NANOPARTICLES FOR PHOTOVOLTAIC AND LED DEVICES AND METHODS OF MAKING THE SAME

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application Nos. 62/343,251 and 62/464,946 filed May 31, 2016 and Feb. 28, 2017, respectively, the contents of which are incorporated herein by reference in their entirety.

CONTRACTUAL ORIGIN

This invention was made with Government support under Grant No. DE-AC36-08GO28308 awarded by the U.S. Department of Energy, and Grant No. NNX13AL60H awarded by the National Aeronautics and Space Administration (NASA). The Government has certain rights in the invention.

BACKGROUND

Halide perovskites have resulted in breakthrough performances in optoelectronic applications such as solar cells, and light emitters. The prototypical perovskite material for photovoltaics (PVs) (first applied to PV in 2009) is $\text{CH}_3\text{NH}_3\text{PbI}_3$. In only seven years of research, perovskite PV devices processed cheaply from solution inks have now been verified to convert >22% of incident sunlight into electricity, on par with the best thin film chalcogenide devices and silicon devices. One major hurdle in the commercialization of this technology lies in the long-term stability and durability of the semiconductor. Under environmental stresses, the compound can easily dissociate into PbI_2 and $\text{CH}_3\text{NH}_3\text{I}$, the latter of which is volatile.

Thus, there remains a need for new perovskite materials that can provide improved durability and sustained long-term performance for solar and light-emitting diode (LED) applications.

SUMMARY

An aspect of the present disclosure is a composition that includes a particle and a surface species, where the particle has a characteristic length between greater than zero nm and 100 nm inclusively, and the surface species is associated with a surface of the particle such that the particle maintains a crystalline form when the composition is at a temperature between -180°C . and 150°C . In some embodiments of the present disclosure, the particle may include at least one of a metal chalcogenide, a Group III-V material, a metal oxide, and/or a perovskite. In some embodiments of the present disclosure, the particle may include the perovskite comprising at least one of CsPbI_3 , CsPbBr_3 , CsPbCl_3 , RbPbI_3 , RbPbBr_3 , and/or RbPbCl_3 . In some embodiments of the present disclosure, the crystalline form may be substantially cubic.

In some embodiments of the present disclosure, the surface species may be associated with the surface of the particle by at least one of a covalent bond, an ionic bond, van der Waals interactions, dipole-dipole interactions, Debye interactions, and/or hydrogen-bonding. In some embodiments of the present disclosure, the surface species may be associated with the surface of the particle by at least one ionic bond. In some embodiments of the present disclosure, the surface species may include at least one of a saturated

2

hydrocarbon, an unsaturated hydrocarbon, a thiol-containing molecule, an acid, and/or a metal halide. In some embodiments of the present disclosure, the surface species may include at least one of oleate and/or oleylammonium. In some embodiments of the present disclosure, a metal of the metal halide may include at least one of lead, germanium, and/or tin. In some embodiments of the present disclosure, the metal halide may include at least one of PbI_2 , PbBr_2 , PbCl_2 , GeI_2 , GeBr_2 , GeCl_2 , SnI_2 , SnBr_2 , and/or SnCl_2 .

In some embodiments of the present disclosure, the composition may further include an organic cation (A) associated with the surface of the particle. In some embodiments of the present disclosure, A may include at least one of methylammonium (MA) and/or formamidinium (FA).

An aspect of the present disclosure is a device that includes an active layer that includes a particle and a surface species, where the particle has a characteristic length between greater than zero nm and 100 nm inclusively, and the surface species is associated with a surface of the particle such that the particle maintains a crystalline form when the device is at a temperature between -180°C . and 150°C . In some embodiments of the present disclosure, the particle may be a perovskite that includes at least one of CsPbI_3 , CsPbBr_3 , CsPbCl_3 , RbPbI_3 , RbPbBr_3 , and/or RbPbCl_3 . In some embodiments of the present disclosure, the crystalline form may be substantially cubic.

An aspect of the present disclosure is a method that includes dispersing a first surface species and a particle in a mixture that includes an alkyl acetate, where the first surface species is associated with a surface of the particle, the particle has characteristic length between greater than 0 nm and 100 nm, the dispersing removes a first portion of the first surface species from the surface, the particle has a first crystalline form before the dispersing and a second crystalline form after the dispersing, and the second crystalline form is maintained, after the dispersing, when the particle is at a temperature between -180°C . and 150°C .

In some embodiments of the present disclosure, the particle may include at least one of a metal chalcogenide, a Group III-V material, a metal oxide, and/or a perovskite. In some embodiments of the present disclosure, the particle may include a perovskite that includes at least one of CsPbX_3 , RbPbX_3 , CsGeX_3 , RbGeX_3 , CsSnX_3 , and/or RbSnX_3 , and X is a halogen. In some embodiments of the present disclosure, the second crystalline form may be substantially cubic. In some embodiments of the present disclosure, the first surface species may include at least one of a saturated hydrocarbon, an unsaturated hydrocarbon, a thiol-containing molecule, an acid, and/or a metal halide.

In some embodiments of the present disclosure, the first portion may be less than 100% of the first surface species and a remainder of the first surface species may remain associated with the surface of the particle, after the dispersing. In some embodiments of the present disclosure, the alkyl acetate may include at least one of ethyl acetate, methyl acetate, propyl acetate, and/or butyl acetate. In some embodiments of the present disclosure, the mixture may further include at least one of acetate ester, acetone, acetonitrile, diethyl ether, and/or propylene carbonate.

In some embodiments of the present disclosure, the mixture may further include a first salt that includes at least one of an acetate, a nitrate, a carbonate, a thiocyanate, and/or a phosphate, and a metal that includes at least one of lead, germanium and/or tin, the dispersing may result in the first salt forming a second surface modifier that includes the metal and the halogen, the first portion may be substantially 100% of the first surface modifier, at least a fraction of the

second modifier may associate with the surface of the particle, and the second crystalline form is maintained when the particle is at a temperature between -180°C . and 150°C . In some embodiments of the present disclosure, the second modifier may include a metal halide. In some embodiments of the present disclosure, the method may further include, after the dispersing, contacting the particle with a solution that includes an aprotic solvent and a second salt, resulting in the forming of a third surface species that associates with the surface of the particle.

BRIEF DESCRIPTION OF THE DRAWINGS

Exemplary embodiments are illustrated in referenced figures of the drawings. It is intended that the embodiments and figures disclosed herein are to be considered illustrative rather than limiting.

FIGS. 1-3 illustrate methods for modifying a starting nanoparticle to produce a modified nanoparticle, according to embodiments of the present disclosure.

FIG. 4 illustrates a device using an active layer constructed of modified nanoparticles, according to embodiments of the present disclosure.

FIGS. 5A-5D summarize performance data of CsPbI_3 nanoparticles (NPs) produced according to embodiments of the present disclosure; (FIG. 5A) ultra-violet (UV)-visible absorption spectra and photographs of suspensions of CsPbI_3 NPs synthesized at (a) 60°C . (3.4 nm), (b) 100°C . (4.5 nm), (c) 130°C . (5 nm), (d) 150°C . (6.8 nm), (e) 170°C . (8 nm), (f) 180°C . (9 nm), (g) 185°C . (12.5 nm), average size (measured via transmission electron microscopy analysis) shown in parentheses. (FIG. 5B) Normalized photoluminescence spectra and photographs under UV illumination of the NPs from FIG. 5A. (FIG. 5C) High resolution transmission electron micrograph of CsPbI_3 NPs synthesized at 180°C . (FIG. 5D) x-ray diffraction (XRD) patterns of NPs synthesized at (a) 60°C ., (b) 100°C ., (c) 170°C ., (d) 180°C ., and (e) 185°C . NPs confirming that they crystallize in the cubic phase of CsPbI_3 .

FIG. 6 illustrates luminescent CsPbI_3 powders, according to embodiments of the present disclosure; photographs under room light (top row) and UV illumination (bottom row) of CsPbI_3 NP powders synthesized at (Column A) 130°C ., (Column B) 150°C ., and (Column C) 180°C .

FIG. 7 illustrates full width at half maximum (FWHM) of the emission peak and photoluminescence quantum yield, of films made according to embodiments of the present disclosure; photoluminescence (PL) quantum yield (diamonds, left ordinate) and PL line width (circles, right ordinate) with varying NP size/ E_g .

FIG. 8 illustrates the poor phase stability of unwashed NPs. UV-Visible absorption spectra of NPs synthesized at 60°C . and stored in ambient conditions without separating NPs from unreacted precursors for 2 days (unwashed, day zero—dashed line; unwashed, day 2—solid line).

FIGS. 9A-C illustrate phase stability data of CsPbI_3 nanoparticles produced according to embodiments of the present disclosure; (FIG. 9A) XRD patterns (day 60—dashed line; day 1—solid line) and (FIG. 9B) UV-Visible absorption spectra, normalized at 370 nm, of CsPbI_3 NPs synthesized at 170°C . and stored in ambient conditions for a period of 1 day (solid line), 30 days (long dashes), and 60 days (short dashes). (FIG. 9C) Rietveld refinement of CsPbI_3 NP XRD pattern revealing pure cubic phase CsPbI_3 (experimental data—squares; simulated data—solid line). Inset in FIG. 9B shows the slight blue shift, which is seen in the excitonic peak with extended storage.

