A computer network method for conducting payment over a network by crediting and debiting telecommunication accounts. The computer network includes a computer connected to the Internet, which performs the following functions: (1) receiving a payment request from a prospective payer; (2) confirming the request and assigning a unique transaction identifier; (3) receiving an electronic authority from the payer's telecommunication service computer indicating whether or not such request has been approved; (4) crediting and debiting payer's and payee's telecommunication accounts with their respective telecommunication service providers and (5) confirming this transaction by responding a receipt to the payer's mobile device and to payee's server.

FIELD OF THE INVENTION

[0004] The present invention relates to methods for making payments for the purchase of goods or services over a network such as the Internet by crediting and debiting telecommunication accounts belonging to the seller and buyer respectively. Specifically, the invention provides for receiving payments as credits in a telecommunication account including means, at merchant point-of-sale locations such as web site, and includes means for debiting a payer's telecommunication account in response to the payment. The user's wireless communication device is used as the means to confirm, authenticate and validating the transaction. A central processor or payment processor is provided to facilitate the process.

BACKGROUND OF THE INVENTION

[0005] The present invention relates to methods of using a cellular phone or other wireless communication device communicating with a payment processor to confirm, authorize purchases over the Internet and provide a simple verification of the valid purchase. The purchase cost is debited from the buyer's prepaid account with the telecommunication provider or in the case of non prepaid buyers, accrued as a payable item on their monthly telecommunication statement. This same purchase amount is then credited to the payee's telecommunication account. There is no transfer of funds from any accounts either from a financial institution or otherwise. Merchants receiving payment will have their own telecommunication credits in dollars recorded in their statements and the payer will have the telecommunication debits recorded for non prepaid accounts to be settled later according to the terms as set by the telecommunication provider. Other terms such as a ceiling of max purchase cost may be set. This invention is primarily designed for small value items.

[0006] Prior to the present invention, cellular phones and/or other wireless communication devices have been used in a variety of different procedures involving the transfer of funds between different accounts involving financial institutions and different accounts. These procedures leave something to be desired in that they are unduly complicated and less convenient and/or less secure and costly.

SUMMARY OF THE INVENTION

[0007] The present invention avoids the failings of the prior art by providing methods which are highly reliable and

simple to follow using existing technology. The main advantage here is that no funds is physically being transferred from one physical account or another and purchases are either billed by the telecommunication provider or alternatively debited directly if it is a prepaid account. And in both cases they are merely book entries into the accounts with the telecommunication providers. Money paid will be in the form of credits to the receiver or merchant as the case may be which is either in the form of telecommunication service credits or a direct cash pay out. Having it within the telecommunication accounting system and bill means little or no changes to existing accounting requirements.

[0008] In accordance with the present invention, a method is used to purchase goods or services over the Internet and where such purchase is debited into the mobile phone owner's account and the receiver/merchant's account is credited with the amount less a fee. This invention includes confirmation, authorisation and to provide validation of the purchase on presentation. The final step is particularly important for services where the buyer needs to present proof of purchase in order to receive on the spot service purchase such as tickets.

[0009] The method of crediting and debiting between different telecommunication accounts within the same telecommunication service provider comprising the steps of expanding the function of a service provider's central processing unit to include account and authorization information, generating a function code over the net to the user, requesting user to re-enter the function code provided on the keypad of a cellular phone or other wireless communication device or by voice, sending the function code to the central processing unit of the provider which identifies the desired transaction and the payer and payee, determining at the central processing unit whether a personal identification number is needed, and supplying the central processing unit with the personal identification number where this personal identification number can be keyed in or spoken on the cellular phone, upon confirmation of the identity of the payer either by the personal identification number or by voice patterns, authorizing the desired transaction, determining the different accounts involved in the transaction, making a debit entry to the payer's account, making a credit entry to payee's account and confirming completion of the transaction.

[0010] The method includes the steps of expanding the function of a service provider's central processing unit such as the telecommunication carrier to include user sub account.

