AB The present invention provides substituted azaindole prodrugs of vemurafenib, methods of making said prodrugs, pharmaceutical compns. of said prodrugs and methods of using said prodrugs and pharmaceutical compns. thereof to treat or prevent diseases or disorders such as cancer. The prodrugs have general formula I, wherein each of X and Y is independently H, -C(:O)R3, -C(:O)OR4, -C(R1R2)OC(:O)R3, -C(R1R2)OC(:O)OR4 or -C(R1R2)OP(:O)(OR4)(OR4a), with the proviso that when Y is H, X is not -C(:O)CH3 or H; each R1 and R2 is independently H, D, C1-6alkyl, etc.; each R3 is independently H, D, C1-10alkyl, etc.; and each R4 and R4a is independently H, C1-10alkyl, C3-8cycloalkyl, etc. Example compound II was prepared by reacting vemurafenib with Et chloroformate. Various prodrugs of the invention were studied for their stability in liver microsomes, their oral and i.v. bioavailability, and their antitumor properties.

AB A review. Treatment with cabozantinib, an inhibitor of MET and VEGFR2 signaling, has demonstrated clin. benefit in early trials in men with metastatic prostate cancer. Preclin. evidence suggests that cabozantinib can kill cancer cell seeds while disrupting angiogenesis and stromal cells in the metastatic soil.

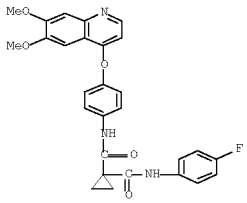
DOCUMENT TYPE: Journal



LANGUAGE: English

AB Purpose: Cabozantinib, an orally available multityrosine kinase inhibitor with activity against mesenchymal epithelial transition factor (MET) and VEGF receptor 2 (VEGFR2), induces resolution of bone scan lesions in men with castration-resistant prostate cancer bone metastases. The purpose of this study was to determine whether cabozantinib elicited a direct antitumor effect, an indirect effect through modulating bone, or both. Exptl. Design: Using human prostate cancer xenograft studies in mice, we determined the impact of cabozantinib on tumor growth in soft tissue and bone. In vitro studies with cabozantinib were performed using (i) prostate cancer cell lines to evaluate its impact on cell growth, invasive ability, and MET and (ii) osteoblast cell lines to evaluate its impact on viability and differentiation and VEGFR2. Results: Cabozantinib inhibited progression of multiple prostate cancer cell lines (Ace-1, C4-2B, and LuCaP 35) in bone metastatic and soft tissue murine models of prostate cancer, except for PC-3 prostate cancer cells in which it inhibited only s.c. growth. Cabozantinib directly inhibited prostate cancer cell viability and induced apoptosis in vitro and in vivo and inhibited cell invasion in vitro. Cabozantinib had a dose-dependent biphasic effect on osteoblast activity and inhibitory effect on osteoclast production in vitro that was reflected in vivo. It blocked MET and VEGFR2 phosphorylation in prostate cancer cells and osteoblast-like cells, resp. Conclusion: These data indicate that cabozantinib has direct antitumor activity, and that its ability to modulate osteoblast activity may contribute to its antitumor efficacy. AB The invention provides substituted pyrazolone compds.of formula I, stereoisomers, geometric isomers, tautomers, oxynitrides, hydrates, solvates, metabolites, pharmaceutically acceptable salts or prodrugs thereof, and pharmaceutical preparation for regulating the activity of protein kinases and adjusting the signal response in the cell or between cells. The invention also relates to pharmaceutical compns. comprising the compds. and a method for treating hyperproliferative disorder of mammal, particularly human using the compns. Compds. of formula I [wherein Q is H, NH2 and derivative, OH and derivs., -NHCOR, etc.; W is (un)substituted CH or N; X, Y, and Z are independently H, D, C1-6 alkyl, C3-8 cycloalkyl-C1-4 alkylene, etc.; R1-R6 are independently H, D, F, Cl, Br, CN, etc.; R is H, C1-6 alkyl, C3-8 cycloalkyl-C1-4 alkylene, C3-7 heterocycloalkyl, etc.] and their stereoisomers, geometric isomers, tautomers, oxynitrides, hydrates, solvates, metabolites, pharmaceutically acceptable salts or prodrugs thereof, are claimed and exemplified. For example, II was prepared in a multistep process (procedure given). I were evaluated for stability in liver microsomes and pharmacokinetic properties in mice, rats, dogs, and monkeys (data given). Binding of I to receptor tyrosine kinases was determined using KINOMEscan where II exhibited binding constant (Kd) values of 23 nM for KDR tyrosine kinase and 4.4 nM for c-Met tyrosine kinase.

AB This invention relates to the field of lipid kinases and modulators thereof. In particular, the invention relates to compds. I [W = D, CN, N3, (un)substituted C5-12 spirobicyclyl or C=CX; X = H, D, alkyl, cycloalkyl, etc.; R1 = H, D, Cl, alkyl, etc.; R2 = alkyl, cycloalkyl, aryl, etc.] as modulators of phosphatidylinositol 3-kinases (PI3 kinases or PBKs) signaling pathways, and methods of their use. Twenty-nine compds. I were prepared and disclosed. E.g., a multi-step synthesis of II, starting from 5-bromo-2-chloro-3-nitropyridine, was described. Exemplified compds. I exhibited potent activities in the PI3Kα(h) and mTOR(h) assays (data given for representative compds. I). The invention also provides pharmaceutically acceptable compns. comprising compds. I and methods of using the compns. in modulating of PI3K signaling pathways and their related disorders in mammals, especially humans.

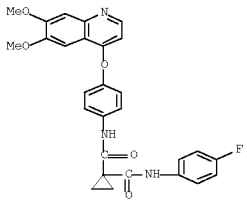
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB Through transcriptome an in-frame fusion of 2 genes (CEP55 and RET) of human chromosome 10 was found in patients with diffuse-type gastric cancer. The fused genes can be used for evaluation of the effectiveness of an antitumor agent such as RET tyrosine kinase inhibitors. Antibody to CEP55 or RET protein is also claimed.

AB A review. Although targeted therapy against VEGF and mTOR have revolutionized the treatment of advanced renal cell carcinoma (RCC), addnl. agents are required due to toxicity and resistance to currently available drugs. Some next-generation tyrosine kinase inhibitors have focused on VEGF, narrowing the spectrum of receptors which are inhibited and enhancing binding affinity. However, targeting novel receptors with tyrosine kinase inhibition of addnl. receptor targets has also emerged as an important future therapeutic strategy for RCC, both clear cell and variant histol. New pathways being targeted include FGF, angiopoietin and MET. In this review, we highlight five novel tyrosine kinase inhibitors in development for RCC: tivozanib; dovitinib; regorafenib; cabozantinib; and tivantinib.

therapeutic value in cancer therapy. Focus on the selectivity of both types of inhibitors, with potent selectivity or multi-targets, have demonstrated antitumor efficacy. The network pharmacol. and clin. trials integrated would provide powerful tools to further evaluate the superiority of both inhibitors in continued efficacy and toxicity.

AB A review. Introduction: The receptor tyrosine kinase c-MET displays aberrant activation in the malignant phenotype of various tumors, and thus, has drawn considerable attention as drug target for cancer therapy. Many c-MET inhibitors are now under clin. investment, and one of them - Cabozantinib - has been approved by US FDA in 2012 for the treatment of medullary thyroid cancer, which further proved the feasibility of c-MET inhibition method in cancer therapy. Areas covered: This article briefly outlines the role of c-MET in oncogenesis and provides a broad overview of the assays used to characterize new inhibitors. Then, a series of representative small-mol. inhibitors of c-MET, especially from the published patent literature from 2011 to 2013, are recorded. Herein, the challenges in the kinase inhibitor design, such as the inhibitor selectivity and resistance mutations, are also discussed. Expert opinion: Up to now, at least 17 inhibitors of c-MET are under clin. evaluation, and several agents exhibit encouraging results. Thus, inhibiting c-MET signaling has major

AB In prostate cancer, multiple metastases from the same patient share similar copy number, mutational status, erythroblast transformation specific (ETS) rearrangements, and methylation patterns supporting their clonal origins. Whether actionable targets such as tyrosine kinases are also similarly expressed and activated in anatomically distinct metastatic lesions of the same patient is not known. We evaluated active kinases using phosphotyrosine peptide enrichment and quant. mass spectrometry to identify druggable targets in metastatic castration-resistant prostate cancer obtained at rapid autopsy. We identified distinct phosphopeptide patterns in metastatic tissues compared with treatment-naive primary prostate tissue and prostate cancer cell line-derived xenografts. Evaluation of metastatic castration-resistant prostate cancer samples for tyrosine phosphorylation and upstream kinase targets revealed SRC, epidermal growth factor receptor (EGFR), rearranged during transfection (RET), anaplastic lymphoma kinase (ALK), and MAPK1/3 and other activities while exhibiting intrapatient similarity and interpatient heterogeneity. Phosphoproteomic analyses and identification of kinase activation states in metastatic castration-resistant prostate cancer patients have allowed for the prioritization of kinases for further clin. evaluation.

AB Background: A limited no. of approved therapeutic options are available to metastatic medullary thyroid cancer (MTC) patients, and the response to conventional chemotherapy and/or radiotherapy strategies is inadequate. Sporadic and inherited mutations in the tyrosine kinase RET result in oncogenic activation that is associated with the pathogenesis of MTC. Cabozantinib is a potent inhibitor of MET, RET, and vascular endothelial factor receptor 2 (VEGFR2), as well as other tyrosine kinases that have been implicated in tumor development and progression. The object of this study was to determine the in vitro biochem. and cellular inhibitory profile of cabozantinib against RET, and in vivo antitumor efficacy using a xenograft model of MTC.Methods: Cabozantinib was evaluated in biochem. and cell-based assays that determined the potency of the compound against wild type and activating mutant forms of RET. Addnl., the pharmacodynamic modulation of RET and MET and in vivo antitumor activity of cabozantinib was examined in a MTC tumor model following subchronic oral administration.Results: In biochem. assays, cabozantinib inhibited multiple forms of oncogenic RET kinase activity, including M918T and Y791F mutants. Addnl., it inhibited proliferation of TT tumor cells that harbor a C634W activating mutation of RET that is most often associated with MEN2A and familial MTC. In these same cells grown as xenograft tumors in nude mice, oral administration of cabozantinib resulted in dose-dependent tumor growth inhibition that correlated with a reduction in circulating plasma calcitonin levels. Moreover, immunohistochem. analyses of tumors revealed that cabozantinib reduced levels of phosphorylated MET and RET, and decreased tumor cellularity, proliferation, and vascularization.Conclusions: Cabozantinib is a potent inhibitor of RET and prevalent mutationally activated forms of RET known to be associated with MTC, and effectively inhibits the growth of a MTC tumor cell model in vitro and in vivo.

AB Purpose of review: Several new targeted therapies with multikinase inhibitors targeting vascular endothelial growth factor (VEGF), rearranged during transfection and v-raf murine sarcoma viral oncogene homolog B1 pathways have been tested in clin. trials for radioiodine-refractory differentiated thyroid cancer (DTC) and medullary thyroid cancer (MTC) in the past 10 years. Recent findings: Results of the first phase III trial of VEGF-targeted therapy (sorafenib) in DTC were presented in June 2013, and two phase III trials with VEGF and rearranged during transfection-targeted therapies (vandetanib and cabozantinib) in MTC have led to approval by US Food and Drug Administration in the past 2 years. Whereas such therapies increase median progression-free survival compared to placebo, there is no therapy proven to improve overall survival yet. Significant potential adverse event risks associated with such therapies need to be recognized. Dissemination of knowledge about targeted therapies is critical for various medical specialists as patient care for thyroid cancers is best delivered in a multidisciplinary setting. Summary: Successful development of targeted systemic therapies in DTC and MTC in the past 5 years is incredibly exciting in the field and patients with advanced DTC/MTC now have new standard-of-care therapy options.

AB The present invention provides novel substituted alkynyl pyridine compds., pharmaceutical acceptable salts and formulations thereof useful in modulating the protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans.

AB When using molecularly targeted agents (MTAs), oncologists and patients face new and sometimes unexpected toxicities. Though ocular adverse events (OAEs) are not uncommon with chemotherapy, they are rarely severe or dose limiting. Ocular toxicity profile may differ with MTAs, indeed severe and dose limiting toxicities have been described with targeted therapies currently under investigation. Our study aimed to review OAEs experienced with MTAs approved in solid tumors. This review revealed that many OAEs, frequent and potentially severe, exist and concern most MTAs. The suggestion is prompt referral of patients with severe pain and/or visual impairment to the ophthalmologist since these symptoms can be associated with potentially severe OAE and need ophthalmic assessment. Oncologists must be aware of such events and their potential severity for better treatment and better diagnosis in daily practice as well as in clin. trials.

AB Background Anti-angiogenic treatment of glioblastoma characteristically results in therapy resistance and tumor progression via diffuse infiltration. Monitoring tumor progression in these patients is thwarted because therapy results in tumor invisibility in contrast-enhanced (CE) MRI. To address this problem, we examined whether tumor progression could be monitored by metabolic mapping using 1H MR spectroscopic imaging (MRSI). Methods We treated groups of BALB/c nu/nu mice carrying different orthotopic diffuse-infiltrative glioblastoma xenografts with bevacizumab (anti-vascular endothelial growth factor [VEGF] antibody, n = 13), cabozantinib (combined VEGF receptor 2/c-Met tyrosine kinase inhibitor, n = 11), or placebo (n = 15) and compared CE-MRI with MRS-derived metabolic maps before, during, and after treatment. Metabolic maps and CE-MRIs were subsequently correlated to histol. and immunohistochem. Results In vivo imaging of choline/n-acetyl aspartate ratios via multivoxel MRS is better able to evaluate response to therapy than CE-MRI. Lactate imaging revealed that diffuse infiltrative areas in glioblastoma xenografts did not present

with excessive glycolysis. In contrast, glycolysis was observed in hypoxic areas in angiogenesis-dependent compact regions of glioma only, especially after anti-angiogenic treatment. Conclusion Our data present MRSI as a powerful and feasible approach that is superior to CE-MRI and may provide handles for optimizing treatment of glioma. Furthermore, we show that glycolysis is more prominent in hypoxic areas than in areas of diffuse infiltrative growth. The Warburg hypothesis of persisting glycolysis in tumors under normoxic conditions may thus not be valid for diffuse glioma.

AB Purpose: Cabozantinib, a tyrosine kinase inhibitor (TKI) of hepatocyte growth factor receptor (MET), vascular endothelial growth factor receptor 2, and rearranged during transfection (RET), demonstrated clin. activity in patients with medullary thyroid cancer (MTC) in phase I. Patients and Methods: We conducted a double-blind, phase III trial comparing cabozantinib with placebo in 330 patients with documented radiog. progression of metastatic MTC. Patients were randomly assigned (2:1) to cabozantinib (140 mg per day) or placebo. The primary end point was progression-free survival (PFS). Addnl. outcome measures included tumor response rate, overall survival, and safety. Results: The estimated median PFS was 11.2 mo for cabozantinib vs. 4.0 mo for placebo (hazard ratio, 0.28; 95% CI, 0.19 to 0.40; P < .001). Prolonged PFS with cabozantinib was observed across all subgroups including by age, prior TKI treatment, and RET mutation status (hereditary or sporadic). Response rate was 28% for cabozantinib and 0% for placebo; responses were seen regardless of RET mutation status. Kaplan-Meier ests. of patients alive and progression-free at 1 yr are 47.3% for cabozantinib and 7.2% for placebo. Common cabozantinib-associated adverse events included diarrhea, palmar-plantar erythrodysesthesia, decreased weight and appetite, nausea, and fatigue and resulted in dose redns. in 79% and holds in 65% of patients. Adverse events led to treatment discontinuation in 16% of cabozantinib-treated patients and in 8% of placebo-treated patients. Conclusion: Cabozantinib (140 mg per day) achieved a statistically significant improvement of PFS in patients with progressive metastatic MTC and represents an important new treatment option for patients with this rare disease. This dose of cabozantinib was associated with significant but manageable toxicity.

AB The invention relates to substituted alkynyl pyridine compds. of formula I as protein kinase regulator useful in treatment of various diseases and their preparation Compds. I, wherein R1, R2, R3, R4, R5 and R6 are independently H, D or F; X is C6-10 aryl or heteroaryl containing 5-10 atoms; Z is C1-6 alkyl, C3-6 cycloalkyl, C3-6 heterocyclic radical, etc.; their stereoisomers, solvates, N-oxidants, pharmaceutically acceptable salts, are claimed. Compound II was prepared by multi-step procedure (procedure given). The invention compds. were evaluated for their ALK(h) kinase activity. From assay, it was determined that II exhibited the IC50 value of 52 nM against ALK(h).

AB A review. The landscape of castration-resistant prostate carcinoma has changed completely in the last few years, with the approval of four new agents with proven benefit in overall survival. Abiraterone, cabazitaxel, enzalutamide and radium-223 dichloride have been added to the armamentarium of available agents for the treatment of these patients. We still lack information about which agent works best in an individual patient and how to optimally use them in a sequential strategy. Cabozantinib, a targeted agent against MET and vascular endothelial growth factor receptor-2, has shown promising results and could become the first targeted therapy to be approved for castration-resistant prostate carcinoma. This paper reviews the clin. development of cabozantinib in prostate cancer and future research possibilities for this drug.

AB Cabozantinib is an inhibitor of multiple receptor tyrosine kinases, including MET and VEGFR2. In a phase II clin. trial in advanced prostate cancer (PCa), cabozantinib treatment improved bone scans in 68% of evaluable patients. Our studies aimed to determine the expression of cabozantinib targets during PCa progression and to evaluate its efficacy in hormone-sensitive and castration-resistant PCa in preclin. models while delineating its effects on tumor and bone. Using immunohistochem. and tissue microarrays containing normal prostate, primary PCa, and soft tissue and bone metastases, our data show that levels of MET, P-MET, and VEGFR2 are increasing during PCa progression. Our data also show that the expression of cabozantinib targets are particularly pronounced in bone metastases. To evaluate cabozantinib efficacy on PCa growth in the bone environment and in soft tissues we used androgen-sensitive LuCaP 23.1 and castration-resistant C4-2B PCa tumors. In vivo, cabozantinib inhibited the growth of PCa in bone as well as growth of s.c. tumors. Furthermore, cabozantinib treatment attenuated the bone response to the tumor and resulted in increased normal bone volume In summary, the expression pattern of cabozantinib targets in primary and castration-resistant metastatic PCa, and its efficacy in two different models of PCa suggest that this agent has a strong potential for the effective treatment of PCa at different stages of the disease.

AB A review. Cabozantinib (XL184) is an orally bioavailable tyrosine kinase inhibitor with activity against MET and vascular endothelial growth factor receptor 2. We evaluated the activity of cabozantinib in patients with castration-resistant prostate cancer (CRPC) in a phase II randomized discontinuation trial with an expansion cohort. Patients received 100 mg of cabozantinib daily. Those with stable disease per RECIST at 12 wk were randomly assigned to cabozantinib or placebo. Primary end points were objective response rate at 12 wk and progression-free survival (PFS) after random assignment. One hundred seventy-one men with CRPC were enrolled. Random assignment was halted early based on the observed activity of cabozantinib. Seventy-two percent of patients had regression in soft tissue lesions, whereas 68% of evaluable patients had improvement on bone scan, including complete resolution in 12%. The objective response rate at 12 wk was 5%, with stable disease in 75% of patients. Thirty-one patients with stable disease at week 12 were randomly assigned. Median PFS was 23.9 wk (95% CI, 10.7 to 62.4 wk) with cabozantinib and 5.9 wk (95% CI, 5.4 to 6.6 wk) with placebo (hazard ratio, 0.12; P<.001). Serum total alkaline phosphatase and plasma cross-linked C-terminal telopeptide of type I collagen were reduced by≥50% in 57% of evaluable patients. On retrospective review, bone pain improved in 67% of evaluable patients, with a decrease in narcotic use in 56%. The most common grade 3 adverse events were fatigue (16%), hypertension (12%), and hand-foot syndrome (8%). Cabozantinib has clin. activity in men with CRPC, including reduction of soft tissue lesions, improvement in PFS, resolution of bone scans, and redns. in bone turnover markers, pain, and narcotic use.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Methods and compns. are provided for diagnosing or inhibiting invasion or metastasis of a cancer in a subject based on MenaINV. A method is provided of identifying an agent as an inhibitor of sarcoma or carcinoma cell invasion or as an inhibitor of metastasis of a carcinoma or sarcoma, comprising contacting a preparation comprising a growth factor receptor and a protein tyrosine phosphatase 1b (PTP1b) in the presence of an amount of MenaINV and an amount of Mena and quantifying the association of the growth factor receptor and PTP1b in the presence of the agent and in the absence of the agent. An agent that increases the association of growth factor receptor and PTP1b in the presence of the agent as compared to in the absence of the agent is identified as an inhibitor of sarcoma or carcinoma cell invasion or of metastasis, and an agent that does not increase, or decreases, the association of growth factor receptor and PTP1b in the presence of the agent as compared to in the absence of the agent is not identified as an inhibitor of sarcoma or carcinoma cell invasion or metastasis. A further method is provided of identifying an agent as an inhibitor of sarcoma or carcinoma cell invasion or of metastasis of a carcinoma or sarcoma, the method comprising contacting a preparation comprising an amount of MenaINV, an amount of Mena, and a protein, wherein the protein is phosphorylated, with the agent and PTP1b and quantifying phosphorylation of the protein at the site or sites. A decrease in phosphorylation in (a) the presence of the agent and PTP1b as compared to (b) in the absence of the agent and presence of PTP1b identifies the agent as an inhibitor of sarcoma or carcinoma cell invasion or metastasis, and wherein an increase in, or no change in, phosphorylation in (i) the presence of the agent and PTP1b as compared to (ii) in the absence of the agent and presence of PTP1b does not identify the agent as an inhibitor of sarcoma or carcinoma cell invasion or metastasis.

AB The present invention relates to a method for the prognosis of bone metastasis in triple neg. (including basal-like) breast cancer or, alternatively, ER+

breast cancer (including luminal A and β) which comprises determining if the c-MAF gene is amplified in a primary tumor sample. Likewise, the invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise determining the c-MAF gene expression level, amplification or translocation. The invention also relates to a method for predicting early bone metastasis in a subject suffering breast cancer. The invention also relates to a c-MAF inhibitor as therapeutic agent for use in the treatment of triple neg. (including basal-like) breast cancer metastasis or, alternatively, ER+ breast cancer (including luminal A and B) metastasis. The invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the invention relates to a method for typing of a subject suffering breast cancer and for classifying a subject from breast cancer into a cohort.

AB A new type of signaling network element, called cancer signaling bridges (CSB), has been shown to have the potential for systematic and fast-tracked drug repositioning. On the basis of CSBs, we developed a computational model to derive specific downstream signaling pathways that reveal previously unknown target-disease connections and new mechanisms for specific cancer subtypes. The model enables us to reposition drugs based on available patient gene expression data. We applied this model to repurpose known or shelved drugs for brain, lung, and bone metastases of breast cancer with the hypothesis that cancer subtypes have their own specific signaling mechanisms. To test the hypothesis, we addressed specific CSBs for each metastasis that satisfy (i) CSB proteins are activated by the maximal number of enriched signaling pathways specific to a given metastasis, and (ii) CSB proteins are involved in the most differential expressed coding genes specific to each breast cancer metastasis. The identified signaling networks for the three types of breast cancer metastases contain 31, 15, and 18 proteins and are used to reposition 15, 9, and 2 drug candidates for the brain, lung, and bone metastases. We conducted both in vitro and in vivo preclin. expts. as well as anal. on patient tumor specimens to evaluate the targets and repositioned drugs. Of special note, we found that the Food and Drug Administration-approved drugs, sunitinib and dasatinib, prohibit brain metastases derived from breast cancer, addressing one particularly challenging aspect of this disease.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The present invention relates to a method for the prognosis of bone metastasis in triple neg. (including basal-like) breast cancer which comprises determining if the c-MAF gene is amplified in a primary tumor sample. Likewise, the invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise determining the c-MAF gene expression level. The invention also relates to a method for predicting early bone metastasis in a subject suffering breast cancer. The invention also relates to a c-MAF inhibitor as therapeutic agent for use in the treatment of triple neg. (including basal-like) breast cancer metastasis. The invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the invention relates to a method for typing of a subject suffering breast cancer and for classifying a subject from breast cancer into a cohort.

AB The present invention provides spirobicyclic compds. of general formula I (wherein R1-R6 are independently H, D, or F; each X and Y is independently (un)substituted C6-10aryl or (un)substituted 5-10 membered heteroaryl; Z is (un)substituted C5-12spirobicyclyl or (un)substituted -(C1-4alkylene)-(C5-12spirobicyclyl)-, with provisos), pharmaceutical acceptable salts and formulations thereof useful in modulating protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans. Synthetic procedures for preparing I are exemplified. For example, II was prepared in a 12-step synthesis that culminated in reaction of intermediates III and IV. II inhibited ALK kinase and c-Met kinase with IC50 values of 15 and 9 nM, resp.

AB The authors disclose the targeting of epithelial membrane protein 2 (EMP2) for the treatment and prevention of endometrial cancer. In one example, EMP2 expression directly correlated with VEGF protein levels as well as with secreted protein expression by endometrial adenocarcinoma cells. Ribozyme-mediated reduction of EMP2 resulted in undetectable levels of VEGF.

AB RET kinase is aberrantly activated in thyroid cancers and in rare cases of lung and colon cancer, and has been validated as a mol. target in these tumors. Vandetanib was recently approved for the treatment of medullary thyroid cancer. However, vandetanib is ineffective in vitro against RET mutants carrying bulky aminoacids at position 804, the gatekeeper residue, similarly to drug-resistant BCR-ABL mutants in chronic myeloid leukemia. Ponatinib is a multi-target kinase inhibitor that was recently approved for treatment-refractory Philadelphia-pos. leukemia. We show here potent inhibition of oncogenic RET by ponatinib, including the drug-insensitive V804M/L mutants. Ponatinib inhibited the growth of RET+ and BCR-ABL+ cells with similar potency, while not affecting RET-neg. cells. Both in biochem. and in cellular assays ponatinib compared favorably with known RET inhibitors, such as vandetanib, cabozantinib, sorafenib, sunitinib and motesanib, used as reference compds. We suggest that ponatinib should be considered for the treatment of RET+ tumors, in particular those expressing vandetanib-resistant V804M/L mutations.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB A method for identifying cancer patients that are likely to be responders or non-responders to a signal transduction pathway inhibitor is described. The present invention is directed to methods and tests that help predict the likelihood that a tumor will respond to a targeted therapy so that those cancer patients most likely to benefit can receive that drug in a timely manner and those patients unlikely to benefit from a particular drug can instead be prescribed alternative therapies. The test comprises a panel of two or more biomarkers that are part of a signal transduction pathway. The biomarkers included in the panel, in combination, express differently in tumors that respond the drug from those that do not respond. The drugs to which these tests predict response may be designed or determined to target the signal transduction pathway of which the biomarker panel is associated Examples of such drugs are those that target angiogenesis pathways like VEGF or cellular growth pathways like mTOR. Alternatively, the drugs might target something other than the pathway with which the biomarkers are associated but activation of that pathway might otherwise limit or defeat the effectiveness of that drug. Examples of such drugs are those that block cellular receptors but for which activation of downstream signaling pathways nevertheless maintains cellular growth.

AB The present invention relates to a combination therapy comprising selective inhibitors of vascular endothelial growth factor receptor-2 (VEGFR-2) tyrosine kinase and inhibitors of MAP kinase kinase (MEK). Accordingly, a pharmaceutical composition is provided that comprises a selective inhibitor of vascular endothelial growth factor receptor-2 (VEGFR-2) tyrosine kinase or a pharmaceutically acceptable salt, solvate and/or hydrate thereof, and an inhibitor or a pharmaceutically acceptable salt, solvate and/or hydrate thereof, for use in medicine, especially in the treatment of cancer, like lung cancer, such as non-small cell lung cancer, lung adenocarcinoma or small cell lung cancer. Also a method for identifying patients that are particularly susceptible to such a combination therapy is subject of the present invention. The method comprises the evaluation of the expression level of VEGFR-2 and/or VEGF. An increase in said expression level indicates susceptibility to the combination therapy.

AB A review. Cabozantinib (XL184) is an oral multiple receptor tyrosine kinase inhibitor manufactured by Exelixis Inc., CA, USA. It mainly inhibits three tyrosine kinase receptors: MET, VEGFR2 and RET. In both preclin. and clin. studies it has been shown to inhibit tumor angiogenesis, invasiveness and metastases. The most frequent side effects are fatigue, diarrhea, decreased appetite, nausea, weight loss and palmar-plantar erythrodysesthesia. A Phase III clin. trial (EXAM study) of XL184 vs. placebo in advanced and progressive medullary thyroid cancer showed a 28 vs. 0% overall response rate and a progression-free survival of 11.2 vs. 4.0 mo (hazard ratio: 0.28; 95% CI: 0.19-0.40; $p < 0.0001$) in patients treated with cabozantinib and placebo, resp. The drug has been approved by the US FDA for the treatment of advanced/progressive metastatic medullary thyroid cancer in the USA. The EMA is now evaluating its approval in Europe.

After long-term cabozantinib treatment, PDA cells had altered anti- and pro-apoptotic signaling, but still responded to cabozantinib, as apoptosis only slightly decreased and viability only slightly increased suggesting a low resistance-inducing potential of cabozantinib. In parallel, c-Met expression and the pluripotency transcription factor SOX2 were downregulated, which might counteract development of full therapy resistance in long-term treated subclones. In single-treatment studies, cabozantinib increased efficacy of gemcitabine. Most importantly, cabozantinib strongly induced apoptosis and reduced viability in PDA cell lines, which are completely resistant toward gemcitabine. In primary, CSC-enriched spheroidal cultures cabozantinib downregulated CSC markers SOX2, c-Met and CD133 and induced apoptosis. These findings suggest that the clin. use of cabozantinib may be more effective than current chemotherapeutics.

AB Pancreatic ductal adenocarcinoma (PDA) is one of the most lethal malignancies. Cancer stem cells (CSCs), which are not targeted by current therapies, may be the reason for pronounced therapy resistance. A new treatment option in phase II trials is cabozantinib that inhibits the pancreatic CSC surface marker and tyrosine kinase receptor c-Met. The purpose of this study was to evaluate the effect of cabozantinib to stem-like features and therapy resistance. Established PDA cell lines, a gemcitabine-resistant subclone, non-malignant pancreatic ductal cells and primary spheroidal cultures from patient tumors were analyzed by MTT-assay, flow cytometry, colony and spheroid formation assays, western blotting, qRT-PCR, antibody protein array, immunohistochem. and morphol. features. Cabozantinib inhibited viability and spheroid formation and induced apoptosis in malignant cells with minor effects in non-malignant cells.

AB A review. Prostate cancer is the second-leading cause of cancer-related mortality in men in Western societies. Androgen receptor (AR) signaling is a critical survival pathway for prostate cancer cells, and androgen-deprivation therapy (ADT) remains the principal treatment for patients with locally advanced and metastatic disease. Although a majority of patients initially respond to ADT, most will eventually develop castrate resistance, defined as disease progression despite serum testosterone levels of <20 ng/dL. The recent discovery that AR signaling persists during systemic castration via intratumoral production of androgens led to the development of novel anti-androgen therapies including abiraterone acetate and enzalutamide. Although these agents effectively palliate symptoms and prolong life, metastatic castration-resistant prostate cancer remains incurable. An increased understanding of the mechanisms that underlie the pathogenesis of castrate resistance is therefore needed to develop novel therapeutic approaches for this disease. The aim of this review is to summarize the current literature on the biol. and treatment of castrate-resistant prostate cancer.

AB The discovery of RET fusions in lung cancers has uncovered a new therapeutic target for patients whose tumors harbor these changes. In an unselected population of non-small cell lung carcinomas (NSCLCs), RET fusions are present in 1%to2% of cases. This incidence increases substantially, however, in never-smokers with lung adenocarcinomas that lack other known driver oncogenes. Although preclin. data provide exptl. support for the use of RET inhibitors in the treatment of RET fusion-pos. tumors, clin. data on response are lacking. We report preliminary data for the first three patients treated with the RET inhibitor cabozantinib on a prospective phase II trial for patients with RET fusion-pos. NSCLCs (NCT01639508). Confirmed partial responses were observed in 2 patients, including one harboring a novel TRIM33-RET fusion. A third patient with a KIF5B-RET fusion has had prolonged stable disease approaching 8 mo (31 wk). All three patients remain progression-free on treatment.

AB In this article, tumor angiogenesis an attractive target in castration-resistant prostate cancer is studied. Indeed, impressive single-agent activity has been reported with cabozantinib, a small mol. inhibitor of the tyrosine kinases MET and VEGFR2. The author reports on randomly allocated 1050 patients with castration-resistant prostate cancer to treatment with docetaxel plus prednisone with or without bevacizumab-the median overall survival for patients receiving bevacizumab was 22.6 mo compared with 21.5 mo for patients treated with placebo (hazard ratio 0.91, 95% CI 0.78-1.05; stratified log-rank p=0.181).

AB Background: Cabozantinib is an oral MET/VEGFR2 inhibitor. A recent phase II study of cabozantinib (100 mg daily) showed improved bone scans in subjects with metastatic castration-resistant prostate cancer (mCRPC), but adverse events (AE) caused frequent dose redns. This study was designed to determine the efficacy and tolerability of cabozantinib at lower starting doses. Exptl. Design: An adaptive design was used to determine the lowest active daily dose among 60, 40, and 20 mg. The primary endpoint was week 6 bone scan response, defined as ≥30% decrease in bone scan lesion area. The secondary endpoint was change in circulating tumor cells (CTC). Results: Among 11 evaluable subjects enrolled at 40 mg, there were 9 partial responses (PR), 1 complete response, and 1 stable disease (SD). Of 10 subjects subsequently enrolled at 20 mg, there were 1 PR, 5 SDs, and 4 with progressive disease. Among 13 subjects enrolled on the 40 mg expansion cohort, there were 6 PRs and 7 SDs. No subjects required dose reduction or treatment interruption at 6 or 12 wk; 3 subjects at dose level 0 discontinued due to AEs by 12 wk. At 40 mg, median treatment duration was 27 wk. 58% of subjects with ≥5 CTCs/7.5mL at baseline converted to <5. Conclusions: Cabozantinib 40 mg daily was associated with a high rate of bone scan response. Cabozantinib 40 mg daily was associated with better tolerability than previously reported for cabozantinib 100 mg daily. These observations informed the design of phase III studies of cabozantinib in mCRPC. Clin Cancer Res; 19(11); 3088-94. ©2013 AACR.

AB A review. The recommendation of sorafenib as std. of care in advanced hepatocellular carcinoma has lent support to the increased use of antiangiogenic therapies. However, in three phase 3 randomised trials that compared other antiangiogenics with sorafenib, results did not show superiority or non-inferiority of the new therapies. The 10-mo median overall survival shown in these studies for patients given sorafenib might be a ceiling for single-agent antiangiogenic therapy. Strategies to increase survival time include combination therapies that pair antiangiogenic treatment with biol. therapy or chemotherapy. The combination of sorafenib and erlotinib was not superior to sorafenib alone, which suggests no pos. interaction between antiangiogenics and tyrosine kinase inhibitors in the treatment of advanced hepatocellular carcinoma. A combination of sorafenib and doxorubicin is being assessed in a randomised phase 3 trial. Differences in patient outcome with sorafenib because of disease cause and the ethnic origin of patients suggest that sorafenib's multitarget capacity, including RAF kinase inhibition, might be important. MET inhibitors cabozantinib and tivantinib are drugs that might also bypass the so-called antiangiogenic ceiling and have led to selective treatment of patients that overexpress MET with these drugs. Although this intense period of research activity has not yet resulted in significant improvements in survival for patients with advanced hepatocellular carcinoma, we are certainly closer to a customised treatment, which should increase the antiangiogenic survival ceiling.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

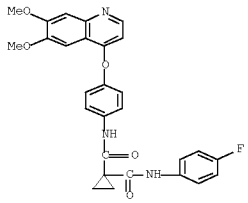
AB A fusion protein including N-terminal domain of a fusion partner at N-terminal and C-terminal domain of RET protein at C-terminal and the gene encoding are identified as diagnostic markers for cancers, especially lung cancers. The somatic mutation forming the chimeric gene was identified in a poorly differentiated lung adenocarcinoma. The adenocarcinoma did not show any of the most common lung cancer-associated mutations, but several discordant reads, indicating transposition events, were identified. Expression of the chimeric KIF5B-RET gene in NIH-3T3 resulted in a neoplastic phenotype. Growth of these cells could be inhibited by the ret kinase inhibitor cabozantinib.



IT 849217-68-1

RL: THU (Therapeutic use); BIOL (Biological study); USES (Uses)

(as inhibitor of ret receptor fusion protein in cancer therapy; fusion proteins with C-terminal domain of gene ret receptor and their use in cancer diagnosis)

AB A review. Until recently, few therapeutic options were available for patients with castration-resistant prostate cancer (CRPC). Since 2010, four new mols. with a demonstrated benefit (sipuleucel-T, cabazitaxel, abiraterone and denosumab) have been approved in this setting and to-date several other agents are under investigation in clin. trials. The purpose of this review is to present an update of targeted therapies for CRPC. Presented data are obtained from literature and congress reports updated until Dec. 2011. Targeted therapies in advanced phases of clin. development include novel androgen signaling inhibitors, inhibitors of alternative signaling pathways, anti-angiogenic agents, inhibitors that target the bone microenvironment and immunotherapeutic agents. Radium-223 and MDV3100 demonstrated a survival advantage in phase III trials and the road for their introduction in clin. practice is rapidly ongoing. Results are also awaited for phase III studies currently underway or planned with new drugs given as monotherapy (TAK-700, cabozantinib, tasquinimod, PROSTVAC-VF, ipilimumab) or in combination with docetaxel (custirsen, aflibercept, dasatinib, zibotentan). The optimal timing, combination and sequencing of emerging therapies remain unknown and require further investigation. Addnl., the identification of novel markers of response and resistance to these therapies may better individualize treatment for patients with CRPC.

AB Purpose of review: Therapeutic options for men with metastatic prostate cancer are expanding. Here we discuss the scientific progress in this disease that led to approval of several agents in the last decade and highlight ongoing clin. investigation. Recent findings: In androgen-sensitive disease, trials are evaluating the role of intermittent androgen-deprivation therapy, early chemotherapy, and novel targeted and hormonal therapies. For chemotherapy-naive, metastatic castration-resistant prostate cancer (mCRPC), abiraterone is effective. Trials with addnl. agents targeting androgen receptor (AR) signaling, such as TAK-700 and enzalutamide, are ongoing. Other agents in development target the endothelin pathway, angiogenesis, AR chaperones, and immune mechanisms. Docetaxel with prednisone remains the standard first-line chemotherapeutic regimen as trials incorporating novel agents with docetaxel have been neg. Postdocetaxel, enzalutamide improves survival. Early results with cabozantinib are encouraging, and phase III studies are ongoing. Denosumab and radium-223 reduce the risk of skeletal-related events (SREs), but only radium-223 improves survival. Summary: Progress in understanding the disease biol. and mechanisms of castration resistance led to significant therapeutic advancements, particularly in the setting of mCRPC in which several phase III trials, each incorporating agents with different mechanisms of action, have improved survival. As a result, new options exist, and the standard of care has changed significantly. Further advances are anticipated.

AB A review. It was first posited in the 1970s that angiogenesis may prove to be a useful target for anticancer therapies. Since then, a number of agents have been developed and tested across a range of tumor types; however, to date, there have unfortunately been more failures than successes. Prostate cancer (PCa) is no exception in this regard, and despite a strong preclin.

rationale for targeting angiogenesis in men with PCa, there has yet to be an antiangiogenic therapy proven to prolong survival in this group of patients. Drugs have been developed to target a host of angiogenesis mediators. These include vascular endothelial growth factor (VEGF), the VEGF receptors, antiangiogenic factors (e.g., thrombospondin-1), and downstream mediators of angiogenesis (e.g., hypoxia-inducible factor-1α and MET). At present, there are 2 drugs being tested in the phase III setting for men with PCa: cabozantinib and tasquinimod. Cabozantinib, a dual VEGF receptor-2/MET inhibitor, has shown dramatic beneficial effects on radiog. evident bone metastases and pain in the phase II setting. There are currently 2 large phase III trials underway to further investigate cabozantinib's role in treating men with PCa. Both trials randomize subjects to cabozantinib vs. mitoxantrone: one is designed to evaluate overall survival, and the other, pain response durability. The other drug, tasquinimod, has a somewhat poorly understood mechanism of action. It is thought to exert an antiangiogenic effect through the inhibition of myeloid-derived suppressor cells, key to the support of an angiogenic environment, and down-regulation of hypoxia-inducible factor-1α. A phase II trial randomizing men to tasquinimod vs. placebo revealed a median progression-free survival advantage in the exptl. arm (7.6 vs. 3.3 mo with placebo; P = 0.0042). Based on these encouraging phase II results, a randomized, double-blind, placebo-controlled trial in men with metastatic castration-resistant PCa was launched. That trial is powered for a primary endpoint of progression-free survival and is expected to enroll 1200 men.

AB A review. Effective management of bone metastases in men with castration-resistant prostate cancer (CRPC) remains an important unmet medical need. MET and vascular endothelial growth factor receptor (VEGFR) are rational targets for intervention in CRPC. Clin. trials involving agents that inhibit one but not both pathways have reported modest activity and no improvement in overall survival. Cabozantinib is an oral multitargeted tyrosine kinase inhibitor that inhibits both MET and VEGFR-2. A phase II randomized discontinuation study involving subjects with CRPC demonstrated that cabozantinib therapy is associated with improvement in bone scans, bone turnover markers, and pain response, but with significant adverse events leading to dose reduction and treatment discontinuation. Lower doses of cabozantinib retain high levels of activity with less toxicity. Ongoing phase III clin. trials will define the role of cabozantinib in CRPC. We summarize the rationale for targeting MET and VEGFR pathways in CRPC and the clin. data available to date.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The invention provides combination therapies for treating a pathol. condition, such as cancer, wherein a c-met antagonist (e.g. crizotinib, tivantinib, anti-HGF antibody, onartuzumab) is combined with a B-raf antagonist (e.g. vemurafenib), thereby providing significant antitumor activity. C-met expression was inversely correlated with sensitivity to vemurafenib treatment. In one aspect, provided are methods for treating a cancer patient who has increased likelihood of developing resistance to B-raf antagonist comprising administering an effective amount (in combination) of B-raf antagonist and c-met antagonist. In addition, patients with B-raf mutant melanoma who had higher levels of circulating hepatocyte growth factor (HGF) showed substantially reduced progression free survival and overall survival when treated with B-raf antagonist, relative to patients with lower circulating HGF levels treated with B-raf antagonist.

AB A review. Introduction: Conventional treatment modalities for thyroid cancer lead to complete remission in only one-third of patients with distant metastases. On the other hand, medullary thyroid cancer (MTC) and anaplastic thyroid cancer (ATC), although rare, are responsible for a significant percentage of thyroid cancer-related deaths. New treatments are needed to treat such patientsAreas covered: The aim of this review is to provide the latest information on , a new tyrosine kinase inhibitor (TKI) that is currently used mainly as a treatment of MTC. The authors collated data that were retrieved from a PubMed literature search.Expert opinion: CBZ targets multiple cell-signaling pathways involved in the mol. pathogenesis of thyroid cancer. These are namely VEGF receptor-2, hepatocyte growth factor receptor and rearranged during transfection receptor. Furthermore, it is a drug which may be used in cases where conventional therapies (mainly for MTC) are proved ineffective or have shown poor results with a good outcome. CBZ may also be administered alone or in combination with other drugs of the same family.

AB Anti-angiogenic treatment of glioblastoma with Vascular Endothelial Growth Factor (VEGF)- or VEGF Receptor 2 (VEGFR2) inhibitors normalizes tumor vessels, resulting in a profound radiol. response and improved quality of life. This approach however does not halt tumor progression by diffuse infiltration, as this phenotype is less angiogenesis dependent. Combined inhibition of angiogenesis and diffuse infiltrative growth would therefore be a more effective treatment approach in these tumors. The HGF/c-MET axis is important in both angiogenesis and cell migration in several tumor types including glioma. We therefore analyzed the effects of the c-MET- and VEGFR2 tyrosine kinase inhibitor cabozantinib (XL184, Exelixis) on c-MET pos. orthotopic E98 glioblastoma xenografts, which routinely present with angiogenesis-dependent areas of tumor growth, as well as diffuse infiltrative growth. In in vitro cultures of E98 cells, cabozantinib effectively inhibited c-MET phosphorylation, concomitant with inhibitory effects on AKT and ERK1/2 phosphorylation, and cell proliferation and migration. VEGFR2 activation in endothelial cells was also effectively inhibited in vitro. Treatment of BALB/c nu/nu mice carrying orthotopic E98 xenografts resulted in a significant increase in overall survival. Cabozantinib effectively inhibited angiogenesis, resulting in increased hypoxia in angiogenesis-dependent tumor areas, and induced vessel normalization. Yet, tumors ultimately escaped cabozantinib therapy by diffuse infiltrative outgrowth via vessel co-option. Of importance, in contrast to the results from in vitro expts., in vivo blockade of c-MET activation was incomplete, possibly due to multiple factors including restoration of the blood-brain barrier resulting from cabozantinib-induced VEGFR2 inhibition. In conclusion, cabozantinib is a promising therapy for c-MET pos. glioma, but improving delivery of the drug to the tumor and/or the surrounding tissue may be needed for full activity.

AB A review. Parafollicular C-cell-derived medullary thyroid cancer (MTC) comprises 3% to 4% of all thyroid cancers. While cytotoxic treatments have been shown to have limited efficacy, targeted mol. therapies that inhibit rearranged during transfection (RET) and other tyrosine kinase receptors that are mainly involved in angiogenesis have shown great promise in the treatment of metastatic or locally advanced MTC. Multi-tyrosine kinase inhibitors such as vandetanib, which is already approved for the treatment of progressive MTC, and cabozantinib have shown distinct advantages with regard to rates of disease response and control. However, these types of tyrosine kinase inhibitor compds. are able to concurrently block several types of targets, which limits the understanding of RET as a specific target. Moreover, important resistances to tyrosine kinase inhibitors can occur, which limit the long-term efficacy of these treatments. Deregulated cellular signaling pathways and genetic alterations in MTC, particularly the activationof the RAS/mammalian target of rapamycin (mTOR) cascades and RET crosstalk signaling, are now emerging as novel and potentially promising therapeutic treatments for aggressive MTC.

AB A review. Cabozantinib/XL184 (Exelexis, Inc.) has demonstrated remarkable responses in kidney cancer. Preclin. results revealed VEGF, KIT and MET inhibition in a variety of solid tumors such as thyroid, ovarian, renal, lung, liver and prostate cancers. A phase II trial demonstrated efficacy in renal cancer with a 28 % objective response rate, stable disease rate of 62 % and median progression free survival of 14.7 mo. Predominant toxicities of fatigue and diarrhea were noted. Dramatic responses in bone metastases (three of four patients) make the agent especially valuable for palliation in a disease, where presence of bone metastases is a predictor of worse survival. Cabozantinib is an emerging novel agent with promising activity in advanced kidney cancer. Randomized trials are planned in comparison with standard VEGF inhibitor therapy. Defining the role of MET overexpression would help patient selection and enrich and enhance the future evaluation of this targeted novel agent.

AB A review. Mutation detection in samples from thyroid cancer with the addition of BRAF mutation, and also the detection of RAS, RET/PTC, and PAX8/PPARγ mutations, may also contribute to cancer diagnosis. On the other hand, the MAPK/ERK (mitogen-activated protein kinase/extracellular signal-regulated kinase signaling pathway) and PI3K/Akt (lipid kinase phoshoinositid-3-kinase signaling pathway) play an important role in the transmission of cell signals. The genes, coding the signaling cascade proteins (RET, RAS, BRAF, PI3K, PTEN, AKT), are mutated or aberrantly expressed in thyroid cancer derived from follicular thyroid cells. Genetic and epigenetic alternations, concerning MAPK/ERK and PI3K/Akt signaling pathways, contribute to their activation and interaction as a consequence of malignant follicular cell transformation. The understanding of this mol. mechanism provides access to novel mol. prognostic and therapeutic strategies for inhibiting the oncogenic activity of the signaling pathways. This ability to investigate tumor biol. allows for the selection of different drugs. Nowadays the most relevant are treatments directed to tyrosine kinase receptors that bind for a wide variety of ligands and are frequently mutated and induce a constitutive activation such that a chimerical protein expression takes place in follicular cells in the domain of RET, as well as in other receptors. Many mols. such as: motesanib, sorafenib, vandetanib, sunitinib, XL-184, imatinib, axitinib, pazopanib, lenvatinib, combretastatin, gefitinib, cetuximab, bortezomib and thiazoldonedione have been developed. Some of them also can act in receptors of vascular endothelial growth factor and epidermal growth factor receptors. Information obtained through cytol. or biopsy samples permits the study of complex metabolic or genetic pathways, thus providing researchers with a high throughput tool for elucidating changes in the global expression patterns seen in tumor cells and allowing for different therapeutic strategies in thyroid cancer which take into account the predominant altered pathways observed in these samples.

AB Purpose: Cabozantinib (XL 184) is an orally bioavailable tyrosine kinase inhibitor with activity against MET and vascular endothelial growth factor receptor 2. We evaluated the activity of cabozantinib in patients with castration-resistant prostate cancer (CRPC) in a phase II randomized discontinuation trial with an expansion cohort. Patients and Methods: Patients received 100 mg of cabozantinib daily. Those with stable disease per RECIST at 12 wk were randomly assigned to cabozantinib or placebo. Primary end points were objective response rate at 12 wk and progression-free survival (PFS) after random assignment. Results: One hundred seventy-one men with CRPC were enrolled. Random assignment was halted early based on the observed activity of cabozantinib. Seventy-two percent of patients had regression in soft tissue lesions, whereas 68% of evaluable patients had improvement on bone scan, including complete resolution in 12%. The objective response rate at 12 wk was 5%, with stable disease in 75% of patients. Thirty-one patients with stable disease at week 12 were randomly assigned. Median PFS was 23.9 wk (95% CI, 10.7 to 62.4 wk) with cabozantinib and 5.9 wk (95% CI, 5.4 to 6.6 wk) with placebo (hazard ratio, 0.12; P < .001). Serum total alkaline phosphatase and plasma cross-linked C-terminal telopeptide of type I collagen were reduced by ≥ 50% in 57% of evaluable patients. On retrospective review, bone pain improved in 67% of evaluable patients, with a decrease in narcotic use in 56%. The most common grade 3 adverse events were fatigue (16%), hypertension (12%), and hand-foot syndrome (8%). Conclusion: Cabozantinib has clin. activity in men with CRPC, including reduction of soft tissue lesions, improvement in PFS, resolution of bone scans, and redns. in bone turnover markers, pain, and narcotic use.

