(57) **ABSTRACT**

A surface cleaning apparatus has a dirty air inlet and an air
treatment member. The air treatment member includes a dirt
collection region having an openable door. When an acces-
sory is connected to the dirty air inlet, the openable door is
inhibited from opening.

SURFACE CLEANING APPARATUS**CROSS-REFERENCE TO RELATED APPLICATIONS**

This application is a continuation in part of co-pending U.S. patent application Ser. No. 15/095,714, which was filed Apr. 11, 2016 and is incorporated herein in its entirety by reference.

FIELD

The specification relates to surface cleaning apparatus. In a preferred embodiment, the surface cleaning apparatus comprises a portable surface cleaning apparatus, such as a hand vacuum cleaner or a pod.

INTRODUCTION

The following is not an admission that anything discussed below is part of the prior art or part of the common general knowledge of a person skilled in the art.

Various types of surface cleaning apparatus are known. Surface cleaning apparatus include vacuum cleaners. Currently, a vacuum cleaner typically uses at least one cyclonic cleaning stage. More recently, cyclonic hand vacuum cleaners have been developed. See for example, U.S. Pat. No. 7,931,716 and US 2010/0229328. Each of these discloses a hand vacuum cleaner which includes a cyclonic cleaning stage. U.S. Pat. No. 7,931,716 discloses a cyclonic cleaning stage utilizing two cyclonic cleaning stages wherein both cyclonic stages have cyclone axis of rotation that extends vertically. US 2010/0229328 discloses a cyclonic hand vacuum cleaner wherein the cyclone axis of rotation extends horizontally and is coaxial with the suction motor. In addition, hand carriable cyclonic vacuum cleaners are also known (see U.S. Pat. Nos. 8,146,201 and 8,549,703).

SUMMARY

This summary is intended to introduce the reader to the more detailed description that follows and not to limit or define any claimed or as yet unclaimed invention. One or more inventions may reside in any combination or sub-combination of the elements or process steps disclosed in any part of this document including its claims and figures.

In accordance with one aspect of this disclosure, a hand vacuum cleaner has a uniflow cyclone with a front cyclone air inlet and a rear air cyclone outlet. Accordingly, the cyclone axis extends rearwardly from the front end of the cyclone. The cyclone air inlet may be in an upper portion of the cyclone and may be in an upper portion of the sidewall (e.g., most and preferably essentially all of the inlet opening may be in the sidewall of the cyclone above the axis of rotation of the cyclone). The dirt collection area may be a dirt collection chamber that is external to the cyclone chamber and may be provided below the cyclone chamber. The dirt outlet of the cyclone chamber may be provided in a lower portion of the sidewall of the cyclone near or at the rear end of the cyclone.

In accordance with this aspect, there is provided a hand vacuum cleaner having a front end having a dirty air inlet, a rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end having a dirty air inlet, a lower end, a front end and a rear end, the main body housing a suction motor and fan assembly,

2

the suction motor and fan assembly having a suction motor axis of rotation; and,

- (b) a cyclone unit comprising a cyclone having a cyclone axis of rotation, a front end having a cyclone air inlet and a longitudinally spaced apart rear end having a cyclone air outlet, wherein the cyclone air inlet is in an upper portion of the cyclone;

wherein when the hand vacuum cleaner is oriented with the cyclone underneath the upper end, the cyclone axis of rotation is generally horizontal.

In some embodiments, when the hand vacuum cleaner is positioned with the bottom on a horizontal surface, the cyclone axis of rotation may be generally horizontal.

In some embodiments, when the hand vacuum cleaner is oriented with the cyclone underneath the upper end, the suction motor axis of rotation may be generally horizontal.

In some embodiments, when the hand vacuum cleaner is oriented with the cyclone underneath the upper end, the suction motor axis of rotation may be positioned below the cyclone axis of rotation.

In some embodiments, the cyclone has a sidewall having an upper portion and a lower portion and a dirt outlet may be provided in the lower portion and is in communication with a dirt collection chamber that is exterior to the cyclone. Optionally, the cyclone air inlet may be provided in the upper portion of the sidewall of the cyclone.

In some embodiments, the cyclone axis of rotation may be generally parallel to the suction motor axis of rotation.

In some embodiments, the main body may be provided with a handle.

In some embodiments, the hand vacuum cleaner further comprises a handle having a hand grip portion that may extend upwardly and forwardly when the hand vacuum cleaner is oriented with the cyclone underneath the upper end.

In some embodiments, the lower end of the main body may comprise the bottom.

In some embodiments, the cyclone unit may be provided on the front end of the main body. Alternately, or in addition, the cyclone unit may be removably mounted to the main body.

In some embodiments, the dirty air inlet may be provided on a front end of the cyclone unit.

In some embodiments, the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end and an outlet end and has a longitudinal passage axis, the outlet end of the inlet passage communicates with the cyclone air inlet and the inlet passage axis may be positioned between an upper and a lower end of a handle of the hand vacuum cleaner.

In some embodiments, the handle may comprise a hand grip portion that extends upwardly and forwardly when the hand vacuum cleaner is oriented with the cyclone underneath the upper end. In some of these embodiments, the suction motor axis of rotation may be positioned below the cyclone axis of rotation when the hand vacuum cleaner is oriented with the cyclone underneath the upper end.

In some embodiments, the inlet passage may have a longitudinal passage axis that is linear and all of the longitudinal passage may be positioned above the cyclone axis of rotation when the hand vacuum cleaner is oriented with the cyclone underneath the upper end.

In accordance with this aspect, there is also provided a surface cleaning apparatus comprising the hand vacuum cleaner discussed herein, a surface cleaning head and a rigid air flow conduit extending between the surface cleaning head and the hand vacuum cleaner wherein an outlet end of

3

the rigid air flow conduit is removable connectable in air flow communication with the inlet passage.

In accordance with this aspect, there is also provided a hand vacuum cleaner having a front end, a rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end and a rear end, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation; and,
- (b) an air treatment member having a front end having an air treatment member air inlet and a longitudinally rearwardly spaced apart rear end having an air treatment member air outlet, wherein the air treatment member air inlet is in a longitudinally extending side-wall of the air treatment member; and,
- (c) a dirty air inlet comprising an inlet passage that extends longitudinally between an inlet end and an outlet end and has a longitudinal passage axis, the outlet end of the inlet passage communicates with the air treatment member air inlet.

In some embodiments, air travels through the air treatment member air outlet in a flow direction and the flow direction may be generally parallel to the suction motor axis of rotation.

In accordance with another aspect of this disclosure, a hand vacuum cleaner has an air treatment member with an air flow conduit or passage wherein the conduit is also a handle of the air treatment member.

In accordance with this aspect, there is provided a hand vacuum cleaner having a front end having a dirty air inlet, a rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end, a rear end and a driving handle, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation;
- (b) an air treatment member comprising an air treatment member handle, a dirt collection region having an openable door and an openable door lock comprising a door release actuator wherein the door is moveable to an open position when the door release actuator is actuated; and,
- (c) an air inlet comprises an inlet passage that extends longitudinally between an inlet end and an outlet end and has a longitudinal passage axis and the inlet passage comprises the air treatment member handle.

In some embodiments, the driving handle may comprise a portion spaced from the main body whereby a finger receiving area is provided between the driving handle and the main body.

In some embodiments, the driving handle may be provided at the rear end of the main body.

In some embodiments, the air treatment member handle may comprise a portion spaced from the air treatment member whereby a finger receiving area is provided between the air treatment member handle and the air treatment member.

The In some embodiments, the air treatment member handle may be provided above the air treatment member.

In some embodiments, the openable door may be provided at the front end of the hand vacuum cleaner.

4

In some embodiments, the openable door may have a lower end that is moveably mounted to the air treatment member and an upper end that may be engaged by the door lock.

In some embodiments, the door release actuator may be positioned proximate the air treatment member handle.

In some embodiments, the inlet passage may extend generally rearwardly.

In some embodiments, the door release actuator may be positioned at a forward end of the inlet passage.

In accordance with this aspect, there is also provided a hand vacuum cleaner having a front end having a dirty air inlet, a rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end, a rear end and a driving handle, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation; and,
- (b) a cyclone unit comprising a cyclone having a cyclone axis of rotation, a cyclone unit handle, a dirt collection region having an openable door and an openable door lock comprising a door release actuator wherein the door is moveable to an open position when the actuator is actuated;

wherein when a user's hand is holding the cyclone unit by the cyclone unit handle, the door release actuator is operable by the same hand.

In some embodiments, the driving handle may comprise a portion spaced from the main body whereby a finger receiving area is provided between the driving handle and the main body.

In some embodiments, the driving handle may be provided at the rear end of the main body.

In some embodiments, the cyclone unit handle may comprise a portion spaced from the cyclone unit whereby a finger receiving area is provided between the cyclone unit handle and the cyclone unit.

In some embodiments, the cyclone unit handle may be provided above the cyclone unit.

In some embodiments, the openable door may be provided at the front end of the hand vacuum cleaner.

In some embodiments, the air inlet may comprise an inlet passage that extends longitudinally between an inlet end and an outlet end and the inlet passage comprises the cyclone unit handle.

In some embodiments, when the hand vacuum cleaner is positioned with the bottom on a horizontal surface, the cyclone axis of rotation may be generally horizontal.

In accordance with another aspect of this disclosure, the air treatment member, e.g., a cyclone unit, may be removably mounted to the rest of the hand vacuum cleaner. The air treatment member may include a dirty air inlet that is connectable to an upper end of a longitudinally extending rigid member (e.g., which may be hollow to enable airflow therethrough) and a surface cleaning head may be provided (preferably removably connected) to a lower end of the longitudinally extending rigid member. When assembled as an upright or stick vacuum cleaner with the hand vacuum cleaner drivingly connected to the surface cleaning head by the longitudinally extending rigid member (e.g., a rigid wand), the handle of the hand vacuum cleaner may be used to steer the surface cleaning head. An advantage of this configuration is that the hand vacuum cleaner may be easily converted to an upright or stick vacuum cleaner.

In such a configuration, lateral stresses (i.e., stresses transverse to the longitudinal forward/rearward axis of the

5

hand vacuum cleaner) may occur as the handle of the hand vacuum cleaner is used to steer the surface cleaning head. In order to assist in stabilizing the joint of the air treatment member and the rest of the hand vacuum cleaner, lateral stability members may be provided at the interface of the air treatment member and the rest of the hand vacuum cleaner. For example, one or more pairs of inter-engagement members may be provided which extend in a direction that extends generally between the lower end and the upper end of the hand vacuum cleaner. These lateral stability members may extend continuously or they may have discontinuities and they may extend linearly or otherwise. As the lateral stresses are exerted in a direction that is at an angle between 0-90°, 25-90°, 45-90° or 70-90° to the lateral stability members, and may be generally perpendicular (90°) thereto, the lateral stability members will strengthen the joint of the air treatment member and the rest of the hand vacuum cleaner. Preferably, at least one pair is provided on either lateral side of a center line extending in the longitudinal forward/rearward direction of the hand vacuum cleaner. The lateral stability members may be any members that have sides that abut to resist the lateral stresses and may comprise a longitudinally extending protrusion or spline and a mating groove or abutting longitudinally extending protrusions or splines.

In accordance with this aspect, there is provided a surface cleaning apparatus comprising:

- (a) a hand vacuum cleaner having a front end having a dirty air inlet, a longitudinally spaced apart rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:
 - (i) a main body comprising an upper end, a lower end, a front end and a rear end, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation;
 - (ii) an air treatment member removably mounted at the front end of the main body, the air treatment member comprising an upper end, a lower end, a front end and a rear end, the lower end of the air treatment member is rotationally mounted to the lower end of the main body; and,
 - (iii) an air treatment member release lock comprising a release actuator and first and second engagement members wherein the first engagement member is provided on the upper end of the air treatment member and the second engagement member is provided on the upper end of the main body and the release actuator is provided on one of the air treatment member and the main body,
- (b) a surface cleaning head; and,
- (c) a rigid air flow conduit extending between the surface cleaning head and the hand vacuum cleaner wherein an outlet end of the rigid air flow conduit is removably connectable in air flow communication with the inlet passage.

In some embodiments, the lower end of one of the air treatment member and the main body may be provided with a transversely extending rod and the lower end of the other of the air treatment member and the main body may be provided with a hook removably connectable with the rod.

In some embodiments, the lower end of the air treatment member may be rotationally mounted to the lower end of the main body at a position longitudinally spaced from the first and second engagement members.

In some embodiments, the lower end of the air treatment member may be rotationally mounted to the lower end of the

6

main body at a position longitudinally spaced from a position at which the upper end of the air treatment member abuts the upper end of the main body.

In some embodiments, one of the air treatment member and the main body may be provided with an outwardly extending protrusion and the other of the air treatment member and the main body may be provided with a groove in which the outwardly extending protrusion is received when the air treatment member is secured to the main body.

In some embodiments, the main body may have a driving handle and the dirty air inlet is part of the air treatment member.

In some embodiments, the air treatment member may comprise a cyclone unit and the driving handle may be provided at the rear end of the main body and the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end provided at a front end of the cyclone unit and an outlet end, and the inlet end may be adapted to receive an accessory cleaning tool. The accessory cleaning tool may comprise a rigid air flow conduit.

In some embodiments, the air treatment member may comprise a cyclone unit and the driving handle may be provided at the rear end of the main body and the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end provided at a front end of the cyclone unit and an outlet end, and the inlet end may be positioned forward of the cyclone unit.

In some embodiments, dirty air inlet may be provided above the air treatment member.

In some embodiments, the air treatment member may comprise a dirt collection region having an openable door and the openable door may be provided at the front end of the air treatment member.

In some embodiments, when the hand vacuum cleaner is oriented with the air treatment member below the upper end, the cyclone axis of rotation may be generally horizontal.