FIGS. 10A and 10B illustrate performance data of CsPbI_3 nanoparticle films produced according to embodiments of the present disclosure; (FIG. 10A) UV-visible absorption (solid lines) and PL spectra (dashed lines) of CsPbI_3 NPs in solution (thicker lines) and cast as films (thinner lines) for NPs synthesized at 100, 150, and 180°C . (FIG. 10B) Fourier-transform infrared (FTIR) spectra showing the infrared (IR) transmission of a CsPbI_3 NP film as cast (solid line), after washing with MeOAc (dashed line).

FIGS. 11A-C illustrate the effects of $\text{Pb}(\text{OAc})_2$ treatment on photoluminescence, according to embodiments of the present disclosure; Photoluminescence of 3 mL of $\sim 3.6\text{ }\mu\text{g mL}^{-1}$ in hexane, synthesized at 180°C ., upon the addition of (FIG. 11A) a saturated solution of $\text{Pb}(\text{OAc})_2$ in MeOAc, and (FIG. 11B) neat MeOAc. (FIG. 11C) Photoluminescence of a NP film before (solid line) and after dip-coating in saturated $\text{Pb}(\text{OAc})_2$ (dashed line).

FIGS. 12A-E illustrate data from CsPbI_3 solar cells produced according to embodiments of the present disclosure; (FIG. 12A) Schematic (with high-resolution transmitting electron microscopy (HRTEM) image of NPs) and scanning electron microscopy (SEM) cross-section of the CsPbI_3 solar cells. (FIG. 12B) Current-voltage curves of a device measured in air over the course of 1 day (short dashes), 9 days (long dashes), and 15 days (solid line); $\text{Eff}_{\text{AM 1.5G}}=10.77\%$, $V_{\text{OC}}=1.23\text{ V}$, $J_{\text{SC}}=13.47\text{ mA/cm}^2$, $\text{FF}=0.650$. The diamond represents the stabilized output of the device at 0.92 V, as shown in FIG. 13. (FIG. 12C) External quantum efficiency (left ordinate) and integrated current density (right ordinate) of the device. (FIG. 12D) electroluminescence (EL) spectra of CsPbI_3 solar cell (CsPbI_3 synthesized at 170°C .) under forward bias. The inset shows a photograph of the luminescent device. (FIG. 12E) PL (dashed lines) and EL (solid lines) spectra of completed devices fabricated using CsPbI_3 NPs synthesized at 170 (top data set) and 180°C . (bottom data set) demonstrating size quantization effects in the completed devices.

FIG. 13 illustrates the stabilized power output of a device made according to embodiments of the present disclosure; measured current response (solid line) of the device over 120 seconds when held at a constant voltage of 0.92 V. The corresponding power is shown in the dashed line.

FIG. 14 illustrates a monolithic tandem solar cell that includes perovskite quantum dots, according to some embodiments of the present disclosure.

FIG. 15 illustrates current density results attained from a monolithic tandem solar like that illustrated in FIG. 14, according to some embodiments of the present disclosure. (Cs, FA, MA) $\text{Pb}(\text{I, BR})_3$ Bottom Cell (solid line); CsPbI_3 QD Top Cell (dashed line).

FIG. 16 illustrates current density plots for various post-treatment perovskite films/devices, according to some embodiments of the present disclosure.

FIG. 17 illustrates external quantum efficiency (EQE) results for various post-treatment perovskite films/devices, according to some embodiments of the present disclosure.

FIG. 18 illustrates light absorption spectra for various post-treatment perovskite films/devices, according to some embodiments of the present disclosure.

FIG. 19 illustrates a cartoon summary of a method/process for assembling films containing perovskite particles (e.g. nanoparticles/quantum dots) having increased thicknesses due to layer-by-layer assembly of the nanoparticles, followed by a post-treatment step of a metal halide solution (e.g. AX in ethyl acetate), according to some embodiments of the present disclosure.

DETAILED DESCRIPTION

The present disclosure may address one or more of the problems and deficiencies of the prior art discussed above. However, it is contemplated that some embodiments as disclosed herein may prove useful in addressing other problems and deficiencies in a number of technical areas. Therefore, the embodiments described herein should not necessarily be construed as limited to addressing any of the particular problems or deficiencies discussed herein.

The present disclosure relates to synthetic routes to produce nanoparticles (NPs), such as CsPbI₃ nanoparticles. Experimental results presented herein demonstrate that, once purified, CsPbI₃ NPs made by methods described herein, easily retain a cubic phase in ambient air and even at cryogenic temperatures (e.g. less than 180° C.), as well as at elevated temperatures up to at least 150° C. Methods described herein are capable of forming CsPbI₃ perovskite films that are capable of long-range electronic transport between perovskite NPs (where “long-range” corresponds to charge transport through multiple nanoparticles corresponding to distances up to 100 nm, 200 nm, 300 nm, 400 nm, and/or 500 nm or greater). These CsPbI₃ films resulted in colloidal CsPbI₃ perovskite nanoparticle solar cell devices capable of long-term stability over a wide range of temperatures and environmental conditions, where the term “colloidal” refers to the dispersion and/or suspension of NPs in a liquid, rather than dissolving NPs into dissolved ions. These CsPbI₃ devices demonstrated excellent performance metrics, including high efficiencies and stabilized power out-

6

puts, producing up to 1.23 V at open circuit. CsPbI₃ perovskite nanoparticle devices were also shown to function as light-emitting diodes (LEDs), emitting visible light in the red-region of the optoelectronic spectrum, with low turn-on voltages (e.g. between 1.4 volts and 1.5 volts for a bandgap energy of about 1.7 eV) when forward biased.

FIG. 1 illustrates a starting nanoparticle 100 having a solid core 120 and a first surface modifier 110 associated with a surface of the solid core 120. FIG. 1 illustrates two different routes (e.g. treatments, 105A, 105B) that modify at least one physical and/or performance metric of the starting nanoparticle 100, resulting in modified nanoparticles (130A and 130B) having at least one physical property and/or performance metric that is different than those of the starting nanoparticle 100. For example, treating the starting nanoparticle 100 by treatment 105A may remove at least a portion of the first surface modifier 110 from a surface of the solid core 120 of the starting nanoparticle 100, resulting in a modified nanoparticle 130A. Treatment 105B illustrates another example that may transform the starting nanoparticle 100 to a modified nanoparticle 130B by removing at least a portion of the first surface modifier 110 from the surface of the solid core 120 and replacing at least portion of the first surface modifier 110 with a second surface modifier 140, resulting in the modified nanoparticle 130B. Thus, some of the treatments (e.g. 105A) described herein may remove at least a portion of a first surface modifier 110 (e.g. organic ligands and/or inorganic ligands) associated with the external surfaces of a solid core 120 (e.g. semiconductor material) of a starting nanoparticle 100, resulting in a modified nanoparticle 130A having a solid core 120 that is substantially free of the first surface modifier 110 or any other surface modifier, compound, and/or element associated with its surface. In addition, some treatments (e.g. 105B) may not only remove a first surface modifier 110, but also replace at least a portion of the first surface modifier 110 (e.g. organic ligands and/or inorganic ligands) with a second surface modifier 140 (e.g. organic ligands and/or inorganic ligands).

In some embodiments of the present disclosure, removal of a first surface modifier 110 from the surface of a solid core 120 of a starting nanoparticle 100 and/or removal of the first surface modifier 110 and/or the replacement of the first surface modifier 110 by a second surface modifier 140 may change the solid core 120 such as at least one physical property of the solid core 120. In some embodiments of the present disclosure, removal of a first surface modifier 110 from a solid core 120 of a starting nanoparticle 100 and/or removal of the first surface modifier 110 and/or the replacement of the first surface modifier 110 by a second surface modifier 140 may change the solid core 120 such as at least one optoelectronic property of the solid core 120, for example a bandgap, a emission spectra, a nanoparticle density, nanoparticle ordering, electron mobility, electron conductivity, photoluminescence quantum yield, and/or trap state density of the nanoparticles and/or nanoparticle film. Thus, some of the embodiments described herein, provide methods for treating a starting nanoparticle film having a starting set of physical and/or optoelectronic properties, resulting in a modified nanoparticle film having a second set of physical and/or optoelectronic properties that are different than the starting set. Some of the methods described herein, may transfer starting nanoparticles (e.g. from an intermediate solution) to a solid film in a final target device, such that the transfer of the starting nanoparticles modifies at least one physical and/or optoelectronic property of the starting nanoparticles, resulting in modified nanoparticles having at least

one improved physical and/or optoelectronic property. In some embodiments, methods may transfer starting nanoparticles (e.g. from an intermediate solution) to a solid film in a final target device, where the final physical and/or optoelectronic properties of the nanoparticles in the solid film are substantially the same as the properties of the starting nanoparticles.