AB A review. The research of Smith et al. (2013) entitled, 'Cabozantinib in patients with advanced prostate cancer: Results of a phase II randomized discontinuation trial' is reviewed with commentary and refs. The authors presented data on a novel orally bioavailable tyrosine kinase inhibitor (TKI), cabozantinib, with activity against multiple targets including

mesenchymal-epithelial transition factor (MET), also known as hepatocyte growth factor receptor, and the vascular endothelial growth factor receptor 2 (VEGFR2). They reported a reduction in uptake on bone scan with improvement in 68% of men (79 of 116) with bone metastasis and complete resolution in 14 patients.

AB A review. Medullary thyroid cancer is an uncommon malignancy for which until recently little effective treatment existed. It is often characterized by mutation and overexpression of the receptor tyrosine kinases RET (rearranged during transfection), VEGFR2 (vascular endothelial growth factor receptor 2) and MET (mesenchymal-epithelial transition factor), which make attractive targets for drug development. Cabozantinib is an orally bioavailable tyrosine kinase inhibitor which blocks MET, VEGRF2 and RET, and has shown considerable activity in medullary thyroid cancer in a Phase III trial, including in heavily pretreated patients. Its novel combination of vascular endothelial growth factor and MET inhibition is believed to address the MET escape pathway, which is thought to be the cause of nonsustained tumor responses resulting from inhibition of vascular endothelial growth factor alone.

AB A review. Discoveries of mol. mechanisms and therapeutic targets in metastatic castration-resistant prostate cancer (CRPC) have led to significant advancements in the development of effective agents in this setting, with diverse mechanisms of action. Within the past 2 years, 5 agents have been approved for the treatment of patients with metastatic CRPC (cabazitaxel, abiraterone, sipuleucel-T, denosumab, and enzalutamide), and another (Alpharadin) has shown overall survival benefit in a phase III trial.

This article summarizes the phase III data showing clin. benefit from these agents, highlights other promising therapies in phase III studies as single agents (PROSTVAC-VF, ipilimumab, cabozantinib), discusses important unanswered questions regarding these therapies, and provides a schema for their use based on current regulatory approval and how this is likely to evolve as data from ongoing studies are reported. Although curative interventions in metastatic CRPC still do not exist, the hope is that optimization of therapeutic strategies can reduce the morbidity and mortality associated with this disease.

AB A review. Introduction Patients with advanced medullary thyroid cancer (MTC) have poor prognoses and limited treatment options. Improved knowledge about mol. aberrations associated with MTC and the availability of novel targeted tyrosine kinase inhibitors (TKIs) have led to new potential treatment modalities. Cabozantinib is an oral multitargeted TKI with activity against multiple receptors including RET, vascular endothelial growth factor receptor type 2 (VEGFR2), and MET that has been evaluated in MTC in the preclin. and clin. arenas. Methods This article reviews unmet clin. needs in advanced MTC. The authors consider novel agents that have been studied in MTC, with a focus on the investigational agent cabozantinib. Up-to-date clin. data of cabozantinib in MTC are discussed. Results Recent clin. evaluation suggests that cabozantinib is the first agent to prolong progression-free survival in patients with progressive MTC. These findings indicate that cabozantinib may be an effective therapy in advanced MTC. No improvement in overall survival has been demonstrated but data are not mature. Conclusion Cabozantinib may be an effective treatment option for patients with advanced MTC and is worthy of further evaluation.

AB A review. Castrate-resistant prostate cancer (CRPC) occurs when disease progresses in the presence of castrate levels of androgens and remains sensitive to further hormonal manipulation. For many years the treatment of CRPC was limited to the use of docetaxel for metastatic disease. However, this has recently changed with the approval of several new agents. Sipuleucel-T, an immunotherapeutic vaccine, is now available in the US for patients with non-metastatic CRPC and abiraterone, an oral enzyme inhibitor of androgen biosynthesis, as well as cabazitaxel, a cytotoxic chemotherapeutic, have been approved for the treatment of metastatic CRPC. Also, denosumab, a s.c. antibody, is now an option for the treatment of patients with CRPC with bone metastases, in addition to zoledronic acid, an i.v. bisphosphonate. Further treatment advances for metastatic CRPC therapeutics are in late stage phase III development. These include therapies affecting the androgen receptor (MDV3100) as well as addnl. immune-based therapeutics, PROSTVAC and ipilimumab. A broad range of agents is also emerging under the term targeted therapies. The endothelin-A receptor antagonist zibotentan, the tyrosine kinase inhibitors dasatinib, sorafenib and cabozantinib, the anti-angiogenic agent aflibercept, and the clusterin inhibitor custirsen, are all currently being tested for efficacy in metastatic CRPC. The mechanism of action of these and other promising agents are discussed alongside current therapeutic options and their potential place in the treatment landscape for CRPC is considered.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB The present invention provides assays and methods for predicting the post-operative survival of a subject having an early stage gastric cancer after tumor surgery. The present invention also provides methods for treating a subject having an early stage gastric cancer by administering a combination therapy tailored to the signal transduction biomarkers that are activated in the cancer. In particular embodiments, the methods of the invention rely on the detection of the activation state or level of a specific combination of signal transducer analytes in a cancer cell obtained from the subject. Thus, the methods of the invention are particularly useful for predicting the survival or prognosis of a subject having an early stage gastric cancer and for guiding both pre- and post-operative treatment decisions by identifying subjects who would benefit from combination therapy as opposed to monotherapy.

AB The present invention provides novel substituted quinoline compds. I [R1, R2 = H, alkoxy, hydroxyalkoxy; R3 = H, F; R4 = H, F, Cl, Br, I, etc.; X = CH or N, wherein at least one of R1 and R2 = hydroxyalkoxy], pharmaceutical acceptable salts and formulations thereof useful in modulating the protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. Syntheses of exemplified compds. I were described. E.g., a multi-step synthesis of the pyrazolecarboxamide II, starting from 3-benzyloxybenzenamine, was provided. Exemplified compds. I were tested for their efficacy as inhibitors of receptor tyrosine kinases such as c-Met, VEGFR and Axl, and as antitumor agents (data given). The invention also provides pharmaceutically acceptable compns. comprising compds. I and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The invention provides methods for detecting cancer, for detg. whether a cancer is responding to treatment, and /or for determining whether a cancer is likely to respond to treatment that involve detecting of circulating biomarkers. The invention relates that said circulating biomarkers can includie nucleic acids, proteins, vesicles and/or microRNAs. The invention also relates that said biol. samples used in the disclosed methods include isolated extracellular microvesicle populations. The invention also provides kits comprising all reagents used in the disclosed methods. In the examples, the invention disclosed that specific biomarkers are elevated in specific types of cancer, which can used in diagnosis and in determining treatments.

AB The invention is directed to processes for prepg. quinoline compds. of formula I wherein X1 is H, Br, Cl and F; X2 is H, Br, Cl and F; n is 1-2 and m is 1-2; and pharmaceutically acceptable salts thereof. Example compound II L-malate was prepared by chlorination of 6,7-dimethoxyquinolin-4-ol followed by etherification of 4-chloro-6,7-dimethoxyquinoline with 4-aminophenol; the resulting 4-(6,7-dimethoxyquinolin-4-yloxy)phenylamine underwent acylation with 1-[(4-fluorophenyl)carbamoyl]cyclopropanecarbonyl chloride to give compound II, which underwent addition of L-malic acid to give the desired product.

AB Specific peptides, and derived ionization characteristics of those peptides, from the Bcl-2-like protein 11 (BIM) are provided that are particularly advantageous for quantifying the BIM protein directly in biol. samples that have been fixed in formalin by the method of Selected Reaction Monitoring (SRM) mass spectrometry, or what can also be termed as Multiple Reaction Monitoring (MRM). Such biol. samples are chemical preserved and fixed where the biol. sample is selected from tissues and cells treated with formaldehyde containing agents/fixatives including formalin-fixed tissue/cells, formalin- fixed/paraffin embedded (FFPE) tissue/cells, FFPE tissue blocks and cells from those blocks, and tissue culture cells that have been formalin fixed and or paraffin embedded. A protein sample is prepared from the biol. sample using the Liquid Tissue reagents and protocol, and the BIM protein is quantitated in the Liquid Tissue sample by the method of SRM/MRM mass spectrometry by quantitating in the protein sample at least one or more of the peptides described. These peptides can be quantitated if they reside in a modified or an unmodified form. An example of a modified form of a BIM peptide is phosphorylation of a tyrosine, threonine, serine, and/or other amino acid residues within the peptide sequence. Samples were prepared with Liquid Tissue and digested with trypsin. Three peptides from BIM were found to be suitable for SRM/MRM assay.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The present invention provides methods for selecting a suitable anticancer drug therapy, and for identifying and predicting response, for the treatment of a malignant cancer involving aberrant c-Met signaling. The present invention also provides methods for monitoring the status of a malignant cancer involving aberrant c-Met signaling and monitoring how a patient with the malignant cancer is responding to anticancer drug therapy. Information on the expression and/or activation states of components of signal transduction pathways (e.g., HER3 and/or c-Met signal transduction pathway components) derived from practice of the present invention can be used for malignant cancer diagnosis, prognosis, and in the design of cancer treatments for malignancies involving aberrant c-Met signaling. Certain embodiments comprise administering a cMet inhibitor alone or a cMet inhibitor in combination with a pathway-directed therapy based upon the differences

AB The present invention relates to metastases. More specifically, the invention relates to compns. and methods for the inhibition of metastases of cancer cells, such as prostate cancer cells, to bones and soft tissue. The present invention also relates to the treatment of cancer, including but not limited to prostate cancer. Also provided are animal models for studying cancer metastasis; particularly, prostate cancer metastasis.

AB Purpose of review: This review will focus on the recent advances in mol. pathogenesis and targeted therapies for medullary thyroid carcinoma (MTC). Unlike hereditary MTC in which rearranged during transfection (RET) mutations are the most important precipitating events, in sporadic MTC the genetic or mol. biomarkers are yet to be established. Recent findings: Targeted mol. therapies that inhibit RET and other tyrosine kinase receptors involved in angiogenesis have shown great promise in the treatment of metastatic or locally advanced MTC and are under investigation. In addition, the recent findings of H-RAS mutations in 56% of RET-neg. sporadic MTC and the activation of the mammalian target of rapamycin (mTOR) intracellular signaling pathway in hereditary MTC suggests that addnl. or alternative genetic events are important for MTC pathogenesis. Summary: Recently, vandetanib (ZD6474), an inhibitor of vascular endothelial growth factor receptor (VEGFR) 2 and VEGFR 3, RET, and epidermal growth factor receptor (EGFR), was approved for the treatment of adults with symptomatic or progressive MTC. Significant advantages for vandetanib over placebo were seen in terms of response rate, disease control rate, and biochem. response in a phase III study. Furthermore, cabozantinib (XL184), an inhibitor of VEGFR 1 and VEGFR 2, hepatocyte growth factor receptor (MET), and RET, was associated with partial response and stable disease in 29 and 41%, resp.

AB A review. Improved understanding of mechanisms underlying metastatic castration-resistant prostate cancer (mCRPC) progression has led to the recognition of multiple mol. targets and advances in the therapeutic landscape. The addition of abiraterone acetate, sipuleucel-T, cabazitaxel, and denosumab to the therapeutic armamentarium and the impending addition of MDV-3100 and radium-223 underscore the importance of androgen pathway inhibition, immunotherapy, tubulin antagonism, and pathophysiol. of bone metastasis. Review the next generation of mol. targets in mCRPC. Medline databases were searched for >100 original articles published as of Oct. 18, 2011, with the search terms metastatic castration-resistant prostate cancer, targeted therapy, biol. agents, and immunotherapy. Proceedings from the last 5 yr of conferences of the American Society of Clin. Oncol., American Urol. Association, European Society of Medical Oncol., and the European Association of Urol. were also searched. We included novel and promising drugs that have reached clin. trial evaluation. The major findings were addressed in an evidence-based fashion. Prospective trials and important preclin. data were analyzed.mCRPC is a disease with multiple mol. drivers. Mol. pathways being targeted in ongoing phase 3 trials are androgen signaling (MDV3100, TAK700), immunoregulatory pathways (ipilimumab, Prostvac-VF-TRICOM), Src (dasatinib), Met (cabozantinib), clusterin (custirsen), and angiogenesis (aflibercept, tasquinimod). The strides made in identifying multiple other novel mol. targets offer potential opportunities for further improving outcomes.

AB A review. XL-184 (cabozantinib) is a novel, small-mol., multi-targeted receptor tyrosine kinase inhibitor with particular activity against hepatocyte growth factor receptor (tyrosine-protein kinase Met), vascular endothelial growth factor receptor 2 (VEGFR-2) and proto-oncogene tyrosine-protein kinase receptor Ret. There is ample evidence of Met, VEGFR-2 and Ret signaling in several tumor types. Preclin. data suggest that XL-184 has activity in tumors derived from both epithelial and mesenchymal origins. Phase I and II clin. studies support significant antitumor activity, particularly in medullary thyroid cancer and cancers metastatic to the bone. This review will evaluate XL-184's preclin. pharmacol., pharmacokinetics, drug interactions and clin. activity in phase I through phase III studies.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The authors disclose the use of c-met as a biomarker for patient selection and patient prognosis in cancer. In a clin. trial, combination treatment with MetMAb (onartuzumab) and erlotinib provided a clin. meaningful benefit to patients with non-small cell lung cancer (NSCLC) that expressed high levels of c-met biomarker. The results showed that the efficacy, as evaluated by progression free survival (PFS) and overall survival (OS), was pos. especially when compared to PFS and OS data for erlotinib treatment alone. The addition of MetMAb to erlotinib nearly doubled the progression free and overall survival in patients with NSCLC that expressed high levels of c-met biomarker. The clin. trial data also showed that treatment with MetMAb in combination with erlotinib increased the risk of progression and death in patients with NSCLC that expressed low levels of c-met biomarker.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Biomarkers can be assessed for diagnostic, therapy-related or prognostic methods to identify phenotypes, such as a condition or disease, or the stage or progression of a disease. Circulating biomarkers from a bodily fluid can be used in profiling of physiol. states or determining phenotypes. These include nucleic acids, protein, and circulating structures such as vesicles. Biomarkers can be used for theranostic purposes to select candidate treatment regimens for diseases, conditions, disease stages, and stages of a condition, and can also be used to determine treatment efficacy. The biomarkers can be circulating biomarkers, including vesicles and microRNA. Various anti-DLL4 antibodies were tethered to beads and used to capture vesicles in blood samples from subjects with breast cancer, colorectal cancer or normal subjects. The bead captured vesicles were detected with fluorescently-labeled antibodies against the tetraspanins CD9, CD63, and CD81. The median fluorescence intensity of the captured and labeled vesicles was measured using laser detection. There were noticeable differences both among normals and breast cancer plasma as well as between the avs. of normals and cancer patients.

AB A review. Epidermal growth factor receptor (EGFR) is a validated target in different human malignancies. EGFR tyrosine kinase inhibitors (TKIs) are known to contribute considerably to the extension of progression-free survival in EGFR-mutant non-small cell lung cancer and monoclonal antibodies (mAbs) targeting EGFR have also improved the efficacy outcomes in KRAS wild-type colorectal cancer. Nevertheless, a significant percentage of lung and colorectal cancer patients do not respond to anti-EGFR agents and secondary resistance after initial benefit is a challenging reality faced by clinicians. Extensive preclin. work on the potential mechanisms of resistance to EGFR inhibitors in different disease settings has guided the development of second-generation irreversible EGFR TKIs, more efficient anti-EGFR mAbs, and combination strategies with agents targeting other receptors and downstream effectors. In order to elucidate the role of the multiple therapeutic strategies under investigation to overcome EGFR inhibitors-resistance, rational drug development based on stringent preclin. data, biomarker validation and proper selection of patients in the ongoing clin. trials are of paramount importance. Preliminary results of clin. trials evaluating these approaches will be discussed in this manuscript, with emphasis on TKIs in lung cancer and mAbs in advanced colorectal cancer.

AB A review. The hepatocyte growth factor/mesenchymal-epithelial transition factor (HGF/c-MET) receptor tyrosine kinase (RTK) pathway plays a pleotropic role in cell proliferation, migration, invasion, angiogenesis and survival. Although it has critical physiol. functions in embryonic development and tissue repair, this signaling cascade is frequently deregulated in a wide range of tumors. Aberrant HGF/c-MET signaling, driven by various mechanisms, including constitutive activation and over-expression, has multifunctional effects in oncogenesis and is implicated in the acquisition of an aggressive phenotype with metastatic potential. The central role of c-MET activity in cancer progression, as well as disparities between quiescent HGF/c-MET signaling in normal tissue and overexpression in tumor may provide a degree of tumor selectivity for therapeutic intervention, making HGF or c-MET inhibition an attractive proposition in oncol. This review focuses on the underlying oncogenic role of aberrant HGF/c-MET signaling in malignant progression, as well as recent preclin. and clin. data on the different strategies employed in inhibiting HGF/c-MET function.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB Administration of a hypoxia activated prodrug in combination with an antiangiogenic agent is useful for treating cancer. Hypoxia activated prodrug is selected from the group consisting of TH-281, TH-302, and TH-308. The antiangiogenic agent is selected from the group consisting of an anti-VEGF antibody, a VEGF-trap, an anti-VEGFR antibody, a VEGFR inhibitor, thalidomide etc.

AB A review. The c-MET (mesenchymal-epithelial transition factor) pathway is dysregulated in many human cancers and promotes tumor growth, invasion and dissemination. The c-MET receptor tyrosine kinase can be activated via gene mutation, gene amplification, protein overexpression and/or a Ligand-dependent autocrine/paracrine loop. Abnormalities in c-MET signaling have been reported to correlate with poor clin. outcomes and drug resistance in patients with cancer. Significant progress has been made in advancement of c-MET pathway inhibitors through to clin. trials. A robust pipeline of high-quality inhibitors targeting different aspects of c-MET activation is currently being explored in phase I, II and III clin. trials across multiple tumor types. Preliminary data demonstrate promising clin. activity with these agents, along with an acceptable toxicity profile. In this manuscript, the pharmacol. profile of drugs targeting the c-MET pathway and available data from ongoing clin. trials of these drugs are discussed.

AB The signaling pathway of the receptor tyrosine kinase MET and its ligand hepatocyte growth factor (HGF) is important for cell growth, survival, and motility and is functionally linked to the signaling pathway of VEGF, which is widely recognized as a key effector in angiogenesis and cancer progression. Dysregulation of the MET/VEGF axis is found in a number of human malignancies and has been associated with tumorigenesis. Cabozantinib (XL184) is a small-mol. kinase inhibitor with potent activity toward MET and VEGF receptor 2 (VEGFR2), as well as a number of other receptor tyrosine kinases that have also been implicated in tumor pathobiol., including RET, KIT, AXL, and FLT3. Treatment with cabozantinib inhibited MET and VEGFR2 phosphorylation in vitro and in tumor models in vivo and led to significant redns. in cell invasion in vitro. In mouse models, cabozantinib dramatically altered tumor pathol., resulting in decreased tumor and endothelial cell proliferation coupled with increased apoptosis and dose-dependent inhibition of tumor growth in breast, lung, and glioma tumor models. Importantly, treatment with cabozantinib did not increase lung tumor burden in an exptl. model of metastasis, which has been observed with inhibitors of VEGF signaling that do not target MET. Collectively, these data suggest that cabozantinib is a promising agent for inhibiting tumor angiogenesis and metastasis in cancers with dysregulated MET and VEGFR signaling. Mol Cancer Ther; 10(12); 2298-308.

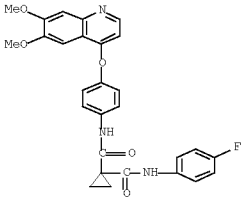
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB Methods of delivering cytosine deaminase variants for prodrug activation using retroviral expression vectors are described. The vector includes the viral gag, pol, and env genes with the cytosine deaminase gene being coexpressed using an internal ribosome entry site. Vectors were derived from the prior art pACE-GFPemd vector. The envelope protein of the virus is amphotropic and excess viral sequences outside the long terminal repeats were removed. The resulting vector was named pACE-emdGFP. The vector was stable in storage and replicated efficiently in mammalian cells and could be used to deliver a range of therapeutic genes. The Saccharomyces cerevisiae cytosine deaminase gene was modified to give a codon usage suitable for mammalian cells and to improve thermostability of the enzyme. Use of these vectors results in high intracellular copy nos. for the therapeutic gene and these cells can be superinfected by the vector.

IT 1140909-48-3

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Biomarkers can be assessed for diagnostic, therapy-related or prognostic methods to identify phenotypes, such as a condition or disease, or the stage or progression of a disease. Circulating biomarkers from a bodily fluid can be used in profiling of physiol. states or determining phenotypes. These include nucleic acids, protein, and circulating structures such as vesicles. Biomarkers can be used for theranostic purposes to select candidate treatment regimens for diseases, conditions, disease stages, and stages of a condition, and can also be used to determine treatment efficacy. The biomarkers can be circulating biomarkers, including microvesicles and their protein content and microRNAs.

AB A review. Systemic chemotherapies for advanced or metastatic thyroid carcinomas have been of only limited effectiveness. For patients with differentiated thyroid epithelial or medullary thyroid carcinomas unresponsive to conventional treatments, novel therapies are needed to improve disease outcomes. Multiple novel therapies primarily targeting angiogenesis have entered clin. trials for metastatic thyroid carcinoma. Partial response rates up to 30% have been reported in single agent studies, but prolonged disease stabilization is more commonly seen. The most successful agents target the vascular endothelial growth factor receptors, with potential targets including the mutant kinases associated with papillary and medullary oncogenesis. Two drugs approved for other malignancies, sorafenib and sunitinib, have had promising preliminary results reported, and are being used selectively for patients who do not qualify for clin. trials. Addnl. agents targeting tumor vasculature, nuclear receptors, epigenetic abnormalities, and the immune response to neoplasia have also been investigated. Randomized trials for several agents are under way that may lead to eventual drug approval for thyroid cancer. Treatment for patients with metastatic or advanced thyroid carcinoma now emphasizes clin. trial opportunities for novel agents with considerable promise. Alternative options now exist for use of these mol. targeted therapies, especially tyrosine kinase inhibitors, which are well tolerated and may prove worthy of regulatory approval for this disease.

LANGUAGE: English
AB Purpose: XL184 (cabozantinib) is a potent inhibitor of MET, vascular endothelial growth factor receptor 2 (VEGFR2), and RET, with robust antiangiogenic, antitumor, and anti-invasive effects in preclin. models. Early observations of clin. benefit in a phase I study of cabozantinib, which included patients with medullary thyroid cancer (MTC), led to expansion of an MTC-enriched cohort, which is the focus of this article. Patients and Methods: A phase I dose-escalation study of oral cabozantinib was conducted in patients with advanced solid tumors. Primary end points included evaluation of safety, pharmacokinetics, and maximum-tolerated dose (MTD) determination Addnl. end points included RECIST (Response Evaluation Criteria in Solid Tumors) response, pharmacodynamics, RET mutational status, and biomarker analyses. Results: Eighty-five patients were enrolled, including 37 with MTC. The MTD was 175 mg daily. Dose-limiting toxicities were grade 3 palmar plantar erythrodysesthesia (PPE), mucositis, and AST, ALT, and lipase elevations and grade 2 mucositis that resulted in dose interruption and reduction Ten (29%) of 35 patients with MTC with measurable disease had a confirmed partial response. Overall, 18 patients experienced tumor shrinkage of 30% or more, including 17 (49%) of 35 patients with MTC with measurable disease. Addnl., 15 (41%) of 37 patients with MTC had stable disease (SD) for at least 6 mo, resulting in SD for 6 mo or longer or confirmed partial response in 68% of patients with MTC. Conclusion: Cabozantinib has an acceptable safety profile and is active in MTC. Cabozantinib may provide clin. benefit by simultaneously targeting multiple pathways of importance in MTC, including MET, VEGFR2, and RET. A global phase III pivotal study in MTC is ongoing (ClinicalTrials.gov number NCT00215605).

DOCUMENT TYPE: Journal
LANGUAGE: English
AB Medullary and papillary thyroid carcinoma (MTC and PTC) are 2 types of thyroid cancer that can originate from activating mutations or rearrangements in the RET gene. Therapeutic options are limited in recurrent disease, but because RET is a tyrosine kinase (TK) receptor involved in cellular growth and proliferation, treatment with a TK inhibitor might be promising. Several TK inhibitors were tested in clin. trials, but it is unknown which inhibitor is most effective and whether there is any specificity for particular RET mutations. We aimed to compare the effect of 4 TK inhibitors (axitinib, sunitinib, vandetanib, and XL184) on cell proliferation, RET expression and autophosphorylation, and ERK activation in cell lines expressing a MEN2A (MTC-TT), a MEN2B (MZ-CRC-1) mutation, and a RET/PTC (TPC-1) rearrangement. The 3 cell lines were cultured and treated with the 4 TK inhibitors. Effects on cell proliferation and RET and ERK expression and activation were determined XL184 and vandetanib most effectively inhibited cell proliferation, RET autophosphorylation in combination with a reduction of RET expression, and ERK phosphorylation in MTC-TT and MZ-CRC-1, resp. TPC-1 cells showed a decrease in RET autophosphorylation after treatment with XL184, but no effect was observed on ERK activation. There is indeed specificity for different RET mutations, with XL184 being the most potent inhibitor in MEN2A and PTC and vandetanib the most effective in MEN2B in vitro. No TK inhibitor was superior for all the cell lines tested, indicating that mutation-specific therapies could be beneficial in treating MTC and PTC.

DOCUMENT TYPE: Journal; General Review
LANGUAGE: English
AB Purpose of review: This review highlights recent therapeutic advances in systemic therapies for prostate cancer (PCa). Recent findings: Progress in PCa therapeutics has been made during the past year with the approval of a vaccine therapy, second-line chemotherapy, and reported survival advantage for a CYP (17,20) lyase inhibitor in castration-resistant prostate cancer (CRPC). This report will summarize the recently reported and expected data for PCa trials including an evaluation of intermittent vs. continuous androgen deprivation therapy. Denosumab is shown to support bone mineral d. in hormonal sensitive PCa patients. Targeting of androgen-dependent pathways in CRPC postchemotherapy has been shown to improve survival with the lyase inhibitor abiraterone, and lead to prostate-specific antigen and objective responses with an androgen receptor antagonist (MDV3100). However, the addition of bevacizumab to docetaxel/prednisone in treating metastatic CRPC failed to provide a survival benefit. Cabazitaxel in metastatic CRPC postdocetaxel did demonstrate a survival benefit. Provenge, an autologous dendritic cell-based vaccine, demonstrated a reduction in the risk of death in metastatic CRPC. Other immunotherapy agents, including Prostvac and ipilimumab are under investigation. We also discuss the receptor tyrosine kinase inhibitor XL184 and poly (ADP-ribose) polymerase inhibitors which are in early clin. trials. Summary: Recent advances in androgen targeting, chemotherapy, immunotherapy, and other targeted therapies have led to significant improvements in the care of CRPC patients.

AB A review. Surgical resection followed by radiotherapy and temozolomide in newly diagnosed glioblastoma can prolong survival, but it is not curative. For patients with disease progression after frontline therapy, there is no standard of care, although further surgery, chemotherapy, and radiotherapy may be used. Antiangiogenic therapies may be appropriate for treating glioblastomas because angiogenesis is critical to tumor growth. In a large, noncomparative phase II trial, bevacizumab was evaluated alone and with irinotecan in patients with recurrent glioblastoma; combination treatment was associated with an estimated 6-mo progression-free survival (PFS) rate of 50.3%, a median overall survival of 8.9 mo, and a response rate of 37.8%. Single-agent bevacizumab also exceeded the predetd. threshold of activity for salvage chemotherapy (6-mo PFS rate, 15%), achieving a 6-mo PFS rate of 42.6% (p<0.0001). On the basis of these results and those from another phase II trial, the US Food and Drug Administration granted accelerated approval of single-agent bevacizumab for the treatment of glioblastoma that has progressed following prior therapy. Potential antiangiogenic agents - such as cilengitide and XL184 - also show evidence of single-agent activity in recurrent glioblastoma. Moreover, the use of antiangiogenic agents with radiation at disease progression may improve the therapeutic ratio of single-modality approaches. Overall, these agents appear to be well tolerated, with adverse event profiles similar to those reported in studies of other solid tumors. Further research is needed to determine the role of antiangiogenic therapy in frontline treatment and to identify the optimal schedule and partnering agents for use in combination therapy.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB The present invention provides methods for selecting a suitable anticancer therapy, and for identifying and predicting response for the treatment of a gastric cancer. The present invention provides compns. and methods for detecting the status (e.g., expression and/or activation levels) of components of signal transduction pathways in tumor cells (e.g., gastric tumor cells). Information on the expression and/or activation states of components of signal transduction pathways (e.g., HER2 and/or c-Met signal transduction pathway components) derived from practice of the present invention can be used for gastric cancer diagnosis, prognosis, and in the design of gastric cancer treatments. The compns. and methods of the present invention advantageously provide accurate prediction, selection, and monitoring of cancer patients (e.g., gastric cancer patients) most likely to benefit from targeted therapy by performing pathway profiling on easily accessible tumor cells using multiplexed, antibody-based proximity assays.

AB A review. After ligand binding induces dimerization, the RET receptor tyrosine kinase activates multiple signal transduction pathways. Constitutively activating mutations and chromosomal rearrangements are the primary oncogenic event in a significant number of medullary thyroid cancers (MTC) and papillary thyroid cancers (PTC), resp. When specific germline mutations in RET are identified early, prophylactic thyroidectomy can be timed to remove at-risk tissue in patients with multiple endocrine neoplasia 2 (MEN2) syndromes who would otherwise develop MTC. Conventional therapy for progressive metastatic MTC is limited. Small-mol. tyrosine kinase inhibitors can target multiple kinases at nanomolar concns., including RET, and have shown efficacy against a variety of malignancies. Initial clin. evidence suggests that several of these inhibitors, including sorafenib, vandetanib, motesanib, sunitinib, and XL-184, may have some benefit in treating progressive MTC. Although initial success seen in these trials seems to be modest, it represents a major breakthrough in the treatment of patients with widespread metastatic MTC. Clin Cancer Res; 16(24); 5936-41.

AB Purpose: To compare clin. outcomes of metastatic head and neck cancer patients treated in phase I clin. trials with clin. outcomes of those patients who had their last Food and Drug Administration (FDA)-approved therapy in the setting of metastatic disease. Exptl. Design: We retrospectively reviewed the outcomes of 61 consecutive patients with head and neck tumors treated in 36 phase I trials at The University of Texas M.D. Anderson Cancer Center between July 2004 and Sept. 2009. Results: The most common histol. was head and neck squamous cell carcinoma (62%). Median age was 55 years (range, 26-80). Eastern Cooperative Oncol. Group performance status was 0 to 1 for 95% of patients. Fifty-nine patients had received FDA-approved drugs as the backbone of their last systemic therapy before inclusion in phase I trials (median, 2 systemic therapies). Progression-free survival (PFS) on phase I trials was not inferior to PFS on their last FDA-approved therapies (12 vs. 10.7 wk, log-rank P = 0.87). Fifty-three patients were evaluable for response by Response Evaluation Criteria in Solid Tumors criteria. Four (7%) had partial responses and 16 (26%) had stable disease for ≥4 mo. In univariate anal., number of metastatic sites, lactate dehydrogenase (LDH) levels at baseline, and Royal Marsden Hospital prognosis scores were significant predictors of survival. Only LDH was significant in multivariate anal. (hazard ratio, 6.35; P ≤ 0.0001). Conclusions: For patients with heavily pretreated advanced head and neck tumors, PFS on phase I trials is not inferior to PFS with their last FDA-approved therapy. The only significant predictor of survival in the multivariate anal. was baseline LDH.

AB A review. XL-184 (BMS-907351), under development by Exelixis Inc and Bristol-Myers Squibb Co, is a pan-tyrosine kinase inhibitor for the potential oral treatment of medullary thyroid cancer, glioblastoma multiforme and NSCLC. The prinicipal targets of XL-184 are MET, VEGFR-2 and RET, but the drug is also reported to display inhibitory activity against KIT, FLT3 and TEK. Preclin. studies demonstrated that XL-184 potently inhibited multiple receptor tyrosine kinases in various cancer cell lines and animal xenograft models, and that the drug exhibited significant oral bioavailability and blood-brain barrier penetration. A phase I clin. trial in patients with advanced solid malignancies indicated that XL-184 accumulated dose-dependently in the plasma and had a long terminal half-life. A phase II trial in patients with progressive or recurrent glioblastoma revealed modest but promising median progression-free survival. Toxicity and side effects for the drug have generally been of low-to-moderate severity. At the time of publication, three addnl. trials of XL-184 were recruiting patients, including a phase I trial in combination with standard of care in patients with glioblastoma, a phase I/II trial in combination with erlotinib

in patients with NSCLC, and a phase III trial in patients with medullary thyroid cancer.

AB N-[4-[[6,7-bis(methyloxy)quinolin-4-yl]oxy]phenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide malate salts were prepared Thus, 1-(4-fluorophenylcarbamoyl)cyclopropanecarboxylic acid (preparation given) was stirred with (COCl)2 in THF/DMF at ≤30° and the mixture was added to 4-(6,7-dimethoxyquinolin-4-yloxy)phenylamine (preparation given) and K2CO3 in THF/H2O followed by addition of H2O and stirring for 10 h to give N-[4-[[6,7-bis(methyloxy)quinolin-4-yl]oxy]phenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide. The latter in EtOH was treated with malic acid in H2O followed by addition of C, thiol silica, heating to 78°, and addition of H2O followed by filtration, addition of Me2CHOH, cooling, and filtration to give N-[4-[[6,7-bis(methyloxy)quinolin-4-yl]oxy]phenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide malate.

AB A review. The treatment of thyroid cancer is evolving. The mol. mechanisms of carcinogenesis for many thyroid cancers have been investigated, and have yielded targets for potential therapies. These targets include VEGFR in the treatment of all thyroid cancers, BRAF in the treatment of papillary thyroid cancer, and RET in the treatment of medullary thyroid cancer (MTC). Many promising drugs that target one or more of these proteins are currently being evaluated, including sorafenib and sunitinib, both of which are still under development for the treatment of thyroid cancer but which have been approved for use in other malignancies. In addition, compds. such as vandetanib (AstraZeneca plc) and XL-184 (Bristol-Myers Squibb Co/Exelixis Inc) have demonstrated activity in early-phase clin. trials of MTC and are being tested further in randomized trials.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

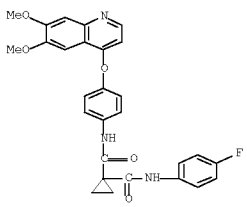
AB Recombinant replication-competent retroviral (RCR) vectors are provided comprising: a retroviral gag protein; a retroviral pol protein; a retroviral envelop, a retroviral polynucleotide comprising long terminal repeat (LTR) sequence at the 3' end of the retroviral polynucleotide sequence; a mammalian-suitable promoter sequence at the 5' end of the retroviral polynucleotide, a cassette comprising an internal ribosome entry site (IRES) operably linked to a heterologous polynucleotide; and cis-acting sequences necessary for reverse transcription, packaging and integration in a target cell. The RCR maintains higher replication competency after 6 passages compared to a pACE vector. The heterologous polynucleotide may encode modified cytosine deaminase (thermostabilized and codon optimized), single-chain antibody to CTLA-4, microRNAs miR-128-1 and miR-128-2, γ-interferon, interleukin 2, or other therapeutic proteins of interest. The disclosure further relates to cells and vector expressing or comprising such modified CDs and methods of using such modified CDs in the treatment of disease and disorders, and in particular cell proliferative disorders such as cancer.



IT 1140909-48-3, XL 184
RL: THU (Therapeutic use); BIOL (Biological study); USES (Uses)
(combination cancer therapy with; recombinant replication-competent retroviral vectors expressing therapeutic products for treatment of proliferative disorders)

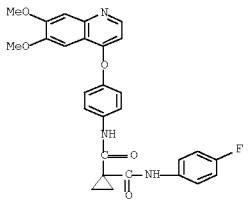
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The present invention provides an approach for the detn. of the activation states of a plurality of proteins in single cells. This approach permits the rapid detection of heterogeneity in a complex cell population based on activation states, expression markers and other criteria, and the identification of cellular subsets that exhibit correlated changes in activation within the cell population. Moreover, this approach allows the correlation of cellular activities or properties. In addition, the use of



modulators of cellular activation allows for characterization of pathways and cell populations. Several exemplary diseases that can be analyzed using the invention include AML, MDS, and MPN.

DOCUMENT TYPE: Journal; General Review
LANGUAGE: English
AB Purpose of review: Metastatic medullary thyroid cancer (MTC) is an incurable disease once metastasis becomes unresectable. Many therapeutic drugs and methods have been tried to circumvent this difficulty. We review currently published treatments and hope for future developments of more effective treatment methods. Recent findings: Motesanib, vandetanib, axitinib (tyrosine kinase inhibitors), and XL184 (multikinase inhibitor) have been shown to achieve partial response or stable disease state of metastatic MTC. Sunitinib and sorafenib, currently available tyrosine kinase inhibitors, can also be tried for patients with MTC. However, these medications are not curative and do not improve survival rate. Only carcinoembryonic antigen-I-iodine-based radioimmunotherapy improved survival of a subset of patients with a very aggressive type of MTC. Drugs currently available for possible use of MTC treatment include bortezomib (proteasome inhibitor), valproic acid (histone deacetylase inhibitor), capecitabine (5-fluorouracil prodrug), and indomethacin (NSAID), although clin. studies have yet to be done. Cardiac natriuretic hormones and an extract of the plant Cautleya gracilis are new agents to be studied for MTC. Summary: Kinase inhibitors are the first drugs showing some efficacy in MTC. To improve survival, unconventional drugs or other therapies with or without kinase inhibitors need to be considered.

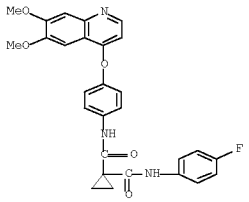
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB This invention is directed to methods and compns. for diagnosis, prognosis and for determining methods of treatment. The physiol. status of cells present in a sample (e.g. clin. sample) can be used in diagnosis or prognosis of a condition (e.g. chronic lymphocytic leukemia), in patient selection for therapy, to monitor treatment and to modify or optimize therapeutic regimens. The physiol. status of a cell can be determined by comparing the intracellular status of one or more activation elements (e.g. the phosphorylation status of a signaling mol.) in a cell (e.g. a cancer cell) to that of another cell (e.g. a normal cell). The physiol. status of a cell can be further classified by adding one or more modulators (e.g. an inhibitor or activator) to the cell in question. In some embodiments, the invention is directed to methods of determining a phenotypic profile of a population of cells.

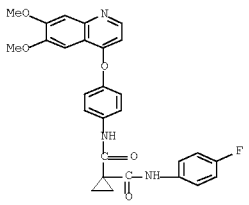
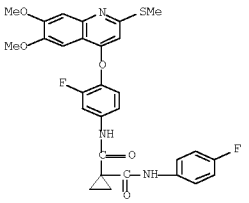
I



II



AB A method of treating a disease in a mammal, comprising administering to the mammal a therapeutically effective amount of a JAK-2 compound of formula I, or a pharmaceutical composition comprising a therapeutically effective amount of the JAK-2 compound of formula I and a pharmaceutically acceptable carrier, in combination with an active agent selected from of a Raf inhibitor, an EGFR inhibitor, a VEGFR inhibitor, a ErbB2 inhibitor, a BCR-Abl, inhibitor, a Flt3 inhibitor, a Src inhibitor, a c Kit inhibitor, an Akt inhibitor, a Ret inhibitor, an IFG1R inhibitor, an m-Tor inhibitor, a PI3K inhibitor, a PI3Kalpha inhibitor, wherein the mammal is in need of the treatment. Compds. of formula I wherein D and E are independently H, halo, CF3, heterocycloalkyl and alkyl; D and E taken together to form a 5- to 7-membered heteroaryl, and 5- to 7-membered heterocycloalkyl; L is a bond, O and NH; Z is alkoxy, cycloalkyl, and (un)substituted heteroaryl; Z and R25 taken together for form a 5- to 6-membered heterocycloalkyl, 5- to 6-membered heteroaryl, 5- to 6-membered cycloalkyl, etc.; each R25 is independently alkyl, alkenyl, lower alkyl, halo, haloalkyl, haloalkoxy, amino, etc.; R1 is H; R2 is (un)substituted aryl, (un)substituted heteroaryl, alkyl, etc.; n is 0 - 4; and pharmaceutically acceptable salts thereof, are claimed. Example compound II was prepared by acylation of 2-(4-aminophenylamino)-5-(4-acetylaminophenyl)pyrimidine with 2,6-dichlorobenzoyl chloride. All the invention compds. were evaluated for their JAK-2 inhibitory activity (some data given).

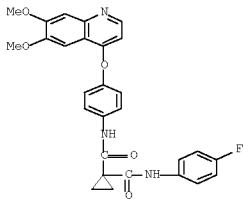
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB Provided herein are methods for treating cancer that is resistant to treatment with an anti- ErbB therapeutic agent and which is associated with an activating MET gene mutation or a MET gene amplification. The methods involve administering to a subject a combination of an anti- ErbB therapeutic and an anti-MET therapeutic. Also provided are methods for reducing ErbB mediated signaling or PI3 kinase mediated signaling in a cancer cell.

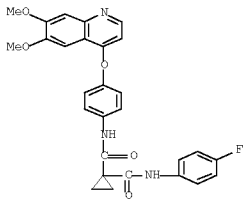
I



II

AB The invention provides methods of treating cancer by administering a compound of formula I, or a pharmaceutically acceptable salt or solvate thereof, in combination with other cancer treatments. Compds. of formula I wherein ring A is (un)substituted (hetero)arylene; X is (halo)alkyl, halo and haloalkoxy; R1, R2, R3, R4, R5 and R6 are independently H, halo, NO2, NH2 and derivs., OH and derivs., NHSO2H and derivs., CN, SH and derivs., etc.; R7 is H, halo and alkyl; and their pharmaceutically acceptable salts and solvates thereof are claimed. Example compound II was prepared by amidation of 3,4-difluoro-2-[(2-fluoro-4- iodophenyl)amino]benzoic acid with azetidin-3-ol hydrochloride. All the invention compds. were evaluated for their MEK inhibitory activity (some data given).

AB The invention relates to agents which possess anti-angiogenic activity and are accordingly useful in methods of treatment of disease states associated with angiogenesis in the animal or human body. More specifically the invention concerns a combination of a monoclonal antibody against human angiopoietin 2 (anti-Ang-2) and an antagonist of the biol. activity of VEGF-A, and/or KDR receptor, and/or FLT1, and uses of such antagonists. The nucleotide sequences and the encoded amino acid sequences of anti-Ang-2 monoclonal antibodies are disclosed.

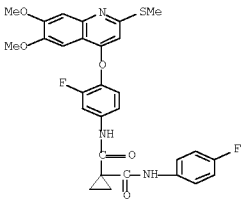
II



AB The present invention provides compds. (shown as I; variables defined below; e.g. N-[4-[[7-[[2-(diethylamino)ethyl]oxy]-6-(methyloxy)quinolin-4-yl]oxy]-3-fluorophenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide (shown as II)) for modulating protein kinase enzymic activity for modulating cellular activities such as proliferation, differentiation, programmed cell death, migration and chemoinvasion. More specifically, the invention provides quinazolines and quinolines which inhibit, regulate and/or modulate kinase receptors, particularly c-Met, KDR, c-Kit, flt-3 and flt-4, signal transduction pathways related to the changes in cellular activities as mentioned above, compns. which contain these compds., and methods of using them to treat kinase-dependent diseases and conditions. The present invention also provides methods for making compds. as mentioned above, and compns. which contain these compds. For I: R1 = H, halogen, OR3, NO2, NH2, NR3R4, and (un)substituted lower alkyl; A1 = :N-, :C(H)-, and :C(CN)-; Z = -S(O)0-2-, -O-, and -NR5-; Ar is aryl or heteroaryl; D = -O-, -S(O)0-2-, and -NR15-; R50 = R3 or bicyclic radical; addnl. details are given in the claims. Methods of preparation are claimed and .apprx.80 example prepns. of I and intermediates are included. For example, II was prepared (34 %) from 2-(diethylamino)ethanol and cyclopropane-1,1-dicarboxylic acid N-[3-fluoro-4-[(7-hydroxy-6-methoxyquinolin-4-yl)oxy]phenyl]amide N-(4-fluorophenyl)amide, which was prepared (89 %) by deprotection of cyclopropane-1,1-dicarboxylic acid N-[4-[(7-benzyloxy-6-methoxyquinolin-4-yl)oxy]-3-fluorophenyl]amide N-(4-fluorophenyl)amide, which was prepared (48 %) from trifluoromethanesulfonic acid 7-benzyloxy-6-methoxyquinolin-4-yl ester and cyclopropane-1,1-dicarboxylic acid N-(3-fluoro-4-hydroxyphenyl)amide N-(4-fluorophenyl)amide, which was prepared (85 %) by deprotection of cyclopropane-1,1-dicarboxylic acid N-(4-benzyloxy-3-fluorophenyl)amide N-(4-fluorophenyl)amide, which was prepared (98 %) from (4-benzyloxy-3-fluorophenyl)amine and 1-(4-fluorophenylcarbamoyl)cyclopropanecarboxylic acid; addnl. details are given in the examples.

PUBLISHER: Elsevier
DOCUMENT TYPE: Journal; (online computer file)
LANGUAGE: English
AB Cabozantinib is an oral multikinase inhibitor that exhibits anti-tumor activity in several cancers. We found that cabozantinib was significantly cytotoxic to MV4-11 and Molm-13 cells that harbored FLT3-ITD, resulting in IC50 values of 2.4 nM and 2.0 nM, resp. However, K562, OCI-AML3 and THP-1 (leukemia cell lines lacking FLT3-ITD) were resistant to cabozantinib, showing IC50 values in the micromolar range. Cabozantinib arrested MV4-11 cell growth at the G0/G1 phase within 24 h, which was associated with decreased phosphorylation of FLT3, STAT5, AKT and ERK. Addnl., cabozantinib induced MV4-11 cell apoptosis in a dose-dependent manner (as indicated by annexin V staining and high levels of cleaved caspase 3 and PARP-1), down-regulated the anti-apoptotic protein survivin and up-regulated the pro-apoptotic protein Bak. Thus, cabozantinib is selectively cytotoxic to leukemia cells with FLT3-ITD, causing cell-cycle arrest and apoptosis. In mouse xenograft model, cabozantinib significantly inhibited MV4-11 and Molm-13 tumor growth at a dosage of 10 mg/kg and showed longer survival rate. Clin. trials evaluating the efficacy of cabozantinib in acute myeloid leukemia (AML) with FLT3-ITD are warranted.

AB The invention discloses a quick-release medicine phosphatide compd. and pharmaceutical composition thereof. In this compound I, medicine Y1 and Y2 are connected with quick-release hydrophobic spacer arm and enhancement type hydrophobic spacer arm through chemical bond. Two kinds of the spacer arms collaborate with each other and strengthen hydrophobic action to form hydrophobic lipophilic chain. Two hydrophobic chains are connected with phospholipid hydrophilic head to constitute amphipathic mol. Pharmaceutical composition is quick-release medicine phosphatide compound or combined medicinal combination of this compound and pharmaceutically acceptable carrier. The quick-release medicine phosphatide compound and lipidosome nanoparticle thereof can be used as liquid preparation, solid preparation, semi-solid preparation, sterilized preparation and sterile preparation with low toxicity, and can be used for the efficient treatment of diseases such as various tumors.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A method for predicting and/or monitoring the efficacy of a c-Met inhibitor using a biomarker; a method for selecting a subject suitable for the application of a c-Met inhibitor using a biomarker; and a method for preventing and/or treating cancer comprising administering a c-Met inhibitor to the selected subject. In particular embodiments, provided are biomarkers for use in predicting and/or monitoring the therapeutic effect of a c-Met inhibitor or selecting a subject suitable for the application of a c-Met inhibitor, including IL-8, bIG-H3, KRAS or BRAF and nucleic acids encoding the proteins. Another embodiment provides a c-Met inhibitor or a pharmaceutical composition including a c-Met inhibitor, for use in inhibiting c-Met and/or treating a cancer in a subject, wherein the subject has a higher level of IL-8 or bIG-H3 compared to a reference sample in which a c-Met inhibitor is not effective, and/or has a mutation of KRAS and/or BRAF. KRAS protein comprises at least one amino acid mutation selected from the group consisting of G12A, G12D, G12R, G12C, G12S, G12V, A146T, A59T, L23R, G13N, G13D, I24F, Q61L, Q61H, G13C, and Q61K; and BRAF protein comprises at least one amino acid mutation selected from the group consisting of G596R, V600E, V600K, V600R, K601E, D594G, K601E, G469A, V600M, G469A, V600L, G466V, V600D, G469V, D594G, D594N, N581S, L597V, L597S, L597Q, K601N, G466V, G466E, G464V, and G469E.

AB We wanted to define the transcriptome of small intestinal neuroendocrine tumors in order to identify clin. relevant subgroups of tumors, prognostic markers and novel targets for treatment. Genome-wide expression profiling was conducted on tumor biopsies from 33 patients with well-differentiated neuroendocrine tumors of the distal ileum and metastatic disease at the time of diagnosis. Unsupervised hierarchical clustering anal. identified three groups of tumors. The largest group, comprising half of the tumors, was characterized by longer patient survival and higher expression of neuroendocrine markers, including SSTR2. Tumors with higher grade (G2/3) or gain of chromosome 14 were associated with shorter patient survival and increased expression of cell cycle-promoting genes. Pathway anal. predicted the prostaglandin E receptor 2 (PTGER2) as the most significantly activated regulator in tumors of higher grade, whereas Forkhead box M1 (FOXM1) was the most significantly activated regulator in tumors with gain of chromosome 14. Druggable genes identified from expression profiles included clin. proven SSTR2 and also novel targets, for example, receptor tyrosine kinases (RET, FGFR1/3, PDGFRB and FLT1), epigenetic regulators, mol. chaperones and signal transduction mols. Evaluation of candidate drug targets on neuroendocrine tumors cells (GOT1) showed significant inhibition of tumor cell growth after treatment with tyrosine kinase inhibitors or inhibitors of HDAC, HSP90 and AKT. In conclusion, we have defined the transcriptome of small intestinal neuroendocrine tumors and identified novel subgroups with clin. relevance. We found specific gene expression patterns associated with tumor grade and chromosomal alterations. Our data also suggest novel prognostic biomarkers and therapies for these patients.

