

6 Reasons Why You Should Start Using A Multi Server Environment

James William

Posted on November 7, 2019 • 8 min read

Many companies are shifting to the multi-server environment because of the high reliability and proficiency of their businesses. There are many reasons, you should use the multi-server environment for your business. In this article, I will discuss some benefits of a multi-server environment for your business and what are the best multi-server service options available in the market. The use of multi-server systems in the business generally helps guarantee high performance and uptime, sustain security, and enable more efficient resource allocation. There are many other benefits of dividing the resources onto many servers and on each server running changed operating systems. Web apps can be typically divided into application and web tiers if needed. All of the servers are configured and provisioned based on the demands of the function.

The agencies and SMBs can also get an advantage from resource server splitting to run various functions on multiple servers. This allows us to make more connections and reduce the dependability of a single server. This rapidly turns out to be the most cost-effective way to confirm system performance and reliability and it is also an indicator of the mature network. Eventually, agencies and enterprises with huge networks may end up with a separate server for each function to reduce the redundancy. Here are some of the major benefits you can get from a multi-server environment.

- [9. VPS Servers](#)
- [10. Conclusion](#)

Effective Resource Monitoring

The monitoring of your resources, data, or system very much depends on your server setup. The multi server environment allows more effective monitoring of the resources. For any organization, the monitoring of the functions and resources is essential to ensure better performance and efficiency, but a granular interpretation usually helps to confirm maximum uptime better performance, and [security](#), and in most cases, it also allows more competent allocation of resources to multiple systems. There are many possible profits to splitting off the functions on more than one server, as well as using the different OS on the servers.

For rapidly growing businesses or even startups with a growing business model, the effective monitoring of the resources is essential. So, it can be said that multiple server architectures are the ideal choice for large companies to improve their monitoring of servers and other resources.

More Security

As we know, with the advancement of technology and digitalization of businesses the threat of data and resource security is also increasing. For any business online security is one of the major concerns because if you are not keeping your data and resources secure, your business is always at stake. One of the best things about using multiple servers is that it provides better security against cybersecurity issues and other data protection problems. When you are using multiple servers for resource allocation your data is separate from the core servers and in case of some security attack happening on the servers, it would not have any impact on the database or other resources separated from the servers. On the other side, when you are using all of the resources on the same servers, a virus or hacker attack can damage these resources at once and you can lose your data with the exploitation of resources.

For the companies who have to deal with confidential data, for example, banks who have to handle the confidential and financial information of clients should use the Multi-Server Environment by splitting off the database from the servers. Separating the database would keep your information safe and secure and in case of any cyber-attack, your database would remain inaccessible for a hacker. I would recommend that large and growing businesses use the Multi-Server Environment to ensure more security and safety of their data and resources and it is also an indicator of their long-term success.

Improves Server Performance

In the Multi-Server Environment, the allocation of the system resources unequally to numerous servers depends on the needs of their functions, in doing so the resources can be efficiently used. The database server's overall performance can often be upgraded by organizing it to cache common tables and queries, and by modifying the quantity of real-time connections acceptable, for example by [MySQL](#) server "max_connections" variable setup. Multi-server environment improves server performance and resource scalability.

There are numerous organizations, yet, that could improve their system performance, cost efficiency, and reliability by dividing the resources but do not go for it. If you are currently making a plan to take online expenses or serve any industry, you may need to have some separate functions band resources for this purpose. In case, your company has updated its server with content growth, and particularly if the resource requirements of one specific function are triggering major problems, splitting off the resources is probably the best option available to deal with the issues.

Cost Efficiency

You should know that the upgrades of the server raise the overall cost, but not essentially consistently. If you are going through some issues related to server performance, especially in the resources like RAM or CPU, a multi-server environment is the more cost-effective to improve the performance rather than upgrading the system. In case, you cannot afford more servers or run out of RAM space, dividing your functions into multiple servers would help you to optimize the resources and

resolve all performance-related issues. Separating the resources from the servers would allow you to perform all functions and tasks separately and it is one of the most beneficial ways to get the maximum benefit of your server environment. In some of the situations, businesses can improve their system reliability, dropping its cost. The needs and roles of databases and applications or web servers are fairly different, and splitting them off would benefit you a lot.

A multi-server environment allows you to have more services and connections, supports keeping the system in working condition because of dependency of resources on a single system is reduced, and is also less expensive each month server's architecture than constantly adding resources to the server. There are said to be two or three servers in the lower price level, adjusted to service-oriented, separate roles will typically offer better performance at a lesser price as compared with the most influential server setup available. In some cases, a quad-core CPU or high-end dual server can price more on its own as compared with the 2 or 3 systems running modest CPU resources.

