and structure specification MMCO command unless the current picture is an I or EI picture with RESET equal to "1". The picture height and width shall not change within the bitstream except within a picture containing a buffer size and structure specification MMCO command with RESET equal to "1" (or within a picture in which the ERPS mode is not in use).

If a B picture using single-picture backward prediction is present in the bitstream, exactly one temporally subsequent non-B picture in the reference layer of the B picture shall precede the B picture in bitstream order, as specified in subclause O.2. No memory management control operations shall be present within any ERPS layer of this immediately temporally subsequent non-B picture within the reference layer of the B picture which mark any part of that immediately temporally succeeding non-B picture as "unused", since that reference layer picture is needed for display until after the decoding of the B picture.

The transmission order constraints specified in subclause O.2 are adjusted as necessary for B pictures using two-picture backward prediction. If a B picture using two-picture backward prediction is present in the bitstream, exactly two temporally

subsequent non-B pictures in the reference layer of the B picture shall precede the B picture in bitstream order. The other restrictions on the transmission order of the B picture in the bitstream specified in O.2 shall apply, but as adjusted for the use of two temporally subsequent reference layer pictures. No memory management control operations shall be present within any ERPS layer of these two immediately temporally subsequent two non-B pictures within the reference layer of the B picture which mark any part of these two non-B pictures as "unused", since these reference layer pictures are needed for display until after the decoding of the B picture.

A "stored picture" is defined as a non-B picture which does not contain an MMCO command in its ERPS layer which marks that (entire) picture as "unused". If the current picture is not a stored picture, its ERPS layer shall not contain any of the following types of MMCO commands:

- An MMCO command to specify the buffer size and structure with RESET equal to "1",
- Any MMCO command which marks any other picture (other than the current picture) as "unused" that has not also been marked as "unused" in the ERPS layer of a prior stored picture,
- Any MMCO command which assigns a long-term index to a picture that has not also been assigned the same long-term index in the ERPS layer of a prior stored picture, or
- Any MMCO command which marks sub-picture areas of any picture as "unused" that have not also been marked as "unused" in the ERPS layer of a prior stored picture.

Table U.3/H.263

Memory Management Control Operation (MMCO) Values

Value	Memory Management Control Operation	Associated Data Fields Following
'1'	End MMCO Loop	None (end of ERPS layer)
'011'	Mark a Short-Term Picture as "Unused"	DPN
'0100'	Mark a Long-Term Picture as "Unused"	LPIN
'0101'	Assign a Long-Term Index to a Picture	DPN and LPIN
'00100'	Mark Short-Term Sub-Picture Areas as "Unused"	DPN and SPRB
'00101'	Mark Long-Term Sub-Picture Areas As "Unused"	LPIN and SPRB
'00110'	Specify the Maximum Long-Term Picture Index	MLIP1
'00111'	Specify the Buffer Size and Structure	SPWI, SPHI, SPTN, and RESET

U.3.1.5.8 Difference of Picture Numbers (DPN) (variable length)

DPN is present when indicated by MMCO. DPN follows MMCO if present. DPN is transmitted using codewords in Table U.1 and is used to calculate the PN of a picture for a memory control operation. It is used in order to assign a long-term index to a picture, mark a short-term picture as "unused", or mark sub-picture areas of a short-term picture as "unused". If the current decoded picture number is PNC and the decoded value from Table U.1 is DPN, an operation mathematically equivalent to the following equations shall be used for calculation of PNQ, the specified picture number in question:

```
if (PNC – DPN < 0)
  PNQ = PNC – DPN + 1024;
else
  PNQ = PNC – DPN;
```

Similarly, the encoder may compute the DPN value to encode using the following relation:

```
if (PNC – PNQ < 0)
  DPN = PNC – PNQ + 1024;
else
  DPN = PNC – PNQ;
```

For example, if the decoded value of DPN is zero and MMCO indicates marking a short-term picture as "unused", the current decoded picture shall be marked as "unused" (thus indicating that the current picture is not a stored picture).

U.3.1.5.9 Long-term Picture Index (LPIN) (variable length)

LPIN is present when indicated by MMCO. LPIN is transmitted using codewords in Table U.1 and specifies the long-term picture index of a picture. It follows DPN if the operation is to assign a long-term index to a picture. It follows MMCO if the operation is to mark a long-term picture as "unused" or to mark sub-picture areas of a long-term picture as "unused".

U.3.1.5.10 Sub-Picture Removal Bit-Map (SPRB) (fixed length)
SPRB is a fixed length codeword that contains one bit for each sub-picture area of a picture and is present when indicated by MMCO. The number of bits of SPRB data is determined by the most recent values of SPWI and SPHI. SPRB is used to indicate which sub-picture areas of a buffered picture are to be marked as "unused". SPRB follows DPN if the operation is to mark sub-picture areas of a short-term picture as "unused", and follows LPIN if the operation is to mark sub-picture areas of a long-term picture as "unused".

Sub-pictures are numbered in raster scan order starting from the upper-left corner of the picture. For example, consider a case in which a reference picture, specified by DPN, is partitioned into six sub-pictures. Let "s_1 s_2 s_3 s_4 s_5 s_6" represent six bits of SPRB data. If bit s_i is "1", then the decoder should mark the ith sub-picture in the indicated reference picture as "unused". For example, if the SPRB is '000110', then the fourth and fifth sub-pictures areas are marked as "unused".

To prevent start code emulation, all necessary SPREPB emulation prevention bits shall be inserted within or following the SPRB data as specified in subclause U.3.1.5.11.

If SPRB is present and the specified picture has previously been affected by a prior SPRB bit-map, the bit-map specified by SPRB shall contain a "1" for any sub-picture area that contained a "1" in that previous SPRB bit-map. Every SPRB bit-map shall contain at least one bit having the value "0" and at least one bit having the value "1".

U.3.1.5.11 Sub-Picture Removal Emulation Prevention Bit (SPREPB) (one bit)
SPREPB is a single bit fixed length codeword having the value "1" which shall be inserted immediately after any string of 8 consecutive zero bits of SPRB data.

U.3.1.5.12 Maximum Long-Term Picture Index Plus 1 (MLIP1) (variable length)
MLIP1 is a variable length codeword that is present if indicated by MMCO. MLIP1 follows MMCO if present. MLIP1 is transmitted using codewords in Table U.1. If present, MLIP1 is used to determine the maximum index allowed for long-term reference pictures (until receipt of another value of MLIP1). The decoder shall initially assume MLIP1 is "0" until some other value has been received. Upon receiving an MLIP1 parameter, the decoder shall consider all long-term pictures having indices greater than the decoded value of MLIP1 – 1 as "unused" for referencing by the decoding process for subsequent pictures. For all other pictures in the multi-picture buffer, no change of status shall be indicated by MLIP1.

U.3.1.5.13 Sub-Picture Width Indication (SPWI) (7 bits)
SPWI is a fixed length codeword of 7 bits that is present if indicated by MMCO. SPWI follows MMCO when indicated. SPWI specifies the width of a sub-picture in units of 16 luminance samples, such that the indicated sub-picture width is 16·(SPWI+1) luminance samples. The current picture has a width in sub-picture units of ceil(ceil(pw / 16) / (SPWI+1)) sub-pictures, where pw is the width of the picture and "/" indicates floating-point division. For positive numbers, the ceiling function, ceil(x), equals x if x is an integer and otherwise ceil(x) equals one plus the integer part of x. If a minimum picture unit (MPU) size defining the minimum width and height of a sub-picture has been negotiated by external means (for example, Recommendation H.245), the sub-picture width specified by SPWI shall be an integer multiple of the width of the MPU; otherwise, the sub-picture width specified by SPWI shall be such that SPWI is equal to ceil(pw / 16) – 1.

U.3.1.5.14 Sub-Picture Height Indication (SPHI) (7 bits)
SPHI is a fixed length codeword of 7 bits that is present if SPWI is present (as indicated by MMCO). SPHI follows SPWI if present. SPWI specifies the height of a sub-picture in units of 16 luminance samples, such that the indicated sub-picture height is 16·SPHI. The allowed range of values of SPHI is from 1 to 72. The current picture has a height of ceil(ceil(ph / 16) / SPHI) sub-pictures, where ph is the height of the picture and "/" indicates floating-point division. If a minimum picture unit (MPU) size defining the minimum width and height of a sub-picture has been negotiated by external means (for example, Recommendation H.245), the sub-picture height specified by SPHI shall be an integer multiple of the height of the MPU; otherwise, the sub-picture height specified by SPHI shall be such that SPHI is equal to ceil(ph / 16).

U.3.1.5.15 Sub-Picture Total Number (SPTN) (variable length)
SPTN is a variable length codeword that is present if SPWI and SPHI are present (as indicated by MMCO). SPTN follows SPHI if present. SPTN is coded using Table U.1, where the index into Table U.1 corresponds to the decoded value of SPTN – 1. The decoded value of STPN is the total operational size capacity of the multi-picture buffer in units of sub-pictures as specified by SPWI and SPHI. The memory capacity needed for the decoding of current pictures is not included in SPTN – only the memory capacity needed for storing the reference pictures to use for the prediction of other pictures. When sub-picture removal is not in use (i.e. when SPWI and SPHI have whole-picture dimensions), the maximum number of active short-

term reference pictures (for example, for sliding window operation) is thus given by SPTN minus the number of pictures that have been assigned to long-term indices and have not been subsequently marked as "unused".

U.3.1.5.16 Buffer Reset Indicator (RESET) (1 bit)

RESET is a single bit fixed length codeword that is present if SPWI, SPHI, and SPTN are present (as indicated by MMCO). RESET follows SPTN if present. The values of RESET shall be as follows:

"0": The buffer contents are not reset,
"1": The buffer contents are reset.

If RESET is "1", all pictures in the multi-picture buffer (but not the current picture unless specified separately) shall be marked "unused" (including both short-term and long-term pictures).

U.3.2 Macroblock layer syntax

U.3.2.1 P-Picture and Improved PB frames Macroblock Syntax

The macroblock layer syntax is modified if the ERPS layer is present for P-pictures and Improved PB frames when the number of selected forward reference pictures may be greater than one, as indicated by MRPA. The field MRPA is signaled in the ERPS layer. The macroblock layer syntax is shown in Figure U.7 when MRPA is "1". Otherwise, the macroblock syntax format in a P picture or Improved PB frame is not altered from that shown in Figure 10.

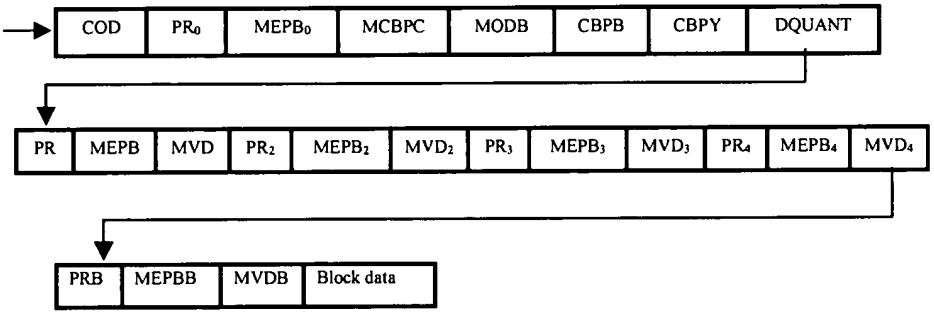

FIGURE U.7/H.263

Structure of P-picture and Improved PB frame Macroblock layer for the ERPS mode

U.3.2.1.1 Interpretation of COD

If the COD bit is "1", no further information is transmitted for the macroblock. In that case, the decoder shall treat the macroblock as an INTER macroblock with the motion vector for the entire macroblock equal to zero, picture reference parameter equal to zero, and with no coefficient data. If the COD bit is "0", indicating that the macroblock is coded, the syntax of the macroblock layer is depicted in Figure U.7 with the fields PR_0, PR, PR_2, PR_3, PR_4, and PRB being included in the syntax. PR_0, PR, PR_2, PR_3, PR_4, and PRB each consist of a variable length codeword as given in Table U.1.

U.3.2.1.2 Picture Reference Parameter 0 (PR_0) (variable length)

PR_0 is a variable length codeword as specified in Table U.1. It is present whenever COD is "0". If PR_0 has a decoded value of zero (codeword "1"), it indicates that further information will follow for the macroblock. If decoded as non-zero, it indicates the coding of the macroblock using only a picture reference parameter.

If the field PR_0 does not have a decoded value of zero (codeword '1'), no further information is transmitted for this macroblock. In that case the decoder shall treat the macroblock as an INTER macroblock with the motion vector for the whole block equal to zero, the picture reference parameter equal to PR_0, and with no coefficient data.

If the field PR_0 has a decoded value of zero (codeword '1'), the macroblock is coded. The meaning and usage of the fields MCBPC, CBPB, CBPY, and DQUANT remains unaltered. The field PR is included together with the field MVD for all

INTER macroblocks (and in Improved PB frames mode also for INTRA macroblocks). The use of MODB in Improved PB frames is described in subclause U.3.2.1.4.

U.3.2.1.3 Macroblock Emulation Prevention Bit 0 ($MEPB_0$) (1 bit)

$MEPB_0$ is a single bit fixed length codeword having the value "1" that follows PR_0 if and only if PR_0 is present and has a decoded value of "1" (codeword '000'), and either of the following two conditions are satisfied:

1. the slice structured mode (see Annex K) is in use, or
2. the COD for the current macroblock immediately follows after another macroblock which also has COD = "0" and PR_0 = "1" (codeword '000'), and the PR_0 of the previous macroblock is not followed by an $MEPB_0$ bit.

The purpose of $MEPB_0$ is to prevent start-code emulation and, in the slice structured mode, to aid in determining the number of macroblocks in a slice.

U.3.2.1.4 Macroblock Picture Reference Parameters (PR, PR_{2-4}, and PRB) (variable length)

PR is the primary picture reference parameter. PR is present whenever MVD is present. The three codewords PR_{2-4} are included together with MVD_{2-4} if indicated by PTYPE and if MCBPC specifies an INTER4V or INTER4V+Q macroblock (a macroblock of type 2 or 5 in Tables 8 and 9). PR_{2-4} and MVD_{2-4} are only present when in Advanced Prediction mode (see Annex F) or Deblocking Filter mode (see Annex J). PRB is only present in an Improved PB frame when MODB indicates that MVDB is present. PR, PR_{2-4}, and PRB each specify a picture reference relative index into the multi-picture buffer.

PR is used as the picture reference parameter for motion compensation of the entire macroblock if the macroblock is not an INTER4V or INTER4V+Q macroblock. If the macroblock is an INTER4V or INTER4V+Q macroblock, PR is used for motion compensated prediction of the first of the four 8×8 luminance blocks in the macroblock and for the two chrominance blocks of the macroblock (with the motion compensation process otherwise as specified in subclause 6.1). PR_{2-4} are used for motion compensation of the remaining three 8×8 blocks of luminance data in the macroblock. If MODB indicates that MVDB is present, PRB is the picture reference parameter for forward prediction of the B part of the Improved PB frame.

In Improved PB frames when MODB indicates B_{PB} bidirectional prediction, the values of TR_D and TR_B shall be computed as the temporal reference increments based on the temporal reference data of the current picture and that of the most recent previous reference picture, regardless of whether or not the most recent previous reference picture has been re-mapped to a difference relative index order, marked as "unused", or assigned to a long-term index. The picture used as the forward reference picture for B_{PB} bidirectional prediction in Improved PB frames shall be the picture specified by PR.

U.3.2.1.5 Macroblock Emulation Prevention Bits (MEPB , $MEPB_{2-4}$, and MEPBB) (1 bit each)

MEPB, $MEPB_{2-4}$, and MEPBB are each a single bit having the value "1" if present. Each shall be present if and only if the Unrestricted Motion Vector mode (see Annex D) is not in use and the associated PR, PR_{2-4}, or PRB field is present and has the decoded value "1" (codeword '000'). Their purpose is to prevent start-code emulation.

U.3.2.2 B-Picture and EP-Picture Macroblock Syntax

The macroblock layer syntax for B and EP pictures (see Annex O) is modified in a similar fashion as in P pictures. The COD bit, if equal to "1", indicates a skipped macroblock as defined in Annex O, using a picture reference parameter of zero for the forward (skipped) prediction in an EP picture and for the forward part of direct (skipped) bidirectional prediction in a B picture and using the first backward prediction picture for the backward part of direct (skipped) bidirectional prediction in a B picture (in the case of two-picture backward prediction, as when BSBBW is present and equal to "0"). If COD is "0", a PR_0 parameter is inserted into the syntax and is used in a similar manner as described in U.3.2.1.2. If PR_0 is present and does not have a decoded value of zero (codeword '1'), it indicates that the macroblock is to be predicted with forward INTER prediction using a zero-valued motion vector and a picture reference parameter of PR_0. If PR_0 has a decoded value of zero, MBTYPE follows and specifies the macroblock type. The format of the CBPC, CBPY, and DQUANT fields is unchanged. The MVDFW and MVDBW fields are encoded in the same manner as when the ERPS mode is not in use, but are each used in conjunction with a picture reference, and possibly an emulation prevention bit.

For a B picture, the backward reference pictures in the multi-picture buffer are defined as follows:

- In the case of single-picture backward prediction, there is only one backward reference picture, which is the first picture in (possibly re-mapped) relative index order, and
- In the case of two-picture backward prediction, there are two backward reference pictures, which are the first two pictures in (possibly re-mapped) relative index order.

The forward reference pictures in the multi-picture buffer are defined as the pictures in the multi-picture buffer other than the backward reference pictures. The relative indexing for forward prediction is a relative index into the forward reference picture set, and the relative indexing for backward prediction is a relative index into the backward reference picture set.

For example, if the buffer contains three short-term pictures with short-term picture numbers 300, 302, and 303 (which were transmitted in increasing picture-number order) and two long-term pictures with long-term picture indices 0 and 3, the default index order in the case of two-picture backward prediction is:

- default backward relative index 0 refers to the short-term picture with picture number 303,
- default backward relative index 1 refers to the short-term picture with picture number 302,
- default forward relative index 0 refers to the short-term picture with picture number 300,
- default forward relative index 1 refers to the long-term picture with long-term picture index 0, and
- default forward relative index 2 refers to the long-term picture with long-term picture index 3;

and in the case of single-picture backward prediction:

- the single default backward reference picture is the short-term picture with picture number 303,
- default forward relative index 0 refers to the short-term picture with picture number 302,
- default forward relative index 1 refers to the short-term picture with picture number 300,
- default forward relative index 2 refers to the long-term picture with long-term picture index 0, and
- default forward relative index 3 refers to the long-term picture with long-term picture index 3;

and if these pictures have been re-mapped to a new relative indexing order of short-term picture 302, followed by short-term picture 303, followed by long-term picture 0, followed by short-term picture 300, followed by long-term picture 3, the new relative index order in the case of two-picture backward prediction is:

- re-mapped backward relative index 0 refers to the short-term picture with picture number 302,
- re-mapped backward relative index 1 refers to the short-term picture with picture number 303,
- re-mapped forward relative index 0 refers to the long-term picture with long-term picture index 0,
- re-mapped forward relative index 1 refers to the short-term picture with picture number 300, and
- re-mapped forward relative index 2 refers to the long-term picture with long-term picture index 3;

and in the case of single-picture backward prediction:

- the single re-mapped backward reference picture is the short-term picture with picture number 302,
- re-mapped forward relative index 0 refers to the short-term picture with picture number 303,
- re-mapped forward relative index 1 refers to the long-term picture with long-term picture index 0,
- re-mapped forward relative index 2 refers to the short-term picture with picture number 300, and
- re-mapped forward relative index 3 refers to the long-term picture with long-term picture index 3.

The TR_D used for direct bidirectional prediction in a B picture shall be computed as the temporal reference increment between the first forward reference picture in (possibly re-mapped) relative index order and the first backward reference picture in (possibly re-mapped) relative index order (i.e. if two-picture backward prediction is in use, this would be the picture referenced when BSBBW is "0" as described in sub-clause U.3.2.2.3). The TR_B used for direct bidirectional prediction in a B picture shall be computed as the temporal reference increment between the B picture and the first forward reference picture in (possibly re-mapped) relative index order. The relative index order used in the computation of TR_D and TR_B shall be that specified by the ERPS layer at the picture level of the B picture syntax (i.e. re-mappings at the GOB or slice level shall not affect the values of TR_D and TR_B).

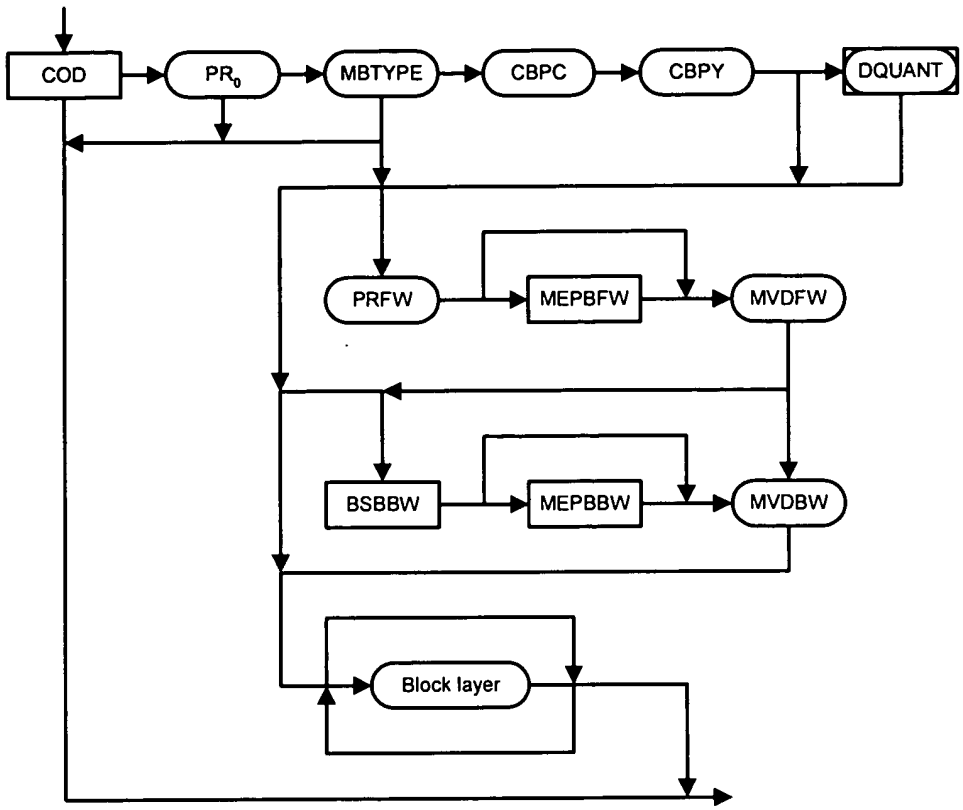

FIGURE U.8/H.263

Structure of EP and B picture Macroblock layer for the ERPS mode

U.3.2.2.1 Picture Reference for Forward Prediction (PRFW) (variable length)
PRFW is a variable length picture reference parameter that is present whenever MVDFW is present, and is encoded using Table U.1. PRFW is a relative index into the set of forward reference pictures.

U.3.2.2.2 Emulation Prevention Bit for Forward Prediction (MEPBFW) (1 bit)
MEPBFW is a single bit fixed length codeword having the value "1" which shall be inserted after PRFW if and only if PRFW is present and has a decoded value of "1" (codeword '000') and the unrestricted motion vector mode (see Annex D) is not in use.

U.3.2.2.3 B-Picture Selection Bit for Backward Prediction (BSBBW) (1 bit)
BSBBW is a single bit fixed length codeword that is present only for B pictures when MVDBW is present and only when two-picture backward prediction is specified for the B picture operation. The meaning of this bit shall be defined as:

"0" : Prediction from the first backward reference picture in relative index order (in default order, this would be the most recent short-term reference picture if that picture has not been assigned a long-term index or marked as "unused")

"1" : Prediction from the second backward reference picture in relative index order (in default order, this would be the second-most recent short-term reference picture if neither of the last two reference pictures has been assigned a long-term index or marked as "unused")

U.3.2.2.4 Emulation Prevention Bit for Backward Prediction (MEPBBW) (1 bit)
MEPBBW is a single bit fixed length codeword having the value "1" that is present only under the following conditions:

- BSBBW is present and equal to "0", and
- The unrestricted motion vector mode (see Annex D) is not in use, and
- BSBBW is preceded by five bits having the value '00000'

U.4 Decoder Process

The decoder for the ERPS mode stores the reference pictures for inter-picture decoding in a multi-picture buffer. The decoder may need additional memory capacity to store the multiple decoded pictures (relative to the memory capacity needed without support of the ERPS mode). The decoder replicates the multi-picture buffer of the encoder according to the reference picture buffering type and any memory management control operations specified in the bitstream. The buffering scheme may also be operated when partially erroneous pictures are decoded.

Each transmitted and stored picture is assigned a Picture Number (PN) which is stored with the picture in the multi-picture buffer. PN represents a sequential picture counting identifier for stored pictures. PN is constrained, using modulo 1024 arithmetic operation. For the first transmitted picture, PN should be "0". For each and every other transmitted and stored picture, PN shall be increased by 1 (within a given scalability layer, if Annex O is in use). If the difference (modulo 1024) of the PNs of two consecutively received and stored pictures is not 1, the decoder should infer a loss of pictures or corruption of data. In such a case, a back-channel message indicating the loss of pictures may be sent to the encoder.

Besides the PN, each picture stored in the multi-picture buffer has an associated index, called the default relative index. When a picture is first added to the multi-picture buffer it is given default relative index 0 – unless it is assigned to a long-term index. The default relative indices of pictures in the multi-picture buffer are modified when pictures are added to or removed from the multi-picture buffer, or when short-term pictures are assigned to long-term indices.

The pictures stored in the multi-picture buffers can also be divided into two categories: long-term pictures and short-term pictures. A long-term picture can stay in the multi-picture buffer for a long time (more than 1023 coded and stored picture intervals). The current picture is initially considered a short-term picture. Any short-term picture can be changed to a long-term picture by assigning it a long-term index according to information in the bitstream. The PN is the unique ID for all short-term pictures in the multi-picture buffer. When a short-term picture is changed to a long-term picture, it is also assigned a long-term picture index (LPIN). A long-term picture index is assigned to a picture by associating its PN to an LPIN. Once a long-term picture index has been assigned to a picture, the only potential subsequent use of the long-term picture's PN within the bitstream shall be in a repetition of the long-term index assignment. The PNs of the long-term pictures are unique within 1024 transmitted and stored pictures. Therefore, the PN of a long-term picture cannot be used for assignment of a long-term index after 1023 transmitted subsequent stored pictures. LPIN becomes the unique ID for the life of a long-term picture.

PN (for a short-term picture) or LPIN (for a long-term picture) can be used to re-map the pictures into re-mapped relative indices for efficient reference picture addressing.

U.4.1 Decoder Process for Short/Long-term Picture Management

The decoder may have both long-term pictures and short-term pictures in its multi-picture buffer. The MLIP1 field is used to indicate the maximum long-term picture index allowed in the buffer. If no prior value of MLIP1 has been sent, no long-term pictures shall be in use, i.e. MLIP1 shall initially have an implied value of "0" upon invocation of the ERPS mode. Upon receiving an MLIP1 parameter, a new MLIP1 shall take effect until another value of MLIP1 is received. Upon receiving a new MLIP1 parameter in the bitstream, all long-term pictures with associated long-term indices greater than or equal to MLIP1 shall be considered marked "unused". The frequency of transmitting MLIP1 is out of the scope of this Recommendation. However, the encoder should send an MLIP1 parameter upon receiving an error message, such as an Intra request message.