In accordance with this aspect, there is also provided a hand vacuum cleaner having a front end having a dirty air inlet, a longitudinally spaced apart rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end and a rear end, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation;
- (b) a cyclone unit removably mounted at the front end of the main body, the cyclone unit comprising an upper end, a lower end, a front end, a rear end and a cyclone axis of rotation, the lower end of the cyclone unit is rotationally mounted to the lower end of the main body; and,
- (c) a cyclone unit release lock comprising a release actuator and first and second engagement members wherein the first engagement member is provided on the upper end of the cyclone unit and the second engagement member is provided on the upper end of the main body and the release actuator is provided on one of the cyclone unit and the main body.

In some embodiments, the lower end of one of the cyclone unit and the main body may be provided with a transversely extending rod and the lower end of the other of the cyclone unit and the main body may be provided with a hook removably connectable with the rod.

In some embodiments, the lower end of the cyclone unit may be rotationally mounted to the lower end of the main body at a position longitudinally spaced from the first and second engagement members.

7

In some embodiments, the lower end of the cyclone unit may be rotationally mounted to the lower end of the main body at a position longitudinally spaced from a position at which the upper end of the cyclone unit abuts the upper end of the main body.

In some embodiments, one of the cyclone unit and the main body may be provided with an outwardly extending protrusion and the other of the cyclone unit and the main body is provided with a groove in which the outwardly extending protrusion is received when the cyclone unit is secured to the main body.

In some embodiments, the main body may have a driving handle and the dirty air inlet is part of the cyclone unit.

In some embodiments, the driving handle may be provided at the rear end of the main body and the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end provided at a front end of the cyclone unit and an outlet end, and the inlet end may be adapted to receive an accessory cleaning tool. The accessory cleaning tool may comprise a rigid air flow conduit.

In some embodiments, the driving handle may be provided at the rear end of the main body and the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end provided at a front end of the cyclone unit and an outlet end, and the inlet end may be positioned forward of the cyclone unit.

In some embodiments, the dirty air inlet may be provided above the cyclone unit.

In some embodiments, the cyclone unit may comprise a dirt collection region having an openable door and the openable door may be provided at the front end of the cyclone unit.

In some embodiments, when the hand vacuum cleaner is oriented with the cyclone below the upper end, the cyclone axis of rotation may be generally horizontal.

In accordance with another aspect of this disclosure an air treatment member includes an air flow passage which functions as a handle of the air treatment member. An advantage of this design is that the air treatment member may be provided with a handle that is not an additional part. The air flow passage may be part of the air flow path from a dirty air inlet to the air treatment member air inlet. Alternately or in addition, the air flow passage may be part of an air flow path for a bleed stream and a bleed valve may be provided in the air flow passage.

In accordance with this aspect of the disclosure, there is provided a hand vacuum cleaner having a front end, a rear end, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end, a rear end and a driving handle, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation; and,
- (b) an air treatment member, the air treatment member comprising an air treatment member axis and an air treatment member handle wherein the air treatment member handle comprises an air flow passage.

In some embodiments, the air flow passage may comprise an inlet passage of the air treatment member.

In some embodiments, the inlet passage may extend longitudinally between a dirty air inlet end and an outlet end.

In some embodiments, the air treatment member handle may comprise a portion spaced from the air treatment member whereby a finger receiving area is provided between the air treatment member handle and the air treatment member.

8

In some embodiments, the air treatment member handle may be provided above the air treatment member.

In some embodiments, the passage may extend generally axially in the direction of the air treatment member axis.

In some embodiments, the driving handle may comprise a portion spaced from the main body whereby a finger receiving area is provided between the driving handle and the main body.

In some embodiments, the driving handle may be provided at the rear end of the main body.

In some embodiments, the air treatment member may be removable from the main body and the air treatment member handle may be removable with the air treatment member.

In some embodiments, a bleed valve may be positioned in the air treatment member handle.

In accordance with this aspect, there is also provided a hand vacuum cleaner having a front end, a rear end, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end, a rear end and a driving handle, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation; and,
- (b) a cyclone unit, the cyclone unit comprising a cyclone having a cyclone axis of rotation, a cyclone unit handle, wherein the cyclone unit handle comprises an air flow passage.

In some embodiments, the cyclone unit handle may comprise an inlet passage of the cyclone unit.

In some embodiments, the inlet passage may extend longitudinally between a dirty air inlet end and an outlet end.

In some embodiments, the cyclone unit handle may comprise a portion spaced from the cyclone unit whereby a finger receiving area is provided between the cyclone unit handle and the cyclone unit.

In some embodiments, the cyclone unit handle may be provided above the cyclone unit.

In some embodiments, the passage may extend generally parallel to the cyclone axis.

In some embodiments, the driving handle may comprise a portion spaced from the main body whereby a finger receiving area is provided between the driving handle and the main body.

In some embodiments, the driving handle may be provided at the rear end of the main body.

In some embodiments, the cyclone unit may be removable from the main body and the cyclone unit handle may be removable with the cyclone unit.

In some embodiments, when the hand vacuum cleaner is oriented with the upper end positioned above the lower end, the cyclone axis of rotation may be generally horizontal.

In some embodiments, a bleed valve may be positioned in the cyclone unit handle.

In accordance with another aspect of this disclosure, a surface cleaning apparatus is electrically connectable with an accessory cleaning tool (e.g., a rigid air flow conduit, a crevice tool, a brush or the like) and a circuit electrically connecting the accessory tool with a source or power provided for the surface cleaning apparatus (e.g., AC power from a wall outlet or an on board energy storage member such as one or more batteries) is moved from a circuit open position to a circuit closed position when the accessory tool is mounted in air flow communication with the surface cleaning apparatus. An advantage of this design is that the terminal ends of the electrical outlet of the surface cleaning apparatus are de-energized when they are exposed. In one embodiment, an electrical conductor element of the acces-

sory cleaning tool drives an electrical conductor element of the surface cleaning apparatus to a circuit closed position when the accessory tool is mounted in air flow communication with the surface cleaning apparatus. Accordingly, one or more of the electrical conductor elements of the surface cleaning apparatus may be biased to a circuit open position and may be moveable (e.g., linearly moveable, by contact with the electrical conductor element of the accessory tool). In alternate embodiments, the driving member provided on the accessory cleaning tool may be a non-conductive (e.g., plastic) engagement member (e.g., finger), that engages a member (e.g., a slideable tab of a housing of the electrical conductor elements of the surface cleaning apparatus) to move the electrical conductor elements of the surface cleaning apparatus to a circuit closed position.

In accordance with this aspect, there is provided a surface cleaning apparatus comprising:

- (a) an air flow passage extending between a dirty air inlet and a clean air outlet;
- (b) a main body housing a suction motor and fan assembly that is positioned in the air flow passage;
- (c) an air treatment member positioned in the air flow passage;
- (d) an electrical outlet electrically connectable with an accessory cleaning tool; and,
- (e) a circuit extending between a source of power and the electrical outlet, the circuit comprising first and second electrical conductor elements, at least the first electrical conductor element is biased to a circuit open position wherein the first electrical conductor element is moved to a circuit closed position when an accessory cleaning tool is connected to the dirty air inlet.

In some embodiments, the first and second electrical conductor elements may engage electrical conductors of the accessory tool whereby the first and second electrical conductor elements are electrically connectable with the accessory cleaning tool and at least the first electrical connector conductor may be biased to a circuit open position.

In some embodiments, the first and second electrical conductor elements may comprise first and second electrical connector conductors, each of the electrical conductor elements may have an accessory tool contact end and a terminal end contact end, at least the first electrical connector conductor may be biased to a circuit open position and at least one of the accessory tool contact ends may be recessed in the electrical outlet when in the circuit open position.

In some embodiments, the circuit may comprise electrical conductive members, each of which extends from the source of power to a terminal end, at least the first electrical conductor element may be moveably mounted from a position in which it contacts one of the terminal ends to a position in which it is spaced from the terminal end.

In some embodiments, each of the electrical conductor elements may be moveably mounted from a position in which each of the electrical conductor elements contacts one of the terminal ends to a position in which the electrical conductor elements contacts are spaced from the terminal ends.

In some embodiments, the circuit may comprise electrical conductive members, each of which may extend from the source of power to a terminal end, the first and second electrical conductor elements may comprise first and second electrical connector conductors, each of the electrical conductor elements may have an accessory tool contact end and a terminal end contact end, at least the first electrical conductor element may be moveably mounted from a posi-

tion in which it contacts one of the terminal ends to a position in which it is spaced from the terminal end.

In some embodiments, surface cleaning apparatus may further comprise a compression spring positioned between the first electrical conductor element and one of the terminal ends.

In some embodiments, the compression spring may be non-conductive.

The In some embodiments, the source of power may comprise a power cord.

In some embodiments, the circuit further may comprise a main power switch.

In some embodiments, the accessory cleaning tool may comprise a rigid air flow conduit.

In some embodiments, the surface cleaning apparatus may comprise a hand vacuum cleaner and the electrical outlet is provided adjacent the dirty air inlet.

In accordance with this aspect, there is also provided a surface cleaning apparatus comprising

- (a) a suction motor and fan assembly operable on a source of power;
- (b) an electrical outlet housing having first and second electrical conductor elements, each of the electrical conductor elements has a first contact end and a second contact end; and,
- (c) a circuit including the electrical conductor elements and a main power switch operable between a circuit closed position and a circuit open position, at least the first electrical conductor element is moveable between a circuit closed position and a circuit open position and is biased to the circuit open position wherein the first electrical conductor element is moved to a circuit closed position upon mechanical engagement of a part having an air flow conduit with the electrical outlet housing.

In some embodiments, the circuit may comprise electrical conductive members, each of which may extend from the source of power to a terminal end, at least the first electrical conductor element may be moveably mounted from a position in which it contacts one of the terminal ends to a position in which it is spaced from the terminal end.

In some embodiments, each of the electrical conductor elements may be moveably mounted from a position in which each of the electrical conductor elements contacts one of the terminal ends to a position in which the electrical conductor elements contacts are spaced from the terminal ends.

In some embodiments, the surface cleaning apparatus may further comprise a compression spring positioned between the first electrical conductor element and the one of the terminal ends.

In some embodiments, the compression spring may be non-conductive.

In some embodiments, the source of power may comprise a power cord.

In some embodiments, the first electrical conductor element may be longitudinally moveable in the electrical outlet housing

In some embodiments, the surface cleaning apparatus may comprise a hand vacuum cleaner and the electrical outlet housing is provided adjacent a dirty air inlet.

In accordance with another aspect of this disclosure, a hand vacuum cleaner is provided with a front openable door of a dirt collection area and the hand vacuum cleaner has a handle that extends upwardly and forwardly when the hand vacuum cleaner is oriented with the upper end above the lower end (e.g., when the hand vacuum cleaner is seated on

11

a horizontal surface). An advantage of this design is that the handle is oriented to permit the user to point the hand vacuum cleaner downwardly to empty the dirt collection area when the door is opened.

In accordance with this aspect, there is provided a hand vacuum cleaner having a front end having a dirty air inlet, a rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end, a rear end and a driving handle, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation wherein the driving handle has a hand grip portion that extends upwardly and forwardly when the hand vacuum cleaner is oriented with the upper end above the lower end; and,
- (b) an air treatment member comprising a dirt collection region having an openable door provided on a front end of the air treatment member and an openable door lock comprising a door release actuator wherein the door is moveable to an open position when the door release actuator is actuated.

In some embodiments, the hand grip portion may be spaced from the main body whereby a finger receiving area is provided between the hand grip portion and the main body.

In some embodiments, at least a portion of the finger receiving area may be positioned linearly rearwardly from the air treatment member.

In some embodiments, the main body may comprise a suction motor housing and the driving handle has an end that may extend from the suction motor housing.

In some embodiments, the main body may comprise a suction motor housing and the driving handle may have an end that extends upwardly and forwardly from the suction motor housing.

In some embodiments, the driving handle may be provided at the rear end of the main body.

In some embodiments, the inlet passage may extend generally rearwardly.

In some embodiments, the inlet passage may be positioned above the openable door.

In some embodiments, the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end and an outlet end and has a longitudinal passage axis and the longitudinal passage axis intersects the driving handle.

In some embodiments, the air treatment member may have a front end having an air treatment member air inlet and a longitudinally rearwardly spaced apart rear end having an air treatment member air outlet.

In some embodiments, the inlet passage may be positioned above the openable door.

In accordance with this aspect, there is also provided a hand vacuum cleaner having a front end having a dirty air inlet, a rear end, a clean air outlet, an upper end and a bottom, the hand vacuum cleaner comprising:

- (a) a main body comprising an upper end, a lower end, a front end, a rear end and a driving handle, the main body housing a suction motor and fan assembly, the suction motor and fan assembly having a suction motor axis of rotation wherein the driving handle has a hand grip portion that extends upwardly and forwardly when the hand vacuum cleaner is oriented with the upper end above the lower end; and,
- (b) a cyclone unit comprising a cyclone having a cyclone axis of rotation, a dirt collection region having an openable door provided on a front end of the cyclone

12

unit and an openable door lock comprising a door release actuator wherein the door is moveable to an open position when the actuator is actuated.

In some embodiments, the hand grip portion may be spaced from the main body whereby a finger receiving area is provided between the hand grip portion and the main body.

In some embodiments, at least a portion of the finger receiving area may be positioned linearly rearwardly from the cyclone unit.

In some embodiments, the main body may comprise a suction motor housing and the driving handle has an end that extends from the suction motor housing.

In some embodiments, the main body may comprise a suction motor housing and the driving handle has an end that extends upwardly and forwardly from the suction motor housing.

In some embodiments, the driving handle may be provided at the rear end of the main body.

In some embodiments, the inlet passage may extend generally rearwardly.

In some embodiments, the inlet passage may be positioned above the openable door.

In some embodiments, the dirty air inlet may comprise an inlet passage that extends longitudinally between an inlet end and an outlet end and has a longitudinal passage axis and the longitudinal passage axis intersects the driving handle.

In some embodiments, the inlet passage may be positioned above the openable door.