[0011] The method of crediting and debiting between different telecommunication accounts with two different telecommunication providers comprising the steps of expanding the function of a telecommunication service provider's central processing unit to include account and authorization information. A separate payment processor linked to participating telecommunication providers is used to generate a function code over the net to the user, requesting user to re-enter the function code provided on the keypad of a cellular phone or other wireless communication device or by voice, sending the function code to the payment processor unit which identifies the desired transaction and the payer and payee. Determining at the payment processing unit whether a personal identification number is needed, and

supplying the central processing unit at the payer's telecommunication with the personal identification number where this personal identification number can be keyed in or spoken on the cellular phone. Upon confirmation of the identity of the payer either by the personal identification number or by voice patterns by the central processing unit at the buyer's telecommunication carrier, payment processor will authorize the desired transaction, determining the different accounts involved in the transaction, further instructing a debit entry to the payer's account with the first telecommunication carrier, instructing a credit entry to payee's account with the second telecommunication carrier and confirming completion of the transaction with both payer and payee.

[0012] Preferably, the method includes the step of initiating a purchase over the Internet by entering the mobile phone number as the identifying account to be debited. This step is similar to using credit card but instead of the credit card number, a phone number is used instead. Upon confirmation of such an account, the service provider will issue an activation code over the net to the user's web browser where such activation code is use to confirm the purchase. The carrier or service provider will initiate a purchase call to the owner of the mobile phone as per the mobile phone number provided. This step can be substitute by the user calling the carrier instead if required. Having connected to the telecommunication carrier, the user will enter first the activation code as shown on the web page to confirm the purchase. This code must be spoken directly to the mobile phone where the voice pattern of the user of the mobile phone is compared with the stored voice pattern stored in the sub account or key in on the mobile phone keypad if user has selected this option. This is followed by an authorisation query where the user/purchaser will need to response by entering his or her password which is earlier set on opening the purchase telecommunication sub account. This password can be keyed in or by using the voice protocol as mentioned above. Upon receiving and verifying the authorisation code the carrier will check for available credits in the account in the case of a prepaid account holder. In the case of a non prepaid account holder, the purchase cost will be entered and included as part of the user's monthly phone bill invoice to be paid. A credit book entry amounting to the cost of the purchase less a fee will also be made to the payee's telecommunication sub account. A confirmation receipt is then sent to the mobile phone as a short message service (SMS) where such receipt is encrypted with information about the purchase and purchase identification or other relevant data such as time of purchase as determined by the payment processor. In addition, upon completion of the transaction the merchant's server will receive an encrypted receipt from the payment processor where such receipt is stored as a record for validation if required. For validation purposes, the user will download this stored message to the buyer's or merchant's server using an coupling device suitable for this means. Both messages will be compared by the merchant's server.

[0013] In case of a dispute, the user or payer can resent this encrypted message to the payment processor to be decrypted and the payment processor will either confirm or denied such message and sent the results to both user's mobile phone and merchant's server.

BRIEF DESCRIPTION OF THE DRAWINGS

[0014] The foregoing aspects and the attendant advantages of this invention will become more readily appreciated through reference to the following detailed description, when read and considered in conjunction with the accompanying drawings, wherein:

[0015] **FIG. 1** is a block diagram introducing the various components involved in the system and methods of the present invention.

[0016] **FIG. 2** is a flow chart illustrating a method for processing the payment transaction of a payer account maintained on a prepaid platform, utilizing an payment processor system according to the invention.

[0017] **FIG. 3** is a flow chart illustrating a method for processing the payment transaction of a payer account maintained on a prepaid platform where the point of sale is a vending machine, utilizing an payment processor system according to the invention.

[0018] **FIG. 4** is a flow chart illustrating a method for activating a sub account with a telecommunication carrier.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

[0019] **FIG. 1** illustrates the principle components of a system and methods according to the present invention to provide payment for the purchase of goods and services over the internet by debiting and crediting the payment amount sought in telecommunication carrier accounts from two separate carriers. Referring to **FIG. 1**, a customer **70** with a mobile phone or wireless device represents a person who has established one or more payment accounts linked to their telecommunication account with at least one provider according the invention. Customer **70** is illustrated as having a mobile device and visiting at a point-of-sale. A point-of-sale can be a conventional "brick and mortar" retail merchant location, such as a store or restaurant or a vending machine having a link to the Internet through a communication device with display monitor. A point-of-sale for present purposes can also be a kiosk, touch-screen or other data terminal as further described herein at any location accessible to users as long as they are linked at least by a telecommunication network. In **FIG. 1**, for the sake of simplicity, the point of sale is a web site in a web server connected to the internet network.