The solid core **120** of the starting nanoparticle **100** and/or the modified nanoparticle **130** may be crystalline, amorphous, or a combination thereof. Thus, when the solid core **120** is in a crystalline form, a “nanoparticle” may be referred to as a “nanocrystal” or “quantum dot”. When crystalline, the crystalline phase of a nanoparticle may be cubic, hexagonal, tetragonal, rhombohedral, orthorhombic, monoclinic, and/or triclinic. A nanoparticle may have a characteristic length that is between about 1 nm to about 100 nm, or in some embodiments between about 1 nm and about 20 nm. A solid core **120** may include one or more metal chalcogenides including at least one of PbS, PbSe, PbTe, CdSe, CdS, CdTe, CuInS, CuInSe, ZnS, ZnSe, ZnTe, HgTe, and/or CdHgTe. In some embodiments, a solid core **120** may include one or more IUPAC Group III-V materials including InP, InAs, GaAs, Si, Ge, SiGe, and/or Sn. In some embodiments, the material used in a solid core **120** may include at least one of ZnO, MoO, TiO₂, and/or any other suitable metal oxides. A solid core **120** may be any solid crystalline material, including CsPbI₃, CsPbBr₃, CsPbCl₃, RbPbI₃, RbPbBr₃, and/or RbPbCl₃. Thus, a solid core **120** may include the combination of a Group 1 element (e.g. Na, K, Rb, and/or Cs), a Group 14 element (e.g. Si, Ge, Sn, and/or Pb) and/or a halogen (e.g. F, Cl, Br, I, and/or At). A solid core **120** may also include one or more perovskite oxides and/or perovskite chalcogenides with examples including BaTiO₃, CaTiO₃, BaTiS₃, BaTiSe₃ and/or any other suitable material or alloy. Thus, a solid core **120** may include at least one of an oxide perovskite, a chalcogenide perovskite, and/or a halide perovskite.

FIG. 1 shows that a starting nanoparticle **100** may have a first surface modifier **110** associated with an external surface of the solid core **120**. Similarly, a modified nanoparticle **130B** may have a second surface modifier **140** associated with an external surface of the solid core **120**. Examples of a surface modifier (first surface modifier **120** and/or second surface modifier **140**) include saturated hydrocarbons, unsaturated hydrocarbons, thiol-containing molecules, amines, alkylamines, carboxylates, carboxylic acids, and/or acids. Examples of thiol-containing molecules suitable for embodiments of the present disclosure include methanethiol, ethanethiol, ethanedithiol, 1-propanethiol, propanedithiol, butanedithiol, octanethiol, and/or any other suitable thiol- and/or dithiol-containing molecule. Examples of acid surface modifiers include oleic acid, stearic acid, acetic acid, formic acid, oxalic acid, perfluorotetradecanoic acid, tetradecylphosphonic acid, and/or mercaptopropionic acid. Other examples of surface modifiers include oleate, perfluorocyclobutane, octadecylamine, poly(vinyl butyral-covinyl alcohol-covinyl acetate), trioctylphosphine, trioctylphosphine dioxide, pyridine, thiocresol, oleylamine, benzoquinone. First surface modifiers **120** and second surface modifiers **140** may associate with a surface of a solid core **120** covalently, ionically, by van der Waals interactions, by dipole-dipole interactions, by Debye interactions, and/or by hydrogen-bonding. Examples of covalent bonding include X-type binding, L-type binding, and/or Z-type binding. In some embodiments of the present disclosure, for example for the cases where a surface modifier is at least one of

oleate, oleylammonium, and/or a metal halide, the surface modifier associates with a surface of the particle by ionic interactions.

FIG. 2 illustrates an example of a method **200**, for converting a starting nanoparticle into a modified nanoparticle. This example method **200** begins with NP synthesizing **210**, either to produce a NP precursor and/or a final NP product. Such methods for NP synthesizing **210** may include molecular beam epitaxy (MBE), ion implantation, e-beam lithography, x-ray lithography, wet-chemical solution processing, and/or vapor-phase processing. Wet-chemical solution processing may include precipitation methods that involve nucleation and growth of the nanoparticles. Nucleation processes may be homogeneous, heterogeneous, and/or secondary nucleation. Homogeneous nucleation occurs when solute atoms or molecules combine and reach a critical size without the assistance of a pre-existing solid interface. Wet-chemical methods may include hot-injection, microemulsion, sol-gel, competitive reaction chemistry, hot-solution decomposition, sonic waves, microwaves, and/or electrochemistry. Vapor phase processing may include at least one of MBE, sputtering, liquid metal ion sources, and/or aggregation of gaseous monomers. NP synthesizing **210** may be a colloidal method resulting in a colloidal starting nanoparticle and/or quantum dot. In some embodiments of the present disclosure, NP synthesizing **210** to produce starting nanoparticles may include arrested precipitation, templated growth, organometallic synthesis, organic surface modifiers (e.g. ligands), inorganic surface modifiers (e.g. ligands), and/or any other suitable technique (see *Journal of Coordination Chemistry* Vol. 65, No. 13, 2012, 2391-2414, which is incorporated herein by reference in its entirety).

Referring again to FIG. 2, example method **200** for manufacturing nanoparticles and for transferring the nanoparticles to a photovoltaic and/or LED device may include, after completion of nanoparticle synthesizing **210**, nanoparticle pretreating **220**, which may include one or more processing steps that treat the starting nanoparticles; e.g. precipitating, separating, purifying, and/or creating a solution containing the starting nanoparticles. For example, nanoparticle pretreating **220** may include adding starting nanoparticles to a carrier solvent in which the starting nanoparticles do not completely dissolve and stay substantially in the solid phase, resulting in the formation of a storage/delivery solution of the starting nanoparticles. Such a storage/delivery solution may then facilitate nanoparticle applying **230** in a subsequent processing step, for example, application of the starting nanoparticles to a device substrate, such as glass, by any suitable solution processing method; e.g. dip-coating, spin-coating, curtain-coating, etc. Thus, nanoparticle applying **230** may result in a layer, coating, and/or film of a solution containing the starting nanoparticles on a substrate. The nanoparticle applying **230** may be followed by a nanoparticle modifying **240** step. Nanoparticle modifying **240**, as illustrated in FIG. 1, may modify a starting nanoparticle **100**, resulting in a modified nanoparticle (**130A** and **130B**). Examples of nanoparticle modifying **240** include removal of at least a portion of a first surface modifier **110** from a surface of a solid core **120** of a starting nanoparticle **100** and/or replacement of at least a portion of the first surface modifier **110** with a second surface modifier **140**. Thus, in some embodiments of the present invention, nanoparticle modifying **240** may be accomplished by submerging a substrate having a coating of a solution containing the starting nanoparticles into different solution, such that the submerging results in the removal of at least a portion of a first surface modifier and/or the

replacement of at least a portion of the first surface modifier with a second surface modifier to produce the modified nanoparticles. In some embodiments of the present invention, nanoparticle modifying **240** may be accomplished by spraying a modifying solution onto a coating of the solution containing the starting nanoparticles, such that the spraying contacts the solution containing the starting nanoparticles with the modifying solution, which may result in the removal of at least a portion of a first surface modifier and/or the replacement of at least a portion of the first surface modifier with a second surface modifier to produce the modified nanoparticles. The nanoparticle modifying **240** may result in a change to at least one physical property of the individual nanoparticle or the collective properties of a film of the nanoparticles, including optical, electrical, and/or magnetic properties, and/or performance metric of the nanoparticles, such that the modified nanoparticles have at least one physical property, and/or performance metric that is different from those of the starting nanoparticles. As a device having a coating or film of the starting nanoparticles may be treated by a nanoparticle modifying **240** step, nanoparticle modifying **240** may result in a modified film containing modified nanoparticles such that the modified film has significantly different properties than the starting film.

FIG. **2** illustrates that the method **200** may include a nanoparticle post-treating step **250**. For example, post-treating **250** may include removal of a component from the modified film containing modified nanoparticles; e.g. a carrier solvent, at least a portion of a modifying solution, etc. Other examples of post-treating **250** include drying and/or annealing. In some embodiments of the present disclosure, the post-treating **250** may result in a film of modified nanoparticles in the final form desired for the device being fabricated; e.g. photovoltaic device or LED. In some embodiments of the present disclosure, post-treating **250** may include vapor annealing. Finally, FIG. **2** illustrates that one or more of the NP applying **230**, NP modifying **240**, and/or the NP post-treating may be repeated one or more times, for example, to apply additional layers of modified nanoparticles to the device to build thickness and/or provide varying nanoparticles with different behavior, performance, and/or properties. Thus, decision step **260** may result in any of the upstream steps being repeated one or more times, depending on the application and/or the final device operating requirements.