A short-term picture can be changed to a long-term picture by using an MMCO command with an associated DPN and LPIN. The short-term picture number is derived from DPN and the long-term picture index is LPIN. Upon receiving such an MMCO command, the decoder shall change the short-term picture with PN indicated by DPN to a long-term picture and shall assign it to the long-term index indicated by LPIN. If a long-term picture with the same long-term index already exists in the buffer, the previously-existing long-term picture shall be marked "unused". An encoder shall not assign a long-term index greater than MLIP1−1 to any picture. If LPIN is greater than MLIP1−1, this condition should be treated by the decoder as an error. For error resilience, the encoder may send the same long-term index assignment operation or MLIP1 specification message repeatedly. If the picture specified in a long-term assignment operation is already associated with the required LPIN, no action shall be taken by the decoder. An encoder shall not assign the same picture to more than one long term index value. If the picture specified in a long-term index assignment operation is already associated with a different long-term index, this condition should be treated as an error. An encoder shall only change a short-term picture to a long-term picture within 1024 transmitted consecutive stored pictures. In other words, a short-term picture shall not stay in the short-term buffer after more than 1023 subsequent stored pictures have been transmitted. An encoder shall not assign a long-term index to a short-term picture that has been marked as "unused" by the decoding process prior to the first such assignment message in the bitstream. An encoder shall not assign a long-term index to a picture number that has not been sent.

U.4.2 Decoder Process for Reference Picture Buffer Mapping

The decoder employs indices when referencing a picture for motion compensation on the macroblock layer using the fields PR_0, PR, PR_2, PR_3, PR_4, PRB, PRFW, and BSBBW. In pictures other than B pictures, these indices are the default relative indices of pictures in the multi-picture buffer when the fields ADPN and LPIR are not present in the current picture, GOB, or slice layer as applicable, and are re-mapped relative indices when these fields are present. In B pictures, the first one or two pictures (depending on BTPSM) in relative index order are used for backward prediction, and the forward picture reference parameters specify a relative index into the remaining pictures for use in forward prediction.

The indices of pictures in the multi-picture buffer can be re-mapped onto newly specified indices by transmitting the RMPNI, ADPN, and LPIR fields. RMPNI indicates whether ADPN or LPIR is present. If ADPN is present, RMPNI specifies the sign of the difference to be added to a picture number prediction value. The ADPN value corresponds to the absolute difference between the PN of the picture to be re-mapped and a prediction of that PN value. The first transmitted ADPN is computed as the absolute difference between the PN of the current picture and the PN of the picture to be re-mapped. The next transmitted ADPN field represents the difference between the PN of the previous picture that was re-mapped using ADPN and that of another picture to be re-mapped. The process continues until all necessary re-mapping is complete. The presence of re-mappings specified using LPIR does not affect the prediction value for subsequent re-mappings using ADPN. If RMPNI indicates the presence of an LPIR field, the re-mapped picture corresponds to a long-term picture with a long-term index of LPIR. If any pictures are not re-mapped to a specific order by RMPNI, these remaining pictures shall follow after any pictures having a re-mapped order in the indexing scheme, following the default order amongst these non-re-mapped pictures.

If the decoder detects a missing picture, it may invoke some concealment process, and may insert an error-concealed picture into the multi-picture buffer. Missing pictures can be identified if one or several picture numbers are missing or if a picture not stored in the multi-picture buffer is indicated in a transmitted ADPN or LPIR. Concealment may be conducted by copying the closest temporally preceding picture that is available in the multi-picture buffer into the position of the missing picture. The temporal order of the short-term pictures in the multi-picture buffer can be inferred from their default relative index order and PN fields. In addition or instead, the decoder may send a forced INTRA update signal to the encoder by external means (for example, Recommendation H.245), or the decoder may use external means or back-channel messages (for example, Recommendation H.245) to indicate the loss of pictures to the encoder. A concealed picture may be inserted into the multi-picture buffer when using the "Sliding Window" buffering type. If a missing picture is detected when decoding a GOB or Slice layer, the concealment may be applied to the picture as if the missing picture had been detected at the picture layer.

U.4.3 Decoder Process for Sub-Picture Removal

Sub-Picture Removal may be used to reduce the amount of memory required to save multiple reference pictures. In sub-picture removal operation, each reference picture is partitioned into smaller equal-sized sub-pictures. The memory reduction is accomplished by marking undesired sub-picture areas as "unused". The strategy used by the encoder to decide which of the sub-pictures to mark as "unused" is outside the scope of this document. The encoder signals to the decoder the size of the sub-pictures and which of the sub-pictures to mark as "unused" using MMCO commands in the enhanced reference picture selection (ERPS) layer. The encoder shall not send information in the bitstream that causes any samples in reference pictures or sub-pictures that it has caused to be marked as "unused" to be indicated for use in the prediction of subsequent pictures.

The sub-picture removal capability is negotiated by external means (for example, Recommendation H.245). In addition, the decoder signals, also by external means, the minimum partition unit (MPU) which is described in terms of a minimum width and height (in units of 16 luminance samples) of a sub-picture and the total amount of memory it has available for its multi-picture buffer. Memory management is facilitated by the partition rules described below.

Each reference picture is partitioned into rectangular sub-pictures of equal size. The encoder specifies the sub-picture size which shall be an integer multiple of the MPU. The width and height of the sub-picture shall be integer multiples of the minimum MPU width and height negotiated externally. The upper-left-hand corner of the first sub-picture is coincident with the upper-left-hand corner of the reference picture. Consequently, the entire partition may be described by specifying the width and height of a sub-picture. If the picture size is not an integer multiple of the sub-picture size, some sub-pictures may extend beyond the right and bottom boundaries of the reference picture if the picture size is not an integer multiple of the sub-picture size. When a sub-picture that extends past the reference picture boundary is saved, a convenient memory management strategy is to set aside enough memory to save the entire sub-picture, rather than just the memory necessary to save the portion of the reference picture that lies within that sub-picture. This is the convention which shall be followed in any calculation of buffer spare capacity for the purpose of determining buffer fullness (e.g. in order to determine whether to automatically mark buffered pictures as "unused" in "sliding window" operation). A decoder designed such that each sub-picture occupies the same amount of memory will prevent the possibility of memory fragmentation.

An example method designed to access referenced picture samples when sub-picture removal is in use is described briefly as follows. One important element in any reference picture access technique is a mechanism to identify where the samples in each sub-picture are stored in memory. If there are R reference pictures and each picture is partitioned into S sub-pictures then there are a total of $K = R \cdot S$ sub-pictures. For example, the sub-picture in the upper-left hand corner of the first reference picture number can be considered sub-picture number 0, and the sub-picture to the right of it can be considered sub-picture number 1 and so on in raster scan order progressing from reference picture 0 to R–1 until all K sub-pictures have a label. The total buffer

capacity is SPTN sub-picture memory buffers, and SPTN is typically less than K. A K-element array can be defined, subPicMem[K], such that t = subPicMem[k] corresponds to the sub-picture memory area that contains the samples in sub-picture k. For example, a case can be considered in which R = 5 reference pictures each have S = 12 sub-pictures. Then the samples for the sub-picture 6 in reference picture 3 would be found in sub-picture memory area t = subPicMem[k] where k = 3·S+6 = 42.

For example, when referencing samples for motion-compensated prediction of one block of luminance or chrominance data when the Advanced Prediction and Reduced Resolution Update optional modes are not in use, it is necessary to acquire n×m samples, where n and m may take values of 8 or 9 to accommodate half-integer motion compensation. Since the samples in one block may lie in up to four different sub-pictures, four separate cases must be considered. In all cases, the first step is to find the location in memory that contains the upper-left hand sample (U) of the block to be referenced. The sub-picture containing U can be identified by dividing the horizontal or vertical location of U by the sub-picture width or height. If U lies in sub-picture k, then that sample will be located in the subPicMem[k] sub-picture memory area. Next, if both the sample m–1 samples to the right of U (i.e. the upper-right-hand corner of the block) and the sample n–1 samples down from U (i.e. the lower-left-hand corner of the block) lie in sub-picture k, this can be considered case number one. If the sample n–1 samples down from U lies within k, but the sample m–1 samples to the right of U does not, this can be considered case two. If the sample m–1 samples to the right of U lies within k, but the sample n–1 down does not, this can be considered case three. Otherwise, when both the sample m–1 samples to the right of U and the one n–1 samples down lie outside of sub-picture k, this can be considered case four.

In case number one, all samples in the reference block are contained within the kth sub-picture. In this case, all relevant n×m samples may be found in sub-picture memory area subPicMem[k]. In case two, the samples that lie in the kth sub-picture can be obtained from sub-picture memory area subPicMem[k] and the remaining samples can be obtained from subPicMem[k_r] where k_r is the sub-picture to the right of k. In case three, the samples that lie in the kth sub-picture can be obtained from memory area subPicMem[k], and the remaining samples can be obtained from subPicMem[k_d] where k_d is the sub-picture below k. In case four, the samples that lie in the kth sub-picture can be obtained from sub-picture memory area subPicMem[k] and the remaining samples can be obtained from memory areas subPicMem[k_r], subPicMem[k_d] and subPicMem[k_{rd}] where k_r and k_d are defined above and k_{rd} is the sub-picture to the right and below k.

U.4.4 Decoder Process for Multi-Picture Motion Compensation

Multi-picture motion compensation is applied if the MRPA field indicates the use of more than one reference picture. For multi-picture motion compensation, the decoder chooses a reference picture as indicated using the fields PR_0, PR, PR_2, PR_3, PR_4, PRB, PRFW, PRBW, and BSBBW on the macroblock layer. Once, the reference picture is specified, the decoding process for motion compensation proceeds as described in subclause 6.1.

In case four motion vectors per macroblock are used and the MRPA field indicates the use of more than one reference picture, the picture reference index for both chrominance blocks is that associated with the first of the four motion vectors (with the motion compensation process otherwise as specified by subclause 6.1).

U.4.5 Decoder Process for Reference Picture Buffering

The buffering of the currently decoded picture can be specified using the reference picture buffering type (RPBT) for non-B pictures. The buffering may follow a first-in, first-out ("Sliding Window") mode. Alternatively, the buffering may follow a customized adaptive buffering ("Adaptive Memory Control") operation that is specified by the encoder in the forward channel. B pictures do not affect buffer contents.

The "Sliding Window" buffering type operates as follows. First, the decoder determine whether the picture can be stored into "unused" buffer capacity. If there is insufficient "unused" buffer capacity, the short term picture with the largest default relative index (i.e. the oldest short-term picture in the buffer) shall be marked as "unused". This process is repeated if necessary (in the case of sub-picture removal) until sufficient memory capacity is freed to hold the current decoded picture. The current picture is stored in the buffer and assigned a default relative index of zero. The default relative index of all other short-term pictures is incremented by one. The default relative indices of all long-term picture are incremented by one minus the number of short-term pictures removed.

In the "Adaptive Memory Control" buffering type, specified pictures or sub-picture areas may be removed from the multi-picture buffer explicitly. The currently decoded picture, which is initially considered a short-term picture, may be inserted into the buffer with default relative index 0, may be assigned to a long-term index, or may be marked as "unused" by the encoder. Other short-term pictures may also be assigned to long-term indices. The buffering process shall operate in a manner functionally equivalent to the following: First, the current picture is added to the multi-picture buffer with default relative index 0, and the default relative indices of all other pictures are incremented by one. Then, the MMCO commands are processed:

- If MMCO indicates a reset of the buffer contents by using RESET equal to "1", all pictures in the buffer are marked as "unused" except the current picture (which will be the picture with default relative index 0 since a buffer reset must be the first MMCO command as required by subclause U.3.1.5.7).

- If MMCO indicates a maximum long-term index using MLIP1, all long-term pictures having long-term indices greater than or equal to MLIP1 are marked as "unused" and the default relative index order of the remaining pictures are not affected.
- If MMCO indicates that a picture is to be marked as "unused" in the multi-picture buffer and if that picture has not already been marked as "unused", the specified picture is marked as "unused" in the multi-picture buffer and the default relative indices of all subsequent pictures in default order are decremented by one.
- If MMCO indicates that sub-picture areas of some picture are to be marked as "unused" in the multi-picture buffer, the specified sub-picture areas are marked as "unused" and the default relative index order of the pictures is not affected. As required by subclause, U.3.1.5.10, not all sub-picture areas of any given picture will be marked "unused" by a sub-picture removal MMCO command (instead, the encoder should send an MMCO command marking the picture as a whole as "unused").
- If MMCO indicates the assignment of a long-term index to a specified short-term picture and if the specified long-term index has not already been assigned to the specified short-term picture, the specified short-term picture is marked in the buffer as a long-term picture with the specified long-term index. If another picture is already present in the buffer with the same long-term index as the specified long-term index, the other picture is marked as "unused". All short-term pictures that were subsequent to the specified short-term picture in default relative index order and all long-term pictures having a long-term index less than the specified long-term index have their associated default relative indices decremented by one. The specified picture is assigned to a default relative index of one plus the highest of the incremented default relative indices, or zero if there are no such incremented indices.

The resulting buffered quantity of pictures or sub-picture regions not marked as "unused" shall not exceed the buffer capacity indicated by the most recent value of SPTN. If the decoder detects this condition, it should be treated as an error.

U.5 Back-Channel Messages

An out-of-band channel, which need not necessarily be reliable, can be used to convey back-channel messages. The syntax of this out-of-band channel (which could be a separate logical channel, for example using Recommendation H.223 or Recommendation H.225.0) should be the one defined herein. The "videomux" operation of back-channel messages as defined in Annex N is not supported in the ERPS mode.

U.5.1 BCM Separate Logical Channel Layer

The BCM layer as specified in subclause U.5.2 should be carried by a BCM Separate Logical Channel layer as shown in Figure U.9.

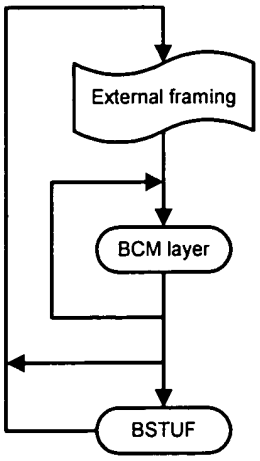

FIGURE U.9/H.263

Structure of BCM Separate Logical Channel layer for ERPS mode

U.5.1.1 External Framing

External framing of back-channel messages should be provided as shown in Figure U.9. The external framing is used to determine the starting point for the back-channel messages and the amount of back-channel message data to follow.

U.5.1.2 Back-Channel Stuffing (BSTUF) (variable length)

BSTUF is a variable length codeword that may be present only after the last back-channel message in an external frame. BSTUF consists of a codeword of variable length consisting of one or more bits of value "0".

U.5.2 Back-Channel Message Layer Syntax

The syntax for the back-channel message (BCM) layer defined herein shall be as shown in Figure U.10.

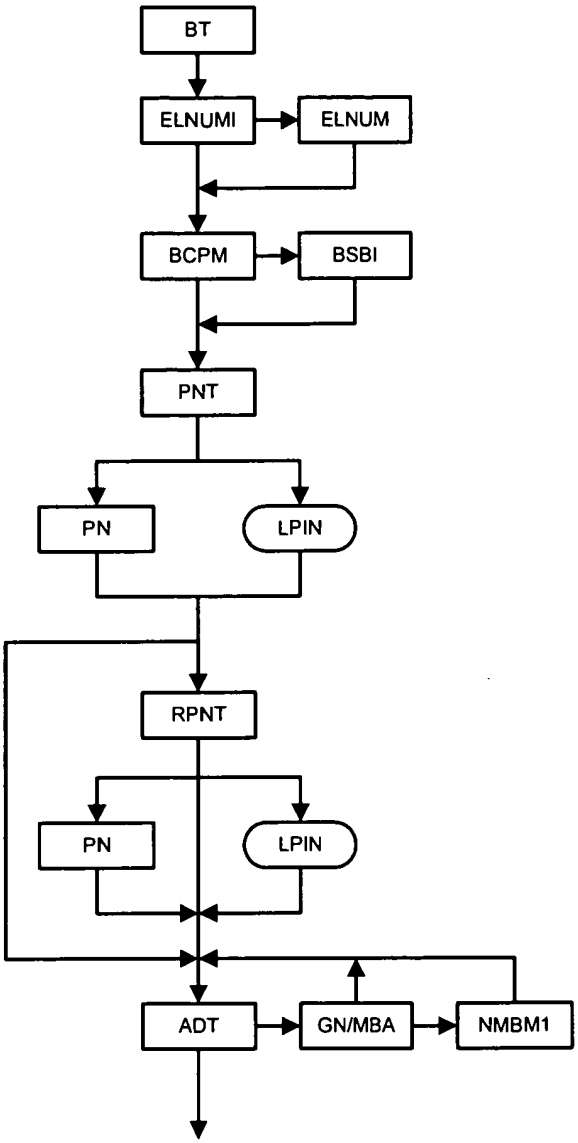

FIGURE U.10/H.263

Structure of Back-Channel Message (BCM) layer for ERPS mode

U.5.2.1 Back-Channel Message Type (BT) (2 bits)

BT is a two bit fixed length codeword which indicates the type of back-channel message. BT is the first codeword present in each back-channel message. Which type or types of message are requested by the encoder is indicated in the RPSMF field of the forward-channel syntax. The values of BT shall be defines as:

"00": Reserved for future use,

"01": Reserved for future use,

"10": NACK: This indicates the loss or erroneous decoding of the corresponding part of the forward channel data,
"11": ACK: This indicates the correct decoding of the corresponding part of the forward channel data.

U.5.2.2 Enhancement Layer Number Indication (ELNUMI) (1 bit)
ELNUMI is a single bit fixed length codeword that follows BT in the back-channel message. ELNUMI shall be "0" unless the optional Temporal, SNR, and Spatial Scalability mode (see Annex O) is used in the forward channel and some enhancement layers of the forward channel are combined in one logical channel and the back-channel message refers to an enhancement layer (rather than the base layer), in which case ELNUMI shall be "1".

U.5.2.3 Enhancement Layer Number (ELNUM) (4 bits)
ELNUM is a 4 bit fixed length codeword that is present only if ELNUMI is "1". It follows ELNUMI if present. When present, ELNUM contains the layer number of the enhancement layer referred to in the back-channel message.

U.5.2.4 Back-Channel CPM Indicator (BCPM) (1 bit)
BCPM is a single bit fixed length codeword that follows ELNUMI or ELNUM in the back-channel message. BCPM shall be "0" unless the CPM mode (see subclause 5.2.4 and Annex C) is used in the forward channel data, in which case BCPM shall be "1". If BCPM is "1", this indicates that BSBI is present.

U.5.2.5 Back-Channel Sub-Bitstream Indicator (BSBI) (2 bits)
BSBI is a 2 bit fixed length codeword that follows BCPM when present. BCPM is present only if BCPM is "1". BSBI is the natural binary representation of the Sub-Bitstream number in the forward channel data to which the back-channel message refers (see subclause 5.2.4 and Annex C).

U.5.2.6 Picture Number Type (PNT) (1 bit)
PNT is a single bit fixed length codeword that is always present and follows BCPM or BSBI in the back-channel message. The values of PNT shall be defined as:
"0": The message concerns a picture specified by a short-term picture number (PN),
"1": The message concerns a picture specified by a long-term picture index (LPIN).
PNT is followed by PN or LPIN, depending on the value of PNT. PN and LPIN shall be represented as specified for use in forward channel data in subclauses U.4.1.3 and U.4.1.5.9, respectively.

U.5.2.7 Requested Picture Number Type (RPNT) (2 bits)
RPNT is a 2 bit fixed length codeword that is present only if BT indicates a NACK message. It follows PN or LPIN when present. It determines how to identify a picture in the multi-picture buffer which may be used as a reference for the coding of subsequent pictures. The values of RPNT shall be defined as:
"00": No valid pictures in buffer – buffer should be reset by an I or EI picture with RESET equal to "1",
"01": No particular picture is identified to be used as a reference,
"10": A picture which may be used as a reference is identified by a short-term picture number (PN),
"11": A picture which may be used as a reference is identified by a long-term picture index (LPIN).

If RPNT is "10" or "11", RPNT is followed by PN or LPIN, depending on the value of RPNT. PN and LPIN shall be represented as specified for use in forward channel data in subclauses U.4.1.3 and U.4.1.5.9, respectively. Typically the PN or LPIN specified using RPNT identifies the last correctly decoded spatially-corresponding picture area for the picture or region identified in the back-channel message.

U.5.2.8 Additional Data Type (ADT) (2 bits)
ADT is a 2 bit fixed length codeword that is present after PN, LPIN, or RPNT, as determined by PNT (in an ACK message) or RPNT (in a NACK message). It may occur multiple times if present. It specifies the type of additional data used to identify a region of the picture of concern to which the back-channel message applies. The values of ADT shall be defined as:
"00": End of additional data,
"01": A region is identified by only a GN/MBA field,
"10": A region is identified as a raster-scan area within a picture by GN/MBA and NMBM1,
"11": A region is identified as a raster-scan area within a rectangular slice by GN/MBA and NMBM1.

If ADT is "00", no more data follows in the back-channel message. If ADT is "01", ADT is followed by GN/MBA and then by another ADT. If ADT is "10" or "11", ADT is followed by GN/MBA and NMBM1 and then by another ADT.

If ADT is "10", the region is identified as a region starting at a particular spatial location specified by GN/MBA and containing a specified number of macroblocks in raster-scan order within the picture. If ADT is "11", the region is identified as a region starting at a particular spatial location specified by GN/MBA and containing a specified number of macroblocks in raster-scan order within a rectangular slice. If ADT is present only once and is "00", the region identified is the picture as a whole. If ADT is present more than once, the value "00" is used only to end the loop rather than to identify a region.

U.5.2.9 GOB Number/Macroblock Address (GN/MBA) (5/6/7/9/11/12/13/14 bits)

GN/MBA is a fixed length codeword which specifies a GOB number or macroblock address. GN/MBA follows ADT when present. GN/MBA is present when indicated by ADT. If the optional Slice Structured mode (see Annex K) is not in use, GN/MBA contains the GOB number of the beginning of an area to which the back-channel message refers. If the optional Slice Structured mode is in use, GN/MBA contains the macroblock address of the beginning of the area to which the back-channel message refers. The length of this field shall be as specified elsewhere in this Recommendation for GN or MBA.

U.4.5.2.10 Number of Macroblocks Minus 1 (NMBM1) (5/6/7/9/11/12/13/14 bits)

NMBM1 is a fixed length codeword which specifies a number of macroblocks. NMBM1 is present when indicated by ADT. It follows GN/MBA when present. It contains the natural representation of the number of specified macroblocks minus 1. The length of this field shall be the length defined for a macroblock address in subclause K.2.5 and Table K.2.

Annex V
Data Partitioned Slice Mode

(This annex forms an integral part of this Recommendation.)

V.1 Introduction

This annex describes the optional data-partitioned slice (DPS) mode of H.263. The capability of this mode is signaled by external means (for example Recommendation H.245). The use of this mode shall be indicated by setting the formerly-reserved bit 17 of the optional part of the PLUSPTYPE (OPPTYPE) to '1'. This mode uses the header structure defined in Annex K.

Data partitioning provides robustness in error prone environments. This is accomplished using a rearrangement of the H.263 syntax to enable early detection of and recovery from errors that have been introduced during transmission.

V.2 Structure of data partitioning

When data partitioning is used, the data is arranged as a video picture segment, as defined in Section R.2. The MB's in the segment are rearranged so that the header information for all the MB's in the segment are transmitted together, followed by the MV's for all the MB's in the segment, and then by the DCT coefficients for all the MB's in the segment. The segment header uses the same syntax as described in Section K.2. The header, MV, and DCT partitions are separated by markers, allowing for resynchronization at the end of the partition in which an error occurred. Each segment shall contain the data for an integer number of MB's. When this mode is in use the syntax shown in Figure V.1 shall be used.

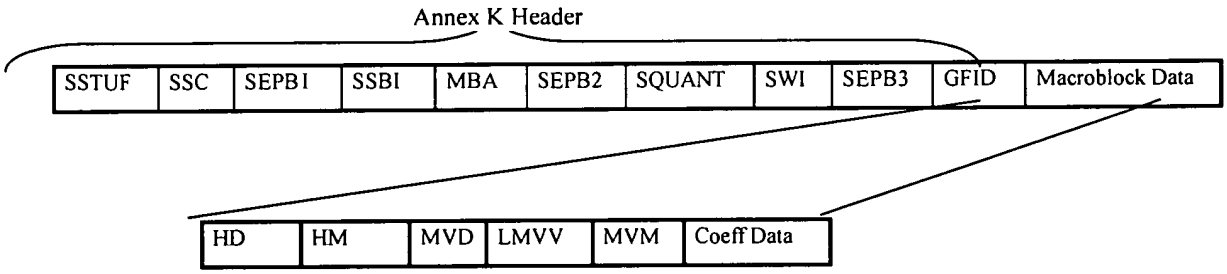

FIGURE V.1/H.263

Data Partitioning Syntax

Note that when this annex is not active, the MV and DCT data are transmitted in an interleaved fashion for all the MB's in a video picture segment, in which case an error normally results in the loss of all information for the remaining MB's in the packet.

V.2.1 Header Data (HD) (Variable length)

The Header Data field contains the COD and MCBPC information for all the MB's in the packets, plus the MODB data in case of PB-frames or Improved PB-frames. A reversible variable length code (RVLC) is used to combine the COD and the MCBPC for all the MB's in the packet. This code is shown in Tables V.1 through V.5/H.263. If Annex O is in use, the COD is only combined with the MB TYPE to form the RVLC for B and EP pictures using tables V.3 and V.4, and the CBPC is coded with codewords in Table O.4. If COD=0 and Annex G or Annex M is in use, the codeword for the COD+MCBPC shall be immediately followed by the reversible variable-length encoded data corresponding to the MODB field of the macroblock. Table V.6 shall be used for PB-frames, Table V.7 shall be used for Improved PB-frames.

V.2.2 Header Marker (HM) (9 bits)

A codeword of 9 bits. Its value is 1010 0010 1. The HM terminates the header partition. When reversed decoding is used by a decoder, the decoder searches for this marker. This value cannot occur naturally in the HD field.

V.2.3 Motion Vector Data Layer(Variable length)

V.2.3.1 Motion Vector Difference Coding

For the motion vectors, the RVLC codewords shown in Table D.3/H.263 are used to encode the difference between the motion vector and the motion vector prediction. Note that this annex only uses the entropy coding from Annex D, but not the other aspects of it unless Annex D is also in use.

V.2.3.2 Prediction of Motion Vector Values

The first motion vector in the packet is coded using a predictor value of 0 for both horizontal and vertical components, and the MV's for the subsequent coded MB's are coded predictively using the MV difference (MVD). This differs from the method otherwise used for coding the MV's in which the MV's following a skipped or INTRA MB are coded using a predictor value of 0 for both horizontal and vertical components.

Forward Direction: $MV_i = MV_{i-1} + MVD_i = MV_{i-1} + (MV_i - MV_{i-1})$

Backward Direction: $MV_{i-1} = MV_i - MVD_i = MV_i - (MV_i - MV_{i-1})$.

(MV_i and MVD_i are the *i*th MV and MV Difference in the packet respectively)

The motion vector information for the last motion vector in the packet is coded in this manner and is also coded again in the LMVV field as described below in V.2.4. This allows the decoder to independently decode the sequence of MV's using two different prediction paths: 1) in the forward direction, starting from the beginning of the motion data of the packet, and 2) in the backward direction, from the end of the motion data in a packet. This provides robustness for better error detection and concealment.

NOTE: When the DPS mode is not in use, motion vectors are predictively coded, with the prediction of the current motion vector being the median value of 3 motion vectors of neighboring locations as described in Section 6.1.1. Because packets in this annex are formed in a way such that the number of MB's coded in each packet is variable, using the median predictive coding method (which involves motion vectors on different rows of the frame) would prevent reversible decoding of the motion vectors in a slice. When the DPS mode is in use, a single prediction thread is formed for the MV's in the whole packet. This is shown in Figure V.2.

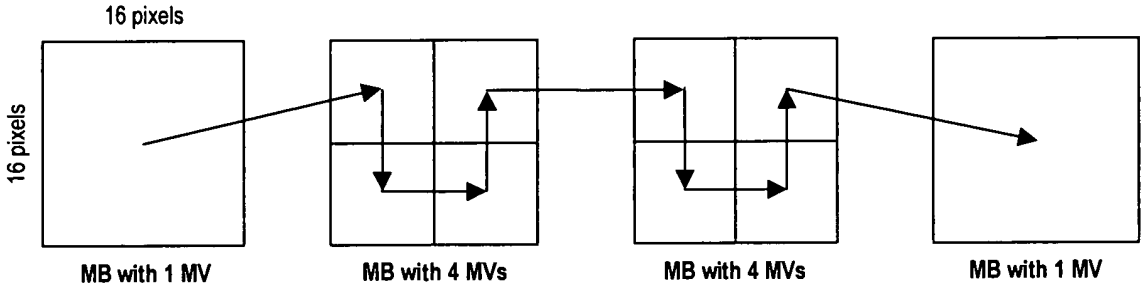

FIGURE V.2/H.263

Single Thread Motion Vector Prediction

In case of B pictures or EP pictures (Annex O), MVDFW and MVDBW may be present as indicated by the MBTYPE codeword in tables V.3 and V.4. MVDFW is predictively encoded using the same single prediction thread as described above and MVDBW (when present in B pictures) shall be encoded as specified in O.4.6. MVDFW and MVDBW shall be coded with the codewords from Table D.3/H.263.