[0020] In **FIG. 1**, the merchant **20** refers generically to the proprietor of a point-of-sale establishment or payee, such as a web site on the Internet example; www.amazon.com. According to the present invention, as further described later, the customer **70** is connected to this web site by requesting its Universal Resource Locator (URL) over the Internet from a terminal using a program such as known as a browser and intends to purchase a particular item and this intention is transmitted to the payment processor **40** by a hyperlink such as <http://www.paymentel.com/merchant/XY-Z.asp?merchantid=1234567&itemid=12342&ran=12342sd>, generated by scripts such as CGI or ASP residing on the merchant server **20**.

[0021] Where “merchantid” represents the id of the merchant, “itemid” represents the item the purchaser wish to purchase and the cost by “ran” which are all encrypted. Other variables may be included depending on the system requirements.

[0022] The heart of the present system is a payment processor 40, which can be conveniently implemented on a suitable general purpose digital computer programmed as explained in greater detail later and connected to the network linking the participants. The principle features and functions of the payment processor, each of which will be described in greater detail in turn, include a means 30 for accessing an existing telecommunication network to communicate transaction data; payment interface to customer 60; payment clearing, settlement and reporting services 50 and carriers 100/110. It is important to note that this payment processor 40 may be coupled with or as part of an extension of at least one telecommunication carrier main central processor rather than as an individual entity as depicted here. The reasons for a single external entity here is to illustrated the separation of functions between the central processor at payer’s carrier and payment processor. This is crucial for accountability particularly in a payment transaction which requires a third party to reconcile the accounts.

[0023] It is critical to note that in this application, the customer 70 is an individual (or business) who is currently utilizing goods or services provided by at least one telecommunication carrier 110/100. The user’s account for the purposes of making payment from, which we also refer to as the sub account, is maintained by the wireless carrier 110 on a prepaid platform or non prepaid such as an accrual platform where the customer 70 is billed on a periodical basis. The system is intended to serve the needs of multiple merchants (each of which has its own universe of end-users as well as the payment gateway for their respective carriers). One important feature of the present system is that the customer 70 must already have an existing account with their respective carriers prior to using this service and the target merchant must agree as the counter party of this service since payment in the form of monetary credits will be accrued into their telecommunication account. With this telecommunication account, they will be able to set up a sub account using account activation service 80. The sub account is a “virtual” account separating entries between real telecommunication cost and other transactions as authorised by the payer under terms with the service provider and is consolidated with the main telecommunication account for billing purposes. The telecommunication service provider may provide limits on this sub account. This sub account also contained authorisation data to gain access. It is therefore necessary that payer and payee involved in the transaction to have telecommunication accounts with at least one participating carrier and subsequently open an sub account. The payment processor 40 maintains a database of the transactions and respective account holders, each of which is “associated” with a corresponding carrier’s user account, as further explained below. This is purely for record keeping and for profiling the users. This database do not have any relevant information such as passwords or voice patterns required to authenticate the transaction which are held with their respective carriers as it should be.

[0024] FIG. 2 is a flow chart illustrating the basic method for processing a payment transaction to purchase a product

from a web merchant where the payer account is maintained on a prepaid platform with Carrier 1 (110). In this example, the web merchant has an account with Carrier 2 (100) and both carriers are parties to this payment service. To illustrated this further, we have separated the payment processor 40 as an independent hosted server providing the payment services but it is recognised that the payment processor can be integrated with at least one of the carrier and service as many other carriers participating in this arrangement. The main reason for this separation is an administrative rather than a technical one.

[0025] We have also applied an prepaid account for customer 70 where such account is held with Carrier 1 (110) while the merchant 20 has an non-prepaid account where such account is held with Carrier 2 (100). The prepaid mobile phone user/customer 70 visits a merchant at point-of-sale 20 using his browser program from his terminal over the Internet. The customer 70 indicates he wants to make a purchase or make payment at the web site by clicking a hyper link text on the web page residing on the merchant’s server over the Internet through connection 50. As mentioned previously, when the payer click on the hyperlink linking to the payment processor via the web site 20, the unique identification of the merchant, cost and other relevant data are communicated through connection 51 via a telecommunication network 30 to the payment processor 40 where upon the payment processor replies in the form of a web page on its web server to the payer’s browser and requesting for payer’s mobile phone number.