FIG. **3** illustrates an example of a method **300**, according to some embodiments of the present disclosure, for manufacturing a film of modified nanoparticles. In this example, the method **300** may begin with a precursor synthesizing step **305** for synthesizing cesium-oleate as a cesium precursor. The precursor synthesizing **305** may be followed by a nanoparticle synthesizing step **310**, for example, the synthesis of colloidal CsPbI₃ starting nanoparticles. For this example, a solution of PbI₂ may be created by combining PbI₂ with 1-octadecene, oleic acid, and oleylamine, such that the cesium-oleate precursor may be rapidly injected. The method **300** may then proceed with a nanoparticle precipitating step **320A**, where anhydrous methyl acetate (MeOAc) may be added to the solution resulting from the nanoparticle synthesizing **310**, which may result in the precipitation of the CsPbI₃ starting nanoparticles from the synthesis solution. Next, the precipitated CsPbI₃ starting nanoparticles may be suspended in hexane and/or octane in a nanoparticle suspending step **320B**. A nanoparticle applying step **330** may follow, which may be accomplished by spin-coating the starting nanoparticles suspended in the hexane and/or octane solution onto a substrate. After the nanoparticle applying

330, the resulting coating of the starting nanoparticle-containing hexane and/or octane solvent may be immediately (e.g. within 1 second to 10 seconds) submerged (e.g. dipped), at least once, into a modifying solution in a starting nanoparticle modifying step **340**. The modifying solution may be a substantially saturated solution of at least one of PbO(Ac)₂, Pb(SCN)₂, and/or Pb(NO₃)₂ in anhydrous MeOAc. The method **300** may conclude with a rinsing step (not shown) using anhydrous MeOAc, followed by drying **350** by evaporation, which may result in a solid film containing modified nanoparticles. Method **300** shows that at least one of the steps, nanoparticle applying **330**, the nanoparticle modifying **340**, and/or the drying **350**, may be repeated at least one time, for example to increase the film thickness of modified nanoparticles on the device being fabricated. Thus, decision step **360** may result in any of the upstream steps being repeated one or more times, depending on the application and/or the final device operating requirements.

In some embodiments of the present disclosure, a film of modified nanoparticles may be treated with an AX post-treatment, where X is at least one halogen, and A is a cation with examples include formamidinium (FA⁺), methyl ammonium (MA⁺), Cs⁺, or Rb⁺. For example, as demonstrated herein, a significant increase in carrier mobility in a film of CsPbI₃ nanoparticles may be achieved by such an AX post-treatment, enabling increased photocurrent and a power conversion efficiency (PCE) of 13.4%, presumably by improving the electronic coupling between the nanoparticles, resulting in enhanced carrier mobility in the nanoparticle film.

FIG. **4** illustrates a device **400** having a modified nanoparticle-containing active layer **440**, which was deposited using methods described herein. In this example, the nanoparticle-containing active layer **440** contains modified CsPbI₃ nanoparticles having a crystalline cubic crystallographic phase, where a first surface modifier of oleylamine/oleylammonium and oleic acid/oleate has been substantially removed and at least partially replaced with PbI₂, accomplished by submerging a starting film containing stabilizing oleylamine/oleylammonium and oleic acid/oleate groups into a solution of MeOAc saturated with Pb(OAc)₂·3H₂O or Pb(NO₃)₂. The device **400** also includes a substrate **410**, in this example a glass substrate, a first current collector **420**, in this example a layer of fluorine-doped tin(IV) oxide. The device **400** also includes an electron-transport layer **430** and a hole-transport layer **450**, with the nanoparticle-containing active layer **440** sandwiched between the electron-transport layer **430** and the hole-transport layer **450**. In the example shown in FIG. **4**, the electron-transport layer **430** was constructed of TiO₂, and the hole-transport layer **450** was constructed of spiro-OMeTAD. Further, the device **400** includes a second current collector **470**, in this case constructed of aluminum. FIG. **4** also shows that a MoO_x layer **460** may be positioned between the second current collector **470** and the hole-transport layer **450**, which may improve the performance of the second current collector **470**. In summary, a device **400** may include in order, a substrate **410** in electrical contact with a first current collector **420**, an electron-transport layer **430**, an active layer **440**, a hole-transport layer **450**, a MoO_x layer **460**, and a second current collector **470**.

In some embodiments of the present disclosure, a device **400** may have a substrate **410** constructed of glass, plastic, and/or metal. A device **400** may have a first current collector **420** constructed of one or more transparent conducting films including indium(III) tin(IV) oxide, fluorine-doped tin(IV)

11

oxide, zinc oxide, organic films, and/or polymers. Examples of organic films that may be used as a first current collector **420** include carbon nanotube networks and/or graphene. Examples of transparent conducting polymers that may be used as a first current collector **420** include poly(3,4-ethylenedioxythiophene) (PEDOT), PEDOT combined with poly(styrene sulfonate) (PSS), Poly(4,4'-dioctylcyclopentadithiophene), and/or any other suitable derivatives of polyacetylene, polyaniline, polypyrrole and/or polythiophenes. A device may have an electron-transport layer **430** constructed of at least one of PEDOT, PSS, zinc oxide, tin(IV) oxide, poly(2-(dimethylamino)ethylmethacrylate), Cs_2CO_3 , Nb_2O_5 , amino-functionalized conjugated metallopolymer, and/or $\text{CdS}/2,9$ -dimethyl-4,7-diphenyl-1,10-phenanthroline. A device may have a hole-transport layer **450** constructed of at least one of PEDOT, PSS, MoO_3 , V_2O_5 , WO_3 , NiO, and/or other metal oxides. A device may have a second current collector **470** constructed of a thin layer of metal such as aluminum, calcium/aluminum, LiF/aluminum, silver, and/or gold. Any other suitable electron-transport material and/or hole-transport material may be used in embodiments of the present disclosure (see *Electronics* 2014, 3, 132-164, which is incorporated herein by reference in its entirety).

EXAMPLES

FIG. 5A illustrates the tunability of the optical energy bandgap (e.g. between about 600 nm and about 680 nm), due to quantum confinement, in a series of CsPbI_3 nanoparticles (e.g. QDs) synthesized at temperatures between 60 and 185° C. CsPbI_3 has the largest Bohr excitonic diameter of the CsPbX_3 system, and thus the lowest energy excitonic peak, which shifts between 585 and 670 nm corresponding to nanoparticles having sizes between 3 nm and 12.5 nm. The corresponding normalized PL spectra of the samples are shown in FIG. 5B, along with a photograph of the NPs suspended in hexane. Upon ultra-violet (UV) excitation, emission is in the orange (600 nm) to red (680 nm) range corresponding to a bandgap between about 2.07 and about 1.82 eV. Photographs showing PL from dried nanoparticle powders upon UV excitation are shown in FIG. 6. The full width at half maximum of the PL for the smallest NPs is 83 meV, and increases slightly for the larger sizes while the PL quantum yield varied from 21 to 55% for different sizes, as shown in FIG. 7.

The isolation of CsPbI_3 in the cubic phase can be difficult due to loss of surface modifier during extraction, causing reversion of the particles to the orthorhombic phase. To maintain adequate surface modifier coverage (e.g. on the surface of nanoparticle), and thereby preserve the cubic phase of the CsPbI_3 NPs, an antisolvent approach utilizing anhydrous methyl acetate (MeOAc) was developed and is described herein.

The high-resolution transmission electron TEM image of the sample synthesized at 180° C. (see FIG. 5C) shows an interplanar distance of 0.62 nm, consistent with the (100) plane of cubic phase CsPbI_3 . These nanoparticles, if left unpurified, transform to the high energy absorbing orthorhombic phase within several days, as shown in FIG. 8. On the other hand, properly treated NPs remain in the cubic phase for months while stored in ambient conditions. FIGS. 9A and 9B illustrate powder XRD patterns and UV-vis absorption spectra, respectively, which confirm the absence of diffraction peaks or the high energy (~3 eV) sharp absorption characteristic of orthorhombic phase formation, despite 60 days of storage in ambient. The nanoparticles also

12

maintained high luminescence throughout the duration of the study, a signature of the presence of the stable cubic phase. Additionally, the nanoparticles remained in the cubic phase (as shown in FIG. 8) even after the solution was cooled to 77 K, further demonstrating the expanded temperature stability of the cubic phase in CsPbI_3 nanoparticles.

Rietveld refinement of the XRD patterns, shown in FIG. 9C, allows quantification of the contribution from cubic and orthorhombic phases. No orthorhombic phase is found. Additionally, lattice parameters of three different size CsPbI_3 NP samples are estimated and shown in Table 1. The lattice parameter values show a size dependence and are lower than the previously measured experimental value (6.2894 Å at 634 K) of bulk cubic CsPbI_3 . It should be noted that these measurements were performed at 273K.