In case of PB-frames (Annex G) and Improved PB-frames (Annex M), the MVDB data shall be encoded as specified in corresponding annexes and shall be coded using the codewords from Table D.3/H.263.

NOTE – If the backward decoding mode is engaged in a B frame (Annex O) or in Improved PB-frames (Annex M), MVDB and MVDBW should be discarded by the decoder as the Motion Vector data for the backward prediction may not be recovered properly across the packet boundaries.

V.2.3.3 Start-Code Emulation Prevention in Motion Vector Difference Coding

The MVD start-code-emulation avoidance method is changed from the method described in Section D.2 of Annex D, in order to facilitate independent parsing in the backward direction. A MVD=0 (codeword "1") shall be inserted between any two consecutive MVD's that are both equal to 1 (codeword "000"). This differs from Annex D, in which the bit is only inserted when two consecutive MVD=1 form a pair (i.e. when the first MVD is the horizontal component, and the second is the vertical component). If Annex D and Annex V are both in use, this Annex V method of start-code-emulation avoidance method shall be used instead of the method described in Section D.2.

V.2.4 Last Motion Vector Value (LMVV) (Variable length)

The LMVV field contains the last MV in the packet. It is coded using a predictor value of 0 for both the horizontal and vertical components. If there are no motion vectors or only one motion vector in the packet, LMVV shall not be present. (This use of a fixed zero-valued predictor enables the use of reversible decoding.)

V.2.5 Motion Vector Marker (MVM) (10 bits)

A codeword of 10 bits having the value '0000 0000 01'. The MVM terminates the motion vector partition. When reverse decoding is used in a decoder, the decoder searches for this marker. The Motion Vector Marker (MVM) shall not be included in the packet if the packet does not contain Motion Vector Data (if all the macroblocks in the packet are intra-coded or with COD's equal to 1).

V.2.6 Coefficient Data Layer (Variable length)

The DCT data layer contains INTRA_MODE (if present), CBPB (if present), CBPC (if present), CBPY, DQUANT (if present), and DCT coefficients coded as specified in Sections I.2, 5.3.4, O.4.3, 5.3.5, 5.3.6, and 5.4.2, respectively. The syntax diagram of DCT Data is illustrated in Figure V.3. The presence of CBPC is indicated in tables V.3 and V.4.

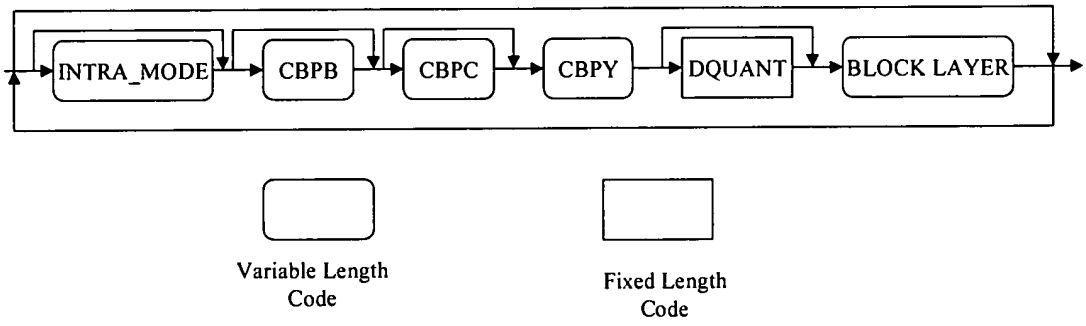

FIGURE V.3/H.263

Coefficient Data syntax

V.3 Interaction with Other Optional Modes

The DPS mode acts effectively as a sub-mode of the Slice Structured mode of Annex K, and uses its outer picture and slice header structures. The SS mode shall therefore be indicated as being in use whenever the DPS mode is in use. Both of the other sub-modes of the Slice Structured mode (the Arbitrary Slice Ordering and Rectangular Slice sub-modes) may be used in conjunction with the DPS mode.

The Syntax-Based Arithmetic Coding mode of Annex E shall not be used with this annex, as it does not allow for reversible decoding.

Annex H Forward Error Correction should not be used with this annex, as it can result in the bitstream being disrupted in undesirable places. However, the use of Annex H with the DPS mode is not forbidden, as the FEC defined in Annex H is required in some existing standard system designs.

The Temporal, SNR, and Spatial Scalability (TSSS) mode of Annex O may be used in conjunction with the DPS mode. When the TSSS and DPS modes are used together, the codewords provided in Tables V.3, V.4, and V.5 shall be used instead of those defined in Annex O.

Annex U shall not be used with this Annex.

Annex W
Additional Supplemental Enhancement Information Specification

(This annex forms an integral part of this Recommendation.)

W.1 Introduction

This annex describes the format of the additional supplemental enhancement information sent in the PSUPP field of the picture layer of H.263, which adds to the functionality defined in Annex L. The capability of a decoder to provide any or all of the capabilities described in this annex may be signaled by external means (for example, Recommendation H.245). Decoders which do not provide the additional capabilities may simply discard any of the newly defined PSUPP information bits that appear in the bitstream. The presence of this supplemental enhancement information is indicated by the presence of both the PEI bit, and by the following PSUPP octet whose FTYPE field has one of the two newly defined values. The basic interpretation of PEI, PSUPP, FTYPE, and DSIZE is identical to Annex L and to sections 5.1.24 and 5.1.25.

W.2 References

The following Recommendations and other references contain provisions which, through reference in this text, constitute provisions of this Recommendation. At the time of publication, the editions indicated were valid. All Recommendations and other references are subject to revision; all users of this Recommendation are therefore encouraged to investigate the possibility of applying the most recent edition of the Recommendations and other references listed below.

[8] ISO/IEC 10646-1 (1993): Universal Multiple Octet Coded Character Set

[9] IETF RFC 2396 (1998): Uniform Resource Identifiers (URI): Generic Syntax

W.3 Additional FTYPE Values

Two values that were reserved in Annex L, Table L.1 are defined as follows.

TABLE W.1/H.263

FTYPE Function Type Values

13	Fixed-Point IDCT
14	Picture Message

W.4 Recommended Maximum Number of PSUPP Octets

When using any of the aforementioned FTYPE functions defined in this annex, the total number of PSUPP octets per picture should, in relation to the coded picture size, be kept reasonably small, and should not exceed 256 octets regardless of the coded picture size.

NOTE: Some data transmission protocols used for conveyance of the video bitstream may provide for external repetition of picture header contents for error resilience purposes, and may place limits on the amount of such data that can be repeated from a picture header (e.g., 504 bits in the IETF RFC 2429 packetization format). The inclusion of a large number of PSUPP octets may result in the lack of such an external protocol to provide for full repetition of the picture header contents.

W.5 Fixed-Point IDCT

The fixed-point IDCT function indicates that a particular IDCT approximation is used in construction of the bitstream. DSIZE shall be equal to 1 for the fixed-point IDCT function. The octet of PSUPP data that follows specifies the particular IDCT implementation. A value of 0 indicates the reference IDCT 0 as described in W.5.3; values of 1 through 255 are reserved.

W.5.1 Decoder Operation

The capability of a decoder to perform a particular fixed-point IDCT may be signaled to the encoder by external means (for example, Recommendation H.245). When receiving an encoded bitstream with the fixed-point IDCT indication, a decoder shall use the particular fixed-point IDCT if it is capable of doing so.

W.5.2 Removal of Forced Updating

Annex A specifies the accuracy requirements for the inverse discrete cosine transform (IDCT), allowing numerous compliant implementations. To control accumulation of errors due to mismatched IDCTs at the encoder and decoder, Section 4.4 Forced Updating requires that macroblocks be coded in INTRA mode at least once every 132 times when coefficients are transmitted.

If the fixed-point IDCT function type is indicated in the bitstream, then the forced updating requirement is removed, and the frequency of INTRA coding is unregulated. An encoder should continue to use forced updating, however, unless it has ascertained through external means that the decoder is capable of the particular fixed-point IDCT specified herein; otherwise there may be mismatch.

W.5.3 Reference IDCT 0

The reference IDCT 0 is any implementation that, for every input block, produces identical output values as the C source program listed below.

NOTE: This fixed-point IDCT is compliant with Annex A of ITU-T Recommendation H.263, but is not compliant with the extended range of values requirement in Annex A of ITU-T Recommendation H.262 | ISO/IEC 13818-2.

```

W.6 Picture Message

The picture message function indicates the presence of one or more octets representing message data. The first octet of the message data is a message header with the following structure.

FIGURE W.1/H.263

Structure of first message octet

DSIZE shall be equal to the number of octets in the message data corresponding to a picture message function, including the first octet shown in Figure W.1.

Decoders shall parse picture message data as required by basic PSUPP syntax, but decoder response to picture messages is otherwise undefined.

W.6.1 Continuation (CONT) (1 bit)

If equal to "1", CONT indicates that the message data associated with this picture message function is part of the same logical message as the message data associated with the next picture message function. If equal to "0", CONT indicates that the message data associated with this picture message function terminates the current logical message. CONT may be used, for example, to represent logical messages that span more than 14 octets.

W.6.2 End Bit Position or Track Number (EBIT) (3 bits)

For non-text picture messages, EBIT specifies the number of least significant bits that shall be ignored in the last message octet. In non-text picture messages, if CONT is "1", or if there is only one message octet (i.e. the octet in Figure W.1), EBIT shall equal "0". The number of valid message bits for a non-text picture message function excluding the CONT/EBIT/MTYPE bits is equal to (DSIZE-1)·8 – EBITS. The number of valid message bits for a logical message may be greater due to continuation.

For picture message types containing text information, EBIT shall contain a text track number. The precise meaning of the text track number is not specified herein, but should indicate a particular type (e.g., language) for the text. Track number zero should be considered the default track.

W.6.3 Message Type (MTYPE) (4 bits)

MTYPE indicates the type of message. The defined types are shown in Table W.2.

TABLE W.2/H.263

MTYPE Message Type Values

0	Arbitrary Binary Data
1	Arbitrary Text
2	Copyright Text
3	Caption Text
4	Video Description Text
5	Uniform Resource Identifier Text
6	Current Picture Header Repetition
7	Previous Picture Header Repetition
8	Next Picture Header Repetition, Reliable TR
9	Next Picture Header Repetition, Unreliable TR
10	Top Interlaced Field Indication
11	Bottom Interlaced Field Indication
12	Picture Number
13	Spare Reference Pictures
14..15	Reserved

W.6.3.1 Arbitrary Binary Data

Arbitrary binary data is used to convey any non - ISO/IEC 10646-1 UTF-8 coded binary message. The interpretation of contents of the arbitrary binary data are outside the scope of this Recommendation, but should begin with some identifying pattern (e.g. a four octet identifier code) to aid in distinguishing one type of such data from others.

W.6.3.2 Arbitrary Text

Arbitrary text is used to convey a generic ISO/IEC 10646-1 UTF-8 coded text message. More specific text messages such as copyright information should be represented with other message types (e.g. copyright text) as appropriate.

W.6.3.3 Copyright Text

Copyright text shall be used only to convey intellectual property information regarding the source or the encoded representation in the bitstream. The copyright message shall be coded according to ISO/IEC 10646-1 UTF-8.

W.6.3.4 Caption Text

Caption text shall be used only to convey caption information associated with the current and subsequent pictures of the bitstream. The caption message shall be coded according to ISO/IEC 10646-1 UTF-8. The caption text shall be inserted in the bitstream as if it were to be displayed in a separate text area where new text is appended at the end of previous text and earlier text scrolled away from the point of insertion. The Form Feed (hexadecimal "0x000C") control code shall be used to indicate clearing of the visible text area. The End of Medium (hexadecimal "0x0019") control code shall be used to indicate "caption off" status. However, this Recommendation puts no restriction on how caption text is actually displayed and stored.

W.6.3.5 Video Description Text

Video description text shall be used only to convey descriptive information associated with the information contents of the current bitstream. The video description shall be coded according to ISO/IEC 10646-1 UTF-8. The video description text shall be inserted in the bitstream as if it were to be displayed in a separate text area where new text is appended at the end of previous text and earlier text scrolled away from the point of insertion. The Form Feed (hexadecimal "0x000C") control code shall be used to indicate clearing of the visible text area. The End of Medium (hexadecimal "0x0019") control code shall be used to indicate "description off" status. However, this Recommendation puts no restriction on how video description text is actually displayed and stored.

W.6.3.6 Uniform Resource Identifier (URI) Text

The message consists of a uniform resource identifier (URI), as defined in IETF RFC 2396. The URI shall be coded according to ISO/IEC 10646-1 UTF-8.

W.6.3.7 Current Picture Header Repetition

The picture header from the current picture is repeated in this message. The repeated bits exclude any supplemental enhancement information (PEI/PSUPP). All other bits up to the GOB or Slice layer should be included, subject to the limitations of W.4.

W.6.3.8 Previous Picture Header Repetition

The picture header from the previously transmitted picture is repeated in this message. The repeated bits exclude the first two bytes of picture start code (PSC) and any supplemental enhancement information (PEI/PSUPP). All other bits up to the GOB or Slice layer should be included, subject to the limitations of W.4.

W.6.3.9 Next Picture Header Repetition, Reliable TR

The picture header from the next picture to be transmitted is repeated in this message. The repeated bits exclude the first two bytes of picture start code (PSC) and any supplemental enhancement information (PEI/PSUPP). All other bits up to the GOB or Slice layer should be included, subject to the limitations of W.4.

W.6.3.10 Next Picture Header Repetition, Unreliable TR

The picture header from the next picture to be transmitted is repeated in this message. The repeated bits exclude the first three bytes of picture header and any supplemental enhancement information (PEI/PSUPP). All other bits up to the GOB or Slice layer should be included, subject to the limitations of W.4. Any TR or ETR bits in the repeated picture header are not necessarily the same as the corresponding bits in the next picture header.

W.6.3.11 Interlaced Field Indications

In the case of interlaced field indications, the message consists of an indication of interlaced field coding. This indication does not affect the decoding process. However, it indicates that the current picture was not actually scanned as a progressive-scan picture. In other words, it indicates that the current coded picture contains only half of the lines of the full resolution source picture. DSIZE shall be 1, CONT shall be 0, and EBIT shall be 0 for interlaced field indications. In the case of interlaced field coding, each increment of the temporal reference denotes the time between the sampling of alternate half-picture fields of a picture, rather than the time between two complete pictures. In the case of a top interlaced field indication, the current picture contains the first (i.e., top), third, fifth, etc. lines of the complete picture. In the case of a bottom interlaced field indication, the current picture contains the second, fourth, sixth, etc. lines of the complete picture. When sending interlaced field indications, an encoder shall conform to the following conventions:

1. The encoder shall use a picture clock frequency (custom picture clock frequency, if necessary) such that each new field of the original source video corresponds to an increment of 1 in the temporal reference.
2. The encoder shall use a picture size (custom picture size, if necessary) such that the picture dimensions correspond to those of a single field.
3. The encoder shall use a pixel aspect ratio (custom pixel aspect ratio, if necessary) such that the full-height picture aspect ratio corresponds to the picture aspect ratio derived from the pixel aspect ratio of the single field represented by the current encoded picture.

Interlaced field scanning was introduced originally as an analog video compression technique. Although progressive picture scanning is generally regarded as superior for digital compression and display, the use of interlaced field scanning has persisted in many camera and display designs. Interlaced field coding (which can be implemented with lower delay than either interlaced full-picture coding or progressive-scan picture coding at half the interlaced field rate) is therefore supported by the indications herein.

An encoder shall not send interlaced field indications unless the capability of the decoder to receive and properly process such field-based pictures has been established by external means (for example, Recommendation H.245). Failure to establish such a decoder capability may produce a visually annoying small-amplitude vertical shaking behavior in the decoded picture received and displayed by a decoder.

For example, an encoder may use interlaced field coding with application of the Reference Picture Selection mode (specified in Annex N) or the Enhanced Reference Picture Selection mode (specified in Annex U) to allow the addressing of more than one prior field. For "525/60" interlaced field coding for a 4:3 picture aspect ratio with 704 coded luminance samples per line and 240 coded luminance lines per field, the encoder shall use a custom picture size having a picture width of 704 and a picture height of 240, a custom pixel aspect ratio of 5:11, and a custom picture clock frequency specified with a clock conversion code '1' and a clock divisor of 30. For "625/50" interlaced field coding for a 4:3 picture aspect ratio with 704 coded luminance samples per line and 288 coded luminance lines per field, the encoder shall use a custom picture size having a picture width of 704 and a picture height of 288, a custom pixel aspect ratio of 6:11, and a custom picture clock frequency specified with a clock conversion code '0' and a clock divisor of 36.

The vertical sampling positions of the chrominance samples in interlaced field coding of a top field picture are specified as shifted up by 1/4 luminance sample height relative to the field sampling grid in order for these samples to align vertically to the usual position relative to the full-picture sampling grid. The vertical sampling positions of the chrominance samples in interlaced field coding of a bottom field picture are specified as shifted down by 1/4 luminance sample height relative to the field sampling grid in order for these samples to align vertically to the usual position relative to the full-picture sampling grid. The horizontal sampling positions of the chrominance samples are specified as unaffected by the application of interlaced field coding. The vertical sampling positions are shown with their corresponding temporal sampling positions in Figure W.2/H.263.

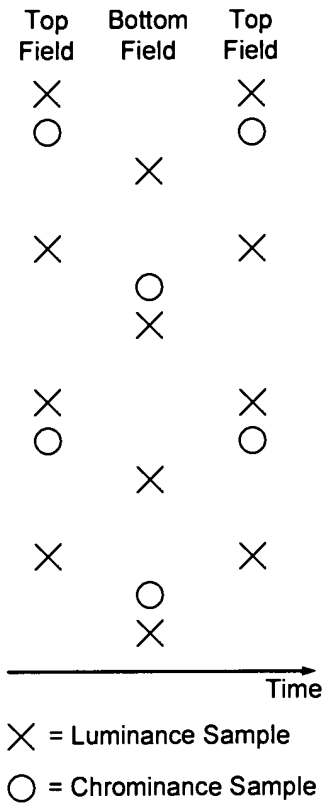

FIGURE W.2/H.263

Vertical and Temporal Alignment of Chrominance Samples for Interlaced Field Coding

W.6.3.12 Picture Number

This message shall not be used if Annex U is in use. The message contains two data bytes that carry a 10-bit Picture Number. Consequently, DSIZE shall be 3, CONT shall be 0, and EBIT shall be 6. Picture Number shall be incremented by 1 for each coded and transmitted I or P picture or PB or Improved PB frame, in a 10-bit modulo operation. For EI and EP pictures, Picture Number shall be incremented for each EI or EP picture within the same scalability enhancement layer. For B pictures, Picture Number shall be incremented relative to the value in the most recent non-B picture in the reference layer of the B picture which precedes the B picture in bitstream order (a picture which is temporally subsequent to the B picture). If adjacent pictures in the same enhancement layer have the same temporal reference, and if the reference picture selection mode (see Annex N) is in use, the decoder shall regard this occurrence as an indication that redundant copies have been sent of approximately the same pictured scene content, and all of these pictures shall share the same Picture Number. If the difference (modulo 1024) of the Picture Numbers of two consecutively received non-B pictures in the same enhancement layer is not 1, and if the pictures do not represent approximately the same pictured scene content as described above, the decoder should infer a loss of pictures or corruption of data.

W.6.3.13 Spare Reference Pictures

Encoders can use this message to instruct decoders which pictures resemble the current motion compensation reference picture so well that one of them can be used as a spare reference picture if the actual reference picture is lost during transmission. If a decoder lacks an actual reference picture but can access a spare reference picture, it should not request for an INTRA picture update. It is up to encoders to choose the spare reference pictures if any. The message data bytes contain the Picture Numbers of the spare reference pictures in preference order (the most preferred appearing first). Picture Numbers refer to the values that are transmitted according to Annex U or section W.6.3.12. This message can be used for P, B, PB, Improved PB, and EP picture types. However, if Annex N or Annex U is in use and if the picture is associated with multiple reference pictures, this message shall not be used. For EP pictures, the message shall be used only for forward prediction, whereas upward prediction is always done from the temporally corresponding reference layer picture. For B, PB, and Improved PB picture types, it specifies a picture for use as a forward motion prediction reference. This message shall not be used if the picture is an I or EI picture.

Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 14496-15 was prepared by ISO/IEC/TC JTC 1/SC 29.

© ISO/IEC 2002 — All rights reserved

Introduction

The Advanced Video Codec (AVC), jointly developed by the ITU and ISO/IEC SC29/WG11 (MPEG), offers not only increased coding efficiency and enhanced robustness, but also interesting opportunities and challenges for the systems which use it. To enable the best visibility of, and access to, those features, and to enhance the opportunities for the interchange and interoperability of media, this standard defines a storage format for video streams compressed using AVC and using carrying within the MPEG-4 Systems Framework (ISO/IEC 14496-1:2001 and its various amendments).

This specification defines a storage format based on, and compatible with, the ISO Media File format ISO/IEC 14496-12 | 15444-12), which is used by the MP4 file format (ISO/IEC 14496-14) and the Motion JPEG 2000 file format (ISO/IEC 15444-1) among others. This specification enables AVC video streams to:

- be used in conjunction with other media streams, such as audio;
- be used in an MPEG-4 systems environment, if desired;
- be formatted for delivery by a streaming server, using hint tracks;
- inherit all the use cases and features of the ISO Media file format on which MP4 and MJ2 are based.

The ISO Media File format is becoming increasingly common as a general-purpose media container format for the exchange of digital media, and its use in this context should accelerate both adoption and interoperability.

Extensions to the base format are defined here to expose the new systems aspects of the AVC codec.

Information technology — Coding of audio-visual objects — Part 15: AVC File Format

1 SCOPE

This document specifies the storage format for AVC (ISO/IEC 14496-10 | ITU Recommendation H.264) video streams. It also specifies how such streams are carried in an MPEG-4 context.

[Ed's Note: It is expected that the specification of carriage of AVC streams in MPEG-4 Systems will move into an appropriate MPEG-4 Systems Amendment].

3 TERMS AND DEFINITIONS

For the purposes of this specification, the terms and definitions specified in normative references ISO/IEC 14496-1 and ISO/IEC 14496-10 | ITU Recommendation H.264 shall apply. In addition, the following terms and abbreviations shall apply to all clauses in this specification.

3.1 Terminology

3.1.1 Parameter Set

A parameter set is either a sequence parameter set or a picture parameter set. This term is used to refer to both types of parameter sets.

3.1.2 Parameter Set Elementary Stream

An elementary stream containing access units made up only of sequence and picture parameter set NAL units synchronized with the video elementary stream.

3.1.3 Video Elementary Stream

An elementary stream containing access units made up of NAL units for coded picture data.

© ISO/IEC 2002 — All rights reserved

3.2 Symbols and abbreviated terms

AVC	ISO/IEC 14496-10, Advanced Video Coding
NAL	Network Abstraction Layer
SEI	Supplementary Enhancement Information

4 USE OF AVC IN MPEG-4 SYSTEMS

4.1 AVC Streams

This subclause specifies the elementary stream format used to carry AVC visual content within the MPEG-4 systems framework.

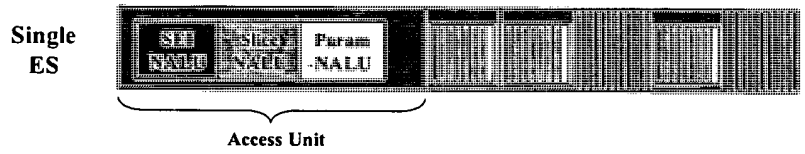
4.1.1 Structure of the AVC streams

This subclause defines two elementary streams for carriage of AVC content within the MPEG-4 systems framework: a video elementary stream for carrying video data and an optional parameter set elementary stream for carrying parameter sets out-of-band from the video data.

AVC specifies a set of Network Abstraction Layer units, which contain different types of data. While the syntax of each NAL unit is specified by AVC, how NAL units are to be carried as elementary streams in the MPEG-4 Systems framework is not specified by ISO/IEC 14496-10. This subclause specifies the format of MPEG-4 elementary streams for AVC content for use within MPEG-4 Systems.

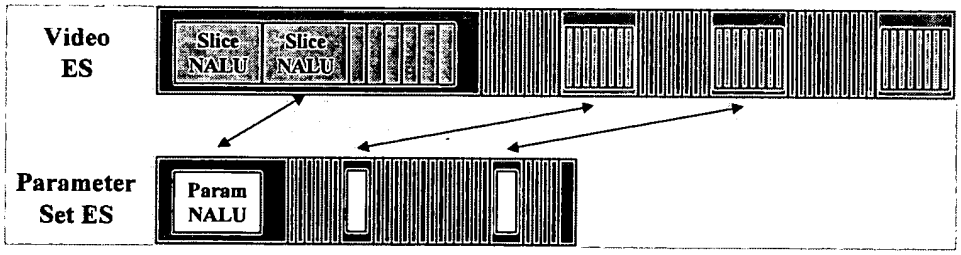
AVC content shall be carried in MPEG-4 Systems in either one or two elementary streams:

- **Video Elementary Stream**: This elementary stream, structured into video access units, contains video coding related NAL units (i.e. those NAL units containing video data or signaling video structure. If the optional parameter set elementary stream is not present, sequence and picture parameter set NAL units may be present in this stream.



- **Parameter Set Elementary Stream**: This optional stream is used to transmit only sequence and picture parameter set NAL units. If this stream is used, sequence and picture parameter set NAL units shall not be carried in the video elementary stream.

The set types of NAL units are allowed in each of video and parameter set elementary streams is specified in Table 1.



© ISO/IEC 2002 — All rights reserved

Table 1 -- NAL Unit Types in Elementary Streams

Value of nal_unit_type	Description	Video ES	Parameter Set ES
0x0	Reserved for external use	No	No
0x1	Coded slice	Yes	No
0x2	Coded data partition A (DPA)	Yes	No
0x3	Coded data partition B (DPB)	Yes	No
0x4	Coded data partition C (DPC)	Yes	No
0x5	Coded slice of an IDR picture	Yes	No
0x6	Supplemental Enhancement Information (SEI)	Yes	No
0x7	Sequence Parameter Set (SPS)	Yes, if parameter ES is not used.	Yes
0x8	Picture Parameter Set (PPS)	Yes, if parameter ES is not used.	Yes
0x9	Picture Delimiter (PD)	Yes	No
0xA	Filler Data (FD)	Yes	Yes
0xB – 0x17	Reserved	No	No
0x18 – 0x1F	For external use	Not specified by this standard.	Not specified by this standard.

(a) Single Video Elementary Stream containing all NAL Units

(b) Synchronized Video and Parameter with arrows denoting synchronization between streams.

Figure 1: AVC Elementary Stream Structure

4.1.2 Time Base for AVC Streams

The time base associated to an AVC stream shall be indicated using the means provided by MPEG-4 systems. If present, an AVC parameter set elementary stream shall adhere to the same time base as the AVC video elementary stream.

© ISO/IEC 2002 — All rights reserved

4.1.3 Access unit definition

An AVC access unit consists of one or more NAL units, as defined in ISO/IEC 14496-10. All NAL units that are to be processed at the same instant in time shall constitute a single access unit. Access units in AVC streams shall be labelled and time-stamped by suitable means. This shall be done via the related flags and the composition time stamps, respectively, in the SL packet header (see ISO/IEC 14496-1:2001, subclause 10.2.4). The composition time indicates the point in time at which the decoded data shall be composed. The decoding and composition time for an AVC access unit can have different values.

An AVC access unit shall set the `randomAccessPointFlag` in the SL packet header to '1' for this access if ALL of the following conditions are met:

- All video data NAL unit indicate a coded slice of an instantaneous decoder refresh (IDR) picture.
- All sequence and picture parameter sets needed to decode the video data in the access unit are contained in the decoder specific information for the video elementary stream.

Otherwise, the `randomAccessPointFlag` shall be set to '0'.

An AVC access unit shall include the following NAL units:

- **Video Data NAL Units (Coded Slice, Coded DPA, Coded DPB, Coded DPC, Coded IDR)**: All slice and data partition NAL units for a single picture shall be contained with the access unit whose decoding time and composition time is that of the picture. A single picture is one of a frame, a top and bottom field for one frame, or a single top or bottom field. Each AVC access unit shall contain at least one Video Data NAL unit.
- **SEI Message NAL Units**: All SEI NAL units shall be contained in the access unit whose decoding time is that before which the SEI messages come into effect instantaneously. This means that the SEI messages for a picture shall be included in the access unit containing to that picture and that SEI messages pertaining to a sequence of pictures shall be included in the access unit containing the first picture of the sequence to which the SEI message pertains. SEI messages that pertain to the picture level or higher levels shall occur prior to any video data NAL units in the access unit. Slice level messages may occur anywhere within an access unit.
- **Filler Data NAL Units:** Filler data NAL units can be included in any access unit. An access unit shall not consist entirely of filler data NAL units.
- **Picture Delimiter NAL Units**: Picture delimiter NAL units, if present, shall occur once at the beginning of the access unit whose decoding time is that of the picture being delimited.
- **Parameter Sets**: If a single video elementary stream is used to carry AVC content, all sequence and picture parameter sets NAL units shall be contained in the access unit whose decoding time is the time equal or prior to when the parameter sets come into effect. As specified in ISO/IEC 14496-10, any sequence or picture parameter sets present in an access unit shall occur prior to any video coding NAL units and SEI NAL units in that access unit. If a parameter set elementary steam is used, then the access unit in the parameter stream shall have a decoding time equal or prior to when the parameter set(s) comes into effect instantaneously. This means that for a parameter set to be used in a picture it must be sent prior to the access unit containing that picture or in the access unit for that picture.

The following restrictions apply to the Access Units:

© ISO/IEC 2002 — All rights reserved

a) **Timing SEIs**: The Temporal Reference SEI message and the clock timestamp SEI messages that define the timing information shall not be present in the video elementary stream as timing is provided by the MPEG-4 Sync Layer.

b) **Start Codes** shall not be present in the stream.

The sequence of NAL units in an access unit shall be any legal decoding order conforming to that specified in ISO/IEC 14496-10.

4.1.4 AVC Access Unit Syntax and Semantics

This subclause specifies the syntax and semantics of access units for AVC video. Access Units are externally framed and have a size supplied by that external framing. The structure of an AVC access unit is depicted in Figure 2.

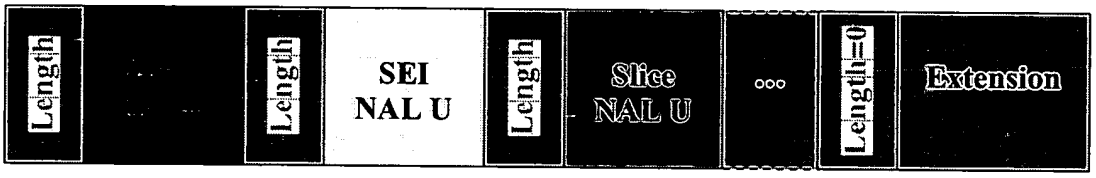


Figure 2: The structure of an AVC Access Unit

An AVC access unit contains a succession of coded picture representations, each of which is made up of a set of NAL units. Each NAL units is is represented with a:

- *Length*: Indicates the length in bytes of the following NAL Unit. The length field can be configured to be of 1, 2, 3 or 4 bytes.
- *NAL Unit*: Contains the NAL unit data as specified in ISO/IEC 14496-10.

If a length field contains the value 0, then all remaining bytes in the access unit contain extension data which is reserved for use in future versions of this specification and must be ignored; those bytes are not NAL Units and must not be passed to the AVC decoder. No coded pictures or their data may occur after such a zero length field. In other words, extension data must be at the very end of the access unit.

4.1.4.1 Syntax