[0026] In the same communication, the payment processor also sent a random generated number (also known as transaction number) to associate this transaction to customer 70 within the same web page. The payment processor will initiate the necessary sequence to authenticate the customer 70 as well as to check the merchant’s details are valid prior to generating the random number to associate this transaction in its database. It should be appreciated, the initial step to establish contact with the payment processor varies from different point of sale as we shall see later. On receiving the mobile phone number from the customer 70, payment processor will contact the carrier where the customer has provided the account with, in this case carrier 1 (110). Payment Processor 40 will query Carrier 1 (110) whether this account exists in their customer database and if it is a prepaid account to also verify if enough funds are current to pay for the goods through connection 52. Payment processor may also query if there is any special limitations to this account where such limitations are pre set by the carrier’s main processor. If carrier 1 replies with affirmative to both queries, Payment Processor 40 will then communicate through connection 54 & 56 with the customer using the payment interface to customer 60 by calling and connecting to the provided mobile number sent by the customer 70. Alternatively, the customer 70 may call the payment processor 40 if a number is provided being routed through the payment interface to customer 60. This stage of the process is generally refers to transaction confirmation. This transaction is performed when the customer 70 is asked to provide the random number generated earlier as shown in the web page and is required to associate the transaction with the payment system (transaction) account number at the payment processor 40. This transaction can be managed by either an interactive voice response (IVR) application that is running on a voice response unit (VRU) or through a live customer care representative. Typically this transaction will occur only at the beginning of the call and if the requested

number entered is in error after a number of tries, the call will be terminated and the caller number recorded. The requested transaction number is keyed in on the key-pad of the mobile phone or by speech through connection 57 where another program such as a voice recognition software at 60 will decipher the results and passed it through connection 55 to Payment Processor 40 for processing.

[0027] Provided the payment processor 40 can confirm the transaction exist and good, then is followed by the authentication stage where the payment processor is required to authenticate the customer 70 as the legitimate account holder before able to process the payment. Payment Processor 40 commenced by either requesting for a password or as the case may be to authenticate the user's voice pattern using payment interface to customer 60.

[0028] On receiving the data from connection 55, payment processor 40 will interrogate Carrier 1 (110) about the account holder and the password provided. These data are kept at the Carrier's database at the time the sub account is established using account activation service 80 (not shown in FIG. 2). The main reason for keeping these data with their respective carrier is that each carrier may have a different accounting system to track their customers' credit status in real time. Only carriers will have the latest detail of their customers in real time. If the data such as the password is keyed in and sent by the customer 70 is verified by carrier and provided there are sufficient funds for a prepaid user, then Carrier 1 will send a good response to Payment Processor 40. If both password and voice pattern are required, then the customer 70 need to speak the password into the mobile phone for verification.

[0029] Once a good response is received from Carrier 1 (110), payment processor 40 will through Payment Clearing, Settlement and Reporting Services 50 instructs carrier 1 (110) to deduct the amount from the customer's prepaid account in real time and at the same time instruct Carrier 2 (100) where the merchant's telecommunication sub account is held to credit the account with the same amount deducted from customer's account at carrier 1 (110) less a service fee.

[0030] For a payer having an accrual account, in reality there is no actual "deduction" taking place since this are actually book entries into the sub account. The amount owned is accrued as like a real telecommunication charge but maintained separately in a sub account. To explain, this is similar to a provisional account (for bad debts) in accounting terminology where provisions are made 'ready' to be deducted on realisation. For a prepaid account the debit in the sub account is realised straightaway.

[0031] This credit connection 58 and debit connection 59 are performed by Payment Clearing, Settlement and Reporting Services 50 through connection 62 and controlled by Payment Processor 40.

[0032] On completion as confirmed by 50, Payment Processor 40 confirms again by sending an electronic receipt to Merchant 20 using connection 58 and 61 and to Customer 70 using connections 54 and 56 in the form of a short message text. On receiving this receipt, Merchant 20 is obligated to release the goods or services as ordered by the customer 70 in order to conclude this purchase transaction.