In some embodiments, when the hand vacuum cleaner may be oriented with the upper end above the lower end, the cyclone axis of rotation is generally horizontal.

In accordance with another aspect of this disclosure, a surface cleaning apparatus has an air treatment member that includes a dirt collection region having an openable door. The openable door provides access to empty and/or clean the air treatment member. For example, if the air treatment member is a cyclone assembly which comprises a cyclone chamber and a dirt collection chamber exterior to the cyclone chamber, the door may provide access to the cyclone chamber and/or the dirt collection chamber. When an accessory (e.g. a wand, crevice tool, or brush) is connected to the dirty air inlet of the surface cleaning apparatus, the openable door is inhibited from opening. An advantage of this design is that the presence of a connected accessory may inhibit or prevent a user from inadvertently opening the dirt collection region of the air treatment member if, e.g., the door open actuator is located on or proximate to a handle of the surface cleaning apparatus.

For example, it may be unlikely that a user would try and empty the dirt collection region when an accessory tool is connected. Accordingly, if a user tries to actuate a release actuator for the openable door when an accessory is connected, it may be desirable to inhibit the door from opening, as the presence of the connected accessory may indicate that the user may not have intended to actuate a door release actuator, and may have instead intended to actuate a different actuator, button, or mechanism of the surface cleaning apparatus.

Also, the presence of a connected accessory may indicate that it is more likely that the surface cleaning apparatus is being used to clean a surface, as the accessory may typically be disconnected after a surface cleaning operation has been performed. Accordingly, it may be desirable to inhibit or prevent opening of the dirt collection region when an accessory is connected, in the event that a user inadvertently

13

bumps a door release actuator against furniture or another object when manipulating the surface cleaning apparatus with a connected accessory.

In accordance with this aspect, there is provided a surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door; and,
- (c) an accessory removably connectable to the dirty air inlet wherein, when the accessory is connected to the dirty air inlet, the openable door is inhibited from opening.

In some embodiments, the surface cleaning apparatus may further comprise a front end having the dirty air inlet and the openable door may be provided on the front end.

In some embodiments, the accessory may be removably mounted to the dirty air inlet.

In some embodiments, when the accessory is connected to the dirty air inlet, the accessory may physically inhibit the openable door from opening.

In some embodiments, when the accessory is connected to the dirty air inlet, the accessory may overlie a portion of the openable door.

In some embodiments, when the accessory is connected to the dirty air inlet, the accessory may abut a portion of the openable door.

In some embodiments, the openable door may have first and second opposed sides, the first side having a hinge for the openable door and, when the accessory is connected to the dirty air inlet, the accessory may interact with the second opposed side thereby inhibiting the openable door from opening.

In some embodiments, the surface cleaning apparatus may further comprise an openable door lock comprising a lock engaging member and a door release actuator drivingly connected to the lock engaging member, the lock engaging member may be moveable between an engaged position in which the lock engaging member secures the openable door in a closed position and a disengaged position in which the openable door is openable wherein the lock engaging member is inhibited from moving to the disengaged position when the accessory is connected to the dirty air inlet.

In some embodiments, the accessory may have a blocking portion that inhibits the lock engaging member moving to the disengaged position when the accessory is connected to the dirty air inlet.

In some embodiments, the openable door lock may include a moveable portion that moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the disengaged position, the moveable portion having an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

In some embodiments, the moveable portion may be part of a drive member drivingly connecting the door release actuator to the lock engaging member.

In some embodiments, the surface cleaning apparatus may further comprise a lock deactivation member and the accessory may have a blocking portion that activates the lock deactivation member when the accessory is connected to the dirty air inlet.

In some embodiments, the lock deactivation member may include a moveable portion that moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engag-

14

ing member is in the disengaged position, the moveable portion having an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

In some embodiments, the surface cleaning apparatus may further comprise an openable door lock wherein the openable door may be moveable to an open position when the openable door lock is moved to an open position and wherein the openable door lock may be inhibited from moving to the open position when the accessory is connected to the dirty air inlet.

In some embodiments, the accessory may be a longitudinally extending rigid member air flow member, an accessory cleaning tool, or a flexible hose.

Also in accordance with this broad aspect, there is also provided a surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door;
- (c) an accessory removably connectable in air flow communication with the dirty air inlet; and,
- (d) an openable door lock comprising a lock engaging member and a door release actuator drivingly connected to the lock engaging member, the lock engaging member is moveable between an engaged position in which the lock engaging member secures the openable door in a closed position and a disengaged position in which the openable door is openable wherein the lock engaging member is inhibited from moving to the disengaged position when the accessory is connected in air flow communication with the dirty air inlet.

In some embodiments, the accessory may have a blocking portion that inhibits the lock engaging member moving to the disengaged position when the accessory is connected to the dirty air inlet.

In some embodiments, the openable door lock may include a moveable portion that moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the disengaged position, the moveable portion having an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

In some embodiments, the moveable portion may be part of a drive member drivingly connecting the door release actuator to the lock engaging member.

Also in accordance with this broad aspect, there is also provided a surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door;
- (c) an accessory removably connectable in air flow communication with the dirty air inlet; and,
- (d) a lock deactivation member and the accessory has a blocking portion which activates the lock deactivation member when the accessory is connected in air flow communication with the dirty air inlet.

In some embodiments, the lock deactivation member may include a moveable portion that moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the disengaged position, the moveable portion having an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

15

Also in accordance with this broad aspect, there is also provided a surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door;
- (c) an accessory removably connectable in air flow communication with the dirty air inlet wherein, when the accessory is connected to the dirty air inlet, the accessory physically inhibits the openable door from opening.

In some embodiments, when the accessory is connected in air flow communication with the dirty air inlet, the accessory may overlie a portion of the openable door.

In some embodiments, when the accessory is connected in air flow communication with the dirty air inlet, the accessory may abut a portion of the openable door.

In some embodiments, the openable door may have first and second opposed sides, the first side having a hinge for the openable door and, when the accessory is connected in air flow communication with the dirty air inlet, the accessory may interact with the second opposed side thereby inhibiting the door from opening.

It will be appreciated that the aspects and embodiments may be used in any combination or sub-combination.

DESCRIPTION OF VARIOUS EMBODIMENTS

Numerous embodiments are described in this application, and are presented for illustrative purposes only. The described embodiments are not intended to be limiting in any sense. The invention is widely applicable to numerous embodiments, as is readily apparent from the disclosure herein. Those skilled in the art will recognize that the present invention may be practiced with modification and alteration without departing from the teachings disclosed herein. Although particular features of the present invention may be described with reference to one or more particular embodiments or figures, it should be understood that such features are not limited to usage in the one or more particular embodiments or figures with reference to which they are described.

The terms “an embodiment,” “embodiment,” “embodiments,” “the embodiment,” “the embodiments,” “one or more embodiments,” “some embodiments,” and “one embodiment” mean “one or more (but not all) embodiments of the present invention(s),” unless expressly specified otherwise.

The terms “including,” “comprising” and variations thereof mean “including but not limited to,” unless expressly specified otherwise. A listing of items does not imply that any or all of the items are mutually exclusive, unless expressly specified otherwise. The terms “a,” “an” and “the” mean “one or more,” unless expressly specified otherwise.

As used herein and in the claims, two or more parts are said to be “coupled,” “connected,” “attached,” or “fastened” where the parts are joined or operate together either directly or indirectly (i.e., through one or more intermediate parts), so long as a link occurs. As used herein and in the claims, two or more parts are said to be “directly coupled,” “directly connected,” “directly attached,” or “directly fastened” where the parts are connected in physical contact with each other. As used herein, two or more parts are said to be “rigidly coupled,” “rigidly connected,” “rigidly attached,” or “rigidly fastened” where the parts are coupled so as to move as one while maintaining a constant orientation relative to each other. None of the terms “coupled,” “connected,” “attached,” and “fastened” distinguish the manner in which two or more parts are joined together.

Referring to FIG. 1, an embodiment of a surface cleaning apparatus 100 is shown. The following is a general discussion of this embodiment which provides a basis for under-

18

standing each of the features which is discussed herein. As discussed in detail subsequently, each of the features may be used in other embodiments.

In the embodiment illustrated, the surface cleaning apparatus 100 is a hand-held vacuum cleaner, which is commonly referred to as a “hand vacuum cleaner” or a “handvac”. As used herein and in the claims, a hand-held vacuum cleaner or hand vacuum cleaner or handvac is a vacuum cleaner that can be operated one-handedly to clean a surface while its weight is held by the same one hand. This is contrasted with upright and canister vacuum cleaners, the weight of which is supported by a surface (e.g. floor below) during use. Optionally, surface cleaning apparatus 100 could be removably mountable on a base so as to form, for example, an upright vacuum cleaner, a canister vacuum cleaner, a stick vac, a wet-dry vacuum cleaner and the like. Power can be supplied to the surface cleaning apparatus 100 by an electrical cord (not shown) that can be connected to a standard wall electrical outlet. Alternatively, or in addition, the power source for the surface cleaning apparatus can be an onboard energy storage device, including, for example, one or more batteries.

As exemplified in FIGS. 1-4, the surface cleaning apparatus 100 may comprise a main body 104 having a handle 108, an air treatment member 112 connected to the main body 104, a dirty air inlet 116, a clean air outlet 120, and an air flow path extending between the inlet 116 and outlet 120. Surface cleaning apparatus 100 includes a front end 121, a rear end 122, an upper end 123, and a bottom 125. In the embodiment shown, the dirty air inlet 116 is at the front end 121. As exemplified, dirty air inlet 116 is the inlet end 124 of an inlet passage 128. Dirty air inlet 116 may be positioned forward of air treatment member 112 as shown. Optionally, the inlet end 124 can be used as a nozzle to directly clean a surface. Alternatively, the inlet end 124 can be connected or directly connected to the downstream end of any suitable accessory tool such as a rigid air flow conduit (e.g. wand, crevice tool, mini brush or the like) for example. For example, FIGS. 5 and 5A show an exemplary surface cleaning apparatus 132 (e.g. a stickvac) including surface cleaning apparatus 100 with connector inlet end 124 directly connected to a wand 136 (e.g., wand outlet end 612 may be removably connectable in air flow communication with inlet connector 128) that is pivotally connected to a surface cleaning head 140. Wand may be securable to connector 128 by any means known in the art such as a locking member or a friction fit. In the illustrated configuration of FIG. 5, the surface cleaning apparatus 100 can be used to clean a floor or other surface in a manner analogous to conventional upright-style vacuum cleaners.

From the dirty air inlet 116, the air flow path may extend through an air treatment member 112. The air treatment member 112 may be any suitable member that can treat the air in a desired manner, including, for example, removing dirt particles and debris from the air. In the illustrated example, the air treatment member is a cyclone unit 112, which may be of any design. Alternatively or in addition, the air treatment member may comprise one or more of a bag, a filter or other air treating means.

Cyclone unit 112 may include one or a plurality of cyclones for separating dirt from the air flow, and one or a plurality of dirt collection regions for receiving dirt separated in the cyclone(s). As exemplified in FIG. 6, cyclone unit 112 includes a cyclone or cyclone chamber 160 and an external dirt collection chamber 164. The cyclone 160 and dirt collection chamber 164 may be of any configuration suitable for separating dirt from an air stream and collecting

19

the separated dirt, respectively. For example, it will be appreciated that in some dirt collection area may be internal of the cyclone chamber, e.g., a dirt collection area may be provided at a longitudinal end of the cyclone chamber. Cyclone 160 may be oriented in any direction. For example, when surface cleaning apparatus 100 is positioned with bottom 125 on a horizontal surface 584, cyclone axis of rotation 484 may be oriented horizontally as exemplified, vertically, or at any angle between horizontal and vertical.

As also exemplified in FIG. 6, a suction motor and fan assembly 152 may be mounted within a motor housing portion 156 of the main body 104. In this configuration, the suction motor and fan assembly 152 is downstream from the cyclone unit 112, and the clean air outlet 120 is downstream from the suction motor and fan assembly 152.

Optionally, one or more pre-motor filters may be placed in the air flow path between the air treatment member and the suction motor and fan assembly. Alternatively, or in addition, one or more post-motor filters may be provided downstream from the suction motor and fan assembly.

As exemplified in FIG. 6, main body 104 is shown including a pre-motor filter housing portion 208 that is positioned in the air flow path downstream of cyclone unit 112. Pre-motor filter housing 208 may be of any construction known in the vacuum cleaner art. As exemplified, filter housing 208 may be bounded by one or more walls, which may be integral with or discrete from the main body exterior walls 212. Turning to FIG. 8, pre-motor filter housing 208 is shown including a filter housing first wall 216 axially opposite a filter housing second wall 220, and a filter housing sidewall 224 that extends in the direction of the cyclone axis of rotation between the first and second walls 216 and 220. It will be appreciated that first wall 216 is optional and second wall 220 may be in the form of ribs to hold the filter in place. In the illustrated example, filter housing sidewall 224 is discrete from main body exterior walls 212, which may provide enhanced sound insulation for air passing through the pre-motor filter housing 208. In alternative embodiments, filter housing sidewall 224 may be defined in whole or in part by main body exterior walls 212 for a more compact design.

Referring back to FIG. 6, one or more filters made of or comprising a porous filter media may be positioned within the pre-motor filter housing 208 to filter particles remaining in the air flow exiting the cyclone air outlet 184, before the air flow passes through the suction motor and fan assembly 152. In the illustrated embodiments, pre-motor filter housing 208 contains an upstream filter 228 and a downstream filter 232. The pre-motor filters 228 and 232 may be of any suitable configuration and formed from any suitable materials. Preferably, the pre-motor filters 228 and 232 are made of porous media such as foam, felt, or filter paper. Preferably a foam pre-motor filter is provided upstream of a felt pre-motor filter.