```
class aligned(8) AVCAccessUnit
{
   if(AVCConfigurationRecord.PictureLengthSize > 0)
      unsigned int(8)    PictureCount
   else
      PictureCount = 1;
   for(i=0; i<PictureCount; i++)
   {
      if(AVCConfigurationRecord.PictureLengthSize > 0)
         unsigned int(AVCConfigurationRecord.PictureLengthSize*8)
            PictureLength;
         for (i=0; ; i++;)     // to end of the picture
         {
            unsigned int((AVCConfigurationRecord.LengthSizeMinusOne+1)*8) NALUnitLength;
            if (NALUnitLength==0) {
```

© ISO/IEC 2002 — All rights reserved

```
            bit() reserved; // to end of the picture
            break;
          } else {
            bit(NALUnitLength * 8) NALUnit;
          }
      }
    }
}
```

4.1.4.2 Semantics

An AVC Video Access Unit consists of a set of NAL units with the same decoding and composition time. A single access unit can contain more than one picture if it contains multiple coded representations of the same picture (either redundant pictures or multiple switching pictures). The syntax of an access unit is configured via the decoder specific configuration for the AVC elementary stream. An AVC Parameter Set Access Unit contains one or more sequence and picture parameter set NAL units. If the coded representations of a picture are redundant pictures then the primary picture (redundant_pic_cnt = 0) shall occur first and all subsequence redundant picture shall occur in ascending order of their redundant picture (redundant_pic_cnt) value.

A video elementary stream is a random access point if and only if it contains an IDR picture and either of the following conditions holds:

- All of the sequence and picture parameter sets necessary to decode the IDR picture; or,
- A separate parameter set elementary stream is used.

A parameter set elementary stream access unit is a random access point if and only if it contains all sequence and picture parameter sets used from that time forward in the video coding stream and parameter set stream until the next time any parameter set is updated.

`PictureCount` indicates the number of coded representations of the same picture contained within this unit. Such pictures may not be identical objective representations of the same picture. This field shall have a value of at least one.

`PictureLength` indicates the number of bytes contained the coded data for this picture's representation, which is made up of the set of NAL units preceded by length fields. The length of a picture comprises the number of bytes in all NAL units and the size of all `NALUnitLength` fields. If an access unit includes extension data then the picture length field does not include the size of the data or the `NALUnitLength` field whose value is zero.

`NALUnitLength` indicates the size of a NAL unit measured in bytes. The length field includes the size of both the one byte NAL header and the EBSP payload but does not include the length field itself.

`NALUnit` contains a single NAL unit. The syntax of an NAL unit is defined in ISO/IEC 14496-10 and includes both the one byte NAL header and the variable length encapsulated byte stream payload.

4.1.5 Decoder Specific Information

This subclause specifies the decoder specification information for ISO/IEC 14496-10 video content.

4.1.5.1 AVC Decoder Configuration Record

This record contains the size of the length field used in each access unit to indicate the length of its contained NAL units as well as the initial parameter sets. This record is externally framed (its size must be supplied by the structure which contains it).

© ISO/IEC 2002 — All rights reserved

This record contains a version field. This version of the specification defines version 1 of this record. Incompatible changes to the record will be indicated by a change of version number. Readers must not attempt to decode this record or the streams to which it applies if the version number is unrecognized.

Compatible extensions to this record will extend it and will not change the configuration version code. Readers should be prepared to ignore unrecognized data beyond the definition of the data they understand (e.g. after the parameter sets in this specification).

When used to provide the configuration of a parameter set elementary stream, the configuration record shall contain no sequence or picture parameter sets (`numOfParameterSets` shall have the value 0).

4.1.5.1.1 Syntax

```
aligned(8) class AVCConfigurationRecord {
   unsigned int(8) configurationVersion = 1;
   unsigned int(8) AVCProfileIndication;
   unsigned int(8) AVCLevelIndication;
   unsigned int(8) PictureLengthSize;
   unsigned int(16) nonStoredDegredationPriorityLow;
   unsigned int(16) nonStoredDegredationPriorityHigh;
   bit(6) reserved = '111111'b;
   unsigned int(2) lengthSizeMinusOne;
   unsigned int(8) numOfSequenceParameterSets;
   for (i=0; i< numOfSequenceParameterSets;  i++) {
      unsigned int(16) sequenceParameterSetLength ;
      bit(8*sequenceParameterSetLength) sequenceParameterSetNALUnit;
   }
   unsigned int(8) numOfPictureParameterSets;
   for (i=0; i< numOfPictureParameterSets;  i++) {
      unsigned int(16) pictureParameterSetLength;
      bit(8*pictureParameterSetLength) pictureParameterSetNALUnit;
   }
}
```

4.1.5.1.2 Semantics

`AVCProfileLevelIndication` contains the profile code defined in Annex A of the AVC specification [ISO/IEC 14496-10 | ITU Recommendation H.264].

`AVCLevelIndication` contains the level code defined in Annex A of the AVC specification [ISO/IEC 14496-10 | ITU Recommendation H.264].

`PictureLengthSize` indicates the length of the picture size field used to indicate the size of a coded picture representation. A value of zero indicates that only a single coded picture representation is allowed in an access unit.

`nonStoredDegrediationPriorityHigh` indicates the largest value of the range of degradation priorities that correspond to AVC non-stored frames (nal_type_idc=0). If the value of `nonStoredDegrediationPriorityHigh` exceeds `nonStoredDegrediationPriorityLow` then no correspondence between degradation priorities and non-stored frames is defined.

`nonStoredDegrediationPriorityLow` indicates the smallest value of the range of degradation priorities that correspond to AVC non-stored frames (nal_type_idc=0).

`lengthSizeMinusOne` indicates the length in bytes of the `NALUnitLength` field in an AVC video access unit of the associated stream minus one. For example, a size of one byte is indicated with a value of 0.

`numOfSequenceParameterSets` indicates the number of sequence parameter sets that are used as the initial set of sequence parameter sets for decoding the AVC elementary stream.

© ISO/IEC 2002 — All rights reserved

`sequenceParameterSetLength` indicates the length of the parameter set NAL unit as defined in ISO/IEC 14496-10.

`sequenceParameterSetNALUnit` contains a sequence parameter set NAL Unit, as specified in ISO/IEC 14496-10. Sequence parameter sets shall occur in order of ascending parameter set identifier with gaps being allowed.

`numOfPictureParameterSets` indicates the number of picture parameter sets that are used as the initial set of picture parameter sets for decoding the AVC elementary stream.

`pictureParameterSetLength` indicates the length of the parameter set NAL unit as defined in ISO/IEC 14496-10.

`pictureParameterSetNALUnit` contains a parameter set NAL Unit, as specified in ISO/IEC 14496-10. Picture parameter sets shall occur in order of ascending parameter set identifier with gaps being allowed.

4.1.5.2 AVC Stream DecoderSpecificInfo

This subclause defines the `DecoderSpecificInfo` descriptor for an AVC elementary stream.

4.1.5.2.1 Syntax

```
aligned(8) class AVCDecoderSpecificInfo extends DecoderSpecificInfo : bit(8)
tag=DecSpecificInfoTag {
     AVCVideoConfigurationRecord config;
}
```

4.1.5.2.2 Semantics

The decoder specific information for an AVC stream contains an AVC video stream decoder configuration record.

`config` contains the decoder configuration record for the AVC elementary stream decoder configuration.

4.1.5.3 Parameter Set

Initial sequence and picture parameter sets are supplied in the `DecoderSpecificInfo` for the AVC video stream, as defined in subclause 4.1.5.1. If a parameter set must be updated, then one of two methods can be used:

a) Sequence or Picture Parameter Set NAL units may be inserted in the video stream;

b) A separate parameter set stream may be used to carry parameter sets, possibly using a transport with different error resilience or reliability characteristics.

4.1.6 AVC DecoderConfigDescriptor

The `DecoderConfigDescriptor` shall set the value of `streamtype` equal to 0x04 for both AVC video elementary stream and the AVC parameter set elementary streams.

The `DecoderConfigDescriptor` for an AVC video elementary stream, possibly including in-line sequence or picture parameter sets, shall set `objectTypeIndication` to be 0x21 (ISO/IEC 14496-10 Visual). For the AVC parameter set elementary stream, the `objectTypeIndication` value shall equal 0x22 (ISO/IEC 14496-10 Visual Parameter Sets).

© ISO/IEC 2002 — All rights reserved

4.1.7 Elementary Stream Descriptor

If the parameter set elementary stream is present, the elementary stream descriptors for the two streams shall satisfy the following conditions:

(1) The video elementary stream is dependent on the parameter set elementary stream and the `ES_Descriptor` for the video elementary stream shall have a `streamDependenceFlag` equal to true and indicate the ESID of the parameter in the `dependsOnESID` field. The `streamDependenceFlag` in the `ES_Descriptor` for the parameter set elementary stream shall be false.

(2) The elementary stream clocks for the parameter set elementary stream and the video elementary stream shall be the same and synchronized. The `OCRstreamflag` and `OCR_ES_Id` fields in the `ESDescriptor` for the video elementary stream and parameter set elementary streams shall be used to indicate that both streams share the same OCR.

4.2 Codepoints

4.2.1 visualProfileLevelIndication

Ed's Note: What should the visual profile level indication in the initial object descriptor be? Is it even necessary to add a new one? The list below does not seem up to date anyway and I do not recall any amendments to MPEG-4 Systems that touch this table.

Replace Table 6 in ISO/IEC 14496 with the following table:

Table 2 - visualProfileLevelIndication Values

Value	Profile	Level

[a] This object type shall be used for all streamTypes defined in ISO/IEC 144961 except IPMP streams.

[b] Includes associated Amendment(s) and Corrigendum(a)

[c] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-2 and are conveyed in the DecoderSpecificInfo as specified in ISO/IEC 144962, Annex K.

[d] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-3 and are conveyed in the DecodeSpecificInfo as specified in ISO/IEC 144963 subpart 1 subclause 6.2.1.

[e] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-10 and are conveyed in the DecoderSpecificInfo as specified in this admendmat, subclause 4.1.5.

4.3 Extensibility

The configuration description format may be extended in future versions of this specification. Similarly, the definition of an AVC Access Unit allows for extension by future versions of this specification.

5 File Format

5.1 Introduction

This subclause defines how to store ISO/IEC 14496-10 data in the MP4 file format. The storage of AVC content uses the existing capabilities of the MP4 file format but also defines new features to support the following features of the AVC codec in the MP4 file format:

- **Switching Pictures**: To enable switching between different coded streams and substitution of pictures within the same stream.
- **Enhanced Group of Pictures**: Provides a structuring of the dependencies of a group of pictures to provide both random access and flexible stream structure (e.g. temporal scalability and layering).
- **Parameter Sets**: The values needed to decode a video coding data are grouped together into a single picture parameter set, which is referenced from each slice.

5.2 Terminology

Table 4 summarizes the correspondences between the sets of terminology used in AVC Video, MPEG-4 Systems (ISO/IEC 14494-1), and MP4 (ISO/IEC 14496-1

Table 4: Correspondence of Terms in AVC, MPEG-4 Systems, and MP4

AVC	MPEG-4 Systems	MP4
-	Presentation	Movie
Stream	Elementary Stream	Track
Picture	Access Unit	Sample

© ISO/IEC 2002 — All rights reserved

5.3 AVC File type and identification

Conformance with this specification is indicated by the presence of the brand 'jvt1' in the compatible-brands list of the `FileTypeBox` as defined in the ISO Media File Format specification [ISO 14496-1:2001, Amd. 5].

Readers conformant to this specification should read the file if this brand occurs in the compatible-brands list. Other structures and/or track types, defined in other specifications, may be present, and these may be ignored by a conformant reader.

If the major-brand is 'jvt1', then

a) the minor-version, as defined in this version of this specification, shall be 1.

b) the file extension shall be ".jvt" [to be checked for collision]

c) the mime type used to serve the file shall be "video/jvt" [to be allocated]

5.4 AVC Track Structure

In the terminology of the ISO Media File Format Specification, an AVC track is a video or visual track. It therefore uses:

a) a `handler_type` of `'vide'` in the `HandlerBox`;

b) a video media header `'vmhd'`;

c) and, as defined below, a derivative of the `VisualSampleEntry`.

5.5 Canonical order and restrictions

The AVC elementary stream is stored in the MP4 file format in a *canonical* format. The canonical format is as *neutral* as possible so that systems that need to customize the stream for delivery over different transport protocols – MPEG-2 Systems, RTP, and so on — should not have to *remove* information from the stream while being free to *add* to the stream. Furthermore, a canonical format allows such operations to be performed against a known initial state.

The canonical stream format is an AVC video stream that satisfies the following conditions:

- *No parameter sets in the video elementary stream.* All sequence and picture parameter set information shall be stored in the sample descriptions for the track or in a separate parameter set track containing a parameter set elementary stream. This ensures that it is not necessary to examine every part of the elementary stream to find relevant parameter sets. It also avoids dependencies of indefinite duration between the sample that contains the parameter set definition and the samples that use it. Parameter sets may be inserted into the video elementary stream when the file is streamed over a transport that permits such parameter set updates.

- *Parameter Set Track:* If present, a parameter set track shall be constructed so that all parameter set samples are random access points. This implies that each there shall be a parameter set access unit at each point a parameter set is updated. Each parameter set shall contain exactly the sequence and picture parameter sets needed to decode

Note: The use of a parameter track in the file format does not require that a system delivering AVC content a use a separate elementary stream for parameter sets. Instead, implementations may choose to map parameter sets to

© ISO/IEC 2002 — All rights reserved

in-band parameter set NAL units in the video elementary stream or use some out-of-band delivery mechanism defined by the transport layer.

- *All timing information is external to stream.* Timing SEI messages that define presentation or composition timestamps shall not be included in the AVC elementary stream. All timing information is stored in the various sample metadata tables. If timing information were embedded in the stream, then there would be a great danger of inconsistency, and a key feature of MP4, that editing can take place without modifying elementary streams, would break.

- *All SEI messages are at the beginning of an AU.* NAL units included in an access unit shall be ordered so that all SEI messages occur before all video NAL units (slices or data partitions) in the access unit. This allows a rapid inspection of the sample to determine whether it contains SEI messages. All SEI messages shall be contained in a single SEI message NAL unit.

- *Redundant Picture*: NAL units within a single access shall be ordered in non-decreasing order of redundant picture count (redundant_pic_cnt).

- *Slice Groups*: NAL units within a single picture (the same value of picture order count) shall be ordered in non-decreasing order of slice group identifier. Within the same slice group, slices shall be ordered by their first Macroblock location (first_mb in the slice header).

- *Partition Ordering:* All data partitions of a slice shall occur in the order: 'A' partition, 'B' partition, and 'C' partition. No interleaving of partitions from different slices is allowed.

- *No start codes.* The elementary stream shall not include start codes. As stored, each NAL Unit is preceded by a length field; this enables easy scanning of the sample's NAL Units. Systems that use start-codes will reformat the stream to use start codes.

- *Picture delimiter NAL units.* Picture delimiter NAL units may be present in the sample data. If present, they shall occur as the first NAL unit in a sample.

- *No filler data.* Video data is naturally represented as VBR in the file format and should be filled for transmission if needed. Filler NAL units and Filler SEI messages shall not be present in the file format stored stream.

Note that these restrictions are more restrictive than the use of AVC in MPEG-4 systems.

5.6 Sample format

A file format sample is a picture in AVC terms, and an access unit in MPEG-4 terms. The sample data shall follow the syntax and semantics defined for AVC video access units in subclause 4.1.4. Note, this format is used for storing data only and does not require the use of MPEG-4 systems framework to carry AVC visual data.

5.7 Template Fields Used

The ISO Media File Format defines a number of fields which have default values but which may be defined for use by specific sub-systems. Tracks containing AVC data use the following template fields:

a) `alternate_group` in the `TrackHeaderBox` (see subclause 5.12 on stream switching);

© ISO/IEC 2002 — All rights reserved

5.8 Visual Width and Height

The width and height fields in a `VisualSampleEntry` must correctly document the encoded width and height as indicated by the sequence parameter sets in the AVC stream that is described by that entry. These *must* correspond to the picture size established by the vui_pic_parameters, which includes optional frame cropping information. The width and height fields do *not* reflect any changes in size caused by SEI messages such as Pan-scan. The visual handling of SEI messages such as pan-scan is both optional and terminal-dependent. If the width and height of the sequence changes, then a new sample description is needed.

The width and height fields in the track header may not be the same as the width and height fields in the one or more `VisualSampleEntry` in the video track. As specified in the ISO Media File Format, if normalized visual presentation is needed, all the sequences are normalized to the track width and height for presentation.

5.9 Sample Table elements

5.9.1 Sample description name and format

5.9.1.1 Sample Description Box

5.9.1.1.1 Definition

Box Types: 'jvt1', 'jvtC', 'm4ds'
Container: Sample Table Box ('stbl')
Mandatory: Yes
Quantity: Exactly one

An AVC visual sample entry shall contain an AVC Visual Stream Configuration Box, as defined below. This includes a `AVCVideoDecoderConfigurationRecord`, as defined in subclause 4.1.5.1 as the content of `DecoderSpecificInfo` for MPEG-4.

Extension descriptors that should be inserted into the Elementary Stream Descriptor, when used in MPEG-4, may also be present.

Multiple sample descriptions may be used, as permitted by the ISO Media File format specification, to indicate sections of video that use different configurations of parameter sets.

5.9.1.1.2 Syntax

```
   // Visual Sequences
class AVCConfigurationBox extends Box('jvtC') {
   AVCVideoConfigurationRecord() AVCConfig;
}

class MPEG4DescriptorsBox extends Box('m4ds') {
   Descriptor Descr[0 .. 255];
}

class AVCSampleEntry() extends VisualSampleEntry ('jvt1'){
   AVCConfigurationBox  config;
   MPEG4ExtensionDescriptorsBox (); // optional
}
```

© ISO/IEC 2002 — All rights reserved

5.9.1.1.3 Semantics

`Compressorname` in the base class `VisualSampleEntry` indicates the name of the compressor used with the value `"\016JVT/AVC Coding"` being recommended (\016 is 14, the length of the string as a byte)

`config` is defined in subclause 4.1.5.2.

`Descr` is a descriptor which should be placed in the `ElementaryStreamDescriptor` when this stream is used in an MPEG-4 context. This does not include `SLConfigDescriptor` or `DecoderConfigDescriptor`, but includes the other descriptors in order to be placed after the `SLConfigDescriptor`. The use of this field is specified in subclause 5.14.1.

5.9.1.2 Parameter Sets

Each AVC sample description, which contains the AVC video stream decoder specific information, includes a group of sequence and picture parameter sets. This group of parameter sets functions much like a codebook. Each parameter set has an identifier, and each slice references the parameter set it was coded against using the parameter set's identifier.

In the file format each configuration of parameter sets is represented separately. A parameter set cannot be updated without causing a different sample description to be used. For example, suppose that samples 1-4 use picture parameter sets identified as 1, 2, 3 and a single sequence parameter set identified as 1. At sample 5 a new value of picture parameter set 2 is required but picture parameter sets 1 and 3 remain unaltered and are used until sample 10. In this case, the sample description for samples 1 through 4 is the same and contains the initial values of picture parameter sets 1, 2, 3 and sequence parameter set 1. At sample 5 the sample description must change to a second sample description, which contains the updated value for picture parameter set 2 *as well as* the original values of picture parameter sets 1 and 3 and sequence parameter set 1. This second sample description is used for samples 5 through 10.

Systems wishing to send sequence or picture parameter set updates will need to compare the two configurations to find the differences in order to send the appropriate parameter set updates.

5.9.2 Decoding Time (DTS) and Composition Time (DTS)

Samples are stored in the file format in decoding order. If frame reordering is not used, this is also presentation order, and only the time-to-sample 'stts' table is used. Note that any kind of picture may be reordered in AVC video, not only B-frames.

If decoding time must be stored, the composition time-to-sample 'ctts' is also used.

5.9.3 Sync sample (IDR)

A sync sample shall correspond to an instantaneously decodable picture in the AVC stream (also known as an Instantaneously Decodable Refresh point (IDR)).

5.9.4 Shadow sync

The use of the shadow sync table to indicate alternate encodings of a sample for random access are supported for as defined in the ISO Base Media File format. A shadow sync shall indicate a sample that is an independently decodable sample, which shall be encoded as either an I-frame or a SI-frame.

While the use of shadow sync for AVC content is supported for backward compatibility reasons, this use is deprecated and use of the mechanisms defined in subclause 5.12 is recommended.

© ISO/IEC 2002 — All rights reserved

5.10 Sample Groups

5.10.1 Introduction

This subclause specifies a generic mechanism for representing a partition of the samples in a track. A *sample grouping* is an assignment of each sample in a track to be a member of one *sample group,* based on a grouping criterion. A sample group in a sample grouping is not limited to being contiguous samples and may contain non-adjacent samples. As there may be more than one sample grouping for the samples in track, each sample grouping has a type field to indicate the type of grouping. For example, a file might contain two sample groupings for the same track: one based on an assignment of sample to layers and another to sub-sequences.

Sample groupings are represented by two linked data structures: (1) a `SampleToGroup` box represents the assignment of samples to sample groups; (2) a `SampleGroupDescription` box contains a *sample group entry* for each sample group describing the properties of the group. There may be multiple instances of the `SampleToGroup` and `SampleGroupDescription` boxes based on different grouping criteria. These are distinguished by a type field used to indicate the type of grouping.

One example of using these tables is to represent the assignments of samples to *layers.* In this case each sample group represents one layer, with an instance of the `SampleToGroup` box describing which layer a sample belongs to. For more details, please refer to subclause 5.11

5.10.1.1 SampleToGroup Box

5.10.1.1.1 Definition

Box Type: 'sbgp'
Container: Sample Table Box ('stbl')
Mandatory: No
Quantity: Zero or more.

This table can be used to find the group that a sample belongs to and the associated description of that sample group. The table is compactly coded with each entry giving the index of the first sample of a run of samples with the same sample group descriptor. The sample group description ID is an index that refers to a `SampleGroupDescription` box, which contains entries describing the characteristics of each sample group.

There may be mutiple instance of this box if there is more the one sample grouping for the samples in a track. Each instance of the `SampleToGroup` box has a type code that distinguishes different sample groupings. Within a track, there shall be a most instance of this box with a particular grouping type. The associated `SampleGroupDescription` shall indicate the same value for the grouping type.

5.10.1.1.2 Syntax

```
aligned(8) class SampleToGroupBox
   extends FullBox('sbst', version = 0, 0)
{
   unsigned int(32)  grouping_type;
   unsigned int(32)  entry_count;
   for (i=1; i <= entry_count; i++)
```

© ISO/IEC 2002 — All rights reserved

```
    {
        unsigned int(32)  sample_count;
        unsigned int(32)  group_description_index;
    }
}
```

5.10.1.1.3 Semantics

`version` is an integer that specifies the version of this box.

`grouping_type` is an integer that identifies the type (i.e. criterion used to form the sample groups) of the sample grouping and links it to its sample group description table with the same value for grouping type. At most once occurrence of this box with the same value for `grouping_type` value shall exist for a track.

`entry_count` is an integer that gives the number of entries in the following table.

`sample_count` is an integer that gives the number of consecutive samples in the group.

`group_description_index` is an integer that gives the index of the sample group entry which describes the samples in this group. The index ranges from 1 to the number of sample group entries in the `SampleGroupDescription` Box.

5.10.1.2 Sample Group Description Box

5.10.1.2.1 Definition

Box Types: 'sgpd'
Container: Sample Table Box ('stbl')
Mandatory: No
Quantity: Zero or more, with one for each Sample Group Table box.

This description table gives information about the characteristics of sample groups. The descriptive information is any other information needed to define or characterize the sample group.

There may be mutiple instance of this box if there is more the one sample grouping for the samples in a track. Each instance of the `SampleGroupDescription` box has a type code that distinguishes different sample groupings. Within a track, there shall be a most instance of this box with a particular grouping type. The associated `SampleToGroup` shall indicate the same value for the grouping type.

The information is stored in the sample group description box after the entry-count. An abstract entry type is defined and sample groupings shall define derived types to represent the description of each sample group. For video tracks, an abstract `VisualSequenceEntry` is used with similar types for audio and hint tracks.

5.10.1.2.2 Syntax