[0033] On completion as confirmed by carrier 100/110 and earlier by Payment Clearing, Settlement and Reporting Services 50, Payment Processor 40 will record this transaction as settled in its database.

[0034] Where the response from payer's carrier is bad such that the password is not verified or insufficient funds, payment processor 40 will sent a negative message to the merchant 20 and terminated the connections. All messages sent are encrypted.

[0035] Referring to FIG. 3, in the case of a vending machine where there is no display screen or data terminal, the customer 70 indicates his willingness to purchase a product from the vending machine by ringing a special number shown on the vending machine where this number is linked directly to Payment Processor 40 through an interactive voice response interface programmed into 60. The special number called by the customer 70 provides the payment processor 40 with the identity of the vending machine and since the call was made from the customer's mobile phone, the mobile phone's number is captured at the same time to provide the payment processor to the user's account and the respective carrier that the user is currently with. To identify the goods and amount data, customer is asked, when prompted, to key in the number under the displayed goods in the vending machine on connecting to Payment Interface to Customer 60. For example, a can of Coca-Cola may have the number 123456# and for 1 can, 1 # etc. To begin, Customer 70 call up Payment Interface to customer 60 and sent data at connections 71, 74 to payment processor to record the transaction where upon, Payment Processor 40 sent the details through connection 77 of the customer 70 to Carrier 1 (110) to check the sub account holder's status to ensure sufficient funds are available assuming that this is a prepaid account. If this is good, Carrier 1 (110) will response to payment processor 40 through connection 76 and follow by payment processor 40 initiating a request for authentication usually a password through connection 73. Payment Interface to customer 60 will prompt customer 70 by either keying in the password or by voice depending on the option chosen through connection 72. Upon receiving the authentication data from customer 70 through connection 71 and 74, a request 77 is sent to Carrier 1 (110) to verify the password sent by the customer 70 from payment processor 40. If it is good, Payment Processor will then instruct through connection 75 to Payment Clearing, Settlement and Reporting Services 50 to debit the account in Carrier 1 (110) by the amount sought through connection 79 and credit the same amount less a fee through connection 78 at Carrier 2 (100) which is representing the merchant's account. As a rule, this amount is never the same as the amount of the payment made by customer 70 to the merchant, depending upon various fees, discounts, or promotional programs that may apply. All of these considerations and options can be taken into account through suitable programming in the processor 40. Once this process is completed, Payment Processor 40 will sent a good approval message to the vending machine 20 to release the good purchase through connection 45.

[0036] The payment processor 40 preferably is coupled to all the participants, via a high bandwidth data communications link, such as frame relay connection, to minimize delay.

[0037] FIG. 4 is a flow chart illustrating methods for establishing the sub account with the carrier. This applica-

tion is required in order to activate the customer 70's sub account with the carrier by associating this account with their main telecommunication account. In this invention, we have coupled service 80 with various carriers' main processor.

[0038] To begin, the customer need to have an existing telecommunication account and contacts the Account activation service 80 at their respective carrier which can be implemented on the carrier (100 & 110) systems or on another platform such as the payment processor 40 so long that it can communicate with the carrier's processor or system. This account activation service 80 can be implemented using interactive voice response technology, which is commercially available. On receiving a request from a customer usually by a mobile phone connection 200, the account activation service 80 communicates with the carrier's main database to confirm 210 that the main telecommunication account is valid and in good standing 220. This is followed by requiring the user to provide a password or/and a voice pattern by speaking a number of words 230. This are recorded and confirmed by 80 and a sub account is created within the carrier's database system associating the password and voice pattern 240. Similarly for the Merchant 20 if they want to use their telecommunication accounts, they must go through the same process as the customer 70 above. Below is a description of each of the transaction types and the payment processing that is associated with them.