AB Targeted polypharmacol. of kinases has emerged as a promising strategy to design efficient and safe therapeutics. Here, we perform a systematic study of kinase-ligand binding modes for the human structural kinome at scale (208 kinases, 1777 unique ligands, and their complexes) by integrating chemical genomics and structural genomics data and by introducing a functional site interaction fingerprint (Fs-IFP) method. New insights into kinase-ligand binding modes were obtained. We establish relationships between the features of binding modes, the ligands, and the binding pockets, resp. We also drive the intrinsic binding specificity and which correlation with amino acid conservation. Third, we explore the landscape of the binding modes and highlight the regions of "selectivity pocket" and "selectivity entrance". Finally, we demonstrate that Fs-IFP similarity is directly correlated to the exptl. determined profile. These improve our understanding of kinase-ligand interactions and contribute to the design of novel polypharmacol. therapies targeting kinases.

LANGUAGE: English
AB Nonlinear mixed effects models were developed to describe the relationship between cabozantinib exposure and target lesion tumor size in a phase III study of patients with progressive metastatic medullary thyroid cancer. These models used cabozantinib exposure ests. from a previously published population pharmacokinetic model for cabozantinib in cancer patients that was updated with data from healthy-volunteer studies. Semi-mechanistic models predict well for tumors with static, increasing, or decreasing growth over time, but they were not considered adequate for predicting tumor sizes in medullary thyroid cancer patients, among whom an early reduction in tumor size was followed by a late stabilization phase in those receiving cabozantinib. A semi-empirical tumor model adequately predicted tumor profiles that were assumed to have a net growth rate constant that was piecewise continuous in the regions of 0-110 and 110-280 days. Emax models relating average concentration to average change in tumor size predicted that an average concentration of 79 and 58 ng/mL, resp., would yield 50% of the maximum possible tumor reduction during the first 110 days of dosing and during the subsequent 110-280 days of dosing. Simulations of tumor responses showed that daily doses of 60 mg or greater are expected to provide a similar tumor reduction Both model evaluation of observed data and simulation results suggested that the two protocol-defined cabozantinib dose redns. from 140 to 100 mg/day and from 100 to 60 mg/day are not projected to result in a marked reduction in target lesion regrowth.

AB The prevailing approach to addressing secondary drug resistance in cancer focuses on treating the resistance mechanisms at relapse. However, the dynamic nature of clonal evolution, along with potential fitness costs and cost compensations, may present exploitable vulnerabilities-a notion that we term "temporal collateral sensitivity.". Using a combined pharmacol. screen and drug resistance selection approach in a murine model of Ph+ acute lymphoblastic leukemia, we indeed find that temporal and/or persistent collateral sensitivity to non-classical BCR-ABL1 drugs arises in emergent tumor subpopulations during the evolution of resistance toward initial treatment with BCR-ABL1-targeted inhibitors. We determined the sensitization mechanism via genotypic, phenotypic, signaling, and binding measurements in combination with computational models and demonstrated significant overall survival extension in mice. Addnl. stochastic math. models and small-mol. screens extended our insights, indicating the value of focusing on evolutionary trajectories and pharmacol. profiles to identify new strategies to treat dynamic tumor vulnerabilities.

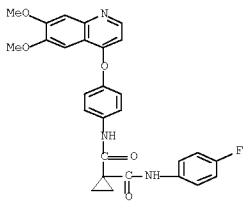
AB Deregulation of the receptor tyrosine kinase RET has been implicated in medullary thyroid cancer, a small percentage of lung adenocarcinomas,



endocrine-resistant breast cancer and pancreatic cancer. There are several clin. approved multi-kinase inhibitors that target RET as a secondary pharmacol. but addnl. activities, most notably inhibition of KDR, lead to dose-limiting toxicities. There is, therefore, a clin. need for more specific RET kinase inhibitors. Herein we report our efforts towards identifying a potent and selective RET inhibitor using vandetanib 1 as the starting point for structure-based drug design. Phenolic anilinoquinazolines exemplified by 6 showed improved affinities towards RET but, unsurprisingly, suffered from high metabolic clearance. Efforts to mitigate the metabolic liability of the phenol led to the discovery that a flanking substituent not only improved the hepatocyte stability, but could also impart a significant gain in selectivity. This culminated in the identification of 36; a potent RET inhibitor with much improved selectivity against KDR.

AB We undertake an anal. of ongoing BC targeted therapy trials registered to CT.gov to describe patterns of ongoing clin. research, highlight gaps in current research programs and identify ways of optimizing ongoing initiatives. A search of clinicaltrials.gov was conducted on Sept. 4, 2013 to identify ongoing randomized phase II and III trials of targeted therapies in BC. A total of 280 trials were analyzed, the majority conducted in either human epidermal growth factor receptor 2 (HER2)-pos. (n = 79, 28.2 %) or hormone receptor (HR)-pos. (n = 104, 37.1 %) populations. Less than half of all trials were conducted in populations selected to match the agent under investigation (n = 126, 45 %). HER2-directed therapy is the single most investigated class of targeted agents (n = 73, 26.1 %), but trials investigating anti-angiogenic agents are also common (n = 49, 17.5 %). The most common new classes of agents under investigation in HR-pos. and triple neg. (TN)/BRCA-pos. disease, are non-receptor protein kinase-inhibitors (n = 12; 11.5 %) and poly (ADP-ribose) polymerase inhibitors (n = 6; 30 %), resp. The majority of regimens combine new targeted agents with either chemotherapy (n = 164, 58.6 %) or endocrine therapy (n = 113, 40.4 %); a total of 8 trials (2.8 %) investigated peptide-drug conjugates. The most frequently utilized end-points were pathol. complete response in the neo-adjuvant setting (n = 36, 52.9 %) and time-to-event end-points in the adjuvant and advanced settings (77.3 and 72.6 %, resp.). Our findings suggest a need for more target-matched agent development, maintenance of a value-based focus in research and a need for the clin. development of agents to treat TN/BRCA-pos. and HR-pos. BC.

AB Many protein kinases are valid drug targets in oncol. because they are key components of signal transduction pathways. The number of clin. kinase inhibitors is on the rise, but these mols. often exhibit polypharmacol., potentially eliciting desired and toxic effects. Therefore, a comprehensive assessment of a compound's target space is desirable for a better understanding of its biol. effects. The enzyme ferrochelatase (FECH) catalyzes the conversion of protoporphyrin IX into heme and was recently found to be an off-target of the BRAF inhibitor Vemurafenib, likely explaining the phototoxicity associated with this drug in melanoma patients. This raises the question of whether FECH binding is a more general feature of kinase inhibitors. To address this, we applied a chemical proteomics approach using kinobeads to evaluate 226 clin. kinase inhibitors for their ability to bind FECH. Surprisingly, low or submicromolar FECH binding was detected for 29 of all compds. tested and isothermal dose response measurements confirmed target engagement in cells. We also show that Vemurafenib, Linsitinib, Neratinib, and MK-2461 reduce heme levels in K562 cells, verifying that drug binding leads to a loss of FECH activity. Further biochem. and docking expts. identified the protoporphyrin pocket in FECH as one major drug binding site. Since the genetic loss of FECH activity leads to photosensitivity in humans, our data strongly suggest that FECH inhibition by kinase inhibitors is the mol. mechanism triggering photosensitivity in patients. We therefore suggest that a FECH assay should generally be part of the preclin. mol. toxicol. package for the development of kinase inhibitors.

DOCUMENT TYPE: Journal; (online computer file)
LANGUAGE: English
AB In the current study we have investigated the interaction of newly approved kinase inhibitors namely Cabozantinib (CBZ) and Tofacitinib (TFB) with human Alpha-1 acid glycoprotein (AAG) under simulated physiol. conditions using fluorescence quenching measurements, CD, dynamic light scattering and mol. docking methods. CBZ and TFB binds to AAG with significant affinity and the calculated binding constant for the drugs lie in the order of 104. With the increase in temperature the binding constant values decreased for both CBZ and TFB. The fluorescence resonance energy transfer (FRET) from AAG to CBZ and TFB suggested the fluorescence intensity of AAG was quenched by the two studied drugs via the formation of a non-fluorescent complex in the static manner. The mol. distance r value calculated from FRET is around 2 nm for both drugs, fluorescence spectroscopy data was employed for the study of thermodn. parameters, standard Gibbs free energy change at 300K was calculated as - 5.234 kcal mol- 1 for CBZ-AAG interaction and - 6.237 kcal mol- 1 for TFB-AAG interaction, standard enthalpy change and standard entropy change for CBZ-AAG interaction are - 9.553 kcal mol- 1 and - 14.618 cal mol- 1K- 1 resp. while for AAG-TFB interaction, standard enthalpy and standard entropy change was calculated as 4.019 kcal mol- 1 and 7.206 cal mol- 1K- 1 resp. Protein binding of the two drugs caused the tertiary structure

alterations. Dynamic light scattering measurements demonstrated the reduction in the hydrodynamic radii of the protein. Furthermore mol. docking results suggested the Hydrophobic interaction and hydrogen bonding were the interactive forces in the binding process of CBZ to AAG while in case of TFB only hydrophobic interactions were found to be involved, overlap of the binding site for two studied drugs on the AAG mol. was revealed by docking results.

DOCUMENT TYPE: Journal; (online computer file)
LANGUAGE: English

AB BACKGROUND : Cabozantinib inhibits mesenchymal-epithelial transition factor (MET) and vascular endothelial growth factor receptor 2 (VEGFR2) and has demonstrated activity in patients with recurrent glioblastoma, warranting evaluation of the addition of cabozantinib to radiotherapy (RT) and temozolomide (TMZ) for patients with newly diagnosed high-grade glioma. METHODS : Cabozantinib doses of 40 mg and 60 mg were explored. Patients on the concurrent treatment arm received cabozantinib daily with standard TMZ and after RT continued cabozantinib daily with adjuvant TMZ. In the maintenance arm, patients who completed RT and ≥1 adjuvant cycle of TMZ continued adjuvant TMZ with added cabozantinib (3 schedules: days 1-28, days 1-14, or days 8-21). RESULTS : A total of 26 patients (25 with recurrent glioblastoma and 1 patient with anaplastic astrocytoma) aged 30 to 72 years were enrolled (10 to the concurrent arm and 16 to the maintenance arm). The median number of post-RT TMZ cycles was 4.5 (range, 0-14 cycles) in the concurrent arm and 5.5 (range, 1-12 cycles) in the maintenance arm. Cabozantinib at a dose of 60 mg daily was the maximum administered dose and a dose of 40 mg daily was determined to be the maximum tolerated dose for both treatment arms (schedule of days 1-28). The most frequent grade 3/4 adverse events were thrombocytopenia (31% of patients), leukopenia (27% of patients, including 5 patients with neutropenia), and deep vein thrombosis and/or pulmonary embolism (23% of patients) (adverse events were graded according to the National Cancer Institute Common Terminol. Criteria for Adverse Events [version 3.0]). CONCLUSIONS : Cabozantinib at a dose of 40 mg daily with RT plus TMZ and post-RT TMZ for patients with newly diagnosed high-grade glioma was generally well tolerated, and demonstrated no pharmacokinetic interactions with concurrent TMZ. Given the strong theor. rationale for combining anti-VEGF and anti-MET activity with standard therapy, cabozantinib at a dose of 40 mg daily warrants evaluation in combination with standard therapy for patients with newly diagnosed glioblastoma. I

II

AB The invention provides substituted 2-aminopyrido[2,3-d]pyrimidin-7(8H)-one compds. of formula I, which can be used for treating inflammation and cell proliferation diseases. The compound of the invention is a powerful cyclin-dependent kinase 4 (CDK 4) or cyclin-dependent kinase 6 (CDK 6) inhibitor. Compds. of formula I wherein L is a bond, (un)substituted C0-4 alkylene, (un)substituted amino-C0-4 alkyl, (un)substituted O-C0-4 alkyl, etc.; A is bicyclic heteroaryl, and bicyclic heterocyclyl; R is H, C3-9 cycloalkyl, C1-9 heteroaryl, C2-9 heterocyclyl, etc.; and stereoisomers, geometric isomers, tautomers, N-oxides, hydrates, solvates, metabolites, pharmaceutically acceptable salts and prodrugs thereof, are claimed. Example compound II was prepared by a multistep procedure (procedure given). The invention compds. were evaluated for their CDK inhibitory activity. From the assay, it was determined that compound II exhibited IC50 values of 6.8 nM and 29.2 nM toward CDK4 and CDK6, resp.

AB Title compds. I [B = Ph, pyridazinyl, pyrimidinyl, pyrazinyl, etc.; L = bond, CH2, CH2CH2, CH2NHCH2, etc.; R1 and R2 independently = H, F, Cl, Br, OH, alkyl, etc.; R3 = H, heteroaryl, cycloalkyl, heterocyclyl, etc.], and their pharmaceutically acceptable salts, are prepared and disclosed as CDK small-mol. inhibitors. Thus, e.g., II was prepared by amination of 6-(2-chloro-5-fluoropyrimidin-4-yl)-4-fluoro-1-isopropyl-2-methyl-1H-benzo[d]imidazole with 3-(1-methyl-1,2,3,6-tetrahydropyridin-4-yl)-1H-indol-5-amine. Select I were evaluated in enzymic inhibition activity assays (data given).

AB The invention relates to a method of prepg. compds. of I [wherein R1 and R2 = independently alkoxy or haloalkoxy; R3 - H, F, Cl, etc.; R4 = F, 18F, Cl, etc.] such as cabozantinib II, R4 = F, and [18F]-II, R4 = 18F, comprising the reaction of 4-aminophenol with 4-chloro-6,7-dimethoxyquinoline yielding the ether intermediate, III, which undergoes coupling with 1-carboxycyclopropanecarbonyl chloride providing IV, followed by amidation of IV with 4-fluoroaniline or [18F]-4-fluoroaniline under microwave heating yielding cabozantinib or [18F]-labeled cabozantinib. [18F]-II was administered to mice implanted with U87 tumors (glioblastoma) and to tumor-free animals. PET imaging resulted in visualization of the tumors in the brains of the tumor bearing animals and little or no uptake of [18F]-II in control animals suggesting [18F]-II does not cross the blood brain barrier in tumor-free mice but has significant uptake in U87 implanted mice.

AB Purpose: We performed parallel investigations in cabozantinib-treated patients in a phase II trial and simultaneously in patient-derived xenograft (PDX) models to better understand the roles of MET and VEGFR2 as targets for prostate cancer therapy. Exptl. Design: In the clin. trial, radiog. imaging and serum markers were examined, as well as mol. markers in tumors from bone biopsies. In mice harboring PDX intrafemurally or s.c., cabozantinib effects on tumor growth, MET, PDX in which MET was silenced, VEGFR2, bone turnover, angiogenesis, and resistance were examined Results: In responsive patients and PDX, islets of viable pMET–pos. tumor cells persisted, which rapidly regrew after drug withdrawal. Knockdown of MET in PDX did not affect tumor growth in mice nor did it affect cabozantinib-induced growth inhibition but did lead to induction of FGFR1. Inhibition of VEGFR2 and MET in endothelial cells reduced the vasculature, leading to necrosis. However, each islet of viable cells surrounded a VEGFR2–neg. vessel. Reduction of bone turnover was observed in both cohorts. Conclusions: Our studies demonstrate that MET in tumor cells is not a persistent therapeutic target for metastatic castrate-resistant prostate cancer (CRPC), but inhibition of VEGFR2 and MET in endothelial cells and direct effects on osteoblasts are responsible for cabozantinib-induced tumor inhibition. However, vascular heterogeneity represents one source of primary therapy resistance, whereas induction of FGFR1 in tumor cells suggests a potential mechanism of acquired resistance. Thus, integrated cross-species investigations demonstrate the power of combining preclin. models with clin. trials to understand mechanisms of activity and resistance of investigational agents. AB Purpose: Pos. results of phase I studies evaluating lenvatinib in solid tumors, including thyroid cancer, prompted a phase II trial in advanced medullary thyroid carcinoma (MTC). Exptl. Design: Fifty-nine patients with unresectable progressive MTC per Response Evaluation Criteria In Solid Tumors (RECIST) v1.0 within the prior 12 mo received lenvatinib (24-mg daily, 28-day cycles) until disease progression, unmanageable toxicity, withdrawal, or death. Prior anti–VEGFR therapy was permitted. The primary endpoint was objective response rate (ORR) by RECIST v1.0 and independent imaging review. Results: Lenvatinib ORR was 36% [95% confidence interval (CI), 24%–49%]; all partial responses. ORR was comparable between patients with (35%) or without (36%) prior anti-VEGFR therapy. Disease control rate (DCR) was 80% (95% CI, 67%–89%); 44% had stable disease. Among responders, median time to response (TTR) was 3.5 mo (95% CI, 1.9–3.7). Median progression-free survival (PFS) was 9.0 mo (95% CI, 7.0–not evaluable). Common toxicity criteria grade 3/4 treatment-emergent adverse events included diarrhea (14%), hypertension (7%), decreased appetite (7%), fatigue, dysphagia, and increased alanine aminotransferase levels (5% each). Ret proto-oncogene status did not correlate with outcomes. Low baseline levels of angiopoietin-2, hepatocyte growth factor, and IL8 were associated with tumor reduction and prolonged PFS. High baseline levels of VEGF, soluble VEGFR3, and platelet-derived growth factor BB, and low baseline levels of soluble Tie-2, were associated with tumor reduction Conclusions: Lenvatinib had a high ORR, high DCR, and a short TTR in patients with documented progressive MTC. Toxicities were managed with dose modifications and medications. Clin Cancer Res; 22(1); 44-53. ©2015 AACR.

AB In structure-based drug design, automated de novo design methods are helpful tools for lead discovery as well as lead optimization. In a previous study the authors reported a new de novo design method, namely, Automatic Tailoring and Transplanting (AutoT&T). It overcomes some intrinsic problems in conventional fragment-based buildup methods. In this study, the authors describe an upgraded version, namely, AutoT&T2. Structural operations conducted by AutoT&T2 have been largely optimized by introducing several new algorithms. As a result, its overall speed in multiround optimization jobs has been improved by a few thousand fold. With this improvement, it is now practical to conduct structural crossover among multiple lead mols. using AutoT&T2. Three different test cases are described in this study that demonstrate the new features and versatile applications of AutoT&T2. The AutoT&T2 software suite is available to the public. Besides, a Web portal for running AutoT&T2 online is provided at http://www.sioc-ccbg.ac.cn/software/att2 for testing.

AB A review with 69 ref. is given on research advances of FLT3 inhibitors in treatment of acute myeloid leukemia. Acute myeloid leukemia (AML) is one of the most common acute leukemia in adults. Those patients with FLT3 mutations have a particularly poor prognosis. Recently, the emergence of a variety of targeted inhibitors has shown the capability of suppressing FLT3 signaling in vivo, which provided a new way to treat AML. In this paper, we reviewed those inhibitors based on their structures, which include indolone-related inhibitors, indolocarbazo-related inhibitors, benzimidazole/benzopyrazole-related inhibitors, quinoline/quinoxaline/quinazoline-related inhibitors, tricyclic inhibitors, pyrimidine-related inhibitors and others.

AB Nanoscale drug delivery vehicles can facilitate multimodal therapies of cancer by promoting tumor-selective drug release. However, few are effective because cancer cells develop ways to resist and evade treatment. Here, we introduce a photoactivable multi-inhibitor nanoliposome (PMIL) that imparts light-induced cytotoxicity in synchrony with a photoinitiated and sustained release of inhibitors that suppress tumor regrowth and treatment escape signaling pathways. The PMIL consists of a nanoliposome doped with a photoactivable chromophore (benzoporphyrin derivative, BPD) in the lipid bilayer, and a nanoparticle containing cabozantinib (XL184)-a multikinase inhibitor-encapsulated inside. Near-IR tumor irradiation, following i.v. PMIL administration, triggers photodynamic damage of tumor cells and microvessels, and simultaneously initiates release of XL184 inside the tumor. A single PMIL treatment achieves prolonged tumor reduction in two mouse models and suppresses metastatic escape in an orthotopic pancreatic tumor model. The PMIL offers new prospects for cancer therapy by enabling spatiotemporal control of drug release while reducing systemic drug exposure and associated toxicities.

AB The title compds. I [ring A and ring E = (independently) C6-10 aryl or C1-12 heteroaryl; each J = G(CH2)nR2;each G = (independently) O, S(O)t, S, C(O), etc.; R1, R1a = H, F, Cl, Br, etc.; R2 = alkyl, cycloalkyl, heterocyclyl, etc.; ring K = 5-6 membered heteroaryl;each L = (independently) NH2, NO2, alkylthio, alkyl, etc.; each a and e = (independently) 0-4; each n, d and b = (independently) 1-4; and each t = (independently) 0-2], useful for preventing, managing, treating or lessening a proliferative disease, and modulating the activity of protein kinase, were prepared and claimed. E.g., a multi-step synthesis of the urea II, starting from 2-fluoro-4-iodophenol and N-(3-chloropropyl)morpholine, was described. Exemplified compds. I were tested for their activity against FLT3 kinase (data given for representative compds. I). Pharmaceutical compns. comprising compound I, alone or in combination with other therapeutic agents, were disclosed.

AB Activation of the hepatocyte growth factor (HGF) -Met pathway evokes dynamic biol. responses that support the morphogenesis, regeneration and survival of cells and tissues. A characterization of conditional Met knockout mice indicates that the HGF-Met pathway plays important roles in the regeneration, protection and homeostasis of cells such as hepatocytes, renal tubular cells and neurons. Preclin. studies in disease models have indicated that recombinant HGF protein and expression plasmid for HGF are biol. drug candidates for the treatment of patients with diseases or injuries that involve impaired tissue function. The phase-I and phase-I/II clin. trials of the intrathecal administration of HGF protein for the treatment of patients with amyotrophic lateral sclerosis and spinal cord injury, resp., are ongoing. Biol. actions of HGF that promote the dynamic movement, morphogenesis and survival of cells also closely participate in invasion-metastasis and resistance to the mol.-targeted drugs in tumor cells. Different types of HGF-Met pathway inhibitors are now in clin. trials for treatment of malignant tumors. Basic research on HGF and Met has lead to drug discoveries in regenerative medicine and tumor biol.

AB Purpose: Abiraterone improves the overall survival of men with metastatic castration-resistant prostate cancer. However, de novo or adaptive resistance to abiraterone limits its activity. Rational combinations of drugs with different mechanisms of action that overcome resistance mechanisms may improve the efficacy of therapy. To that end, we studied the mol. and phenotypic effects of the combination of cabozantinib plus abiraterone. Exptl. Design: Three prostate cancer cell lines were used to interrogate the in vitro mol. and antiproliferative effects of the single agents and combination of cabozantinib and abiraterone. The in vivo impact of the combination was assessed using the LAPC4-CR xenograft mouse model. Results: In vitro proliferation studies demonstrated single-agent doses between 2 μmol/L and 10 μmol/L for abiraterone and cabozantinib inhibit prostate cancer cell proliferation in a dose-dependent manner, and the anticancer activity of abiraterone is enhanced when combined with cabozantinib. In vivo LAPC4-CR xenograft mouse studies also showed that cabozantinib can improve the antitumor activity of abiraterone. Cabozantinib, a multiple receptor tyrosine kinase inhibitor, enhances the ability of abiraterone to inhibit AR activity in a cell line-dependent manner. In addition, our cell line studies demonstrate abiraterone-stimulated insulin-like growth factor I receptor (IGFIR) phosphorylation with downstream activation of MEK1/2 and ERK1/2, and that this potential adaptive resistance mechanism was inhibited by cabozantinib. Conclusions: Cabozantinib can enhance the efficacy of abiraterone by blocking multiple compensatory survival mechanisms, including IGFIR activation, and supports the assessment of the combination in a clin. trial. AB In addn. to target efficacy, drug safety is a major requirement during the drug discovery process and is influenced by target specificity. Therefore, it is imperative that every new drug candidate be profiled against various liability panels that include protein kinases. Here, an effective methodol. to streamline kinase inhibitor profiling is described. An accessible standardized profiling system for 112 protein kinases covering all branches of the kinome was developed. This approach consists of creating different sets of kinases and their corresponding substrates in multi-tube strips. The kinase stocks are pre-standardized for optimal kinase activity and used for inhibitor profiling using a bioluminescent ADP detection assay. The authors show that these strips can routinely generate inhibitor selectivity profiles for small or broad kinase family panels. Lipid kinases were also assembled in strip format and profiled together with protein kinases. The authors identified two specific PI3K inhibitors that have off-target effects on CK2 that were not reported before and would have been missed if compds. were not profiled against lipid and protein kinases simultaneously. To validate the accuracy of the data generated by this method, the authors confirmed that the inhibition potencies observed are consistent with published values produced by more complex technologies such as radioactivity assays.

AB Background: Drug discovery for the neglected tropical disease schistosomiasis has a high priority. Anticancer drugs, especially protein kinase inhibitors, might serve as a starting point for drug discovery owing to the importance of protein kinases in helminth growth and development. Furthermore, the Schistosoma mansoni genome encodes several genes for targets of drugs marketed for human use, including several anticancer drugs. Methods: In this study, we screened the approved oncol. drug set of the National Cancer Institute's Developmental Therapeutic Program for antischistosomal activity. Drugs were tested in vitro against the larval and adult stage of S. mansoni. IC50 values and albumin binding were determined for active compds. Lead compds. were tested in the chronic S. mansoni mouse model. Results: Eleven of the 114 compds. tested revealed IC50 values ≤ 10 μM against both S. mansoni stages. Five of these lost activity against adult S. mansoni in the presence of serum albumin. Of 6 compds. studied in vivo, the highest activity was observed from two kinase inhibitors trametinib, and vandetanib, which reduced worm burden by 63.6 and 48.1 % resp., after a single oral dose of 400 mg/kg body weight Conclusion: Our study has confirmed that oncol. drugs possess antischistosomal activity. There is space for further investigation, including elucidation of the mechanisms of action of schistosome-active cancer drugs, application of different treatment courses, and structure-activity relationship studies for improving drug potency.

AB The blood fluke Schistosoma haematobium causes urogenital schistosomiasis, a neglected tropical disease (NTD) that affects more than 110 million people. Treating this disease by targeted or mass administration with a single chemical, praziquantel, carries the risk that drug resistance will develop in this pathogen. Therefore, there is an imperative to search for new drug targets in S. haematobium and other schistosomes. In this regard, protein kinases have potential, given their essential roles in biol. processes and as targets for drugs already approved by the US Food and Drug Administration (FDA) for use in humans. In this context, we defined here the kinome of S. haematobium using a refined bioinformatic pipeline. We classified, curated and annotated predicted kinases, and assessed the developmental transcription profiles of kinase genes. Then, we prioritised a panel of kinases as potential drug targets and inferred chems. that bind to them using an integrated bioinformatic pipeline. Most kinases of S. haematobium are very similar to those of its congener, S. mansoni, offering the prospect of designing chems. that kill both species. Overall, this study provides a global insight into the kinome of S. haematobium and should assist the repurposing or discovery of drugs against schistosomiasis.

AB A review. Hepatocellular carcinoma (HCC) is a major pathol. type of primary liver cancer. Sorafenib has demonstrated definite efficacy in targeted therapy for HCC. However, when treatment with sorafenib fails, suitable drugs must be found for further treatment. This article reports a case of an HCC patient who was treated with angiogenesis inhibitor axitinib and c-Met inhibitor cabozantinib following treatment with sorafenib. The report focuses on clin. treatment and toxicity. Rational application of targeted therapy is also explored.

LANGUAGE: English
AB A review. Until recently, no therapeutic options were available for the treatment of advanced medullary thyroid cancer (MTC). Cabozantinib (XL184) is a novel tyrosine kinase inhibitor (TKI) that inhibits several tyrosine kinase receptors, in particular those coded by MET, VEGFR-2 and RET oncogenes that are considered to be involved in the pathogenesis of MTC. This article provides an overview of the phase I and III trials that demonstrated the efficacy of cabozantinib in two cohorts of advanced MTC patients who were naive or previously treated with other TKIs. The benefits in terms of progression-free survival (PFS), overall survival (OS) and the demog. clin. and mutational status of the two cohorts of MTC patients are reported and discussed. The possibility to have a therapeutic option for the treatment of patients with advanced and progressive MTC and, in particular, the evidence that the drug can be active also in those patients who already experienced disease progression while taking another TKI is a great opportunity as demonstrated in cases treated with cabozantinib after vandetanib such as the one reported in this paper.

AB Resistance to currently available targeted therapies significantly hampers the survival of patients with prostate cancer with bone metastasis. Here we demonstrate an important resistance mechanism initiated from tumor-induced bone. Studies using an osteogenic patient-derived xenograft, MDA-PCa-118b, revealed that tumor cells resistant to cabozantinib, a Met and VEGFR-2 inhibitor, reside in a "resistance niche" adjacent to prostate cancer-induced bone. We performed secretome anal. of the conditioned medium from tumor-induced bone to identify proteins (termed "osteocrines") found within this resistance niche. In accordance with previous reports demonstrating that activation of integrin signaling pathways confers therapeutic resistance, 27 of the 90 osteocrines identified were integrin ligands. We found that following cabozantinib treatment, only tumor cells positioned adjacent to the newly formed woven bone remained viable and expressed high levels of pFAK-Y397 and pTalin-S425, mediators of integrin signaling. Accordingly, treatment of C4-2B4 cells with integrin ligands resulted in increased pFAK-Y397 expression and cell survival, whereas targeting integrins with FAK inhibitors PF-562271 or defactinib inhibited FAK phosphorylation and reduced the survival of PC3-mm2 cells. Moreover, treatment of MDA-PCa-118b tumors with PF-562271 led to decreased tumor growth, irresp. of initial tumor size. Finally, we show that upon treatment cessation, the combination of PF-562271 and cabozantinib delayed tumor recurrence in contrast to cabozantinib treatment alone. Our studies suggest that identifying paracrine de novo resistance mechanisms may significantly contribute to the generation of a broader set of potent therapeutic tools that act combinatorially to inhibit metastatic prostate cancer. AB Provided are novel acetylenedicarboxyl linkers used for the specific conjugation of compds./cytotoxic agents to a cell-binding mol., through bridge linking pairs of thiols on the cell-binding mol. Also provided are methods of making such linkers, and of using such linkers in making homogeneous conjugates, as well as of application of the conjugates in treatment of cancers, infections and autoimmune disorders. Particularly provided is a bridge linker compound of the Formula (I), wherein:The acetylenedicarboxyl group is capable of reacting with a pair of sulfur atoms of the cell-binding agent; Z1 and Z2 are the same or different a function group that enables to react with a cytotoxic drug; R1 and R2 are the same or different linear alkyl; X1 and X2 are independently selected from NH, N(R3), O, S or CH2; R3 is H, linear alkyl.

AB A review. Hepatocellular carcinoma (HCC) can be lethal due to its aggressive course and lack of effective systemic therapies for advanced disease. Sorafenib is the only systemic therapy that has demonstrated an overall survival benefit in patients with advanced HCC, and new agents for treatment of advanced HCC are needed. The multiple pathways involved in HCC oncogenesis, proliferation and survival provide many opportunities for the development of molecularly targeted therapies. Mol. targets of interest have expanded from angiogenesis to cancer cell-directed oncogenic signaling pathways for treatment of advanced HCC. Agents targeting vascular endothelial growth factor receptor, epidermal growth factor receptor, fibroblast growth factor receptor, platelet-derived growth factor receptor, c-mesenchymal-epithelial transition factor-1 and mammalian target of rapamycin signaling have been actively explored. This article focuses on the evaluation of mol. agents targeting pathogenic HCC and provides a review of recently completed phase III drug studies (e.g. involving sorafenib, sunitinib, brivanib, linifanib, erlotinib, everolimus, ramucirumab or orantinib) and ongoing drug studies (e.g. involving lenvatinib, regorafenib, tivantinib or cabozantinib) of molecularly targeted agents in advanced HCC, including a brief description of the biol. rationale behind these agents.

AB A review. Cabozantinib (XL-184) is a potent inhibitor of MET, VEGFR 2/KDR, RET and other receptor tyrosine kinases, such as KIT, AXL and FLT3. Its efficacy against MTC has been demonstrated in a prospective, randomized, placebo-controlled study (EXAM). Cabozantinib comparing to placebo significantly prolonged progression free survival both in hereditary and sporadic MTC, 11.2 vs. 4.0 mo, resp. Final anal. showed no global differences in overall survival (OS) between cabozantinib and placebo. However, in a subgroup with RET M918T mutation the difference in OS was significant: 44.3 vs. 18.9 mo, resp. Among the most frequent cabozantinib-related adverse events (AEs), observed in >30% of patients were diarrhea, palmar-plantar erythrodysesthesia, decreased weight, decreased appetite, nausea, fatigue, dysgeusia, hair color changes and hypertension. Expert Commentary: Cabozantinib constitutes an effective treatment option with acceptable toxicity in MTC patients showing either germinal or sporadic tumor RET M918T mutation as the drug prolonged OS in these subjects.

AB The invention relates to a new marker, the hepatocyte growth factor (HGF) in serum or plasma for the prognosis of small-cell lung cancer (SCLC). The invention also provides methods for selecting subjects suffering from SCLC that are candidate to respond to certain substances inhibiting certain kinases expressed in the tumors. There are also encompassed the use of immunoassay and nucleic acid reagents for detecting HGF in serum or plasma, said reagents for carrying out the prognostic method.

I II

AB The invention described compds. of formula I and a method of treating cancer comprising administering to a subject having cancer one of the compds. in conjunction with another therapeutic treatment of cancer. The compds. I inhibit signaling by a member of the TGF-β superfamily such as nodal or activin. Compds. of formula I wherein Cy1 is (un)substituted Ph, benzofuranyl, (un)substituted C1-3 alkyl, etc.; Cy2 is pyrazolo[1,5-a]pyrimidinyl, benzothiazolyl, imidazo[1,2-a]pyridinyl, (un)substituted phenylsulfonyl, etc.; R is (un)substituted Ph, (un)substituted heteroaryl and (un)substituted heterocycloalkyl; and pharmaceutically acceptable salts thereof, are claimed. Example compound II was prepared by cross-coupling of 2-chloro-2-(3-methylphenyl)pyridine with 1-methyl-1H-benzimidazole-6-boronic acids. The invention compds. were evaluated for their TGF-β inhibitory activity (some data given).

* STRUCTURE DIAGRAM TOO LARGE FOR DISPLAY - AVAILABLE VIA OFFLINE PRINT *

AB The present invention relates to novel linkers contg. a 2,3-disubstituted succinic group, or 2-monosubstituted, or 2,3-disubstituted fumaric or maleic (trans (E)- or cis (Z)-butenedioic) group, e.g., (I), for conjugation of two or more compds./cytotoxic agents per linker to a cell-binding mol., through bridge linking pairs of thiols (reduced from the interchain disulfide bonds of the cell-binding agent by a reducing agent, such as dithiothreitol, dithioerythritol, L-glutathione and tris(2-carboxyethyl)phosphine (TCEP), or/and β-mercaptoethanol) on the cell-binding mol. specifically. The invention is also related to methods of making cell-binding agent-drug (cytotoxic agent) conjugates in a specific manner comprising either modification of drugs with these linkers first, followed by reaction with prepared cell-binding agents; or modification of cell-binding agents with these linkers first, followed by treating reaction with drugs and to their use for cancers, infections and autoimmune disorders. Thus, linker I was prepared by cyclization of 2,3-dibromosuccinic acid in CH2Cl2 in the presence of P2O5. R1-COCHBrCHBrCO-R (II) was prepared in 3 steps from I and R1-H (preparation given) using R = H (preparation given). A herceptin antibody conjugate with II was prepared by reacting herceptin with and TCEP and II. The resulting conjugate was evaluated for its in vitro cytotoxicity against a human gastric carcinoma N87 cells, human ovarian carcinoma SK-OV-3 cells and promyelocytic leukemia HL-60 cells. The specificity of the conjugate for N87 cell was over 889 and for SK-OV-3 cell was over 800. Five-week-old female BALB/c Nude mice inoculated s.c. in the area under the right shoulder with N-87 carcinoma cells treated with the conjugate had completely no tumor measurable at day 13 till day 60 (the end of experiment) in an in vivo antitumor activity study.

AB The invention discloses method for screening antitumor drug biomarkers, and application thereof. The method comprises the steps of: (1) providing tumor cells as starting cells, and tumor cells are from identical tumor tissue of the same object, (2) performing passage of the starting cells, establishing cell lines, and detecting genomic information of the cell lines so as to obtain at least 5 tumor cell lines that have genomic differences and are highly homologous, (3) performing antitumor drug sensitivity testing of the tumor cell lines, and typing the tumor cell lines based on the testing results, and (4) based on the typing results, analyzing the genomic information of the tumor cell lines to determine anti-tumor drug biomarkers. The method can maximally reduce background noise between different tumor cell lines, and can help to efficiently and accurately screen biomarkers of antitumor drugs.

AB The aim of combination drug treatment in cancer therapy is to improve response rate and to decrease the probability of the development of drug resistance. Preferably, drug combinations are synergistic rather than additive, and, ideally, drug combinations work synergistically only in cancer cells and not in non-malignant cells. We have developed a workflow to identify such targeted synergies, and applied this approach to selectively inhibit the proliferation of cell lines with mutations in genes that are difficult to modulate with small mols. The approach is based on curve shift anal., which we demonstrate is a more robust method of determining synergy than combination matrix screening with Bliss-scoring. We show that the MEK inhibitor trametinib is more synergistic in combination with the BRAF inhibitor dabrafenib than with vemurafenib, another BRAF inhibitor. In addition, we show that the combination of MEK and BRAF inhibitors is synergistic in BRAF-mutant melanoma cells, and additive or antagonistic in, resp., BRAF-wild type melanoma cells and non-malignant fibroblasts. This combination exemplifies that synergistic action of drugs can depend on cancer genotype. Next, we used curve shift anal. to identify new drug combinations that specifically inhibit cancer cell proliferation driven by difficult-to-drug cancer genes. Combination studies were performed with compds. that as single agents showed preference for inhibition of cancer cells with mutations in either the CTNNB1 gene (coding for β-catenin), KRAS, or cancer cells expressing increased copy nos. of MYC. We demonstrate that the Wnt-pathway inhibitor ICG-001 and trametinib acted synergistically in Wnt-pathway-mutant cell lines. The ERBB2 inhibitor TAK-165 was synergistic with trametinib in KRAS-mutant cell lines. The EGFR/ERBB2 inhibitor neratinib acted synergistically with the spindle poison docetaxel and with the Aurora kinase inhibitor GSK-1070916 in cell lines with MYC amplification. Our approach can therefore efficiently discover novel drug combinations that selectively target cancer genes.

AB Cabozantinib is a small mol. tyrosine kinase inhibitor that has been approved for the treatment of patients with progressive, metastatic medullary thyroid cancer. Cabozantinib exhibits a pH-dependent solubility profile in vitro. Two phase 1 clin. pharmacol. studies were conducted in healthy subjects to evaluate whether factors that may affect cabozantinib solubility and gastric pH could alter cabozantinib bioavailability: a food effect study (study 1) and a drug-drug interaction (DDI) study with the proton pump inhibitor (PPI) esomeprazole (study 2). Following a high-fat meal (study 1), cabozantinib Cmax and AUC were increased (40.5% and 57%, resp.), and the median tmax was delayed by 2 h. Cabozantinib should thus not be taken with food (patients should not eat for at least 2 h before and at least 1 h after administration). In the DDI study (study 2), the 90% confidence intervals (CIs) around the ratio of least-squares means of cabozantinib with esomeprazole vs.

AB This study examd. whether oral administration of erlotinib to rats with cabozantinib led to any pharmacokinetic interactions or not. Twenty four rats were randomly divided into 3 groups, cabozantinib group (cabozantinib 30 mg/kg, n = 8), erlotinib group (erlotinib 25 mg/kg, n = 8) and co-administration group (erlotinib 25 mg/kg and cabozantinib 30 mg/kg, n = 8). The concentration of cabozantinib and erlotinib in rat plasma was determined by a sensitive and simple UPLC-MS/MS method. There was statistical pharmacokinetics difference for cabozantinib in the cabozantinib group and co-administration group, when co-oral administration cabozantinib with erlotinib, the AUC(0-t) and Cmax increased ($p < 0.01$). There was statistical pharmacokinetics difference for erlotinib in the erlotinib group and co-administration group, when co-oral administration erlotinib with cabozantinib, the AUC(0-t) increased and CL decreased ($p < 0.05$). These data indicate erlotinib could influence the pharmacokinetic profile of cabozantinib in rats, and vice versa, which might cause drug-drug interactions when using cabozantinib with erlotinib.

AB The invention is related to the prepn. of cytotoxic auristatin analogs, e.g., I, in particular monomethyl auristatin F (MMAF) conjugates of such cytotoxic agents with a cell-binding agent, methods of using them to arrest or retard abnormal cell growth and /or proliferation and to their use for targeted treatment of cancer, autoimmune disease, and infectious diseases. Thus, I [R = H] was prepared and coupled to 4-maleimidobutyric acid to provide I [R = R1] linker drug conjugate. A herceptin antibody-I [R = R1] conjugate was prepared and evaluated for its in vitro potency against N-87 human gastric carcinoma cells.

AB The invention is related to the prepn. of novel linkers contg. a hydrazine unit, e.g., I, used for the specific conjugation in particular cytotoxic agents to a cell-binding mol., through bridge linking a pair of thiols on the cell-binding mol. The invention is also related to methods of making cell-binding agent-drug (cytotoxic agent) conjugates in a specific manner comprising either modification of drugs with these linkers first, followed by reaction with prepared cell-binding agents; or modification of cell-binding agents with these linkers first, followed by reaction with drugs and to their use for treating especially cancer. Thus, the linker I [R1 = OH] was prepared by a multi-step synthesis starting from O-benzylhydroxylamine hydrochloride and tert-Bu acrylate using tert-Bu 3-aminopropanoate and 3-maleimidopropanoic acid. Reaction of I with oxalyl chloride, and treatment of the diacid dichloride with II [R = H] gave I [R1 = II wherein R is absent]. A herceptin antibody-I [R1 = II wherein R is absent] conjugate was prepared and evaluated for its in vitro cytotoxicity against a human gastric carcinoma N87 cells, human ovarian carcinoma SK-OV-3 cells and promyelocytic leukemia HL-60 cells. The specificity of the conjugate for N87 cell was over 105 and for SK-OV-3 cell was over 3136.

AB The invention is related to the prepn. of novel bridge linkers contg. an acetylenedicarboxylic group, e.g., I, to link two drugs to a cell-binding agent (e.g., an antibody). The invention is also related to methods of making cell-binding agent-drug (cytotoxic agent) conjugates in a specific manner comprising either modification of drugs with these linkers first, followed by reaction with prepared cell-binding agents; or modification of cell-binding agents with these linkers first, followed by reaction with drugs and to their use for treating especially cancer. Thus, I [R = 2,5-dioxopyrrolidin-1-yloxy] was prepared by reacting 13-amino-bis(4,7,10-trioxadodecanoic acid) (preparation given) with bis(2,5-dioxopyrrolidin-1-yl)but-2-ynedioate (preparation given) and treatment of the tetraacid with NHS. Amidation of I [R = 2,5-dioxopyrrolidin-1-yloxy] with tubulysin analog R1-H gave R1-I [R = absent] containing 4 tubulysins analog per bridge linker. A herceptin antibody-R1-I [R = absent] conjugate was prepared and evaluated for its in vitro cytotoxicity against a human gastric carcinoma N87 cells, human ovarian carcinoma SK-OV-3 cells and promyelocytic leukemia HL-60 cells. The specificity of the conjugate for N87 cell was over 270 (IC50>10/IC50 = 0.037), and for SK-OV-3 cell was over 344.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB The authors disclose a cancer treatment method comprising the administering of an anti-angiogenesis agent and an OX40 binding agonist. In the one example, anti-VEGF antibody treatment resulted in reduced tumor growth, compared to anti-gp120 (control), in a syngeneic mouse colon carcinoma model. Anti-OX40 antibody treatment exhibited little activity alone. Anti-OX40 treatment in combination with anti-VEGF treatment demonstrated superior tumor growth inhibition when compared to single agent administration or anti-gp120 treatment.

AB Uncontrolled activation of FGFRs induces the progression of various cancers. It was recently reported that FGFR2-activating mutants are implicated in about 12% of endometrial carcinomas. AZD4547, a potent pan-FGFR inhibitor, is currently being evaluated in clin. trials for several FGFR-driven cancers. However, AZD4547 has not been examined yet against FGFR2 mutant-driven endometrial cancers. Thus, we evaluated the activity of AZD4547 against four different endometrial cancer cells, including AN3-CA, MFE296, MFE280, and HEC1A, where all but HEC1A cells express distinctive FGFR2 mutations. We found that AZD4547 exhibits potent antiproliferative activity (EC50 = 31 nmol/L) against AN3-CA cells harboring FGFR2-K310R/N550K mutant. Anal. using a phospho-kinase array revealed that AZD4547 blocks FGFR2 downstream signaling, such as p38, ERK1/2, JNK, p70S6K, and PLCγ. Moreover, oral administration of AZD4547 (30 mg/kg, every day) remarkably delayed tumor growth in a mouse xenograft model of AN3-CA cells. Unbiased reporter gene assay showed that AZD4547 antagonizes the aFGF-induced activation of several transcription factors, including EGR1, ELK-1/SRF, AP-1, and NFκB. Genome-wide transcriptome anal. revealed that AZD4547 perturbs a number of transcriptions, and EGR1 was identified as one of the major targets of AZD4547. The significance of the FGFR2-EGR1 axis in endometrial cancer progression has not been reported. In addition, using kinome-wide inhibition profiling anal., we first identified potential new target kinases of AZD4547, including MAP4K3, MAP4K5, IRR, RET, and FLT3. Our study demonstrated that AZD4547 exhibits its therapeutic activity against endometrial cancer cells by perturbing various regulatory mechanisms related to FGFR signaling. AB A review. TAM (Tyro3-Axl-Mer) receptor tyrosine kinases and Met are implicated in several hallmarks of cancer progression including sustained angiogenesis, enhanced motility, tissue invasion and acquisition of metastatic potential through the upregulation of epithelial-to-mesenchymal transition. Increasing evidence has confirmed Axl and Met as emerging central drivers of adaptive resistance to targeted therapies across a wide variety of cancers. In this issue of Oncogene, Zhou et al. describe the mechanisms linking Axl and Met activation to acquired resistance to sunitinib in renal cell carcinoma (RCC), providing a pre-clin. rationale for the development of Axl and Met inhibitors including cabozantinib in anti-angiogenic resistant RCC.

AB A review. Cabozantinib is an oral once-daily multitarget tyrosine kinase inhibitor of MET, VEGFR2, RET, acting against KIT, AXL, FLT3 and Tie-2. Cabozantinib has shown anti-cancer effects in preclin. and clin. models of cancers derived from both epithelial and mesenchymal origins [prostate cancer, non small lung cancer, medullary thyroid cancer (MTC) and differentiated thyroid cancer (DTC), renal cell carcinoma, etc.]. In a Phase III clin. study, cabozantinib improved PFS (11.2 mo vs. 4.0 mo in the placebo group) of patients with MTC (independently of age, bone metastases, RET status and prior treatment). Cabozantinib was approved in 2012 by FDA for metastatic MTC and in 2013 by EMA. Cabozantinib has been also evaluated in metastatic DTC patients, because they have activation on tyrosine kinases, including MET, VEGFR2 and RET, suggesting the possible use of cabozantinib in metastatic DTC. Actually, two Phase II trials of cabozantinib in DTC patients resistant to RAI are ongoing. To increase the antineoplastic effect of cabozantinib, and to overcome the occurrence of drug resistance, combination studies with other anticancer agents are ongoing. In conclusion, cabozantinib has shown to exert an important therapeutic effect in patients with MTC improving PFS. In DTC patients, cabozantinib has shown promising results.

AB Purpose: Children with high-risk neuroblastoma have poor survival rates, and novel therapies are needed. We hypothesized that cabozantinib would be effective against neuroblastoma tumor cells and tumors in preclin. models via inhibition of receptor tyrosine kinase signaling pathways. Methods: We determined neuroblastoma cell viability after treatment with cabozantinib alone and in combination with 13-cis-retinoic acid, topotecan, and temozolomide using MTT assays. Inhibition of RET and intracellular signaling was measured by Western blot anal. of treated and untreated cells. To investigate the efficacy of cabozantinib against neuroblastoma tumors in vivo, neuroblastoma cells were injected orthotopically into immunocompromised mice, and mice were treated with oral cabozantinib. Tumors were evaluated for growth by determination of in vivo luminescence and final tumor wts. Results: All neuroblastoma cell lines were sensitive to cabozantinib, and IC50 values ranged from 1.6 to 16.2 μM. Cabozantinib treatment was synergistic with 13-cis-retinoic acid and chemotherapy agents topotecan and temozolomide. Cabozantinib treatment inhibited RET phosphorylation in all cell lines and ERK phosphorylation in more sensitive neuroblastoma cell lines. In mice with neuroblastoma xenograft tumors, cabozantinib treatment significantly reduced tumor growth. Conclusions: Treatment of neuroblastoma tumor cells with cabozantinib inhibits RET and ERK phosphorylation and is effective against neuroblastoma tumor cell lines alone and in combination with 13-cis-retinoic acid, topotecan, and temozolomide. Cabozantinib treatment is also effective in reducing tumor growth in vivo. Cabozantinib therefore represents a novel therapeutic agent for neuroblastoma, and further preclin. and clin. studies are warranted.

DOCUMENT TYPE: Journal; (online computer file)

LANGUAGE: English

AB Bone metastasis remains incurable with treatment restricted to palliative care. Cabozantinib (CBZ) is targeted against multiple receptor tyrosine kinases involved in tumor pathobiol., including hepatocyte growth factor receptor (MET) and vascular endothelial growth factor receptor 2 (VEGFR-2). CBZ has demonstrated clin. activity in advanced prostate cancer with resolution of lesions visible on bone scans, implicating a potential role of the bone microenvironment as a mediator of CBZ effects. We characterised the effects of short-term administration of CBZ on bone in a range of in vivo models to determine how CBZ affects bone in the absence of tumor. Studies were performed in a variety of in vivo models including male and female BALB/c nude mice (age 6-17-wk). Animals received CBZ (30 mg/kg, 5 × weekly) or sterile H2O control for 5 or 10 days. Effects on bone integrity (μCT), bone cell activity (PINP, TRAP ELISA), osteoblast and osteoclast number/mm trabecular bone surface, area of epiphyseal growth plate cartilage, megakaryocyte nos. and bone marrow composition were assessed. Effects of longer-term treatment (15-day & 6-wk administration) were assessed in male NOD/SCID and beige SCID mice. CBZ treatment had significant effects on the bone microenvironment, including reduced osteoclast and increased osteoblast nos. compared to control. Trabecular bone structure was altered after 8 administrations. A significant elongation of the epiphyseal growth plate, in particular the hypertrophic chondrocyte zone, was observed in all CBZ treated animals irresp. of administration schedule. Both male and female BALB/c nude mice had increased megakaryocyte nos./mm2 tissue after 10-day CBZ treatment, in addition to vascular ectasia, reduced bone marrow cellularity and extravasation of red blood cells into the extra-vascular bone marrow. All CBZ-induced effects were transient and rapidly lost following cessation of treatment. Short-term administration of CBZ induces rapid, reversible effects on the bone microenvironment in vivo highlighting a potential role in mediating treatment responses.