TABLE 1

Results of the Rietveld refinement.			
Reaction temperature	a (Å)	R_{wp}	NP Size (nm)
170° C.	6.231 ± 0.002	3.42	9 ± 1
180° C.	6.220 ± 0.002	6.50	10 ± 1
185° C.	6.189 ± 0.002	7.79	17 ± 2

To utilize highly phase-stable CsPbI_3 nanoparticles in optoelectronic devices, a method was developed to cast electronically conductive NP films. Film deposition consists of a combined spin-coating and dip-coating process in which nanoparticles are first spin-cast from octane, then dipped in a saturated MeOAc solution of either $\text{Pb}(\text{OAc})_2$ or $\text{Pb}(\text{NO}_3)_2$ (neat MeOAc was used as a control). This process is repeated multiple times, in some embodiments from 3 to 5 times, to produce NP films with thicknesses between 100 nm and 400 nm. FIGS. 10A and 10B illustrate characterization of the treated thin films used for device fabrication. In FIG. 10A, the optical absorption and PL spectra are shown for three samples with indicated reaction temperature. In each case, the film absorbance and PL is red-shifted ~20 nm from that of the nanoparticles in solution, while the tunable emission properties of the films indicate that quantum confinement is preserved, even after casting the film (e.g. heating/drying). Fourier transform infrared (FTIR) spectra show the removal of organic surface modifiers from the film with exposure to neat MeOAc (see FIG. 10B) due to the near absence of C—H modes near 3000 cm^{-1} or below ~2000 cm^{-1} belonging to oleylammonium, oleate, octadecene and other organics.

Furthermore, the interaction of Pb^{2+} salts with NPs in solution and on films was investigated by monitoring the fluorescence (see FIGS. 11A-C). Titration of a small amount of $\text{Pb}(\text{OAc})_2$ to the NP solution showed an enhancement in PL, suggesting improved surface passivation. Similarly, dip-coating of the NP film in a saturated solution of $\text{Pb}(\text{OAc})_2$ in MeOAc results in a significant PL enhancement.

CsPbI_3 nanoparticles have attractive properties such as strong, sharp absorption and excellent chemical stability compared to the methylammonium analog. Additionally, the nanoparticles exhibit a stable cubic phase at room temperature. Based on these findings, solar cells were fabricated employing CsPbI_3 nanoparticles as a photoactive material, resulting very promising results. FIG. 12A illustrates a schematic of a device architecture used, and a corresponding scanning electron micrograph cross section of the device

13

fabricated. The reverse scan current density-voltage (JV) curves show an open-circuit voltage of 1.23 V, and 10.77% power conversion efficiency for devices made and tested completely in ambient conditions (relative humidity ~15-25%) (see FIG. 12B). Furthermore, the device efficiency improved over the course of 15 days with storage of the device in a desiccator in the dark. FIG. 13 shows the stabilized power output of the fabricated device by measuring the current density while the device was biased at 0.92 V. FIG. 12C illustrates the spectral response of the solar cell. Dip-coating spin-cast films in neat MeOAc, and MeOAc saturated with $\text{Pb}(\text{OAc})_2$ or $\text{Pb}(\text{NO}_3)_2$ all perform well (JV-scanned PCE>9%) in the photovoltaic devices fabricated in this work.

It was also determined that the photovoltaic devices described above can also produce visible electroluminescence (EL) when biased above the V_{OC} . FIG. 12D illustrates the EL properties of the NP devices described herein. The EL is characterized by a low turn on voltage near the band gap of the CsPbI_3 with increasing intensity at larger applied biases. These spectra also provide direct evidence that quantum confinement is retained in the complete devices as seen by the shift in both the EL and PL spectra of devices with different size NPs (see FIG. 12E).

Materials and Methods

Chemicals: All chemicals were purchased from Sigma Aldrich and used without purification, unless otherwise noted. Cesium carbonate (Cs_2CO_3 , 99.9%), lead (II) iodide (PbI_2 , 99.9985%, Alfa Aesar), oleic acid (OA, technical grade 90%), oleylamine (OAm, technical grade 70%), 1-octadecene (ODE, technical grade 90%), toluene (anhydrous 99.8%), hexane (reagent grade $\geq 95\%$), octane (anhydrous, $\geq 99\%$), 1-butanol (anhydrous 99.8%), methyl acetate (MeOAc, anhydrous 99.5%), lead acetate trihydrate ($\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$, 99.999%), lead nitrate ($\text{Pb}(\text{NO}_3)_2$, 99.999%), rhodamine-6G (99%), ethanol (EtOH, 200 proof, $\geq 99.5\%$), titanium ethoxide ($\geq 97\%$), hydrochloric acid (HCl, 37% in water), 2,2',7,7'-tetrakis(N,N-di-p-methoxyphenylamine)-9,9'-spirobifluorene (spiro-OMeTAD, Lumtec, $\geq 99.5\%$), chlorobenzene (anhydrous, 99.8%), 4-tert-butylpyridine, bis(trifluoromethane)sulfonimide lithium salt (Li-TFSI), and acetonitrile (anhydrous, 99.8%).

Synthesis of Cs-oleate as a cesium precursor: 0.5 g of Cs_2CO_3 , 2 mL OA and 50 mL ODE were added to a 100 mL 3-necked round bottom flask and stirred under vacuum for 30 min at 120° C. The flask was purged with N_2 for 10 minutes and then placed back under vacuum. This process of alternately applying vacuum and N_2 was repeated 3 times to remove moisture and O_2 . The reaction was considered complete when the solution was clear, indicating that the Cs_2CO_3 had reacted with the OA. The Cs-oleate solution in ODE was stored in N_2 until it was needed for the NP synthesis.

Synthesis of colloidal CsPbI_3 nanoparticles: PbI_2 (1 g) and ODE (50 mL) were stirred in a 500 mL round bottom flask and degassed under vacuum (~0.1 Torr) at 120° C. for 1 hour. The flask was then filled with N_2 and kept under constant N_2 flow. OA and OAm (5 mL each, pre-heated at ~70° C.) were injected. The flask was put under vacuum again until the PbI_2 completely dissolved and the solution was no longer releasing gas (15-30 minutes). The temperature was then varied depending on the desired NP size (60° C. for 3.4 nm, 100° C. for 4.5 nm, 130° C. for 5 nm, 150° C. for 6.8 nm, 170° C. for 8 nm, 180° C. for 9 nm NPs and 185° C. for 12.5 nm). The Cs-oleate (~0.0625 M, 8 mL) precursor, pre-heated at 70° C. under N_2 atmosphere, was swiftly injected into the reaction mixture. The reaction mixture

14

turned dark red and the reaction was quenched by immediate immersion of the flask into an ice bath (~5 seconds after injection).

Isolation of colloidal CsPbI_3 nanoparticles: Due to the ionic nature of the CsPbI_3 NPs and the proposed ionic binding of the surface modifiers, polar non-solvents traditionally used to wash NPs from reaction solutions instead dissolve the CsPbI_3 NPs. A variety of low polarity non-solvents were tested: 1-butanol, acetone and ethyl acetate destabilized the NPs and resulted in a yellowish suspension, while MeOAc successfully extracted cubic phase CsPbI_3 NPs. The synthesized CsPbI_3 NPs were precipitated by adding 200 mL MeOAc (ratio of NP reaction solution: MeOAc is 1:3) and then centrifuged at 8000 RPM for 5 minutes. The wet pellet of NPs in each centrifuge tube was redispersed in 3 mL hexane, precipitated again with an equal volume MeOAc and centrifuged at 8000 RPM for 2 min. The NPs were dispersed in 20 mL of hexane and centrifuged again at 4000 RPM for 5 min to remove excess PbI_2 and Cs-oleate. The solution of colloidal CsPbI_3 NPs was kept in the dark at 4° C. for 48 hours to remove agglomerated nanoparticles, excess Cs-oleate and Pb-oleate, which solidify at low temperatures. The NP solution was decanted and centrifuged again at 4000 RPM for 5 min before use. For device fabrication, the hexane was dried and the NPs were dissolved in octane at a concentration of ~50 mg/mL. The temperature range of the synthesis is determined by the solubility of the precursors; Cs-oleate will not dissolve in ODE below 60° C. and PbI_2 begins to precipitate out of the reaction solution above 185° C.

Characterization: UV-visible absorption spectra were recorded using a Shimadzu UV-3600 UV-Vis-NIR spectrophotometer. Steady state photoluminescence (PL) and room temperature PL quantum yields were measured using a Horiba Jobin Yvon fluoromax-4 spectrophotometer. For quantum yield measurements, the NPs were dispersed in toluene using rhodamine 6G in EtOH as a reference. UV-visible absorption and PL experiments were done in solution and on thin films (prepared as described below). Powder X-ray diffraction data were recorded using a Bruker D8 Discover X-ray diffractometer with a Hi-Star 2D area detector using $\text{Cu K}\alpha$ radiation (1.54 Å). Transmission electron microscopy (TEM) studies were carried out using FEI T30 at 300 kV. TEM grids were prepared by dropping a dilute colloidal solution of NPs in a hexane-octane mixture onto the carbon coated copper grids.