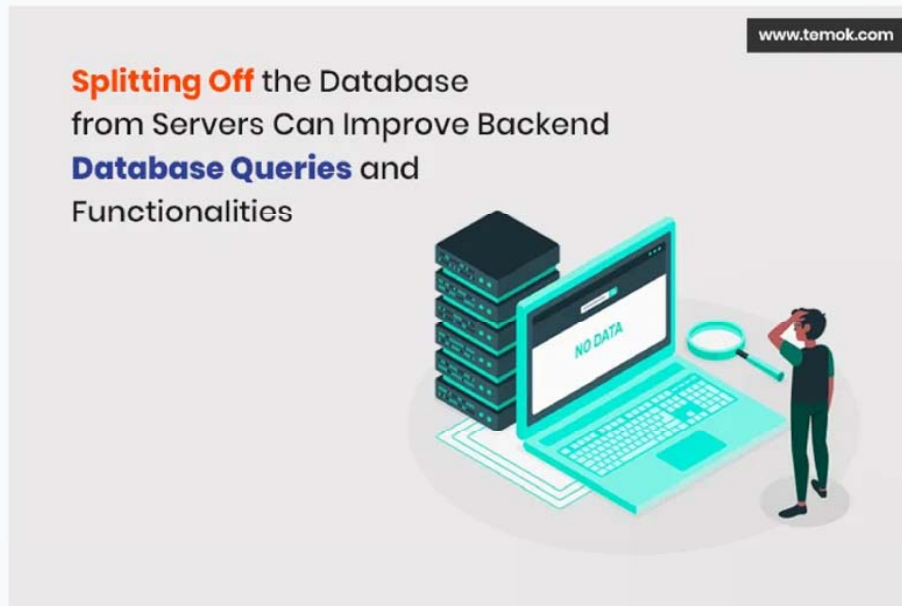

Reduce Dependability

In the multi-server environment, each server is responsible for its functions and tasks. Using these servers would reduce the dependability of the resources on each other. For example, if you have a separate database server, and your core server does it would not have any impact on the database servers. In a single server, all of the database resources are dependent on one

server and it also causes resource contention when using the same server. So, it can be said that the multi-server environment is one of the most reliable options to make your online business more secure and reliable. Deploying multiple servers can reduce your dependency on a single server.

Improve Database Functions

Assigning more CPU centers to a database server is very effective, for example, you can control and manage simultaneous queries at higher volumes. Maybe more significantly, by using numerous servers, each server configuration can be personalized to the function that it has to perform. The database server performance can be enhanced by organizing it to cache common tables and queries, and the modification of the simultaneous connections is also allowed.

Moreover, a lot of regulations and best practices are needed for the Separation of Duties, for example, the PCI-DSS. According to the PCI-DSS rule, any database record that contains PCI data such as credit card information should be kept on a server that does not connect to the internet. Dividing the resources into two appropriately organized servers offers this separation and makes the system obedient to this instruction.

The requirements and roles of the system database and application servers are very different from each other, and dividing them can offer a lot of benefits. By using these servers, you can also support more services and connections, and in case of any issue at one server, it would not have any effect on the performance of other servers. Arranging the database to a separate server is one of the first main landmarks in the standard small IT system evolution to a bigger one, this kind of server is also more suitable for a web-based business.

Numerous issues are restricting the quantity of connections a separate system can control in practice. The single server that hosts applications, databases, and as a minimum one website goes down any of the connections are weak.

Solutions for Multi-Server Environment

There are many ways to get multiple server environment services. Many platforms are offering multiple system platform setups. Here are some of the major and most effective services that you can consider when going for a multi-purpose server.

PaaS Platform

The Platform as a Service (PaaS) is said to be a cloud computing model that provides the third-party provider software and hardware tools — typically needed for the development of some applications for the internet. A PaaS provider offers [hosting services](#) such as software and hardware on its setup. A PaaS service provider supplies and builds an enhanced and resilient environment that allows the user can install data sets and applications. Users can emphasize running and creating applications instead of maintaining construction and the fundamental services and infrastructure. This platform also offers storage and computing infrastructure with version management, text editing, testing, and compiling services that would help the designers create new software efficiently and quickly.

VPS Servers

A Virtual Private Server (VPS) is said to be the fastest and most innovative option for getting the services for implementing the multi server environment. Here, you can also split the single server into separate virtual machines, working on their own operating systems management custom configurations. The [VPS servers](#) have dedicated resources such as RAM and CPU which work separately from all websites on the same server. So, it can be said that a virtual private server of good quality frequently ranges from RAM 2 GB and 2 vCPUs up to 16 GB of RAM and 8vCPUs. There are a lot of VPS packages available online and many of the hosting providers in the market are offering the VPS services at reasonable rates. The low-cost VPS can offer a lot of resources for numerous new startups, but growing the amounts of resources on servers or allocating separate servers for each resource would not only help you to manage the resources effectively but also allow you to manage the traffic on all website effectively or if you have one large website, it would allow you to effectively manage the functions and database of that website.

For businesses with a low budget, the VPS is the most appropriate option to go for. Some of the hosting companies can also divide up the overall maintenance and operating cost of the server among all tenants that are working on the same server. In doing so, you would see a clear reduction in your overall budget.

So, it can be said that, if you are a large company or business in the growing phase, the VPS multi server services are probably the best option available for you.

Conclusion

In this article, I have shared with you some of the major benefits of using the multi-server environment and how it would help your business to ensure long-term stability and success. Some of the best service platforms are also mentioned in this article to implement the multi server environment. I hope this information will help you to make a better decision about your server setups.