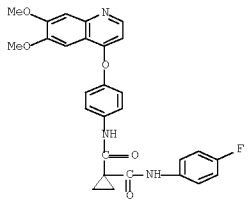
LANGUAGE: English



AB Background : There is probably significant overtreatment of patients with prostate cancer due to a lack of sufficient diagnostic tools to predict aggressive disease. Vascular endothelial growth factors (VEGFs) and their receptors (VEGFRs) are potent mediators of angiogenesis and tumor proliferation, but have been examined to a limited extent in large prostate cancer studies. Meanwhile, recent promising results on VEGFR-2 inhibition have highlighted their importance, leading to the need for further investigations regarding their expression and prognostic impact. Design : Using tissue microarray and immunohistochem., the expression of VEGFs (VEGF-A and VEGF-C) and their receptors (VEGFR-2 and VEGFR-3) were measured in neoplastic tissue and corresponding stroma from radical prostatectomy specimens in 535 Norwegian patients. Their expression was evaluated semiquantatively and assocns. with event-free survival were calculated Results : High expression of VEGFR-2 in either stroma or epithelium was independently associated with a higher incidence of prostate cancer relapse (HR = 4.56, P = 0.038). A high combined expression of either VEGF-A, VEGFR-2 or both in stroma was independently associated with a higher incidence of biochem. failure (HR = 1.77, P = 0.011). Conclusions : This large study highlights the prognostic importance of VEGF-A and VEGFR-2 stromal expression. Analyses of these biomarkers may help distinguish which patients will benefit from radical treatment. Together with previous studies showing efficiency of targeting VEGFR-2 in prostate cancer, this study highlights its potential as a target for therapy, and may aid in future selection of prostate cancer patients for novel anti-angiogenic treatment. ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Disclosed is a system and method for targeted therapy designs which model a cancer pathway for predicting the effectiveness of targeted anti-cancer drugs. The disclosed system and method includes utilization of a computer processor allowing for the selection of a set of drugs from available drugs using approximation algorithms utilizing cell viability data associated with a testable culture of a patient's tumor for generating a probabilistic target inhibition map (PTIM) from viability data for considering the selection of a set of drugs from available drugs, and further supports a wide variety of scenarios for personalized cancer therapy, related products and services.

AB A new chimeric fusion transcript of KIF5B (the kinesin family 5B gene) and the RET (Rearranged during Transcription) oncogene, KIF5B-RET, was found in 1-2 % of lung adenocarcinomas (LADCs) in 2012. Several related clin. trials for non-small cell lung cancer (NSCLC) with KIF5B-RET rearrangements using existing RET inhibitors, such as cabozantinib, lenvatinib, vandetanib, sunitinib, ponatinib, and AUY922, have been swiftly initiated by the discovery of the KIF5B-RET fusion gene. Anti-RET activity and the status of clin. development of cabozantinib for KIF5B-RET fusion-pos. NSCLC are discussed.

AB A series of novel 4-phenoxyquinoline derivs. contg. 3-amino-2-cyano-acrylamide framework was designed and synthesized, and the in vitro cytotoxic activities of them against five cancer cell lines(HT-29, H460, A549, MKN-45, and U87MG) were evaluated. Most of the compds. exhibited moderate-to-significant cytotoxicity and high selectivity against one or more cell lines as compared with Foretinib. The studies of their preliminary structure-activity relationships(SARs) indicate that the compds. containing Me groups, especially Me groups at 4-position of the Ph ring(moiety B) are more effective. Among them, compound 36 shows the most potent antitumor activities with IC50 values of 0.04, 0.09, 0.67, 0.39 and 1.10 μmol/L against HT-29, H460, A549, MKN-45 and U87MG cell lines, resp.

AB This study characterized the incidence and clin. features of oral adverse events among cancer patients who received VEGFR-directed multitargeted tyrosine kinase inhibitor (VR-TKI) therapies.Electronic medical records of adult cancer patients treated with sunitinib, sorafenib, regorafenib, pazopanib, cabozantinib, imatinib, and bevacizumab therapy at Dana-Farber Cancer Institute from 2009 to 2012 were reviewed. Data collected included patient characteristics, oral and non-oral adverse events, and time to onset. Time oral adverse event-free was the primary outcome.A total of 747 patients with 806 individual courses of therapy were treated for a median of 3.9 mo with sunitinib (n = 161), sorafenib (n = 172), regorafenib (n = 15), pazopanib (n = 132), cabozantinib (n = 23), imatinib (n = 144), or bevacizumab (n = 159) for lung cancer (21%), gastrointestinal stromal tumor (15%), and metastatic renal cell carcinoma (13%). An oral adverse event was reported in 23.7% of patients at a median of 1.9 mo after starting therapy. The most commonly reported oral adverse event was oral mucosal sensitivity (dysesthesia), occurring in 12% of patients, typically without clin. findings. Multivariate models showed patients who received VR-TKI therapy were at greater risk of any oral adverse event compared with patients treated with imatinib or bevacizumab. Patients receiving VR-TKI therapy who developed an oral adverse event were also at increased risk for hand-foot skin reaction (15.9%).VR-TKI associated oral adverse events are characterized primarily by dysesthesia with lack of clin. signs. Oral dysesthesia is more commonly associated with VR-TKIs than with bevacizumab or imatinib. Management is largely empirical and requires further investigation.

AB We investigated whether personalized dietary intervention could improve clin. measurements such as immune cell-mediated cytotoxicity, serum albumin, derivs. of reactive oxygen metabolites (D-ROMS), D-dimer, and fibrinogen. Cancer patients received either a treatment support diet (TD, for those with chemotherapy), or a remission support diet (RD; for those in remission) for at least 3 wk (21-61 days). Both diets were low glycemic, low fat, and high plant protein diets; the diet for the TD group contained an addnl. 0.5 servings of protein. Based on clin. values, addnl. amts. of garlic, onion, tomato, shiitake, rice bran, kale, blueberry, pineapples, and/or turmeric powder were provided in regular meals. Estimated daily intake of protein, plant fat, garlic, onion, allicin, and quercetin was greater in the TD compared to the RD. An increased intake of vitamin A, vitamin C, vitamin E and selenium and a reduction in D-dimer were noted compared to baseline diets in both groups. A decrease in D-ROMS in the RD and an increase in albumin and an increased tendency in cytotoxicity in the TD were observed In conclusion, personalized diets with supplemented functional ingredients improved antioxidant status and/or anticoagulant activity in cancer patients undergoing chemotherapy and in remission.

AB Oncogenic ROS1 fusion proteins are mol. drivers in multiple malignancies, including a subset of non-small cell lung cancer (NSCLC). The phylogenetic proximity of the ROS1 and anaplastic lymphoma kinase (ALK) catalytic domains led to the clin. repurposing of the Food and Drug Administration (FDA)-approved ALK inhibitor crizotinib as a ROS1 inhibitor. Despite the antitumor activity of crizotinib observed in both ROS1- and ALK-rearranged NSCLC patients, resistance due to acquisition of ROS1 or ALK kinase domain mutations has been observed clin., spurring the development of second-generation inhibitors. Here, we profile the sensitivity and selectivity of seven ROS1 and/or ALK inhibitors at various levels of clin. development. In contrast to crizotinib's dual ROS1/ALK activity, cabozantinib (XL-184) and its structural analog foretinib (XL-880) demonstrate a striking selectivity for ROS1 over ALK. Mol. dynamics simulation studies reveal structural features that distinguish the ROS1 and ALK kinase domains and contribute to differences in binding site and kinase selectivity of the inhibitors tested. Cell-based resistance profiling studies demonstrate that the ROS1-selective inhibitors retain efficacy against the recently reported CD74-ROS1G2032R mutant whereas the dual ROS1/ALK inhibitors are ineffective. Taken together, inhibitor profiling and stringent characterization of the structure-function differences between the ROS1 and ALK kinase domains will facilitate future rational drug design for ROS1- and ALK-driven NSCLC and other malignancies.

AB Altiratinib (DCC-2701) was designed based on the rationale of engineering a single therapeutic agent able to address multiple hallmarks of cancer (1). Specifically, altiratinib inhibits not only mechanisms of tumor initiation and progression, but also drug resistance mechanisms in the tumor and microenvironment through balanced inhibition of MET, TIE2 (TEK), and VEGFR2 (KDR) kinases. This profile was achieved by optimizing binding into the switch control pocket of all three kinases, inducing type II inactive conformations. Altiratinib durably inhibits MET, both wild-type and mutated forms, in vitro and in vivo. Through its balanced inhibitory potency vs. MET, TIE2, and VEGFR2, altiratinib provides an agent that inhibits three major evasive (re)vascularization and resistance pathways (HGF, ANG, and VEGF) and blocks tumor invasion and metastasis. Altiratinib exhibits properties amenable to oral administration and exhibits substantial blood-brain barrier penetration, an attribute of significance for eventual treatment of brain cancers and brain metastases. AB C-MET is a receptor tyrosine kinase and potential oncol. target for cancer therapy. The activities of 1,2,3-triazolo[4,5-b]pyrazine series of c-MET inhibitors were analyzed according to the three-dimensional quant. structure-activity relationship and mol. docking methods. The results indicated that the hydrophobic and electrostatic fields play key roles in activity and QSAR model was reliable enough for activity prediction. Moreover, the docking results do validate the predicted 3D-QSAR scores, vital residues Asp1222, Asp1231, Met1160, Tyr1259 and Tyr1230 found in binding site. Four new c-MET inhibitor analogs designed in this Letter which are being currently synthesized by our labs.

AB The invention relates to a stable water-in-oil emulsion compn. contg.: 20% to 40% (volume/volume) aqueous phase in the form of droplets and containing an anti-cancer agent; and 60% to 80% (volume/volume) lipid phase containing an iodized oil and at least one surfactant, having formula I, in a proportion, of surfactant mass relative to the total volume of the composition, of 0.3% to 5%, formula II for said surfactant being the following in which: s has a value of 0 or 1; m is a whole number from 2 to 30; R1 is a formula I grouping wherein n is a whole number from 4 to 10, o is a whole number from 1 to 4, p is a whole number from 3 to 7; q is a whole number from 2 to 10, and r has a value of 0 or 1; R2 is a hydrogen atom or is identical to R1; and each R3 is, sep., a hydrogen atom or is identical to R1. The invention also relates to an emulsion obtained from said composition, to the preparing method thereof, and to the use thereof for treating cancer and the metastases thereof. An emulsion containing 50 mg doxorubicin, 1% PGPR in Lipidol, and 2.5 mL Xenetix 250 was prepared

AB Mutations in the MET exon 14 RNA splice acceptor and donor sites, which lead to exon skipping, deletion of the juxtamembrane domain containing the CBL E3-ubiquitin ligase-binding site, and decreased turnover of the resultant aberrant MET protein, were previously reported to be oncogenic in preclin. models. We now report responses to the MET inhibitors crizotinib and cabozantinib in four patients with stage IV lung adenocarcinomas harboring mutations leading to MET exon 14 skipping, highlighting a new therapeutic strategy for the 4% of lung adenocarcinoma patients whose tumors harbor this previously underappreciated genetic alteration. Significance: Oncogenic mutations in the MET exon 14 splice sites that cause exon 14 skipping occur in 4% of lung adenocarcinomas. We report responses to the MET inhibitors crizotinib and cabozantinib in patients with lung adenocarcinomas harboring MET exon 14 splice site mutations, identifying a new potential therapeutic target in this disease. Cancer Discov; 5(8); 842-9. ©2015 AACR. See related commentary by Ma, p. 802. See related article by Frampton et al., p. 850. This article is highlighted in the In This Issue feature, p. 783.

AB Cabozantinib is a small-mol. tyrosine kinase inhibitor that has been approved for the treatment of patients with progressive, metastatic medullary thyroid cancer. In vitro data indicate that (1) cytochrome P 450 (CYP) 3A4 is the primary CYP isoenzyme involved in the metabolism of cabozantinib, and (2) CYP2C8 is the CYP isoenzyme most potently inhibited by cabozantinib with potential for in vivo inhibition at clin. relevant plasma exposures. Pharmacokinetic (PK) drug-drug interactions (DDIs) were evaluated clin. between cabozantinib and (1) a CYP3A inducer (rifampin) in healthy volunteers, (2) a CYP3A inhibitor (ketoconazole) in healthy volunteers, and (3) a CYP2C8 substrate (rosiglitazone) in patients with solid tumors. Compared with cabozantinib given alone, coadministration with rifampin resulted in a 4.3-fold higher plasma clearance (CL/F) of cabozantinib and a 77% decrease in cabozantinib plasma AUC0-inf, whereas coadministration with ketoconazole decreased cabozantinib CL/F by 29% and increased cabozantinib AUC0-inf by 38%. Chronic coadministration with cabozantinib resulted in no significant effect on rosiglitazone plasma Cmax, AUC0-24, or AUC0-inf. In summary, chronic use of strong CYP3A inducers and inhibitors should be avoided when cabozantinib is administered, and cabozantinib at clin. relevant exposures is not anticipated to markedly affect the PK of concomitant medications via CYP enzyme inhibition.

AB Small-mol. kinase inhibitors (SMKIs), 28 of which are approved by the US Food and Drug Administration (FDA), have been actively pursued as promising targeted therapeutics. Here, we assess the key structural and physicochem. properties, target selectivity and mechanism of function, and therapeutic indications of these approved inhibitors. Our anal. showed that >30% of approved SMKIs have a mol. weight (MW) exceeding 500 and all have a total ring count of between three and five. The assumption that type II inhibitors tend to be more selective than type I inhibitors has been proved to be unreliable. Although previous SMKI research was concentrated on tyrosine kinase inhibitors for cancer treatment, recent progress indicates diversification of SMKI research in terms of new targets, mechanistic types, and therapeutic indications.

AB Cabozantinib is a multi-targeted tyrosine kinase inhibitor targeting vascular endothelial growth factor (VEGF) receptor (VEGFR)-2, MET (c-Met, also called hepatocyte growth factor (HGF) receptor), and other receptor tyrosine kinases. Cabozantinib has recently been approved for treating advanced medullary thyroid carcinoma (MTC), but its long-term benefit remains uncertain and dose-dependent adverse events are very common. The present study has demonstrated that 2-methoxyestradiol (2ME2), an inhibitor of hypoxia-inducible factors (HIFs) and a promising anticancer agent under investigation in clin. trials, strengthens anticancer activities of cabozantinib against MTC cells in vitro and in vivo. The activated hypoxia-inducible pathways, which are mainly regulated by HIF-1, contribute to the resistance of hypoxic MTC cells to cabozantinib. Cabozantinib upregulated HIF-1α expression at translational levels and increased the expression of the downstream factors including VEGF, lactate dehydrogenase A (LDHA), HGF, and MET. 2ME2 corrected the activated pathways by cabozantinib through downregulating HIF-1α expression and inhibiting its nuclear translocation in hypoxic MTC cells. Administration of 2ME2 enhanced the efficacy of cabozantinib in suppressing the growth of MTC cell line xenografts and patient-derived xenografts established in mice. Given that 2ME2 targets insensitive hypoxic cancer cells to cabozantinib and can inhibit the activated pathways by cabozantinib, the present results warrant further investigation of 2ME2, particularly in combination with cabozantinib, for the treatment of MTC.

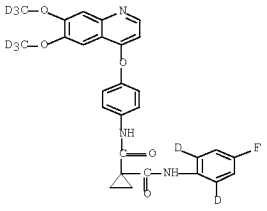
I



AB The invention is related to the prepn. of deuterated cabozantinib derivs. I and their application as anticancer agents. The invention compound I, wherein R1, R2, R3, R4, R5, R6, R7, R8, R9, R10, R11, R12, R13, R14, R15, R16, R17, R18, R19, R20, R21, and R22 are H or D independently and contain at least one D and their pharmaceutically acceptable salts, crystalline hydrates, solvates, prodrugs, single crystal or polymorph are claimed. Compound I was prepared by multi-step procedure (procedure given). The deuterated cabozantinib derivs. have slow decomposition in vivo, thereby reducing adverse metabolism of drugs. The invention compds. were evaluated for their anticancer activity.

AB Background and Objectives: Cabozantinib is a tyrosine kinase inhibitor approved in the USA and EU for the treatment of patients with progressive, metastatic medullary thyroid cancer (MTC). The indicated cabozantinib dose is 140 mg/day, with dose modifications allowed for patients who develop adverse events (AEs). The anal. objective was to develop a population pharmacokinetic (PopPK) model in MTC patients and to use the model for exposure-response (ER) anal. of dose modifications. Methods: A PopPK model for cabozantinib was developed using data from three clin. trials (2079 evaluations from 289 patients), including a randomized, double-blind, placebo-controlled phase III study of patients with progressive, metastatic MTC. The PopPK model predictions [model-predicted steady-state area under the plasma concentration-time curve (AUCss,pred)] were used for an ER anal. of the time to first dose modification. Results: The final PopPK model was a one-compartment model with first-order absorption and first-order elimination. Estimated cabozantinib apparent oral clearance (CL/F) and apparent volume of distribution (Vc/F) were 106 L/day [±2.98 % relative standard error (RSE)] (males) and 349 L (±2.73 % RSE), resp. CL/F was reduced by 22 % (to 83 L/day) in females. Sex and body mass index (BMI) were significant covariates that combined contributed 15 % to the variability in cabozantinib CL/F, but did not warrant dose adjustment. Higher cabozantinib AUCss,pred was correlated to an increased risk of early dose modification and a lower average dose through to Day 85. Early cabozantinib dose modification was not associated with a reduction in progression-free survival (PFS). Conclusion: A PopPK model was developed for cabozantinib pharmacokinetics in MTC patients. Higher cabozantinib exposure was associated with earlier first dose modification and a lower average administered dose through to Day 85. Early first dose modification did not appear to impact PFS.

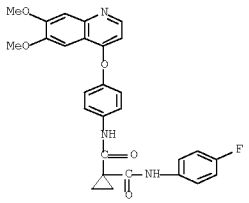
I



II

AB This invention features compds. of formula I that modulate the activity of liver X receptors, pharmaceutical compns. including the compds. of the invention, and methods of utilizing those compns. for modulating the activity of liver X receptors in the treatment of cancer. Compds. of formula I wherein A is substituted Ph, (un)substituted azacyclyl, and (un)substituted oxobenzopyranyl; L is absent, O, S, amino and CR4R5; m is 2, 3, 4, 5, 6, 7 and 8;, n, p and q are independently 0 and 1; R1, R2, R6, R7, R8 and R9 are independently H, OH, halo, amino, thio, etc.; R3 is H, OH, amino, (un)substituted Cl-6 alkyl, etc.; R4 and R6 are independently H, OH, halo, amino, thio, etc.; and pharmaceutically acceptable salts and prodrugs thereof, are claimed. Example compound II was prepared by reductive amination of 2-chloro-3-trifluoromethylbenzaldehyde with 2,2-diphenethylamine followed by alkylation with 1,3-dibromopropane; the resulting (3-bromopropyl)({[2-chloro-3-(trifluoromethyl)phenyl]methyl})(2,2-diphenylethyl)amine underwent etherification with Me 3-hydroxyphenylacetate to give Me 2-{3-[3-({[2-chloro-3-(trifluoromethyl)phenyl]methyl}-(2,2-diphenylethyl)- amino)-propoxy]phenyl}acetate, which underwent amidation with hydroxylamine hydrochloride to give compound II. The invention compds. were evaluated for their LXR agonistic activity. From the assay it was determine that compound exhibited ApoE induction . 80% at 1 μM and > 40 % at 10 μM, and EC50 value of 1.0 μM.

AB Background: Gastric cancer (GC) is a major global cancer burden and the second most common cause of global cancer-related deaths. The addition of anti-ERBB2 (HER2) targeted therapy to chemotherapy improves survival for ERBB2-amplified advanced GC patients; however, the majority of GC patients do not harbor this alteration and thus cannot benefit from targeted therapy under current practice paradigms. Materials and Methods: Prospective comprehensive genomic profiling of 116 predominantly locally advanced or metastatic (90.0%) gastric cancer cases was performed to identify genomic alterations (GAs) associated with a potential response to targeted therapies approved by the U.S. Food and Drug Administration or targeted therapy-based clin. trials. Results: Overall, 78% of GC cases harbored one clin. relevant GA or more, with the most frequent alterations being found in TP53 (50%), ARID1A (24%), KRAS (16%), CDH1 (15%), CDKN2A (14%), CCND1 (9.5%), ERBB2 (8.5%), PIK3CA (8.6%), MLL2 (6.9%), FGFR2 (6.0%), and MET (6.0%). Receptor tyrosine kinase genomic alterations were detected in 20.6% of cases, primarily ERBB2, FGFR2, and MET amplification, with ERBB2 alterations evenly split between amplifications and base substitutions. Rare BRAF mutations (2.6%) were also observed One MET-amplified GC patient responded for 5 mo to crizotinib, a multitargeted ALK/ROS1/MET inhibitor. Conclusion: Comprehensive genomic profiling of GC identifies clin. relevant GAs that suggest benefit from targeted therapy including MET-amplified GC and ERBB2 base substitutions.

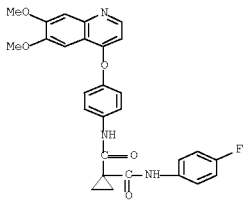
DOCUMENT TYPE: Journal; (online computer file)

LANGUAGE: English



AB Metab. and excretion of cabozantinib, an oral inhibitor of receptor tyrosine kinases, was studied in 8 healthy male volunteers after a single oral dose of 175 mg cabozantinib l-malate containing 14C-cabozantinib (100 μCi/subject). Total mean radioactivity recovery within 48 days was 81.09%; radioactivity was eliminated in feces (53.79%) and urine (27.29%). Cabozantinib was extensively metabolized with 17 individual metabolites identified by liquid chromatog.-tandem mass spectrometry (LC-MS/MS) in plasma, urine, and feces. Relative plasma radioactivity exposures (analyte AUC0-t/total AUC0-t for cabozantinib + major metabolites) were 27.2, 25.2, 32.3, 7, and 6% for cabozantinib and major metabolites monohydroxy sulfate (EXEL-1646), 6-desmethyl amide cleavage product sulfate (EXEL-1644), N-oxide (EXEL-5162), and amide cleavage product (EXEL-5366), resp. Comparable relative plasma exposures determined by LC-MS/MS anal. were 32.4, 13.8, 45.9, 4.9, and 3.1%, resp. These major metabolites each possess in vitro inhibition potencies ≤1/10th of parent cabozantinib against the targeted kinases MET, RET, and VEGFR2/KDR. In an in vitro cytochrome P 450 (CYP) panel, cabozantinib and EXEL-1644 both inhibited most potently CYP2C8 (Kiapp = 4.6 and 1.1 μM, resp.). In an in vitro drug transporter panel, cabozantinib inhibited most potently MATE1 and MATE2-K (IC50 = 5.94 and 3.12 μM, resp.) and was a MRP2 substrate; EXEL-1644 inhibited most potently OAT1, OAT3, OATP1B1, MATE1, and OATP1B3 (IC50 = 4.3, 4.3, 6.1, 16.7, and 20.6 μM, resp.) and was a substrate of MRP2, OAT3, OATP1B1, OATP1B3, and possibly P-gp. Therefore, cabozantinib appears to be the primary pharmacol. active circulating analyte, whereas both cabozantinib and EXEL-1644 may represent potential for drug-drug interactions.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A biomarker for predicting and/or monitoring the efficacy of a c-Met inhibitor; a composition for predicting and/or monitoring the efficacy of a c-Met inhibitor, comprising a material detecting the biomarker; a composition for selecting a subject suitable for the application of a c-Met inhibitor, comprising a material detecting the biomarker is presented. In addition a method for predicting and/or monitoring the efficacy of a c-Met inhibitor using the biomarker; a method for selecting a subject suitable for the application of a c-Met inhibitor using the biomarker; and a method for preventing and/or treating cancer comprising administering a c-Met inhibitor to the selected subject is given. One embodiment provides a biomarker for use in predicting and/or monitoring the therapeutic effect of a c-Met inhibitor or selecting a subject suitable for the application of a c-Met inhibitor, wherein the biomarker includes at least one selected from the group consisting of IL-8, BIGH3, or MIF and nucleic acids encoding the proteins. Another embodiment provides a c-Met inhibitor or a pharmaceutical composition including a c-Met inhibitor, for use in inhibiting c-Met and/or treating a cancer in a subject, wherein the subject has a high level of IL-8 or a nucleic acid encoding IL-8 compared to a reference sample in which a c-Met inhibitor is not effective; shows a decreased level of IL-8, BIGH3, MIF, and/or nucleic acids encoding them after administering a c-Met inhibitor; and/or has a mutation of KRAS, BRAF, and/or nucleic acids encoding them. A specific example shows the IL-8 levels in cancer cell-implanted mouse models showing relationship between IL-8 level and responsiveness to an anti-c-Met antibody.

AB The current std. treatment option for advanced hepatocellular carcinoma (HCC) is sorafenib, but its clin. benefit is modest. In spite of many attempts, few drugs can provide any significant improvement of survival as the first- or second-line therapy of choice in phase III randomized controlled trials. Recently, the subgroup anal. of a phase II randomized controlled trial has shown that tivantinib, a selective MET inhibitor, can significantly improve the overall survival in patients with MET-pos. advanced HCC after the failure or intolerance of a prior systemic therapy. These findings enlighten the role of MET inhibitors in the treatment of advanced HCC. In this paper, we review all ongoing and completed clin. trials regarding this topic. As for the first-line therapy of advanced HCC, INC280 and foretinib are being evaluated in 2 phase II single-arm trials; and MSC2156119J and golvatinib plus sorafenib are being compared with sorafenib alone in 2 phase II randomized controlled trials. As for the second-line therapy of advanced HCC, tivantinib and cabozantinib are being compared with placebo in 2 phase II randomized controlled trials.

AB Context: Many tyrosine kinase inhibitors (TKIs) have been studied in patients with thyroid carcinoma (TC). However, the effect and toxicity of various TKIs in differentiated TC (DTC) and medullary TC (MTC) patients have not been directly compared. The aim of the present systematic review and meta-anal. was to systematically summarize response and toxicity of TKIs in TC patients. Methods: All major databases were systematically searched for publications on TKIs in TC. Primary endpoint was objective response; secondary endpoints were clin. benefit, percentage TKI dose reduction/discontinuation, hand-foot syndrome, diarrhea, and nausea/vomiting. Meta-anal. was performed using an exact likelihood approach and a logistic regression. Pooled percentages and 95% CIs were reported. Results: In total, 22 publications were included. For DTC patients, gefitinib induced no objective responses. Pooled percentage was highest for pazopanib, 49 (95% CI 33-64)%, and was 17 (95% CI 12-24)% for sorafenib. For MTC, gefitinib and imatinib induced no objective responses, whereas sunitinib induced objective response in 43 (95% CI 14-77)%. For vandetanib and cabozantinib, these nos. were 40 (95% CI 34-46)% and 27 (95% CI 22-32)% resp. Clin. benefit was found in 53 (95% CI 48-59)% of DTC patients on sorafenib, and in 84 (95% CI 79-88)% and 55 (95% CI 49-61)% of MTC patients on vandetanib and cabozantinib resp. All TKIs were associated with considerable toxicity. Conclusion: The currently studied TKIs show a modest response, while side effects are not negligible. Therefore, we suggest to solely consider TKIs in TC patients with rapid progressive disease, for whom the benefits of treatment outweigh toxicity.

AB This invention relates to heterocyclic modulators of lipid synthesis as well as pharmaceutically acceptable salts thereof; to pharmaceutical compns. comprising such compds.; and to methods of treating conditions characterized by dysregulation of a fatty acid synthase pathway by the administration of such compds. and combinations of such compds. and other therapeutic agents. Method of treating a condition characterized by dysregulation of a fatty acid synthase pathway in a subject by administering to the subject a therapeutically effective amount of compound I [LAr = II-IV; Ar = V-IX (wherein Het = 5-6 membered heteroaryl; R1 = H, CN, halo, etc.; R2 = H, halo, alkyl; R3 = H or F; R11 = H or Me); R21 = H, halo, alkyl, etc.; R22 = H, halo, alkyl; R24 = H, CN, alkyl, etc.; R25 = halo, CN, alkyl, etc.], in combination with other therapeutic agent, was claimed. Over three-hundred-eighty compds. I and their heterocyclic analogs were prepared E.g., a multi-step synthesis of X, starting from tert-Bu 4-iodopiperidine-1-carboxylate and 4-bromobenzonitrile, was described. The antiviral activities of the exemplified compds. I were assessed using the HCV1b replicon system (data given).

AB Context: The aberrant silencing of iodide-handling genes accompanied by up-regulation of glucose metabolism presents a major challenge for

radioiodine treatment of papillary thyroid cancer (PTC). Objective: This study aimed to evaluate the effect of tyrosine kinase inhibitors on iodide-handling and glucose-handling gene expression in BHP 2-7 cells harboring RET/PTC1 rearrangement. Main Outcome Measures: In this in vitro study, the effects of sorafenib or cabozantinib on cell growth, cycles, and apoptosis were investigated by cell proliferation assay, cell cycle anal., and Annexin V-FITC apoptosis assay, resp. The effect of both agents on signal transduction pathways was evaluated using the Western blot. Quant. real-time PCR, Western blot, immunofluorescence, and radioisotope uptake assays were used to assess iodide-handling and glucose-handling gene expression. Results: Both compds. inhibited cell proliferation in a time-dependent and dose-dependent manner and caused cell cycle arrest in the G0/G1 phase. Sorafenib blocked RET, AKT, and ERK1/2 phosphorylation, whereas cabozantinib blocked RET and AKT phosphorylation. The restoration of iodide-handling gene expression and inhibition of glucose transporter 1 and 3 expression could be induced by either drug. The robust expression of sodium/iodide symporter induced by either agent was confirmed, and 125I uptake was correspondingly enhanced. 18F-fluorodeoxyglucose accumulation was significantly decreased after treatment by either sorafenib or cabozantinib. Conclusions: Sorafenib and cabozantinib had marked effects on cell proliferation, cell cycle arrest, and signal transduction pathways in PTC cells harboring RET/PTC1 rearrangement. Both agents could be potentially used to enhance the expression of iodide-handling genes and inhibit the expression of glucose transporter genes.

LANGUAGE: English

AB We previously reviewed the cardiovascular safety of 16 tyrosine kinase inhibitors (TKIs), approved for use in oncol. as of 30 Sept. 2012. Since then, the indications for some of them have been widened and an addnl. nine TKIs have also been approved as of 30 Apr. 2015. Eight of these nine are indicated for use in oncol. and one (nintedanib) for idiopathic pulmonary fibrosis. This report is an update on the cardiovascular safety of those 16 TKIs, including the post-marketing data concerning their pro-arrhythmic effects, and reviews the cardiovascular safety of the nine new TKIs approved since (afatinib, cabozantinib, ceritinib, dabrafenib, ibrutinib, lenvatinib, nintedanib, ponatinib, and trametinib). As before, we focus on specific aspects of cardiovascular safety, namely their potential to induce QT interval prolongation, left ventricular (LV) dysfunction and hypertension but now also summarise the risks of arterial thromboembolic events (ATEs) associated with these agents. Of the newer TKIs, cabozantinib and ceritinib have been shown to induce a mild to moderate degree of QTc interval prolongation while cardiac dysfunction has been reported with the use of afatinib, dabrafenib, lenvatinib, ponatinib and trametinib. The label for axitinib was revised to include a new association with cardiac dysfunction. Hypertension is associated with cabozantinib, lenvatinib, nintedanib, ponatinib and trametinib. Ponatinib, within 10 mo of its approval in Dec. 2012, required voluntary (temporary) suspension of its marketing until significant safety revisions (restricted indication, addnl. warnings and precautions about the risk of arterial occlusion and thromboembolic events and amended dose) were made to its label. Compared with the previous 16 TKIs,

more of the recently introduced TKIs are associated with the risk of LV dysfunction, and fewer with QT prolongation. Available data on morbidity and mortality associated with TKIs, together with post-marketing experience with lapatinib and ponatinib, emphasize the need for effective pharmacovigilance and ongoing re-assessment of their risk/benefit after approval of these novel agents. If not adequately managed, these cardiovascular effects significantly decrease the quality of life and increase the morbidity and mortality in a population already at high risk. Evidence accumulated over the last decade suggests that their clin. benefit, although worthwhile, is modest and extends only to progression-free survival and complete response without any effect on overall survival. During uncontrolled use in routine clin. practice, their risk/benefit is likely to be inferior to that perceived from highly controlled clin. trials.

AB The invention relates to aminopyridine compds. of formula I, their pharmaceutically acceptable salts, and pharmaceutical formulations, which is used for regulating protein kinase activity, and adjusting signal response within cells or between cells. The invention also relates to compds. I and their stereoisomer, tautomers, nitrogen oxides, solvates, metabolites, pharmaceutically acceptable salts or prodrugs which are used in treating mammal, particularly to human hyperproliferative disorders. The pharmaceutical compns. includes the title compds., pharmaceutically acceptable carriers, excipients, diluents, adjuvants, and/or mediums, and other treating agents. The pharmaceutical compns. are used in preparing medicines for preventing, handling, treating or relieving proliferative disorders such as metastatic cancer, colon cancer, gastric adenocarcinoma, bladder cancer, breast cancer, kidney cancer, liver cancer, lung cancer, thyroid cancer, head and neck cancer, prostate cancer, pancreatic cancer, central nervous system cancer, spongioblastoma, bone marrow hyperplasia, atherosclerosis or pulmonary fibrosis. Compds. of formula I wherein R1- R6 are independently H, D or F; X, Y are independently (un)substituted C6-10 aryl, (un)substituted C5-10 heteroaryl; W is C3-8 cycloalkyl, -(C1-4 alkylene)-(C3-8 cycloalkyl), C3-7 heterocyclyl or -(C1-4 alkylene)-(C3-7 heterocyclyl), etc.; and their stereoisomer, tautomers, nitrogen oxides, solvates, metabolites, pharmaceutically acceptable salts or prodrugs as protein kinase receptor inhibitors useful in the treatment of proliferative disorders thereof, are claimed. Compds. of formula I were prepared by using condensation, reduction, and cross-coupling as the key steps. All the invention compds. were evaluated for their protein kinase inhibitory activity.

AB Targeted therapy is a rational and promising strategy for the treatment of advanced cancer. For the development of clin. agents targeting oncogenic signaling pathways, it is important to define the specificity of compds. to the target mol. pathway. Genome-wide transcriptomic anal. is an unbiased approach to evaluate the compound mode of action, but it is still unknown whether the anal. could be widely applicable to classify molecularly targeted anticancer agents. We comprehensively obtained and analyzed 129 transcriptomic datasets of cancer cells treated with 83 anticancer drugs or related agents, covering most clin. used, molecularly targeted drugs alongside promising inhibitors of mol. cancer targets. Hierarchical clustering and principal component anal. revealed that compds. targeting

similar target mols. or pathways were clustered together. These results confirmed that the gene signatures of these drugs reflected their modes of action. Of note, inhibitors of oncogenic kinase pathways formed a large unique cluster, showing that these agents affect a shared mol. pathway distinct from classical antitumor agents and other classes of agents. The gene signature anal. further classified kinome-targeting agents depending on their target signaling pathways, and we identified target pathway-selective signature gene sets. The gene expression anal. was also valuable in uncovering unexpected target pathways of some anticancer agents. These results indicate that comprehensive transcriptomic anal. with our database (http://scads.jfcr.or.jp/db/cs/) is a powerful strategy to validate and re-evaluate the target pathways of anticancer compds.

AB A review. Cabozantinib is a receptor tyrosine kinase inhibitor with activity against MET, VEGFR2, FLT3, c-KIT, and RET. Activity of cabozantinib toward a broad range of tumor models could be detected in several preclin. studies. Of note, cabozantinib decreases metastasis potential and tumor invasiveness when compared with placebo or agents that target VEGFR and have no activity against MET. Clin. phase I and II studies with cabozantinib have been conducted in various malignancies including medullary thyroid cancer (MTC), NSCLC, breast, ovarian, pancreatic, and prostate cancer. In MTC, gain of function mutations of RET are central for tumorigenesis. Hereditary forms of MTC (MEN II) are caused by germline mutations of RET, in sporadic MTC in up to 50 % of cases RET mutations occur. Addnl., activating mol. changes in VEGFR and MET pathways have also been implicated in MTC progression. Clin. responses with cabozantinib in MTC could be observed in early clin. trials, and following confirmation of clin. benefit in a randomized phase III trial, cabozantinib gained FDA approval for first-line treatment of advanced MTC in 2012. In prostate cancer models, MET expression increases with androgen ablation and clin. progression of bone and lymph node metastasis. A phase II trial with cabozantinib also showed very promising response rates in patients with metastatic prostate cancer. Therefore, randomized phase III studies are currently ongoing to validate the efficacy of cabozantinib in heavily pretreated prostate cancer patients.

AB These findings offer a preclin. rationale to immediately reposition the MET kinase inhibitor cabozantinib for clin. evaluation in treatment of gastrointestinal stromal tumors that are either sensitive or resistant to imatinib, the kinase inhibitor used to treat this type of sarcoma. Gastrointestinal stromal tumors (GIST) are the most common adult sarcomas and the oncogenic driver is usually a KIT or PDGFRA mutation. Although GISTs are often initially sensitive to imatinib or other tyrosine kinase inhibitors, resistance generally develops, necessitating backup strategies for therapy. In this study, we determined that a subset of human GIST specimens that acquired imatinib resistance acquired expression of activated forms of the MET oncogene. MET activation also developed after imatinib therapy in a mouse model of GIST (KitV558del/+ mice), where it was associated with increased tumor hypoxia. MET activation also occurred in imatinib-sensitive human GIST cell lines after imatinib treatment in vitro. MET inhibition by crizotinib or RNA interference was cytotoxic to an imatinib-resistant human GIST cell population. Moreover, combining crizotinib and imatinib was more effective than imatinib alone in imatinib-sensitive GIST models. Finally, cabozantinib, a dual MET and KIT small-mol. inhibitor, was markedly more effective than imatinib in multiple preclin. models of imatinib-sensitive and imatinib-resistant GIST. Collectively, our findings showed that activation of compensatory MET signaling by KIT inhibition may contribute to tumor resistance. Furthermore, our work offered a preclin. proof of concept for MET inhibition by cabozantinib as an effective strategy for GIST treatment. Cancer Res; 75(10); 2061-70. ©2015 AACR.

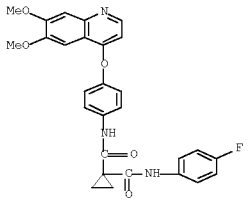
AB A centrifugal mixing device can include a shaft assembly that is operably coupled to a motor such that the motor rotates the shaft assembly about a first axis. The devices can further include a turret that is rotatably coupled to the shaft assembly such that the turret rotates about the first axis relative to the shaft assembly. The turret can include a first support,



a first canister rotatably coupled to the first support such that the first canister rotates about a second axis, and a second canister rotatably coupled to the first support such that the second canister rotates about a third axis. The turret is configured to rotate about the first axis in a first rotational direction and each of the first and second canisters is configured to rotate about the second and third axes, resp., in a second rotational direction that is opposite the first rotational direction. The centrifugal mixing device consists of the canisters comprising at least 2 different particulate materials. The particulate materials comprises an active pharmaceutical ingredient.

AB The no. of thyroid cancers is increasing. Std. treatment usually includes primary surgery, TSH suppressive therapy, and ablation of the thyroid remnant with radioactive iodine (RAI). Despite the generally good prognosis of thyroid carcinoma, about 5% of patients will develop metastatic disease, which fails to respond to RAI, exhibiting a more aggressive behavior. The lack of specific, effective and well-tolerated drugs, the scarcity of data about the association of multi-targeting drugs, and the limited role of radioiodine for dedifferentiated thyroid cancer, call for further efforts in the field of new drugs development. Rearranged during transfection (RET)/papillary thyroid carcinoma gene rearrangements, BRAF (B-RAF proto-oncogene, serine/threonine kinase) gene mutations, RAS (rat sarcoma) mutations, and vascular endothelial growth factor receptor 2 angiogenesis pathways are some of the known pathways playing a crucial role in the development of thyroid cancer. Targeted novel compds. have been demonstrated to induce clin. responses and stabilization of disease. Sorafenib has been approved for differentiated thyroid cancer refractory to RAI.

AB The present invention relates to a method for the prognosis of bone metastasis in HER2+ breast cancer, which comprises determining if the MAF gene is amplified in a primary tumor sample. Likewise, the present invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise determining the MAF gene expression level, amplification or translocation. The present invention also relates to a method for predicting early bone metastasis in a subject suffering breast cancer. The present invention also relates to a c-Maf inhibitor as therapeutic agent for use in the treatment of HER2+ breast cancer metastasis. The present invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the present invention relates to a method for typing of a subject suffering breast cancer and for classifying a subject from breast cancer into a cohort.

AB Background : The dermatol. adverse events (AEs) of various molecularly targeted therapies are well-described in adult cancer patients. Little has been reported on the incidence and clin. presentation of such AEs in pediatric patients with cancer. To address this gap, we analyzed the dermatol. AEs reported across clin. trials of targeted anticancer therapies in pediatric patients. Procedures : We conducted an electronic literature search (PubMed, American Society of Clin. Oncol. annual meetings' abstrs., , NCI's Pediatric Oncol. Branch webpage) to identify clin. trials involving targeted anticancer therapies that reported dermatol. AEs in their safety data. Studies were limited to the pediatric population, monotherapy trials (oncol.), and English language publications. Results : Pooled data from 19 clin. studies investigating 11 targeted anticancer agents (alemtuzumab, rituximab, imatinib, dasatinib, erlotinib, vandetanib, sorafenib, cabozantinib, pazopanib, everolimus, and temsirolimus) were analyzed. The most frequently encountered dermatol. AEs were rash (127/660; 19%), xerosis (18/100; 18%), mucositis (68/402; 17%), and pruritus (12/169; 7%). Other AEs included pigmentary abnormalities of the skin/hair (13%), hair disorders (trichomegaly, hypertrichosis, alopecia, and madarosis; 14%), urticaria (7%), palmoplantar erythrodysesthesia (7%), erythema, acne, purpura, skin fissures, other 'unknown skin changes', exanthem, infection, flushing, telangiectasia, and photosensitivity. Conclusion : This study describes the dermatol. manifestations of targeted anticancer therapy-related AEs in the pediatric population. Since these AEs are often associated with significant morbidity, it is imperative that pediatric oncologists be familiar with their recognition and management, to avoid unnecessary dose modifications and/or termination, and to prevent impairments in patients' quality of life. AB The present invention provides novel substituted pyridine compds. of general formula I (wherein each of R1, R2, R3, R4, R5 and R6 is independently H, D or F; each of X and Y is independently C6-10aryl or 5-10 membered heteroaryl, both optionally substituted; W is C3-8cycloalkyl, -(C1-4-alkylene)(C3-8cycloalkyl), C3-7heterocyclyl or -(C1-4-alkylene)-C3-7heterocyclyl, each optionally substituted), pharmaceutical acceptable salts and formulations thereof useful in modulating protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans. Example compound II was prepared in a 4-step synthesis that involved reaction of intermediate tert-Bu 4-(5-bromopyridin-2-yl)piperazine-1-carboxylate with III, and deprotecting the intermediate formed. The stability of the example compds. in human and rat liver microsomes, their pharmacokinetic profile in rats, and their ALK kinase and c-met kinase inhibitory activities were measured.

AB Purpose: The increasing prevalence of distant metastases from non-small cell lung cancer (NSCLC) indicates an urgent need for novel therapeutic modalities. Brain metastasis is particularly common in NSCLC, with severe adverse effects on clin. prognosis. Although the mol. heterogeneity of NSCLC and availability of various targeted agents suggest personalized therapeutic approaches for such brain metastases, further development of appropriate preclin. models is needed to validate the strategies. Exptl. Design: We established patient-derived xenografts (PDX) using NSCLC brain metastasis surgical samples and elucidated their possible preclin. and clin. implications for personalized treatment. Results: NSCLC brain metastases (n = 34) showed a significantly higher successful PDX establishment rate than primary specimens (n = 64; 74% vs. 23%). PDXs derived from NSCLC brain metastases recapitulated the pathol., genetic, and functional properties of corresponding parental tumors. Furthermore, tumor spheres established in vitro from the xenografts under serum-free conditions maintained their in vivo brain metastatic potential. Differential phenotypic and mol. responses to 20 targeted agents could subsequently be screened in vitro using these NSCLC PDXs derived from brain metastases. Although PDX establishment from primary NSCLCs was significantly influenced by histol. subtype, clin. aggressiveness, and genetic alteration status, the brain metastases exhibited consistently adequate in vivo tumor take rate and in vitro tumor sphere formation capacity, regardless of clin. and mol. conditions. Conclusions: Therefore, PDXs from NSCLC brain metastases may better represent the heterogeneous advanced NSCLC population and could be utilized as preclin. models to meet unmet clin. needs such as drug screening for personalized treatments. AB The present invention relates to a novel crystal form of quinoline compd. N-(4-{[6,7-dimethoxyquinolin-4-yl]oxy}phenyl)-N'-(4-fluorophenyl)cyclopropane-1,1-dicarbonamide and preparation method thereof, and belongs to medicinal chemical field. The crystal form is basically pure crystal form I or crystal form II. In the X-ray powder diffraction pattern of crystal form I, there are peaks at 2θ angles of about 11.9, 12.9, 14.4, 16.0, 22.1 and 26.0 degrees. In the X-ray powder diffraction pattern of crystal form II, there are peaks at 2θ angles of about 11.6, 14.1, 18.5, 21.1, 22.2, 23.2, 24.1 and 29.0 degrees. The novel crystal form possesses good stability and mobility, which is conducive to operate in storage, transfer and production, and the novel crystal form can be used for preparing pharmaceutically acceptable salt thereof for application in pharmaceutics.

AB Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor deriving from the thyroid parafollicular cell. Thyroidectomy continues to serve as the primary initial treatment for this cancer. Because standard cytotoxic chemotherapy has proven ineffective, reoperation and external beam radiation therapy had been the only tools to treat recurrences or distant disease. The discovery that aberrant activation of RET, a receptor tyrosine kinase, is a primary driver of MTC tumorigenesis led to clin. trials using RET-targeting tyrosine kinase inhibitors. The successes of those trials led to the approval of vandetanib and cabozantinib for treating patients with progressive or symptomatic MTC. The availability of these drugs, along with addnl. targeted therapies in development, requires a thoughtful reconsideration of the approach to treating patients with unresectable locally advanced and/or metastatic progressive MTC.

AB Protein kinase inhibitors (PKIs) have emerged as highly promising therapies in progressive metastatic radioiodine-refractory differentiated thyroid cancer and in medullary thyroid cancer; two were recently approved in the USA for use in medullary thyroid cancer (vandetanib, cabozantinib), and another for use in progressive metastatic radioiodine-refractory differentiated thyroid cancer (sorafenib). Although more than 90% of thyroid cancer patients fare well in response to conventional treatment, PKI therapy has the potential to provide benefit. Nonetheless, PKIs produce numerous side effects, may worsen quality of life, may hasten mortality (by 1-2%), require discerning clin. acumen, are not yet proven to improve thyroid cancer survival and are very costly. This raises questions about who should prescribe PKIs, and about whether their use in thyroid cancer is truly beneficent and ethically justified. Restraint should be exercised in their use in thyroid cancer, with potential risks and benefits carefully weighed and solns. devised to help ameliorate many of the problems associated with their use.

AB Objective : To examine prostate-specific antigen (PSA) levels after enzalutamide discontinuation to assess whether an antiandrogen withdrawal syndrome (AAWS) exists with enzalutamide. Methods : We retrospectively identified 30 consecutive patients with metastatic prostate cancer who were treated with enzalutamide after docetaxel. Post-discontinuation PSA results were available for all patients and were determined at 2-weekly intervals until starting further anticancer systemic therapy. PSA withdrawal response was defined as a PSA decline by ≥50% from the last on-treatment PSA, with a confirmed decrease ≥3 wk later. Patient characteristics were evaluated in relation to the AAWS using univariate logistic regression anal. Results : The median (range) patient age was 70.5 (56-86) years and the median (range) follow-up was 9.0 (0.5-16) months. The most common metastatic sites were the bone (86.7%) and lymph nodes (66.7%). Most patients (70%) had previously received abiraterone and 12 patients (40%) had also received cabazitaxel. The median (range) treatment duration with enzalutamide was 3.68 (1.12-21.39) months. PSA levels after enzalutamide withdrawal were monitored for a median (range) time of 35 (10-120) days. Only one patient (3.3%) had a confirmed PSA response ≥50% after enzalutamide discontinuation. One patient (3.3%) had a confirmed PSA response of between 30 and 50% and another patient (3.3%) had an unconfirmed PSA response of between 30 and 50%. The median overall survival was 15.5 mo (95% CI 8.1-24.7). None of the factors analyzed in the univariate anal. were significant predictors of PSA decline after enzalutamide discontinuation. Conclusions : This retrospective study provides the first evidence that enzalutamide may have an AAWS in a minority of patients with metastatic castration-resistant prostate cancer. Further studies are needed to confirm the existence of an enzalutamide AAWS and to assess its relevance in prostate cancer management.

AB Antiangiogenic therapy is commonly used for the treatment of colorectal cancer (CRC). Although patients derive some clin. benefit, treatment resistance inevitably occurs. The MET signaling pathway has been proposed to be a major contributor of resistance to antiangiogenic therapy. MET is upregulated in response to vascular endothelial growth factor pathway inhibition and plays an essential role in tumorigenesis and progression of tumors. In this study, we set out to determine the efficacy of cabozantinib in a preclin. CRC patient-derived tumor xenograft model. We demonstrate potent inhibitory effects on tumor growth in 80% of tumors treated. The greatest antitumor effects were observed in tumors that possess a mutation in the PIK3CA gene. The underlying antitumor mechanisms of cabozantinib consisted of inhibition of angiogenesis and Akt activation and significantly decreased expression of genes involved in the PI3K pathway. These findings support further evaluation of cabozantinib in patients with CRC. PIK3CA mutation as a predictive biomarker of sensitivity is intriguing and warrants further elucidation. A clin. trial of cabozantinib in refractory metastatic CRC is being activated.