To further explore the structural properties of the NPs, Rietveld analysis of the XRD data was performed using Materials Analysis Using Diffraction (MAUD) software (see FIG. 9C). In this analysis, the background structural parameters (atomic coordinates, occupancies, lattice parameters, etc.), and microstructural parameters (particle size, lattice strain, residual stress, etc.) are refined through a least-squares method. This XRD refinement shows that the cubic model provides quantitative fits of the experimental XRD patterns, while using the experimentally measured lattice parameters of the orthorhombic phase cannot be fitted with the XRD pattern. Due to the extreme peak broadening and increased background of the smallest size, Rietveld refinement of smaller sized CsPbI_3 nanoparticles is not possible, however peaks of cubic CsPbI_3 nanoparticles are observed to be present in the XRD data of all NP sizes.

Film fabrication: Surface modifier (e.g. ligand) solutions were made by sonicating 10-20 mg of powder ($\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$ or $\text{Pb}(\text{NO}_3)_2$) in 20 mL of anhydrous MeOAc for 10 minutes. The excess salt was removed by centrifugation at 4000 RPM for 5 minutes. The NPs (~50 mg/mL in

15

octane) were spin-cast at 1000 RPM for 20 seconds followed by 2000 RPM for 5 seconds on the substrate and swiftly dipped 2-3 times in the surface modifier solution. The film was then rinsed using neat, anhydrous MeOAc, then dried with a stream of air. Films grown using only MeOAc were simply treated with a single rinsing step. This treatment was repeated multiple (3-5) times to form films with thickness between about 100 nm and about 500 nm.

Device fabrication: A ~50 nm TiO₂ layer was deposited via a sol-gel method onto pre-patterned FTO on glass substrates (Thin Film Devices, Inc.). Sol-gel TiO₂ was prepared by mixing 5 mL EtOH, 2 drops HCl, 125 μ L deionized water, and 375 μ L of titanium ethoxide resulting in a clear solution. The headspace of the vial was filled with nitrogen and the solution was stirred for 48 hours, and then kept in the freezer until use. The sol-gel was spin-cast at 3000 RPM for 20 seconds, annealed at 115° C. and 450° C. for 30 minutes each. The CsPbI₃ NP photoactive layer was deposited using the procedure described above, resulting in a total thickness of ~150 nm. The hole-transporting layer was spin-coated from a solution consisting of 72.3 mg of spiro-OMeTAD in 1 mL of chlorobenzene, 28.8 μ L of 4-TBP, and 17.5 μ L of Li-TFSI solution (520 mg/mL in acetonitrile). All of the spin-coating processes were performed in ambient. MoO₃ was deposited at a rate of 0.2-1.0 Å/s at a base pressure lower than 2×10^{-7} torr for a total thickness of 15 nm. Al electrodes were evaporated at a rate ranging from 0.5-2 Å/s for a total thickness of 200 nm.

FIG. 14 illustrates an all-inorganic monolithic tandem solar cell constructed using colloidal CsPbI₃ perovskite nanoparticle thin films that exhibit a crystalline phase not seen in thin films of the same material below 300° C. This is the first colloidal nanoparticle perovskite solar cell made and has open circuit voltages in excess of 1.2 V for nanoparticles having a bandgap of 1.75 eV. Such a high voltage has not been seen in any other material with bandgap below 2 eV except single crystal III-V compounds (GaInP₂ and AlGaAs). Some embodiments of the present disclosure include CsPbI₃ nanoparticle devices that generate 1.23 V for nanoparticles possessing a 1.75 eV bandgap and thus represent a starting point to mimic the top cell of a 31.6% III-V tandem, which is based on a 1.85 eV GaInP₂ top cell that delivers 1.45 V at open circuit and 14 mA/cm² at short circuit. The top cell in this configuration is the most critical toward achieving the final goal, and the perovskite nanoparticles described herein have the greatest voltage of non-III-V systems.

Thus, in some embodiments of the present disclosure, the V_{OC} of a CsPbI₃ nanoparticle top cell may be improved by at least one of 1) tuning the E_g via the nanoparticle size effect, 2) tuning the E_g via composition (with A- and/or X-site substitution), 3) improving the PLQY, and 4) minimizing voltage losses at the contacts to nanoparticle layer. In some embodiments of the present disclosure, reducing the size of the nanoparticles and alloying the A-site with Rb⁺ or the X-site with Br⁻ may increase the bandgap of the perovskite layer and increase the PLQY. It is anticipated that combination of 1) through 4) will span a 1.8-2.0 eV range to maximize the V_{OC} and the ability to perform photon recycling and luminescent coupling. In some embodiments of the present disclosure, the solar cell devices may contain Spiro-MeOTAD and TiO₂ as the hole- and electron-collecting layers, respectively.

In some embodiments of a monolithic tandem solar cell, the bottom cell may include a highly alloyed perovskite absorber (FA,Cs,MA)Pb(I,Br)₃, which is capable of up to a 20% 1-sun efficiency. A combination of the top cell and

16

bottom cell described herein, has been shown to provide the following performance metrics: 12 mA/cm², 2.334 V and FF of 72.5% yield >20% performance. FIG. 15 illustrates a current density versus voltage plot for an all-inorganic monolithic tandem solar cell constructed using colloidal CsPbI₃ perovskite nanoparticle thin films, as described herein.

As mentioned above, a further aspect of the present disclosure includes treating a film of modified nanoparticles with an AX post-treatment, where X is at least one halogen, and A is a cation with examples include formamidinium (FA⁺), methyl ammonium (MA⁺), or Cs⁺. For example, FIG. 16 compares devices like those shown in FIG. 4 treated with FAI to those treated with neat methyl acetate, which illustrates a ~60% improvement in short-circuit current density (J_{SC}), improving the PCE obtained from a current density-voltage (J-V) scan from 8.49% up to 13.76%. Without wishing to be bound by theory, this photocurrent increase may occur due to a broadband improvement in the external quantum efficiency (EQE), as shown in FIG. 17 rather than a change in the EQE onset. The absorbance of the films prepared with the neat EtAc and FAI treatments show similar onsets at ~700 nm, consistent with the EQE spectra, but also show similar overall light absorption FIG. 18, which may indicate that the improvement in J_{SC} arises from enhanced charge carrier collection.

A variety of AX salts were tested to investigate the generality of the AX post-treatment. To fabricate these AX-treated CsPbI₃ nanoparticle films, CsPbI₃ nanoparticle films were deposited from octane solutions by spin-coating and treated with a saturated Pb(NO₃)₂ solution in MeOAc to partially remove the native surface modifiers, as described above. After building up a layer having thickness between 100 nm and 500 nm CsPbI₃ nanoparticle film (3-4 deposition cycles), the films were soaked in a saturated AX salt solution in EtAc (FIG. 19). A series of solar cells was fabricated by applying this AX salt post-treatment as well as a neat EtAc post-treatment and a control device without any post-treatment. The resultant J-V scans are shown in FIG. 16; relevant J-V parameters are provided in Table 2. All of the AX post-treatments improved the PCE compared to the control devices which was primarily the result of increased J_{SC}, demonstrating the generality of this surface treatment scheme. The highest PCE of 13.4% was achieved from the FAI treatment with a J_{SC} of 14.37 mA/cm², which was much better than the neat EtAc control with a PCE and J_{SC} of 8.49% and 9.22 mA/cm², respectively. CsPbI₃ nanoparticle devices treated with MAI and FABr yielded PCEs of 12.6%, with MAI-treated films producing a slightly higher J_{SC} and FABr-treated films producing a slightly higher V_{OC} and FF. As shown previously for FAI-treated films, the differences in J_{SC} are not accompanied by any observable change in the EQE onset (see FIG. 17).

TABLE 2

AX salt post-treatment	V _{oc} (V)	J _{sc} (mA cm ⁻²)	Fill factor	PCE (%)
FAI (EtAc)	1.20	14.37	0.78	13.43
FABr (EtAc)	1.22	12.70	0.81	12.61
MAI (EtAc)	1.20	13.39	0.79	12.61
MABr (EtAc)	1.21	11.27	0.82	11.22
CsI (EtAc)	1.20	10.64	0.81	10.31
neat EtAc	1.17	9.22	0.78	8.49
Control (no treatment)	1.14	6.27	0.64	4.58

17

While all of the AX post-treatments improved device performance by primarily increasing J_{SC} , the role of the FAI treatment on the morphology, optical properties and crystal structure of the CsPbI₃ nanoparticle films were investigated to elucidate any changes that may be occurring due to this post-treatment. The presence of FA in the film was verified by transmission FTIR, as shown in FIG. 20, by the emergence of a peak at 1712 cm⁻¹ following FAI treatment which is characteristic of the C=N stretch in FA. As it is confirmed that FA is present in the treated films, again without wishing to be bound by theory, four scenarios are hypothesized as to the interaction between FA and the CsPbI₃ nanoparticle film: (i) the FA interactions could be limited to the nanoparticle surface, either binding to the nanoparticle or infilling the void space between nanoparticles, (ii) a cation exchange could result in a Cs_xFA_(1-x)PbI₃ alloying of the nanoparticle core, (iii) a FAPbI₃ matrix could form around the nanoparticles if excess of Pb and I are present, and (iv) the FAI salt could be inducing grain growth in the CsPbI₃ nanoparticle film meaning that there are no longer individual nanoparticles present in the treated films and the films now resemble bulk CsPbI₃ or alloyed FA_xCs_{1-x}PbI₃ films which have been shown to achieve J_{SC} values as high as 22 mA/cm².