[0039] 1. Account crediting. Account crediting is a transaction which provides a credit entry amounting to the payment value in the payee's sub account as recorded at the customer database with their respective telecommunication carrier less a fee. Upon receipt of an account crediting transaction, the payment clearing, settlement and reporting services 50 performs a series of verifications to determine if the transaction is valid. These verifications can include, for example, authentication of payment transaction, ensure that a corresponding account debit has been recorded, identification of the payment account with the target telecommunication carrier, assessing transactional velocity and limits, validation of merchant, and detection of duplicate transactions. If the transaction passes the validation checks then the payment clearing, settlement and reporting services 50 prepares the transaction for remote processing at the payee's carrier processor. The payment processor 40 identifies and verifies the payee, the payee's carrier, and the sub account number based on the payment transaction number and receives a confirmation from payment clearing, settlement and reporting services 50 when this transaction is passed to the carrier.

[0040] 2. Account debiting. Account debiting is a transaction which provides a debit entry of the payment value in the payer's sub account at the customer database with the payer telecommunication carrier less a fee. Upon receipt of an account debiting transaction, the payment clearing, settlement and reporting services 50 performs a series of verifications to determine if the transaction is valid.

[0041] Payment Clearing, settlement and Reporting Services 50 upon instruction from payment processor 40 prepares the transaction for remote processing at the payer's carrier processor and records this transaction as completed. The payment processor 40 identifies the payer, the payer's

carrier, and the sub account number based on the mobile phone number and subsequently created payment transaction number. At completion of both Account Debit and Credit with confirmation from Payment Clearing, settlement and Reporting Services 50, Payment Processor 40 will return a receipt to merchant 20 and payer 70.

[0042] 3. Account authentication. Account authentication is a transaction to verify that the payer's account number (e.g. a cell phone number) exists in the customer database, a sub account linking to the main telecommunication account for payment or receiving payment and the proper authority of the payer by verifying the password or voice patterns linked to the account. This transaction is performed when the payer's account number is being associated with the payment system transaction number ready for payment. This transaction is managed remotely by payment processor 40 querying the payer's telecommunication carrier in regards to the above information or other pre-programmable information such as account limit or purchase limit etc and to receive a good or bad response from carrier's main processor.

Communications

[0043] Referring again to FIG. 2, the connection between the payment system (processor 40) and the merchant (point of sale) 20, telecommunication carriers (100, 110), Customer 70 can be a Frame Relay network or some other secure link, in a presently preferred embodiment, although various communications hardware and protocols can be used. The communications protocol over which the transaction message will be transmitted to and from the payment system to all parties can be, for example VOIP, TCP/IP or WAP.

Processing the Transaction at the Carrier

[0044] Each transaction type is processed in a different way. Once the transaction type is identified, the processing that is likely to occur is described below.

[0045] 1. Account Validation. Lookup the customer's account based on the customer account number. Log the transaction. Respond to the payment processor.

[0046] 2. Account Authentication. Lookup the user's previously stored password or voice pattern and matched it against the data sent by customer. Perform validation checks such as credit limitation, prepaid account amount etc. Log the transaction. Respond to payment processor.

[0047] 3. Account Debiting. Upon receiving instruction from Payment Clearing, Settlement and Reporting Services 50, lookup the user's account and add payment to non-prepaid account or deduct amount from a prepaid account. Log the transaction. Respond to payment processor.

[0048] 4. Account crediting. Upon receiving instruction from Payment Clearing, Settlement and Reporting Services 50, lookup the payee's account and add amount paid by payer as credit entry in the sub account. Log the transaction. Respond to payment processor.

Settlement and Clearing

[0049] In Payment, Clearing, Settlement and Reporting Services 50, upon receiving payment transaction instruction

from payment processor **40**, means to contact the respective carrier's main processor to provide payment details directly. On receiving conformation from the respective carriers directly to payment processor, the payment transaction is logged in the payment processor **40** database. It is important to note that each transaction sent to Payment, Clearing, Settlement and Reporting Services **50** must be matched with a corresponding confirmation from the carrier to be considered settled otherwise it is known as "clear" but not "settled" in this invention. The risk that the payer will not settle in the ordinary sense with the telecommunication service provider is not a concern of this method. At the end of the processing day, the payment processor aggregates all of the payment transactions for the day based on merchant and customers into the database. The payment processor system performs various accounting functions.

Reporting Functions

[0050] A payment reporting services provide daily activities summaries to its customer, telecommunication carriers and merchant, and can also provide periodic activity and financial summaries for a fee. Each carrier will then reconcile with this statement. Finally, reporting services can provide real-time activity summaries to the wireless carriers prepaid platform on demand. All parties can individually access the Payment Processor's reporting services over its web server using their browser program to log in to check details. Users need to register for this service.