AB C-Met has emerged as an attractive target for targeted cancer therapy because of its abnormal activation in many cancer cells. To identify high potent and selective c-Met inhibitors, we started with profiling the potency and in vitro metabolic stability of a reported hit 7. By rational design, a novel sulfonylpyrazolo[4,3-b]pyridine 9 with improved DMPK properties was discovered. Further elaboration of π-π stacking interactions and solvent accessible polar moieties led to a series of highly potent and selective type I c-Met inhibitors. On the basis of in vitro and in vivo pharmacol. and pharmacokinetics studies, compound 46 was selected as a preclin. candidate for further anticancer drug development.

AB Background: Growing awareness of the complexity of carcinogenesis has made multimodal therapies for cancer increasingly compelling and relevant. In recent years, immunotherapy has gained acceptance as an active therapeutic approach to cancer treatment, even though cancer is widely considered an immunosuppressive disease. Combining immunotherapy with targeted agents that have immunomodulatory capabilities could significantly improve its efficacy. Methods: We evaluated the ability of cabozantinib, a receptor tyrosine kinase inhibitor, to modulate the immune system in vivo as well as alter the phenotype of tumor cells in vitro in order to determine if this inhibitor could act synergistically with a cancer vaccine. Results: Our studies indicated that cabozantinib altered the phenotype of MC38-CEA murine tumor cells, rendering them more sensitive to immune-mediated killing. Cabozantinib also altered the frequency of immune sub-populations in the periphery as well as in the tumor microenvironment, which generated a more permissive immune environment. When cabozantinib was combined with a poxviral-based cancer vaccine targeting a self-antigen, the combination significantly reduced the function of regulatory T cells and increased cytokine production from effector T cells in response to the antigen. These alterations to the immune landscape, along with direct modification of tumor cells, led to markedly improved antitumor efficacy. Conclusions: These studies support the clin. combination of cabozantinib with immunotherapy for the treatment of cancer.

AB The invention provides novel substituted pyrazolone compds. of formula I [each of R1-R7 is independently H, F, Cl, (C1-C6)alkyl, (C1-C6)haloalkyl, etc.; each of X, Y and Z is independently H, (C1-C6)alkyl, (C6-C10)aryl, etc.; W is CR7 or N; Q as defined in the disclosure], pharmaceutical acceptable salts and formulations thereof useful in modulating the protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. The example compound II was prepared in two-step synthesis (procedure shown) was tested in multiple bioassay for activity in modulation of protein tyrosine kinase, pharmacokinetics and metabolic stability, as well as for antiproliferative activity. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans.

AB Provided are dielectrophoresis (DEP) devices and methods that allow cell sorting to identify, isolate, and/or sep. cells of interest based on elec. and phys. properties of the cells. Particularly, provided are systems and methods for manipulating particles suspended in a fluid, e.g., cells, micro- or nano-particles, using their elec. signatures. Such methods can be performed using DEP, iDEP, and/or cDEP (contactless dielectrophoresis, where direct contact between the electrodes and the sample is avoided). Typically, an elec. field is induced in a sample comprising the target particles and/or cells, such as cancer cells, and the spatial distribution of cells is measured to identify one or more characteristics or properties of the cancer cells. The identified characteristics of the sorted cells can be used to determine drug efficacy and/or resistance with respect to the cells.

AB The present disclosure describes methods of treating a cancer based on the targeted disruption of alpha connexin 43-zonula occludens-1 (ZO-1) interaction. The methods may include administering to a subject an effective amount of a composition comprising a peptide with a contiguous sequence of amino acids representing a portion of the C-terminus of an alpha connexin protein or conservative variant thereof, wherein said C-terminus includes the sequence up to the transmembrane domain, optionally in combination with administration of a chemotherapeutic agent. In embodiments, the cancer is glioma and the chemotherapeutic agent is temozolomide. The methods may also include administration of vectors encoding the peptide or host cells comprising the vectors. Also described are compns. for treating a cancer comprising one or more peptides, nucleic acids, vectors, and/or host cells, optionally in combination with a chemotherapeutic agent such as temozolomide.

AB A simple, rapid and sensitive high-performance liq. chromatog. tandem mass-spectrometric method (LC-MS/MS) for the novel multiple tyrosine kinase inhibitor (TKI) cabozantinib was developed and validated using erlotinib as internal standard (IS). Plasma samples were pre-treated by liquid-liquid extraction with Et acetate. Separation was achieved on a reversed phase C18 column (50 × 2 mm, 5 μm) at ambient temperature using isocratic elution with acetonitrile-water (45:55, volume/volume) containing 5 mM ammonium formate buffer (finally adjusted to apparent pH* = 5.0 with formic acid) at a flow rate of 0.4 mL/min. The analytes were monitored by a triple quadrupole tandem mass spectrometer with electrospray ionization source in the pos. ion mode. Calibration curve was linear (r > 0.99) in a concentration range of 0.5-1000 ng/mL with the lower limit of quantification (LLOQ) of 0.5 ng/mL. Intra- and inter-day accuracy and precision were validated by relative error values (RE) and relative standard deviation values (RSD), resp., which were both lower than the limit of 15%. This method was successfully applied to a pharmacokinetic study of cabozantinib in rats.

AB A review. A new chimeric fusion transcript of KIF5B (the kinesin family 5B gene) and the RET (Rearranged during Transcription) oncogene, KIF5B-RET, was found in 1-2% of lung adenocarcinomas (LADCs) in late 2011. Several related clin. trials for non-small-cell lung cancer (NSCLC) with KIF5B-RET rearrangements using existing RET inhibitors, such as lenvatinib, vandetanib, sunitinib, ponatinib, cabozantinib, and AUY922, have been swiftly initiated by the discovery of the KIF5B-RET fusion gene. Anti-RET activity and the status of clin. development of these known RET tyrosine kinase inhibitors (TKIs) for KIF5B-RET fusion-pos. NSCLC are discussed. A kinase inhibitor that can target a driver mutation specifically may lead to a superior clin. benefit compared with broad-spectrum kinase inhibitors. In this regard, an anal. of the structure of RET kinase and its complex with known RET inhibitors are also briefly discussed.

AB Cabozantinib (XL184) is a novel small mol. inhibitor of receptor tyrosine kinases (RTKs) targeted at mesenchymal-epithelial transition factor (MET). To study the pharmacokinetics and tissue distribution in rat, a specific ultra-performance liquid chromatog.-tandem mass spectrometry (UPLC-MS/MS) method was developed with midazolam as internal standard The calibration curves in plasma and tissues were linear in the range of 5-5000 ng/mL (R2 > 0.99). The recoveries were better than 80.4% and matrix effects ranged from 96.9% to 105.1%. Then, the developed UPLC-MS/MS method was applied to determine the concentration of XL184 in blood and tissues. The pharmacokinetics of four different dosages (iv 5, 10 mg/kg and ig 15, 30 mg/kg) revealed that XL184 was eliminated slowly, the t1/2 was longer than 10 h and the absolute bioavailability was 25.6±8.3%. The concentration distribution of XL184 in tissues was liver > lung > kidney > spleen > heart. Based on the concentration-time of XL184 in tissues, a BP-ANN distribution model was developed with good performance, and can be used to predict the concentration of XL184 in tissues.

AB Background: Multi-targeted vascular endothelial growth factor receptor (VEGFR) tyrosine kinase inhibitors (TKIs) are known to cause cardiac toxicity, but the relative risk (RR) of QTc interval prolongation and serious arrhythmias associated with them are not reported. Methods: We conducted a trial-level meta-anal. of randomized phase II and III trials comparing arms with and without a US Food and Drug Administration-approved VEGFR TKI (sunitinib, sorafenib, pazopanib, axitinib, vandetanib, cabozantinib, ponatinib and regorafenib). A total of 6548 patients from 18 trials were selected. Statistical analyses were conducted to calculate the summary incidence, RR and 95% CIs. Results: The RR for all-grade and high-grade QTc prolongation for the TKI vs no TKI arms was 8.66 (95% CI 4.92-15.2, P<0.001) and 2.69 (95% CI 1.33-5.44, P=0.006), resp., with most of the events being asymptomatic QTc prolongation. Resp., 4.4% and 0.83% of patients exposed to VEGFR TKI had all-grade and high-grade QTc prolongation. On subgroup anal., only sunitinib and vandetanib were associated with a statistically significant risk of QTc prolongation, with higher doses of vandetanib associated with a greater risk. The rate of serious arrhythmias including torsades de pointes did not seem to be higher with high-grade QTc prolongation. The risk of QTc prolongation was independent of the duration of therapy. Conclusions: In the largest study to date, we show that VEGFR TKI can be associated with QTc prolongation. Although most cases were of low clin. significance, it is unclear whether the same applies to patients treated off clin. trials.

AB Over 80% of men with castration-resistant prostate cancer have bone metastases. This condition can dramatically impact quality of life and is associated with short-term survival. Consequently, the development of bone-targeted therapies is a relevant topic on prostate cancer management. Hepatocyte growth factor receptor and vascular endothelial growth factor signaling pathways have been identified to play a role in prostate cancer progression and bone metastasis and are potential targets for therapeutic intervention. Early-phase studies have shown encouraging responses in bone metastases and pain control with cabozantinib, a multi-tyrosine kinase inhibitor targeting hepatocyte growth factor receptor and vascular endothelial growth factor receptor. Despite striking responses seen in some patients, preliminary results from a pivotal Phase III study have failed to produce survival benefit. This review encompasses preclin. and clin. data of cabozantinib in metastatic castration-resistant prostate cancer highlighting future research options for this agent.

AB A review. These NCCN Guidelines Insights focus on some of the major updates to the 2014 NCCN Guidelines for Thyroid Carcinoma. Kinase inhibitor therapy may be used to treat thyroid carcinoma that is symptomatic and/or progressive and not amenable to treatment with radioactive iodine. Sorafenib may be considered for select patients with metastatic differentiated thyroid carcinoma, whereas vandetanib or cabozantinib may be recommended for select patients with metastatic medullary thyroid carcinoma. Other kinase inhibitors may be considered for select patients with either type of thyroid carcinoma. A new section on "Principles of Kinase Inhibitor Therapy in Advanced Thyroid Cancer" was added to the NCCN Guidelines to assist with using these novel targeted agents.

AB Certain idiosyncratic adverse drug reactions (IADRs) can be triggered by electrophilic protein-reactive metabolites that are formed in the process of drug metabolism While methodologies (e.g., structural alert concept in drug design, glutathione (GSH) trapping, and protein covalent binding) for examining reactive metabolite (RM) formation are available, predicting the IADR potential applying these parameters remains a significant challenge. The present work examines toxicity trends associated with the aniline structural alert in the top 200 prescribed drugs of 2011 and recently approved (2009-2013) small mol. drugs, in relation with 30 aniline-based drugs withdrawn from com. use or associated with a black box warning for IADRs. The aniline sub-structure was found in several drugs from the toxic, mostprescribed, and recently approved category. RMs resulting from the bioactivation of the aniline alert was also noted in the three categories chosen for comparison. A major discriminator between the toxic drugs and the majority of drugs in the most-prescribed list, however, was the daily dose - drugs most frequented associated with IADRs were the ones with higher daily doses (exceeding hundreds of milligrams). A greater tolerance for IADRs was also noted with certain drugs intended to treat rare, unmet medical needs (e.g., cancer). Overall, the anal. suggests that optimization of pharmacol. potency and pharmacokinetics that would lead to a lower daily dose, and therefore, a lower body burden of parent drug/metabolites, should be taken into consideration in drug discovery.

AB A review. Thyroid cancers are characterized by a good prognosis but 10 to 15% of patients progress and become refractory to current therapies. Systemic treatment based on chemotherapy in these settings has shown limited efficacy, with response rates not exceeding 25%. At progression, differentiated thyroid cancer is characterized by a high level of expression of vascular endothelial growth factor (VEGF). This high expression of VEGF is associated with an aggressive tumor behavior and a poor clin. outcome.; We will review the recent advances in targeting angiogenesis in the treatment of recurrent and metastatic thyroid carcinoma.

AB A review with 28 ref. is given on development of therapeutic drug for castration-resistant prostate cancer. The treatment of castration-resistant prostate cancer (CRPC) is still a challenge, as there are few effective therapies to lengthen life of patients. Many novel approaches with extended survival benefit currently in development yielded promising results for patients. This review describes the therapeutic drug for CRPC. The therapeutic drug comprises antiandrogen drug such as abiraterone, enzalutamide, orteronel, galeterone; cytotoxic chemotherapy such as docetaxel, cabazitaxel; immunotherapy such as sipuleucel-T,

rilimogene galvacirepvec, ipilimumab; targeting therapy including endothelin-A receptor antagonist such as atrasentan, zibotentan, tyrosine kinase inhibitor such as dasatinib and sorafenib, cabozantinib, anti-angiogenesis agent such as bevacizumab, aflibercept, tasquinimod, clusterin inhibitor such as custirsen, and radium chloride.

AB Purpose: ROS1 rearrangement leads to constitutive ROS1 activation with potent transforming activity. In an ongoing phase I trial, the ALK tyrosine kinase inhibitor (TKI) crizotinib shows remarkable initial responses in patients with non-small cell lung cancer (NSCLC) harboring ROS1 fusions; however, cancers eventually develop crizotinib resistance due to acquired mutations such as G2032R in ROS1. Thus, understanding the crizotinib-resistance mechanisms in ROS1-rearranged NSCLC and identification of therapeutic strategies to overcome the resistance are required. Exptl. Design: The sensitivity of CD74-ROS1-transformed Ba/F3 cells to multiple ALK inhibitors was examined Acquired ROS1 inhibitor-resistant mutations in CD74-ROS1 fusion were screened by N-ethyl-N-nitrosourea mutagenesis with Ba/F3 cells. To overcome the resistance mutation, we performed high-throughput drug screening with small-mol. inhibitors and anticancer drugs used in clin. practice or being currently tested in clin. trials. The effect of the identified drug was assessed in the CD74-ROS1-mutant Ba/F3 cells and crizotinib-resistant patient-derived cancer cells (MGH047) harboring G2032R-mutated CD74-ROS1. Results: We identified multiple novel crizotinib-resistance mutations in the ROS1 kinase domain, including the G2032R mutation. As the result of high-throughput drug screening, we found that the cMET/RET/VEGFR inhibitor cabozantinib (XL184) effectively inhibited the survival of CD74-ROS1 wild-type (WT) and resistant mutants harboring Ba/F3 and MGH047 cells. Furthermore, cabozantinib could overcome all the resistance by all newly identified secondary mutations. Conclusions: We developed a comprehensive model of acquired resistance to ROS1 inhibitors in NSCLC with ROS1 rearrangement and identified cabozantinib as a therapeutic strategy to overcome the resistance. AB A review. The process of angiogenesis involves the formation of new blood vessels from pre-existing vasculature by the over expression of certain factors leading to the growth and development of all solid tumor types. Hepatocyte growth factor receptor abbreviated as c-Met and vascular endothelial growth factor abbreviated as VEGF are some of the factors responsible for the induction in tumor growth and development. Recently a number of analogs associated with these receptors are under study. US FDA on Nov. 29, 2012 approved a drug named cabozantinib formerly known as XL184 which is being marketed under the trade name of Cometriq for the treatment of Medullary Thyroid Cancer (MTC). Designing of the drug has been done in such a fashion that it can inhibit both VEGFR2 and c-Met simultaneously without over expressing any of the factors leading to the inhibition of angiogenesis. The drug is still under study for the evaluation of its efficacy in cases of many other solid tumor types including breast cancer, castration resistant prostate cancer (CRPC), renal cell carcinoma (RCC), hepatocellular carcinoma (HCC), gastric or gastroesophageal junction cancer, melanoma, small cell lung cancer (SCLC), ovarian cancer and primary peritoneal or fallopian tube carcinoma. This review article consists of preclin. and clin. data of cabozantinib and its efficacy and safety towards various types of solid tumors.

AB A review. In the recent years, treatment options for castration-resistant prostate cancer had evolved from conventional antiandrogens and chemotherapy to novel androgen receptor signaling inhibitors, a new generation of taxanes, and immunotherapy. Randomized clin. trials had shown that docetaxel, cabazitaxel, enzalutamide, abiraterone acetate, radium-223, and sipuleucel-T could improve the overall survival of the patients with androgen-independent prostate cancer. However, drug resistance was inevitable and androgen-independent prostate cancer remained a major clin. burden, which urgently called for novel therapeutic options for the improvement of the patients' survival and quality of life. Angiogenesis played a central role in the formation and progression of prostate cancer, and the anti angiogenic targeted therapy was shown in many clin. trials to be an effective therapeutic supplement for advanced prostate cancer beyond surgery and endocrine treatment. The recent findings of antiangiogenic mugs for castration-resistant prostate cancer was reviewed.

AB Purpose Cabozantinib (XL184), an oral inhibitor of multiple receptor tyrosine kinases such as MET and VEGFR2, was evaluated in a phase II nonrandomized expansion study in castration-resistant prostate cancer (CRPC). Patients and Methods Patients received open-label cabozantinib at daily starting doses of 100 mg or 40 mg until disease progression or unacceptable toxicity. The primary end point was bone scan response, defined as ≥ 30% reduction in bone scan lesion area. Other efficacy end points included overall survival, pain, analgesic use, and biomarkers. Results One hundred forty-four patients sequentially enrolled in either a 100-mg (n = 93) or 40-mg (n = 51) study cohort. Ninety-one patients (63%) had a bone scan response, often by week 6. Treatment resulted in clin. meaningful pain relief (57% of patients) and reduction or discontinuation of narcotic analgesics (55% of patients), as well as improvements in measurable soft tissue disease, circulating tumor cells, and bone biomarkers. Improvements in each of these outcomes were observed in both cohorts: bone scan response in 73% and 45%, resp.; redns. in measurable soft tissue disease in 80% and 79%, resp. Median overall survival was 10.8 mo for the entire population. Most common grade 3 or 4 adverse events were fatigue (22%) and hypertension (14%). Fewer dose redns. because of toxicity were required in the 40-mg group. Conclusion The evidence suggests that cabozantinib has clin. meaningful activity in CRPC. Cabozantinib resulted in improvements in bone scans, pain, analgesic use, measurable soft tissue disease, circulating tumor cells, and bone biomarkers. Taken together, these phase II observations warrant further development of cabozantinib in prostate cancer.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The ophthalmic drug delivery vehicles include 1-15% nonionic surfactant, one or more non-Newtonian high blend viscosity enhancing, non-gelling agents and 0.025-0.90% sodium chloride. Particularly, formulations that have the non-Newtonian characteristics at 37° of creating a viscosity increase in ratio of 3:1 within 1-2 s at the low shear force between blinks and drops within the fraction of a second to the high shear force of each blink, which on dilution maintain a viscosity of ≥10 cPs during each blink and which do not cause excessive stinging or discomfort, are disclosed. Thus, a formulation comprised dexmedetomidine 0.09, CM-cellulose 0.75, Poloxamer-407 5.50, NaCl 0.25, an benzalkonium chloride 0.02%.

AB A review. Context: Medullary thyroid cancer (MTC) is a rare form of thyroid cancer comprising approx. 4% of all thyroid cancers. The majority of patients have a relatively good prognosis; however, a subgroup of patients will require systemic therapy. Large phase III randomized trials led to the approval of two drugs-vandetanib and cabozantinib-for progressive or symptomatic MTC. The decision regarding which drug to initiate first is not entirely clear and is a common concern amongst treating physicians. Evidence Acquisition and Synthesis: A review of the literature in English was conducted, and data were summarized and integrated into a decision matrix. Conclusions: The decision regarding which drug to initiate first for progressive MTC should be based on a careful review of the medical history, phys. examination findings, medication list, ECG, laboratory results, and tumor characteristics. It is necessary to consider the relative contraindications when choosing which drug to initiate first.

AB A series of 3-amino-benzo[d]isoxazole-/3-aminoindazole-based compds. were designed, synthesized and pharmacol. evaluated as tyrosine kinase c-Met inhibitors. The SAR study was conducted leading to identification of nine compds. with IC50s less than 10 nM against c-Met. Compound I stood out as the most potent c-Met inhibitor displaying potent inhibitory effects both at enzymic (IC50 = 1.8 nM) and cellular (IC50 = 0.18 μM on EBC-1 cells) levels. In addition, I had a relatively good selectivity compared to a panel of the inhouse 14 RTKs.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB This study of cancer cell signaling perturbed by the tyrosine kinase inhibitor dasatinib suggests rational combinations to improve the efficacy of this drug in the subset of lung cancers where it is used. DDR2 mutations occur in approx. 4% of lung squamous cell cancer (SCC) where the tyrosine kinase inhibitor dasatinib has emerged as a new therapeutic option. We found that ERK and AKT phosphorylation was weakly inhibited by dasatinib in DDR2-mutant lung SCC cells, suggesting that dasatinib inhibits survival signals distinct from other oncogenic receptor tyrosine kinases (RTK) and/or compensatory signals exist that dampen dasatinib activity. To gain better insight into dasatinib's action in these cells, we assessed altered global tyrosine phosphorylation (pY) after dasatinib exposure using a mass spectrometry-based quant. phosphoproteomics approach. Overlaying protein-protein interaction relationships upon this dasatinib-regulated pY network revealed decreased phosphorylation of Src family kinases and their targets. Conversely, dasatinib enhanced tyrosine phosphorylation in a panel of RTK and their signaling adaptor complexes, including EGFR, MET/GAB1, and IGF1R/IRS2, implicating a RTK-driven adaptive response associated with dasatinib. To address the significance of this observation, these results were further integrated with results from a small-mol. chemical library screen. We found that dasatinib combined with MET and insulin-like growth factor receptor (IGF1R) inhibitors had a synergistic effect, and ligand stimulation of EGFR and MET rescued DDR2-mutant lung SCC cells from dasatinib-induced loss of cell viability. Importantly, we observed high levels of tyrosine-phosphorylated EGFR and MET in a panel of human lung SCC tissues harboring DDR2 mutations. Our results highlight potential RTK-driven adaptive-resistant mechanisms upon DDR2 targeting, and they suggest new, rationale cotargeting strategies for DDR2-mutant lung SCC. AB Oncogenic rearrangements of the RET gene have recently been described in 1% to 2% of lung adenocarcinomas. We report five cases of RET-rearranged lung adenocarcinoma with an unusual constellation of clin. and histol. features that has not previously been described in tumors with this genomic alteration. The age at diagnosis of the five patients (4F, 1M) ranged from 44 to 77 years. All were never-smokers. Radiol., four tumors showed lymphangitic spread within the lungs at presentation; three of these had multiple bilateral lung nodules. Histol. showed psammoma bodies within the tumor in four of five cases. Mol. testing for activating EGFR mutations by standard genotyping and ALK expression by immunohistochem. was neg. in all cases. Addnl. mol. anal. was prompted by the clin. profile in that all five patients were never-smokers with metastatic, relapsed, and/or refractory disease; and also by unusual histol. findings in two cases. Comprehensive genomic profiling performed by means of a clin. grade cancer gene panel next-generation sequencing assay demonstrated a KIF5B-RET fusion in three; and fluorescence in-situ hybridization documented a RET rearrangement in two. Three of the patients were treated with the RET inhibitor cabozantinib. By Response Evaluation Criteria In Solid Tumors (RECIST) criteria, two had a confirmed partial response (at 6 wk and 4 wk) and one had stable disease. Our findings suggest that the combination of lymphangitic spread and psammoma bodies may be characteristic of a subset of advanced stage RET-rearranged lung adenocarcinomas. These findings should prompt addnl. mol. testing for RET translocations, particularly in never-smokers with EGFR- and ALK-neg. lung adenocarcinoma.

AB Introduction: New therapeutic options for both differentiated thyroid cancer (DTC) and medullary thyroid cancer (MTC) have opened up during the past few years, as the key role of tyrosine kinases in the pathogenesis of thyroid carcinoma has been proved. Recently, two tyrosine kinase inhibitors (TKIs) targeting VEGFR vandetanib (Caprelsa) and cabozantinib (Cometriq) have been approved for advanced MTC, whereas, sorafenib (Nexavar) has been accepted to treat late-stage of DTC. Their efficacy was demonstrated in Phase III studies, compared to placebo; each of them significantly prolonged the progression-free survival. Areas covered: Common adverse reactions related to VEGFR blockade are hypertension, proteinuria, impaired wound healing, hemorrhage and thrombosis, and congestive heart failure. Fatigue, different gastrointestinal disturbances with diarrhea, appetite decrease and weight loss are observed in the majority of patients. Another frequent TKI side effect is TSH increase secondary to inhibition of MCT8-dependent T3 and T4 uptake in pituitary. Expert opinion: So far, no direct comparison of both treatment outcomes and toxicity between particular drugs has been carried out. The evidence-based medicine guidelines are necessary to precisely indicate what drug to use: more effective or less toxic and when to start the treatment.

AB The present invention relates to a method for the prognosis of bone metastasis in renal cell carcinoma which comprises determining if the c-MAF gene is amplified in a primary tumor sample. Likewise, the invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise determining the c-MAF gene expression level, amplification or translocation. The invention also relates to a method for predicting early bone metastasis in a subject suffering renal cell carcinoma. The invention also relates to a c-MAF inhibitor as therapeutic agent for use in the treatment of renal cell carcinoma metastasis. The invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the invention relates to a method for typing of a subject suffering renal cell carcinoma and for classifying a subject from renal cell carcinoma into a cohort.

LANGUAGE: English

AB Background: Castration resistant prostate cancer (CRPC) is a leading cause of cancer-related deaths in men. The primary cause of mortality and morbidity in patients is bone metastases and remodeling resulting in osteoblastic and osteolytic lesions. Recently, cabozantinib, a multi-kinase inhibitor (VEGFR2 and c-MET inhibitor), was shown to have efficacy on bone lesions in patients. In this study we tested multi-kinase inhibitors: axitinib (VEGFR inhibitor) and crizotinib (c-MET inhibitor) in a combination trial in mice models. Methods: VCaP-Luc cells were grown as s.c. implants in intact and castrated NOD-SCID-gamma (NSG) mice to confirm the androgen dependency. For bone metastasis model two cohorts of NSG mice (castrated and intact) received orthotopic injection of VCaP-Luc cells into the bone marrow cavity of left tibia. Mice were monitored weekly for tumor growth using bioluminescence imaging. Animals were randomized into 4 groups based on the tumor bioluminescence signal: vehicle, crizotinib alone, axitinib alone, crizotinib and axitinib in combination. Animals were imaged weekly by in vivo 2-D X-ray imaging to monitor bone remodeling. At the end of the study animals were euthanized and both tibias were extracted for ex vivo high-resolution 3-D micro-computed tomog. (μCT) imaging. Results: S.c. model showed that androgen stimulation may be helpful but not essential for the growth of VCaP-Luc cells. VCaP-Luc cells grown intra-tibially in intact animals caused extensive remodeling of bone with mixed osteoblastic (bone formation) and osteolytic (bone matrix dissoln.) lesions. The osteoblastic lesions were predominant and at times extended beyond the tibial shaft into the surrounding tissue. In contrast, only osteolytic lesions were prominent throughout the study in castrated animals. Treatment with crizotinib alone reduced the osteolytic lesions in castrated animals. Axitinib alone reduced the osteoblastic lesions in the intact animals. Combination therapy with axitinib and crizotinib remarkably inhibited the tibial remodeling by VCaP-Luc cells which resulted in a significant reduction of both osteoblastic and osteolytic lesions. Conclusion: Our data show that combined inhibition of c-MET and VEGFR can be beneficial for treatment of metastatic bone disease in CRPC and that the drugs act on two different stages of the disease.

AB A review with 33 refs. Lung cancer is the leading cause of cancer-related death worldwide, mol. target therapy has become a hot research direction of non-small cell lung cancer(NSCLC) treatment. RET fusion gene with an identifiable clin. pathol. features, is present in some subsets of lung cancer, and its treatment is effective by RET inhibitor, suggesting that RET fusion gene may be a new target for individualized treatment to the subgroup of NSCLC. This article reviews the structural characteristics of RET fusion gene and expression model in clin. samples, and treatment of NSCLC.

AB Giant cell tumor of bone (GCTB) is a very rare tumor entity, which is little examined owing to the lack of established cell lines and mouse models and the restriction of available primary cell lines. The stromal cells of GCTB have been made responsible for the aggressive growth and metastasis, emphasizing the presence of a cancer stem cell population. To identify and target such tumor-initiating cells, stromal cells were isolated from eight freshly resected GCTB tissues. Tumorigenic properties were examined by colony and spheroid formation, differentiation, migration, MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay, immunohistochem., antibody protein array, Alu in situ hybridization, FACS anal. and xenotransplantation into fertilized chicken eggs and mice. A sub-population of the neoplastic stromal cells formed spheroids and colonies, differentiated to osteoblasts, migrated to wounded regions and expressed the metastasis marker CXC-chemokine receptor type 4, indicating self-renewal, invasion and differentiation potential. Compared with adherent-growing cells, markers for pluripotency, stemness and cancer progression, including the CSC surface marker c-Met, were enhanced in spheroidal cells. This c-Met-enriched sub-population formed xenograft tumors in fertilized chicken eggs and mice. Cabozantinib, an inhibitor of c-Met in phase II trials, eliminated CSC features with a higher therapeutic effect than standard chemotherapy. This study identifies a c-Met+ tumorigenic sub-population within stromal GCTB cells and suggests the c-Met inhibitor cabozantinib as a new therapeutic option for targeted elimination of unresectable or recurrent GCTB.

AB The present invention relates to cabozantinib malate and its prepn. method, and specifically, the present invention relates to cabozantinib·n malate, its preparation method, and a pharmaceutical composition comprising the same. The inventive cabozantinib·n malate has excellent stability, and can be used for preparing medicines for the treatment of tumors, especially in preparation of medicine for the treatment of medullary thyroid cancer. The preparation method of cabozantinib·n malate includes: (a) adding cabozantinib to an organic solvent, (b) adding malic acid n times molar amount of cabozantinib to mixture of step (a), and (c) precipitating to obtain cabozantinib·n malate, wherein, n is selected from 0.4-0.6, preferably 0.5.

AB Background: Cabozantinib targets tyrosine kinases including MET, vascular endothelial growth factor (VEGF) receptor 2, and rearranged during transfection (RET). Differentiated thyroid cancer (DTC) is a tumor type that may be sensitive to cabozantinib. Therefore, we evaluated cabozantinib in a cohort of heavily pretreated patients with metastatic DTC. .Methods: This single-arm open-label phase I trial assessed the safety, tolerability, and antitumor activity of cabozantinib in DTC patients taking part in a drug-drug interaction study. Adult patients with histol. confirmed metastatic or surgically unresectable DTC (including papillary, follicular, or Huerthle cell) were enrolled. Patients received daily oral dosing of 140 mg cabozantinib. Safety was assessed by evaluation of adverse events (AEs), vital signs, electrocardiograms, laboratory tests, and concomitant medications. Tumor response by magnetic resonance imaging or computed tomog. scan was investigator assessed using Response Evaluation Criteria In Solid Tumors (RECIST) v1.0. Results: The study enrolled 15 patients who had failed standard radioactive iodine therapy. Patients had received a median of two prior systemic agents, and 11 patients (73%) had previously received at least one VEGF pathway inhibiting therapy. Common AEs included diarrhea, nausea, fatigue, and decreased appetite. Partial response was reported in eight patients (53%). Median progression-free survival and median overall survival were not reached. Conclusions: Cabozantinib demonstrates a safety profile similar to other multitargeted VEGFR inhibitors in advanced DTC patients. The antitumor activity observed in this study warrants further investigation of cabozantinib in patients with advanced DTC.

AB A review. The MET/hepatocyte growth-factor (HGF) signaling pathway plays a key role in the processes of embryogenesis, wound healing, and organ regeneration. Aberrant activation of MET/HGF occurs through multiple mechanisms including gene amplification, mutation, protein overexpression, and abnormal gene splicing interrupting autocrine and paracrine regulatory feedback mechanisms. In many cancers including non-small-cell lung cancer, colorectal, gastric, renal, and hepatocellular cancer, dysregulation of MET may lead to a more aggressive cancer phenotype and may be a neg. prognostic indicator. Successful therapeutic targeting of the MET/HGF pathway has been achieved using monoclonal antibodies against the MET receptor and its ligand HGF in addition to MET-specific and multitargeted small-mol. tyrosine-kinase inhibitors with several drugs in late-phase clin. trials including onartuzumab, rilotumumab, tivantinib, and cabozantinib. MET frequently interacts with other key oncogenic tyrosine kinases including epidermal growth-factor receptor (EGFR) and HER-3 and these interactions may be responsible for resistance to anti-EGFR therapies. Similarly, resistance to MET inhibition may be mediated through EGFR activation, or alternatively by increasing levels of MET amplification or acquisition of novel "gatekeeper" mutations. In order to optimize development of effective inhibitors of the MET/HGF pathway clin. trials must be enriched for patients with demonstrable MET-pathway dysregulation for which robustly standardized and validated assays are required.

AB A review. Medullary thyroid cancer is uncommon and patients typically present with advanced disease. Treatment options for patients with progressive, metastatic medullary thyroid cancer had been limited until recently. Tyrosine kinase inhibitors have garnered increasing interest in this subset of patients. The US Food and Drug Administration recently approved cabozantinib, a tyrosine kinase inhibitor, after promising results were shown in a large Phase III clin. trial. This review summarizes the clin. pharmacol., clin. trials, and safety data for cabozantinib and concludes with a discussion of possible future directions for the treatment of medullary thyroid cancer.

AB This invention provides methods and compns. useful for treating early and late stage metastatic cancer to prevent or treat acquired resistance due to gene amplification or mutation in response to chemotherapeutic and/or targeted drugs. In particular, the methods and compns. include carboxyamidotriazole orotate (CTO) alone or in combination with specific regimens of chemotherapeutic and/or targeted drugs designed to overcome the genomic resistance raised to prior therapy.

AB Background. Hepatocellular carcinoma is one of the most common and lethal malignant tumors worldwide. Over the past 15 years, the incidence of HCC has more than doubled. Due to late diagnosis and/or advanced underlying liver cirrhosis, only limited treatment options with marginal clin. benefit are available in up to 70% of patients. During the last decades, no effective conventional cytotoxic systemic therapy was available contributing to the dismal prognosis in patients with HCC. A better knowledge of mol. hepatocarcinogenesis provides today the opportunity for targeted therapy. Materials and Methods. A search of the literature was made using cancer literature, the PubMed, Scopus, and Web of Science (WOS) database for the following keywords: "hepatocellular carcinoma," "mol. hepatocarcinogenesis," "targeted therapy," and "immunotherapy." Discussion and Conclusion. Treatment decisions are complex and dependent upon tumor staging, presence of portal hypertension, and the underlying degree of liver dysfunction. The knowledge of mol. hepatocarcinogenesis broadened the horizon for patients with advanced HCC. During the last years, several mol. targeted agents have been evaluated in clin. trials in advanced HCC. In the future, new therapeutic options will be represented by a blend of immunotherapy-like vaccines and T-cell modulators, supplemented by molecularly targeted inhibitors of tumor signaling pathways.

AB The present invention relates to crosslinked peptides that are assocd. with human eIF4G and bind to eIF4E, uses thereof and pharmaceutical compns. comprising the peptides. Described below are crosslinked peptides related to a portion of human eIF4E. These crosslinked peptides contain at least two modified amino acids that together form an internal crosslink (also referred to as a staple) that can help to stabilize the alpha-helical secondary structure of a portion of eIF4G1 that is thought to be important for binding of eIF4E to eIF4G. Accordingly, a crosslinked peptide described herein can have improved biol. activity relative to a corresponding peptide that is not crosslinked. The crosslinked eIF4G1 peptides are thought to interfere with binding of eIF4G1 to eIF4G thereby inhibiting the increased translation of mRNAs with highly structured 5'UTRs. The crosslinked eIF4G1 peptide described herein can be used therapeutically, e.g., to treat or prevent a variety of cancers in a subject.

AB Aims : Congestive heart failure (CHF) assocd. with vascular endothelial growth factor tyrosine-kinase inhibitors (VEGFR-TKIs) has emerged as a relevant problem in clin. and scientific communities. We performed an up-to-date, comprehensive meta-anal. to determine the overall incidence and risk of CHF in cancer patients receiving VEGFR-TKIs. Methods : The databases

of PubMed, Web of Science and abstrs. presented at the American Society of Clin. Oncol. up to August 31 2013 were searched for relevant articles. Statistical analyses were conducted to calculate the summary incidence, odds ratio (OR) and 95% confidence intervals (CIs) by using either random effects or fixed effect models according to the heterogeneity of included studies. Results : A total of 10 553 patients from 36 clin. trials were included. The overall incidence of all grade and high grade CHF associated with VEGFR-TKIs was 3.2% (95% CI 1.8%, 5.8%) and 1.4% (95% CI 0.9%, 2.3%), resp. The use of VEGFR-TKIs significantly increased the risk of developing all grade (OR 2.37, 95% CI 1.76, 3.20, P < 0.001) and high grade (OR 3.51, 95% CI 1.74, 7.05, P < 0.001) CHF. In subgroup analyses, the risk of CHF did not significantly vary with tumor types (P = 0.071 for all grade; P = 0.72 for high grade) and VEGFR-TKIs (P = 0.55 for all grade; P = 0.99 for high grade). Meta-regression indicated that CHF might possibly occur early in the treatment of VEGFR-TKIs. No evidence of publication bias was observed Conclusion : The use of VEGFR-TKIs is associated with a significantly increased risk of developing congestive heart failure in cancer patients. Clinicians should be aware of this risk and provide close monitoring in patients receiving these therapies.

AB The invention relates to a method for the prognosis of bone metastasis in cancer which comprises using a probe to determine if a gene of interest is amplified in a primary tumor sample. Likewise, the invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise using a probe to determine the expression level of a gene of interest, or the amplification or translocation of a gene of interest. The invention also relates to a method for predicting early bone metastasis in a subject suffering cancer. The invention also relates to a c-MAF inhibitor as therapeutic agent for use in the treatment of cancer metastasis. The invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the invention relates to a method for typing of a subject suffering cancer and for classifying a subject from cancer into a cohort.

AB Cabozantinib, an inhibitor of vascular endothelial growth factor and hepatocyte growth factor signaling, decreases bone lesions in patients with prostate cancer. To determine direct effects of cabozantinib on bone, resorption in neonatal mouse bone organ culture and on gene expression, proliferation, and phenotypic markers in osteoblast and osteoclast cell lines were examined Cabozantinib, 0.3 and 3 μM, prevented PTHrP-stimulated calcium release from neonatal mouse calvaria. Since the effect on resorption could reflect effects on osteoblasts to prevent osteoclast activation, or direct inhibition of osteoclasts, responses in osteoblastic and osteoclast precursor cell lines were examined Twenty-four-hour treatment of osteoblastic MC3T3-E1 cells with 3 μM cabozantinib decreased expression of receptor activator of NFkB ligand (RANKL) and alkaline phosphatase. Forty-eight-hour treatment of MC3T3-E1 cells with 3 μM cabozantinib inhibited cell proliferation and decreased MTT activity. Effects on alkaline phosphatase activity were biphasic, with small stimulatory effects at concns. below 3 μM. When RAW 264.7 osteoclast precursor cells differentiated with 20 ng/mL RANKL were co-treated for 24 h with 3 μM cabozantinib, expression of RANK, TRAP, cathepsin K, alpha v or beta 3 integrin, or NFATc1 were unaffected. Five-day treatment of RANKL-treated RAW 264.7 cells with 3 μM cabozantinib decreased TRAP and MTT activity. The results suggest that the osteoblast could be the initial target, with subsequent direct and indirect effects on osteoclastogenesis leading to decreased resorption. The multiple effects of cabozantinib on the cell microenvironment of bone are consistent with its effectiveness in reducing lesions from prostate cancer metastases. J. Cell. Biochem. 115: 2033-2038, 2014. © 2014 Wiley Periodicals, Inc.

AB The present invention provides novel substituted pyridinyl compds. of general formula I, pharmaceutical acceptable salts and formulations thereof useful in modulating protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. For I, each of R1, R2, R3, R4, R5 and R6 is independently H, D or F; X is C6-C10 aryl or 5-10 membered heteroaryl that are optionally substituted; and Y is an (un)substituted bicyclic heterocyclyl. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans. Example compound II was prepared in a 6-step reaction that culminated in coupling of intermediates III and 5-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-2,3-dihydro-1H-inden-1-ol. Example compds. of the invention were also tested in ALK and c-Met kinase inhibition assays. Pharmacokinetic profiles were also examined in rats, as was compound stability in human and rat liver microsomes.

AB The anti-proliferative activities of all twenty-five targeted kinase inhibitor drugs that are in clin. use were measured in two large assay panels: (1) a panel of proliferation assays of forty-four human cancer cell lines from diverse tumor tissue origins; and (2) a panel of more than 300 kinase enzyme activity assays. This study provides a head-on comparison of all kinase inhibitor drugs in use, and for six of these drugs, the first kinome profiling data in the public domain. Correlation of drug activities with cancer gene mutations revealed novel drug sensitivity markers, suggesting that cancers dependent on mutant CTNNB1 will respond to trametinib and other MEK inhibitors, and cancers dependent on SMAD4 to small mol. EGFR inhibitor drugs. Comparison of cellular targeting efficacies reveals the most targeted inhibitors for EGFR-, ABL1- and BRAF(V600E)-driven cell growth, and demonstrates that the best targeted agents combine high biochem. potency with good selectivity. For ABL1 inhibitors, we computationally deduce optimized kinase profiles for use in a next generation of drugs. Our study shows the power of combining biochem. and cellular profiling data in the evaluation of kinase inhibitor drug action.

AB A review. High-grade undifferentiated sarcomas (HGUS) are rare malignancies accounting for 6 % of all uterine sarcomas and have a very poor outcome. Histol. classification of HGUS is currently debated as a subgroup with uniform nucleoli, and frequently YWHAE-FAM22 transcript has been described, constituting a potential target for new therapies. In localized HGUS, surgery involving total hysterectomy and bilateral oophorectomy is recommended. Adjuvant radiotherapy has recently been suggested in a retrospective study to decrease local recurrence and improve survival vs. observation in localized HGUS. In metastatic or recurrent disease, chemotherapy with doxorubicin with or without ifosfamide constitutes the standard of care. Gemcitabine plus docetaxel also seems to be an interesting alternative. Targeted therapies such as pazopanib are now available for soft tissue sarcomas and so could be proposed for uterine sarcoma patients after first- or second-line chemotherapy in the metastatic phase. Further investigations are needed to determine their indications and targets. A European Organization for Research and Treatment of Cancer (EORTC) randomized trial testing maintenance therapy with cabozantinib after first-line chemotherapy in HGUS is ongoing.

AB The invention provides heteroarom. derivs. and pharmaceutically acceptable salts and formulations thereof useful in modulating the protein kinase activity, especially phosphatidylinositol 3-kinases (PI3K) and mammalian target of rapamycin (mTOR), and in modulating inter- and/or intra-cellular signaling activities such as proliferation, differentiation, apoptosis, migration and invasion. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans. Compds. of formula I [wherein W1, W2, and W3 are independently N or CRc; Z is D, CN, N3, etc.; Y is C1-6 alkyl, C3-6 cycloalkyl, C3-C6 heterocyclyl, etc.; R1 is H, Cl, C3-6 cycloalkyl, etc.; each Rc is independently H, D, F, etc.] or stereoisomers, geometric isomers, tautomers, N-oxides, solvates, metabolites, prodrugs, or pharmaceutically acceptable salts thereof are claimed and exemplified. Example compound II was prepared in seven steps (procedure given). Candidate compds. of I were assayed for their stability in liver microsomes, their oral and i.v. bioavailability, and inhibitory activity against PI3K and mTOR kinase (data given).

AB The chem. stability of cabozantinib (CBZ) was investigated using a novel stability-indicating LC method. Forced degradation of CBZ was carried out under acidic, basic, thermal, oxidative and photolytic stress conditions. Hydrolysis and oxidation were the primary pathways for this compound and three major unknown degradation products were characterized by LC/TOF-MS and LC-MS/MS. The major oxidative degradation product was isolated by preparative LC and identified by UV, HRMS and NMR techniques to be N-(4-[(N-oxide-6,7-dimethoxyquinolin-4-yl)oxy]phenyl)-N'-(4-fluorophenyl)- cyclopropane-1,1-dicarboxamide. The developed method was validated as per ICH guidelines and then successfully applied to investigate the degradation kinetics of CBZ. Degradation of CBZ followed first-order kinetics under all exptl. conditions. A V-shaped pH-rate profile over the pH range 2-10 was observed with maximum stability at pH 6. The effect of temperature on the rate of CBZ degradation was characterized using the Arrhenius equation. The activation energy for hydrolysis was 57.31 kJ mol-1 in alkaline solution

AB A review. Cabozantinib (XL184) is a multitargeted receptor tyrosine kinase with predominantly MET and vascular endothelial growth factor inhibition properties. It is currently approved by the US Food and Drug Administration for the treatment of progressive metastatic medullary thyroid cancer. The agent has a convenient once-daily oral dosing schedule and has demonstrated encouraging activity in metastatic castrate-resistant prostate cancer (CRPC). A Phase I/II trial demonstrated responses in soft tissue, visceral disease, and bone metastases in CRPC. An objective response rate of 5%, a stable disease rate of 75%, and a median progression-free survival of 6 mo was observed As compared with the 140 mg daily dose used in thyroid cancer, a lower dose of 60 mg daily is currently being utilized in prostate cancer studies due to the fact that toxicity could be reduced without compromising efficacy. Randomized trials are ongoing in comparison with prednisone or with mitoxantrone and prednisone in pretreated metastatic CRPC. Cabozantinib has demonstrated a unique mechanism of action and preliminary efficacy in the crowded therapeutic field of prostate cancer. Since multiple therapies have recently demonstrated overall survival benefit in metastatic CRPC, cabozantinib will likely face some challenges in clin. application. At present, in this rapidly evolving field, it is unclear what proportion of patients with prostate cancer will be eligible to receive this therapy. The cost of cabozantinib is likely to be another deterrent, especially if it remains more expensive than other oral therapies, such as abiraterone and enzalutamide. Defining the role of MET overexpression and RET mutations as biomarkers in prostate cancer may help to guide patient selection, and enrich and enhance the future applications of this targeted novel agent.

AB A review. Although the pipeline for new drugs seemed to be drying up, the number of new 'first-in-class' drugs appeared to be increasing. First-in-class drugs are those which use a new and unique mechanism for treating a disease or medical condition. They are a subset of new mol. entities (NMEs). The FDA reports that in 2012, 39 NMEs were approved. Twenty of these NMEs (.apprx. 50%) were identified by the FDA as first-in-class drugs. Of the 39 NMEs, 13 were designated orphan drugs and 9 of those orphan drugs were first-in-class. In 2013, there were 27 NMEs of which 9 were first-in-class. In 2013, nos. of NMEs are lower than the 2011 or 2012 but are based on fewer applications than in those years. There were 33% of NMEs that were first-in-class and 33% of the NMEs were orphan drugs. The FDA data indicate that creative new products are being developed for rare diseases.

AB A review. Background: Thyroid dysfunction is a common adverse event associated with tyrosine kinase inhibitors (TKI), but its underlying pathophysiol. is unclear. Cabozantinib is a novel TKI currently Food and Drug Administration approved for advanced medullary thyroid cancer and tested in clin. trials on solid tumors including prostate, liver, bladder, breast, and ovarian cancer. Methods: We analyzed the thyroid function of patients enrolled in two phase 2 clin. trials using cabozantinib at the National Institutes of Health Clin. Center. Two cases of thyroiditis associated with cabozantinib therapy are presented in detail, and a systematic review of the literature on TKI-associated thyroid dysfunction is also discussed. Results: Between Sept. 2012 and Sept. 2013, 33 patients were treated with cabozantinib, and follow-up thyroid function tests were available for 31 (20 males, 11 females; age 59±1 years). Thyroid dysfunction was recorded in the majority of patients (93.1%), with a predominance of subclin. hypothyroidism. Two cases showed a biphasic pattern of thyroid dysfunction characterized by a transient thyrotoxicosis followed by hypothyroidism. Color Doppler demonstrated an increase in vascularization during the thyrotoxic phase, but no uptake was visualized on nuclear medicine imaging. A systematic review of the literature resulted in the identification of 40 original manuscripts, of which 13 were case series and 6 were case reports describing TKI-associated thyroid dysfunction. Conclusion: TKI therapy often results in clin. significant thyroid dysfunction. Cabozantinib treatment commonly results in thyroid dysfunction varying from subclin. hypothyroidism to symptomatic thyrotoxicosis. Early detection and characterization of cabozantinib-associated thyroid dysfunction and close follow-up are essential to provide adequate management of this common adverse event.

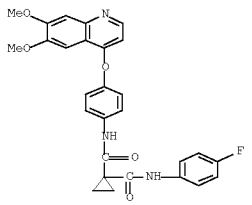
AB A review. Cabozantinib (Cometriq) is an orally administered small mol. inhibitor of multiple tyrosine kinase receptors, including those involved in the pathogenesis of medullary thyroid cancer (MTC) [i.e. rearranged during transfection (RET), MET and vascular endothelial growth factor receptor (VEGFR)-2]. Cabozantinib is indicated for the treatment of adults with progressive, unresectable locally advanced (in the EU) or metastatic (in the EU and USA) MTC. Compared with placebo, cabozantinib significantly prolonged progression-free survival, reflecting a 72 % reduction in the risk of disease progression or death, in patients with unresectable, locally advanced or metastatic MTC participating in a multinational, phase III study. A significantly higher proportion of patients receiving cabozantinib than those receiving placebo achieved an objective response or disease



stabilization (i.e. a complete or partial response, or stable disease). The overall survival benefit with cabozantinib is as yet unclear, with no significant benefit observed in two interim analyses (one prespecified, and one unplanned and conducted at the request of the US FDA). The tolerability profile of oral cabozantinib is typical for a small mol. targeting the VEGFR and other tyrosine kinase-mediated pathways, with adverse events associated with the inhibition of the VEGF pathway (e.g. gastrointestinal perforation, hemorrhage, hypertension and venous thrombosis) reported in the phase III study. Treatment-emergent adverse events were generally managed with supportive therapy, dose redns. and/or dose interruptions. Although final overall survival data are awaited, current evidence suggests cabozantinib to be a valuable treatment option for adults with progressive, unresectable locally advanced or metastatic MTC.