Considering the EQE onset (see FIG. 17) remained unchanged and only a slight red shift in the absorption onset and photoluminescence is observed (see FIG. 21), drastic changes to chemical composition of the film are unlikely, as one might expect a greater red-shift in the case of a Cs_xFA_(1-x)PbI₃ alloy and an absorption onset at ~840 nm in the case of a FAPbI₃ matrix. X-ray diffraction patterns before and after the FAI treatment are absent of any detectable peak shifts or new peaks, which would indicate alloying or formation of a new perovskite phase, respectively. Additionally, we see a decrease in the C—H modes associated with the as-synthesized oleate and oleylammonium ligands near 3000 cm⁻¹ in the FTIR, suggesting more native surface modifiers have been removed, increasing nanoparticle coupling. To assess whether the increased charge carrier collection is the result of CsPbI₃ nanoparticle grain growth induced by the FAI treatment, the PL from film of three different sizes of nanoparticles was measured by varying the reaction temperature with lower reaction temperatures resulting in smaller nanoparticles. After performing the FAI treatment, there was still a significant blue shift in the PL with decreasing nanoparticle size (see FIG. 21) which verifies that quantum confinement is retained following the FAI treatment. High resolution SEM images of the nanoparticle films before and after FAI treatment can readily resolve individual nanoparticles in the films and confirms that the nanoparticle film morphology is maintained after the FAI treatment. Thus, it is clear that the CsPbI₃ nanoparticle structure remains intact, despite the addition of FA to the film. Because confinement is clearly preserved in the FAI treated films, it is hypothesized that the slight red-shift seen in the absorbance and PL following FAI treatment arises from the improved electronic coupling between individual nanoparticles. Increasing the wavefunction overlap between neighboring nanoparticles relaxes confinement in the nanoparticles and improves charge carrier transport, shown by the increased J_{SC} in the FAI-treated devices. Therefore, the mobility of the charge carriers of the FAI treated films was investigated using terahertz spectroscopy. A significant enhancement in the charge carrier mobility of FAI-treated CsPbI₃ nanoparticle films compared to the untreated counterpart. In addition to measuring the charge carrier mobility of the CsPbI₃ nanoparticle films with and without the FAI treatment, the charge carrier mobility of these films com-

18

pared to lead chalcogenide nanoparticles and perovskite thin films was analyzed. It was found that the charge carrier mobility of the CsPbI₃ nanoparticle film is higher than that of the lead chalcogenide nanoparticles, but also significantly lower than that of the thin film perovskites. The lower charge carrier mobility in the CsPbI₃ nanoparticle films compared to that of the thin film perovskite is consistent with a hopping transport mechanism in nanoparticle films, whereas the higher charge carrier mobility relative to the lead chalcogenide nanoparticles is likely due to the defect tolerance and lack of mid-gap trap states of perovskite materials.

FURTHER EXAMPLES

Example 1

A composition comprising a particle and a surface species, wherein: the particle has a characteristic length between greater than zero nm and 100 nm inclusively, and the surface species is associated with a surface of the particle such that the particle maintains a crystalline form when the composition is at a temperature between -180° C. and 150° C.

Example 2

The composition of example 1, wherein the characteristic length is between 50 nm and 100 nm inclusively.

Example 3

The composition of example 1, wherein the particle comprises at least one of a metal chalcogenide, a Group III-V material, a metal oxide, or a perovskite.

Example 4

The composition of example 3, wherein the particle comprises the metal chalcogenide comprising at least one of PbS, PbSe, PbTe, CdSe, CdS, CdTe, CuInS, CuInSe, ZnS, ZnSe, ZnTe, HgTe, or CdHgTe.

Example 5

The composition of example 3, wherein the particle comprises the Group III-V material comprising at least one of InP, InAs, GaAs, Si, Ge, or Sn.

Example 6

The composition of example 3, wherein the particle comprises the metal oxide comprising at least one of ZnO, MoO, or TiO₂.

Example 7

The composition of example 3, wherein the particle comprises the perovskite comprising at least one of CsPbI₃, CsPbBr₃, CsPbCl₃, RbPbI₃, RbPbBr₃, or RbPbCl₃.

Example 8

The composition of example 7, wherein the crystalline form is substantially cubic.

Example 9

The composition of example 1, wherein the surface species is associated with the surface of the particle by at least

19

one of a covalent bond, an ionic bond, van der Waals interactions, dipole-dipole interactions, Debye interactions, or hydrogen-bonding.

Example 10

The composition of example 9, wherein the surface species is associated with the surface of the particle by at least one ionic bond.

Example 11

The composition of example 1, wherein the surface species comprises at least one of a saturated hydrocarbon, an unsaturated hydrocarbon, a thiol-containing molecule, an acid, or a metal halide.

Example 12

The composition of example 11, wherein thiol-containing molecule comprises at least one of methanethiol, ethanethiol, ethanedithiol, or 1-propanethiol.

Example 13

The composition of example 11, wherein the acid comprises at least one of acetic acid, formic acid, oxalic acid, or mercaptopropionic acid.

Example 14

The composition of example 11, wherein the surface species comprises at least one of oleate or oleylammonium.

Example 15

The composition of example 11, wherein a metal of the metal halide comprises at least one of lead, germanium, or tin.

Example 16

The composition of example 15, wherein the metal halide comprises at least one of PbI_2 , PbBr_2 , PbCl_2 , GeI_2 , GeBr_2 , GeCl_2 , SnI_2 , SnBr_2 , or SnCl_2 .

Example 17

The composition of example 1, further comprising an organic cation (A) associated with the surface of the particle.

Example 18

The composition of example 17, wherein A comprises at least one of methylammonium (MA) or formamidinium (FA).

Example 19

The composition of example 17, wherein A forms an organic-inorganic perovskite on the surface of the particle.

Example 20

The composition of example 19, wherein the organic-inorganic perovskite comprises $\text{A}_x\text{Cs}_{1-x}\text{PbI}_3$, where $0 < x < 1$.

20

Example 21

The composition of example 20, wherein the organic-inorganic perovskite comprises $\text{FA}_x\text{Cs}_{1-x}\text{PbI}_3$.

Example 22

A device comprising: an active layer comprising: a particle; and a surface species, wherein: the particle has a characteristic length between greater than zero nm and 100 nm inclusively, and the surface species is associated with a surface of the particle such that the particle maintains a crystalline form when the device is at a temperature between -180°C . and 150°C .

Example 23

The device of example 22, wherein the particle is a perovskite comprising at least one of CsPbI_3 , CsPbBr_3 , CsPbCl_3 , RbPbI_3 , RbPbBr_3 , or RbPbCl_3 .

Example 24

The device of example 23, wherein the crystalline form is substantially cubic.

Example 25

The device of example 22, wherein the active layer has a thickness between 100 nm and 500 nm.

Example 26

The device of example 22, further comprising a first charge transport layer and a second charge transport layer, wherein the active layer is positioned between the first charge transport layer and the second charge transport layer.

Example 27

The device of example 26, wherein the first charge transport layer comprises TiO_2 .

Example 28

The device of example 26, wherein the second charge transport layer comprises 2,2',7,7'-tetrakis(N,N-di-p-methoxyphenylamine)-9,9'-spirobifluorene.

Example 29

The device of example 22, wherein the active layer absorbs light having a bandgap greater than 1.70 eV.

Example 30

The device of example 29, wherein the bandgap is about 1.75 eV.

Example 31

The device of example 22, wherein the active layer is capable of emitting light having a wavelength between 600 nm and 680 nm.

Example 32

A method comprising: dispersing a first surface species and a particle in a mixture comprising an alkyl acetate,

21

wherein: the first surface species is associated with a surface of the particle, the particle has characteristic length between greater than 0 nm and 100 nm, the dispersing removes a first portion of the first surface species from the surface, the particle has a first crystalline form before the dispersing and a second crystalline form after the dispersing, and the second crystalline form is maintained when the particle is at a temperature between -180°C . and 150°C .

Example 33

The method of example 32, wherein the particle comprises a cationic element in the +1 state, a metal, and at least one of a halogen or a pseudohalogen.

Example 34

The method of example 33, wherein the cationic element comprises at least one of cesium, rubidium, potassium, sodium, or copper.

Example 35

The method of example 33, wherein the pseudohalogen comprises at least one of cyanide, cyanate, thiocyanate, or azide.

Example 36

The method of example 32, wherein the characteristic length is between 10 nm and 100 nm inclusively.

Example 37

The method of example 32, wherein the particle comprises at least one of a metal chalcogenide, a Group III-V material, a metal oxide, or a perovskite.

Example 38

The method of example 37, wherein the particle comprises a metal chalcogenide comprising at least one of PbS, PbSe, PbTe, CdSe, CdS, CdTe, CuInS, CuInSe, ZnS, ZnSe, ZnTe, HgTe, or CdHgTe.