Pre-motor filter housing 208 may include a filter housing air inlet and a filter housing air outlet of any suitable design and arrangement within the housing 208. In the illustrated embodiment, pre-motor filter housing 208 includes a filter housing air inlet 236 formed in filter housing first wall 216, and a filter housing air outlet 240 formed in filter housing second wall 220.

Still referring to FIG. 6, pre-motor filter housing 208 may promote the air flow to broadly distribute across the pre-motor filters 228 and 232 inside. This allows the collected dust particles to be more evenly distributed throughout pre-motor filters 228 and 232 instead of concentrating in a narrow air flow path. An advantage of this design is that the

20

pre-motor filters 228 and 232 will have a greater effective dirt capacity, which allows the pre-motor filters 228 and 232 to be cleaned or replaced less frequently. To this end, pre-motor filter housing 208 may have any structure suitable for broadly distributing the air flow across pre-motor filters 228 and 232. For example, pre-motor filter housing 208 may provide an upstream header 256, a downstream header 260, or both as shown. Headers 256 and 260 may be provided by spacing the pre-motor filters from the filter housing end walls 216 and 220 respectively. In some embodiments, pre-motor filter housing 208 includes spacing members positioned to hold the pre-motor filters 228 and 232 away from the filter housing end walls 216 and 220. For example, referring to FIGS. 6 and 8, filter housing first wall 216 may include upstanding ribs 264 that hold the upstream side 268 of pre-motor filter 228 spaced apart from filter housing first wall 216 to allow air from filter housing air inlet 236 to flow laterally between pre-motor filter 228 and filter housing first wall 216 before penetrating pre-motor filter 228. The illustrated example also shows filter housing second wall 220 including upstanding ribs 272 that hold the downstream side 276 of pre-motor filter 232 spaced apart from filter housing second wall 220 to allow air exiting pre-motor filter 232 to flow laterally between pre-motor filter 232 and filter housing second wall 220, to filter housing air outlet 240.

Cyclone with a Unidirectional Flow of Air

The following is a description of a cyclone that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed including uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, pre-motor filter housing door, air treatment member door actuator, air treatment member door control, counterweight stand, and electrical coupling members.

In accordance with this aspect a cyclone comprises a cyclone with a unidirectional flow of air or a "uniflow" cyclone. As discussed in more detail, the uniflow cyclone may be horizontally disposed as opposed to being vertically disposed which is typical in the art. In other words, when held by hand and used to clean a surface, the axis of the cyclone chamber may be closer to horizontal than vertical.

In accordance with this aspect, the cyclone air inlet may be at the front end and the cyclone air outlet may be at the rear end. An advantage of this design is that the cyclone inlet may be used to redirect the air from the inlet passage 124 to the cyclone chamber and the air may exit the cyclone and travel linearly to the pre-motor filter. Accordingly, dirty air may travel from the dirty air inlet to the pre-motor filter without passing through any bends, thereby reducing the backpressure created by flow through the vacuum cleaner.

Alternately or in addition, in accordance with this aspect, the cyclone air inlet may be in an upper portion of the sidewall 168 of the cyclone. An advantage of this design is that it inhibits dirt that may remain in cyclone chamber 160 from exiting or blocking the air inlet when the apparatus is moved to various operating angles.

Alternately or in addition, in accordance with this aspect, the dirt collection chamber 164 may be external to the cyclone chamber 160. Further, the dirt outlet 188 of the cyclone chamber 160 may be at a rear end of the cyclone chamber and/or may be in a lower portion of the cyclone chamber, such as in a lower part of sidewall 168 of the cyclone chamber. An advantage of placing the dirt outlet 188 in a lower portion of the rear end of the cyclone chamber 160 is that, when the handvac is in use with inlet 116 pointed

21

downwardly, dirt will enter the dirt collection chamber **164** and fall forwardly due to gravity thereby preventing outlet **188** from becoming blocked until the dirt collection chamber **164** is full.

FIG. 7 exemplifies a cyclone unit including these aspects. As exemplified, cyclone **160** comprises a cyclone sidewall **168** extending axially from a cyclone first end **172** (e.g. front end comprising first end wall **192**) to a cyclone second end **176** (e.g. rear end comprising second end wall **196**), a cyclone air inlet **180** which enters cyclone **160** at a front portion of sidewall **168**, a cyclone air outlet **184** provided in cyclone second end wall **196**, and a cyclone dirt outlet **188**. Cyclone sidewall **168** includes an upper wall **169** and a lower wall **171**. As exemplified in FIG. 6, dirty air may enter cyclone **160** tangentially at cyclone air inlet **180** (which may be provided in the upper wall **169**), and swirl (e.g. move cyclonically) through cyclone **160** to separate dirt from the air flow, and then exit cyclone **160** through cyclone air outlet **184**. The separated dirt may exit cyclone **160** through cyclone dirt outlet **188** and deposit into dirt collection chamber **164**.

As exemplified a vortex finder **204** may extend axially between cyclone first and second ends **172** and **176**. Vortex finder **204** may have any configuration known in the art. For example, vortex finder **204** may be connected to cyclone second end wall **196** and extend axially towards cyclone first end **172**. Vortex finder **204** may surround cyclone air outlet **184**, so that air exiting cyclone **160** travels downstream through vortex finder **204** to cyclone air outlet **184**. Vortex finder **204** may include filter media **206** (e.g. mesh) to capture large dirt particles (e.g. hair and coarse dust) that remains in the air flow exiting cyclone **160**.

It will be appreciated that if cyclone air inlet **180** is located at an upper end of the cyclone **160**, then inlet passage **128** may be located above the central longitudinal axis of cyclone **160** and preferably is located above cyclone **160**. For example, as exemplified in FIGS. 1, 6 and 7, cyclone air inlet **180** may be a tangential air inlet so that air entering the cyclone **160** will tend to rotate as the air travels axially through the cyclone **160**, thereby dis-entraining dirt and debris from the air flow, before leaving the cyclone via the air outlet **184**. Further, inlet passage **128** extends longitudinally between passage inlet end **124** (i.e., the dirty air inlet **116**) and passage outlet end **130** along a longitudinal passage axis **364**, and passage outlet end **130** communicates (e.g. is positioned upstream) of cyclone air inlet **180**. Passage axis **364** may be linear, and all of the longitudinal passage axis **364** may be positioned above cyclone axis of rotation **484** when surface cleaning apparatus **100** is positioned with bottom **125** on a horizontal surface **584**.

Cyclone air inlet **180** may be positioned and constructed in any manner suitable for directing air tangentially into cyclone **160**. In the illustrated example of FIG. 22, cyclone air inlet **180** is formed as a curved passage extending from a cyclone air inlet upstream end **532** to a cyclone air inlet downstream end **536**. The cyclone air inlet downstream end **536** may be oriented to direct air substantially tangentially to the inner surface of sidewall **168**. As exemplified, cyclone air inlet **180** may be positioned above cyclone axis of rotation **484** and suction motor axis of rotation **540**. For example, cyclone air inlet **180** may be positioned at an upper end **544** of cyclone **160**. This allows gravity to assist with inhibiting dirt inside cyclone **160** from blocking or exiting cyclone air inlet **180**. This is because at least a portion of the cyclone **160** will be positioned below the cyclone air inlet

22

180 when apparatus **100** is held at various operating angles, so that the dirt inside will tend to fall away from cyclone air inlet **180**.

Still referring to FIG. 22, cyclone air inlet **180** is formed in cyclone sidewall **168** at cyclone first end **172**, and cyclone air outlet **184** is formed in cyclone second end wall **196** at cyclone second end **176**. As exemplified, air may exit cyclone air outlet **184** in a flow direction **616** that is generally parallel to the suction motor axis of rotation **540**.

As exemplified in FIG. 6, main body lower end **568** may comprise bottom **125**. In the illustrated example, when bottom **125** is placed on a horizontal surface, cyclone **160** may be oriented horizontally if bottom or base **125** is parallel to the cyclone axis. It will be appreciated that if bottom **125** is oriented at an angle to the horizontal, e.g., so that dirty air inlet **116** points downwardly when bottom **125** is on a horizontal surface, cyclone **160** may not be oriented horizontally when bottom **125** is on a horizontal surface. It will be appreciated that, as referred to herein, cyclone **160** being horizontal relates to the orientation if bottom **125** is parallel to the cyclone axis of rotation **484**.

As exemplified in FIG. 5A, when inlet connector **128** is mounted to a wand **557** (i.e. rigid air flow conduit), the wand axis **559**, the inlet connector axis **364**, and the cyclone axis of rotation **484** may be parallel. An advantage of this embodiment is that this reduces bends in the air flow for improved air efficiency. It will be appreciated that only some of these axes may be parallel. For example, only the inlet connector axis **364** and the cyclone axis of rotation **484** may be parallel.

Positioning of the Dirt Collection Chamber

The following is a description of a dirt collection chamber that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, pre-motor filter housing door, air treatment member door actuator, air treatment member door control, counterweight stand, and electrical coupling members.

In accordance with this aspect of the disclosure, a dirt collection chamber for a cyclone chamber may be provided external to and below the cyclone chamber. An advantage of this design is that a cyclone dirt outlet **188** may be provided in a lower portion of the cyclone chamber (e.g., cyclone dirt outlet **188** is provided in lower wall **171**) such that dirt which remains in the cyclone chamber after termination of operation of the vacuum cleaner may fall into the dirt collection chamber when the vacuum cleaner is held with the cyclone extending horizontally and slightly upwardly. A further advantage is that the width of the vacuum cleaner may be narrower as the dirt collection chamber is not located on the lateral sides of the cyclone chamber. Therefore, as exemplified in FIG. 18, the maximum width of a handvac may be determined by the width of the suction motor housing or the width of the cyclone **160**.

As exemplified in FIG. 18, dirt collection chamber **164** extends around approximately one-half of cyclone **160**. As exemplified, partition wall **556** may circumscribe approximately one-half of cyclone **160**. In other embodiments, dirt collection chamber **164** may extend around less than or greater than one-half of cyclone **160**, and partition wall **556** may similarly circumscribe less than or greater than one-half of cyclone **160**. In alternative embodiments, dirt collection chamber **164** may not surround cyclone **160**.

23

It will be appreciated that cyclone sidewall 168 and dirt collection chamber sidewall 548 may have any construction suitable for separating the cyclone 160 from dirt collection chamber 164 and allowing the passage of dis-entrained dirt therebetween. For example, cyclone sidewall 168 and dirt collection chamber sidewall 548 may be discrete walls that are spaced apart and connected by a dirt outlet passage. As exemplified in FIG. 18, dirt collection chamber sidewall 548 is formed at least in part by portions of cyclone sidewall 168 and portions of cyclone unit exterior wall 552. Similarly, cyclone sidewall 168 as shown is formed at least in part by portions of dirt collection chamber sidewall 548 and cyclone unit exterior wall 552. Accordingly, the wall portion 556 in common between cyclone 160 and dirt collection chamber 164 may operate as a dividing wall. Sharing a common dividing wall may help reduce the overall size of the cyclone unit 112, for a more compact design.

Returning to FIG. 22, cyclone 160 may include any dirt outlet 188 suitable for directing dis-entrained dirt from cyclone 160 to dirt collection chamber 164. For example, dirt outlet 188 may be formed in or connected to one or more (or all) of cyclone sidewall 168 and cyclone end walls 192 and 196. In the illustrated embodiment, dirt outlet 188 is formed in cyclone sidewall 168. Dirt outlet 188 may have any shape and size suitable for allowing dirt particles to pass into dirt collection chamber 164. In the illustrated embodiment, dirt outlet 188 is formed as a rectangular aperture in wall portion 556. In alternative embodiment, dirt outlet 188 may be circular, triangular, or another regular or irregularly shaped aperture. As exemplified, cyclone dirt outlet 188 may be bounded in part by cyclone second end wall 196.

It will be appreciated that cyclone dirt outlet 188 may be positioned anywhere at or between cyclone first and second ends 172 and 176. In the illustrated embodiment, cyclone 160 is a uniflow cyclone and accordingly cyclone dirt outlet 188 is positioned at cyclone second end 176 proximate cyclone air outlet 184. This allows the dirt and air to travel towards the same end of the cyclone 160 before parting ways—the air exiting through air outlet 184 and the dirt exiting through dirt outlet 188.

In use, the air stream inside cyclone 160 swirls towards cyclone air outlet 184 at cyclone second end 176, which dis-entrains dirt particles against cyclone sidewall 168. Under the influence of the rearward air stream, the dirt particles travel towards cyclone second end 176 and exit through cyclone dirt outlet 188 to dirt collection chamber 164.

Referring to FIG. 18, dirt collection chamber 164 may have any size and shape suitable to accommodate dirt separated by cyclone 160 during one or more uses. A larger dirt collection chamber 164 can store more dirt to allow apparatus 100 to run longer before emptying dirt collection chamber 164, but will add bulk and weight to the apparatus 100. A smaller dirt collection chamber 164 is smaller and lighter, but must be emptied more frequently.

Orientation of the Suction Motor

The following is a description of the orientation of a suction motor that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the positioning of the dirt collection chamber, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, pre-motor filter housing door, air treatment member door actuator, air treatment member door control, counterweight stand, and electrical coupling members.

24

As exemplified in FIG. 22, in accordance with this aspect, the axis of rotation of the suction motor may be generally parallel to the cyclone axis of rotation and/or the inlet conduit axis. An advantage of this design is that the air may travel generally rearwardly from the cyclone air outlet to the suction motor air inlet, thereby reducing the backpressure through this portion of the vacuum cleaner due to a reduction in the number of bends in the air flow path.

As exemplified in FIG. 22, when surface cleaning apparatus 100 is positioned with bottom 125 on a horizontal surface 584, the suction motor axis of rotation 540 may be generally horizontal. For example, cyclone sidewall 168 may extend generally horizontally between longitudinally spaced apart cyclone end walls 172 and 176, when surface cleaning apparatus 100 is positioned with bottom 125 on a horizontal surface 584. As exemplified, suction motor axis of rotation 540 may be generally parallel with cyclone axis of rotation 484. This allows for fewer bends in the air flow between dirty air inlet 116 and clean air outlet 120, which can result in reduced backpressure, all other elements remaining the same.