```
// Sequence Entry
abstract class SampleGroupDesriptionEntry (unsigned int(32) handler_type)
{
}

// Visual Sequence
abstract class VisualSampleGroupEntry (type) extends SampleGroupDesriptionEntry
(type)
```

© ISO/IEC 2002 — All rights reserved

```
{
}

// Audio Sequences
abstract class AudioSampleGroupEntry (type) extends SampleGroupDesriptionEntry(type)
{
}

aligned(8) class SampleGroupDescriptionBox (unsigned int(32) handler_type)
   extends FullBox('sgpd', 0, 0){
   unsigned int(32) grouping_type;
   unsigned int(32) entry_count;
   int i;
   for (i = 1 ; i <= entry_count ; i++){
      switch (handler_type){
         case 'vide': // for video tracks
            VisualSampleGroupEntry ();
            break;
         case 'soun': // for audio tracks
            AudioSampleGroupEntry();
            break;
         case 'hint': // for hint tracks
            HintSampleGroupEntry();
            break;
      }
   }
}
```

5.10.1.2.3 Semantics

`version` is an integer that specifies the version of this box.

`grouping_type` is an integer that identifies the `SampleToGroup` box that is associated with this sample group description.

`entry_count` is an integer that gives the number of entries in the following table.

5.11 Layering and sub-sequences

Streams may be constructed so that the referential dependencies between samples allow only subsets of the samples to be sent to the decoder. This mechanism is called *thinning* a stream and is entirely transparent to the decoder receiving the elementary stream. Thinning discards entire sets of samples using knowledge of what other sets of pictures this set of pictures depends on and what picture sets in turn depend on it.

The referential dependencies between samples in a stream are structured into *layers* and *sub-sequences*. Samples in higher layers can only depend on samples in lower layers. Layers are numbered, and the samples organized such that a sample in layer N has no dependencies on samples in layers greater than N.

© ISO/IEC 2002 — All rights reserved

Sub-sequences are sets of samples that have external referential dependencies on other sets of samples. Dependency relations between sub-sequences represent the dependency structure of a stream. The samples in a sub-sequence can be disposed of as a unit when thinning streams. Each sub-sequence belongs to one and only one layer. A sample shall reside in one layer and in one sub-sequence only.

Layering and sub-sequences are not features of the codec but this information is represented in the file format to allow systems reading the files to understand the ways in which stream thinning may be achieved without having to examine the dependency structure of every sample.

5.11.1.1 Sub-Sequence Description Entry

Box Types: 'jvss"
Container: Sample Group Description Box ('sgpd')
Mandatory: No
Quantity: Zero or more.

A sub-sequence description entry is a sample group entry that describes a sub-sequence. A sub-sequence is a set of samples in a track belonging to the same layer. A sub-sequence depends on another sub-sequence if and only if there exists a sample in the this sub-sequence that is directly referentially dependent on some sample in the other sub-sequence. All sample in a sub-sequence shall be depend only on other samples within the same sub-sequence or samples in the sub-sequences on which is it dependent. A sub-sequence can depend on zero or more sub-sequences in the same or lower layers. A sub-sequence shall not depend on sub-sequences in the higher scalability layers.

5.11.1.1.1 Syntax

```
aligned(8) class DependencyInfo
{
     unsigned int(8)   layerNumber;
     unsigned int(32)  subSequenceIdentifier;
}

class AVCSubSequenceEntry () extends VisualSampleGroupEntry ('jvss')
{
     unsigned int(32) subSequenceIdentifer;
     unsigned int(32) avgBitRate;
     unsigned int(32) avgFrameRate;
     unsigned int(16) numReferences;
     DependencyInfo dependency[numReferences];
   }
}
```

5.11.1.1.2 Semantics

`layerNumber` and `subSequenceIdentifier` within the `DependencyInfo` class identify a sub-sequence that is used as a reference for this sub-sequence. Only direct, not indirect, referential dependencies shall be identified.

`subSequenceIdentifier` in the Sub-Sequence Box gives the identifier for the sub-sequence.

`avgBitRate` gives the average bit rate in bits/second of the sub-sequence within the segment. All NAL units belonging to pictures in the layer are taken into account in the calculation. A value of zero means an undefined bit rate.

`avgFrameRate` gives the average frame rate in frames/(256 seconds) of the sub-sequence within the segment. A value of zero means an undefined frame rate.

© ISO/IEC 2002 — All rights reserved

`numReferences` gives the number of sub-sequences directly referenced in this sub-sequence. `dependency` is an array of `DependencyInfo` structures giving the identification information of the referenced sub-sequences.

5.11.1.2 Layer Description Entry

Box Types: 'jvll'
Container: Sample Group Description Box ('sgpd')
Mandatory: No
Quantity: Zero or more.

A layer sample group entry defines the layer information for all samples in a layer. Layers are ordered hierarchically based on their dependency on each other: The first or base layer is independently decodable. The second and subsequent layers are enhancement layers that depend on some data in the base layer. Pictures in a higher layer can only depend on pictures in lower layers.

5.11.1.2.1 Syntax

```
class AVCLayerEntry() extends VisualSampleGroupEntry ('jvll')
{
   unsigned int(8)  layerNumber;
   unsigned int(32) avgBitRate;
   unsigned int(32) avgFrameRate;
}
```

5.11.1.2.2 Semantics

`layerNumber` gives the number of this layer with the base layer being numbered as zero and all enhancement layers being numbered as one or higher with consecutive numbers.

`avgBitRate` gives the average bit rate in bits/second of the layer within the segment. A value of zero indicates an undefined bit rate.

`avgFrameRate` gives the average frame rate in frames per 1000 seconds of this layer with a value of zero indicating an undefined frame rate.

5.12 Alternate Streams and Switching Pictures

In typical streaming scenarios, one of the key requirements is to scale the bit rate of the compressed data in response to changing network conditions. The simplest way to achieve this is to encode multiple streams with different bandwidths and quality settings for representative network conditions. The server can then switch amongst these pre-coded streams in response to network conditions. In current standards, switching between streams is only possible at I-frames, because the frames can only be switched when there are no dependencies on prior pictures for reconstruction.

AVC has adopted SP-pictures and SI-pictures ("switching pictures") that allow switching from one stream to another while still supporting inter-frame coding of switching pictures. Figure 3 shows how SP frames are used to switch between two different bit streams.

© ISO/IEC 2002 — All rights reserved

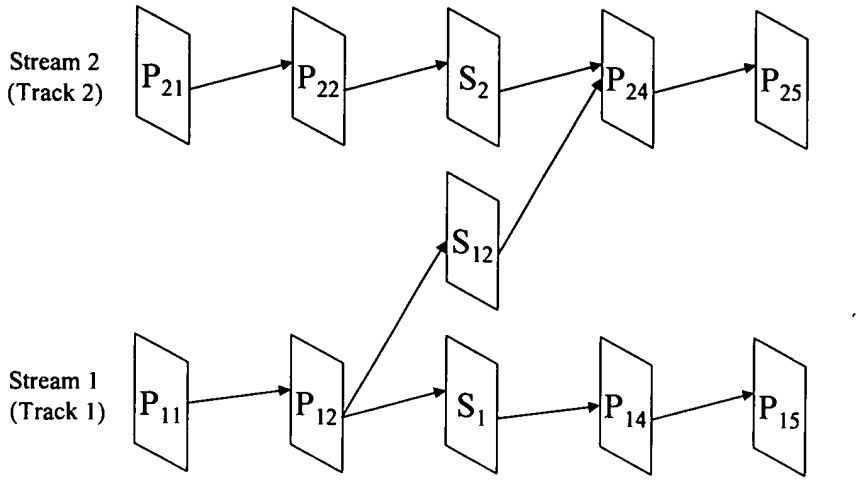

Figure 3: Stream Switching

In the file format, switching pictures are stored in *switching picture* tracks, which are tracks separate from the track that is being switched from and the track being switched to. Switching picture tracks can be identified by the existence of a specific required track reference in that track. A switching picture is an alternative to the sample in the destination track that has exactly the same decoding time. If all switching pictures are SI pictures, then no further information is needed.

If any of the pictures in the switching track are SP pictures, then two extra pieces of information may be needed. First, the source track, that is being switched from, must be identified by using a track reference (the source track may be the same track as the destination track). Second, the dependency of the switching picture on the samples in the source track may be needed, so that a switching picture is only used when the pictures on which it depends have been supplied to the decoder.

This dependency is represented by means of an optional extra sample table. There is one entry per sample in the switching track. Each entry records the relative sample numbers in the source track on which the switching picture depends. If this array is empty for a given sample, then that switching sample contains an SI picture. If the dependency box is not present, then only SI-frames shall be present in the track.

A switching sample may have multiple coded representations with different dependencies. For AVC video, the multiple representations are stored in the same sample (i.e. access unit) using the existing facility to have multiple coded representations in the same access unit. For example, one switch sample might contain a SP-picture representation dependent on some earlier samples, used for stream switching, and another representation as an SI-picture, used for random access.

5.12.1 Alternate Group

The ISO media file format (but not the version one specification of the MPEG-4 file format, which is branded as 'mp41') supports the use of what is called *alternate tracks.* Each track can optionally specify an *alternate group* (in the track header box) that groups together alternate encodings of the same content. Thus, each alternate bit-stream can be stored as a separate track in the MP4 and related together as alternate tracks. All the tracks which form a group which may be switched between, but not the tracks containing the switching pictures, must be a member of an `alternate_group` with a non-zero group identifier.

An alternate group is not needed if there is only one primary track, with a switching track. This switching track may contain SI pictures, or SP pictures for trick modes or error resilience, which predict both from and to the same track.

© ISO/IEC 2002 — All rights reserved

5.12.2 Track references

The switching track must be linked to the track into which it switches (the destination track) by a track reference of type 'swto' in the switching picture track.

If the switching track contains SP pictures, the switching track must be linked to the track from which it switches (the source track) by a track reference of type 'swfr' in the switching picture track.

5.12.3 Sample dependency

This subclause defines the dependencies of each switching sample on sample(s) in the source track. This table is only needed in a switching track which has a source ('swfr') track dependency.

5.12.3.1 Definition

Box Type: 'sdep'
Container: Sample Table 'stbl'
Mandatory: No
Quantity: Zero or exactly one.

This box contains the sample dependencies for each switching sample. The dependencies are stored in the table, one record for each sample. The size of the table, `sample_count` is taken from the `sample_count` in the Sample Size Box ('stsz').

5.12.3.1.1 Syntax

```
aligned(8) class SampleDependencyBox
   extends FullBox('sdep', version = 0, 0) {
   bit(1) multiple_representation_flag;
   bit(7) reserved = 0;
   for (i=0; i < sample_count; i++)
      if (multipleRep)
         representation_count = 1;
      else
         unsigned int(16)  representation_count;
      for (j=0; j < representation_count; j++) {
         unsigned int(16) dependency_count;
         for (k=0; k < dependency_count; k++) {
            signed int(16) relative_sample_number;
         }
      }
   }
}
```

5.12.3.1.2 Semantics

`mutiple_representation_flag` - is an flag that indicates whether each switching sample has multiple representations, each with its own separate dependency information.

`representation_count` - is an integer that a counts the number of representations in the switch sample. If

`dependency_count` - is an integer that a counts the number of samples in the source track on which this switching sample directly depends.

© ISO/IEC 2002 — All rights reserved

`relative_sample_number` - is an integer that identifies a sample in the source track. The relative sample numbers are encoded as follows. If there is a sample in the source track with the same decoding time, it has a relative sample number of 0. Whether or not this sample exists, the sample in the source track which immediately precedes the decoding time of the switching sample has relative sample number –1, the sample before that –2, and so on. Similarly, the sample in the source track which immediately follows the decoding time of the switching sample has relative sample number +1, the sample after that +2, and so on.

5.13 Representation of new structures in Movie Fragments

[TBD]

5.14 Use of the AVC File Format in MPEG-4 Systems

This subclause specifies how the AVC file format shall be used when the file is marked as being compatible with the MPEG-4 file format specified in ISO/IEC 14496-1:2001 Amendment 6. This subclause applies when the file is branded with the MPEG-4 file format brand of 'mp41' or 'mp42', and the AVC video data must be used in an MPEG-4 systems context.

5.14.1 Forming the Elementary Stream Descriptor

As is normal for MPEG-4 streams, the TrackID is related to the `ElementaryStreamID`, and the `SLConfigDescriptor` is generated following the rules for any MPEG-4 stream The format of the ES Descriptor is specified in chapter 13 of the MPEG-4 systems specification [ISO/IEC 14966:2001].

If the Elementary Stream Descriptor should contain any other descriptors than `SLConfigDescriptor` or `DecoderConfigDescriptor`, they are stored in the Sample Description as defined in subclause 5.9.1.1.

5.14.2 Forming the DecoderConfigDescriptor

The object type and stream type indications have the values defined in subclause 4.2 for AVC streams.

The `buffersizeDB`, `maxBitrate`, and `avgBitrate` fields can be filled by inspection of the VUI Sequence Parameters, if present in the sequence parameter set for the AVC stream.

The `DecoderSpecificInfo` is formed using the contents of the `AVCConfigurationBox`.

5.14.3 Profile and Level Indication

The MPEG-4 `ProfileLevelIndication` can be deduced from the AVC Profile and Level Indication found in the `AVCDecoderConfiguration`.

[Editor's note: Until the code-points are assigned, it's not clear whether this is a one-one mapping.]

5.14.4 Elementary Stream Descriptors

The use of multiple non-dependent elementary stream descriptors may *also* be indicated by the presence of more than one independent AVC video elementary stream descriptors in an object descriptor.

© ISO/IEC 2002 — All rights reserved

5.14.5 Switching Picture Tracks

Switching picture tracks are *not* MPEG-4 elementary streams and shall not be included within an MPEG-4 object descriptor.

5.15 Possible issues

5.15.1 Typical patterns of NAL Unit sizes etc.

This design could probably benefit from more knowledge of typical patterns of use and sizes etc. For example, repeating patterns etc. can be leveraged to reduce overhead, and the sizes of fields adjusted (e.g. the relative sample number). See, for example, N8708.

5.15.2 Do we need better visibility into where SEIs occur?

If an application wishes to answer "where are the SEI messages in this stream?" it must search all samples for those beginning with SEIs. We are unaware of a need for such a search, but if such need arises, some kind of indexing for the SEIs may be needed.

5.15.3 Do we need to allow parameter set updates in the OD stream?

The file format effectively allowing update of `DecoderSpecificInfo`, which might change parameters such as the visual width and height (though the file format normalizes these). Does MPEG-4 systems need to allow such re-configuration of existing streams, or should we express constraints on the changes in configuration permitted in an MPEG-4 context?

5.15.4 Will chunking be affected by Parameter Set changes?

All the samples in a chunk share a single configuration. If parameter sets change frequently, and this causes the configuration to change frequently, this would have a significant adverse impact on the size of the file-format sample tables. Typical patterns of use would again be of assistance here.

5.15.5 Layering and sub-sequences

This whole area is provisional before we get clarification on a number of issues, including, but not limited to:

i. Clarifying whether there is one division into layers and sub-sequences, or multiple;

ii. What 'layers' mean if sub-sequences may be selected from any layer, provided that their dependents have been decoded;

iii. Given that sub-sequences begin and end and then begin again, what the exact meaning of a 'dependency' is (on which instances?);

iv. What the use of sub-sequence identifiers is; whether they refer to definitions or instances, and if the latter, how the identifier space is managed in an indefinite duration sequence;

v. How the beginning and end of a sub-sequence can be identified;

© ISO/IEC 2002 — All rights reserved

vi. Whether dependencies are only direct, or transitive;

vii. What the meaning of the bit-rate etc. are, in the definition of sub-sequences, with respect to the individual instances of the sub-sequences.

Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 14496-15 was prepared by ISO/IEC/TC JTC 1/SC 29.

Deleted: Amendment 7 to ISO/IEC 14496-1:2001

© ISO/IEC 2002 — All rights reserved

Introduction

The Advanced Video Codec (AVC), jointly developed by the ITU and ISO/IEC SC29/WG11 (MPEG), offers not only increased coding efficiency and enhanced robustness, but also interesting opportunities and challenges for the systems which use it. To enable the best visibility of, and access to, those features, and to enhance the opportunities for the interchange and interoperability of media, this standard defines a storage format for video streams compressed using AVC and using carrying within the MPEG-4 Systems Framework (ISO/IEC 14496-1:2001 and its various amendments).

This specification defines a storage format based on, and compatible with, the ISO Media File format ISO/IEC 14496-12 | 15444-12), which is used by the MP4 file format (ISO/IEC 14496-14) and the Motion JPEG 2000 file format (ISO/IEC 15444-1) among others. This specification enables AVC video streams to:

Deleted: (ISO/IEC 14496-1:2001, Amd. 5),

Deleted: 14496-1 Amd. 6)

- be used in conjunction with other media streams, such as audio;
- be used in an MPEG-4 systems environment, if desired;
- be formatted for delivery by a streaming server, using hint tracks;
- inherit all the use cases and features of the ISO Media file format on which MP4 and MJ2 are based.

The ISO Media File format is becoming increasingly common as a general-purpose media container format for the exchange of digital media, and its use in this context should accelerate both adoption and interoperability.

Extensions to the base format are defined here to expose the new systems aspects of the AVC codec.

Information technology — Coding of audio-visual objects — Part 15: AVC File Format

1 SCOPE

This document specifies the storage format for AVC (ISO/IEC 14496-10 | ITU Recommendation H.264) video streams. It also specifies how such streams are carried in an MPEG-4 context.

[Ed's Note: It is expected that the specification of carriage of AVC streams in MPEG-4 Systems will move into an appropriate MPEG-4 Systems Amendment].

3 TERMS AND DEFINITIONS

For the purposes of this specification, the terms and definitions specified in normative references ISO/IEC 14496-1 and ISO/IEC 14496-10 | ITU Recommendation H.264 shall apply. In addition, the following terms and abbreviations shall apply to all clauses in this specification.

3.1 Terminology

3.1.1 Parameter Set

Formatted: Bullets and Numbering

A parameter set is either a sequence parameter set or a picture parameter set. This term is used to refer to both types of parameter sets.

3.1.2 Parameter Set Elementary Stream

An elementary stream containing access units made up only of sequence and picture parameter set NAL units, synchronized with the video elementary stream.

Deleted: that is

3.1.3 Video Elementary Stream

An elementary stream containing access units made up of NAL units for coded picture data.

Deleted: containing video coding layer data, SEI messages, and (optionally) parameter set update NAL units.

3.2 Symbols and abbreviated terms

AVC	ISO/IEC 14496-10, Advanced Video Coding
NAL	Network Abstraction Layer
SEI	Supplementary Enhancement Information

4 USE OF AVC IN MPEG-4 SYSTEMS

4.1 AVC Streams

This subclause specifies the elementary stream format used to carry AVC visual content within the MPEG-4 systems framework.

4.1.1 Structure of the AVC streams

This subclause defines two elementary streams for carriage of AVC content within the MPEG-4 systems framework: a video elementary stream for carrying video data and an optional parameter set elementary stream for carrying parameter sets out-of-band from the video data.

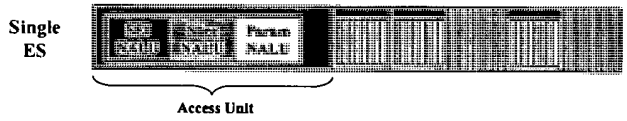
AVC specifies a set of Network Abstraction Layer units, which contain different types of data. While the syntax of each NAL unit is specified by AVC, how NAL units are to be carried as elementary streams in the MPEG-4 Systems framework is not specified by ISO/IEC 14496-10. This subclause specifies the format of MPEG-4 elementary streams for AVC content for use within MPEG-4 Systems.

AVC content shall be carried in MPEG-4 Systems in either one or two elementary streams:

- **Video Elementary Stream**: This elementary stream, structured into video access units, contains video coding related NAL units (i.e. those NAL units containing video data or signaling video structure). If the optional parameter set elementary stream is not present, sequence and picture parameter set NAL units may be present in this stream.

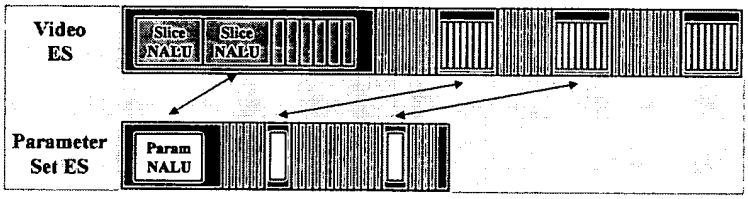
Deleted:), SEI NAL units, and filler data NAL units

- **Parameter Set Elementary Stream**: This optional stream is used to transmit only sequence and picture parameter set NAL units. If this stream is used, sequence and picture parameter set NAL units shall not be carried in the video elementary stream.



Formatted: Bullets and Numbering

The set types of NAL units are allowed in each of video and parameter set elementary streams is specified in Table 1.



© ISO/IEC 2002 — All rights reserved

Table 1 -- NAL Unit Types in Elementary Streams

Value of nal_unit_type	Description	Video_ES	Parameter Set_ES
0x0	Reserved for external use	No	No
0x1	Coded slice	Yes	No
0x2	Coded data partition A (DPA)	Yes	No
0x3	Coded data partition B (DPB)	Yes	No
0x4	Coded data partition C (DPC)	Yes	No
0x5	Coded slice of an IDR picture	Yes	No
0x6	Supplemental Enhancement Information (SEI)	Yes	No
0x7	Sequence Parameter Set (SPS)	Yes, if parameter ES is not used.	Yes
0x8	Picture Parameter Set (PPS)	Yes, if parameter ES is not used.	Yes
0x9	Picture Delimiter (PD)	Yes	No
0xA	Filler Data (FD)	Yes	Yes
0xB – 0x17	Reserved	No	No
0x18 – 0x1F	For external use	Not specified by this standard.	Not specified by this standard.

(a) Single Video Elementary Stream containing all NAL Units

(b) Synchronized Video and Parameter with arrows denoting synchronization between streams.

Figure 1: AVC Elementary Stream Structure

4.1.2 Time Base for AVC Streams

The time base associated to an AVC stream shall be indicated using the means provided by MPEG-4 systems. If present, an AVC parameter set elementary stream shall adhere to the same time base as the AVC video elementary stream.

© ISO/IEC 2002 — All rights reserved

4.1.3 Access unit definition

An AVC access unit consists of one or more NAL units, as defined in ISO/IEC 14496-10. All NAL units that are to be processed at the same instant in time shall constitute a single access unit. Access units in AVC streams shall be labelled and time-stamped by suitable means. This shall be done via the related flags and the composition time stamps, respectively, in the SL packet header (see ISO/IEC 14496-1:2001, subclause 10.2.4). The composition time indicates the point in time at which the decoded data shall be composed. The decoding and composition time for an AVC access unit can have different values.

An AVC access unit shall set the `randomAccessPointFlag` in the SL packet header to '1' for this access if ALL of the following conditions are met:

- All video data NAL unit indicate a coded slice of an instantaneous decoder refresh (IDR) picture.
- All sequence and picture parameter sets needed to decode the video data in the access unit are contained in the decoder specific information for the video elementary stream.

Otherwise, the `randomAccessPointFlag` shall be set to '0'.

An AVC access unit shall include the following NAL units:

- **Video Data NAL Units (Coded Slice, Coded DPA, Coded DPB, Coded DPC , Coded IDR)**: All slice and data partition NAL units for a single picture shall be contained with the access unit whose decoding time and composition time is that of the picture. A single picture is one of a frame, a top and bottom field for one frame, or a single top or bottom field. Each AVC access unit shall contain at least one Video Data NAL unit.
- **SEI Message NAL Units**: All SEI NAL units shall be contained in the access unit whose decoding time is that before which the SEI messages come into effect instantaneously. This means that the SEI messages for a picture shall be included in the access unit containing to that picture and that SEI messages pertaining to a sequence of pictures shall be included in the access unit containing the first picture of the sequence to which the SEI message pertains. SEI messages that pertain to the picture level or higher levels shall occur prior to any video data NAL units in the access unit. Slice level messages may occur anywhere within an access unit.
- **Filler Data NAL Units:** Filler data NAL units can be included in any access unit. An access unit shall not consist entirely of filler data NAL units.
- **Picture Delimiter NAL Units**: Picture delimiter NAL units, if present, shall occur once at the beginning of the access unit whose decoding time is that of the picture being delimited.
- **Parameter Sets**: If a single video elementary stream is used to carry AVC content, all sequence and picture parameter sets NAL units shall be contained in the access unit whose decoding time is the time equal or prior to when the parameter sets come into effect. As specified in ISO/IEC 14496-10, any sequence or picture parameter sets present in an access unit shall occur prior to any video coding NAL units and SEI NAL units in that access unit. If a parameter set elementary steam is used, then the access unit in the parameter stream shall have a decoding time equal or prior to when the parameter set(s) comes into effect instantaneously. This means that for a parameter set to be used in a picture it must be sent prior to the access unit containing that picture or in the access unit for that picture.

The following restrictions apply to the Access Units:

© ISO/IEC 2002 — All rights reserved

a) **Timing SEIs**: The Temporal Reference SEI message and the clock timestamp SEI messages that define the timing information shall not be present in the video elementary stream as timing is provided by the MPEG-4 Sync Layer.

b) **Start Codes** shall not be present in the stream.

The sequence of NAL units in an access unit shall be any legal decoding order conforming to that specified in ISO/IEC 14496-10.

4.1.4 AVC Access Unit Syntax and Semantics

This subclause specifies the syntax and semantics of access units for AVC video. Access Units are externally framed and have a size supplied by that external framing. The structure of an AVC access unit is depicted in Figure 2.

Figure 2: The structure of an AVC Access Unit

An AVC access unit contains a succession of coded picture representations, each of which is made up of a set of NAL units. Each NAL units is is represented with a:

Deleted: NAL Units,

- *Length*: Indicates the length in bytes of the following NAL Unit. The length field can be configured to be of 1, 2, 3 or 4 bytes.
- *NAL Unit*: Contains the NAL unit data as specified in ISO/IEC 14496-10.

If a length field contains the value 0, then all remaining bytes in the access unit contain extension data which is reserved for use in future versions of this specification and must be ignored; those bytes are not NAL Units and must not be passed to the AVC decoder. No coded pictures or their data may occur after such a zero length field. In other words, extension data must be at the very end of the access unit.

Deleted: decoder.¶

4.1.4.1 Syntax

```
class aligned(8) AVCAccessUnit
{
  if(AVCConfigurationRecord.PictureLengthSize > 0)
    unsigned int(8)   PictureCount
  else
    PictureCount = 1;
  for(i=0; i<PictureCount; i++)
  {
    if(AVCConfigurationRecord.PictureLengthSize > 0)
      unsigned int(AVCConfigurationRecord.PictureLengthSize*8)
        PictureLength;
    for (i=0; ; i++;)    // to end of the picture
    {
      unsigned int((AVCConfigurationRecord.LengthSizeMinusOne+1)*8) NALUnitLength;
      if (NALUnitLength==0) {
```

Deleted: Access Unit .