Marketing and Profiling

[0051] Given the amount of data collected by the payment processor about the users, a marketing and profiling system exists to analyse the purchasing patterns of the users and provide the results to marketing companies for a fee. Users may wish to be excluded from being a statistics by paying an opt out fee.

[0052] It should be apparent to one of skill in the art that the method of the present invention can be used for other payment requirements by crediting telecommunication accounts of parties to the transactions for small items that may be too expensive for financial institutions to manage.

[0053] While the present invention has been described above in terms of specific embodiments, it is to be understood that the invention is not limited to the disclosed embodiments. On the contrary, the present invention is intended for various modifications and equivalent structures included within the spirit and scope of the appended claims.

I, the inventor claim:

1. A computer network method for paying for goods or services over the network using telecommunication accounts through at least one telecommunication service provider and a wireless communication device such as a mobile phone comprising:

providing at least a centralized payment processor linked to the network;

extending at least one the telecommunication service provider's main processor for establishing sub accounts for both payer and payee on the provider's main processor having a corresponding account identifier to the main telecommunication account such as their mobile or fixed line phone numbers where such sub

accounts include personal identification such as a password or a voice pattern of the payer and payee in order to gain access;

conducting a payment process initiated by the payer through the payee's point of sale by validating the payer's required mobile phone number or account identifier and the payee's account identifier;

in the payment processor, upon receiving the account identifier of both payer and payee, responding with confirming the accounts with the respective telecommunication service provider's main processor over the network;

in the payment processor, upon receiving a positive response from the said telecommunication service provider of the payer and payee, responding with an activation code sent over the network to the payer and initiating a connection to the payer's mobile phone to request the activation code to be inputted either through the keypad or by speaking the code directly to the microphone piece of the mobile phone so as to be validated, said response includes an indication of approval if the validating step results in identifying and confirming the transaction by assigning an unique transaction number;

in the payment processor, if the validating step results in confirmation of the transaction,

the step of requesting for a password is initiated where the payer is prompted to key in the password using the keypad or saying the password to the microphone so as to authenticate the payer's identity, authorisation and associating the accounts linkage for both payer and payee to the payment transaction;

in the payment processor, upon receiving the password or voice pattern from the payer, this is authenticated with the stored password or voice pattern at the payer's telecommunication service provider in order to gain access to the payer's sub account over the network;

in the payer telecommunication service provider's processor, upon authentication of the password or voice pattern will response as authenticated to the payment processor over the network;

if both confirmation and authenticating steps are validated, where the payer's account is a prepaid account, the step includes a further step of verifying the availability of funds to affect the purchase and on confirmation from the payer's telecommunication provider, the telecommunication service provider will debit an amount of money equal to the payer's payment amount, subject to adjustment as instructed by payment processor over the network;

if both confirmation and authenticating steps are validated, the payer's telecommunication service provider will record a debit entry with an amount of money equal to the payer's payment amount in the monthly telecommunication bill, subject to adjustment where the payer's account is a non-prepaid telecommunication account as instructed by the payment processor over the network;

if both confirmation, authenticating and debiting of the payer's account steps are validated, the payment pro-

cessor will sent an approval code to the payee or merchant server and instruct the merchant's telecommunication service provider where the merchant's sub account is held to record a credit entry with an amount of money equal to the payer's payment amount on the merchant's monthly telecommunication bill over the network, subject to adjustment where such credit can be cashed out only when there is a net positive cash from the total bill on settlement;

at the payee or merchant's server, upon receiving this approval code, requested goods or services will be deemed sold to the payer and will be released according to the terms of sale over the network;

at the completion of payment process, both payer and payee or merchant will receive an encrypted receipt detailing the purchase where the end-user will receive such receipt as a text message into the mobile phone's memory storage and the merchant's server upon receiving this receipt message over the network will stored this into its database;

verification of purchase includes the step of downloading the text message from the payer's mobile phone to the merchant's server using a wireless coupling device and the encrypted message is matched against the copy retrieved from the merchant's database;

and providing the integrity of the receipt includes the step of uploading the encrypted receipt text message from the payer's mobile phone using the reply function to the payment processor server over the network for decryption upon which the details of the transaction will be forwarded to the merchant originating the transaction and a copy of the decrypted text message back to the end-user where such copy may be printed out by way of a wireless printer connected to the mobile phone.