As exemplified, the suction motor axis of rotation 540 may be positioned below cyclone axis of rotation 484. This may provide surface cleaning apparatus 100 with a relatively lower center of gravity for greater stability when surface cleaning apparatus 100 is positioned with bottom 125 on a horizontal surface 584. In such a case, the pre-motor filter air inlet and outlet 236 and 240 may be axially offset as shown. In the illustrated example, filter housing air inlet axis 248 is located above and spaced apart from filter housing air outlet axis 252. An advantage of this design is that one or both of the headers may be used to change to elevation at which the air travels rearwardly with without using a conduit with bends. For example, air may travel generally rearwardly (linearly) into the pre-motor filter housing and air may travel generally rearwardly (linearly) out of the pre-motor filter housing, but at a lower elevation.

In alternate embodiments, filter housing air inlet and outlet axes 248 and 252 may not be spaced apart (e.g. they may be collinear).

In alternate embodiments, it will be appreciated that suction motor and fan assembly 152 may be positioned in main body 104 with its axis of rotation 540 oriented in any direction.

Lateral Stability Members

The following is a description of the lateral stability members that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the air treatment member handle, the position and orientation of a driving handle, pre-motor filter housing door, air treatment member door actuator, air treatment member door control, counterweight stand, and electrical coupling members.

Optionally, the air treatment member may be separable from the main body, such as for emptying, cleaning, or replacing the air treatment member or other internal components of the apparatus, such as the pre-motor filters.

In accordance with this aspect the air treatment member 112 is removable mountable to the main body 104 and is provided with lateral stability members. For example, the air treatment member 112 may abut against a front face of the main body 104 (see for example FIG. 1). Optionally, one of the air treatment member 112 and the main body may be receivable in the other. Accordingly, when unlocked, the air treatment member 112 may be removed from the main body

25

104 by moving it forwardly. During use, a transverse force may be applied to the air treatment member 112. As exemplified, inlet 116 is provided on the removable air treatment member 112. Therefore, when used as part of a stickvac and handle 108 is driving connected to a surface cleaning head (see for example FIG. 5), a force may be provided transverse to wand axis 559. If sufficient pressure is applied, then the air treatment member may break off of the main body or the air tight seal between the air treatment member and the main body may be broken allowing air to bypass the surface cleaning head. The provision of the lateral stability members reinforces the joint of the air treatment member and the main body to resist such transverse forces.

The lateral stability members are provided internal of the handvac and may be provided on opposed facing faces of the air treatment member and the main body. The lateral stability members may comprise generally vertically extending inter-engagement members

Cyclone unit 112 may be securable to main body 104 in any manner that allows the cyclone unit 112 to be selectively separated and reconnected to main body 104. For example, cyclone unit 112 and main body 104 may collectively include any releasable engagement members (e.g. latches, snaps, magnets, straps, etc.) suitable for releasably joining the cyclone unit 112 and main body 104. Further, cyclone unit 112 and main body 104 may collectively include any actuators that allow selective manual release (i.e. by hand) of the releasable engagement member(s). The releasable engagement member(s) and the actuator(s) may be mechanical, electrical, and/or electro-mechanical in nature.

As exemplified in FIGS. 9-11, main body 104 and cyclone unit 112 are separably connected by a cyclone unit release lock 278. As exemplified, cyclone unit release lock 278 includes a pair 280 of engagement members 304 and 308, and a release actuator 328. The release actuator 328 may be manually user operable (e.g. by hand) for selectably unlocking cyclone unit release lock 278 to allow main body 104 and cyclone unit 112 to separate.

In the illustrated example, cyclone unit 112 is also rotationally mounted to main body 104. For example, cyclone unit 112 may be rotationally mounted to main body 104 at a position longitudinally spaced apart from cyclone unit release lock 278. This allows cyclone unit 112 to rotationally separate from main body 104 when cyclone unit release lock 278 is unlocked (e.g. by operation of release actuator 328). In some embodiments, cyclone unit 112 may be rotationally mounted to main body 104 by a detachable pair 284 of engagement members 312 and 316. This allows for the option of fully detaching cyclone unit 112 from main body 104, such as to carry cyclone unit 112 to a garbage bin for emptying or cleaning for example. In alternative embodiments, second pair 284 of engagement members 312 and 316 may provide a permanent rotational connection that is not detachable. It will be appreciated that an alternate connection mechanism may be provided to secure the lower end of the air treatment member 112 and the main body 104 together when cyclone unit release lock 278 is engaged.

Cyclone unit release lock 278 and engagement member pair 284 may be positioned at any location on apparatus 100 suitable for securely joining the main body 104 and cyclone unit 112. For example cyclone unit release lock 278 and engagement member pair 284 may be positioned at opposite ends of apparatus 100, such as longitudinally spaced at apparatus upper end 288 and lower end 292 as shown. In the illustrated example, first cyclone unit engagement member 304 is positioned on cyclone unit upper end 348 and first

26

main body engagement member is positioned on main body upper end 570. In alternate embodiments, the lock positions may be reversed.

Cyclone unit release lock 278 and engagement member pair 284 may take any form suitable for separably joining main body 104 and cyclone unit 112. For example, one or both engagement member pairs 280 and 284 may include a first engagement member removably receivable in a second engagement member. As exemplified, first engagement member pair 280 includes a first cyclone unit engagement member 304 and a first main body engagement member 308, and second engagement member pair 284 includes a second cyclone unit engagement member 312 and a second main body engagement member 316.

Referring to FIG. 12, first cyclone unit engagement member 304 and first main body engagement member 308 are shown formed as hooks which are sized and positioned to interlock when the cyclone unit 112 and main body 104 are brought together. Second cyclone unit engagement member 312 is shown formed as a transversely extending rod which is received in hook-like second main body engagement member 316 when the cyclone unit 112 and main body 104 are brought together. As exemplified, cyclone unit lower end 352 is rotationally mounted to main body lower end 568 when second engagement member pair 284 is connected. When connected, cyclone unit release lock 278 and engagement member pair 284 hold cyclone unit 112 in fluid communication with main body 104, so that an air flow path is formed from dirty air inlet 116 to clean air outlet 120. A gasket or the like may be provided to form an air tight seal.

As exemplified in FIGS. 12-14, one or more of engagement members 304, 308, 312, and 316 may be movable to facilitate manual disconnection of the cyclone unit 112 from main body 104. For example, one or more of engagement members 304, 308, 312, and 316 may be movable away from the other engagement member of its respective engagement member pair 280 or 284 from a locked position to an unlocked position for disconnecting that engagement member pair 280 or 284. It will be appreciated that an engagement member 304, 308, 312, or 316 may be moveable in any direction. For example, it may be translatable in a linear direction or along a curved path, rotatable about any one or more axes, or combinations thereof.

As shown in FIG. 13, first cyclone unit engagement member 304 is in the open or unlocked position wherein it has been moved away from the closed or locked position shown in FIG. 12 in which it engages first main body engagement member 308, thereby disengaging the first engagement member pair 280. As exemplified, first cyclone unit engagement member 304 is pivotally mounted to a first engagement member axle 324 for rotation about the first engagement member axis 320 that extends laterally and first cyclone unit engagement member 304 extends substantially rearwardly whereby rotation of first cyclone unit engagement member 304 about first engagement member axis 320 moves the first cyclone unit engagement member 304 substantially vertically. In this example, first cyclone unit engagement member 304 is formed as a lower upwardly facing hook, first main body engagement member 308 is formed as an upper downwardly facing hook, and first cyclone unit engagement member 304 is pivotal about first engagement member axis 320 to move first cyclone unit engagement member 304 downwardly away from first main body engagement member 308 from the locked position (FIG. 12) to the unlocked position (FIG. 13), thereby disconnecting the first engagement member pair 280.

27

Once the first engagement member pair **280** is disconnected, the cyclone unit **112** and main body **104** may be separated at the apparatus upper end **288**, and then the cyclone unit **112** may be moved relative to the main body **104** to disconnect the second engagement member pair **284** thereby completing the disconnection of the cyclone unit **112** from the main body **104**.

Apparatus **100** may include any actuator **328** suitable for disengaging engagement member **304** and **308** to unlock cyclone unit release lock **278**. Actuator **328** may be provided on either of cyclone unit **112** or main body **104**. Preferably, the actuator **328** is manually operable (i.e. by hand) to allow selective disconnection of the engagement members **304** and **308**. In the illustrated embodiment, first main body engagement member **308** is connected to an actuator **328**. Actuator **328** may take any form such as a button as shown, a switch, or a slider for example. Actuator **328** may be connected to first main body engagement member **308** in manner suitable for directing the movement of first main body engagement member **308**. In the illustrated example, first main body engagement member **308** is integrally formed with a distal end of actuator **328**. In alternative embodiments, actuator **328** may be a discrete component that is rigidly or movably connected to first main body engagement member **308** directly or indirectly by way of one or more intermediary components.

As exemplified, a proximal end of actuator **328** may be pivotally mounted to cyclone unit **112** by first engagement member axle **324** for rotation about first engagement member axis **320**. In use, a user may depress actuator **328** to rotate actuator **328** and first cyclone unit engagement member **304** downwardly, thereby disconnecting the first engagement member pair **280**.

In some embodiments, first cyclone unit engagement member **304** may be biased to the locked position to mitigate the risk of first engagement member pair **280** becoming unlocked during use of apparatus **100**. In the illustrated example, a bias **332** biases first cyclone unit engagement member **304** to the open position. Bias **332** may be formed as a torsional spring, as shown, which is mounted to first engagement member axle **324**. A user may depress actuator **328** to move the first cyclone unit engagement member **304** against the bias of spring **332** and disconnect first engagement member pair **280**.

Reference is now made to FIGS. **15** and **16**, which show apparatus **100** including an alternative first engagement member pair **280**. As exemplified, first cyclone unit engagement member **304** may include an engagement member arm **336** with an engagement member socket **340**, and first main body engagement member **308** may be formed as a peg. In the locked position (FIG. **15**), peg **308** may be received in engagement member socket **340** to securely join first engagement member pair **280**. In the unlocked position (FIG. **16**) peg **308** may be removed from engagement member socket **340** to disconnect first engagement member pair **280**. As exemplified, engagement member arm **336** may be resiliently bendable (i.e. as a living hinge) for moving first main body engagement member **308** between the locked and unlocked positions. For example, engagement member arm **336** can resiliently bend upwardly to remove peg **308** from engagement member socket **340** (FIG. **16**), and vice versa. Preferably, the resiliency of engagement member arm **336** biases first cyclone unit engagement member **304** towards the locked position.

Exemplary lateral stability members are shown in FIGS. **26-30**. As exemplified, air treatment member **112** and main body **104** may collectively include one or more pairs of

28

protrusions and recesses, which mate at the interface between air treatment member **112** and main body **104** when air treatment member **112** is connected to main body **104**. This helps provide a more robust separable connection between air treatment member **112** and main body **104** with enhanced strength and rigidity. Air treatment member rear end **436** and main body front end **432** may be provided with mating protrusions **620** that are receivable in recesses **624**.

Protrusions **620** and recesses **624** may have any size, shape, and position which allows the protrusions **620** to be received in the recesses **624** when air treatment member **112** and main body **104** are connected. As exemplified, each of protrusions **620** and recesses **624** may be formed as elongate segments which are continuous or have discontinuities. In the illustrated embodiment, each of protrusions **620** and recesses **624** extend longitudinally downwardly.

As exemplified in FIGS. **26** and **27**, protrusions **620** are formed in cyclone unit upper end **348** (engagement member arm **336**) and recesses **624** are formed in surface of main body upper end **570** against which engagement member arm **336** abuts. Protrusions **620** are received in recesses **624** when air treatment member **112** is connected to main body **104**.

FIG. **28** shows an alternate embodiment, in which cyclone unit upper end **348** includes recesses **624** and main body upper end **570** includes protrusions **620**.

FIG. **29** shows another alternate embodiment including protrusions **620** and recesses **624** extending across cyclone rear end wall **176** and filter housing front wall **216**.

FIG. **30** shows another embodiment including protrusions **620** extending across cyclone rear end wall **176** and filter housing front wall **216**. When air treatment member **112** is connected to main body **104**, protrusions **620** on cyclone rear end wall **176** contact filter housing front wall **216**, and protrusions **620** on filter housing front wall **216** contact cyclone rear end wall **176**. In this embodiment, protrusion **620** provide rigid beams at the interface between main body **104** and air treatment member **112** which may increase the rigidity and strength of the separable connection.

Air Treatment Member Handle

The following is a description of an air treatment member handle that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the unflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the position and orientation of a driving handle, pre-motor filter housing door, air treatment member door actuator, air treatment member door control, counterweight stand, and electrical coupling members.

In accordance with this aspect, the air treatment member may include a handle in addition to the main body handle ("driving handle"). This allows a user to hold the main body and the air treatment member simultaneously, with different hands before, during, and after disconnecting the main body from the air treatment member.

In one embodiment, the air treatment member handle may for part of an air flow conduit of the air treatment member. Alternately or in addition, the air treatment member handle may extend along the axial direction of the air treatment member and/or may be on an upper portion thereof and/or may provide a gap for receiving fingers of the user.

As exemplified in FIG. **11**, cyclone unit handle **344** is connected to cyclone unit **112** when cyclone unit **112** is disconnected from main body **104**, and driving handle **108** is connected to main body **104** when main body **104** is disconnected from cyclone unit **112**. Cyclone unit handle

29

344 may have any suitable size, shape, and position on cyclone unit 112 which allows a user to easily grasp the cyclone unit handle 344 by hand to carry the cyclone unit 112 (see FIG. 10A). In the illustrated embodiment, cyclone unit handle 344 is formed as a substantially cylindrical member, which extends rearwardly along cyclone unit upper portion 348. In other embodiments, cyclone unit handle 344 may have a different regular or irregular cross-sectional shape, and may extend along a different portion of cyclone unit 112, such as along lower portion 352, or a lateral side 356 for example. As exemplified in FIG. 6, cyclone unit handle 344 may include a portion or gap 347 spaced from cyclone unit 112 whereby a finger receiving area 349 is provided between the cyclone unit handle 344 and the cyclone unit 112.