```
        bit() reserved; // to end of the picture
        break;
      } else {
        bit(NALUnitLength * 8) NALUnit;
      }
    }
  }
}
```

Deleted: Access Unit .

4.1.4.2 Semantics

An AVC Video Access Unit consists of a set of NAL units with the same decoding and composition time. A single access unit can contain more than one picture if it contains multiple coded representations of the same picture (either redundant pictures or multiple switching pictures). The syntax of an access unit is configured via the decoder specific configuration for the AVC elementary stream. An AVC Parameter Set Access Unit contains one or more sequence and picture parameter set NAL units. If the coded representations of a picture are redundant pictures then the primary picture (redundant_pic_cnt = 0) shall occur first and all subsequence redundant picture shall occur in ascending order of their redundant picture (redundant_pic_cnt) value.

Deleted: update

Deleted: ¶

A video elementary stream is a random access point if and only if it contains an IDR picture and either of the following conditions holds:

Formatted: Bullets and Numbering

- All of the sequence and picture parameter sets necessary to decode the IDR picture; or,
- A separate parameter set elementary stream is used.

A parameter set elementary stream access unit is a random access point if and only if it contains all sequence and picture parameter sets used from that time forward in the video coding stream and parameter set stream until the next time any parameter set is updated.

`PictureCount` indicates the number of coded representations of the same picture contained within this unit. Such pictures may not be identical objective representations of the same picture. This field shall have a value of at least one.

`PictureLength` indicates the number of bytes contained the coded data for this picture's representation, which is made up of the set of NAL units preceded by length fields. The length of a picture comprises the number of bytes in all NAL units and the size of all `NALUnitLength` fields. If an access unit includes extension data then the picture length field does not include the size of the data or the `NALUnitLength` field whose value is zero.

`NALUnitLength` indicates the size of a NAL unit measured in bytes. The length field includes the size of both the one byte NAL header and the EBSP payload but does not include the length field itself.

`NALUnit` contains a single NAL unit. The syntax of an NAL unit is defined in ISO/IEC 14496-10 and includes both the one byte NAL header and the variable length encapsulated byte stream payload.

4.1.5 Decoder Specific Information

This subclause specifies the decoder specification information for ISO/IEC 14496-10 video content.

4.1.5.1 AVC Decoder Configuration Record

This record contains the size of the length field used in each access unit to indicate the length of its contained NAL units as well as the initial parameter sets. This record is externally framed (its size must be supplied by the structure which contains it).

© ISO/IEC 2002 — All rights reserved

This record contains a version field. This version of the specification defines version 1 of this record. Incompatible changes to the record will be indicated by a change of version number. Readers must not attempt to decode this record or the streams to which it applies if the version number is unrecognized.

Compatible extensions to this record will extend it and will not change the configuration version code. Readers should be prepared to ignore unrecognized data beyond the definition of the data they understand (e.g. after the parameter sets in this specification).

When used to provide the configuration of a parameter set elementary stream, the configuration record shall contain no sequence or picture parameter sets (`numOfParameterSets` shall have the value 0).

4.1.5.1.1 Syntax

```
aligned(8) class AVCConfigurationRecord {
   unsigned int(8) configurationVersion = 1;
   unsigned int(8) AVCProfileIndication;
   unsigned int(8) AVCLevelIndication;
   unsigned int(8) PictureLengthSize;
   unsigned int(16) nonStoredDegredationPriorityLow;
   unsigned int(16) nonStoredDegredationPriorityHigh;
   bit(6) reserved = '111111'b;
   unsigned int(2) lengthSizeMinusOne;
   unsigned int(8) numOfSequenceParameterSets;
   for (i=0; i< numOfSequenceParameterSets;  i++) {
      unsigned int(16) sequenceParameterSetLength ;
      bit(8*sequenceParameterSetLength) sequenceParameterSetNALUnit;
   }
   unsigned int(8) numOfPictureParameterSets;
   for (i=0; i< numOfPictureParameterSets;  i++) {
      unsigned int(16) pictureParameterSetLength;
      bit(8*pictureParameterSetLength) pictureParameterSetNALUnit;
   }
}
```

Deleted: parameterSetLength; .

Deleted: bit(8*parameterSetLength) parameterSetUpdateNALUnit; .

4.1.5.1.2 Semantics

`AVCProfileLevelIndication` contains the profile code defined in Annex A of the AVC specification [ISO/IEC 14496-10 | ITU Recommendation H.264].

`AVCLevelIndication` contains the level code defined in Annex A of the AVC specification [ISO/IEC 14496-10 | ITU Recommendation H.264].

`PictureLengthSize` indicates the length of the picture size field used to indicate the size of a coded picture representation. A value of zero indicates that only a single coded picture representation is allowed in an access unit.

`nonStoredDegrediationPriorityHigh` indicates the largest value of the range of degradation priorities that correspond to AVC non-stored frames (nal_type_idc=0). If the value of `nonStoredDegrediationPriorityHigh` exceeds `nonStoredDegrediationPriorityLow` then no correspondence between degradation priorities and non-stored frames is defined.

`nonStoredDegrediationPriorityLow` indicates the smallest value of the range of degradation priorities that correspond to AVC non-stored frames (nal_type_idc=0).

`lengthSizeMinusOne` indicates the length in bytes of the `NALUnitLength` field in an AVC video access unit of the associated stream minus one. For example, a size of one byte is indicated with a value of 0.

`numOfSequenceParameterSets` indicates the number of sequence parameter sets that are used as the initial set of sequence parameter sets for decoding the AVC elementary stream.

© ISO/IEC 2002 — All rights reserved

sequenceParameterSetLength indicates the length of the parameter set NAL unit as defined in ISO/IEC 14496-10.

sequenceParameterSetNALUnit contains a sequence parameter set NAL Unit, as specified in ISO/IEC 14496-10. Sequence parameter sets shall occur in order of ascending parameter set identifier with gaps being allowed.

numOfPictureParameterSets indicates the number of picture parameter sets that are used as the initial set of picture parameter sets for decoding the AVC elementary stream.

pictureParameterSetLength indicates the length of the parameter set NAL unit as defined in ISO/IEC 14496-10.

pictureParameterSetNALUnit contains a parameter set NAL Unit, as specified in ISO/IEC 14496-10. Picture parameter sets shall occur in order of ascending parameter set identifier with gaps being allowed.

4.1.5.2 AVC Stream DecoderSpecificInfo

This subclause defines the DecoderSpecificInfodescriptor for an AVC elementary stream.

4.1.5.2.1 Syntax

```
aligned(8) class AVCDecoderSpecificInfo extends DecoderSpecificInfo : bit(8)
tag=DecSpecificInfoTag {
    AVCVideoConfigurationRecord config;
}
```

4.1.5.2.2 Semantics

The decoder specific information for an AVC stream contains an AVC video stream decoder configuration record.

config contains the decoder configuration record for the AVC elementary stream decoder configuration.

4.1.5.3 Parameter Set

Initial sequence and picture parameter sets are supplied in the DecoderSpecificInfo for the AVC video stream, as defined in subclause 4.1.5.1. If a parameter set must be updated, then one of two methods can be used:

a) Sequence or Picture Parameter Set NAL units may be inserted in the video stream;

b) A separate parameter set stream may be used to carry parameter sets, possibly using a transport with different error resilience or reliability characteristics.

4.1.6 AVC DecoderConfigDescriptor

The DecoderConfigDescriptor shall set the value of streamtype equal to 0x04 for both AVC video elementary stream and the AVC parameter set elementary streams.

The DecoderConfigDescriptorfor an AVC video elementary stream, possibly including in-line sequence or picture parameter sets, shall set objectTypeIndicationto be 0x21 (ISO/IEC 14496-10 Visual). For the AVC parameter set elementary stream, the objectTypeIndication value shall equal 0x22 (ISO/IEC 14496-10 Visual Parameter Sets).

Formatted: Bullets and Numbering

4.1.7 Elementary Stream Descriptor

If the parameter set elementary stream is present, the elementary stream descriptors for the two streams shall satisfy the following conditions:

Formatted: Bullets and Numbering

(1) The video elementary stream is dependent on the parameter set elementary stream and the `ES_Descriptor` for the video elementary stream shall have a `streamDependenceFlag` equal to true and indicate the ESID of the parameter in the `dependsOnESID` field. The `streamDependenceFlag` in the `ES_Descriptor` for the parameter set elementary stream shall be false.

(2) The elementary stream clocks for the parameter set elementary stream and the video elementary stream shall be the same and synchronized. The `OCRstreamflag` and `OCR_ES_Id` fields in the `ESDescriptor` for the video elementary stream and parameter set elementary streams shall be used to indicate that both streams share the same OCR.

4.2 Codepoints

4.2.1 visualProfileLevelIndication

Ed's Note: What should the visual profile level indication in the initial object descriptor be? Is it even necessary to add a new one? The list below does not seem up to date anyway and I do not recall any amendments to MPEG-4 Systems that touch this table.

Replace Table 6 in ISO/IEC 14496 with the following table:

[a] This object type shall be used for all streamTypes defined in ISO/IEC 14496-1 except IPMP streams.

[b] Includes associated Amendment(s) and Corrigendum(a).

[c] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-2 and are conveyed in the DecoderSpecificInfo as specified in ISO/IEC 14496-2, Annex K.

[d] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-3 and are conveyed in the DecoderSpecificInfo as specified in ISO/IEC 144963 subpart 1 subclause 6.2.1.

[e] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-10 and are conveyed in the DecoderSpecificInfo as specified in this admendment subclause 4.1.5.

4.3 Extensibility

The configuration description format may be extended in future versions of this specification. Similarly, the definition of an AVC Access Unit allows for extension by future versions of this specification.

5 File Format

5.1 Introduction

This subclause defines how to store ISO/IEC 14496-10 data in the MP4 file format. The storage of AVC content uses the existing capabilities of the MP4 file format but also defines new features to support the following features of the AVC codec in the MP4 file format:

- **Switching Pictures**: To enable switching between different coded streams and substitution of pictures within the same stream.
- **Enhanced Group of Pictures**: Provides a structuring of the dependencies of a group of pictures to provide both random access and flexible stream structure (e.g. temporal scalability and layering).
- **Parameter Sets**: The values needed to decode a video coding data are grouped together into a single picture parameter set, which is referenced from each slice.

5.2 Terminology

Table 4 summarizes the correspondences between the sets of terminology used in AVC Video, MPEG-4 Systems (ISO/IEC 14494-1), and MP4 (ISO/IEC 14496-1

Table 4: Correspondence of Terms in AVC, MPEG-4 Systems, and MP4

Formatted: Bullets and Numbering

Formatted: Bullets and Numbering

Formatted: Bullets and Numbering

5.3 AVC File type and identification

Formatted: Bullets and Numbering

Conformance with this specification is indicated by the presence of the brand 'jvt1' in the compatible-brands list of the `FileTypeBox` as defined in the ISO Media File Format specification [ISO 14496-1:2001, Amd. 5].

Readers conformant to this specification should read the file if this brand occurs in the compatible-brands list. Other structures and/or track types, defined in other specifications, may be present, and these may be ignored by a conformant reader.

If the major-brand is 'jvt1', then

Formatted: Bullets and Numbering

a) the minor-version, as defined in this version of this specification, shall be 1.

b) the file extension shall be ".jvt" [to be checked for collision]

c) the mime type used to serve the file shall be "video/jvt" [to be allocated]

5.4 AVC Track Structure

In the terminology of the ISO Media File Format Specification, an AVC track is a video or visual track. It therefore uses:

Formatted: Bullets and Numbering

a) a `handler_type` of `'vide'` in the `HandlerBox`;

b) a video media header `'vmhd'`;

c) and, as defined below, a derivative of the `VisualSampleEntry`.

5.5 Canonical order and restrictions

The AVC elementary stream is stored in the MP4 file format in a *canonical* format. The canonical format is as *neutral* as possible so that systems that need to customize the stream for delivery over different transport protocols – MPEG-2 Systems, RTP, and so on — should not have to *remove* information from the stream while being free to *add* to the stream. Furthermore, a canonical format allows such operations to be performed against a known initial state.

The canonical stream format is an AVC video stream that satisfies the following conditions:

Formatted: Bullets and Numbering

- *No parameter sets in the video elementary stream.* All sequence and picture parameter set information shall be stored in the sample descriptions for the track or in a separate parameter set track containing a parameter set elementary stream. This ensures that it is not necessary to examine every part of the elementary stream to find relevant parameter sets. It also avoids dependencies of indefinite duration between the sample that contains the parameter set definition and the samples that use it. Parameter sets may be inserted into the video elementary stream when the file is streamed over a transport that permits such parameter set updates.

- *Parameter Set Track:* If present, a parameter set track shall be constructed so that all parameter set samples are random access points. This implies that each there shall be a parameter set access unit at each point a parameter set is updated. Each parameter set shall contain exactly the sequence and picture parameter sets needed to decode

Note: The use of a parameter track in the file format does not require that a system delivering AVC content a use a separate elementary stream for parameter sets. Instead, implementations may choose to map parameter sets to

© ISO/IEC 2002 — All rights reserved

in-band parameter set NAL units in the video elementary stream or use some out-of-band delivery mechanism defined by the transport layer.

- *All timing information is external to stream.* Timing SEI messages that define presentation or composition timestamps shall not be included in the AVC elementary stream. All timing information is stored in the various sample metadata tables. If timing information were embedded in the stream, then there would be a great danger of inconsistency, and a key feature of MP4, that editing can take place without modifying elementary streams, would break.

- *All SEI messages are at the beginning of an AU.* NAL units included in an access unit shall be ordered so that all SEI messages occur before all video NAL units (slices or data partitions) in the access unit. This allows a rapid inspection of the sample to determine whether it contains SEI messages. All SEI messages shall be contained in a single SEI message NAL unit.

- *Redundant Picture*: NAL units within a single access shall be ordered in non-decreasing order of redundant picture count (redundant_pic_cnt).

- *Slice Groups*: NAL units within a single picture (the same value of picture order count) shall be ordered in non-decreasing order of slice group identifier. Within the same slice group, slices shall be ordered by their first Macroblock location (first_mb in the slice header).

- *Partition Ordering:* All data partitions of a slice shall occur in the order: 'A' partition, 'B' partition, and 'C' partition. No interleaving of partitions from different slices is allowed.

- *No start codes.* The elementary stream shall not include start codes. As stored, each NAL Unit is preceded by a length field; this enables easy scanning of the sample's NAL Units. Systems that use start-codes will reformat the stream to use start codes.

- *Picture delimiter NAL units.* Picture delimiter NAL units may be present in the sample data. If present, they shall occur as the first NAL unit in a sample.

- *No filler data.* Video data is naturally represented as VBR in the file format and should be filled for transmission if needed. Filler NAL units and Filler SEI messages shall not be present in the file format stored stream.

Note that these restrictions are more restrictive than the use of AVC in MPEG-4 systems.

5.6 Sample format

A file format sample is a picture in AVC terms, and an access unit in MPEG-4 terms. The sample data shall follow the syntax and semantics defined for AVC video access units in subclause 4.1.4. Note, this format is used for storing data only and does not require the use of MPEG-4 systems framework to carry AVC visual data.

5.7 Template Fields Used

The ISO Media File Format defines a number of fields which have default values but which may be defined for use by specific sub-systems. Tracks containing AVC data use the following template fields:

a) `alternate_group` in the `TrackHeaderBox` (see subclause 5.12 on stream switching);

Formatted: Bullets and Numbering

Formatted: Bullets and Numbering

Formatted: Bullets and Numbering

Formatted: Bullets and Numbering

Formatted: Bullets and Numbering

© ISO/IEC 2002 — All rights reserved

5.8 Visual Width and Height

The width and height fields in a `VisualSampleEntry` must correctly document the encoded width and height as indicated by the sequence parameter sets in the AVC stream that is described by that entry. These *must* correspond to the picture size established by the vui_pic_parameters, which includes optional frame cropping information. The width and height fields do *not* reflect any changes in size caused by SEI messages such as Pan-scan. The visual handling of SEI messages such as pan-scan is both optional and terminal-dependent. If the width and height of the sequence changes, then a new sample description is needed.

The width and height fields in the track header may not be the same as the width and height fields in the one or more `VisualSampleEntry` in the video track. As specified in the ISO Media File Format, if normalized visual presentation is needed, all the sequences are normalized to the track width and height for presentation.

Formatted: Bullets and Numbering

5.9 Sample Table elements

5.9.1 Sample description name and format

5.9.1.1 Sample Description Box

5.9.1.1.1 Definition

Box Types: 'jvt1', 'jvtC', 'm4ds'
Container: Sample Table Box ('stbl')
Mandatory: Yes
Quantity: Exactly one

An AVC visual sample entry shall contain an AVC Visual Stream Configuration Box, as defined below. This includes a `AVCVideoDecoderConfigurationRecord` as defined in subclause 4.1.5.1 as the content of `DecoderSpecificInfo` for MPEG-4.

Extension descriptors that should be inserted into the Elementary Stream Descriptor, when used in MPEG-4, may also be present.

Multiple sample descriptions may be used, as permitted by the ISO Media File format specification, to indicate sections of video that use different configurations of parameter sets.

Formatted: Bullets and Numbering

5.9.1.1.2 Syntax

```
   // Visual Sequences
class AVCConfigurationBox extends Box('jvtC') {
   AVCVideoConfigurationRecord() AVCConfig;
}

class MPEG4DescriptorsBox extends Box('m4ds') {
   Descriptor Descr[0 .. 255];
}

class AVCSampleEntry() extends VisualSampleEntry ('jvt1'){
   AVCConfigurationBox config;
   MPEG4ExtensionDescriptorsBox (); // optional
}
```

© ISO/IEC 2002 — All rights reserved

5.9.1.1.3 Semantics

Formatted: Bullets and Numbering

`Compressorname` in the base class `VisualSampleEntry` indicates the name of the compressor used with the value `"\016JVT/AVC Coding"` being recommended (\016 is 14, the length of the string as a byte)

`config` is defined in subclause 4.1.5.2.

`Descr` is a descriptor which should be placed in the `ElementaryStreamDescriptor` when this stream is used in an MPEG-4 context. This does not include `SLConfigDescriptor` or `DecoderConfigDescriptor`, but includes the other descriptors in order to be placed after the `SLConfigDescriptor`. The use of this field is specified in subclause 5.14.1.

Formatted: Bullets and Numbering

5.9.1.2 Parameter Sets

Each AVC sample description, which contains the AVC video stream decoder specific information, includes a group of sequence and picture parameter sets. This group of parameter sets functions much like a codebook. Each parameter set has an identifier, and each slice references the parameter set it was coded against using the parameter set's identifier.

In the file format each configuration of parameter sets is represented separately. A parameter set cannot be updated without causing a different sample description to be used. For example, suppose that samples 1-4 use picture parameter sets identified as 1, 2, 3 and a single sequence parameter set identified as 1. At sample 5 a new value of picture parameter set 2 is required but picture parameter sets 1 and 3 remain unaltered and are used until sample 10. In this case, the sample description for samples 1 through 4 is the same and contains the initial values of picture parameter sets 1, 2, 3 and sequence parameter set 1. At sample 5 the sample description must change to a second sample description, which contains the updated value for picture parameter set 2 *as well as* the original values of picture parameter sets 1 and 3 and sequence parameter set 1. This second sample description is used for samples 5 through 10.

Systems wishing to send sequence or picture parameter set updates will need to compare the two configurations to find the differences in order to send the appropriate parameter set updates.

Formatted: Bullets and Numbering

5.9.2 Decoding Time (DTS) and Composition Time (DTS)

Samples are stored in the file format in decoding order. If frame reordering is not used, this is also presentation order, and only the time-to-sample 'stts' table is used. Note that any kind of picture may be reordered in AVC video, not only B-frames.

If decoding time must be stored, the composition time-to-sample 'ctts' is also used.

Formatted: Bullets and Numbering

5.9.3 Sync sample (IDR)

A sync sample shall correspond to an instantaneously decodable picture in the AVC stream (also known as an Instantaneously Decodable Refresh point (IDR)).

Formatted: Bullets and Numbering

5.9.4 Shadow sync

The use of the shadow sync table to indicate alternate encodings of a sample for random access are supported for as defined in the ISO Base Media File format. A shadow sync shall indicate a sample that is an independently decodable sample, which shall be encoded as either an I-frame or a SI-frame.

While the use of shadow sync for AVC content is supported for backward compatibility reasons, this use is deprecated and use of the mechanisms defined in subclause 5.12 is recommended.

© ISO/IEC 2002 — All rights reserved

5.10 Sample Groups

Formatted: Bullets and Numbering

5.10.1 Introduction

This subclause specifies a generic mechanism for representing a partition of the samples in a track. A *sample grouping* is an assignment of each sample in a track to be a member of one *sample group*, based on a grouping criterion. A sample group in a sample grouping is not limited to being contiguous samples and may contain non-adjacent samples. As there may be more than one sample grouping for the samples in track, each sample grouping has a type field to indicate the type of grouping. For example, a file might contain two sample groupings for the same track: one based on an assignment of sample to layers and another to sub-sequences.

Sample groupings are represented by two linked data structures: (1) a `SampleToGroup` box represents the assignment of samples to sample groups; (2) a `SampleGroupDescription` box contains a *sample group entry* for each sample group describing the properties of the group. There may be multiple instances of the `SampleToGroup` and `SampleGroupDescription` boxes based on different grouping criteria. These are distinguished by a type field used to indicate the type of grouping.

One example of using these tables is to represent the assignments of samples to *layers*. In this case each sample group represents one layer, with an instance of the `SampleToGroup` box describing which layer a sample belongs to. For more details, please refer to subclause 5.11

Formatted: Bullets and Numbering

5.10.1.1 SampleToGroup Box

5.10.1.1.1 Definition

Box Type: 'sbgp'
Container: Sample Table Box ('stbl')
Mandatory: No
Quantity: Zero or more.

This table can be used to find the group that a sample belongs to and the associated description of that sample group. The table is compactly coded with each entry giving the index of the first sample of a run of samples with the same sample group descriptor. The sample group description ID is an index that refers to a `SampleGroupDescription` box, which contains entries describing the characteristics of each sample group.

There may be mutiple instance of this box if there is more the one sample grouping for the samples in a track. Each instance of the `SampleToGroup` box has a type code that distinguishes different sample groupings. Within a track, there shall be a most instance of this box with a particular grouping type. The associated `SampleGroupDescription` shall indicate the same value for the grouping type.

Formatted: Bullets and Numbering

5.10.1.1.2 Syntax

```
aligned(8) class SampleToGroupBox
   extends FullBox('sbst', version = 0, 0)
{
   unsigned int(32)  grouping_type;
   unsigned int(32)  entry_count;
   for (i=1; i <= entry_count; i++)
```

© ISO/IEC 2002 — All rights reserved

```
    {
        unsigned int(32)  sample_count;
        unsigned int(32)  group_description_index;
    }
}
```

Formatted: Bullets and Numbering

5.10.1.1.3 Semantics

`version` is an integer that specifies the version of this box.

`grouping_type` is an integer that identifies the type (i.e. criterion used to form the sample groups) of the sample grouping and links it to its sample group description table with the same value for grouping type. At most once occurrence of this box with the same value for `grouping_type` value shall exist for a track.

`entry_count` is an integer that gives the number of entries in the following table.

`sample_count` is an integer that gives the number of consecutive samples in the group.

`group_description_index` is an integer that gives the index of the sample group entry which describes the samples in this group. The index ranges from 1 to the number of sample group entries in the `SampleGroupDescription` Box.

Formatted: Bullets and Numbering

5.10.1.2 Sample Group Description Box

5.10.1.2.1 Definition

Box Types: 'sgpd'
Container: Sample Table Box ('stbl')
Mandatory: No
Quantity: Zero or more, with one for each Sample Group Table box.

This description table gives information about the characteristics of sample groups. The descriptive information is any other information needed to define or characterize the sample group.

There may be mutiple instance of this box if there is more the one sample grouping for the samples in a track. Each instance of the `SampleGroupDescription` box has a type code that distinguishes different sample groupings. Within a track, there shall be a most instance of this box with a particular grouping type. The associated `SampleToGroup` shall indicate the same value for the grouping type.

The information is stored in the sample group description box after the entry-count. An abstract entry type is defined and sample groupings shall define derived types to represent the description of each sample group. For video tracks, an abstract `VisualSequenceEntry` is used with similar types for audio and hint tracks.

Formatted: Bullets and Numbering

5.10.1.2.2 Syntax

```
// Sequence Entry
abstract class SampleGroupDesriptionEntry (unsigned int(32) handler_type)
{
}

// Visual Sequence
abstract class VisualSampleGroupEntry (type) extends SampleGroupDesriptionEntry
(type)
```

© ISO/IEC 2002 — All rights reserved

```
{
}

// Audio Sequences
abstract class AudioSampleGroupEntry (type) extends SampleGroupDesriptionEntry(type)
{
}

aligned(8) class SampleGroupDescriptionBox (unsigned int(32) handler_type)
   extends FullBox('sgpd', 0, 0){
   unsigned int(32) grouping_type;
   unsigned int(32) entry_count;
   int i;
   for (i = 1 ; i <= entry_count ; i++){
      switch (handler_type){
         case 'vide': // for video tracks
            VisualSampleGroupEntry ();
            break;
         case 'soun': // for audio tracks
            AudioSampleGroupEntry();
            break;
         case 'hint': // for hint tracks
            HintSampleGroupEntry();
            break;
      }
   }
}
```

Formatted: Bullets and Numbering

5.10.1.2.3 Semantics

`version` is an integer that specifies the version of this box.

`grouping_type` is an integer that identifies the `SampleToGroup` box that is associated with this sample group description.

`entry_count` is an integer that gives the number of entries in the following table.

Formatted: Bullets and Numbering

5.11 Layering and sub-sequences

Streams may be constructed so that the referential dependencies between samples allow only subsets of the samples to be sent to the decoder. This mechanism is called *thinning* a stream and is entirely transparent to the decoder receiving the elementary stream. Thinning discards entire sets of samples using knowledge of what other sets of pictures this set of pictures depends on and what picture sets in turn depend on it.

The referential dependencies between samples in a stream are structured into *layers* and *sub-sequences*. Samples in higher layers can only depend on samples in lower layers. Layers are numbered, and the samples organized such that a sample in layer N has no dependencies on samples in layers greater than N.

© ISO/IEC 2002 — All rights reserved

Sub-sequences are sets of samples that have external referential dependencies on other sets of samples. Dependency relations between sub-sequences represent the dependency structure of a stream. The samples in a sub-sequence can be disposed of as a unit when thinning streams. Each sub-sequence belongs to one and only one layer. A sample shall reside in one layer and in one sub-sequence only.

Layering and sub-sequences are not features of the codec but this information is represented in the file format to allow systems reading the files to understand the ways in which stream thinning may be achieved without having to examine the dependency structure of every sample.

Formatted: Bullets and Numbering

5.11.1.1 Sub-Sequence Description Entry

Box Types: 'jvss'
Container: Sample Group Description Box ('sgpd')
Mandatory: No
Quantity: Zero or more.

A sub-sequence description entry is a sample group entry that describes a sub-sequence. A sub-sequence is a set of samples in a track belonging to the same layer. A sub-sequence depends on another sub-sequence if and only if there exists a sample in the this sub-sequence that is directly referentially dependent on some sample in the other sub-sequence. All sample in a sub-sequence shall be depend only on other samples within the same sub-sequence or samples in the sub-sequences on which is it dependent. A sub-sequence can depend on zero or more sub-sequences in the same or lower layers. A sub-sequence shall not depend on sub-sequences in the higher scalability layers.

Formatted: Bullets and Numbering

5.11.1.1.1 Syntax

```
aligned(8) class DependencyInfo
{
    unsigned int(8)   layerNumber;
    unsigned int(32)  subSequenceIdentifier;
}

class AVCSubSequenceEntry () extends VisualSampleGroupEntry ('jvss')
{
    unsigned int(32) subSequenceIdentifer;
    unsigned int(32) avgBitRate;
    unsigned int(32) avgFrameRate;
    unsigned int(16) numReferences;
    DependencyInfo dependency[numReferences];
}
```

Formatted: Bullets and Numbering

5.11.1.1.2 Semantics

`layerNumber` and `subSequenceIdentifier` within the `DependencyInfo` class identify a sub-sequence that is used as a reference for this sub-sequence. Only direct, not indirect, referential dependencies shall be identified.

`subSequenceIdentifier` in the Sub-Sequence Box gives the identifier for the sub-sequence.

`avgBitRate` gives the average bit rate in bits/second of the sub-sequence within the segment. All NAL units belonging to pictures in the layer are taken into account in the calculation. A value of zero means an undefined bit rate.

`avgFrameRate` gives the average frame rate in frames/(256 seconds) of the sub-sequence within the segment. A value of zero means an undefined frame rate.

© ISO/IEC 2002 — All rights reserved

numReferences gives the number of sub-sequences directly referenced in this sub-sequence. dependency is an array of DependencyInfo structures giving the identification information of the referenced sub-sequences.

5.11.1.2 Layer Description Entry

Formatted: Bullets and Numbering

Box Types: 'jvll'
Container: Sample Group Description Box ('sgpd')
Mandatory: No
Quantity: Zero or more.

A layer sample group entry defines the layer information for all samples in a layer. Layers are ordered hierarchically based on their dependency on each other: The first or base layer is independently decodable. The second and subsequent layers are enhancement layers that depend on some data in the base layer. Pictures in a higher layer can only depend on pictures in lower layers.

5.11.1.2.1 Syntax

Formatted: Bullets and Numbering