AB The present invention relates to oligooxopiperazines for reactivating p53. Methods of using the oligooxopiperazines are also disclosed. A first aspect of the present invention relates to a method of treating or preventing in a subject a disorder mediated by interaction of E6 with CREB-binding protein and/or p300, the method comprising administering to the subject an oligooxopiperazine that substantially mimics helix αB of the C-terminal transactivation domain of Hypoxia-Inducible Factor Iα under conditions effective to treat or prevent the disorder. A second aspect of the present invention relates to a method of inducing apoptosis or decreasing survival and/or proliferation of a cell, the method comprising contacting the cell with an oligooxopiperazine. In this study, the authors took a novel approach and functionally reactivated p53 in Human papillomaviruses (HPV)-pos. head and neck squamous cell carcinoma (HNSCC) by blocking the interaction between E6 and p300. Ectopic expression of the CH1 domain of p300 squelched E6 to disrupt E6-p300 association resulting in an increase in p53 acetylation, accumulation, and activity. CH1 domain inhibitors reactivated p53 and dramatically potentiated the efficacy of cisplatinum in HPV-pos. HNSCC. Taken together, the authors work revealed a novel druggable approach to reactivate p53 in HPV-pos. HNSCC that is expected to translate to other

AB The present invention relates to peptidomimetics for reactivating p53. Methods of using the peptidomimetics are also disclosed. One aspect of the present invention relates to a peptidomimetic, where the peptidomimetic mimics a helix having the formula X1-X2-X2-X3-X2-X2-X1-X4, wherein each X1 is any neg. charged residue, each X2 is any hydrophobic residue, X3 is any pos.-charged residue, and X4 is any polar residue. Addnl., the peptidomimetic may contain one or more bridges linking the side chains of its component amino

acids. Another aspect of the present invention relates to a method of treating or preventing in a subject a disorder mediated by interaction of E6 with CREB-binding protein and/or p300, the method comprising administering to the subject a peptidomimetic of the present invention under conditions effective to treat or prevent the disorder. Another aspect of the present invention relates to a method of inducing apoptosis and decreasing survival and/or proliferation of a cell, the method comprising contacting the cell with a peptidomimetic. In this study, the authors took a novel approach and functionally reactivated p53 in Human papillomaviruses (HPV)-pos. head and neck squamous cell carcinoma (HNSCC) by blocking the interaction between E6 and p300. Ectopic expression of the CH1 domain of p300 squelched E6 to disrupt E6-p300 association resulting in an increase in p53 acetylation, accumulation, and activity. CH1 domain inhibitors reactivated p53 and dramatically potentiated the efficacy of cisplatinum in HPV-pos. HNSCC. Taken together, the authors work revealed a novel druggable approach to reactivate p53 in HPV-pos. HNSCC that is expected to translate to other HPV-pos. carcinomas.

AB Most melanomas harbor oncogenic BRAFv600 mutations, which constitutively activate the MAPK pathway. Although MAPK pathway inhibitors show clin. benefit in BRAFV600-mutant melanoma, it remains incompletely understood why 10% to 20% of patients fail to respond. Here, we show that RAF inhibitor-sensitive and inhibitor-resistant BRAFv600-mutant melanomas display distinct transcriptional profiles. Whereas most drug-sensitive cell lines and patient biopsies showed high expression and activity of the melanocytic lineage transcription factor MITF, intrinsically resistant cell lines and biopsies displayed low MITF expression but higher levels of NF-κ signaling and the receptor tyrosine kinase AXL. In vitro, these MITF-low/NF-κβ-high melanomas were resistant to inhibition of RAF and MEK singly or in combination, and ERK. Moreover, in cell lines, NF- activation antagonized MITF expression and induced both resistance marker genes and drug resistance. Thus, distinct cell states characterized by MITF or NF-κβ activity may influence intrinsic resistance to MAPK pathway inhibitors in BRAFv600-mutant melanoma.

AB Background. The aim of this study was to assess the frequency of potentially actionable genomic alterations in breast cancer that could be targeted with approved agents or investigational drugs in clin. trials using a next-generation sequencing-based genomic profiling assay performed in a Clin. Laboratory Improvement Amendments-certified and College of American Pathologists-accredited com. laboratory Methods. Fifty-one breast cancers were analyzed, including primary tumor biopsies of 33 stage I-II and 18 stage IV cancers (13 soft tissue, 3 liver, and 2 bone metastases). We assessed 3,230 exons in 182 cancer-related genes and 37 introns in 14 genes often rearranged in cancer for base substitutions, indels, copy number alterations, and gene fusions. The average median sequencing depth was 1,154×. Results. We observed 158 genomic alterations in 55 genes in 48 of 51 (94%) tumors (mean 3.1, range 0-9). The average number of potentially therapeutically relevant alterations was similar in primary (1.6, range 0-4) and in heavily pretreated metastatic cancers (2.0, range 0-4) (p = .24). The most common actionable alterations were in PIK3CA (n = 9, phosphatidylinositol 3-kinase [PI3K]/mammalian target of rapamycin [mTOR] inhibitors), NF1 (n = 7, PI3K/mTOR/mitogen-activated protein kinase inhibitors), v-akt murine thymoma viral oncogene homolog 1-3 (n = 7, PI3K/mTOR/AKT inhibitors), BRCA1/2 (n = 6, poly[ADP-ribose] polymerase inhibitors), and CCND1,2 and CCNE (n = 8)/cycline dependent kinase (CDK)6 (n = 1) (CDK4/6 inhibitors), KIT (n = 1, imatinib/sunitinib), ALK (n = 1, crizotinib), FGFR1,2 (n = 5, fibroblast growth factor receptor inhibitors), and EGFR (n = 2, epidermal growth factor receptor inhibitors). Our sequencing assay also correctly identified all six cases with HER2 (ERBB2) amplification by fluorescence in situ hybridization when tumor content was adequate. In addition, two known activating HER2 mutations were identified, both in unamplified cases. Conclusion. Overall, 84% of cancers harbored at least one genomic alteration linked to potential treatment options. Systematic evaluation of the predictive value of these genomic alterations is critically important for further progress in this field.

I

AB The high incidence of MET oncogene activation in human malignancies has prompted researchers to develop MET inhibitors. As part of our efforts to developing effective and safe therapeutic agents against MET-dependent tumors, a pyridone-based class II MET inhibitor, namely, 1-(4-((2-amino-3-iodopyridin-4-yl)-oxy)-3-fluorophenyl)-N-(4-fluorobenzyl)- 4-methoxy-6-oxo-1,6-dihydropyridine-3-carboxamide (3s, I), was identified. Knowledge of the binding mode of class II MET inhibitors led to the design of new inhibitors that utilize 2-pyridone to conformationally restrain key pharmacophoric groups within the mol. Integrated mol. docking and SAR studies resulted in the discovery of a novel class of pyridone MET inhibitors with high potency (IC50 of 0.005 μM) and efficient selectivity (>5000 fold) to VEGFR-2, c-Kit and RET kinases.

AB A review. Since chemotherapy has been shown to be unsuccessful in case of advanced thyroid carcinomas, the research for new therapies is fundamental. Clin. trials of many tyrosine kinase inhibitors as well as anti-angiogenic inhibitors suggest that patients with thyroid cancer could have an advantage with new target therapy. Recently, Food and Drug Administration approved two targeted therapies, vandetanib and cabozantinib for the treatment of metastatic thyroid carcinomas with acceptable outcome. We summarized the results and the toxic effects associated with these treatments reported in clin. trials. Future trials should aim at combinations of targeted agents with or without other treatment modalities to obtain a more effective result in thyroid carcinoma treatment.

AB Context: Sorafenib, a tyrosine kinase inhibitor, is a common first-line therapy for advanced differentiated thyroid cancer (DTC). However, responses are not durable and drug toxicity remains a problem. Objective: The objective of the study was to determine the efficacy of salvage therapy after first-line sorafenib failure. Design: This was a retrospective review at M. D. Anderson Cancer Center from Jan. 2005 to May 2013. Patients: The study included patients with metastatic DTC who received salvage therapy after their initial sorafenib failure (group 2). Patients who received first-line sorafenib only (group 1) were evaluated for comparison of overall survival (OS). Outcome Measures: Progression-free survival, best response, and median OS were measured. Results: Sixty-four patients with metastatic, radioactive iodine refractory DTC were included; 35 were in group 1 and 25 were in group 2, and the groups were well balanced. Median OS of all 64 patients receiving first line sorafenib was 37 mo; median OS was significantly longer with salvage therapy compared with sorafenib alone (58 vs 28 mo, P = .013). In group 2, 17 patients were evaluable for best response, although two patients had toxicity with sorafenib, which was discontinued before restaging. Best responses with first-line sorafenib were partial response in 2 of 15 (13%), stable disease in 10 of 15 (67%), and progressive disease in 3 of 15 (20%) patients. With salvage therapy, partial responses were seen in 7 of 17 (41%) and stable disease in 10 of 17 (59%) patients. Median progression-free survival was 7.4 mo with first-line sorafenib and 11.4 mo with salvage therapy. Salvage therapy included sunitinib (n = 4), pazopanib (n = 3), cabozantinib (n = 4), lenvatinib (n = 3), and vemurafenib (n = 3). Conclusions: Other targeted agents are effective salvage treatments after sorafenib failure, despite similar mechanisms of action, and should be offered to patients who are able to receive salvage therapy.

AB The present invention provides novel substituted pyridinyl compds. of general formula I, pharmaceutical acceptable salts and formulations thereof useful in modulating protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. For I, each of R1, R2, R3, R4, R5 and R6 is independently H, D or F; X is C6-C10 aryl or 5-10 membered heteroaryl that are optionally substituted; and Y is an (un)substituted bicyclic heterocyclyl. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans. Example compound II was prepared in a 6-step reaction that culminated in coupling of intermediates III and 5-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-2,3-dihydro-1H-inden-1-ol. Example compds. of the invention were tested in ALK and c-Met kinase inhibition assays. Pharmacokinetic profiles were also examined in rats, as was compound stability in human and rat liver microsomes.

AB MET signaling was suggested a potential role in hepatocellular carcinoma (HCC) and associated with prometastasis during antiangiogenesis therapy. We investigated the potential association between MET expression and therapeutic response to sorafenib in patients with HCC. Antitumor effects of cabozantinib, a dual inhibitor of MET and VEGFR2, were examined in cultured HCC cells as well as in vivo models. Total MET and phosphorylated MET (p-MET) were measured in 29 resected HCC specimens, and correlated with response to sorafenib as postoperative adjuvant therapy. In the second set of expts. using cultured HCC cells, and mouse xenograft and metastatic models, effects of cabozantinib were examined High level of p-MET in resected HCC specimens was associated with resistance to adjuvant sorafenib therapy. In cultured HCC cells that expressed p-MET, cabozantinib inhibited the activity of MET and its downstream effectors, leading to G1-phase arrest. Cabozantinib inhibited tumor growth in p-MET-pos. and p-MET-neg. HCC by decreasing angiogenesis, inhibiting proliferation, and promoting apoptosis, but it exhibited more profound efficacy in p-MET-pos. HCC xenografts. Cabozantinib blocked the hepatocyte growth factor (HGF)-stimulated MET pathway and inhibited the migration and invasion of the HCC cells. Notably, cabozantinib reduced the number of metastatic lesions in the lung and liver in the exptl. metastatic mouse model. Patients with HCC with high level of p-MET are associated with resistance to adjuvant sorafenib treatment. The dual blockade of VEGFR2 and MET by cabozantinib has significant antitumor activities in HCC, and the activation of MET in HCC may be a promising efficacy-predicting biomarker. AB Purpose of review: There is currently an explosion in the no. of so-called targeted therapies. As new indications for these agents multiply, there is also an increase of new and less new side-effects. Recent findings: Given this rapidly evolving field, any literature on that topic is rapidly obsolete and needs re-evaluation. Summary: Targeted therapies are associated with a wide spectrum of adverse events, which cannot always be easily separated from the complications linked to cancer, its therapy, and comorbidities. A high awareness of these events might improve the patient's quality of life and contribute to the recognition of new syndromes.

AB The invention provides a cabozantinib capsule compn. and its prodn. method. The cabozantinib capsule composition is composed of cabozantinib 10-60wt%, carrier 15-70 wt%, organic solvent 10-30wt%, surfactant 0.5-3.0wt%, micronized silica gel 1.0-3.0wt% and starch 5.0-20wt%. The carrier comprises one or more of glycerol monostearate, polyethylene glycol 6000, cetyl alc. and octyl alc. The organic solvent comprises one or more of ethanol, methanol and acetone. The surfactant comprises one or more of sodium dodecyl sulfate, Tween 80 and lecithin. The production method includes adding carrier into organic solvent, heating to 60°C, adding cabozantinib and surfactant, vacuum drying at 40°C, comminution by gas stream to obtain powder with grain size of 1-8 μm, adding micronized silica gel and starch, mixing, and packaging in. The produced cabozantinib capsule preparation has good oral absorption, high dissoln. rate, high bioavailability, and can remarkably inhibit the growth of tumor volume The invention has simple preparation process, low cost, and applicability for com. process.

AB Background: In the past decade, targeted therapy with antiangiogenic drugs has become standard of care for most types of metastatic, progressive thyroid cancer. While these drugs were thought initially to be less toxic than traditional chemotherapy, they can have rare but serious and fatal toxicities. Once such toxicity that has been reported in other tumor types is upper airway fistula formation, which can be life-threatening. Summary: Here, we describe three patients treated with antiangiogenic tyrosine kinase inhibitors at two academic institutions who developed aerodigestive fistula. All three patients had risk factors for fistula formation, which included external beam radiation and/or large tumor with invasion of the tracheal wall. Conclusions: Fistula formation is a known but rare side effect of antiangiogenic tyrosine kinase inhibitors. Knowledge of the risk factors that may predispose thyroid cancer patients to this serious adverse event is vital prior to prescribing antiangiogenics. Particular caution should be observed when using these drugs in patients undergoing radiation therapy or surgery, or in patients whose tumor is invading vital structures of the neck, as they may be at higher risk of developing this rare complication. In these patients, antiangiogenic tyrosine kinase inhibitors should be used cautiously, patients should be aware of the risk, and physicians should monitor patients for symptoms of fistula.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Compact replicating retroviral vectors using a minimal promoter to express a therapeutic gene with a size of 0.9-1.9 kb are described. An internal ribosome entry sequence may be used for polycistronic expression cassettes. The vectors do not use the prior art SCP1, Ad, or CMV core promoters. Development and optimization of vectors is described.

AB The invention discloses Cabozantinib dispersible tablet and prepn. method and application thereof. The inventive Cabozantinib dispersible tablet consists of the following component according to weight percentage: Cabozantinib 10-60%, filler 10-40%, disintegrant 10-50%, acidulant 10-50%, binder 0.1-10%, and lubricant and glidant 0.1-20%. Compared with the common tablet, the inventive dispersible tablet contains no surfactant, its solubility, dispersivity, and disintegrability are good, and it can be completely disintegrated within 1 min. The prepared Cabozantinib dispersible tablet has high dissoln. rate, high bioavailability, rapid distribution in vivo, stable quality, and good taste. The preparation method is simple, and suitable for industrial production

AB Background Prostate cancer is incurable once it has metastasized to the bone. Appropriate preclin. models are lacking. The therapeutic efficacy of the multikinase inhibitor cabozantinib was assessed in an orthotopic xenograft model of castration-resistant prostate cancer (CRPC) bone metastasis using noninvasive, multimodality functional imaging. Methods NOD/SCID mice were injected intratibially with luciferase-expressing ERG (v-ets avian erythroblastosis virus E26 oncogene homolog) rearranged VCaP human prostate carcinoma cells. The response of VCaP xenografts (n = 7 per group) to cabozantinib was investigated using bioluminescence imaging and anatomical and diffusion weighted magnetic resonance imaging. This enabled quantitation of tumor volume and apparent diffusion coefficient (ADC). Bone uptake of technetium-methylene diphosphonate (99mTc-MDP) was assessed by single-photon emission computed tomog. Ex vivo micro computed tomog. was used to quantify bone volume and correlated with appropriate histopathol. Statistical significance was determined using the two-sided Mann-Whitney test or Wilcoxon signed rank test. Results VCaP xenografts were predominantly osteosclerotic with some osteolytic activity. Fluorescent in situ hybridization anal. confirmed retention of ERG oncogene rearrangements. Cabozantinib induced a statistically significant 52% reduction in tumor luminance (P = .02) and stasis in tumor volume after 15 days of treatment. Tumor ADC statistically significantly increased with cabozantinib and was associated with extensive necrosis (after 10 days, mean tumor ADC ± SD = 556±43×10-6 mm2/s vs pretreatment ADC = 485±43×10-6 mm2/s; P = .02). Tumor-associated uptake of 99mTc-MDP was statistically significantly reduced after 3 days of treatment (P = .02), sustained over 15 days treatment, and associated with a statistically significant (P = .048) reduction in bone growth on the tibial cortex, yet a highly statistically significant (P = .001) increase in trabecular bone volume Conclusions The intratibial VCaP model faithfully emulates clin. disease. Cabozantinib exerts potent effects on both tumor and tumor-induced bone matrix remodeling, and quantitation of ADC provides a clin. translatable imaging biomarker for early, sensitive assessment of treatment response in CRPC bone metastasis.

AB The present invention relates to a method for the diagnosis or the prognosis of metastasis in prostate cancer which comprises determining if the c-MAF gene is amplified in a primary tumor sample. Likewise, the invention also relates to a method for the diagnosis or the prognosis of metastasis in prostate cancer, as well as to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which, comprise determining the c-MAF expression level. Finally, the invention relates to the use of a c-MAF inhibitor as therapeutic target for treating the prostate cancer.

OTHER SOURCE(S): MARPAT 160:555604

AB By using a phage display derived peptide as an initial template, compds. have been developed that are highly specific against Mdm2/Mdm4. These compds. exhibit greater potency in p53 activation and protein-protein interaction assays than a compound derived from the p53 wild-type sequence. Unlike nutlin, a small mol. inhibitor of Mdm2/Mdm4, the phage derived compds. can arrest cells resistant to p53 induced apoptosis over a wide concentration range without cellular toxicity, suggesting they are highly suitable for cyclo-therapy. In one embodiment, there is disclosed the peptide comprising or consisting o f the amino acid sequence of SEQ ID NO 1 (TSFXaaiEYWXaa3LLXaai), wherein Xaa3 can be N or A and wherein in case Xaa3 is N, Xaai is not A and/or Xaa2 is not S. In one embodiment, Xaa3 can be any type of amino acid other than A and wherein in case Xaa3 is N, Xaaj is not A and/or Xaa2 is not S. Those peptides have been shown to inhibit the p53:Mdm2 interactions with a nanomolar affinity.

AB Background: Limited data exist on outcomes for metastatic renal cell carcinoma (mRCC) patients treated with multiple lines of therapy. Benchmarks for survival are required for patient counselling and clin. trial design. Methods: Outcomes of mRCC patients from the International mRCC Database Consortium database treated with 1, 2, or 3+ lines of targeted therapy (TT) were compared by proportional hazards regression. Overall survival (OS) and progression-free survival (PFS) were calculated using different population inclusion criteria. Results: In total, 2705 patients were treated with TT of which 57% received only first-line TT, 27% received two lines of TT, and 16% received 3+ lines of TT. Overall survival of patients who received 1, 2, or 3+ lines of TT were 14.9, 21.0, and 39.2 mo, resp., from first-line TT (P<0.0001). On multivariable anal., 2 lines and 3+ lines of therapy were each associated with better OS (HR=0.738 and 0.626, P<0.0001). Survival outcomes for the subgroups were as follows: for all patients, OS 20.9 mo and PFS 7.2 mo; for those similar to eligible patients in the first-line ADAPT trial, OS 14.7 mo and PFS 5.6 mo; for those similar to patients in first-line TIVO-1 trial, OS 24.8 mo and PFS 8.2 mo; for those similar to patients in second-line INTORSECT trial, OS 13.0 mo and PFS 3.9 mo; and for those similar

to patients in the third-line GOLD trial, OS 18.0 mo and PFS 4.4 mo. Conclusions: Patients who are able to receive more lines of TT live longer. Survival benchmarks provide context and perspective when interpreting and designing clin. trials.

AB A review. Majority of patients with metastatic castrate resistant prostate cancer (mCRPC) develop bone metastases which results in significant morbidity and mortality as a result of skeletal-related events (SREs). Several bone-targeted agents are either in clin. use or in development for prevention of SREs. Bisphosphonates were the first class of drugs investigated for prevention of SREs and zoledronic acid is the only bisphosphonate that is FDA-approved for this indication. Another bone-targeted agent is denosumab which is a fully humanized monoclonal antibody that binds to the RANK-L thereby inhibiting RANK-L mediated bone resorption.While several radiopharmaceuticals were a approved for pain palliation in mCRPC including strontium and samarium, alpharadin is the first radiopharmaceutical to show significant overall survival benefit. Contemporary therapeutic options including enzalutamide and abiraterone have effects on pain palliation and SREs as well. Other novel bone-targeted agents are currently in development, including the receptor tyrosine kinase inhibitors cabozantinib and dasatinib. Emerging therapeutics in mCRPC has resulted in great strides in preventing one of the most significant sources of complications of bone metastases.

AB The invention discloses a synthesis method of antitumor therapeutic drug of cabozantinib., comprising: using 4-(6, 7- dimethoxy quinoline -4- oxy)-phenylamine to react with 1-((4- fluorophenyl) carbamoyl) cyclopropyl acyl halide, an acid-binding agent in organic solvent at -5~20 ℃ for 0.5~2h to obtain cabozantinib; the inventive method uses cheap raw materials, has mild conditions, simple and convenient operation, stable process, good repeatability, high molar yield, low cost, so invention is an applicable method for com. production of cabozantinib. Cabozantinib was prepared via chlorination of 6,7-dimethoxyquinolin-4-ol; the resulting 4-chloro-6,7-dimethoxyquinoline underwent condensation with 4-aminophenol or 4-nitrophenol to give the corresponding ethers, which underwent redn and/or acylation with 1-[(4-fluorophenyl)carbamoyl]cyclopropylcarbonyl halides to give cabozantinib. The said 1-[(4-fluorophenyl)carbamoyl]cyclopropylcarbonyl halides were prepared via condensation of 1,1-cyclopropanedicarboxylic acid with p-fluoroaniline followed by halogenation. The inventive method uses cheap raw materials, has mild conditions, simple and convenient operation, stable process, good repeatability, high molar yield, low cost, so invention is an applicable method for com. production of cabozantinib.

AB The invention relates to process for the prepn. of cabozantinib and its intermediate of formula I from 1,1-cyclopropane dicarboxylic acid diester of formula II [R1 = C1-10 alkyl]. For example, cabozantinib was prepared by hydrolysis of compound II [R1 = Et] to afford 1-(ethoxycarbonyl)cyclopropanecarboxylic acid, which underwent amidation

reaction with 4-aminophenol followed by arylation with 4-chloro-6,7-dimethoxyquinoline to afford compound I [R1 = Et], which underwent hydrolysis followed by amidation with 4-fluoroaniline to afford cabozantinib.

AB Pain neg. affects quality of life for cancer patients. Preliminary data in metastatic castration-resistant prostate cancer (mCRPC) suggested a benefit of the oral tyrosine kinase inhibitor cabozantinib to pain palliation. Prospective evaluation of cabozantinib's benefits on pain and narcotic use in mCRPC.This was a nonrandomized expansion (NRE) cohort (n = 144) of a phase 2 randomized discontinuation trial in docetaxel-refractory mCRPC patients. Pain and interference of symptoms with sleep and general activity were electronically self-reported daily for 7-d intervals at baseline and regularly scheduled throughout the study. Mean per-patient scores were calculated for each interval. Narcotic use was recorded daily during the same intervals.Open-label cabozantinib (100 mg or 40 mg). The following stringent response definition was used: clin. meaningful pain reduction (≥30% improvement in mean scores from baseline) confirmed at a later interval without concomitant increases in narcotics. Only patients with moderate or severe baseline pain were analyzed.Sixty-five patients with moderate or severe baseline pain were evaluable. Of these, 27 (42%) experienced pain palliation according to the stringent response definition. Thirty-seven patients (57%) had clin. meaningful pain relief at two consecutive intervals, reported ≥6 wk apart in the majority. Forty-four patients (68%) had palliation at one or more intervals; 36 (55%) decreased narcotics use during one or more intervals. Clin. meaningful pain reduction was associated with significant ($p \leq 0.001$) improvements in sleep quality and general activity. A limitation of this study was its open-label design. Cabozantinib demonstrated clin. meaningful pain palliation, reduced or eliminated patients' narcotic use,

and improved patient functioning, thus meriting prospective validation in phase 3 studies.We evaluated the potential of cabozantinib to improve symptoms in patients with metastatic prostate cancer that no longer responds to standard therapies. We saw a promising reduction in pain and reduced need for narcotic painkillers. Larger, well-controlled trials are necessary to confirm these findings.

AB The present invention provides substituted azaindole prodrugs of vemurafenib, methods of making said prodrugs, pharmaceutical compns. of said prodrugs and methods of using said prodrugs and pharmaceutical compns. thereof to treat or prevent diseases or disorders such as cancer. The prodrugs have general formula I, wherein each of X and Y is independently H, -C(:O)R3, -C(:O)OR4, -C(R1R2)OC(:O)R3, -C(R1R2)OC(:O)OR4 or -C(R1R2)OP(:O)(OR4)(OR4a), with the proviso that when Y is H, X is not -C(:O)CH3 or H; each R1 and R2 is independently H, D, C1-6alkyl, etc.; each R3 is independently H, D, C1-10alkyl, etc.; and each R4 and R4a is independently H, C1-10alkyl, C3-8cycloalkyl, etc. Example compound II was prepared by reacting vemurafenib with Et chloroformate. Various prodrugs of the invention were studied for their stability in liver microsomes, their oral and i.v. bioavailability, and their antitumor properties.

AB Purpose: Cabozantinib, an orally available multityrosine kinase inhibitor with activity against mesenchymal epithelial transition factor (MET) and VEGF receptor 2 (VEGFR2), induces resolution of bone scan lesions in men with castration-resistant prostate cancer bone metastases. The purpose of this study was to determine whether cabozantinib elicited a direct antitumor effect, an indirect effect through modulating bone, or both. Exptl. Design: Using human prostate cancer xenograft studies in mice, we determined the impact of cabozantinib on tumor growth in soft tissue and bone. In vitro studies with cabozantinib were performed using (i) prostate cancer cell lines to evaluate its impact on cell growth, invasive ability, and MET and (ii) osteoblast cell lines to evaluate its impact on viability and differentiation and VEGFR2. Results: Cabozantinib inhibited progression of multiple prostate cancer cell lines (Ace-1, C4-2B, and LuCaP 35) in bone metastatic and soft tissue murine models of prostate cancer, except for PC-3 prostate cancer cells in which it inhibited only s.c. growth. Cabozantinib directly inhibited prostate cancer cell viability and induced apoptosis in vitro and in vivo and inhibited cell invasion in vitro. Cabozantinib had a dose-dependent biphasic effect on osteoblast activity and inhibitory effect on osteoclast production in vitro that was reflected in vivo. It blocked MET and VEGFR2 phosphorylation in prostate cancer cells and osteoblast-like cells, resp. Conclusion: These data indicate that cabozantinib has direct antitumor activity, and that its ability to modulate osteoblast activity may contribute to its antitumor efficacy. AB A review. Treatment with cabozantinib, an inhibitor of MET and VEGFR2 signaling, has demonstrated clin. benefit in early trials in men with metastatic prostate cancer. Preclin. evidence suggests that cabozantinib can kill cancer cell seeds while disrupting angiogenesis and stromal cells in the metastatic soil.

AB The invention provides substituted pyrazolone compds.of formula I, stereoisomers, geometric isomers, tautomers, oxynitrides, hydrates, solvates, metabolites, pharmaceutically acceptable salts or prodrugs thereof, and pharmaceutical preparation for regulating the activity of protein kinases and adjusting the signal response in the cell or between cells. The invention also relates to pharmaceutical compns. comprising the compds. and a method for treating hyperproliferative disorder of mammal, particularly human using the compns. Compds. of formula I [wherein Q is H, NH2 and derivative, OH and derivs., -NHCOR, etc.; W is (un)substituted CH or N; X, Y, and Z are independently H, D, C1-6 alkyl, C3-8 cycloalkyl-C1-4 alkylene, etc.; R1-R6 are independently H, D, F, Cl, Br, CN, etc.; R is H, C1-6 alkyl, C3-8 cycloalkyl-C1-4 alkylene, C3-7 heterocycloalkyl, etc.] and their stereoisomers, geometric isomers, tautomers, oxynitrides, hydrates, solvates, metabolites, pharmaceutically acceptable salts or prodrugs thereof, are claimed and exemplified. For example, II was prepared in a multistep process (procedure given). I were evaluated for stability in liver microsomes and pharmacokinetic properties in mice, rats, dogs, and monkeys (data given). Binding of I to receptor tyrosine kinases was determined using KINOMEscan where II exhibited binding constant (Kd) values of 23 nM for KDR tyrosine kinase and 4.4 nM for c-Met tyrosine kinase.

AB This invention relates to the field of lipid kinases and modulators thereof. In particular, the invention relates to compds. I [W = D, CN, N3, (un)substituted C5-12 spirobicyclyl or C≡CX; X = H, D, alkyl, cycloalkyl, etc.; R1 = H, D, Cl, alkyl, etc.; R2 = alkyl, cycloalkyl, aryl, etc.] as modulators of phosphatidylinositol 3-kinases (PI3 kinases or PBKs) signaling pathways, and methods of their use. Twenty-nine compds. I were prepared and disclosed. E.g., a multi-step synthesis of II, starting from 5-bromo-2-chloro-3-nitropyridine, was described. Exemplified compds. I exhibited potent activities in the PI3Kα(h) and mTOR(h) assays (data given for representative compds. I). The invention also provides pharmaceutically acceptable compns. comprising compds. I and methods of using the compns. in modulating of PI3K signaling pathways and their related disorders in mammals, especially humans.

AB A review. Although targeted therapy against VEGF and mTOR have revolutionized the treatment of advanced renal cell carcinoma (RCC), addnl. agents are required due to toxicity and resistance to currently available drugs. Some next-generation tyrosine kinase inhibitors have focused on VEGF, narrowing the spectrum of receptors which are inhibited and enhancing binding affinity. However, targeting novel receptors with tyrosine kinase inhibition of addnl. receptor targets has also emerged as an important future therapeutic strategy for RCC, both clear cell and variant histol. New pathways being targeted include FGF, angiopoietin and MET. In this review, we highlight five novel tyrosine kinase inhibitors in development for RCC: tivozanib; dovitinib; regorafenib; cabozantinib; and tivantinib.

AB A review. Introduction: The receptor tyrosine kinase c-MET displays aberrant activation in the malignant phenotype of various tumors, and thus, has drawn considerable attention as drug target for cancer therapy. Many c-MET inhibitors are now under clin. investment, and one of them - Cabozantinib - has been approved by US FDA in 2012 for the treatment of medullary thyroid cancer, which further proved the feasibility of c-MET inhibition method in cancer therapy. Areas covered: This article briefly outlines the role of c-MET in oncogenesis and provides a broad overview of the assays used to characterize new inhibitors. Then, a series of representative small-mol. inhibitors of c-MET, especially from the published patent literature from 2011 to 2013, are recorded. Herein, the challenges in the kinase inhibitor design, such as the inhibitor selectivity and resistance mutations, are also discussed. Expert opinion: Up to now, at least 17 inhibitors of c-MET are under clin. evaluation, and several agents exhibit encouraging results. Thus, inhibiting c-MET signaling has major therapeutic value in cancer therapy. Focus on the selectivity of both types of inhibitors, with potent selectivity or multi-targets, have demonstrated antitumor efficacy. The network pharmacol. and clin. trials integrated would provide powerful tools to further evaluate the superiority of both inhibitors in continued efficacy and toxicity.

AB Background: A limited no. of approved therapeutic options are available to metastatic medullary thyroid cancer (MTC) patients, and the response to conventional chemotherapy and/or radiotherapy strategies is inadequate. Sporadic and inherited mutations in the tyrosine kinase RET result in oncogenic activation that is associated with the pathogenesis of MTC.

AB In prostate cancer, multiple metastases from the same patient share similar copy number, mutational status, erythroblast transformation specific (ETS) rearrangements, and methylation patterns supporting their clonal origins. Whether actionable targets such as tyrosine kinases are also similarly expressed and activated in anatomically distinct metastatic lesions of the same patient is not known. We evaluated active kinases using phosphotyrosine peptide enrichment and quant. mass spectrometry to identify druggable targets in metastatic castration-resistant prostate cancer obtained at rapid autopsy. We identified distinct phosphopeptide patterns in metastatic tissues compared with treatment-naive primary prostate tissue and prostate cancer cell line-derived xenografts. Evaluation of metastatic castration-resistant prostate cancer samples for tyrosine phosphorylation and upstream kinase targets revealed SRC, epidermal growth factor receptor (EGFR), rearranged during transfection (RET), anaplastic lymphoma kinase (ALK), and MAPK1/3 and other activities while exhibiting intrapatient similarity and interpatient heterogeneity. Phosphoproteomic analyses and identification of kinase activation states in metastatic castration-resistant prostate cancer patients have allowed for the prioritization of kinases for further clin. evaluation.

AB Cabozantinib is a potent inhibitor of MET, RET, and vascular endothelial factor receptor 2 (VEGFR2), as well as other tyrosine kinases that have been implicated in tumor development and progression. The object of this study was to determine the in vitro biochem. and cellular inhibitory profile of cabozantinib against RET, and in vivo antitumor efficacy using a xenograft model of MTC.Methods: Cabozantinib was evaluated in biochem. and cell-based assays that determined the potency of the compound against wild type and activating mutant forms of RET. Addnl., the pharmacodynamic modulation of RET and MET and in vivo antitumor activity of cabozantinib was examined in a MTC tumor model following subchronic oral administration.Results: In biochem. assays, cabozantinib inhibited multiple forms of oncogenic RET kinase activity, including M918T and Y791F mutants. Addnl., it inhibited proliferation of TT tumor cells that harbor a C634W activating mutation of RET that is most often associated with MEN2A and familial MTC. In these same cells grown as xenograft tumors in nude mice, oral administration of cabozantinib resulted in dose-dependent tumor growth inhibition that correlated with a reduction in circulating plasma calcitonin levels. Moreover, immunohistochem. analyses of tumors revealed that cabozantinib reduced levels of phosphorylated MET and RET, and decreased tumor cellularity, proliferation, and vascularization.Conclusions: Cabozantinib is a potent inhibitor of RET and prevalent mutationally activated forms of RET known to be associated with MTC, and effectively inhibits the growth of a MTC tumor cell model in vitro and in vivo.

AB Purpose of review: Several new targeted therapies with multikinase inhibitors targeting vascular endothelial growth factor (VEGF), rearranged during transfection and v-raf murine sarcoma viral oncogene homolog B1 pathways have been tested in clin. trials for radioiodine-refractory differentiated thyroid cancer (DTC) and medullary thyroid cancer (MTC) in the past 10 years. Recent findings: Results of the first phase III trial of VEGF-targeted therapy (sorafenib) in DTC were presented in June 2013, and two phase III trials with VEGF and rearranged during transfection-targeted therapies (vandetanib and cabozantinib) in MTC have led to approval by US Food and Drug Administration in the past 2 years. Whereas such therapies increase median progression-free survival compared to placebo, there is no therapy proven to improve overall survival yet. Significant potential adverse event risks associated with such therapies need to be recognized. Dissemination of knowledge about targeted therapies is critical for various medical specialists as patient care for thyroid cancers is best delivered in a multidisciplinary setting. Summary: Successful development of targeted systemic therapies in DTC and MTC in the past 5 years is incredibly exciting in the field and patients with advanced DTC/MTC now have new standard-of-care therapy options.

AB When using molecularly targeted agents (MTAs), oncologists and patients face new and sometimes unexpected toxicities. Though ocular adverse events (OAEs) are not uncommon with chemotherapy, they are rarely severe or dose limiting. Ocular toxicity profile may differ with MTAs, indeed severe and dose limiting toxicities have been described with targeted therapies currently under investigation. Our study aimed to review OAEs experienced with MTAs approved in solid tumors. This review revealed that many OAEs, frequent and potentially severe, exist and concern most MTAs. The suggestion is prompt referral of patients with severe pain and/or visual impairment to the ophthalmologist since these symptoms can be associated with potentially severe OAE and need ophthalmic assessment. Oncologists must be aware of such events and their potential severity for better treatment and better diagnosis in daily practice as well as in clin. trials.

AB Background Anti-angiogenic treatment of glioblastoma characteristically results in therapy resistance and tumor progression via diffuse infiltration. Monitoring tumor progression in these patients is thwarted because therapy results in tumor invisibility in contrast-enhanced (CE) MRI. To address this problem, we examined whether tumor progression could be monitored by metabolic mapping using 1H MR spectroscopic imaging (MRSI). Methods We treated groups of BALB/c nu/nu mice carrying different orthotopic diffuse-infiltrative glioblastoma xenografts with bevacizumab (anti-vascular endothelial growth factor [VEGF] antibody, n = 13), cabozantinib (combined VEGF receptor 2/c-Met tyrosine kinase inhibitor, n = 11), or placebo (n = 15) and compared CE-MRI with MRS-derived metabolic maps before, during, and after treatment. Metabolic maps and CE-MRIs were subsequently correlated to histol. and immunohistochem. Results In vivo imaging of choline/n-acetyl aspartate ratios via multivoxel MRS is better able to evaluate response to therapy than CE-MRI. Lactate imaging revealed that diffuse infiltrative areas in glioblastoma xenografts did not present with excessive glycolysis. In contrast, glycolysis was observed in hypoxic areas in angiogenesis-dependent compact regions of glioma only, especially after anti-angiogenic treatment. Conclusion Our data present MRSI as a powerful and feasible approach that is superior to CE-MRI and may provide handles for optimizing treatment of glioma. Furthermore, we show that glycolysis is more prominent in hypoxic areas than in areas of diffuse infiltrative growth. The Warburg hypothesis of persisting glycolysis in tumors under normoxic conditions may thus not be valid for diffuse glioma.

AB Purpose: Cabozantinib, a tyrosine kinase inhibitor (TKI) of hepatocyte growth factor receptor (MET), vascular endothelial growth factor receptor 2, and rearranged during transfection (RET), demonstrated clin. activity in patients with medullary thyroid cancer (MTC) in phase I. Patients and Methods: We conducted a double-blind, phase III trial comparing cabozantinib with placebo in 330 patients with documented radiog. progression of metastatic MTC. Patients were randomly assigned (2:1) to cabozantinib (140 mg per day) or placebo. The primary end point was progression-free survival (PFS). Addnl. outcome measures included tumor response rate, overall survival, and safety. Results: The estimated median PFS was 11.2 mo for cabozantinib vs. 4.0 mo for placebo (hazard ratio, 0.28; 95% CI, 0.19 to 0.40; P < .001). Prolonged PFS with cabozantinib was observed across all subgroups including by age, prior TKI treatment, and RET mutation status (hereditary or sporadic). Response rate was 28% for cabozantinib and 0% for placebo; responses were seen regardless of RET mutation status. Kaplan-Meier ests. of patients alive and progression-free at 1 yr are 47.3% for cabozantinib and 7.2% for placebo. Common cabozantinib-associated adverse events included diarrhea, palmar-plantar erythrodysesthesia, decreased weight and appetite, nausea, and fatigue and resulted in dose redns. in 79% and holds in 65% of patients. Adverse events led to treatment discontinuation in 16% of cabozantinib-treated patients and in 8% of placebo-treated patients. Conclusion: Cabozantinib (140 mg per day) achieved a statistically significant improvement of PFS in patients with progressive metastatic MTC and represents an important new treatment option for patients with this rare disease. This dose of cabozantinib was associated with significant but manageable toxicity.

AB A review. The landscape of castration-resistant prostate carcinoma has changed completely in the last few years, with the approval of four new agents with proven benefit in overall survival. Abiraterone, cabazitaxel, enzalutamide and radium-223 dichloride have been added to the armamentarium of available agents for the treatment of these patients. We still lack information about which agent works best in an individual patient and how to optimally use them in a sequential strategy. Cabozantinib, a targeted agent against MET and vascular endothelial growth factor receptor-2, has shown promising results and could become the first targeted therapy to be approved for castration-resistant prostate carcinoma. This paper reviews the clin. development of cabozantinib in prostate cancer and future research possibilities for this drug.

AB Cabozantinib is an inhibitor of multiple receptor tyrosine kinases, including MET and VEGFR2. In a phase II clin. trial in advanced prostate cancer (PCa), cabozantinib treatment improved bone scans in 68% of evaluable patients. Our studies aimed to determine the expression of cabozantinib targets during PCa progression and to evaluate its efficacy in hormone-sensitive and castration-resistant PCa in preclin. models while delineating its effects on tumor and bone. Using immunohistochem. and tissue microarrays containing normal prostate, primary PCa, and soft tissue and bone metastases, our data show that levels of MET, P-MET, and VEGFR2 are increasing during PCa progression. Our data also show that the expression of cabozantinib targets are particularly pronounced in bone metastases. To evaluate cabozantinib efficacy on PCa growth in the bone environment and in soft tissues we used androgen-sensitive LuCaP 23.1 and castration-resistant C4-2B PCa tumors. In vivo, cabozantinib inhibited the growth of PCa in bone as well as growth of s.c. tumors. Furthermore, cabozantinib treatment attenuated the bone response to the tumor and resulted in increased normal bone volume In summary, the expression pattern of cabozantinib targets in primary and castration-resistant metastatic PCa, and its efficacy in two different models of PCa suggest that this agent has a strong potential for the effective treatment of PCa at different stages of the disease.

AB Disclosed are methods and assay systems for the identification of chromosomal rearrangements involving the RET kinase gene in cellular samples. Further described are methods for identifying cancer patients who are predicted to respond, or not respond to the therapeutic administration of a chemotherapeutic regimen including one or more kinase inhibitor(s), to treat cancer in the patient.

AB A review. Cabozantinib (XL184) is an orally bioavailable tyrosine kinase inhibitor with activity against MET and vascular endothelial growth factor receptor 2. We evaluated the activity of cabozantinib in patients with castration-resistant prostate cancer (CRPC) in a phase II randomized discontinuation trial with an expansion cohort. Patients received 100 mg of cabozantinib daily. Those with stable disease per RECIST at 12 wk were randomly assigned to cabozantinib or placebo. Primary end points were objective response rate at 12 wk and progression-free survival (PFS) after random assignment. One hundred seventy-one men with CRPC were enrolled. Random assignment was halted early based on the observed activity of cabozantinib. Seventy-two percent of patients had regression in soft tissue lesions, whereas 68% of evaluable patients had improvement on bone scan, including complete resolution in 12%. The objective response rate at 12 wk was 5%, with stable disease in 75% of patients. Thirty-one patients with stable disease at week 12 were randomly assigned. Median PFS was 23.9 wk (95% CI, 10.7 to 62.4 wk) with cabozantinib and 5.9 wk (95% CI, 5.4 to 6.6 wk) with placebo (hazard ratio, 0.12; P<.001). Serum total alkaline phosphatase and plasma cross-linked C-terminal telopeptide of type I collagen were reduced by≥50% in 57% of evaluable patients. On retrospective review, bone pain improved in 67% of evaluable patients, with a decrease in narcotic use in 56%. The most common grade 3 adverse events were fatigue (16%), hypertension (12%), and hand-foot syndrome (8%). Cabozantinib has clin. activity in men with CRPC, including reduction of soft tissue lesions, improvement in PFS, resolution of bone scans, and redns. in bone turnover markers, pain, and narcotic use.

CN 1,1-Cyclopropanedicarboxamide, N'-[4-[(6,7-dimethoxy-4-quinolinyl)oxy]phenyl]-N-(4-fluorophenyl)- (CA INDEX NAME)

AB Methods and compns. are provided for diagnosing or inhibiting invasion or metastasis of a cancer in a subject based on MenaINV. A method is provided of identifying an agent as an inhibitor of sarcoma or carcinoma cell invasion or as an inhibitor of metastasis of a carcinoma or sarcoma, comprising contacting a preparation comprising a growth factor receptor and a protein tyrosine phosphatase 1b (PTP1b) in the presence of an amount of MenaINV and an amount of Mena and quantifying the association of the growth factor receptor and PTP1b in the presence of the agent and in the absence of the agent. An agent that increases the association of growth factor receptor and PTP1b in the presence of the agent as compared to in the absence of the agent is identified as an inhibitor of sarcoma or carcinoma cell invasion or of metastasis, and an agent that does not increase, or decreases, the association of growth factor receptor and PTP1b in the presence of the agent as compared to in the absence of the agent is not identified as an inhibitor of sarcoma or carcinoma cell invasion or metastasis. A further method is provided of identifying an agent as an inhibitor of sarcoma or carcinoma cell invasion or of metastasis of a carcinoma or sarcoma, the method comprising contacting a preparation comprising an amount of MenaINV, an amount of Mena, and a protein, wherein the protein is phosphorylated, with the agent and PTP1b and quantifying phosphorylation of the protein at the site or sites. A decrease in phosphorylation in (a) the presence of the agent and PTP1b as compared to (b) in the absence of the agent and presence of PTP1b identifies the agent as an inhibitor of sarcoma or carcinoma cell invasion or metastasis, and wherein an increase in, or no change in, phosphorylation in (i) the presence of the agent and PTP1b as compared to (ii) in the absence of the agent and presence of PTP1b does not identify the agent as an inhibitor of sarcoma or carcinoma cell invasion or metastasis.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB The present invention relates to a method for the prognosis of bone metastasis in triple neg. (including basal-like) breast cancer or, alternatively, ER+ breast cancer (including luminal A and β) which comprises determining if the c-MAF gene is amplified in a primary tumor sample. Likewise, the invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise determining the c-MAF gene expression level, amplification or translocation. The invention also relates to a method for predicting early bone metastasis in a subject suffering breast cancer. The invention also relates to a c-MAF inhibitor as therapeutic agent for use in the treatment of triple neg. (including basal-like) breast cancer metastasis or, alternatively, ER+ breast cancer (including luminal A and B) metastasis. The invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the invention relates to a method for typing of a subject suffering breast cancer and for classifying a subject from breast cancer into a cohort.

AB A new type of signaling network element, called cancer signaling bridges (CSB), has been shown to have the potential for systematic and fast-tracked drug repositioning. On the basis of CSBs, we developed a computational model to derive specific downstream signaling pathways that reveal previously unknown target-disease connections and new mechanisms for specific cancer subtypes. The model enables us to reposition drugs based on available patient gene expression data. We applied this model to repurpose known or shelved drugs for brain, lung, and bone metastases of breast cancer with the hypothesis that cancer subtypes have their own specific signaling mechanisms. To test the hypothesis, we addressed specific CSBs for each metastasis that satisfy (i) CSB proteins are activated by the maximal number of enriched signaling pathways specific to a given metastasis, and (ii) CSB proteins are involved in the most differential expressed coding genes specific to each breast cancer metastasis. The identified signaling networks for the three types of breast cancer metastases contain 31, 15, and 18 proteins and are used to reposition 15, 9, and 2 drug candidates for the brain, lung, and bone metastases. We conducted both in vitro and in vivo preclin. expts. as well as anal. on patient tumor specimens to evaluate the targets and repositioned drugs. Of special note, we found that the Food and Drug Administration-approved drugs, sunitinib and dasatinib, prohibit brain metastases derived from breast cancer, addressing one particularly challenging aspect of this disease.

AB The present invention provides spirobicyclic compds. of general formula I (wherein R1-R6 are independently H, D, or F; each X and Y is independently (un)substituted C6-10aryl or (un)substituted 5-10 membered heteroaryl; Z is (un)substituted C5-12spirobicyclyl or (un)substituted -(C1-4alkylene)-(C5-12spirobicyclyl)-, with provisos), pharmaceutical acceptable salts and formulations thereof useful in modulating protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. The invention also provides pharmaceutically acceptable compns. comprising such compds. and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans. Synthetic procedures for preparing I are exemplified. For example, II was prepared in a 12-step synthesis that culminated in reaction of intermediates III and IV. II inhibited ALK kinase and c-Met kinase with IC50 values of 15 and 9 nM, resp.

AB The invention provides substituted pyrazolylpyridinamine compds. of formula I as protein tyrosine kinase modulators capable of regulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion for use in the treatment of hyperproliferative disorders. Compds. of formula I [wherein each R1, R2, R3, R4, R5, and R6 are independently H, D, or F; Z is substituted C3-7 heterocyclyl, substituted (C1-4 alkylene)-(C3-7 heterocyclyl), (un)substituted C5-12 fused bicyclyl, etc.;] stereoisomers, geometric isomers, tautomers, N-oxides, solvates, metabolites, or pharmaceutically acceptable salts or prodrugs thereof are claimed and prepared For example, II was prepared by the reaction of 4-iodo-1-(4-((tetrahydro-2H-pyran-2-yl)oxy)tetrahydrofuran-3-yl)-1H-pyrazole with III followed by removal of the tetrahydro-2H-pyran and deprotection of the amine group to afford II in 80% yield. Pharmacodynamic and pharmacokinetic assays were performed on II. II inhibited ALK kinase and c-Met kinase with IC50 of 5 nM and 4 nM resp., demonstrated 82% inhibition of glioblastoma tumor growth when dosed orally at 60 mg/kg to mice, and exhibited a half-life of 35.37 min in human microsomes.

AB RET kinase is aberrantly activated in thyroid cancers and in rare cases of lung and colon cancer, and has been validated as a mol. target in these tumors. Vandetanib was recently approved for the treatment of medullary thyroid cancer. However, vandetanib is ineffective in vitro against RET mutants carrying bulky aminoacids at position 804, the gatekeeper residue, similarly to drug-resistant BCR-ABL mutants in chronic myeloid leukemia. Ponatinib is a multi-target kinase inhibitor that was recently approved for treatment-refractory Philadelphia-pos. leukemia. We show here potent inhibition of oncogenic RET by ponatinib, including the drug-insensitive V804M/L mutants. Ponatinib inhibited the growth of RET+ and BCR-ABL+ cells with similar potency, while not affecting RET-neg. cells. Both in biochem. and in cellular assays ponatinib compared favorably with known RET inhibitors, such as vandetanib, cabozantinib, sorafenib, sunitinib and motesanib, used as reference compds. We suggest that ponatinib should be considered for the treatment of RET+ tumors, in particular those expressing vandetanib-resistant V804M/L mutations.