Returning to FIG. 11, preferably apparatus 100 is configured to allow the user to take whatever action disconnects the main body 104 from air treatment member 112 while holding air treatment member handle 344 with one hand and holding driving handle 108 with the other hand. For example, cyclone unit handle 344 or driving handle 108 may be positioned proximate (e.g. within finger-reach of) an actuator that releases the connector(s) which hold air treatment member 112 and main body 104 together. This would allow the user to use a finger to operate the actuator while holding the handle 344 or 108 with the remaining fingers of their hand. In the illustrated embodiment, cyclone unit handle 344 and actuator 328 are both located on the cyclone unit upper portion 348 and in close proximity. This allows a user to hold air treatment member 112 by handle 344 while simultaneously operating actuator 328 with the same hand to disconnect air treatment member 112 from main body 104. The user may also use the same hand to open a front door of the air treatment member as discussed subsequently in more detail.

Referring to FIG. 6, cyclone unit handle 344 is shown extending along a cyclone unit handle axis 360. In some embodiments, cyclone unit handle axis 360 may be parallel with and may be coaxial with inlet connector axis 364. This may promote a compact shape for apparatus 100 in contrast with handles with an axis that extends above the inlet connector axis 364.

As exemplified in FIGS. 1 and 17, cyclone unit handle 344 may comprise an air flow passage (e.g. an air flow conduit). This may promote a compact design for apparatus 100 by reducing or eliminating the volume added to apparatus 100 to incorporate cyclone unit handle 344. For example, an existing air flow conduit may be reshaped and/or repositioned to provide handle functionality. As exemplified in FIG. 17, handle 344 is positioned rearward and coaxial with the inlet conduit extending from dirty air inlet 116. It will be appreciated that if the inlet to the air treatment member chamber (e.g., cyclone chamber 160) is rearward of the front of handle 344, then part of handle 344 form part of inlet conduit 124. Alternately, or in addition as exemplified in FIG. 17, handle 344 may provide part or all of a bleed air conduit 380 having a longitudinal passage axis 390. Bleed conduit 380 provides a portion of the air flow path between the bleed air inlet 384 and the suction motor and fan assembly 152 and houses bleed valve 388. The bleed valve 388 may be any suitable valve that is known in the art, which typically open automatically in response to low pressure. For example, bleed valve 388 may be a pressure relief valve. Bleed valve 388 may help maintain adequate volumetric air flow through the suction motor and fan assembly 152 during low pressure events to avoid overheating of the suction motor and fan assembly 152. Low pressure

30

may occur where there is a partial or total blockage in the air flow upstream of the suction motor and fan assembly 152 (e.g. a plastic bag is blocking dirty air inlet 116).

It will be appreciated that cyclone unit handle 344 is grasped primarily when apparatus 100 is turned off (e.g. when separating, reconnecting, or transporting cyclone unit 112) so that there is little or no concern of the bleed air inlet 384 being blocked by a user's hands when apparatus 100 is turned on.

FIG. 17 exemplifies an optional air flow path from bleed air inlet 384 to suction motor and fan assembly 152 which bypasses cyclone 160 and pre-motor filters 228 and 232. As exemplified, the air flow path may extend rearwardly through bleed valve conduit 380 to filter housing downstream header 260 bypassing filter housing upstream header 256 and pre-motor filters 228 and 232. In alternate embodiments, the air flow path may extend through pre-motor filters 228 and 232 to filter fine particulates that may be present in the ambient air drawn into bleed air inlet 384. For example, filter housing upstream header 256 may be positioned downstream of bleed valve 388 in the air flow path from bleed air inlet 384.

Position and Orientation of a Driving Handle

The following is a description of a driving handle that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the pre-motor filter housing door, the air treatment member door actuator, air treatment member door control, the counterweight stand, and the electrical coupling members.

In accordance with this aspect, the driving handle is which extends upwardly and forwardly. Driving handle 108 may extend upwardly from the suction motor housing (e.g., an upper surface of the main body that houses the suction motor). Driving handle 108 may terminate at Or above an upper end of the handvac 100. Accordingly, the inlet conduit axis 364 and/or the handle axis 360 may intersect the driving handle 108. An advantage of this design is that the weight of the motor is below the hand grip. Further, the driving axis of the handvac when connected to a wand (the wand axis) is at an opposite end of the handle to the suction motor. This provides improved hand weight for a user.

As exemplified in FIG. 6, driving handle 108 may extend from its lower end 368 to its upper end 372 along a driving handle axis 376. When surface cleaning apparatus 100 is positioned with bottom 125 on a horizontal surface 584 and the bottom 125 extends horizontally, driving handle axis 376 may extend generally upwardly and forwardly (e.g. at an angle 378 of less than 45 degrees to vertical) to provide a comfortable natural grip during use.

As exemplified, driving handle axis 376 may be at an angle to cyclone unit handle axis 360. For example, axes 360 and 376 may be angularly offset by 30 degrees or more. This reflects that the driving handle 108 and cyclone unit handle 344 may have different functions. For example, the driving handle 108 may be configured to provide a comfortable grip for the user during use, and the cyclone unit handle 344 may be configured with a compact design.

In the illustrated embodiment, driving handle 108 includes a portion 377 spaced from main body 104 whereby a finger receiving area 379 is provided between the driving handle 108 and the main body 104. As exemplified, driving handle 108 may be positioned at main body rear end 434 and longitudinally spaced apart from cyclone unit handle 344.

31

Pre-Motor Filter Housing Door

The following is a description of a pre-motor filter door that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, the air treatment member door actuator, air treatment member door control, the counterweight stand, and the electrical coupling members.

In accordance with this aspect, a surface cleaning apparatus may have a pre-motor filter chamber which is closed by an openable door that is accessible when the air treatment member is removed from the remainder of the surface cleaning apparatus (as exemplified in FIG. 6). A pre-motor filter may be accessed for cleaning or replacement when the door is opened. The pre-motor filter door may include a handle for user operation. The pre-motor filter chamber may be provided in the removable air treatment member 112 or the main body 104. The door may be held in a closed position by a part of the surface cleaning apparatus that does not include the pre-motor filter chamber. For example, if the pre-motor filter chamber is provided in the air treatment member, then the door may be held closed by a part of the main body when the air treatment member is attached to the main body. Conversely, if the pre-motor filter chamber is provided in the main body as exemplified in FIG. 8, then the door may be held closed by a part of the air treatment member when the air treatment member is attached to the main body. An advantage of this design is that it allows a simpler design for the pre-motor filter door that is free of locking members such as latches. A further advantage is that unintentional user access to the pre-motor filter housing 208 may be prevented while the apparatus 100 is in operation.

FIGS. 8, 8A and 11 exemplify an embodiment in which pre-motor filter housing 208 is accessible when air treatment member 112 is disconnected from main body 104. For example, one of the filter housing walls 216 and 220 (e.g., filter housing upstream wall 216 as exemplified in FIG. 8) may be exposed when air treatment member 112 is disconnected from main body 104.

The openable filter housing wall may be openable in any manner suitable for providing access to clean or replace the pre-motor filters inside. For example, the openable wall may be moveably mounted or removably mounted. Accordingly, filter housing wall 216 or 220 may be pivotally attached to the pre-motor filter housing 208, slideably attached to the pre-motor filter housing 208, or removable altogether from the pre-motor filter housing 208. In the illustrated embodiment, filter housing upstream wall 216 is pivotally attached to pre-motor filter housing 208.

As exemplified in FIGS. 8A and 11, filter housing upstream wall 216 is rotatable about a filter-housing wall pivot axis 392 between a closed position (FIG. 11), and an open position (FIG. 8A). It will be appreciated that filter housing upstream wall 216 may be rotatable in any manner and direction suitable for moving the filter housing upstream wall 216 generally away from the pre-motor filter housing 208 to provide access to the pre-motor filters 228 and 232 inside. In the illustrated embodiment, filter housing upstream wall 216 is upwardly rotatable about a laterally extending (e.g. horizontal) filter housing wall pivot axis 392 located at an upper end 396 of the pre-motor filter housing 208. As exemplified, the filter housing wall pivot axis 392 is transverse to (e.g. substantially perpendicular to) the inlet

32

connector axis 364, the cyclone unit handle axis 360, and the filter housing air inlet axis 248.

In alternative embodiments, filter housing upstream wall 216 may rotate in a different direction about a different axis. For example, filter housing upstream wall 216 may move laterally outwardly by rotation about a substantially vertical axis positioned proximate a left or right side of the pre-motor filter housing 208.

Still referring to FIGS. 8A and 11, the filter housing upstream wall 216 may have any construction suitable for allowing the filter housing upstream wall 216 to rotate about the filter housing wall pivot axis 392. For example, filter housing upstream wall 216 may be connected to filter housing sidewall 224 by a hinge 404 of any suitable type. In some embodiments, filter housing upstream wall 216 may be resiliently bendable to connect with pre-motor filter housing 208 by a living hinge.

Optionally, filter housing upstream wall 216 may be at least partially transparent (e.g., the wall may be made of a transparent material or it may have a window) to provide visibility of the upstream surface 268 (FIG. 8A) of the pre-motor filter inside. This would allow the user to inspect the pre-motor filter through the filter housing upstream wall 216, without opening the pre-motor filter housing 208, in order to assess whether to clean or replace the pre-motor filter. In alternative embodiments, the filter housing upstream wall 216 may be opaque, and the pre-motor filter may not be visible through the filter housing upstream wall 216.

Still referring to FIGS. 8A and 11, the openable filter housing wall is preferably manually user openable (e.g. by hand). This allows the user to selectively open the openable filter housing wall to access the pre-motor filters inside. In the illustrated example, the filter housing upstream wall 216 includes a filter housing handle 408 that is user operable to move the filter housing upstream wall 216 between the open and closed positions. The filter housing handle 408 may have any construction that allows the user to easily grasp and pull the filter housing handle 408 to open the pre-motor filter housing 208. In the illustrated example, the filter housing handle 408 extends outwardly from an end opposed to the hinged end (in this case lower end 412 of the filter housing upstream wall 216). Referring to FIGS. 11 and 13, the filter housing handle 408 extends from a filter housing handle inboard end 416 to a filter housing handle outboard end 420. As exemplified, the filter housing handle inboard end 416 may be connected to an upstream face 424 of the filter housing upstream wall 216. The filter housing outboard end 420 may include a gripping feature, which may be of any design such a lip 428. In the illustrated example, lip 428 is curls approximately 90 degrees.

As exemplified in FIG. 13, the filter housing handle 408 may extend from filter housing upstream wall 216 outwardly towards cyclone unit 112. In the illustrated example, a front end 432 of main body 104 is connectable to the rear end 436 of cyclone unit 112, and filter housing handle 408 extends forwardly from filter housing upstream wall 216 towards cyclone unit 112. As shown, the filter housing handle outboard end 420 extends into a handle recess 440 of cyclone unit 112 outside of cyclone 160 and dirt collection chamber 164. In this way, the handle may overlap a portion of the cyclone chamber so as to have a longer length in the direction of the cyclone axis. This construction allows the filter housing handle 408 to have a greater dimension 444 between its inboard and outboard ends 416 and 420, while permitting the filter housing upstream wall 216 to contact at least a portion of cyclone second wall 196 to fluidly connect

33

the cyclone air outlet **184** to the filter housing air inlet **236**. In the illustrated example, the filter housing handle **408** extends from filter housing upstream wall lower end **412**, and cyclone unit handle recess **440** is provided in cyclone unit lower portion **352**.

Returning to FIGS. **8A** and **11**, in some embodiments, pre-motor filter housing **208** may be free of locking members, such as latches or clasps, which are operable to secure the openable wall in the closed position. Accordingly, when the main body **104** and cyclone unit **112** are connected together (see, e.g. FIG. **1**) filter housing handle **408** extends forwardly from filter housing upstream wall **216** and abuts a part of air treatment member **112**, e.g., rear end wall **196** of the air treatment member.

As exemplified in FIG. **13**, the openable door of the pre-motor filter housing **208** may be held in its closed position by interaction with cyclone unit **112**, when cyclone unit **112** is connected to main body **104**. For example, at least a portion of cyclone unit rear end **436** may contact filter housing upstream wall **216** to hold the filter housing upstream wall **216** in its closed position. In the illustrated example, cyclone second wall **196** is bordered by a peripheral lip **448** which contacts upstream face **424** of filter housing upstream wall **216**, and cyclone air outlet **184** is bordered by a peripheral lip **452** that contacts a peripheral recess **456** of filter housing air inlet **236**. Peripheral lip **452** and recess **456** may form a substantially air tight connection between cyclone air outlet **184** and filter housing air inlet **236**.

In some embodiments, a gasket, such as an O-ring (not shown) may be provided and compressed when the air treatment member is attached to provide an air tight seal between the openable door and the rest of the pre-motor filter chamber.

Air Treatment Member Door Actuator

The following is a description of an air treatment member door actuator that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, the pre-motor filter housing door, the air treatment member door control, the counterweight stand, and the electrical coupling members.

The air treatment member may include an openable door that provides access to empty or clean the air treatment member (e.g. to empty or clean a dirt collection region of the air treatment member). In accordance with this aspect, the air treatment member door may be openable by an actuator positioned within finger-reach of the air treatment member handle. This allows for one handed operation of the air treatment member door.

Reference is now made to FIGS. **1** and **18**. In some embodiments, air treatment member **112** includes an openable wall (e.g., a door) to provide access to clean or empty the air treatment member (e.g., cyclone **160** and dirt collection chamber **164**). Any portion of air treatment member **112** suitable for emptying air treatment member **112** may be openable.