```
class AVCLayerEntry() extends VisualSampleGroupEntry ('jvll')
{
  unsigned int(8)  layerNumber;
  unsigned int(32) avgBitRate;
  unsigned int(32) avgFrameRate;
}
```

5.11.1.2.2 Semantics

Formatted: Bullets and Numbering

layerNumber gives the number of this layer with the base layer being numbered as zero and all enhancement layers being numbered as one or higher with consecutive numbers.

avgBitRate gives the average bit rate in bits/second of the layer within the segment. A value of zero indicates an undefined bit rate.

avgFrameRate gives the average frame rate in frames per 1000 seconds of this layer with a value of zero indicating an undefined frame rate.

Formatted: Bullets and Numbering

5.12 Alternate Streams and Switching Pictures

In typical streaming scenarios, one of the key requirements is to scale the bit rate of the compressed data in response to changing network conditions. The simplest way to achieve this is to encode multiple streams wi th different bandwidths and quality settings for representative network conditions. The server can then switch amongst these pre-coded streams in response to network conditions. In current standards, switching between streams is only possible at I-frames, because the frames can only be switched when there are no dependencies on prior pictures for reconstruction.

AVC has adopted SP-pictures and SI-pictures ("switching pictures") that allow switching from one stream to another while still supporting inter-frame coding of switching pictures. Figure 3 shows how SP frames are used to switch between two different bit streams.

© ISO/IEC 2002 — All rights reserved

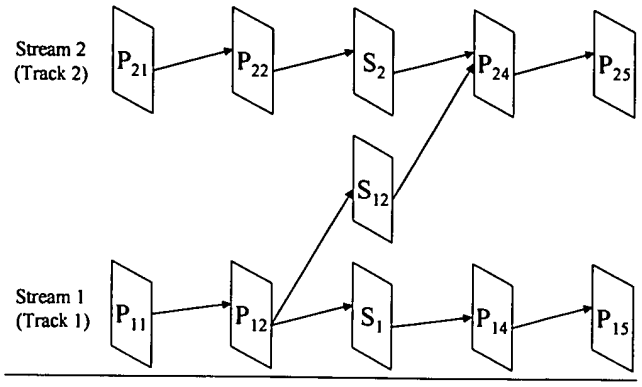

Figure 3: Stream Switching

In the file format, switching pictures are stored in *switching picture* tracks, which are tracks separate from the track that is being switched from and the track being switched to. Switching picture tracks can be identified by the existence of a specific required track reference in that track. A switching picture is an alternative to the sample in the destination track that has exactly the same decoding time. If all switching pictures are SI pictures, then no further information is needed.

If any of the pictures in the switching track are SP pictures, then two extra pieces of information may be needed. First, the source track, that is being switched from, must be identified by using a track reference (the source track may be the same track as the destination track). Second, the dependency of the switching picture on the samples in the source track may be needed, so that a switching picture is only used when the pictures on which it depends have been supplied to the decoder.

This dependency is represented by means of an optional extra sample table. There is one entry per sample in the switching track. Each entry records the relative sample numbers in the source track on which the switching picture depends. If this array is empty for a given sample, then that switching sample contains an SI picture. If the dependency box is not present, then only SI-frames shall be present in the track.

A switching sample may have multiple coded representations with different dependencies. For AVC video, the multiple representations are stored in the same sample (i.e. access unit) using the existing facility to have multiple coded representations in the same access unit. For example, one switch sample might contain a SP-picture representation dependent on some earlier samples, used for stream switching, and another representation as an SI-picture, used for random access.

Formatted: Bullets and Numbering

5.12.1 Alternate Group

The ISO media file format (but not the version one specification of the MPEG-4 file format, which is branded as 'mp41') supports the use of what is called *alternate tracks*. Each track can optionally specify an *alternate group* (in the track header box) that groups together alternate encodings of the same content. Thus, each alternate bit-stream can be stored as a separate track in the MP4 and related together as alternate tracks. All the tracks which form a group which may be switched between, but not the tracks containing the switching pictures, must be a member of an `alternate_group` with a non-zero group identifier.

An alternate group is not needed if there is only one primary track, with a switching track. This switching track may contain SI pictures, or SP pictures for trick modes or error resilience, which predict both from and to the same track.

© ISO/IEC 2002 — All rights reserved

Formatted: Bullets and Numbering

5.12.2 Track references

The switching track must be linked to the track into which it switches (the destination track) by a track reference of type 'swto' in the switching picture track.

If the switching track contains SP pictures, the switching track must be linked to the track from which it switches (the source track) by a track reference of type 'swfr' in the switching picture track.

Formatted: Bullets and Numbering

5.12.3 Sample dependency

This subclause defines the dependencies of each switching sample on sample(s) in the source track. This table is only needed in a switching track which has a source ('swfr') track dependency.

Formatted: Bullets and Numbering

5.12.3.1 Definition

Box Type: 'sdep'
Container: Sample Table 'stbl'
Mandatory: No
Quantity: Zero or exactly one.

This box contains the sample dependencies for each switching sample. The dependencies are stored in the table, one record for each sample. The size of the table, `sample_count` is taken from the `sample_count` in the Sample Size Box ('stsz').

Formatted: Bullets and Numbering

5.12.3.1.1 Syntax

```
aligned(8) class SampleDependencyBox
   extends FullBox('sdep', version = 0, 0) {
   bit(1) multiple_representation_flag;
   bit(7) reserved = 0;
   for (i=0; i < sample_count; i++)
      if (multipleRep)
         representation_count = 1;
      else
         unsigned int(16) representation_count;
      for (j=0; j < representation_count; j++) {
         unsigned int(16) dependency_count;
         for (k=0; k < dependency_count; k++) {
            signed int(16) relative_sample_number;
         }
      }
   }
}
```

Formatted: Bullets and Numbering

5.12.3.1.2 Semantics

`mutiple_representation_flag` - is an flag that indicates whether each switching sample has multiple representations, each with its own separate dependency information.

`representation_count` - is an integer that a counts the number of representations in the switch sample. If

`dependency_count` - is an integer that a counts the number of samples in the source track on which this switching sample directly depends.

© ISO/IEC 2002 — All rights reserved

`relative_sample_number` - is an integer that identifies a sample in the source track. The relative sample numbers are encoded as follows. If there is a sample in the source track with the same decoding time, it has a relative sample number of 0. Whether or not this sample exists, the sample in the source track which immediately precedes the decoding time of the switching sample has relative sample number –1, the sample before that –2, and so on. Similarly, the sample in the source track which immediately follows the decoding time of the switching sample has relative sample number +1, the sample after that +2, and so on.

5.13 Representation of new structures in Movie Fragments

[TBD]

5.14 Use of the AVC File Format in MPEG-4 Systems

This subclause specifies how the AVC file format shall be used when the file is marked as being compatible with the MPEG-4 file format specified in ISO/IEC 14496-1:2001 Amendment 6. This subclause applies when the file is branded with the MPEG-4 file format brand of 'mp41' or 'mp42', and the AVC video data must be used in an MPEG-4 systems context.

5.14.1 Forming the Elementary Stream Descriptor

As is normal for MPEG-4 streams, the TrackID is related to the `ElementaryStreamID` and the `SLConfigDescriptor`is generated following the rules for any MPEG-4 stream The format of the ES Descriptor is specified in chapter 13 of the MPEG-4 systems specification [ISO/IEC 14966:2001].

If the Elementary Stream Descriptor should contain any other descriptors than `SLConfigDescriptor` or `DecoderConfigDescriptor` they are stored in the Sample Description as defined in subclause 5.9.1.1.

5.14.2 Forming the DecoderConfigDescriptor

The object type and stream type indications have the values defined in subclause 4.2 for AVC streams.

The `buffersizeDB`, `maxBitrate`, and `avgBitrate` fields can be filled by inspection of the VUI Sequence Parameters, if present in the sequence parameter set for the AVC stream.

The `DecoderSpecificInfo`is formed using the contents of the `AVCConfigurationBox`

5.14.3 Profile and Level Indication

The MPEG-4 `ProfileLevelIndication`can be deduced from the AVC Profile and Level Indication found in the `AVCDecoderConfiguration`

[Editor's note: Until the code-points are assigned, it's not clear whether this is a one-one mapping.]

5.14.4 Elementary Stream Descriptors

The use of multiple non-dependent elementary stream descriptors may *also* be indicated by the presence of more than one independent AVC video elementary stream descriptors in an object descriptor.

Formatted: Bullets and Numbering

5.14.5 Switching Picture Tracks

Formatted: Bullets and Numbering

Switching picture tracks are *not* MPEG-4 elementary streams and shall not be included within an MPEG-4 object descriptor.

5.15 Possible issues

Formatted: Bullets and Numbering

5.15.1 Typical patterns of NAL Unit sizes etc.

Formatted: Bullets and Numbering

This design could probably benefit from more knowledge of typical patterns of use and sizes etc. For example, repeating patterns etc. can be leveraged to reduce overhead, and the sizes of fields adjusted (e.g. the relative sample number). See, for example, N8708.

5.15.2 Do we need better visibility into where SEIs occur?

Formatted: Bullets and Numbering

If an application wishes to answer "where are the SEI messages in this stream?" it must search all samples for those beginning with SEIs. We are unaware of a need for such a search, but if such need arises, some kind of indexing for the SEIs may be needed.

5.15.3 Do we need to allow parameter set updates in the OD stream?

Formatted: Bullets and Numbering

The file format effectively allowing update of `DecoderSpecificInfo` which might change parameters such as the visual width and height (though the file format normalizes these). Does MPEG-4 systems need to allow such re-configuration of existing streams, or should we express constraints on the changes in configuration permitted in an MPEG-4 context?

5.15.4 Will chunking be affected by Parameter Set changes?

Formatted: Bullets and Numbering

All the samples in a chunk share a single configuration. If parameter sets change frequently, and this causes the configuration to change frequently, this would have a significant adverse impact on the size of the file-format sample tables. Typical patterns of use would again be of assistance here.

5.15.5 Layering and sub-sequences

Formatted: Bullets and Numbering

This whole area is provisional before we get clarification on a number of issues, including, but not limited to:

Formatted: Bullets and Numbering

i. Clarifying whether there is one division into layers and sub-sequences, or multiple;

ii. What 'layers' mean if sub-sequences may be selected from any layer, provided that their dependents have been decoded;

iii. Given that sub-sequences begin and end and then begin again, what the exact meaning of a 'dependency' is (on which instances?);

iv. What the use of sub-sequence identifiers is; whether they refer to definitions or instances, and if the latter, how the identifier space is managed in an indefinite duration sequence;

v. How the beginning and end of a sub-sequence can be identified;

© ISO/IEC 2002 — All rights reserved

vi. Whether dependencies are only direct, or transitive;

vii. What the meaning of the bit-rate etc. are, in the definition of sub-sequences, with respect to the individual instances of the sub-sequences.

© ISO/IEC 2002 — All rights reserved

4.1.5.2AVC Stream DecoderSpecificInfo

This subclause defines the `DecoderSpecificInfo` descriptor for an AVC elementary stream.

4.1.5.2.1Syntax

```
aligned(8) class AVCDecoderSpecificInfo extends DecoderSpecificInfo : bit(8)
tag=DecSpecificInfoTag {
        AVCVideoConfigurationRecord config;
}
```

4.1.5.2.2Semantics

The decoder specific information for an AVC stream contains an AVC video stream decoder configuration record.

`config` contains the decoder configuration record for the AVC elementary stream decoder configuration.

4.1.5.3Parameter Set Update

Initialparameter sets are supplied in the `DecoderSpecificInfo` for the AVC video stream, as defined in subclause 4.1.5.1. Ifparameter sets must be updated, then one of two methods can be used:

a)Parameter Set NAL units may be inserted in the video stream;

b)a separate parameter set stream may be used to carry parameter set updates, possibly using a transport with different error resilience or reliability characteristics.

4.1.6AVC DecoderConfigDescriptor

The `DecoderConfigDescriptor` shall set the value of `streamtype` equal to 0x04 for both AVC video elementary stream and the AVC parameter set elementary streams.

The `DecoderConfigDescriptor` for an AVC video elementary stream, possibly including in-lineparameter set updates, shall set `objectTypeIndication` to be 0x21 (ISO/IEC 14496-10 Visual). For the AVC parameter set elementary stream, the `objectTypeIndication` value shall equal 0x22 (ISO/IEC 14496-10 Visual Parameter Sets).

4.1.7Elementary Stream Descriptor

If the parameter set elementary stream is present, the elementary stream descriptors for the two streams shall satisfy the following conditions:

(1)The video elementary stream is dependent on the parameter set elementary stream and the `ES_Descriptor` for the video elementary stream shall have a `streamDependenceFlag` equal to true and indicate the ESID of the parameter in the

dependsOnESID field. The streamDependenceFlag in the ES_Descriptor for the parameter set elementary stream shall be false.
(2)The elementary stream clocks for the parameter set elementary stream and the video elementary stream shall be the same and synchronized. The OCRstreamflag and OCR_ES_Id fields in the ESDescriptor for the video elementary stream and parameter set elementary streams shall be used to indicate that both streams share the same OCR.

4.2Codepoints

4.2.1visualProfileLevelIndication

Ed's Note:What should the visual profile level indication in the initial object descriptor be? Is it even necessary to add a new one? The list below does not seem up to date anyway and I do not recall any amendments to MPEG-4 Systems that touch this table.

Replace Table 6 in ISO/IEC 14496 with the following table:
Table 11 - visualProfileLevelIndication Values

Value	Profile	Level
0x00	Reserved for ISO use	-
0x01	Simple	L3
0x02	Simple	L2
0x03	Simple	L1
0x04	Simple Scalable	L2
0x05	Simple Scalable	L1
0x06	Core	L2
0x07	Core	L1
0x08	Main	L4

0x6D - 0xBF	reserved for ISO use
0xC0 - 0xFE	user private
0xFF	no object type specified

[a] This object type shall be used for all streamTypes defined in ISO/IEC 14496-1 except IPMP streams.

[b] Includes associated Amendment(s) and Corrigendum(a).

[c] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-2 and are conveyed in the DecoderSpecificInfo as specified in ISO/IEC 14496-2, Annex K.

[d] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-3 and are conveyed in the DecoderSpecificInfo as specified in ISO/IEC 14496-3 subpart 1 subclause 6.2.1.

[e] Includes associated Amendment(s) and Corrigendum(a). The actual object types are defined in ISO/IEC 14496-10 and are conveyed in the DecoderSpecificInfo as specified in this admendment, subclause 4.1.5.

4.3Extensibility

The configuration description format may be extended in future versions of this specification. Similarly, the definition of an AVC Access Unit allows for extension by future versions of this specification.

5File Format

5.1Introduction

This subclause defines how to store ISO/IEC 14496-10 data in the MP4 file format. The storage of AVC content uses the existing capabilities of the MP4 file format but also defines new features to support the following features of the AVC codec in the MP4 file format:

Switch Pictures: To enable switching between different coded streams and substitution of pictures within the same stream.

Enhanced Group of Pictures: Provides a structuring of the dependencies of a group of pictures to provide both random access and flexible stream structure (e.g. temporal scalability and layering).

Parameter Sets: The values needed to decode a video coding data are grouped together into a singleparameter set, which is referenced from each slice.

5.2Terminology

AVC	MPEG-4 Systems	MP4
-	Presentation	Movie
Stream	Elementary Stream	Track
Picture	Access Unit	Sample

AVC File type and identification

Conformance with this specification is indicated by the presence of the brand 'jvt1' in the compatible-brands list of the `FileTypeBox` as defined in the ISO Media File Format specification [ISO 14496-1:2001, Amd. 5].
Readers conformant to this specification should read the file if this brand occurs in the compatible-brands list. Other structures and/or track types, defined in other specifications, may be present, and these may be ignored by a conformant reader.
If the major-brand is 'jvt1', then

the minor-version, as defined in this version of this specification, shall be 1.
the file extension shall be ".jvt" [to be checked for collision]
the mime type used to serve the file shall be "video/jvt" [to be allocated]

AVC Track Structure

In the terminology of the ISO Media File Format Specification, an AVC track is a video or visual track. It therefore uses:

a `handler_type` of `'vide'` in the `HandlerBox`;
a video media header `'vmhd'`;

and, as defined below, a derivative of the `VisualSampleEntry`.

Canonical order and restrictions

The AVC elementary stream is stored in the MP4 file format in a *canonical* format. The canonical format is as *neutral* as possible so that systems that need to customize the stream for delivery over different transport protocols – MPEG-2 Systems, RTP, and so on — should not have to *remove* information from the stream while being free to *add* to the stream. Furthermore, a canonical format allows such operations to be performed against a known initial state.

The canonical stream format is an AVC video stream that satisfies the following conditions:

No parameter sets in the video elementary stream. Allparameter set information shall be stored in the sample descriptions for the track. This ensures that it is not necessary to examine every part of the elementary stream to find relevant parameter sets. It also avoids dependencies of indefinite duration between the sample that contains the parameter set definition and the samples that use it. Parameter sets may be inserted into the video elementary stream when the file is streamed over a transport that permits such parameter set updates.

All timing information is external to stream. Timing SEI messages that define presentation or composition timestamps shall not be included in the AVC elementary stream. All timing information is stored in the various sample metadata tables. If timing information were embedded in the stream, then there would be a great danger of inconsistency, and a key feature of MP4, that editing can take place without modifying elementary streams, would break.

All SEI messages are at the beginning of an AU. NAL units included in an access unit shall be ordered so that all SEI messages occur before all video NAL units (slices or data partitions) in the access unit. This allows a rapid inspection of the sample to determine whether it contains SEI messages. All SEI messages shall be contained in a single SEI message NAL unit.

Slice and Partition Ordering. All slices in a single pictureshall occur in scan order. Similarly, all data partitions of a slice shall occur in the order: 'A' partition, 'B' partition, and 'C' partition. No interleaving of partitions from different slices is allowed.

□*No start codes.* The elementary stream shall not include start codes. As stored, each NAL Unit is preceded by a length field; this enables easy scanning of the sample's NAL Units. Systems that use start-codes will reformat the stream to use start codes.

No picture delimiter NAL units. Picture delimiting is defined by the sample structure of the file format. Picture delimiter NAL units shall not be present in the sample data.

No filler data. Video data is naturally represented as VBR in the file format and should be filled for transmission if needed. Filler NAL units and Filler SEI messages shall not be present in the file format stored stream.

Note that these restrictions are more restrictive than the use of AVC in MPEG-4 systems.

5.6Sample format

A file format sample is a picture in AVC terms, and an access unit in MPEG-4 terms. The sample data shall follow the syntax and semantics defined for AVC video access

units in subclause 4.1.4. Note, this format is used for storing data only and does not require the use of MPEG-4 systems framework to carry AVC visual data.

5.7Template Fields Used

The ISO Media File Format defines a number of fields which have default values but which may be defined for use by specific sub-systems. Tracks containing AVC data use the following template fields:
a)`alternate_group` in the `TrackHeaderBox` (see subclause 5.135.13 on stream switching);

5.8Visual Width and Height

The width and height fields in a `VisualSampleEntry` must correctly document the encoded width and height as indicated by the sequence parameter sets in the AVC stream that is described by that entry.
The width and height fields in the track header may not be the same as the width and height fields in the one or more `VisualSampleEntry` in the video track. As specified in the ISO Media File Format,all the sequences are normalized to the track width and height for presentation.

5.9HRD Conformance

[TBD]

5.10Sample Table elements

5.10.1Sample description name and format

5.10.1.1Sample Description Box

5.10.1.1.1Definition

Box Types: 'jvt1', 'jvtC', 'm4ds'
Container: Sample Table Box ('stbl')
Mandatory: Yes
Quantity: Exactly one
An AVC visual sample entry shall contain an AVC Visual Stream Configuration Box, as defined below. This includes a `AVCVideoDecoderConfigurationRecord`, as defined in subclause 4.1.5.1 as the content of `DecoderSpecificInfo` for MPEG-4. Extension descriptors that should be inserted into the Elementary Stream Descriptor, when used in MPEG-4, may also be present.
Multiple sample descriptions may be used, as permitted by the ISO Media File format specification, to indicate sections of video that use different configurations of parameter sets.

5.10.1.1.2Syntax

```
    // Visual Sequences
class AVCConfigurationBox extends Box('jvtC') {
    AVCVideoConfigurationRecord() AVCConfig;
}

class MPEG4DescriptorsBox extends Box('m4ds') {
    Descriptor Descr[0 .. 255];
}

class AVCSampleEntry() extends VisualSampleEntry ('jvt1'){
    AVCConfigurationBox  config;
    MPEG4ExtensionDescriptorsBox (); // optional
}
```

5.10.1.1.3Semantics

`Compressorname` in the base class `VisualSampleEntry` indicates the name of the compressor used with the value `"\016JVT/AVC Coding"` being recommended (\016 is 14, the length of the string as a byte)
`config` is defined in subclause 4.1.5.2.
`Descr` is a descriptor which should be placed in the `ElementaryStreamDescriptor` when this stream is used in an MPEG-4 context. This does not include `SLConfigDescriptor` or `DecoderConfigDescriptor`, but includes the other descriptors in order to be placed after the `SLConfigDescriptor`. The use of this field is specified in subclause 5.15.15.15.1.

5.10.1.2Parameter Sets

Each AVC sample description, which contains the AVC video stream decoder specific information, includes a group of sequence and picture parameter sets. This group of parameter sets functions much like a codebook. Each parameter set has an identifier, and each slice references the parameter set it was coded against using the parameter set's identifier.
In the file format each configuration of parameter sets is represented separately. A parameter set cannot be updated without causing a different sample description to be used. For example, suppose that samples 1-4 use picture parameter sets identified as 1, 2, 3 and a single sequence parameter set identified as 1. At sample 5 a new value of picture parameter set 2 is required but picture parameter sets 1 and 3 remain unaltered and are used until sample 10. In this case, the sample description for samples 1 through 4 is the same and contains the initial values of picture parameter sets 1, 2, 3 and sequence parameter set 1. At sample 5 the sample description must change to a second sample description, which contains the updated value for picture parameter set 2 *as well as* the original values of picture parameter sets 1 and 3 and sequence parameter set 1. This second sample description is used for samples 5 through 10.
Systems wishing to sendparameter set updates will need to compare the two configurations to find the differences in order to send the appropriate parameter set updates.

5.10.2Decoding Time (DTS) and Composition Time (DTS)

Samples are stored in the file format in decoding order. If frame reordering is not used, this is also presentation order, and only the time-to-sample 'stts' table is used. Note that any kind of picture may be reordered in AVC video, not only B-frames.
If decoding time must be stored, the composition time-to-sample 'ctts' is also used.

5.10.3Sync sample (IDR)

A sync sample shall correspond to an instantaneously decodable picture in the AVC stream (also known as an Instantaneously Decodable Refresh point (IDR)).

5.10.4Shadow sync

The use of the shadow sync table to indicate alternate encodings of a sample for random access are supported for as defined in the ISO Base Media File format. A shadow sync shall indicate a sample that is an independently decodable sample, which shall be encoded as either an I-frame or a SI-frame.
While the use of shadow sync for AVC content is supported for backward compatibility reasons, this use is deprecated and use of the mechanisms defined in subclause 5.135.13 is recommended.

5.11Sample Groups

5.11.1Introduction

This subclause specifies a generic mechanism for representing a partition of the samples in a track. A *sample grouping* is an assignment of each sample in a track to be a member of one *sample group,* based on a grouping criterion. A sample group in a sample grouping is not limited to being contiguous samples and may contain non-adjacent samples. As there may be more than one sample grouping for the samples in track, each sample grouping has a type field to indicate the type of grouping. For example, a file might contain two sample groupings for the same track: one based on an assignment of sample to layers and another to sub-sequences.
Sample groupings are represented by two linked data structures: (1) a `SampleToGroup` box represents the assignment of samples to sample groups; (2) a `SampleGroupDescription` box contains a *sample group entry* for each sample group describing the properties of the group. There may be multiple instances of the `SampleToGroup` and `SampleGroupDescription` boxes based on different grouping criteria. These are distinguished by a type field used to indicate the type of grouping.
One example of using these tables is to represent the assignments of samples to *layers*. In this case each sample group represents one layer, with an instance of the `SampleToGroup` box describing which layer a sample belongs to. For more details, please refer to subclause 5.125.12

5.11.1.1SampleToGroup Box

5.11.1.1.1Definition

Box Type: 'sbgp'
Container: Sample Table Box ('stbl')
Mandatory: No
Quantity: Zero or more.

This table can be used to find the group that a sample belongs to and the associated description of that sample group. The table is compactly coded with each entry giving the index of the first sample of a run of samples with the same sample group descriptor. The sample group description ID is an index that refers to a `SampleGroupDescription` box, which contains entries describing the characteristics of each sample group.

There may be mutiple instance of this box if there is more the one sample grouping for the samples in a track. Each instance of the `SampleToGroup` box has a type code that distinguishes different sample groupings. Within a track, there shall be a most instance of this box with a particular grouping type. The associated `SampleGroupDescription` shall indicate the same value for the grouping type.

5.11.1.1.2Syntax

```
aligned(8) class SampleToGroupBox
                                                    extends FullBox('sbst',
version = 0, 0)
{
                                                    unsigned int(32)
                                                    grouping_type;
                                                    unsigned int(32)
                                                    entry_count;
                                                    for (i=1; i <= entry_count;
i++)
                                                    {
                                                     unsigned int(32)
                                                    sample_count;
                                                     unsigned int(32)
                                                    group_description_index;
                                                    }
}
```

5.11.1.1.3Semantics

`version` is an integer that specifies the version of this box.

`grouping_type` is an integer that identifies the type (i.e. criterion used to form the sample groups) of the sample grouping and links it to its sample group description table with the same value for grouping type. At most once occurrence of this box with the same value for `grouping_type` value shall exist for a track.

`entry_count` is an integer that gives the number of entries in the following table.

`sample_count` is an integer that gives the number of consecutive samples in the group.

`group_description_index` is an integer that gives the index of the sample group entry which describes the samples in this group. The index ranges from 1 to the number of sample group entries in the `SampleGroupDescription` Box.

5.11.1.2Sample Group Description Box

5.11.1.2.1Definition

Box Types: 'sgpd'
Container: Sample Table Box ('stbl')
Mandatory: No
Quantity: Zero or more, with one for each Sample Group Table box.
This description table gives information about the characteristics of sample groups. The descriptive information is any other information needed to define or characterize the sample group.
There may be mutiple instance of this box if there is more the one sample grouping for the samples in a track. Each instance of the `SampleGroupDescription` box has a type code that distinguishes different sample groupings. Within a track, there shall be a most instance of this box with a particular grouping type. The associated `SampleToGroup` shall indicate the same value for the grouping type.
The information is stored in the sample group description box after the entry-count. An abstract entry type is defined and sample groupings shall define derived types to represent the description of each sample group. For video tracks, an abstract `VisualSequenceEntry` is used with similar types for audio and hint tracks.

5.11.1.2.2Syntax

```
// Sequence Entry
abstract class SampleGroupDesriptionEntry (unsigned int(32) handler_type)
{
}

// Visual Sequence
abstract class VisualSampleGroupEntry (type) extends SampleGroupDesriptionEntry
(type)
{
}

// Audio Sequences
abstract class AudioSampleGroupEntry (type) extends
SampleGroupDesriptionEntry(type)
{
}

aligned(8) class SampleGroupDescriptionBox (unsigned int(32) handler_type)
                                                    extends FullBox('sgpd', 0,
0){
                                                    unsigned int(16)
```

```
grouping_type;                                          unsigned int(32)

entry_count;                                            int i;
                                                        for (i = 1 ; i <= entry_count
; i++){
                                                         switch (handler_type){
                                                              case 'vide': // for video
tracks

                                                        VisualSampleGroupEntry
();
                                                                 break;
                                                              case 'soun': // for
audio tracks

                                                        AudioSampleGroupEntry();
                                                                 break;
                                                              case 'hint': // for hint
tracks