2. A method according to claim 1 wherein the payment is in the form of monetary units.

3. A method according to claim 1 wherein the payment from the payer is made as a direct debit transaction in the case of a prepaid telecommunication account.

4. A method according to claim 1 wherein the payment is made from the payer as a debit book entry transaction in the case of a non prepaid telecommunication account where the payment amount is included in the billing statement where the total bill includes regular telecommunication charges.

5. A method according to claim 1 wherein the payment is made to the merchant or payee as a credit book entry in the case of non prepaid telecommunication account and is including in the billing statement where the total may be netted off with regular telecommunication charges.

6. A method according to claim 1 wherein the purchase transaction is initiated at a point of sale by payer by connecting using internet protocol or wireless application protocol.

7. A method according to claim 1 wherein the point-of-sale is connected to the network.

8. A method according to claim 1 wherein the payer and payee sub account are linked to their respective telephone or wireless telephone service account at their telecommunication service provider.

9. A method according to claim 1 wherein the payer's account and payee or merchant's account is a prepaid telephone or wireless telephone service account linked to their sub account.

10. A method according to claim 1 wherein said communicating data indicative of the payment transaction and mobile telephone account from the point-of-sale to the payment processor includes communicating the data from the point-of-sale over a network to the payment processor.

11. A method according to claim 10 wherein the communicating step includes responding with an activation code being sent to the point of sale over a network from the payment processor.

12. A method according to claim 10 wherein said communicating step includes requesting the previously sent activation code to be responded by payer either by voice or by keying into the mobile keypad upon successful connecting to the user's mobile communication device to the payment processor being sent over a network.

13. A method according to claim 10 wherein said communicating step further comprising communicating a request for authentication data to be responded by payer either by voice or by keying into the mobile keypad at the payer's mobile device sent over a network to the payment processor over the network.

14. A method according to claim 13 where authentication data is a password or voice pattern of the user stored in the sub account linked to the telecommunication account with the -payer's carrier required to authorise the transaction.

15. A method according to claim 10 where upon receiving the successful authorisation from the payer's carrier, payment processor will credit the payee's telecommunication sub account and debit the payer's telecommunication sub account, the communicating steps include sending encrypted text receipts to payer's mobile devices and payee's server over the network as confirmation.

16. A method according to claim 1 wherein said communicating data indicative of the transaction from the point-of-sale to the centralized payment processor:

communicating a transaction message indicating the amount of the payment, the identity of the telecommunication payer account holder, the identity of the payee from the point-of-sale to the payment processor;

17. A method according to claim 1 wherein said communicating data indicative of the payment from the payer to the centralized payment processor and telecommunication service provider main processor:

in response, communicating an activation code to the payment processor from the payer's mobile device;

in response, communicating a request for authentication code from the payment processor upon approving the activation code;

in response, communicating an authentication code to the payment processor from the payer's mobile device;

communicating a request to verify the authentication code to the payer's telecommunication service provider's main processor;

receiving a response from the payer's telecommunication service provider main processor;

communicating the credit instruction to payee's telecommunication service provider's main processor;

communicating the debit instruction to payer's telecommunication service provider's main processor;

communicating a text message receipt to payee's server;

communicating a text message receipt to payer's mobile device;

providing a network access point for the payment processor; and

routing the transaction message via the network access point to the payment processor.

18. A method according to claim 1 and further comprising settling the payment transaction by receiving confirmation of debiting an amount of money equal to the payment amount in payer's sub account, subject to adjustment, from

the payer's telecommunication service provider and a confirmation of crediting the said amount subject to adjustment, into the payee's telecommunication account by book entry from payee's telecommunication service provider.

19. A method according to claim 1 including, in the payment processor, maintaining a database of payers' telecommunication accounts and a list telecommunication accounts of participating payees linked to each transaction unique identifier for the purposes of reconciliation and profiling of users.

20. A method according to claim 1 and further comprising a customer interface comprising an interactive voice response module.