In the illustrated example, air treatment member **112** includes an openable front end **472** wherein all of the front end is openable. As exemplified, the air treatment member may be a cyclone unit comprising a cyclone and a dirt collection chamber external to the cyclone and may have a front end **472** that includes cyclone first end wall **192**, and

34

dirt collection chamber first end wall **476**. It will be appreciated that, in some embodiments, only a portion of the front end **472** may be openable.

The openable door may be openable in any manner suitable for providing access to clean or empty air treatment member **112**, e.g., cyclone **160** and dirt collection chamber **164**. For example, the door may be pivotally attached to the air treatment member **112** which is exemplified in FIG. **18**, slideably attached to the air treatment member **112**, and/or removable altogether from the air treatment member **112**.

As exemplified, cyclone unit front door **472** is rotatable about a cyclone unit wall pivot axis **480** between a closed position (FIG. **1**), and an open position (FIG. **18**). It will be appreciated that cyclone unit front door **472** may be rotatable in any manner and direction suitable for moving cyclone unit front door **472** generally away from the cyclone unit **112** to provide access to the cyclone **160** and dirt collection chamber **164** inside. In the illustrated embodiment, cyclone unit front door **472** is downwardly rotatable about a laterally extending (e.g. horizontal) cyclone unit wall pivot axis **480** located at a lower portion **352** of the cyclone unit **112**. As exemplified, the cyclone unit wall pivot axis **480** is transverse to (e.g. substantially perpendicular to) the inlet connector axis **364**, the cyclone unit handle axis **360**, and the cyclone axis of rotation **484**.

In alternative embodiments, cyclone unit front door **472** may rotate in a different direction about a different axis. For example, cyclone unit front door **472** may move laterally outwardly by rotation about a substantially vertical axis positioned proximate a left or right side of the cyclone unit **112**. In other embodiments, cyclone unit front door **472** may move upwardly by rotation about a substantially horizontal axis positioned proximate cyclone unit upper portion **348**.

Still referring to FIGS. **1** and **18**, the cyclone unit front door **472** may have any construction suitable for allowing the cyclone unit front door **472** to rotate about the cyclone unit wall pivot axis **480**. For example, cyclone unit front door **472** may be connected to cyclone unit **112** by a hinge **486** of any type known in the art. In some embodiments, cyclone unit front door **472** may be resiliently bendable to connect with cyclone unit **112** by a living hinge.

Still referring to FIGS. **1** and **18**, the openable cyclone unit wall is locked in the closed position, and manually user openable (e.g. by hand). This allows the openable cyclone unit wall to remain closed while the apparatus **100** is operating, and allows the user to selectively open the openable cyclone unit wall to empty the cyclone **160** and dirt collection chamber **164** inside when the apparatus **100** is turned off. In the illustrated example, cyclone unit **112** includes a door lock **492**, which inhibits opening of cyclone unit front door **472** when engaged. Door lock **492** is user operable to disengage door lock **492** to thereby permit cyclone unit front door **472** to move to its open position.

Door lock **492** may be any type of lock suitable for retaining cyclone unit front door **472** in its closed position, and which is user releasable to permit cyclone unit **112** to open. In some embodiments, door lock **492** may have a manually operable actuator for moving the lock between its engaged and disengaged positions. In the illustrated embodiment, door lock **492** includes an engaging member **496** and an actuator **504**.

Preferably, actuator is positioned proximate the air treatment member handle **344** so that a user may operate actuator **504** with the same hand that is used to hold handle **344**. For example, actuator **504** may be located within close proximity (e.g. finger-reach) of handle **344**, e.g., it may be provided on or adjacent handle **344** and may be provided at the end

35

of handle 344 at which the door is located. Accordingly while holding handle 344, the user may use their thumb of the same hand to operate actuator 504, i.e., door release actuator 504 may be operated by the same hand which is holding the cyclone unit 112 for single-handed emptying of cyclone unit 112. In the illustrated embodiment, unit door release actuator 504 is positioned forward of handle 344 on upper portion 348 (e.g. at a forward end of inlet passage 380). In other embodiments, door release actuator 504 may be located on handle 344, or rearwardly of handle 344.

As exemplified in FIGS. 20 and 21, the door release actuator 504 is manually user operable (i.e. by hand) to move the engaging member 496 between its engaged position (FIG. 20) and its disengaged position (FIG. 21). As exemplified, in the engaged position (FIG. 20), door release actuator 504 may engage cyclone unit front door 472 to inhibit movement of front door 472 to its open position. This prevents front door 472 from rotating about its cyclone unit wall pivot axis 480 to its open position. In the disengaged position (FIG. 21), door release actuator 504 releases cyclone unit front door 472 to permit front door 472 to move to its open position.

Referring to FIGS. 19-21, lock engaging member 496 may be of any construction having an engaged position for retaining the openable cyclone unit wall in its closed position, and a disengaged position for releasing the openable cyclone unit to move to its open position. In the illustrated example, lock engaging member 496 is connected to an exterior of air treatment member 112. As exemplified, lock engaging member 496 has a front end 508 which is sized and positioned to releasably hook onto a recess 512 formed in cyclone unit front door 472 to retain the front door 472 in its closed position.

Lock engaging member 496 may be movable in any suitable manner between its engaged and disengaged positions. For example, lock engaging member 496 may be rotatable as shown, translatable, or combinations thereof. In the illustrated embodiment, lock engaging member 496 is pivotally connected to air treatment member 112 for rotation about a lock engaging member axis 516 (FIG. 19) between its engaged and disengaged positions. As exemplified, in the engaged position, lock engaging member 496 may hook onto front wall lock recess 512. Lock engaging member 496 may then be rotated about its axis 516 away from cyclone unit front door 472 to unhook from front wall lock recess 512. Optionally, lock engaging member 496 may be biased to the locked position. For example, a biasing member (e.g. torsional spring, not shown) may bias lock engaging member 496 to rotate toward the closed position.

Still referring to FIGS. 19-21, door lock 492 may have any door release actuator 504 suitable for moving the lock engaging member 496 between its engaged and disengaged positions. In the illustrated example, door release actuator 504 is formed as a button which is operable to rotate lock engaging member 496 to its unlocked position. As exemplified, door release actuator 504 and lock engaging member 496 may both include abutments 520 and 524, respectively, which make contact to move lock engaging member 496 when door release actuator 504 is depressed. In this example, when door release actuator 504 is depressed, abutment 520 moves abutment 524 downwardly which teeters lock engaging member 496 to rotate about its lock engaging member axis 516 to its disengaged position. It will be appreciated that door release actuator 504 may be movable in any suitable manner. For example, door release actuator 504 may be rotatable (e.g. pivotal) as shown, or translatable (e.g. slidable). In the illustrated example, door

36

release actuator 504 is rotatably connected to cyclone unit 112 about a lock actuator axis 528 between its raised position (FIG. 20) and its depressed position (FIG. 21).

Air Treatment Member Door Control

The following is a description of systems and methods for controlling an openable door of an air treatment member that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the air treatment member door actuator, uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, the pre-motor filter housing door, the counterweight stand, and the electrical coupling members.

The air treatment member may include an openable door that provides access to empty or clean the air treatment member (e.g. to empty or clean a dirt collection region of the air treatment member). In accordance with this aspect, the air treatment member door may be inhibited or prevented from opening when an accessory (e.g. a cleaning tool such as a wand (e.g. a rigid airflow conduit), crevice tool, mini brush, or the like) is connected to or in fluid communication with a dirty air inlet.

In some embodiments, an accessory may be removably connectable to a dirty air inlet of the surface cleaning apparatus, and when the accessory is connected to the dirty air inlet, the accessory may itself physically inhibit an openable door from opening. For example, when the openable door is closed and the accessory is connected to the dirty air inlet, the accessory may overlie or abut at least a portion of the openable door.

An example of such an embodiment is illustrated in FIGS. 5 and 5A. As exemplified a dirty air inlet 116 of surface cleaning apparatus 100 is the inlet end 124 of an inlet passage 128. In the illustrated example, the dirty air inlet 116 is connected to a wand 136. As seen in FIG. 5A, the outlet end 612 of the wand 136 has a collar 702 which is sized to overly a portion of the openable door of the cyclone assembly. Accordingly, when the wand is connected to the dirty air inlet, collar 702 abuts a portion of an openable front end 472 (which may also be referred to as a cyclone unit front door 472) of air treatment member 112, thereby inhibiting or preventing the openable door from opening when the wand is connected. When wand 136 is disconnected from dirty air inlet 116, collar 702 no longer abuts openable door 472, and thus no longer inhibits door 472 from opening.

In some embodiments, the surface cleaning apparatus may include an openable door lock which is moveable between a closed position which inhibits the opening of an openable door of an air treatment member and an open position in which the door may be opened. The door lock is preferably user operable to disengage the door lock to thereby permit the door to move to its open position. In such embodiments, when an accessory is connected to the dirty air inlet, the door lock may be inhibited or prevented from being disengaged. The accessory may itself inhibit the door lock from moving to the open position or it may actuate a mechanism (a motorized mechanism or a mechanical mechanism) that inhibits the door lock from moving to the open position.

In the example illustrated in FIGS. 31 and 32, a door lock 492 inhibits opening of cyclone unit front door 472 when engaged. In the illustrated embodiment, door lock 492 includes an engaging member 496 which, when the door lock is in the closed position that is exemplified in FIG. 31, abuts door 472. Door lock 492 also comprises an actuator

37

504. As exemplified, door release actuator 504 and lock engaging member 496 may both include abutments 520 and 524, respectively, which make contact to move lock engaging member 496 when door release actuator 504 is depressed to move the door lock to the open position (see FIG. 32).

In the illustrated example, an accessory itself has a blocking member that, when the accessory is connected to the dirty air inlet, inhibits the door lock from being disengaged. As exemplified, an outlet end 612 of a wand 136 includes a flange 710 that, when the wand 136 is connected to the dirty air inlet 116 (as shown in FIG. 31), is interposed between the abutment 520 of door release actuator 504 and the abutment 524 of lock engaging member 496. In this position, flange 710 is a physical barrier between the abutments 520 and 524 and thereby inhibits door release actuator 504 from moving lock engaging member 496, thereby inhibiting door 472 from being moved to an open position. When the accessory is disconnected from the dirty air inlet 116 (as shown in FIG. 32), flange 710 no longer inhibits door release actuator 504 from moving lock engaging member 496.

In the example illustrated in FIGS. 33 and 34, the accessory physically engages the door release actuator 504 to thereby inhibit the door lock from being disengaged. For example, door release actuator 504 may have an engagement portion, and a blocking member of an accessory tool may have a mating engagement portion. The engagement portions may interengage when the accessory is mounted to the inlet. As exemplified, an engagement portion in the form of a notch 720 is provided along shaft 725 of door release actuator 504.

As shown in FIG. 33, when the wand 136 is connected to the dirty air inlet 116, an engagement portion of the wand 136 (e.g., flange 710) is received in the notch 720. In this position, flange 710 inhibits door release actuator 504 from moving towards lock engaging member 496, thereby inhibiting door 472 from being moved to an open position. When the accessory is disconnected from the dirty air inlet 116 (as shown in FIG. 34), flange 710 no longer engages the engagement portion 720, and thus no longer inhibits door release actuator 504 from moving lock engaging member 496 to its disengaged position.

FIGS. 35 and 36 exemplify an embodiment wherein the accessory actuates a mechanical mechanism that inhibits the door lock from moving to the open position. As exemplified, the surface cleaning apparatus includes a lock deactivation member that, when an accessory is connected, inhibits the door lock from being disengaged. As exemplified, a lock deactivation member is in the form of a bar 740 that is translatable between a position in which the door lock is inhibited from being disengaged (the closed position of the door lock) and a position in which the door lock is not inhibited from being disengaged (the open position of the door lock).

As shown in FIG. 35, when the wand 136 is connected to the dirty air inlet 116, bar 740 is moved to a position in which it is interposed between the abutment 520 of door release actuator 504 and the abutment 524 of lock engaging member 496. In this position, bar 740 inhibits door release actuator 504 from moving lock engaging member 496, thereby inhibiting door 472 from being moved to an open position. In FIG. 36, the accessory is disconnected from the dirty air inlet 116, and bar 740 has moved so that it no longer inhibits door release actuator 504 from moving lock engaging member 496. It will be appreciated that bar 740 may be moved to the open position of the door lock shown in FIG.

38

36 by wand 136 pulling the bar to the open position, bar 740 being biased to the open position, or the like.

In some embodiments, an openable door lock may be moved to an engaged position by connecting an accessory tool to the surface cleaning apparatus, and moved to a disengaged position by disconnecting the accessory tool from the surface cleaning apparatus. That is, instead of inhibiting or preventing a door lock from being released, connection of an accessory to a dirty air inlet may positively engage a door lock to inhibit or prevent the openable door from opening.

In the example illustrated in FIGS. 37 and 38, a door lock 492 inhibits opening of cyclone unit front door 472 when engaged. In the illustrated embodiment, door lock 492 includes an engaging member 496 and an actuator 504. As exemplified, door release actuator 504 includes a rounded abutment surface 520, and lock engaging member 496 includes an angled abutment surface 524. As exemplified in FIG. 37, when an accessory is connected to the dirty air inlet 116, actuator 504 is driven against lock engaging member 496, and the interaction of the abutment surfaces results in engaging member 496 being driven towards a recess 512 formed in cyclone unit front door 472 to retain the front door 472 in its closed position. When the accessory is disconnected a biasing member such as a spring 750 retracts or draws engaging member 496 towards a disengaged position, as shown in FIG. 38. In this position, door lock 492 does not inhibit door 472 from being moved to an open position.

Counterweight Stand

The following is a description of a counterweight stand that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the unflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, the pre-motor filter housing door, the air treatment member door actuator, the air treatment member door control, and the electrical coupling members.