                                                        HintSampleGroupEntry();
                                                                 break;
                                                         }
                                                        }
}
```

5.11.1.2.3Semantics

`version` is an integer that specifies the version of this box.
`grouping_type` is an integer that identifies the `SampleToGroup` box that is associated with this sample group description.
`entry_count` is an integer that gives the number of entries in the following table.

5.12Layering and sub-sequences

Streams may be constructed so that the referential dependencies between samples allow only subsets of the samples to be sent to the decoder. This mechanism is called *thinning* a stream and is entirely transparent to the decoder receiving the elementary stream. Thinning discards entire sets of samples using knowledge of what other sets of pictures this set of pictures depends on and what picture sets in turn depend on it.
The referential dependencies between samples in a stream are structured into *layers* and *sub-sequences*. Samples in higher layers can only depend on samples in lower layers. Layers are numbered, and the samples organized such that a sample in layer N has no dependencies on samples in layers greater than N.

Sub-sequences are sets of samples that have external referential dependencies on other sets of samples. Dependency relations between sub-sequences represent the dependency structure of a stream. The samples in a sub-sequence can be disposed of as a unit when thinning streams. Each sub-sequence belongs to one and only one layer. A sample shall reside in one layer and in one sub-sequence only.
Layering and sub-sequences are not features of the codec but this information is represented in the file format to allow systems reading the files to understand the ways in which stream thinning may be achieved without having to examine the dependency structure of every sample.

5.12.1.1Sub-Sequence Description Entry

Box Types: 'jvss''
Container: Sample Group Description Box ('sgpd')
Mandatory: No
Quantity: Zero or more.
A sub-sequence description entry is a sample group entry that describes a sub-sequence. A sub-sequence is a set of samples in a track belonging to the same layer. A sub-sequence depends on another sub-sequence if and only if there exists a sample in the this sub-sequence that is directly referentially dependent on some sample in the other sub-sequence. All sample in a sub-sequence shall be depend only on other samples within the same sub-sequence or samples in the sub-sequences on which is it dependent. A sub-sequence can depend on zero or more sub-sequences in the same or lower layers. A sub-sequence shall not depend on sub-sequences in the higher scalability layers.

5.12.1.1.1Syntax

```
aligned(8) class DependencyInfo
{
                                                    unsigned int(8)
layerNumber;
                                                    unsigned int(32)
subSequenceIdentifier;
}

class AVCSubSequenceEntry () extends VisualSampleGroupEntry ('jvss')
{
                                                    unsigned int(32)
subSequenceIdentifer;
                                                    unsigned int(32)
avgBitRate;
                                                    unsigned int(32)
avgFrameRate;
                                                    unsigned int(16)
numReferences;
                                                    DependencyInfo
dependency[numReferences];
```

}

}

5.12.1.1.2Semantics

`layerNumber` and `subSequenceIdentifier` within the `DependencyInfo` class identify a sub-sequence that is used as a reference for this sub-sequence.
`subSequenceIdentifier` in the Sub-Sequence Box gives the identifier for the sub-sequence.
`avgBitRate` gives the average bit rate in bits/second of the sub-sequence within the segment. All NAL units belonging to pictures in the layer are taken into account in the calculation. A value of zero means an undefined bit rate.
`avgFrameRate` gives the average frame rate in frames/(256 seconds) of the sub-sequence within the segment. A value of zero means an undefined frame rate.
`numReferences` gives the number of sub-sequences directly referenced in this sub-sequence. `dependency` is an array of `DependencyInfo` structures giving the identification information of the referenced sub-sequences.

5.12.1.2Layer Description Entry

Box Types: 'jvll'
Container: Sample Group Description Box ('sgpd')
Mandatory: No
Quantity: Zero or more.
A layer sample group entry defines the layer information for all samples in a layer. Layers are ordered hierarchically based on their dependency on each other: The first or base layer is independently decodable. The second and subsequent layers are enhancement layers that depend on some data in the base layer. Pictures in a higher layer can only depend on pictures in lower layers.

5.12.1.2.1Syntax

```
class AVCLayerEntry() extends VisualSampleGroupEntry ('jvll')
{
                                                    unsigned int(8)
layerNumber;
                                                    unsigned int(32)
avgBitRate;
                                                    unsigned int(32)
avgFrameRate;
}
```

5.12.1.2.2Semantics

`layerNumber` gives the number of this layer with the base layer being numbered as zero and all enhancement layers being numbered as one or higher with consecutive numbers.

`avgBitRate` gives the average bit rate in bits/second of the layer within the segment. A value of zero indicates an undefined bit rate.
`avgFrameRate` gives the average frame rate in frames per 1000 seconds of this layer with a value of zero indicating an undefined frame rate.

5.13Alternate Streams and Switch Pictures

In typical streaming scenarios, one of the key requirements is to scale the bit rate of the compressed data in response to changing network conditions. The simplest way to achieve this is to encode multiple streams with different bandwidths and quality settings for representative network conditions. The server can then switch amongst these pre-coded streams in response to network conditions. In current standards, switching between streams is only possible at I-frames, because the frames can only be switched when there are no dependencies on prior pictures for reconstruction.
AVC has adopted SP-pictures and SI-pictures ("switching pictures") that allow switching from one stream to another while still supporting inter-frame coding of switch pictures. Figure 3 shows how SP frames are used to switch between two different bit streams.

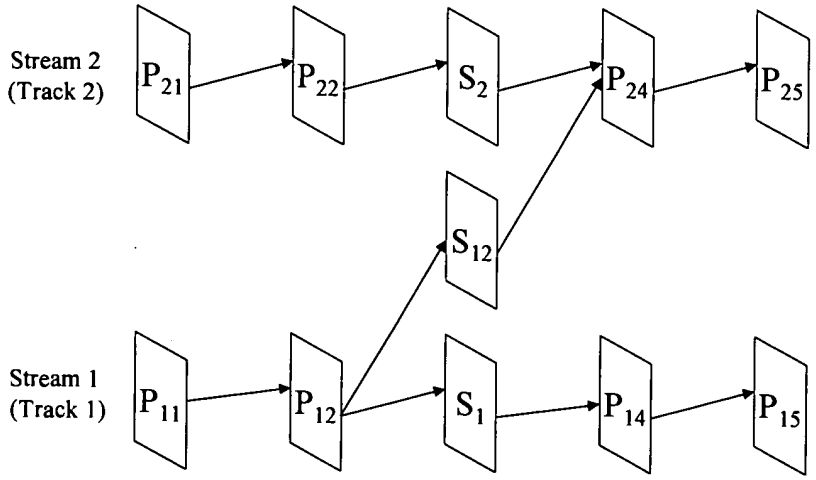

Figure 3: **Stream Switching**

In the file format, switch pictures are stored in *switch picture* tracks, which are tracks separate from the track that is being switched from and the track being switched to. Switch picture tracks can be identified by the existence of a specific required track reference in that track. A switch picture is an alternative to the sample in the destination track that has exactly the same decoding time. If all switch pictures are SI pictures, then no further information is needed.
If any of the pictures in the switch track are SP pictures, then two extra pieces of information may be needed. First, the source track, that is being switched from, must be identified by using a track reference (the source track may be the same track as the destination track). Second, the dependency of the switch picture on the samples in the source track may be needed, so that a switch picture is only used when the pictures on which it depends have been supplied to the decoder.
This dependency is represented by means of an optional extra sample table. There is one entry per sample in the switch track. Each entry records the relative sample numbers in the source track on which the switch picture depends. If this array is empty for a given

sample, then that switch sample contains an SI picture. If the dependency box is not present, then only SI-frames shall be present in the track.

5.13.1Alternate Group

The ISO media file format (but not the version one specification of the MPEG-4 file format, which is branded as 'mp41') supports the use of what is called *alternate tracks*. Each track can optionally specify an *alternate group* (in the track header box) that groups together alternate encodings of the same content. Thus, each alternate bit-stream can be stored as a separate track in the MP4 and related together as alternate tracks. All the tracks which form a group which may be switched between, but not the tracks containing the switch pictures, must be a member of an `alternate_group` with a non-zero group identifier.
An alternate group is not needed if there is only one primary track, with a switch track. This switch track may contain SI pictures, or SP pictures for trick modes or error resilience, which predict both from and to the same track.

5.13.2Track references

The switch track must be linked to the track into which it switches (the destination track) by a track reference of type 'swto' in the switch-picture track.
If the switch track contains SP pictures, the switch track must be linked to the track from which it switches (the source track) by a track reference of type 'swfr' in the switch-picture track.

5.13.3Sample dependency

This subclause defines the dependencies of each switch sample on sample(s) in the source track. This table is only needed in a switch track which has a source ('swfr') track dependency.

5.13.3.1Definition

Box Type: 'sdep'
Container: Sample Table 'stbl'
Mandatory: No
Quantity: Zero or exactly one.
This box contains the sample dependencies for each switch sample. The dependencies are stored in the table, one record for each sample. The size of the table, `sample_count` is taken from the `sample_count` in the Sample Size Box ('stsz').

5.13.3.1.1Syntax

```
aligned(8) class SampleDependencyBox
    extends FullBox('sdep', version = 0, 0) {
    int i;
    for (i=0; i < sample_count; i++) {
        unsigned int(16) dependency_count;
        for (j=0; j < dependency_count; j++) {
            signed int(16) relative_sample_number;
```

```
        }
    }
}
```

5.13.3.1.2Semantics

`dependency_count` - is an integer that a counts the number of samples in the source track on which this switch sampledepends.
`relative_sample_number` - is an integer that identifies a sample in the source track. The relative sample numbers are encoded as follows. If there is a sample in the source track with the same decoding time, it has a relative sample number of 0. Whether or not this sample exists, the sample in the source track which immediately precedes the decoding time of the switch sample has relative sample number –1, the sample before that –2, and so on. Similarly, the sample in the source track which immediately follows the decoding time of the switch sample has relative sample number +1, the sample after that +2, and so on.

5.14Representation of new structures in Movie Fragments

[TBD]

5.15Use of the AVC File Format in MPEG-4 Systems

This subclause specifies how the AVC file format shall be used when the file is marked as being compatible with the MPEG-4 file format specified in ISO/IEC 14496-1:2001 Amendment 6. This subclause applies when the file is branded with the MPEG-4 file format brand of 'mp41' or 'mp42', and the AVC video data must be used in an MPEG-4 systems context.

5.15.1Forming the Elementary Stream Descriptor

As is normal for MPEG-4 streams, the TrackID is related to the `ElementaryStreamID`, and the `SLConfigDescriptor` is generated following the rules for any MPEG-4 stream The format of the ES Descriptor is specified in chapter 13 of the MPEG-4 systems specification [ISO/IEC 14966:2001].
If the Elementary Stream Descriptor should contain any other descriptors than `SLConfigDescriptor` or `DecoderConfigDescriptor`, they are stored in the Sample Description as defined in subclause 5.10.1.15.10.1.1.

5.15.2Forming the DecoderConfigDescriptor

The object type and stream type indications have the values defined in subclause 4.2 for AVC streams.
The `buffersizeDB`, `maxBitrate`, and `avgBitrate` fields can be filled by inspection of the VUI Sequence Parameters, if present in the sequence parameter set for the AVC stream.

The `DecoderSpecificInfo` is formed using the contents of the `AVCConfigurationBox`.

5.15.3Profile and Level Indication

The MPEG-4 `ProfileLevelIndication` can be deduced from the AVC Profile and Level Indication found in the `AVCDecoderConfiguration`.
[Editor's note: Until the code-points are assigned, it's not clear whether this is a one-one mapping.]

5.15.4Elementary Stream Descriptors

The use of multiple non-dependent elementary stream descriptors may *also* be indicated by the presence of more than one independent AVC video elementary stream descriptors in an object descriptor.

5.15.5Switch Picture Tracks

Switch picture tracks are *not* MPEG-4 elementary streams and shall not be included within an MPEG-4 object descriptor.

5.16Possible issues

5.16.1Need a sample fragment table?

Is the use of in-line size indicators for NAL Units sufficient or should those sizes be represented in new meta-data tables? See, for reference, the proposed sample fragment metadata tables in N8708.

5.16.2Typical patterns of NAL Unit sizes etc.

This design could probably benefit from more knowledge of typical patterns of use and sizes etc. For example, repeating patterns etc. can be leveraged to reduce overhead, and the sizes of fields adjusted (e.g. the relative sample number). See, for example, N8708.

5.16.3Do we need better visibility into where SEIs occur?

If an application wishes to answer "where are the SEI messages in this stream?" it must search all samples for those beginning with SEIs. We are unaware of a need for such a search, but if such need arises, some kind of indexing for the SEIs may be needed.

5.16.4Alternatives are tracks but layers are in-stream?

Alternative designs for switching could put the streams into the same track, or for layering could put the layers into different tracks.

5.16.5Do we need to allow parameter set updates in the OD stream?

The file format effectively allowing update of `DecoderSpecificInfo`, which might change parameters such as the visual width and height (though the file format normalizes these). Does MPEG-4 systems need to allow such re-configuration of existing streams,

or should we express constraints on the changes in configuration permitted in an MPEG-4 context?

5.16.6Will chunking be affected by Parameter Set changes?

All the samples in a chunk share a single configuration. If parameter sets change frequently, and this causes the configuration to change frequently, this would have a significant adverse impact on the size of the file-format sample tables. Typical patterns of use would again be of assistance here.

5.16.7SEI Messages and Parameter Sets

Should access units without any video data and containing only SEI messages and/or parameter sets be allowed? Currently, such access units are not supported.

5.16.8Non-stored pictures

When decoding frames to 'roll forward' or other random access, it would save a lot of disk accesses if it were evident from the sample table what was a non-stored frame (i.e. frames on which no others depend).

5.16.9Picture Delimiters

Should we always have a picture delimiter in the frames? If a picture delimiter is present, perhaps it ought to be first, before the SEIs?

5.16.10Timing of Parameter Set Updates in Parameter Set Streams

Should parameter set streams provide for parameter set NAL units whose DTS is *equal* to the DTS time of the first NAL unit (in the video elementary stream) that refers to that parameter set? Or should the DTS of a parameter set NAL unit (in the parameter set elementary stream) always be *prior* to the decoding time of the first NAL unit (in the video elementary stream) that refers to the parameter set?
Note: In the above the DTS of an NAL unit means the DTS of the access unit containing the NAL unit.

ABSTRACT

Region-of-interest coding and unequal error protection are two important tools in video communication systems to improve received visual quality. One common property of the two techniques is that unequal coding or transmission is applied to improve the quality of the most important parts of images. The proposed sub-picture coding technique facilitates both region-of-interest coding and unequal error protection by partitioning images to regions of interest and separating the corresponding coded data units from each other. Simulation results show that the overall subjective quality is considerably improved compared to the conventional coding schemes.

1. INTRODUCTION

1.1. Slice-Based Coding

Modern video coding standards, such as ITU-T Recommendation H.263 and ISO/IEC MPEG-4 Part 2, allow division of coded pictures to slices. Slices can be regarded as a way to split a bit-stream to transport packets that can be decoded independently. While spatial and syntactical prediction is disabled across slice boundaries, motion vectors may cross slice edges. This fact causes spatio-temporal error propagation, when motion vectors point to areas that are reconstructed incorrectly. In order to prevent this phenomenon, H.263 includes the optional independent segment decoding mode (H.263 Annex R). When this optional mode is in use, slice boundaries are treated as picture boundaries, and therefore no spatio-temporal error propagation over slice boundaries occurs. Due to restricted motion prediction, compression efficiency drops compared to normal slice-based operation.

1.2. Region-Of-Interest Coding

Region-of-interest (ROI) coding refers to techniques that code some spatial pictorial regions using more refined method than the rest. One method is to apply smaller quantization parameters (QP) hence allocate more bits to the region of interest [1]. As a result, better quality can be observed in the interested region; and hence the overall subjective quality is improved. A shortcoming of ROI coding is that it may cause a boundary effect between the ROI region and the leftover region due to unequal coding.

1.3. Unequal Error Protection

Unequal error protection (UEP) refers to techniques that protect part of the transmitted bit-stream in the transport system better than the rest. Examples of applicable UEP techniques include application-layer selective retransmission [2][3], transport-layer forward error control (e.g. RFC 2733 [4]), guaranteed network Quality of Service (e.g. QoS architecture of Universal Mobile Telecommunication System [5]), and Differentiated Services (DiffServ) [6][7].

In order to apply unequal error protection, video bit-streams have to be organized in portions of different importance in terms of visual quality. Techniques achieving this goal include data partitioning and scalable video coding. Data partitioning refers to a technique where subjectively equally important codewords of all macroblocks (MBs) in a slice are partitioned into a continuous block of data. Typically, MB headers and motion information form one partition and coded prediction error blocks form another partition. Scalability refers to the capability of a compressed sequence to be decoded at different bit-rates. Scalability can be further categorized into temporal, SNR, and spatial scalability. Video coding schemes with temporal scalability is reviewed in [8], spatial and SNR scalable video coding are reviewed in [9].

1.4. Overview of the Paper

Conventional ROI coding treats the entire bit-stream equally in transmission, while data partitioning and scalable coding generally treat coding of an entire image equally in spatial domain. Arbitrarily shaped objects [10], as defined in the MPEG-4 standard, can be used to extract the regions of interest. However, the arbitrary shape

coding often inherits relatively high processing requirements.

This paper proposes a simple region-based coding method, called sub-picture coding, which is based on rectangular shapes. It can be considered as a simplification of arbitrary shape coding. While sub-picture coding does not provide means to define object boundaries accurately, it suits simultaneously ROI coding and unequal error protection. In addition, a gradual ROI bit allocation method is proposed to reduce the boundary effect between the selected ROI region and the leftover region.

Section 2 of the paper presents the sub-picture coding method. The gradual ROI bit allocation method is described in Section 3. Simulation results of the proposed technique are provided in Section 4. The paper is concluded in Section 5.

2. SUB-PICTURE CODING

The proposal adds a sub-picture coding layer between picture and slice layers. Sub-pictures are rectangular except for the so-called background sub-picture, which consists of the picture area not falling to any of the rectangular sub-pictures. Rectangular sub-pictures are also referred to as foreground sub-pictures. Sub-pictures boundaries are aligned with macroblock (MB) boundaries. Sub-pictures do not overlap. A slice resides within one sub-picture only. A slice in a background sub-picture may not contain spatially adjacent MBs within a MB line, as it can be intervened by foreground sub-pictures. Figure 1 shows an example of a picture having one foreground sub-picture and one background sub-picture, both of which include two slices.

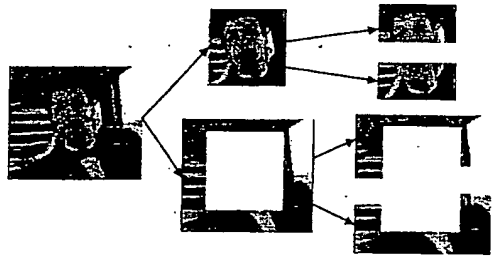

Fig. 1. Example of picture, sub-pictures, and slices.

There are two coding modes associated with sub-pictures: normal mode and independent mode. In the normal mode, sub-picture boundaries are treated as slice boundaries. In the independent mode, boundaries of foreground sub-pictures are treated as picture boundaries and sub-picture segmentation is static over a group of pictures. In other words, in the independent mode, temporal and spatial prediction over sub-picture boundaries is prevented when coding the foreground sub-pictures. No such limitation exists when coding a background sub-picture.

Coding of the foreground sub-pictures takes place before coding of the background sub-picture, therefore different coding methods can applied conveniently to different regions, and the bit-streams of different regions are separated to suit UEP.

3. GRADUAL ROI BIT ALLOCATION

Conventional ROI bit allocation methods, such as the methods proposed in [1], assign two QP values, generally with a large difference, for each picture, one for the ROI region and the other for leftover region. As a result, annoying boundary effects are caused between the two regions. To reduce the boundary effects, a gradual ROI bit allocation scheme described in the following is proposed.

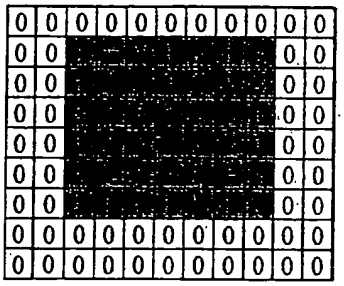

Fig. 2. Gradual ROI bit allocation/quantization.

The background QP, QPb, is fixed for all background MBs. The foreground QP is a function of the distance from regional edge: if a MB is adjacent to the edge, its QP is QPb-1; if the distance between a MB and the edge is larger (e.g. one MB), the QP of the MB is QPb-2; for other foreground MBs, the QP is QPb-3. An example is shown in Figure 2, where the gray colored MBs form the foreground sub-picture.

4. SIMULATIONS

4.1. Conditions

We selected multicast Internet streaming as a target application. As interactive error concealment cannot be used in large scale with IP multicast, transport coding level forward error correction (FEC) according to RFC 2733 [4] was used. We used the ITU-T Video Coding Experts Group (VCEG) common conditions for the low-delay Internet applications [11] as much as we considered appropriate.

Sub-picture coding and the gradual ROI bit allocation were implemented in and tested with H.26L Test Model Long-Term (TML) version 8.6 [12][13]. A constant foreground sub-picture was selected, and finer QPs

decided by the gradual ROI bit allocation method were used in the foreground region. The independent sub-picture decoding mode was in use. The scheme was compared to TML-8.6 with and without ROI quantization (abbreviated as Conv+ROI and Conv, respectively). The ROI quantization for the conventional codec was the same as for the sub-picture coding scheme.

The simulator consisted of the following phases. First, the TML encoder was used to encode a sequence and generated an RTP packet stream. Then, a packet loss simulator erased some of the generated packets according to the error patterns released in [14]. The resulting packets stream was decoded using the TML decoder.

Encapsulation into RTP packets was done as follows: In the sub-picture coding scheme, INTRA pictures were encapsulated into five packets. There were two packets for the foreground sub-picture: one packet contained odd MB rows and another packet contained even MB rows. This slice interleaving mechanism, introduced in [15], was used to obtain a better error concealment result. One parity FEC packet was generated for the two foreground packets according to RFC 2733. The background sub-picture was packetized into another two packets using slice interleaving method. Two consecutive INTER pictures consisted a group, and for each such group there were two foreground sub-picture packets, one parity FEC packet for the foreground packets, and two background sub-picture packets. A sub-picture packet contained data from two pictures: MBs from even rows of a certain frame and MBs from odd rows of the next frame or vice versa. When sub-picture coding was not in use, there were three packets for each INTRA and INTER frame: two packets for the entire picture (slice interleaving applied), and one parity FEC packet for the two packets.

As multicast Internet streaming was assumed, the coding and transport scheme was tailored for the worst expected case. We selected optimal coding parameters and encapsulation options by trial and error according to the PSNR performance in the 20 % packet loss rate. We tested several INTRA macroblock coding rates as well as several slice sizes to find the optimal ones. The packet stream obtaining the best PSNR performance was multicast. The PSNR performance in 0, 3, 5, and 10 % packet loss rate was then simulated with the multicast packet stream. In order to obtain statistically significant results, each packet stream was virtually transported ten times for each packet loss rate. The first loss pattern position of a run starts from where the previous run ended.

4.2. Results

The experiments were done using Carphone, Hall, Coastguard, Foreman, News and Irene sequences, with different frame rates and bit-rates. We present only part of the results due to lack of space, more results can be obtained from the authors.

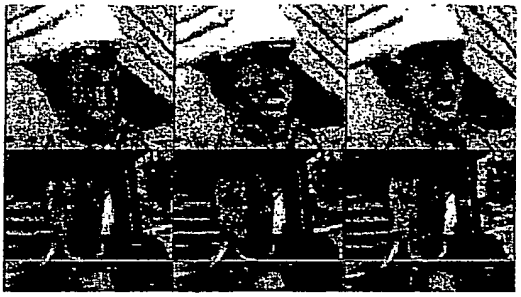

Figure 3. Example snapshots, 20 % packet loss rate. From left to right, the used codecs are Conv, Conv+ROI, and the proposed codec.

Figure 3 shows some example snapshots of Foreman@64 kbps and Carphone@64kbps in 20 % packet loss rate. From left to right in the figure, the snapshots were produced by the Conv, Conv+ROI, and the proposed codec, respectively. It can be seen that in both sequences the proposed sub-picture coding scheme with gradual bit allocation maintains the best subjective image quality.

Figure 4 presents the average luminance PSNR values of the foreground area of Irene@384kbps, News@64kbps, Foreman@64kbps, and Carphone@64kbps. These objective results confirm the subjective ones. Sub-picture coding improves the average luminance PSNR of the foreground area consistently regardless of the packet loss rate. This improvement is gained at the expense of background image quality, which is degraded by coarser quantization and less error protection. In fact, the overall PSNR in the sub-picture coding case drops a little compared to the ROI quantization case and somewhat more compared to the constant quantization case. However, errors in the background are far less noticeable than errors in the foreground, and therefore the overall subjective quality is improved.

5. CONCLUSION

Many video communication systems can make use of region-of-interest coding and unequal error protection to improve received visual quality. In order to apply them, pictures should be partitioned to different regions, or video bit-streams have to be organized in portions, of different importance in terms of visual quality. Techniques achieving these goals include data partitioning, scalable video coding, and region-based video coding.

This paper introduced a simple region-based video coding method called sub-picture coding. It provides means for both region-of-interest coding and unequal error protection based on partitioned regions of interest. In sub-picture coding, a picture is partitioned to one or more

BEST AVAILABLE COPY

rectangular foreground sub-pictures and to a hollow background sub-picture along macroblock boundaries. Sub-picture edges are treated as slice boundaries or as picture boundaries depending on the signaled coding mode.

The sub-picture coding method was simulated in multicast Internet streaming conditions and it was found to be superior to conventional coding. Due to its simplicity and the obtained results, we think that sub-picture coding has some potential to become one of the key video coding tools for region-of-interest coding and unequal error protection.

ABSTRACT

Unequal error protection is one of the key tools in video communication systems operating over error-prone networks. In order to allow unequal protection of a video bit-stream, codewords have to be categorized according to their importance to visual quality. The proposed sub-picture coding method allows partitioning images to regions of interest and helps to maintain a good image quality in the chosen regions. As an example, the sub-picture coding scheme is applied to multicast Internet streaming. It is shown that the overall subjective image quality and the objective foreground image quality are considerably better when compared to the selected conventional coding schemes.

1. INTRODUCTION

1.1. Slice-Based Coding

Modern video coding standards, such as ITU-T Recommendation H.263 and ISO/IEC MPEG-4 Part 2, allow division of coded pictures to slices. A slice consists of a number of consecutive macroblocks in raster scan order. Slices can be regarded as a way to split a bit-stream to transport packets that can be decoded independently. While spatial and syntactical prediction is disabled across slice boundaries, motion vectors may cross slice edges. This fact causes spatio-temporal error propagation, when motion vectors point to areas that are reconstructed incorrectly. In order to prevent this phenomenon, H.263 includes the optional independent segment decoding mode (H.263 Annex R). When this optional mode is in use, slice boundaries are treated as picture boundaries, and therefore no spatio-temporal error propagation over slice boundaries occurs. Due to restricted motion prediction, compression efficiency drops compared to normal slice-based operation. Furthermore, in order to avoid prediction confusions in slice boundaries, each slice must reside within one row of macroblocks, and its shape and position must be constant throughout the group of pictures.

1.2. Unequal Error Protection

Term unequal error protection (UEP) refers to techniques that protect part of the transmitted bit-stream in the transport system better than the rest. Examples of applicable UEP techniques include application-layer selective retransmission [1][2], transport-layer forward error control (e.g. RFC 2733 [3]), guaranteed network Quality of Service (e.g. QoS architecture of Universal Mobile Telecommunication System [4]), and Differentiated Services (DiffServ) [5][6].

In order to apply unequal error protection, video bit-streams have to be organized in portions of different importance in terms of visual quality. Techniques achieving this goal include data partitioning and scalable video coding.

Data partitioning refers to a technique where subjectively equally important codewords of all macroblocks in a slice are partitioned into a continuous block of data. Typically, macroblock headers and motion information form one partition and coded prediction error blocks form another partition.

Scalability refers to the capability of a compressed sequence to be decoded at different bit-rates. Scalability can be further categorized into temporal, SNR, and spatial scalability. Video coding schemes with temporal scalability have been reviewed in [7]. A spatially or SNR-scalable bit-stream [8] is organized into a base layer and one or more enhancement layers, and each additional enhancement layer improves perceptual quality. Fine granularity scalability (FGS) [8] is a specific type of SNR scalability. The FGS coding technique arranges the bit-stream into a base layer and an enhancement layer. Each coded picture in the enhancement layer can be truncated into any number of bits, and the number of enhancement layer bits is proportional to the image quality.