AB The present invention relates to a combination therapy comprising selective inhibitors of vascular endothelial growth factor receptor-2 (VEGFR-2) tyrosine kinase and inhibitors of MAP kinase kinase (MEK). Accordingly, a pharmaceutical composition is provided that comprises a selective inhibitor of vascular endothelial growth factor receptor-2 (VEGFR-2) tyrosine kinase or a pharmaceutically acceptable salt, solvate and/or hydrate thereof, and an inhibitor or a pharmaceutically acceptable salt, solvate and/or hydrate thereof, for use in medicine, especially in the treatment of cancer, like lung cancer, such as non-small cell lung cancer, lung adenocarcinoma or small cell lung cancer. Also a method for identifying patients that are particularly susceptible to such a combination therapy is subject of the present invention. The method comprises the evaluation of the expression level of VEGFR-2 and/or VEGF. An increase in said expression level indicates susceptibility to the combination therapy.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A method for identifying cancer patients that are likely to be responders or non-responders to a signal transduction pathway inhibitor is described. The present invention is directed to methods and tests that help predict the likelihood that a tumor will respond to a targeted therapy so that those cancer patients most likely to benefit can receive that drug in a timely manner and those patients unlikely to benefit from a particular drug can instead be prescribed alternative therapies. The test comprises a panel of two or more biomarkers that are part of a signal transduction pathway. The biomarkers included in the panel, in combination, express differently in tumors that respond the drug from those that do not respond. The drugs to which these tests predict response may be designed or determined to target the signal transduction pathway of which the biomarker panel is associated Examples of such drugs are those that target angiogenesis pathways like VEGF or cellular growth pathways like mTOR. Alternatively, the drugs might target something other than the pathway with which the biomarkers are associated but activation of that pathway might otherwise limit or defeat the effectiveness of that drug. Examples of such drugs are those that block cellular receptors but for which activation of downstream signaling pathways nevertheless maintains cellular growth.

AB Pancreatic ductal adenocarcinoma (PDA) is one of the most lethal malignancies. Cancer stem cells (CSCs), which are not targeted by current therapies, may be the reason for pronounced therapy resistance. A new treatment option in phase II trials is cabozantinib that inhibits the pancreatic CSC surface marker and tyrosine kinase receptor c-Met. The purpose of this study was to evaluate the effect of cabozantinib to stem-like features and therapy resistance. Established PDA cell lines, a gemcitabine-resistant subclone, non-malignant pancreatic ductal cells and primary spheroidal cultures from patient tumors were analyzed by MTT-assay, flow cytometry, colony and spheroid formation assays, western blotting, qRT-PCR, antibody protein array, immunohistochem. and morphol. features. Cabozantinib inhibited viability and spheroid formation and induced apoptosis in malignant cells with minor effects in non-malignant cells. After long-term cabozantinib treatment, PDA cells had altered anti- and pro-apoptotic signaling, but still responded to cabozantinib, as apoptosis only slightly decreased and viability only slightly increased suggesting a low resistance-inducing potential of cabozantinib. In parallel, c-Met expression and the pluripotency transcription factor SOX2 were downregulated, which might counteract development of full therapy resistance in long-term treated subclones. In single-treatment studies, cabozantinib increased efficacy of gemcitabine. Most importantly, cabozantinib strongly induced apoptosis and reduced viability in PDA cell lines, which are completely resistant toward gemcitabine. In primary, CSC-enriched spheroidal cultures cabozantinib downregulated CSC markers SOX2, c-Met and CD133 and induced apoptosis. These findings suggest that the clin. use of cabozantinib may be more effective than current chemotherapeutics.

AB A review. Cabozantinib (XL184) is an oral multiple receptor tyrosine kinase inhibitor manufactured by Exelixis Inc., CA, USA. It mainly inhibits three tyrosine kinase receptors: MET, VEGFR2 and RET. In both preclin. and clin. studies it has been shown to inhibit tumor angiogenesis, invasiveness and metastases. The most frequent side effects are fatigue, diarrhea, decreased appetite, nausea, weight loss and palmar-plantar erythrodysesthesia. A Phase III clin. trial (EXAM study) of XL184 vs. placebo in advanced and progressive medullary thyroid cancer showed a 28 vs. 0% overall response rate and a progression-free survival of 11.2 vs. 4.0 mo (hazard ratio: 0.28; 95% CI: 0.19-0.40; $p < 0.0001$) in patients treated with cabozantinib and placebo, resp. The drug has been approved by the US FDA for the treatment of advanced/progressive metastatic medullary thyroid cancer in the USA. The EMA is now evaluating its approval in Europe.

AB A review. Prostate cancer is the second-leading cause of cancer-related mortality in men in Western societies. Androgen receptor (AR) signaling is a critical survival pathway for prostate cancer cells, and androgen-deprivation therapy (ADT) remains the principal treatment for patients with locally advanced and metastatic disease. Although a majority of patients initially respond to ADT, most will eventually develop castrate resistance, defined as disease progression despite serum testosterone levels of <20 ng/dL. The recent discovery that AR signaling persists during systemic castration via intratumoral production of androgens led to the development of novel anti-androgen therapies including abiraterone acetate and enzalutamide. Although these agents effectively palliate symptoms and prolong life, metastatic castration-resistant prostate cancer remains incurable. An increased understanding of the mechanisms that underlie the pathogenesis of castrate resistance is therefore needed to develop novel therapeutic approaches for this disease. The aim of this review is to summarize the current literature on the biol. and treatment of castrate-resistant prostate cancer.

AB The discovery of RET fusions in lung cancers has uncovered a new therapeutic target for patients whose tumors harbor these changes. In an unselected population of non-small cell lung carcinomas (NSCLCs), RET fusions are present in 1%to2% of cases. This incidence increases substantially, however, in never-smokers with lung adenocarcinomas that lack other known driver oncogenes. Although preclin. data provide exptl. support for the use of RET inhibitors in the treatment of RET fusion-pos. tumors, clin. data on response are lacking. We report preliminary data for the first three patients treated with the RET inhibitor cabozantinib on a prospective phase II trial for patients with RET fusion-pos. NSCLCs (NCT01639508). Confirmed partial responses were observed in 2 patients, including one harboring a novel TRIM33-RET fusion. A third patient with a KIF5B-RET fusion has had prolonged stable disease approaching 8 mo (31 wk). All three patients remain progression-free on treatment.

AB In this article, tumor angiogenesis an attractive target in castration-resistant prostate cancer is studied. Indeed, impressive single-agent activity has been reported with cabozantinib, a small mol. inhibitor of the tyrosine kinases MET and VEGFR2. The author reports on randomly allocated 1050 patients with castration-resistant prostate cancer to treatment with docetaxel plus prednisone with or without bevacizumab-the median overall survival for patients receiving bevacizumab was 22.6 mo compared with 21.5 mo for patients treated with placebo (hazard ratio 0.91, 95% CI 0.78-1.05; stratified log-rank p=0.181).

AB The title medical combination comprises a hepatocyte growth factor receptor (cMet) inhibitor and a Bcl-2 inhibitor. The medical combination can be used for preparing a drug for treating colon cancer, liver cancer, lung cancer, renal cancer, gastric cancer, brain tumor, sarcoma, neurospongioma, pancreas cancer, ovarian cancer or prostatic cancer. The medical combination has the advantages of good synergistic effects, high effects, low administration dosage and low side effects.

AB Background: Cabozantinib is an oral MET/VEGFR2 inhibitor. A recent phase II study of cabozantinib (100 mg daily) showed improved bone scans in subjects with metastatic castration-resistant prostate cancer (mCRPC), but adverse events (AE) caused frequent dose redns. This study was designed to determine the efficacy and tolerability of cabozantinib at lower starting doses. Exptl. Design: An adaptive design was used to determine the lowest active daily dose among 60, 40, and 20 mg. The primary endpoint was week 6 bone scan response, defined as ≥30% decrease in bone scan lesion area. The secondary endpoint was change in circulating tumor cells (CTC). Results: Among 11 evaluable subjects enrolled at 40 mg, there were 9 partial responses (PR), 1 complete response, and 1 stable disease (SD). Of 10 subjects subsequently enrolled at 20 mg, there were 1 PR, 5 SDs, and 4 with progressive disease. Among 13 subjects enrolled on the 40 mg expansion cohort, there were 6 PRs and 7 SDs. No subjects required dose reduction or treatment interruption at 6 or 12 wk; 3 subjects at dose level 0 discontinued due to AEs by 12 wk. At 40 mg, median treatment duration was 27 wk. 58% of subjects with ≥5 CTCs/7.5mL at baseline converted to <5. Conclusions: Cabozantinib 40 mg daily was associated with a high rate of bone scan response. Cabozantinib 40 mg daily was associated with better tolerability than previously reported for cabozantinib 100 mg daily. These observations informed the design of phase III studies of cabozantinib in mCRPC. Clin Cancer Res; 19(11); 3088-94. ©2013 AACR.

AB A review. The recommendation of sorafenib as std. of care in advanced hepatocellular carcinoma has lent support to the increased use of antiangiogenic therapies. However, in three phase 3 randomised trials that compared other antiangiogenics with sorafenib, results did not show superiority or non-inferiority of the new therapies. The 10-mo median overall survival shown in these studies for patients given sorafenib might be a ceiling for single-agent antiangiogenic therapy. Strategies to increase survival time include combination therapies that pair antiangiogenic treatment with biol. therapy or chemotherapy. The combination of sorafenib and erlotinib was not superior to sorafenib alone, which suggests no pos. interaction between antiangiogenics and tyrosine kinase inhibitors in the treatment of advanced hepatocellular carcinoma. A combination of sorafenib and doxorubicin is being assessed in a randomised phase 3 trial. Differences in patient outcome with sorafenib because of disease cause and the ethnic origin of patients suggest that sorafenib's multitarget capacity, including RAF kinase inhibition, might be important. MET inhibitors cabozantinib and tivantinib are drugs that might also bypass the so-called antiangiogenic ceiling and have led to selective treatment of patients that overexpress MET with these drugs. Although this intense period of research activity has not yet resulted in significant improvements in survival for patients with advanced hepatocellular carcinoma, we are certainly closer to a customised treatment, which should increase the antiangiogenic survival ceiling.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A fusion protein including N-terminal domain of a fusion partner at N-terminal and C-terminal domain of RET protein at C-terminal and the gene encoding are identified as diagnostic markers for cancers, especially lung cancers. The somatic mutation forming the chimeric gene was identified in a poorly differentiated lung adenocarcinoma. The adenocarcinoma did not show any of the most common lung cancer-associated mutations, but several discordant reads, indicating transposition events, were identified. Expression of the chimeric KIF5B-RET gene in NIH-3T3 resulted in a neoplastic phenotype. Growth of these cells could be inhibited by the ret kinase inhibitor cabozantinib.

AB A review. Until recently, few therapeutic options were available for patients with castration-resistant prostate cancer (CRPC). Since 2010, four new mols. with a demonstrated benefit (sipuleucel-T, cabazitaxel, abiraterone and denosumab) have been approved in this setting and to-date several other agents are under investigation in clin. trials. The purpose of this review is to present an update of targeted therapies for CRPC. Presented data are obtained from literature and congress reports updated until Dec. 2011. Targeted therapies in advanced phases of clin. development include novel androgen signaling inhibitors, inhibitors of alternative signaling pathways, anti-angiogenic agents, inhibitors that target the bone microenvironment and immunotherapeutic agents. Radium-223 and MDV3100 demonstrated a survival advantage in phase III trials and the road for their introduction in clin. practice is rapidly ongoing. Results are also awaited for phase III studies currently underway or planned with new drugs given as monotherapy (TAK-700, cabozantinib, tasquinimod, PROSTVAC-VF, ipilimumab) or in combination with docetaxel (custirsen, aflibercept, dasatinib, zibotentan). The optimal timing, combination and sequencing of emerging therapies remain unknown and require further investigation. Addnl., the identification of novel markers of response and resistance to these therapies may better individualize treatment for patients with CRPC.

AB The invention is directed to processes for prepg. compds. of formula I (R2 is H, F, Cl and Br) by activation of 1,1-cyclopropanedicarboxylic acid with thionyl chloride followed by amidation with substituted aniline derivative Example compound II L-malate was prepared by chlorination of 6,7-dimethoxyquinolin-4-ol followed by etherification of 4-chloro-6,7-dimethoxyquinoline with 4-aminophenol; the resulting 4-(6,7-dimethoxyquinolin-4-yloxy)phenylamine underwent acylation with 1-[(4-fluorophenyl)carbamoyl]cyclopropanecarbonyl chloride to give compound II, which underwent addition of L-malic acid to give the desired product.

AB To review studies of novel multitargeted kinase inhibitors studied in patients with medullary thyroid cancer (MTC). Search of relevant refs. in PubMed and Google Scholar on "chemotherapy" and "medullary thyroid cancer". Multitargeted kinase inhibitors have revolutionized the role of chemotherapy for progressive MTC, providing for the first time tolerable therapeutic options that can improve outcomes in patients with progressive disease. Drugs thought to inhibit the RET kinase have advanced the furthest for this disease, but these agents also target the VEGF receptor along with other kinases that may be relevant to both beneficial and adverse effects. Vandetanib improved progression-free survival from 19.3 to 30.5 mo compared with placebo in patients with metastatic disease, whereas cabozantinib improved progression-free survival from 4.0 mo to 11.2 mo in a population with more aggressive disease. However, "cure" remains elusive, adverse events frequent, and exactly how such "targeted" agents actually function within MTC remains unclear. New approaches to clin. trial design and the preclin. development of targeted agents may be required to optimize the combination of maximum efficacy with minimal toxicity for patients with metastatic MTC.

AB Purpose of review: Therapeutic options for men with metastatic prostate cancer are expanding. Here we discuss the scientific progress in this disease that led to approval of several agents in the last decade and highlight ongoing clin. investigation. Recent findings: In androgen-sensitive disease, trials are evaluating the role of intermittent androgen-deprivation therapy, early chemotherapy, and novel targeted and hormonal therapies. For chemotherapy-naive, metastatic castration-resistant prostate cancer (mCRPC), abiraterone is effective. Trials with addnl. agents targeting androgen receptor (AR) signaling, such as TAK-700 and enzalutamide, are ongoing. Other agents in development target the endothelin pathway, angiogenesis, AR chaperones, and immune mechanisms. Docetaxel with prednisone remains the standard first-line chemotherapeutic regimen as trials incorporating novel agents with docetaxel have been neg. Postdocetaxel, enzalutamide improves survival. Early results with cabozantinib are encouraging, and phase III studies are ongoing. Denosumab and radium-223 reduce the risk of skeletal-related events (SREs), but only radium-223 improves survival. Summary: Progress in understanding the disease biol. and mechanisms of castration resistance led to significant therapeutic advancements, particularly in the setting of mCRPC in which

several phase III trials, each incorporating agents with different mechanisms of action, have improved survival. As a result, new options exist, and the standard of care has changed significantly. Further advances are anticipated.

AB A review. It was first posited in the 1970s that angiogenesis may prove to be a useful target for anticancer therapies. Since then, a number of agents have been developed and tested across a range of tumor types; however, to date, there have unfortunately been more failures than successes. Prostate cancer (PCa) is no exception in this regard, and despite a strong preclin. rationale for targeting angiogenesis in men with PCa, there has yet to be an antiangiogenic therapy proven to prolong survival in this group of patients. Drugs have been developed to target a host of angiogenesis mediators. These include vascular endothelial growth factor (VEGF), the VEGF receptors, antiangiogenic factors (e.g., thrombospondin-1), and downstream mediators of angiogenesis (e.g., hypoxia-inducible factor-1α and MET). At present, there are 2 drugs being tested in the phase III setting for men with PCa: cabozantinib and tasquinimod. Cabozantinib, a dual VEGF receptor-2/MET inhibitor, has shown dramatic beneficial effects on radiog. evident bone metastases and pain in the phase II setting. There are currently 2 large phase III trials underway to further investigate cabozantinib's role in treating men with PCa. Both trials randomize subjects to cabozantinib vs. mitoxantrone: one is designed to evaluate overall survival, and the other, pain response durability. The other drug, tasquinimod, has a somewhat poorly understood mechanism of action. It is thought to exert an antiangiogenic effect through the inhibition of myeloid-derived suppressor cells, key to the support of an angiogenic environment, and down-regulation of hypoxia-inducible factor-1α. A phase II trial randomizing men to tasquinimod vs. placebo revealed a median progression-free survival advantage in the exptl. arm (7.6 vs. 3.3 mo with placebo; P = 0.0042). Based on these encouraging phase II results, a randomized, double-blind, placebo-controlled trial in men with metastatic castration-resistant PCa was launched. That trial is powered for a primary endpoint of progression-free survival and is expected to enroll 1200 men.

LANGUAGE: English

AB A review. Effective management of bone metastases in men with castration-resistant prostate cancer (CRPC) remains an important unmet medical need. MET and vascular endothelial growth factor receptor (VEGFR) are rational targets for intervention in CRPC. Clin. trials involving agents that inhibit one but not both pathways have reported modest activity and no improvement in overall survival. Cabozantinib is an oral multitargeted tyrosine kinase inhibitor that inhibits both MET and VEGFR-2. A phase II randomized discontinuation study involving subjects with CRPC demonstrated that cabozantinib therapy is associated with improvement in bone scans, bone turnover markers, and pain response, but with significant adverse events leading to dose reduction and treatment discontinuation. Lower doses of cabozantinib retain high levels of activity with less toxicity. Ongoing phase III clin. trials will define the role of cabozantinib in CRPC. We summarize the rationale for targeting MET and VEGFR pathways in CRPC and the clin. data available to date.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The invention provides combination therapies for treating a pathol. condition, such as cancer, wherein a c-met antagonist (e.g. crizotinib, tivantinib, anti-HGF antibody, onartuzumab) is combined with a B-raf antagonist (e.g. vemurafenib), thereby providing significant antitumor activity. C-met expression was inversely correlated with sensitivity to vemurafenib treatment. In one aspect, provided are methods for treating a cancer patient who has increased likelihood of developing resistance to B-raf antagonist comprising administering an effective amount (in combination) of B-raf antagonist and c-met antagonist. In addition, patients with B-raf mutant melanoma who had higher levels of circulating hepatocyte growth factor (HGF) showed substantially reduced progression free survival and overall survival when treated with B-raf antagonist, relative to patients with lower circulating HGF levels treated with B-raf antagonist.

AB A review. Introduction: Conventional treatment modalities for thyroid cancer lead to complete remission in only one-third of patients with distant metastases. On the other hand, medullary thyroid cancer (MTC) and anaplastic thyroid cancer (ATC), although rare, are responsible for a significant percentage of thyroid cancer-related deaths. New treatments are needed to treat such patientsAreas covered: The aim of this review is to provide the latest information on , a new tyrosine kinase inhibitor (TKI) that is currently used mainly as a treatment of MTC. The authors collated data that were retrieved from a PubMed literature search.Expert opinion: CBZ targets multiple cell-signaling pathways involved in the mol. pathogenesis of thyroid cancer. These are namely VEGF receptor-2, hepatocyte growth factor receptor and rearranged during transfection receptor. Furthermore, it is a drug which may be used in cases where conventional therapies (mainly for MTC) are proved ineffective or have shown poor results with a good outcome. CBZ may also be administered alone or in combination with other drugs of the same family.

AB Anti-angiogenic treatment of glioblastoma with Vascular Endothelial Growth Factor (VEGF)- or VEGF Receptor 2 (VEGFR2) inhibitors normalizes tumor vessels, resulting in a profound radiol. response and improved quality of life. This approach however does not halt tumor progression by diffuse infiltration, as this phenotype is less angiogenesis dependent. Combined inhibition of angiogenesis and diffuse infiltrative growth would therefore be a more effective treatment approach in these tumors. The HGF/c-MET axis is important in both angiogenesis and cell migration in several tumor types including glioma. We therefore analyzed the effects of the c-MET- and VEGFR2 tyrosine kinase inhibitor cabozantinib (XL184, Exelixis) on c-MET pos. orthotopic E98 glioblastoma xenografts, which routinely present with angiogenesis-dependent areas of tumor growth, as well as diffuse infiltrative growth. In in vitro cultures of E98 cells, cabozantinib effectively inhibited c-MET phosphorylation, concomitant with inhibitory effects on AKT and ERK1/2 phosphorylation, and cell proliferation and migration. VEGFR2 activation in endothelial cells was also effectively inhibited in vitro. Treatment of BALB/c nu/nu mice carrying orthotopic E98 xenografts resulted in a significant increase in overall survival. Cabozantinib effectively inhibited angiogenesis, resulting in increased hypoxia in angiogenesis-dependent tumor areas, and induced vessel normalization. Yet, tumors ultimately escaped cabozantinib therapy by diffuse infiltrative outgrowth via vessel co-option. Of importance, in contrast to the results from in vitro expts., in vivo blockade of c-MET activation was incomplete, possibly due to multiple factors including restoration of the blood-brain barrier resulting from cabozantinib-induced VEGFR2 inhibition. In conclusion, cabozantinib is a promising therapy for c-MET pos. glioma, but improving delivery of the drug to the tumor and/or the surrounding tissue may be needed for full activity.

AB A review. Parafollicular C-cell-derived medullary thyroid cancer (MTC) comprises 3% to 4% of all thyroid cancers. While cytotoxic treatments have been shown to have limited efficacy, targeted mol. therapies that inhibit rearranged during transfection (RET) and other tyrosine kinase receptors that are mainly involved in angiogenesis have shown great promise in the treatment of metastatic or locally advanced MTC. Multi-tyrosine kinase inhibitors such as vandetanib, which is already approved for the treatment of progressive MTC, and cabozantinib have shown distinct advantages with regard to rates of disease response and control. However, these types of tyrosine kinase inhibitor compds. are able to concurrently block several types of targets, which limits the understanding of RET as a specific target. Moreover, important resistances to tyrosine kinase inhibitors can occur, which limit the long-term efficacy of these treatments. Deregulated cellular signaling pathways and genetic alterations in MTC, particularly the activationof the RAS/mammalian target of rapamycin (mTOR) cascades and RET crosstalk signaling, are now emerging as novel and potentially promising therapeutic treatments for aggressive MTC.

AB A review. Cabozantinib/XL184 (Exelexis, Inc.) has demonstrated remarkable responses in kidney cancer. Preclin. results revealed VEGF, KIT and MET inhibition in a variety of solid tumors such as thyroid, ovarian, renal, lung, liver and prostate cancers. A phase II trial demonstrated efficacy in renal cancer with a 28 % objective response rate, stable disease rate of 62 % and median progression free survival of 14.7 mo. Predominant toxicities of fatigue and diarrhea were noted. Dramatic responses in bone metastases (three of four patients) make the agent especially valuable for palliation in a disease, where presence of bone metastases is a predictor of worse survival. Cabozantinib is an emerging novel agent with promising activity in advanced kidney cancer. Randomized trials are planned in comparison with standard VEGF inhibitor therapy. Defining the role of MET overexpression would help patient selection and enrich and enhance the future evaluation of this targeted novel agent.

AB A review. Mutation detection in samples from thyroid cancer with the addition of BRAF mutation, and also the detection of RAS, RET/PTC, and PAX8/PPARγ mutations, may also contribute to cancer diagnosis. On the other hand, the MAPK/ERK (mitogen-activated protein kinase/extracellular signal-regulated kinase signaling pathway) and PI3K/Akt (lipid kinase phoshoinositid-3-kinase signaling pathway) play an important role in the transmission of cell signals. The genes, coding the signaling cascade proteins (RET, RAS, BRAF, PI3K, PTEN, AKT), are mutated or aberrantly expressed in thyroid cancer derived from follicular thyroid cells. Genetic and epigenetic alternations, concerning MAPK/ERK and PI3K/Akt signaling pathways, contribute to their activation and interaction as a consequence of malignant follicular cell transformation. The understanding of this mol. mechanism provides access to novel mol. prognostic and therapeutic strategies for inhibiting the oncogenic activity of the signaling pathways. This ability to investigate tumor biol. allows for the selection of different drugs. Nowadays the most relevant are treatments directed to tyrosine kinase receptors that bind for a wide variety of ligands and are frequently mutated and induce a constitutive activation such that a chimerical protein expression takes place in follicular cells in the domain of RET, as well as in other receptors. Many mols. such as: motesanib, sorafenib, vandetanib, sunitinib, XL-184, imatinib, axitinib, pazopanib, lenvatinib, combretastatin, gefitinib, cetuximab, bortezomib and thiazoldonedione have been developed. Some of them also can act in receptors of vascular endothelial growth factor and epidermal growth factor receptors. Information obtained through cytol. or biopsy samples permits the study of complex metabolic or genetic pathways, thus providing researchers with a high throughput tool for elucidating changes in the global expression patterns seen in tumor cells and allowing for different therapeutic strategies in thyroid cancer which take into account the predominant altered pathways observed in these samples.

AB Purpose: Cabozantinib (XL 184) is an orally bioavailable tyrosine kinase inhibitor with activity against MET and vascular endothelial growth factor receptor 2. We evaluated the activity of cabozantinib in patients with castration-resistant prostate cancer (CRPC) in a phase II randomized discontinuation trial with an expansion cohort. Patients and Methods: Patients received 100 mg of cabozantinib daily. Those with stable disease per RECIST at 12 wk were randomly assigned to cabozantinib or placebo. Primary end points were objective response rate at 12 wk and progression-free survival (PFS) after random assignment. Results: One hundred seventy-one men with CRPC were enrolled. Random assignment was halted early based on the observed activity of cabozantinib. Seventy-two percent of patients had regression in soft tissue lesions, whereas 68% of evaluable patients had improvement on bone scan, including complete resolution in 12%. The objective response rate at 12 wk was 5%, with stable disease in 75% of patients. Thirty-one patients with stable disease at week 12 were randomly assigned. Median PFS was 23.9 wk (95% CI, 10.7 to 62.4 wk) with cabozantinib and 5.9 wk (95% CI, 5.4 to 6.6 wk) with placebo (hazard ratio, 0.12; P < .001). Serum total alkaline phosphatase and plasma cross-linked C-terminal telopeptide of type I collagen were reduced by ≥ 50% in 57% of evaluable patients. On retrospective review, bone pain improved in 67% of evaluable patients, with a decrease in narcotic use in 56%. The most common grade 3 adverse events were fatigue (16%), hypertension (12%), and hand-foot

AB A review. The research of Smith et al. (2013) entitled, 'Cabozantinib in patients with advanced prostate cancer: Results of a phase II randomized discontinuation trial' is reviewed with commentary and refs. The authors presented data on a novel orally bioavailable tyrosine kinase inhibitor (TKI), cabozantinib, with activity against multiple targets including considerable activity in medullary thyroid cancer in a Phase III trial, including in heavily pretreated patients. Its novel combination of vascular endothelial growth factor and MET inhibition is believed to address the MET escape pathway, which is thought to be the cause of nonsustained tumor responses resulting from inhibition of vascular endothelial growth factor alone.

AB A review. Medullary thyroid cancer is an uncommon malignancy for which until recently little effective treatment existed. It is often characterized by mutation and overexpression of the receptor tyrosine kinases RET (rearranged during transfection), VEGFR2 (vascular endothelial growth factor receptor 2) and MET (mesenchymal-epithelial transition factor), which make attractive targets for drug development. Cabozantinib is an orally bioavailable tyrosine kinase inhibitor which blocks MET, VEGFR2 and RET, and has shown

AB A review. Discoveries of mol. mechanisms and therapeutic targets in metastatic castration-resistant prostate cancer (CRPC) have led to significant advancements in the development of effective agents in this setting, with diverse mechanisms of action. Within the past 2 years, 5 agents have been approved for the treatment of patients with metastatic CRPC (cabazitaxel, abiraterone, sipuleucel-T, denosumab, and enzalutamide), and another (Alpharadin) has shown overall survival benefit in a phase III trial. This article summarizes the phase III data showing clin. benefit from these agents, highlights other promising therapies in phase III studies as single agents (PROSTVAC-VF, ipilimumab, cabozantinib), discusses important unanswered questions regarding these therapies, and provides a schema for their use based on current regulatory approval and how this is likely to evolve as data from ongoing studies are reported. Although curative interventions in metastatic CRPC still do not exist, the hope is that optimization of therapeutic strategies can reduce the morbidity and mortality associated with this disease.

AB A review. Introduction Patients with advanced medullary thyroid cancer (MTC) have poor prognoses and limited treatment options. Improved knowledge about mol. aberrations associated with MTC and the availability of novel targeted tyrosine kinase inhibitors (TKIs) have led to new potential treatment modalities. Cabozantinib is an oral multitargeted TKI with activity against multiple receptors including RET, vascular endothelial growth factor receptor type 2 (VEGFR2), and MET that has been evaluated in MTC in the preclin. and clin. arenas. Methods This article reviews unmet clin. needs in advanced MTC. The authors consider novel agents that have been studied in MTC, with a focus on the investigational agent cabozantinib. Up-to-date clin. data of cabozantinib in MTC are discussed. Results Recent clin. evaluation suggests that cabozantinib is the first agent to prolong progression-free survival in patients with progressive MTC. These findings indicate that cabozantinib may be an effective therapy in advanced MTC. No improvement in overall survival has been demonstrated but data are not mature. Conclusion Cabozantinib may be an effective treatment option for patients with advanced MTC and is worthy of further evaluation.

AB A review. Castrate-resistant prostate cancer (CRPC) occurs when disease progresses in the presence of castrate levels of androgens and remains sensitive to further hormonal manipulation. For many years the treatment of CRPC was limited to the use of docetaxel for metastatic disease. However, this has recently changed with the approval of several new agents. Sipuleucel-T, an immunotherapeutic vaccine, is now available in the US for patients with non-metastatic CRPC and abiraterone, an oral enzyme inhibitor of androgen biosynthesis, as well as cabazitaxel, a cytotoxic chemotherapeutic, have been approved for the treatment of metastatic CRPC. Also, denosumab, a s.c. antibody, is now an option for the treatment of patients with CRPC with bone metastases, in addition to zoledronic acid, an i.v. bisphosphonate. Further treatment advances for metastatic CRPC therapeutics are in late stage phase III development. These include therapies affecting the androgen receptor (MDV3100) as well as addnl. immune-based therapeutics, PROSTVAC and ipilimumab. A broad range of agents is also emerging under the term targeted therapies. The endothelin-A receptor antagonist zibotentan, the tyrosine kinase inhibitors dasatinib, sorafenib and cabozantinib, the anti-angiogenic agent aflibercept, and the clusterin inhibitor custirsen, are all currently being tested for efficacy in metastatic CRPC. The mechanism of action of these and other promising agents are discussed alongside current therapeutic options and their potential place in the treatment landscape for CRPC is considered.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The present invention provides assays and methods for predicting the post-operative survival of a subject having an early stage gastric cancer after tumor surgery. The present invention also provides methods for treating a subject having an early stage gastric cancer by administering a combination therapy tailored to the signal transduction biomarkers that are activated in the cancer. In particular embodiments, the methods of the invention rely on the detection of the activation state or level of a specific combination of signal transducer analytes in a cancer cell obtained from the subject. Thus, the methods of the invention are particularly useful for predicting the survival or prognosis of a subject having an early stage gastric cancer and for guiding both pre- and post-operative treatment decisions by identifying subjects who would benefit from combination therapy as opposed to monotherapy.

AB The present invention provides novel substituted quinoline compds. I [R1, R2 = H, alkoxy, hydroxyalkoxy; R3 = H, F; R4 = H, F, Cl, Br, I, etc.; X = CH or N, wherein at least one of R1 and R2 = hydroxyalkoxy], pharmaceutical acceptable salts and formulations thereof useful in modulating the protein tyrosine kinase activity, and in modulating cellular activities such as proliferation, differentiation, apoptosis, migration and invasion. Syntheses of exemplified compds. I were described. E.g., a multi-step synthesis of the pyrazolecarboxamide II, starting from 3-benzyloxybenzenamine, was provided. Exemplified compds. I were tested for their efficacy as inhibitors of receptor tyrosine kinases such as c-Met, VEGFR and Axl, and as antitumor agents (data given). The invention also provides pharmaceutically acceptable compns. comprising compds. I and methods of using the compns. in the treatment of hyperproliferative disorders in mammals, especially humans.

AB The invention provides methods for detecting cancer, for detg. whether a cancer is responding to treatment, and /or for determining whether a cancer is likely to respond to treatment that involve detecting of circulating biomarkers. The invention relates that said circulating biomarkers can include nucleic acids, proteins, vesicles and/or microRNAs. The invention also relates that said biol. samples used in the disclosed methods include isolated extracellular microvesicle populations. The invention also provides kits comprising all reagents used in the disclosed methods. In the examples, the invention disclosed that specific biomarkers are elevated in specific types of cancer, which can used in diagnosis and in determining treatments.

AB The invention is directed to processes for prepg. quinoline compds. of formula I wherein X1 is H, Br, Cl and F; X2 is H, Br, Cl and F; n is 1-2 and m is 1-2; and pharmaceutically acceptable salts thereof. Example compound II L-malate was prepared by chlorination of 6,7-dimethoxyquinolin-4-ol followed by etherification of 4-chloro-6,7-dimethoxyquinoline with 4-aminophenol; the resulting 4-(6,7-dimethoxyquinolin-4-yloxy)phenylamine underwent acylation with 1-[(4-fluorophenyl)carbamoyl]cyclopropanecarbonyl chloride to give compound II, which underwent addition of L-malic acid to give the desired product.

AB Specific peptides, and derived ionization characteristics of those peptides, from the Bcl-2-like protein 11 (BIM) are provided that are particularly advantageous for quantifying the BIM protein directly in biol. samples that have been fixed in formalin by the method of Selected Reaction Monitoring (SRM) mass spectrometry, or what can also be termed as Multiple Reaction Monitoring (MRM). Such biol. samples are chemical preserved and fixed where the biol. sample is selected from tissues and cells treated with formaldehyde containing agents/fixatives including formalin-fixed tissue/cells, formalin- fixed/paraffin embedded (FFPE) tissue/cells, FFPE tissue blocks and cells from those blocks, and tissue culture cells that have been formalin fixed and or paraffin embedded. A protein sample is prepared from the biol. sample using the Liquid Tissue reagents and protocol, and the BIM protein is quantitated in the Liquid Tissue sample by the method of SRM/MRM mass spectrometry by quantitating in the protein sample at least one or more of the peptides described. These peptides can be quantitated if they reside in a modified or an unmodified form. An example of a modified form of a BIM peptide is phosphorylation of a tyrosine, threonine, serine, and/or other amino acid residues within the peptide sequence. Samples were prepared with Liquid Tissue and digested with trypsin. Three peptides from BIM were found to be suitable for SRM/MRM assay.

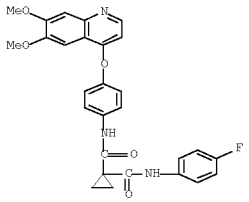
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB The present invention provides methods for selecting a suitable anticancer drug therapy, and for identifying and predicting response, for the treatment of a malignant cancer involving aberrant c-Met signaling. The present invention also provides methods for monitoring the status of a malignant cancer involving aberrant c-Met signaling and monitoring how a patient with the malignant cancer is responding to anticancer drug therapy. Information on the expression and/or activation states of components of signal transduction pathways (e.g., HER3 and/or c-Met signal transduction pathway components) derived from practice of the present invention can be used for malignant cancer diagnosis, prognosis, and in the design of cancer treatments for malignancies involving aberrant c-Met signaling. Certain embodiments comprise administering a cMet inhibitor alone or a cMet inhibitor in combination with a pathway-directed therapy based upon the differences between the expression and/or activation levels of cMet protein and/or HER3 protein in the sample compared to the control protein and/or control sample.

IT 1140909-48-3, XL 184

AB The present invention relates to metastases. More specifically, the invention relates to compns. and methods for the inhibition of metastases of cancer cells, such as prostate cancer cells, to bones and soft tissue. The present invention also relates to the treatment of cancer, including but not limited to prostate cancer. Also provided are animal models for studying cancer metastasis; particularly, prostate cancer metastasis.

AB Purpose of review: This review will focus on the recent advances in mol. pathogenesis and targeted therapies for medullary thyroid carcinoma (MTC). Unlike hereditary MTC in which rearranged during transfection (RET) mutations are the most important precipitating events, in sporadic MTC the genetic or mol. biomarkers are yet to be established. Recent findings: Targeted mol. therapies that inhibit RET and other tyrosine kinase receptors involved in angiogenesis have shown great promise in the treatment of metastatic or locally advanced MTC and are under investigation. In addition, the recent findings of H-RAS mutations in 56% of RET-neg. sporadic MTC and the activation of the mammalian target of rapamycin (mTOR) intracellular signaling pathway in hereditary MTC suggests that addnl. or alternative genetic events are important for MTC pathogenesis. Summary: Recently, vandetanib (ZD6474), an inhibitor of vascular endothelial growth factor receptor (VEGFR) 2 and VEGFR 3, RET, and epidermal growth factor receptor (EGFR), was approved for the treatment of adults with symptomatic or progressive MTC. Significant advantages for vandetanib over placebo were seen in terms of response rate, disease control rate, and biochem. response in a phase III study. Furthermore, cabozantinib (XL184), an inhibitor of VEGFR 1 and VEGFR 2, hepatocyte growth factor receptor (MET), and RET, was associated with partial response and stable disease in 29 and 41%, resp.

AB A review. Improved understanding of mechanisms underlying metastatic castration-resistant prostate cancer (mCRPC) progression has led to the recognition of multiple mol. targets and advances in the therapeutic landscape. The addition of abiraterone acetate, sipuleucel-T, cabazitaxel, and denosumab to the therapeutic armamentarium and the impending addition of MDV-3100 and radium-223 underscore the importance of androgen pathway inhibition, immunotherapy, tubulin antagonism, and pathophysiol. of bone metastasis. Review the next generation of mol. targets in mCRPC. Medline databases were searched for >100 original articles published as of Oct. 18, 2011, with the search terms metastatic castration-resistant prostate cancer, targeted therapy, biol. agents, and immunotherapy. Proceedings from the last 5 yr of conferences of the American Society of Clin. Oncol., American Urol. Association, European Society of Medical Oncol., and the European Association of Urol. were also searched. We included novel and promising drugs that have reached clin. trial evaluation. The major findings were addressed in an evidence-based fashion. Prospective trials and important preclin. data were analyzed.mCRPC is a disease with multiple mol. drivers. Mol. pathways being targeted in ongoing phase 3 trials are androgen signaling (MDV3100, TAK700), immunoregulatory pathways (ipilimumab, Prostvac-VF-TRICOM), Src (dasatinib), Met (cabozantinib), clusterin (custirsen), and angiogenesis (aflibercept, tasquinimod). The strides made in identifying multiple other novel mol. targets offer potential opportunities for further improving outcomes.

AB A review. XL-184 (cabozantinib) is a novel, small-mol., multi-targeted receptor tyrosine kinase inhibitor with particular activity against hepatocyte growth factor receptor (tyrosine-protein kinase Met), vascular endothelial growth factor receptor 2 (VEGFR-2) and proto-oncogene tyrosine-protein kinase receptor Ret. There is ample evidence of Met, VEGFR-2 and Ret signaling in several tumor types. Preclin. data suggest that XL-184 has activity in tumors derived from both epithelial and mesenchymal origins. Phase I and II clin. studies support significant antitumor activity, particularly in medullary thyroid cancer and cancers metastatic to the bone. This review will evaluate XL-184's preclin. pharmacol., pharmacokinetics, drug interactions and clin. activity in phase I through phase III studies.

AB The authors disclose the use of c-met as a biomarker for patient selection and patient prognosis in cancer. In a clin. trial, combination treatment with MetMAb (onartuzumab) and erlotinib provided a clin. meaningful benefit to patients with non-small cell lung cancer (NSCLC) that expressed high levels of c-met biomarker. The results showed that the efficacy, as evaluated by progression free survival (PFS) and overall survival (OS), was pos. especially when compared to PFS and OS data for erlotinib treatment alone. The addition of MetMAb to erlotinib nearly doubled the progression free and overall survival in patients with NSCLC that expressed high levels of c-met biomarker. The clin. trial data also showed that treatment with MetMAb in combination with erlotinib increased the risk of progression and death in patients with NSCLC that expressed low levels of c-met biomarker.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Biomarkers can be assessed for diagnostic, therapy-related or prognostic methods to identify phenotypes, such as a condition or disease, or the stage or progression of a disease. Circulating biomarkers from a bodily fluid can be used in profiling of physiol. states or determining phenotypes. These include nucleic acids, protein, and circulating structures such as vesicles. Biomarkers can be used for theranostic purposes to select candidate treatment regimens for diseases, conditions, disease stages, and stages of a condition, and can also be used to determine treatment efficacy. The biomarkers can be circulating biomarkers, including vesicles and microRNA. Various anti-DLL4 antibodies were tethered to beads and used to capture vesicles in blood samples from subjects with breast cancer, colorectal cancer or normal subjects. The bead captured vesicles were detected with fluorescently-labeled antibodies against the tetraspanins CD9, CD63, and CD81. The median fluorescence intensity of the captured and labeled vesicles was measured using laser detection. There were noticeable differences both among normals and breast cancer plasma as well as between the avs. of normals and cancer patients.

AB A review. Epidermal growth factor receptor (EGFR) is a validated target in different human malignancies. EGFR tyrosine kinase inhibitors (TKIs) are known to contribute considerably to the extension of progression-free survival in EGFR-mutant non-small cell lung cancer and monoclonal antibodies (mAbs) targeting EGFR have also improved the efficacy outcomes in KRAS wild-type colorectal cancer. Nevertheless, a significant percentage of lung and colorectal cancer patients do not respond to anti-EGFR agents and secondary resistance after initial benefit is a challenging reality faced by clinicians. Extensive preclin. work on the potential mechanisms of resistance to EGFR inhibitors in different disease settings has guided the development of second-generation irreversible EGFR TKIs, more efficient anti-EGFR mAbs, and combination strategies with agents targeting other receptors and downstream effectors. In order to elucidate the role of the multiple therapeutic strategies under investigation to overcome EGFR inhibitors-resistance, rational drug development based on stringent preclin. data, biomarker validation and proper selection of patients in the ongoing clin. trials are of paramount importance. Preliminary results of clin. trials evaluating these approaches will be discussed in this manuscript, with emphasis on TKIs in lung cancer and mAbs in advanced colorectal cancer.

AB A review. The hepatocyte growth factor/mesenchymal-epithelial transition factor (HGF/c-MET) receptor tyrosine kinase (RTK) pathway plays a pleotropic role in cell proliferation, migration, invasion, angiogenesis and survival. Although it has critical physiol. functions in embryonic development and tissue repair, this signaling cascade is frequently deregulated in a wide range of tumors. Aberrant HGF/c-MET signaling, driven by various mechanisms, including constitutive activation and over-expression, has multifunctional effects in oncogenesis and is implicated in the acquisition of an aggressive phenotype with metastatic potential. The central role of c-MET activity in cancer progression, as well as disparities between quiescent HGF/c-MET signaling in normal tissue and overexpression in tumor may provide a degree of tumor selectivity for therapeutic intervention, making HGF or c-MET inhibition an attractive proposition in oncol. This review focuses on the underlying oncogenic role of aberrant HGF/c-MET signaling in malignant progression, as well as recent preclin. and clin. data on the different strategies employed in inhibiting HGF/c-MET function.

AB Administration of a hypoxia activated prodrug in combination with an antiangiogenic agent is useful for treating cancer. Hypoxia activated prodrug is selected from the group consisting of TH-281, TH-302, and TH-308. The antiangiogenic agent is selected from the group consisting of an anti-VEGF antibody, a VEGF-trap, an anti-VEGFR antibody, a VEGFR inhibitor, thalidomide etc.

AB Pharmaceutical compns. and unit dosage forms comprising N-[4-[(6,7-dimethoxy-4-quinolinyl)oxy]phenyl]-N'-(4-fluorophenyl)-1,1-cyclopropanedicarboxamide (I) are disclosed. Thus, 6,7-dimethoxyquinolin-4-ol was converted to 4-chloro-6.7-dimethoxyquinoline followed by reaction with 4-aminphenol to give 4-(6,7-dimethoxy-quinolin-4-yloxy)-phenylamine. This was further allowed to react with 1-(4-fluorophenylcarbamoyl)cyclopropanecarbonyl chloride to give I. A tablet composition comprised 31.68% along with excipients such as microcryst. cellulose 38.85, lactose, HPC, and Croscarmellose sodium.

AB A review. The c-MET (mesenchymal-epithelial transition factor) pathway is dysregulated in many human cancers and promotes tumor growth, invasion and dissemination. The c-MET receptor tyrosine kinase can be activated via gene mutation, gene amplification, protein overexpression and/or a Ligand-dependent autocrine/paracrine loop. Abnormalities in c-MET signaling have been reported to correlate with poor clin. outcomes and drug

resistance in patients with cancer. Significant progress has been made in advancement of c-MET pathway inhibitors through to clin. trials. A robust pipeline of high-quality inhibitors targeting different aspects of c-MET activation is currently being explored in phase I, II and III clin. trials across multiple tumor types. Preliminary data demonstrate promising clin. activity with these agents, along with an acceptable toxicity profile. In this manuscript, the pharmacol. profile of drugs targeting the c-MET pathway and available data from ongoing clin. trials of these drugs are discussed.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Methods of delivering cytosine deaminase variants for prodrug activation using retroviral expression vectors are described. The vector includes the viral gag, pol, and env genes with the cytosine deaminase gene being coexpressed using an internal ribosome entry site. Vectors were derived from the prior art pACE-GFPemd vector. The envelope protein of the virus is amphotropic and excess viral sequences outside the long terminal repeats were removed. The resulting vector was named pACE-emdGFP. The vector was stable in storage and replicated efficiently in mammalian cells and could be used to deliver a range of therapeutic genes. The Saccharomyces cerevisiae cytosine deaminase gene was modified to give a codon usage suitable for mammalian cells and to improve thermostability of the enzyme. Use of these vectors results in high intracellular copy nos. for the therapeutic gene and these cells can be superinfected by the vector.

AB The signaling pathway of the receptor tyrosine kinase MET and its ligand hepatocyte growth factor (HGF) is important for cell growth, survival, and motility and is functionally linked to the signaling pathway of VEGF, which is widely recognized as a key effector in angiogenesis and cancer progression. Dysregulation of the MET/VEGF axis is found in a number of human malignancies and has been associated with tumorigenesis. Cabozantinib (XL184) is a small-mol. kinase inhibitor with potent activity toward MET and VEGF receptor 2 (VEGFR2), as well as a number of other receptor tyrosine kinases that have also been implicated in tumor pathobiol., including RET, KIT, AXL, and FLT3. Treatment with cabozantinib inhibited MET and VEGFR2 phosphorylation in vitro and in tumor models in vivo and led to significant redns. in cell invasion in vitro. In mouse models, cabozantinib dramatically altered tumor pathol., resulting in decreased tumor and endothelial cell proliferation coupled with increased apoptosis and dose-dependent inhibition of tumor growth in breast, lung, and glioma tumor models. Importantly, treatment with cabozantinib did not increase lung tumor burden in an exptl. model of metastasis, which has been observed with inhibitors of VEGF signaling that do not target MET. Collectively, these data suggest that cabozantinib is a promising agent for inhibiting tumor angiogenesis and metastasis in cancers with dysregulated MET and VEGFR signaling. Mol Cancer Ther; 10(12); 2298-308.

AB Biomarkers can be assessed for diagnostic, therapy-related or prognostic methods to identify phenotypes, such as a condition or disease, or the stage or progression of a disease. Circulating biomarkers from a bodily fluid can be used in profiling of physiol. states or determining phenotypes. These include nucleic acids, protein, and circulating structures such as vesicles. Biomarkers can be used for theranostic purposes to select candidate treatment regimens for diseases, conditions, disease stages, and stages of a condition, and can also be used to determine treatment efficacy. The biomarkers can be circulating biomarkers, including microvesicles and their protein content and microRNAs.

AB A review. Systemic chemotherapies for advanced or metastatic thyroid carcinomas have been of only limited effectiveness. For patients with differentiated thyroid epithelial or medullary thyroid carcinomas unresponsive to conventional treatments, novel therapies are needed to improve disease outcomes. Multiple novel therapies primarily targeting angiogenesis have entered clin. trials for metastatic thyroid carcinoma. Partial response rates up to 30% have been reported in single agent studies, but prolonged disease stabilization is more commonly seen. The most successful agents target the vascular endothelial growth factor receptors, with potential targets including the mutant kinases associated with papillary and medullary oncogenesis. Two drugs approved for other malignancies, sorafenib and sunitinib, have had promising preliminary results reported, and are being used selectively for patients who do not qualify for clin. trials. Addnl. agents targeting tumor vasculature, nuclear receptors, epigenetic abnormalities, and the immune response to neoplasia have also been investigated. Randomized trials for several agents are under way that may lead to eventual drug approval for thyroid cancer. Treatment for patients with metastatic or advanced thyroid carcinoma now emphasizes clin. trial opportunities for novel agents with considerable promise. Alternative options now exist for use of these mol. targeted therapies, especially tyrosine kinase inhibitors, which are well tolerated and may prove worthy of regulatory approval for this disease.

AB Purpose: XL184 (cabozantinib) is a potent inhibitor of MET, vascular endothelial growth factor receptor 2 (VEGFR2), and RET, with robust antiangiogenic, antitumor, and anti-invasive effects in preclin. models. Early observations of clin. benefit in a phase I study of cabozantinib, which included patients with medullary thyroid cancer (MTC), led to expansion of an MTC-enriched cohort, which is the focus of this article. Patients and Methods: A phase I dose-escalation study of oral cabozantinib was conducted in patients with advanced solid tumors. Primary end points included evaluation of safety, pharmacokinetics, and maximum-tolerated dose (MTD) determination Addnl. end points included RECIST (Response Evaluation Criteria in Solid Tumors) response, pharmacodynamics, RET mutational status, and biomarker analyses. Results: Eighty-five patients were enrolled, including 37 with MTC. The MTD was 175 mg daily. Dose-limiting toxicities were grade 3 palmar plantar erythrodysesthesia (PPE), mucositis, and AST, ALT, and lipase elevations and grade 2 mucositis that resulted in dose interruption and reduction Ten (29%) of 35 patients with MTC with measurable disease had a confirmed partial response. Overall, 18 patients experienced tumor shrinkage of 30% or more, including 17 (49%) of 35 patients with MTC with measurable disease. Addnl., 15 (41%) of 37 patients with MTC had stable disease (SD) for at least 6 mo, resulting in SD for 6 mo or longer or confirmed partial response in 68% of patients with MTC. Conclusion: Cabozantinib has an acceptable safety profile and is active in MTC. Cabozantinib may provide clin. benefit by simultaneously targeting multiple pathways of importance in MTC, including MET, VEGFR2, and RET. A global phase III pivotal study in MTC is ongoing (ClinicalTrials.gov number NCT00215605).