In accordance with this aspect, the apparatus may include a counterweight positioned to adjust the apparatus center of gravity for reducing user-torque required to orient the apparatus at common operating angles. The counterweight may be located at a lower end of the main body to provide a stand for supporting the apparatus on a horizontal surface. The counterweight may be formed by a removable member (e.g. energy storage member), or a permanently attached or integrally molded member (e.g. ribs).

As exemplified in FIG. 23, apparatus 100 includes a counterweight stand 564. The counterweight stand 564 may have any configuration suitable for helping to support apparatus 100 on horizontal surface and for influencing the center of gravity of apparatus 100. As exemplified, counterweight stand 564 may be connected to apparatus lower end 292 for supporting apparatus 100 when apparatus lower end 292 is placed on a horizontal surface (e.g. for storage). In various embodiments, counterweight stand 564 may be connected to main body 104, air treatment member 112, or both. In the illustrated embodiment, counterweight stand 564 is connected to main body lower end 568 to define at least a portion of a lower wall of main body 104 for supporting apparatus 100 on a horizontal surface.

Counterweight stand 564 may be of any size and weight suitable for providing stable support and for influencing the apparatus center of gravity. For example, counterweight stand 564 may be formed of the same material as main body

39

exterior wall **212** (e.g. plastic), and may be formed as a solid member, a hollow member, a porous member, or a plurality of spaced apart members. In the illustrated embodiment, counterweight stand **564** is formed as a plurality of spaced apart counterweight ribs **572** that are integrally formed with the main body exterior wall **212**. As exemplified, counterweight ribs **572** may be rearwardly extending and laterally spaced apart. This allows the counterweight ribs **572** to be distributed across a large area to form a base that may itself or with bottom **125** stably support the apparatus **100** on a horizontal surface. The collective weight of ribs **572**, and thus their influence on the apparatus center of gravity, is determined by varying the number, density, spacing, and distribution of the counterweight ribs **572**. In alternative embodiments, counterweight stand **564** may be formed by a hollow member, and the weight of the counterweight stand **564** is determined by the fill density inside the block. In some embodiments, counterweight stand **564** may be formed from a different material than main body exterior wall **212**, such as a material of greater density to provide greater stability and influence on center of gravity.

Still referring to FIG. **23**, the counterweight stand **564** may be integrally formed, permanently connected, or removably connected to apparatus **100**. In the illustrated embodiment, counterweight stand **564** is permanently connected to apparatus **100**. As exemplified, apparatus **100** may be a corded appliance having a power cord connector **576** for permanently or removably receiving a power cord (not shown) that is connectable to an external power source (e.g. wall outlet). Turning to FIGS. **4** and **24**, another embodiment of apparatus **100** is shown including a counterweight stand **564** formed as an energy storage member **580** (e.g. battery). Energy storage member **580** may be permanently or removably connected to apparatus **100**, and may have a size and weight suitable for helping to support apparatus **100** on a horizontal surface **584** and influencing the center of gravity of apparatus **100**.

Electrical Coupling Members

The following is a description of an electrical coupling members that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein including the uniflow cyclone, the positioning of the dirt collection chamber, the orientation of the suction motor, the lateral stability members, the air treatment member handle, the position and orientation of a driving handle, the pre-motor filter housing door, the air treatment member door actuator, the air treatment member door control, and the counterweight stand.

In accordance with this aspect, the apparatus may include an electrical outlet with electrical conductor element(s) that are movable from a circuit closed position to a circuit open position upon removal of an accessory tool such as a wand, crevice tool, mini brush or the like. The accessory tool which is mounted on the apparatus may have a member which engages a driven member on the apparatus. When engaged, the driven member mechanically moves an element of the circuit to open the circuit so that the electrical conductor elements on the apparatus are not live. This allows the electrical outlet to be safe to touch when the accessory tool is disconnected.

Referring to FIG. **1**, connector **128** may be any suitable connector that is operable to connect to, and preferably detachably connect to, a hose, cleaning tool or other accessory tool. Optionally, in addition to providing an air flow connection, connector **128** may also include an electrical connection. Providing an electrical connection may allow accessory tools that are coupled to the connector **128** to be

40

powered by the surface cleaning apparatus **100**. For example, the surface cleaning unit **100** can be used to provide both power and suction to a surface cleaning head, or other suitable accessory tool. In the illustrated embodiment, the connector **128** includes an electrical outlet **144** in the form of a female socket member, and a corresponding male connector member may be provided on the hose, cleaning tool or other accessory tool that is connected to the connector inlet end **124**. In other embodiments, electrical outlet **144** may include male connectors.

As exemplified in FIG. **25**, apparatus **100** includes an electrical circuit **642** between a source of power and electrical conductor elements **588**. The source of power may be an energy storage member **580** (e.g. battery) or a power cord **628** (connectable to an external power outlet), for example. In accordance with this aspect, electrical conductor elements **588** may be de-energized when not connected with a mating electrical coupling (e.g. of a power accessory). This may prevent user injury from being hurt by inadvertent contact with the electrical conductor elements **588**.

The electrical circuit **642** may include two or more electrical conductor elements **588**, at least one of which, and preferably two of which, may be movable between a circuit closed position and a circuit open position, and biased to the circuit open position. In the circuit closed position, the electrical conductor element **588** is electrically connected to the source of power. In the circuit open position, the electrical conductor **588** is electrically disconnected from the source of power. Accordingly, at least one of the electrical conductor elements **588** is normally electrically disconnected from the source of power, which may prevent accidental electric shock. In use, the electrical conductor element **588** is moved to the circuit closed position upon attaching an accessory tool to dirty air inlet **116**.

In one embodiment, the electrical conductor elements **588** may be moved to the circuit closed position by engagement with the electrical conductor elements of an accessory tool. Accordingly, when the accessory tool is mounted on inlet **116**, the electrical conductor elements of the accessory tool may drive electrical conductor elements **588** to the circuit closed position.

As exemplified, electrical conductor elements **588** may be a rigid rod movably mounted in a housing **596** of electrical outlet **144**. Each electrical conductor element **588** extends from a first contact end **640** to a second contact end **644**. The first contact end **640** may be an accessory tool contact end which makes electrical contact with a mating electrical conductor element of an attached accessory tool. The second contact ends **644** may be a terminal end contact end which makes electrical contact with the terminal ends **636** of electrical conductive members **590** when the electrical conductor elements **588** are in a circuit closed position. Accordingly, when an accessory tool is electrically connected to electrical outlet **144** and electrical conductor elements **588** are in the circuit closed position, the conductor element **588** can conduct electricity from the source of power to the connected accessory tool.

It will be appreciated that electrical conductive members (e.g. wires) **590** extend from the source of power to terminal ends **636**. One or both of electrical conductor elements **588** may be movable between a circuit closed position, in which second contact end **644** contacts terminal end **636** of an electrical conductive member **590**, and a circuit open position, in which second contact end **644** is spaced apart from the terminal ends **636** of electrical conductive members **590**. For example, one or both of electrical conductor elements **588** may be axially slidable in electrical outlet housing

41

between the circuit open and circuit closed positions. In the illustrated example, electrical conductor elements **588** are rearwardly slideable in rearwardly extending housing channels **604** formed in electrical outlet housing **596**.

In some embodiments, the first end **640** of one or both of electrical conductor elements **588** may be recessed into the electrical outlet **144** when in the circuit open position. For example, first end **640** may be positioned rearwardly of electrical outlet front end **608**.

Electrical conductor element **588** may be biased to the circuit open position in any manner. For example, electrical outlet **144** includes a biasing member **648** that applies a biasing force urging electrical conductor element **588** toward the circuit open position. In the illustrated example, biasing member **648** is a compression spring positioned between the electrical conductor element **588** and the terminal end **636** of electrical conductive member **590** which urges electrical conductor element **588** forwardly. The force of biasing member **648** may be overcome when connecting an accessory tool to dirty air inlet **116** to move the electrical conductor element **588** rearwardly to the circuit closed position. Preferably, biasing member **648** is substantially non-electrically conductive. For example, biasing member **648** may be formed of (or coated with) plastic, rubber, a non-conductive metal or another substantially non-electrically conductive material. This helps to prevent biasing member **648** from short circuiting electrical circuit **642** or electrically connecting electrical conductor element **588** and terminal end **636** when the electrical conductor element **588** is in the closed position.

It will be appreciated that, in an alternate embodiment, electrical conductor elements **588** may be mounted in a moveable (e.g., plastic or other non-conductive material) housing and the housing may have an engagement member that is engaged by, e.g., a protrusion or finger provided on the accessory tool. In this way, the electrical conductor elements of the accessory tool need not be used to drive the circuit **642** to a closed position.

In some embodiments, main power switch **650**, which is movable between a circuit closed position and a circuit open position to energize the suction motor, may be part of electrical circuit **642**. The power switch may be manually user. In the circuit open position, power switch **650** electrically disconnects electrical terminal end **636** from the power source. In the circuit closed position, power switch **650** electrically connects circuit terminal end **636** with the power source.

While the above description provides examples of the embodiments, it will be appreciated that some features and/or functions of the described embodiments are susceptible to modification without departing from the spirit and principles of operation of the described embodiments. Accordingly, what has been described above has been intended to be illustrative of the invention and non-limiting and it will be understood by persons skilled in the art that other variants and modifications may be made without departing from the scope of the invention as defined in the claims appended hereto. The scope of the claims should not be limited by the preferred embodiments and examples, but should be given the broadest interpretation consistent with the description as a whole.

The invention claimed is:

1. A surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door;

42

(c) an accessory removably connectable to the dirty air inlet wherein, when the accessory is connected to the dirty air inlet, the openable door is inhibited from opening; and,

(d) an openable door lock comprising a lock engaging member and a door release actuator drivably connected to the lock engaging member, the lock engaging member moveable between an engaged position in which the lock engaging member secures the openable door in a closed position and a disengaged position in which the openable door is openable wherein the lock engaging member is inhibited from moving to the disengaged position when the accessory is connected to the dirty air inlet.

2. The surface cleaning apparatus of claim 1 further comprising a front end having the dirty air inlet and the openable door is provided on the front end.

3. The surface cleaning apparatus of claim 1 wherein the accessory is removably mounted to the dirty air inlet.

4. The surface cleaning apparatus of claim 1 wherein, when the accessory is connected to the dirty air inlet, the accessory physically inhibits the openable door from opening.

5. The surface cleaning apparatus of claim 4 wherein, when the accessory is connected to the dirty air inlet, the accessory overlies a portion of the openable door.

6. The surface cleaning apparatus of claim 5 wherein, when the accessory is connected to the dirty air inlet, the accessory abuts a portion of the openable door.

7. The surface cleaning apparatus of claim 1 wherein the accessory has a blocking portion which inhibits the lock engaging member moving to the disengaged position when the accessory is connected to the dirty air inlet.

8. The surface cleaning apparatus of claim 7 wherein the openable door lock includes a moveable portion which moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the disengaged position, the moveable portion has an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

9. The surface cleaning apparatus of claim 8 wherein the moveable portion is part of a drive member drivably connecting the door release actuator to the lock engaging member.

10. The surface cleaning apparatus of claim 1 further comprising a lock deactivation member and the accessory has a blocking portion which activates the lock deactivation member when the accessory is connected to the dirty air inlet.

11. The surface cleaning apparatus of claim 10 wherein the lock deactivation member includes a moveable portion which moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the disengaged position, the moveable portion has an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

12. The surface cleaning apparatus of claim 1 wherein the accessory is a longitudinally extending rigid member air flow member, an accessory cleaning tool, or a flexible hose.

13. A surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;

43

- (b) an air treatment member comprising a dirt collection region having an openable door wherein the dirty air inlet is positioned above the air treatment member;
- (c) an accessory removably connectable to the dirty air inlet wherein,

wherein the openable door has first and second opposed sides, the first side having a hinge for the openable door and the second opposed side is positioned adjacent the dirty air inlet such that, when the accessory is connected to the dirty air inlet, the accessory overlies the second opposed side thereby inhibiting the openable door from opening.

14. A surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door;
- (c) an accessory removably connectable in air flow communication with the dirty air inlet; and,
- (d) an openable door lock comprising a lock engaging member and a door release actuator drivingly connected to the lock engaging member, the lock engaging member is moveable between an engaged position in which the lock engaging member secures the openable door in a closed position and a disengaged position in which the openable door is openable wherein the lock engaging member is inhibited from moving to the disengaged position when the accessory is connected in air flow communication with the dirty air inlet.

15. The surface cleaning apparatus of claim **14** wherein the accessory has a blocking portion which inhibits the lock engaging member moving to the disengaged position when the accessory is connected to the dirty air inlet.

16. The surface cleaning apparatus of claim **15** wherein the openable door lock includes a moveable portion which moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the dis-

44

gaged position, the moveable portion has an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.

17. The surface cleaning apparatus of claim **16** wherein the moveable portion is part of a drive member drivingly connecting the door release actuator to the lock engaging member.

18. A surface cleaning apparatus comprising:

- (a) an air flow path from a dirty air inlet to a clean air outlet and including a suction motor;
- (b) an air treatment member comprising a dirt collection region having an openable door;
- (c) an accessory removably connectable in air flow communication with the dirty air inlet; and,
- (d) an openable door lock securing the openable door in a closed position, a lock deactivation member and the accessory has a blocking portion which moves the lock deactivation member to a blocking position which inhibits the openable door lock moving to a door openable position when the accessory is connected in air flow communication with the dirty air inlet.

19. The surface cleaning apparatus of claim **18** wherein the accessory has a blocking portion which inhibits the lock engaging member moving to the disengaged position when the accessory is connected to the dirty air inlet.

20. The surface cleaning apparatus of claim **19** wherein the openable door lock includes a moveable portion which moves along a path from a first position when the lock engaging member is in the engaged position to a second position when the lock engaging member is in the disengaged position, the moveable portion has an abutment surface and the blocking portion is positioned in the path of the abutment surface when the accessory is connected to the dirty air inlet.