Example 39

The method of example 37, wherein the particle comprises a Group III-V material comprising at least one of InP, InAs, GaAs, Si, Ge, or Sn.

Example 40

The method of example 37, wherein the particle comprises a metal oxide comprising at least one of ZnO, MoO, or TiO_2 .

Example 41

The method of example 37, wherein: the particle comprises a perovskite comprising at least one of CsPbX_3 , RbPbX_3 , CsGeX_3 , RbGeX_3 , CsSnX_3 , or RbSnX_3 , and X is a halogen.

Example 42

The method of example 32, wherein the second crystalline form is substantially cubic.

22

Example 43

The method of example 32, wherein the first surface species is associated with the surface of the particle by at least one of a covalent bond, an ionic bond, van der Waals interactions, dipole-dipole interactions, Debye interactions, or hydrogen-bonding.

Example 44

The method of example 43, wherein the first surface species is associated with the surface of the particle by at least one ionic bond.

Example 45

The method of example 32, wherein the first surface species comprises at least one of a saturated hydrocarbon, an unsaturated hydrocarbon, a thiol-containing molecule, an acid, or a metal halide.

Example 46

The method of example 45, wherein thiol-containing molecule comprises at least one of methanethiol, ethanethiol, ethanedithiol, or 1-propanethiol.

Example 47

The method of example 45, wherein the acid comprises at least one of acetic acid, formic acid, oxalic acid, or mercaptopropionic acid.

Example 48

The method of example 32, wherein the first surface species comprises at least one of oleate or oleylammonium.

Example 49

The method of example 32, wherein the first portion is less than 100% of the first surface species and a remainder of the first surface species remains associated with the surface of the particle, after the dispersing.

Example 50

The method of example 32, wherein the alkyl acetate comprises at least one of ethyl acetate, methyl acetate, propyl acetate, or butyl acetate.

Example 51

The method of example 32, wherein the mixture further comprises at least one of acetate ester, acetone, acetonitrile, diethyl ether, or propylene carbonate.

Example 52

The method of example 41, wherein: the mixture further comprises a first salt comprising at least one of an acetate, a nitrate, a carbonate, a thiocyanate, or a phosphate and a metal comprising at least one of lead, germanium or tin, the dispersing results in the first salt forming a second surface modifier comprising the metal and the halogen, the first portion is substantially 100% of the first surface modifier, at least a fraction of the second modifier associates with the

23

surface of the particle, and the second crystalline form is maintained when the particle is at a temperature between -180°C. and 150°C.

Example 53

The method of example 52, wherein the second modifier comprises a metal halide.

Example 54

The method of example 53, wherein the metal halide comprises at least one of PbI_2 , PbBr_2 , PbCl_2 , GeI_2 , GeBr_2 , GeCl_2 , SnI_2 , SnBr_2 , or SnCl_2 .

Example 55

The method of example 52, wherein the salt is present in the mixture at a substantially saturated concentration.

Example 56

The method of example 52, wherein the second surface modifier displaces the first modifier.

Example 57

The method of example 32, wherein the dispersing is by a solution method.

Example 58

The method of example 57, wherein the solution method comprises at least one of spin-coating, dip-coating, or curtain-coating.

Example 59

The method of example 32, wherein the dispersing is by spraying the mixture onto the particle.

Example 60

The method of example 32, further comprising, after the dispersing, removing the alkyl acetate from the particle.

Example 61

The method of example 32, further comprising, after the dispersing, contacting the particle with a solution comprising an aprotic solvent and a second salt, resulting in the forming of a third surface species that associates with the surface of the particle.

Example 62

The method of example 61, wherein the aprotic solvent comprises at least one of methyl acetate or ethyl acetate.

Example 63

The method of example 61, wherein the second salt comprises a cation comprising at least one of lead, germanium, tin, cesium, rubidium, methylammonium, or formamidineum.

Example 64

The method of example 63, wherein the second salt comprises an anion comprising a halogen.

24

The foregoing disclosure has been set forth merely to illustrate the invention and is not intended to be limiting. Since modifications of the disclosed embodiments incorporating the spirit and substance of the invention may occur to persons skilled in the art, the invention should be construed to include everything within the scope of the appended claims and equivalents thereof.

What is claimed is:

1. A composition comprising:

a plurality of perovskite particles having a cubic crystalline structure, wherein:

each perovskite particle is electronically coupled to its neighboring perovskite particles,

each particle has a characteristic length between greater than zero nanometers (nm) and 100 nm inclusively, and the perovskite particles remain electronically coupled and maintain the cubic crystalline structure when exposed to a temperature between -180°C. and 150°C.

2. The composition of claim 1, wherein the perovskite particles comprise at least one of a metal chalcogenide, a Group III-V material, or metal oxide.

3. The composition of claim 1, wherein the perovskite particles comprise at least one of CsPbI_3 , CsPbBr_3 , CsPbCl_3 , RbPbI_3 , RbPbBr_3 , or RbPbCl_3 .

4. The composition of claim 1, further comprising an organic cation (A) associated with a surface of at least one of the perovskite particles.

5. The composition of claim 4, wherein A comprises at least one of methylammonium or formamidineum.

6. The composition of claim 1, further comprising a surface species associated with a surface of at least one of the perovskite particles.

7. The composition of claim 6, wherein the surface species is associated with the surface of the at least one perovskite particle by at least one of a covalent bond, an ionic bond, van der Waals interactions, dipole-dipole interactions, Debye interactions, or hydrogen-bonding.

8. The composition of claim 7, wherein the surface species is associated with the surface of the at least one perovskite particle by an ionic bond.

9. The composition of claim 6, wherein the surface species comprises at least one of a saturated hydrocarbon, an unsaturated hydrocarbon, a thiol-containing molecule, an acid, or a metal halide.

10. The composition of claim 9, wherein the surface species comprises at least one of oleate or oleylammonium.

11. The composition of claim 9, wherein a metal of the metal halide comprises at least one of lead, germanium, or tin.

12. The composition of claim 11, wherein the metal halide comprises at least one of PbI_2 , PbBr_2 , PbCl_2 , GeI_2 , GeBr_2 , GeCl_2 , SnI_2 , SnBr_2 , or SnCl_2 .

13. A device comprising: a layer comprising:

a plurality of perovskite particles having a cubic crystalline structure,

wherein:

each perovskite particle is electronically coupled to its neighboring perovskite particles,

each particle has a characteristic length between greater than zero nanometers (nm) and 100 nm inclusively, and the plurality of particles remains electronically coupled and maintain the cubic crystalline structure when the device is exposed to a temperature between -180°C. and 150°C.

25

14. The device of claim 13, wherein the perovskite particles comprise at least one of CsPbI₃, CsPbBr₃, CsPbCl₃, RbPbI₃, RbPbBr₃, or RbPbCl₃.

15. A method comprising:

dispersing a first surface species and a particle in a mixture comprising an alkyl acetate, wherein:

the first surface species is associated with a surface of the particle,

the particle has characteristic length between greater than 0 nm and 100 nm,

the dispersing removes a first portion of the first surface species from the surface,

the particle has a first crystalline form before the dispersing and a second crystalline form after the dispersing, and

the second crystalline form is maintained, after the dispersing, when the particle is at a temperature between -180° C. and 150° C.

16. The method of claim 15, wherein the particle comprises at least one of a metal chalcogenide, a Group III-V material, a metal oxide, or a perovskite.

17. The method of claim 16, wherein:

the particle comprises a perovskite comprising at least one of CsPbX₃, RbPbX₃, CsGeX₃, RbGeX₃, CsSnX₃, or RbSnX₃, and

X is a halogen.

18. The method of claim 17, wherein:

the mixture further comprises a first salt comprising at least one of an acetate, a nitrate, a carbonate, a thiocyanate, or a phosphate and a metal comprising at least one of lead, germanium or tin,

26

the dispersing results in the first salt forming a second surface modifier comprising the metal and the halogen, the first portion is 100% of the first surface modifier, at least a fraction of the second modifier associates with the surface of the particle, and

the second crystalline form is maintained when the particle is at a temperature between -180° C. and 150° C.

19. The method of claim 18, wherein the second modifier comprises a metal halide.

20. The method of claim 15, wherein the second crystalline form is cubic.

21. The method of claim 15, wherein the first surface species comprises at least one of a saturated hydrocarbon, an unsaturated hydrocarbon, a thiol-containing molecule, an acid, or a metal halide.

22. The method of claim 15, wherein the first portion is less than 100% of the first surface species and a remainder of the first surface species remains associated with the surface of the particle, after the dispersing.

23. The method of claim 15, wherein the alkyl acetate comprises at least one of ethyl acetate, methyl acetate, propyl acetate, or butyl acetate.

24. The method of claim 15, wherein the mixture further comprises at least one of acetate ester, acetone, acetonitrile, diethyl ether, or propylene carbonate.

25. The method of claim 15, further comprising, after the dispersing, contacting the particle with a solution comprising an aprotic solvent and a second salt, resulting in the forming of a third surface species that associates with the surface of the particle.