AB Medullary and papillary thyroid carcinoma (MTC and PTC) are 2 types of thyroid cancer that can originate from activating mutations or rearrangements in the RET gene. Therapeutic options are limited in recurrent disease, but because RET is a tyrosine kinase (TK) receptor involved in cellular growth and proliferation, treatment with a TK inhibitor might be promising. Several TK inhibitors were tested in clin. trials, but it is unknown which inhibitor is most effective and whether there is any specificity for particular RET mutations. We aimed to compare the effect of 4 TK inhibitors (axitinib, sunitinib, vandetanib, and XL184) on cell proliferation, RET expression and autophosphorylation, and ERK activation in cell lines expressing a MEN2A (MTC-TT), a MEN2B (MZ-CRC-1) mutation, and a RET/PTC (TPC-1) rearrangement. The 3 cell lines were cultured and treated with the 4 TK inhibitors. Effects on cell proliferation and RET and ERK expression and activation were determined XL184 and vandetanib most effectively inhibited cell proliferation, RET autophosphorylation in combination with a reduction of RET expression, and ERK phosphorylation in MTC-TT and MZ-CRC-1, resp. TPC-1 cells showed a decrease in RET autophosphorylation after treatment with XL184, but no effect was observed on ERK activation. There is indeed specificity for different RET mutations, with XL184 being the most potent inhibitor in MEN2A and PTC and vandetanib the most effective in MEN2B in vitro. No TK inhibitor was superior for all the cell lines tested, indicating that mutation-specific therapies could be beneficial in treating MTC and PTC.

androgen deprivation therapy. Denosumab is shown to support bone mineral d. in hormonal sensitive PCa patients. Targeting of androgen-dependent pathways in CRPC postchemotherapy has been shown to improve survival with the lyase inhibitor abiraterone, and lead to prostate-specific antigen and objective responses with an androgen receptor antagonist (MDV3100). However, the addition of bevacizumab to docetaxel/prednisone in treating metastatic CRPC failed to provide a survival benefit. Cabazitaxel in metastatic CRPC postdocetaxel did demonstrate a survival benefit. Provenge, an autologous dendritic cell-based vaccine, demonstrated a reduction in the risk of death in metastatic CRPC. Other immunotherapy agents, including Prostvac and ipilimumab are under investigation. We also discuss the receptor tyrosine kinase inhibitor XL184 and poly (ADP-ribose) polymerase inhibitors which are in early clin. trials. Summary: Recent advances in androgen targeting, chemotherapy, immunotherapy, and other targeted therapies have led to significant improvements in the care of CRPC patients.

AB Purpose of review: This review highlights recent therapeutic advances in systemic therapies for prostate cancer (PCa). Recent findings: Progress in PCa therapeutics has been made during the past year with the approval of a vaccine therapy, second-line chemotherapy, and reported survival advantage for a CYP (17,20) lyase inhibitor in castration-resistant prostate cancer (CRPC). This report will summarize the recently reported and expected data for PCa trials including an evaluation of intermittent vs. continuous

AB A review. Surgical resection followed by radiotherapy and temozolomide in newly diagnosed glioblastoma can prolong survival, but it is not curative. For patients with disease progression after frontline therapy, there is no standard of care, although further surgery, chemotherapy, and radiotherapy may be used. Antiangiogenic therapies may be appropriate for treating glioblastomas because angiogenesis is critical to tumor growth. In a large, noncomparative phase II trial, bevacizumab was evaluated alone and with irinotecan in patients with recurrent glioblastoma; combination treatment was associated with an estimated 6-mo progression-free survival (PFS) rate of 50.3%, a median overall survival of 8.9 mo, and a response rate of 37.8%. Single-agent bevacizumab also exceeded the predetd. threshold of activity for salvage chemotherapy (6-mo PFS rate, 15%), achieving a 6-mo PFS rate of 42.6% (p<0.0001). On the basis of these results and those from another phase II trial, the US Food and Drug Administration granted accelerated approval of single-agent bevacizumab for the treatment of glioblastoma that has progressed following prior therapy. Potential antiangiogenic agents - such as cilengitide and XL184 - also show evidence of single-agent activity in recurrent glioblastoma. Moreover, the use of antiangiogenic agents with radiation at disease progression may improve the therapeutic ratio of single-modality approaches. Overall, these agents appear to be well tolerated, with adverse event profiles similar to those reported in studies of other solid tumors. Further research is needed to determine the role of antiangiogenic therapy in frontline treatment and to identify the optimal schedule and partnering agents for use in combination therapy.

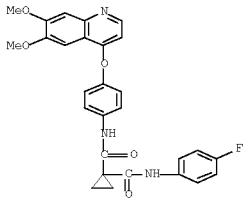
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB The present invention provides methods for selecting a suitable anticancer therapy, and for identifying and predicting response for the treatment of a gastric cancer. The present invention provides compns. and methods for detecting the status (e.g., expression and/or activation levels) of components of signal transduction pathways in tumor cells (e.g., gastric tumor cells). Information on the expression and/or activation states of components of signal transduction pathways (e.g., HER2 and/or c-Met signal transduction pathway components) derived from practice of the present invention can be used for gastric cancer diagnosis, prognosis, and in the design of gastric cancer treatments. The compns. and methods of the present invention advantageously provide accurate prediction, selection, and monitoring of cancer patients (e.g., gastric cancer patients) most likely to benefit from targeted therapy by performing pathway profiling on easily accessible tumor cells using multiplexed, antibody-based proximity assays.

AB A review. After ligand binding induces dimerization, the RET receptor tyrosine kinase activates multiple signal transduction pathways. Constitutively activating mutations and chromosomal rearrangements are the primary oncogenic event in a significant number of medullary thyroid cancers (MTC) and papillary thyroid cancers (PTC), resp. When specific germline mutations in RET are identified early, prophylactic thyroidectomy can be timed to remove at-risk tissue in patients with multiple endocrine neoplasia 2 (MEN2) syndromes who would otherwise develop MTC. Conventional therapy for progressive metastatic MTC is limited. Small-mol. tyrosine kinase inhibitors can target multiple kinases at nanomolar concns., including RET, and have shown efficacy against a variety of malignancies. Initial clin. evidence suggests that several of these inhibitors, including sorafenib, vandetanib, motesanib, sunitinib, and XL-184, may have some benefit in treating progressive MTC. Although initial success seen in these trials seems to be modest, it represents a major breakthrough in the treatment of patients with widespread metastatic MTC. Clin Cancer Res; 16(24); 5936-41.

AB Purpose: To compare clin. outcomes of metastatic head and neck cancer patients treated in phase I clin. trials with clin. outcomes of those patients who had their last Food and Drug Administration (FDA)-approved therapy in the setting of metastatic disease. Exptl. Design: We retrospectively reviewed the outcomes of 61 consecutive patients with head and neck tumors treated in 36 phase I trials at The University of Texas M.D. Anderson Cancer Center between July 2004 and Sept. 2009. Results: The most common histol. was head and neck squamous cell carcinoma (62%). Median age was 55 years (range, 26-80). Eastern Cooperative Oncol. Group performance status was 0 to 1 for 95% of patients. Fifty-nine patients had received FDA-approved drugs as the backbone of their last systemic therapy before inclusion in phase I trials (median, 2 systemic therapies). Progression-free survival (PFS) on phase I trials was not inferior to PFS on their last FDA-approved therapies (12 vs. 10.7 wk, log-rank P = 0.87). Fifty-three patients were evaluable for response by Response Evaluation Criteria in Solid Tumors criteria. Four (7%) had partial responses and 16 (26%) had stable disease for ≥4 mo. In univariate anal., number of metastatic sites, lactate dehydrogenase (LDH) levels at baseline, and Royal Marsden Hospital prognosis scores were significant predictors of survival. Only LDH was significant in multivariate anal. (hazard ratio, 6.35; P ≤ 0.0001). Conclusions: For patients with heavily pretreated advanced head and neck tumors, PFS on phase I trials is not inferior to PFS with their last FDA-approved therapy. The only significant predictor of survival in the multivariate anal. was baseline LDH.

AB A review. XL-184 (BMS-907351), under development by Exelixis Inc and Bristol-Myers Squibb Co, is a pan-tyrosine kinase inhibitor for the potential oral treatment of medullary thyroid cancer, glioblastoma multiforme and NSCLC. The prinicipal targets of XL-184 are MET, VEGFR-2 and RET, but the drug is also reported to display inhibitory activity against KIT, FLT3 and TEK. Preclin. studies demonstrated that XL-184 potently inhibited multiple receptor tyrosine kinases in various cancer cell lines and animal xenograft models, and that the drug exhibited significant oral bioavailability and blood-brain barrier penetration. A phase I clin. trial in patients with advanced solid malignancies indicated that XL-184 accumulated dose-dependently in the plasma and had a long terminal half-life. A phase II trial in patients with progressive or recurrent glioblastoma revealed modest but promising median progression-free survival. Toxicity and side effects for the drug have generally been of low-to-moderate severity. At the time of publication, three addnl. trials of XL-184 were recruiting patients, including a phase I trial in combination with standard of care in patients with glioblastoma, a phase I/II trial in combination with erlotinib in patients with NSCLC, and a phase III trial in patients with medullary thyroid cancer.

AB N-[4-[[6,7-bis(methyloxy)quinolin-4-yl]oxy]phenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide malate salts were prepared Thus, 1-(4-fluorophenylcarbamoyl)cyclopropanecarboxylic acid (preparation given) was stirred with (COCl)2 in THF/DMF at ≤30° and the mixture was added to 4-(6,7-dimethoxyquinolin-4-yloxy)phenylamine (preparation given) and K2CO3 in THF/H2O followed by addition of H2O and stirring for 10 h to give N-[4-[[6,7-bis(methyloxy)quinolin-4-yl]oxy]phenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide. The latter in EtOH was treated with malic acid in H2O followed by addition of C, thiol silica, heating to 78°, and addition of H2O followed by filtration, addition of Me2CHOH, cooling, and filtration to give N-[4-[[6,7-bis(methyloxy)quinolin-4-yl]oxy]phenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide malate.

AB A review. The treatment of thyroid cancer is evolving. The mol. mechanisms of carcinogenesis for many thyroid cancers have been investigated, and have yielded targets for potential therapies. These targets include VEGFR in the treatment of all thyroid cancers, BRAF in the treatment of papillary thyroid cancer, and RET in the treatment of medullary thyroid cancer (MTC). Many promising drugs that target one or more of these proteins are currently being evaluated, including sorafenib and sunitinib, both of which are still under development for the treatment of thyroid cancer but which have been approved for use in other malignancies. In addition, compds. such as vandetanib (AstraZeneca plc) and XL-184 (Bristol-Myers Squibb Co/Exelixis Inc) have demonstrated activity in early-phase clin. trials of MTC and are being tested further in randomized trials.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB Recombinant replication-competent retroviral (RCR) vectors are provided comprising: a retroviral gag protein; a retroviral pol protein; a retroviral envelop, a retroviral polynucleotide comprising long terminal repeat (LTR) sequence at the 3' end of the retroviral polynucleotide sequence; a mammalian-suitable promoter sequence at the 5' end of the retroviral polynucleotide, a cassette comprising an internal ribosome entry site (IRES) operably linked to a heterologous polynucleotide; and cis-acting sequences necessary for reverse transcription, packaging and integration in a target cell. The RCR maintains higher replication competency after 6 passages compared to a pACE vector. The heterologous polynucleotide may encode modified cytosine deaminase (thermostabilized and codon optimized), single-chain antibody to CTLA-4, microRNAs miR-128-1 and miR-128-2, γ-interferon, interleukin 2, or other therapeutic proteins of interest. The disclosure further relates to cells and vector expressing or comprising such modified CDs and methods of using such modified CDs in the treatment of disease and disorders, and in particular cell proliferative disorders such as cancer.
IT 1140909-48-3, XL 184
RL: THU (Therapeutic use); BIOL (Biological study); USES (Uses)
(combination cancer therapy with; recombinant replication-competent retroviral vectors expressing therapeutic products for treatment of proliferative disorders)

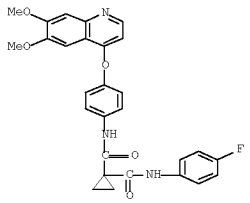
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB The present invention provides an approach for the detn. of the activation states of a plurality of proteins in single cells. This approach permits the rapid detection of heterogeneity in a complex cell population based on activation states, expression markers and other criteria, and the identification of cellular subsets that exhibit correlated changes in activation within the cell population. Moreover, this approach allows the correlation of cellular activities or properties. In addition, the use of modulators of cellular activation allows for characterization of pathways and cell populations. Several exemplary diseases that can be analyzed using the invention include AML, MDS, and MPN.

AB A review. Numerous antiangiogenic agents with diverse mechanisms of action are currently under investigation for the treatment of patients with glioblastoma (GBM), a diagnosis that continues to carry a poor prognosis despite maximal conventional therapy. Early clin. trials suggest that antiangiogenic drugs, which target the blood vessels of these highly angiogenic tumors, may have clin. benefit in GBM patients. Antiangiogenic agents have potent antiedema and steroid-sparing effects in patients, and emerging data suggest that these drugs may modestly improve progression-free survival. Although these early results are encouraging, several issues arise regarding the use and efficacy of these agents. Interpretation of the radiog. changes that occur after treatment with antiangiogenic agents presents a major challenge. Still lacking are reliable radiog. and biol. markers that can predict which patients will benefit from treatment and that accurately indicate response and progression during therapy. In addition, most patients treated with antiangiogenic drugs eventually progress, and the mechanisms by which tumors escape from therapy are only beginning to be understood. Larger prospective trials that incorporate correlative biomarker studies will be required to address these challenges. Here, we summarize the clin. experience with antiangiogenic therapy in patients with malignant gliomas (MG), review the major issues concerning the use and development of these agents, and discuss strategies that may build upon the initial gains observed with antiangiogenic agents.

AB Purpose of review: Metastatic medullary thyroid cancer (MTC) is an incurable disease once metastasis becomes unresectable. Many therapeutic drugs and methods have been tried to circumvent this difficulty. We review currently published treatments and hope for future developments of more effective treatment methods. Recent findings: Motesanib, vandetanib, axitinib (tyrosine kinase inhibitors), and XL184 (multikinase inhibitor) have been shown to achieve partial response or stable disease state of metastatic MTC. Sunitinib and sorafenib, currently available tyrosine kinase inhibitors, can also be tried for patients with MTC. However, these medications are not curative and do not improve survival rate. Only carcinoembryonic antigen-I-iodine-based radioimmunotherapy improved survival of a subset of patients with a very aggressive type of MTC. Drugs currently available for possible use of MTC treatment include bortezomib (proteasome inhibitor), valproic acid (histone deacetylase inhibitor), capecitabine (5-fluorouracil prodrug), and indomethacin (NSAID), although clin. studies have yet to be done. Cardiac natriuretic hormones and an extract of the plant Cautleya gracilis are new agents to be studied for MTC. Summary: Kinase inhibitors are the first drugs showing some efficacy in MTC. To improve survival, unconventional drugs or other therapies with or without kinase inhibitors need to be considered.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB This invention is directed to methods and compns. for diagnosis, prognosis and for determining methods of treatment. The physiol. status of cells present in a sample (e.g. clin. sample) can be used in diagnosis or prognosis of a condition (e.g. chronic lymphocytic leukemia), in patient selection for therapy, to monitor treatment and to modify or optimize therapeutic regimens. The physiol. status of a cell can be determined by comparing the intracellular status of one or more activation elements (e.g. the phosphorylation status of a signaling mol.) in a cell (e.g. a cancer cell) to that of another cell (e.g. a normal cell). The physiol. status of a cell can be further classified by adding one or more modulators (e.g. an inhibitor or activator) to the cell in question. In some embodiments, the invention is directed to methods of determining a phenotypic profile of a population of cells.

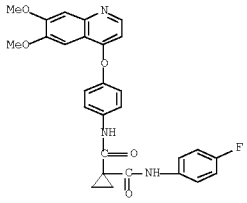
I

II



AB A method of treating a disease in a mammal, comprising administering to the mammal a therapeutically effective amount of a JAK-2 compound of formula I, or a pharmaceutical composition comprising a therapeutically effective amount of the JAK-2 compound of formula I and a pharmaceutically acceptable carrier, in combination with an active agent selected from of a Raf inhibitor, an EGFR inhibitor, a VEGFR inhibitor, a ErbB2 inhibitor, a BCR-Abl, inhibitor, a Flt3 inhibitor, a Src inhibitor, a c Kit inhibitor, an Akt inhibitor, a Ret inhibitor, an IFG1R inhibitor, an m-Tor inhibitor, a PI3K inhibitor, a PI3Kalpha inhibitor, wherein the mammal is in need of the treatment. Compds. of formula I wherein D and E are independently H, halo, CF3, heterocycloalkyl and alkyl; D and E taken together to form a 5- to

7-membered heteroaryl, and 5- to 7-membered heterocycloalkyl; L is a bond, O and NH; Z is alkoxy, cycloalkyl, and (un)substituted heteroaryl; Z and R25 taken together for form a 5- to 6-membered heterocycloalkyl, 5- to 6-membered heteroaryl, 5- to 6-membered cycloalkyl, etc.; each R25 is independently alkyl, alkenyl, lower alkyl, halo, haloalkyl, haloalkoxy, amino, etc.; R1 is H; R2 is (un)substituted aryl, (un)substituted heteroaryl, alkyl, etc.; n is 0 - 4; and pharmaceutically acceptable salts thereof, are claimed. Example compound II was prepared by acylation of 2-(4-aminophenylamino)-5-(4-acetylaminophenyl)pyrimidine with 2,6-dichlorobenzoyl chloride. All the invention compds. were evaluated for their JAK-2 inhibitory activity (some data given).

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Provided herein are methods for treating cancer that is resistant to treatment with an anti- ErbB therapeutic agent and which is associated with an activating MET gene mutation or a MET gene amplification. The methods involve administering to a subject a combination of an anti- ErbB therapeutic and an anti-MET therapeutic. Also provided are methods for reducing ErbB mediated signaling or PI3 kinase mediated signaling in a cancer cell.

II

AB The invention provides methods of treating cancer by administering a compound of formula I, or a pharmaceutically acceptable salt or solvate thereof, in combination with other cancer treatments. Compds. of formula I wherein ring A is (un)substituted (hetero)arylene; X is (halo)alkyl, halo and haloalkoxy; R1, R2, R3, R4, R5 and R6 are independently H, halo, NO2, NH2 and derivs., OH and derivs., NHSO2H and derivs., CN, SH and derivs., etc.; R7 is H, halo and alkyl; and their pharmaceutically acceptable salts and solvates thereof are claimed. Example compound II was prepared by amidation of 3,4-difluoro-2-[(2-fluoro-4- iodophenyl)amino]benzoic acid with azetidin-3-ol hydrochloride. All the invention compds. were evaluated for their MEK inhibitory activity (some data given).

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The invention relates to agents which possess anti-angiogenic activity and are accordingly useful in methods of treatment of disease states associated with angiogenesis in the animal or human body. More specifically the invention concerns a combination of a monoclonal antibody against human anglopoietin 2 (anti-Ang-2) and an antagonist of the biol. activity of VEGF-A, and/or KDR receptor, and/or FLT1, and uses of such antagonists. The nucleotide sequences and the encoded amino acid sequences of anti-Ang-2 monoclonal antibodies are disclosed.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

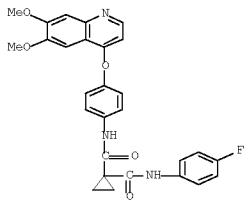
OTHER SOURCE(S): CASREACT 142:373856; MARPAT 142:373856

GI

Z-Ar I

II

AB The present invention provides compds. (shown as I; variables defined below; e.g. N-[4-[[7-[[2-(diethylamino)ethyl]oxy]-6-(methyloxy)quinolin-4-yl]oxy]-3-fluorophenyl]-N'-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide (shown as II)) for modulating protein kinase enzymic activity for modulating cellular activities such as proliferation, differentiation, programmed cell death, migration and chemoinvasion. More specifically, the invention provides quinazolines and quinolines which inhibit, regulate and/or modulate kinase receptors, particularly c-Met, KDR, c-Kit, flt-3 and flt-4, signal transduction pathways related to the changes in cellular activities as mentioned above, compns. which contain these compds., and methods of using them to treat kinase-dependent diseases and conditions. The present invention also provides methods for making compds. as mentioned above, and compns. which contain these compds. For I: R1 = H, halogen, OR3, NO2, NH2, NR3R4, and (un)substituted lower alkyl; A1 = :N-, :C(H)-, and :C(CN)-; Z = -S(O)0-2-, -O-, and -NR5-; Ar is aryl or heteroaryl; D = -O-, -S(O)0-2-, and -NR15-; R50 = R3 or bicyclic radical; addnl. details are given in the claims. Methods of preparation are claimed and .apprx.80 example prepns. of I and intermediates are included. For example, II was prepared (34 %) from 2-(diethylamino)ethanol and cyclopropane-1,1-dicarboxylic acid N-[3-fluoro-4-[(7-hydroxy-6-methoxyquinolin-4-yl)oxy]phenyl]amide N-(4-fluorophenyl)amide, which was prepared (89 %) by deprotection of cyclopropane-1,1-dicarboxylic acid N-[4-[(7-benzyloxy-6-methoxyquinolin-4-yl)oxy]-3-fluorophenyl]amide N-(4-fluorophenyl)amide, which was prepared (48 %) from trifluoromethanesulfonic acid 7-benzyloxy-6-methoxyquinolin-4-yl ester and cyclopropane-1,1-dicarboxylic acid N-(3-fluoro-4-hydroxyphenyl)amide N-(4-fluorophenyl)amide, which was prepared (85 %) by deprotection of cyclopropane-1,1-dicarboxylic acid N-(4-benzyloxy-3-fluorophenyl)amide N-(4-fluorophenyl)amide, which was prepared (98 %) from (4-benzyloxy-3-fluorophenyl)amine and 1-(4-fluorophenylcarbamoyl)cyclopropanecarboxylic acid; addnl. details are given in the examples.



IT 849217-68-1P

RL: PAC (Pharmacological activity); SPN (Synthetic preparation); THU (Therapeutic use); BIOL (Biological study); PREP (Preparation); USES (Uses)

(drug candidate; preparation of quinolines and quinazolines as inhibitors of c-Met and other tyrosine kinases and therapeutic uses against proliferative diseases)

RN 849217-68-1 CAPLUS

CN 1,1-Cyclopropanedicarboxamide, N'-[4-[(6,7-dimethoxy-4-quinolinyl)oxy]phenyl]-N-(4-fluorophenyl)- (CA INDEX NAME)

Acknowledgement of Loss of Entitlement to Entity Status Discount

The entity status change request below filed through Private PAIR on 10/30/2018 has been accepted.

CERTIFICATIONS:

Change of Entity Status:

X Applicant changing to regular undiscounted fee status.

NOTE: Checking this box will be taken to be notification of loss of entitlement to small or micro entity status, as applicable.

This portion must be completed by the signatory or signatories making the entity status change in accordance with 37 CFR 1.4(d)(4).

ISSUE NOTIFICATION

The projected patent number and issue date are specified above.

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b)
(application filed on or after May 29, 2000)

The Patent Term Adjustment is 0 day(s). Any patent to issue from the above-identified application will include an indication of the adjustment on the front page.

If a Continued Prosecution Application (CPA) was filed in the above-identified application, the filing date that determines Patent Term Adjustment is the filing date of the most recent CPA.

Applicant will be able to obtain more detailed information by accessing the Patent Application Information Retrieval (PAIR) WEB site (http://pair.uspto.gov).

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Application Assistance Unit (AAU) of the Office of Data Management (ODM) at (571)-272-4200.

APPLICANT(s) (Please see PAIR WEB site http://pair.uspto.gov for additional applicants):

Jo Ann Wilson, San Francisco, CA;
Khalid Shah, South San Francisco, CA;

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The USA offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to encourage and facilitate business investment. To learn more about why the USA is the best country in the world to develop technology, manufacture products, and grow your business, visit SelectUSA.gov.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), to: Mail Mail Stop ISSUE FEE
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450
or Fax (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence including the Patent, advance orders and notification of maintenance fees will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications.

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

91684 7590 05/26/2017

JONATHAN P. O'BRIEN, PH.D.
HONIGMAN MILLER SCHWARTZ AND COHN LLP
350 EAST MICHIGAN AVENUE, SUITE 300
Kalamazoo, MI 49007-3800

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

Certificate of Mailing or Transmission

I hereby certify that this Fee(s) Transmittal is being deposited with the United States Postal Service with sufficient postage for first class mail in an envelope addressed to the Mail Stop ISSUE FEE address above, or being facsimile transmitted to the USPTO (571) 273-2885, on the date indicated below.

ROZOF, TIMOTHY R	1625	514-312000

1. Change of correspondence address or indication of "Fee Address" (37 CFR 1.363).

☐ Change of correspondence address (or Change of Correspondence Address Form PTO/SB/122) attached.

☐ "Fee Address" indication (or "Fee Address" Indication form PTO/SB/47; Rev 03-02 or more recent) attached. **Use of a Customer Number is required.**

2. For printing on the patent front page, list

(1) The names of up to 3 registered patent attorneys or agents OR, alternatively,

(2) The name of a single firm (having as a member a registered attorney or agent) and the names of up to 2 registered patent attorneys or agents. If no name is listed, no name will be printed.

1 Honigman Miller Schwartz & Cohn LLP
2 Heidi M. Berven, Ph.D.
3 Jonathan P. O'Brien, Ph.D.

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)

PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document has been filed for recordation as set forth in 37 CFR 3.11. Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE: Exelixis, Inc.

(B) RESIDENCE: (CITY and STATE OR COUNTRY): South San Francisco, CA

Please check the appropriate assignee category or categories (will not be printed on the patent): ☐ Individual ☒ Corporation or other private group entity ☐ Government

4a. The following fee(s) are submitted:

☒ Issue Fee (Please apply issue fee paid in this application 11/10/2016)
☐ Publication Fee (No small entity discount permitted)
☐ Advance Order - # of Copies _____

4b. Payment of Fee(s): **(Please first reapply any previously paid issue fee shown above)**

☐ A check is enclosed.
☐ Payment by credit card. Form PTO-2038 is attached.
☒ The director is hereby authorized to charge the required fee(s), any deficiency, or credits any overpayment, to Deposit Account Number 503145 (enclose an extra copy of this form).

5. **Change in Entity Status** (from status indicated above)

☐ Applicant certifying micro entity status. See 37 CFR 1.29
NOTE: Absent a valid certification of Micro Entity Status (see forms PTO/SB/15A and 15B), issue fee payment in the micro entity amount will not be accepted at the risk of application abandonment.

☒ Applicant asserting small entity status. See 37 CFR 1.27
NOTE: If the application was previously under micro entity status, checking this box will be taken to be a notification of loss of entitlement to micro entity status.

☐ Applicant changing to regular undiscounted fee status.
NOTE: Checking this box will be taken to be a notification of loss of entitlement to small or micro entity status, as applicable.

NOTE: This form must be signed in accordance with 37 CFR 1.31 and 1.33. See 37 CFR 1.4 for signature requirements and certifications.

Authorized Signature _____ Date June 14, 2017

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

Commissioner for Patents
United States Patent and Trademark Office
P. O. Box 1450
Alexandria, VA 22313

Re: ***Application No.: 13/984,559***
Inventors: Jo Ann Wilson, et al.
Filing Date: March 20, 2014
Title: Processes for Preparing Quinoline Compounds and Pharmaceutical Compositions Containing Such Compounds
Confirmation No.: 6725
Attorney Docket No.: 224990/10-039C-US/343999

Dear Sir or Madam:

Enclosed for filing please find the following documents:

1. This Cover Letter to the Commissioner for Patents;
2. Part B Fee(s) Transmittal (PTOL-85); and
3. Certificate of Transmission under 37 C.F.R. § 1.8(a).

The Applicant requests that the Office reapply the $480.00 Issue Fee previously paid in this application to Issue Fee set forth in the Notice of Allowance and Fee(s) Due mailed May 26, 2017. It is believed that no additional fees are required. However, if there are any other fees due for this submission, or any credits, please apply them to Deposit Account Number 503145, referencing Attorney Docket Number 224990/10-039C-US/343999.

Very truly yours,

HONIGMAN MILLER SCHWARTZ AND COHN LLP

Heidi M. Berven, Ph.D.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), to: Mail Mail Stop ISSUE FEE
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450
or Fax (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence including the Patent, advance orders and notification of maintenance fees will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications.

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

91684 7596 05/26/2017
JONATHAN P. O'BRIEN, PH.D.
HONIGMAN MILLER SCHWARTZ AND COHN LLP
350 EAST MICHIGAN AVENUE, SUITE 300
Kalamazoo, MI 49007-3800

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

Certificate of Mailing or Transmission
I hereby certify that this Fee(s) Transmittal is being deposited with the United States Postal Service with sufficient postage for first class mail in an envelope addressed to the Mail Stop ISSUE FEE address above, or being facsimile transmitted to the USPTO (571) 273-2885, on the date indicated below.

1. Change of correspondence address or indication of "Fee Address" (37 CFR 1.363).
☐ Change of correspondence address (or Change of Correspondence Address form PTO/SB/(122) attached.
☐ "Fee Address" indication (or "Fee Address" Indication form PTO/SB/47; Rev 03-02 or more recent) attached. Use of a Customer Number is required.

2. For printing on the patent front page, list
(1) The names of up to 3 registered patent attorneys or agents OR, alternatively,
(2) The name of a single firm (having as a member a registered attorney or agent) and the names of up to 2 registered patent attorneys or agents. If no name is listed, no name will be printed.
1 Honigman Miller Schwartz & Cohn LLP
2 Heidi M. Berven, Ph.D.
3 Jonathan P. O'Brien, Ph.D.

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)
PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document has been filed for recordation as set forth in 37 CFR 3.11. Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE	(B) RESIDENCE: (CITY and STATE OR COUNTRY)
Exelixis, Inc.	South San Francisco, CA

Please check the appropriate assignee category or categories (will not be printed on the patent): ☐ Individual ☒ Corporation or other private group entity ☐ Government

4a. The following fee(s) are submitted:
☒ Issue Fee (Please apply issue fee paid in this application 11/10/2016)
☐ Publication Fee (No small entity discount permitted)
☐ Advance Order - # of Copies .....

4b. Payment of Fee(s): (Please first reapply any previously paid issue fee shown above)
☐ A check is enclosed.
☐ Payment by credit card. Form PTO-2038 is attached.
☒ The director is hereby authorized to charge the required fee(s), any deficiency, or credits any overpayment, to Deposit Account Number 503145 (enclose an extra copy of this form).

5. Change in Entity Status (from status indicated above)
☐ Applicant certifying micro entity status. See 37 CFR 1.29
NOTE: Absent a valid certification of Micro Entity Status (see forms PTO/SB/15A and 15B), issue fee payment in the micro entity amount will not be accepted at the risk of application abandonment.
☒ Applicant asserting small entity status. See 37 CFR 1.27
NOTE: If the application was previously under micro entity status, checking this box will be taken to be a notification of loss of entitlement to micro entity status.
☐ Applicant changing to regular undiscounted fee status.
NOTE: Checking this box will be taken to be a notification of loss of entitlement to small or micro entity status, as applicable.

NOTE: This form must be signed in accordance with 37 CFR 1.31 and 1.33. See 37 CFR 1.4 for signature requirements and certifications.

ROZOF, TIMOTHY R	
ART UNIT	PAPER NUMBER
1625	

DATE MAILED: 05/26/2017

APPLICATION NO.	FILING DATE	FIRST NAMED INVENTOR	ATTORNEY DOCKET NO.	CONFIRMATION NO.
13/984,559	03/20/2014	Jo Ann Wilson	224990/10-039C-US/343999	6725

TITLE OF INVENTION: PROCESSES FOR PREPARING QUINOLINE COMPOUNDS AND PHARMACEUTICAL COMPOSITIONS CONTAINING SUCH COMPOUNDS

APPLN. TYPE	ENTITY STATUS	ISSUE FEE DUE	PUBLICATION FEE DUE	PREV. PAID ISSUE FEE	TOTAL FEE(S) DUE	DATE DUE
nonprovisional	SMALL	$480	$0	$480	$480	08/28/2017

THE APPLICATION IDENTIFIED ABOVE HAS BEEN EXAMINED AND IS ALLOWED FOR ISSUANCE AS A PATENT. PROSECUTION ON THE MERITS IS CLOSED. THIS NOTICE OF ALLOWANCE IS NOT A GRANT OF PATENT RIGHTS. THIS APPLICATION IS SUBJECT TO WITHDRAWAL FROM ISSUE AT THE INITIATIVE OF THE OFFICE OR UPON PETITION BY THE APPLICANT. SEE 37 CFR 1.313 AND MPEP 1308.

THE ISSUE FEE AND PUBLICATION FEE (IF REQUIRED) MUST BE PAID WITHIN THREE MONTHS FROM THE MAILING DATE OF THIS NOTICE OR THIS APPLICATION SHALL BE REGARDED AS ABANDONED. THIS STATUTORY PERIOD CANNOT BE EXTENDED. SEE 35 U.S.C. 151. THE ISSUE FEE DUE INDICATED ABOVE DOES NOT REFLECT A CREDIT FOR ANY PREVIOUSLY PAID ISSUE FEE IN THIS APPLICATION. IF AN ISSUE FEE HAS PREVIOUSLY BEEN PAID IN THIS APPLICATION (AS SHOWN ABOVE), THE RETURN OF PART B OF THIS FORM WILL BE CONSIDERED A REQUEST TO REAPPLY THE PREVIOUSLY PAID ISSUE FEE TOWARD THE ISSUE FEE NOW DUE.

HOW TO REPLY TO THIS NOTICE:

I. Review the ENTITY STATUS shown above. If the ENTITY STATUS is shown as SMALL or MICRO, verify whether entitlement to that entity status still applies.

If the ENTITY STATUS is the same as shown above, pay the TOTAL FEE(S) DUE shown above.

If the ENTITY STATUS is changed from that shown above, on PART B - FEE(S) TRANSMITTAL, complete section number 5 titled "Change in Entity Status (from status indicated above)".

For purposes of this notice, small entity fees are 1/2 the amount of undiscounted fees, and micro entity fees are 1/2 the amount of small entity fees.

II. PART B - FEE(S) TRANSMITTAL, or its equivalent, must be completed and returned to the United States Patent and Trademark Office (USPTO) with your ISSUE FEE and PUBLICATION FEE (if required). If you are charging the fee(s) to your deposit account, section "4b" of Part B - Fee(s) Transmittal should be completed and an extra copy of the form should be submitted. If an equivalent of Part B is filed, a request to reapply a previously paid issue fee must be clearly made, and delays in processing may occur due to the difficulty in recognizing the paper as an equivalent of Part B.

III. All communications regarding this application must give the application number. Please direct all communications prior to issuance to Mail Stop ISSUE FEE unless advised to the contrary.

IMPORTANT REMINDER: Utility patents issuing on applications filed on or after Dec. 12, 1980 may require payment of maintenance fees. It is patentee's responsibility to ensure timely payment of maintenance fees when due.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), to: Mail **Mail Stop ISSUE FEE**
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450
or Fax (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence including the Patent, advance orders and notification of maintenance fees will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications.

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b)

(Applications filed on or after May 29, 2000)

The Office has discontinued providing a Patent Term Adjustment (PTA) calculation with the Notice of Allowance.

Section 1(h)(2) of the AIA Technical Corrections Act amended 35 U.S.C. 154(b)(3)(B)(i) to eliminate the requirement that the Office provide a patent term adjustment determination with the notice of allowance. See Revisions to Patent Term Adjustment, 78 Fed. Reg. 19416, 19417 (Apr. 1, 2013). Therefore, the Office is no longer providing an initial patent term adjustment determination with the notice of allowance. The Office will continue to provide a patent term adjustment determination with the Issue Notification Letter that is mailed to applicant approximately three weeks prior to the issue date of the patent, and will include the patent term adjustment on the patent. Any request for reconsideration of the patent term adjustment determination (or reinstatement of patent term adjustment) should follow the process outlined in 37 CFR 1.705.

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Customer Service Center of the Office of Patent Publication at 1-(888)-786-0101 or (571)-272-4200.

OMB Clearance and PRA Burden Statement for PTOL-85 Part B

The Paperwork Reduction Act (PRA) of 1995 requires Federal agencies to obtain Office of Management and Budget approval before requesting most types of information from the public. When OMB approves an agency request to collect information from the public, OMB (i) provides a valid OMB Control Number and expiration date for the agency to display on the instrument that will be used to collect the information and (ii) requires the agency to inform the public about the OMB Control Number's legal significance in accordance with 5 CFR 1320.5(b).

The information collected by PTOL-85 Part B is required by 37 CFR 1.311. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, Virginia 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450. Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

   a) ☐ All b) ☐ Some *c) ☐ None of the:
   1. ☐ Certified copies of the priority documents have been received.
   2. ☐ Certified copies of the priority documents have been received in Application No. _____ .
   3. ☐ Copies of the certified copies of the priority documents have been received in this national stage application from the International Bureau (PCT Rule 17.2(a)).

   * Certified copies not received: _____.

Applicant has THREE MONTHS FROM THE "MAILING DATE" of this communication to file a reply complying with the requirements noted below. Failure to timely comply will result in ABANDONMENT of this application.
THIS THREE-MONTH PERIOD IS NOT EXTENDABLE.

5. ☐ CORRECTED DRAWINGS (as "replacement sheets") must be submitted.
   ☐ including changes required by the attached Examiner's Amendment / Comment or in the Office action of Paper No./Mail Date _____.

   Identifying indicia such as the application number (see 37 CFR 1.84(c)) should be written on the drawings in the front (not the back) of each sheet. Replacement sheet(s) should be labeled as such in the header according to 37 CFR 1.121(d).
6. ☐ DEPOSIT OF and/or INFORMATION about the deposit of BIOLOGICAL MATERIAL must be submitted. Note the attached Examiner's comment regarding REQUIREMENT FOR THE DEPOSIT OF BIOLOGICAL MATERIAL.

Attachment(s)

1. ☐ Notice of References Cited (PTO-892)
2. ☐ Information Disclosure Statements (PTO/SB/08), Paper No./Mail Date _____
3. ☐ Examiner's Comment Regarding Requirement for Deposit of Biological Material
4. ☐ Interview Summary (PTO-413), Paper No./Mail Date _____ .
5. ☐ Examiner's Amendment/Comment
6. ☐ Examiner's Statement of Reasons for Allowance
7. ☐ Other _____.

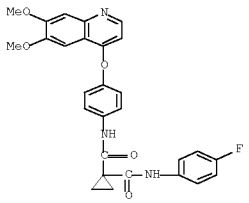
ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT



AB The present invention relates to a method for the diagnosis or the prognosis of metastasis, relapse or recurrence in prostate cancer which comprises determining if the c-MAF gene is amplified in a primary tumor sample. Likewise, the invention also relates to a method for the diagnosis or the prognosis of metastasis, relapse or recurrence in prostate cancer, as well as to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise determining the c-MAF expression level. Finally, the invention relates to the use of a c-MAF inhibitor as therapeutic target for treating the prostate cancer.

IT 849217-68-1, Cabozantinib
RL: PAC (Pharmacological activity); THU (Therapeutic use); BIOL (Biological study); USES (Uses)

AB Purpose To review the use of patient-reported outcome (PRO) data in medical product labeling granted by the US Food and Drug Administration (FDA) for new mol. entities and biol. license applications by the FDA Office of Hematol. and Oncol. Products (OHOP) between Jan. 2010 and Dec. 2014, to elucidate challenges faced by OHOP for approving PRO labeling, and to understand challenges faced by drug manufacturers to include PRO end points in oncol. clin. trials. Methods FDA Drug Approval Reports by Month were reviewed to obtain the number of new mol. entities and biol. license applications approved from 2010 to 2014. Drugs approved by the FDA OHOP during this period were selected for further review, focusing on brand and generic name; approval date; applicant; indication; PRO labeling describing treatment benefit, measures, end point status, and significant results; FDA reviewer feedback on PRO end points; and study design of registration trials. First in class, priority review, fast track, orphan drug, or accelerated approval status was retrieved for selected oncol. drugs from 2011 to 2014. Descriptive analyses were performed by using Microsoft Excel 2010. Results Of 160 drugs approved by the FDA (2010-2014), 40 were approved by OHOP. Three (7.5%) of the 40 received PRO-related labeling (abiraterone acetate, ruxolitinib phosphate, and crizotinib). Compared with nononcol. drugs (2011-2014), oncol. drugs were more likely to be orphan and first in class. The majority of oncol. drug reviews by FDA were fast track, priority, or accelerated. Conclusion Although symptoms and functional decrements are common among patients with cancer, PRO labeling is rare in the United States, likely because of logistical hurdles and oncol. study design. Recent developments within the FDA OHOP to capture PROs in oncol. studies for the purpose of product labeling are encouraging.

AB A significant fraction of patients with advanced prostate cancer treated with androgen deprivation therapy experience relapse with relentless progression to lethal metastatic castration-resistant prostate cancer (mCRPC). Immune checkpoint blockade using antibodies against cytotoxic-T-lymphocyte-associated protein 4 (CTLA4) or programmed cell death 1/programmed cell death 1 ligand 1 (PD1/PD-L1) generates durable therapeutic responses in a significant subset of patients across a variety of cancer types. However, mCRPC showed overwhelming de novo resistance to immune checkpoint blockade, motivating a search for targeted therapies that overcome this resistance. Myeloid-derived suppressor cells (MDSCs) are known to play important roles in tumor immune evasion. The abundance of circulating MDSCs correlates with prostate-specific antigen levels and metastasis in patients with prostate cancer. Mouse models of prostate cancer show that MDSCs (CD11b+Gr1+) promote tumor initiation and progression. These observations prompted the authors to hypothesize that robust immunotherapy responses in mCRPC may be elicited by the combined actions of immune checkpoint blockade agents together with targeted agents that neutralize MDSCs yet preserve T-cell function. Here the authors develop a novel chimeric mouse model of mCRPC to efficiently test combination therapies in an autochthonous setting. Combination of anti-CTLA4 and anti-PD1 engendered only modest efficacy. Targeted therapy against mCRPC-infiltrating MDSCs, using multi-kinase inhibitors such as cabozantinib and BEZ235, also showed minimal anti-tumor activities. Strikingly, primary and metastatic CRPC showed robust synergistic responses when immune checkpoint blockade was combined with MDSC-targeted therapy. Mechanistically, combination therapy efficacy stemmed from the up-regulation of interleukin-1 receptor antagonist and suppression of MDSC-promoting cytokines secreted by prostate cancer cells. These observations illuminate a clin. path hypothesis for combining immune checkpoint blockade with MDSC-targeted therapies in the treatment of mCRPC.

AB Osimertinib has been demonstrated to overcome the epidermal growth factor receptor (EGFR)-T790M, the most relevant acquired resistance to first-generation EGFR-tyrosine kinase inhibitors (EGFR-TKIs). However, the C797S mutation, which impairs the covalent binding between the cysteine residue at position 797 of EGFR and osimertinib, induces resistance to osimertinib. Currently, there are no effective therapeutic strategies to overcome the C797S/T790M/activating-mutation (triple-mutation)-mediated EGFR-TKI resistance. In the present study, we identify brigatinib to be effective against triple-mutation-harbouring cells in vitro and in vivo. Our original computational simulation demonstrates that brigatinib fits into the ATP-binding pocket of triple-mutant EGFR. The structure-activity relationship anal. reveals the key component in brigatinib to inhibit the triple-mutant EGFR. The efficacy of brigatinib is enhanced markedly by combination with anti-EGFR antibody because of the decrease of surface and total EGFR expression. Thus, the combination therapy of brigatinib with anti-EGFR antibody is a powerful candidate to overcome triple-mutant EGFR.

AB Aldehyde oxidase (AOX) is an important drug-metabolizing enzyme. However, the current in vitro models for evaluating AOX metabolism are sometimes misleading, and preclin. animal models generally fail to predict human AOX-mediated metabolism In this study, the authors report a combined

computational and exptl. investigation of drug-like mols. that are potential aldehyde oxidase substrates, of which multiple sites of metabolism (SOMs) mediated by AOX and their preferences for the reaction can be unambiguously identified. In addition, the proposed strategy was used to evaluate the metabolism of newly designed c-Met inhibitors, and a success switch-off of AOX metabolism was observed Overall, this study provide useful information to guide lead optimization and drug discovery based on AOX-mediated metabolism

AB The present invention relates to a pharmaceutical compn. comprising c-MET inhibitor as an active ingredient for enhancing doxorubicin and photodynamic cancer therapy. The pharmaceutical composition may further comprise a PI3K inhibitor, wherein the c-MET inhibitor alone or at least one selected from the group consisting of a c-MET inhibitor, a PI3K inhibitor and a mixture thereof is co-treated with doxorubicin in a cancer cell. The intracellular doxorubicin accumulation and ROS levels are increased, and accumulation of intracellular photosensitizer is increased to induce apoptosis. Therefore, it is possible to prevent the resistance of cancer cells to doxorubicin or photodynamic therapy (PDT) treatment and increase the sensitivity to doxorubicin or PDT to improve the efficiency of chemotherapy.

AB Pancreatic cancer (PC) is largely refractory to existing therapies used in unselected patient trials, thus emphasizing the pressing need for new approaches for patient selection in personalized medicine. KRAS mutations occur in 90% of PC patients and confer resistance to epidermal growth factor receptor (EGFR) inhibitors (e.g., panitumumab), suggesting that KRAS wild-type PC patients may benefit from targeted panitumumab therapy. Here, we use tumor tissue procured by endoscopic ultrasound-guided fine-needle aspirate (EUS-FNA) to compare the in vivo sensitivity in patient-derived xenografts (PDXs) of KRAS wild-type and mutant PC tumors to panitumumab, and to profile the mol. signature of these tumors in patients with metastatic or localized disease. Specifically, RNASeq of EUS-FNA-derived tumor RNA from localized (n = 20) and metastatic (n = 20) PC cases revealed a comparable transcriptome profile. Screening the KRAS mutation status of tumor genomic DNA obtained from EUS-FNAs stratified PC patients into either KRAS wild-type or mutant cohorts, and the engraftment of representative KRAS wild-type and mutant EUS-FNA tumor samples into NOD/SCID mice revealed that the growth of KRAS wild-type, but not mutant, PDXs was selectively suppressed with panitumumab. Furthermore, in silico transcriptome interrogation of The Cancer Genome Atlas (TCGA)-derived KRAS wild-type (n = 38) and mutant (n = 132) PC tumors revealed 391 differentially expressed genes. Taken together, our study validates EUS-FNA for the application of a novel translational pipeline comprising KRAS mutation screening and PDXs, applicable to all PC patients, to evaluate personalized anti-EGFR therapy in patients with KRAS wild-type tumors.

AB Background: Triple neg. breast cancer (TNBC) is a highly heterogeneous and aggressive type of cancer that lacks effective targeted therapy. Despite detailed mol. profiling, no targeted therapy has been established. Hence, with the aim of gaining deeper understanding of the functional differences of TNBC subtypes and how that may relate to potential novel therapeutic strategies, we studied comprehensive anticancer-agent responses among a panel of TNBC cell lines. Method: The responses of 301 approved and investigational oncol. compds. were measured in 16 TNBC cell lines applying a functional profiling approach. To go beyond the standard drug viability effect profiling, which has been used in most chemosensitivity studies, we utilized a multiplexed readout for both cell viability and cytotoxicity, allowing us to differentiate between cytostatic and cytotoxic responses. Results: Our approach revealed that most single-agent anti-cancer compds. that showed activity for the viability readout had no or little cytotoxic effects. Major compound classes that exhibited this type of response included anti-mitotics, mTOR, CDK, and metabolic inhibitors, as well as many agents selectively inhibiting oncogene-activated pathways. However, within the broad viability-acting classes of compds., there were often subsets of cell lines that responded by cell death, suggesting that these cells are particularly vulnerable to the tested substance. In those cases we could identify differential levels of protein markers associated with cytotoxic responses. For example, PAI-1, MAPK phosphatase and Notch-3 levels associated with cytotoxic responses to mitotic and proteasome inhibitors, suggesting that these might serve as markers of response also in clin. settings. Furthermore, the cytotoxicity readout highlighted selective synergistic and synthetic lethal drug combinations that were missed by the cell viability readouts. For instance, the MEK inhibitor trametinib synergized with PARP inhibitors. Similarly, combination of two non-cytotoxic compds., the rapamycin analog everolimus and an ATP-competitive mTOR inhibitor dactolisib, showed synthetic lethality in several mTOR-addicted cell lines. Conclusions: Taken together, by studying the combination of cytotoxic and cytostatic drug responses, we identified a deeper spectrum of cellular responses both to single agents and combinations that may be highly relevant for identifying precision medicine approaches in TNBC as well as in other types of cancers.

AB Approx. 25-40% of patients with lung cancer show bone metastasis. Bone modifying agents reduce skeletal-related events (SREs), but they do not significantly improve overall survival. Therefore, novel therapeutic approaches are urgently required. In this study, we investigated the anti-tumor effect of TAS-115, a VEGFRs and HGF receptor (MET)-targeted kinase inhibitor, in a tumor-induced bone disease model. A549-Luc-BM1 cells, an osteo-tropic clone of luciferase-transfected A549 human lung adenocarcinoma cells (A549-Luc), produced aggressive bone destruction associated with tumor progression after intratibial (IT) implantation into mice. TAS-115 significantly reduced IT tumor growth and bone destruction. Histopathol. anal. showed a decrease in tumor vessels after TAS-115 treatment, which might be mediated through VEGFRs inhibition. Furthermore, the number of osteoclasts surrounding the tumor was decreased after TAS-115 treatment. In vitro studies demonstrated that TAS-115 inhibited HGF-, VEGF-, and macrophage-colony stimulating factor (M-CSF)-induced signaling pathways in osteoclasts. Moreover, TAS-115 inhibited Feline McDonough Sarcoma oncogene (FMS) kinase, as well as M-CSF and receptor activator of NF-κB ligand (RANKL)-induced osteoclast differentiation. Thus, VEGFRs/MET/FMS-triple inhibition in osteoclasts might contribute to the potent efficacy of TAS-115. The fact that concomitant dosing of sunitinib (VEGFRs/FMS inhibition) with crizotinib (MET inhibition) exerted comparable inhibitory efficacy for bone destruction to TAS-115 also supports this notion. In conclusion, TAS-115 inhibited tumor growth via VEGFRkinase blockade, and also suppressed bone destruction possibly through VEGFRs/MET/ FMS-kinase inhibition, which resulted in potent efficacy of TAS-115 in an A549-Luc-BM1 bone disease model. Thus, TAS-115 shows promise as a novel therapy for lung cancer patients with bone metastasis.

AB In one aspect, the invention relates to pharmaceutical compns. and methods for treating a cancer comprising administration of an EGFR inhibitor (e.g. gefitinib) and a MEK inhibitor (e.g. trametinib) or MET inhibitor (e.g. crizotinib). In various aspects, the methods can comprise determination of increased levels of HGF, e.g., determining if a patient has an increased level of serum HGF. This abstract is intended as a scanning tool for purposes of searching in the particular art and is not intended to be limiting of the present invention.

AB Combinatorial therapeutic approaches are an imperative to improve cancer treatment, because it is critical to impede compensatory signaling mechanisms that can engender drug resistance to individual targeted drugs. Currently approved drug combinations result largely from empirical clin. experience and cover only a small fraction of a vast therapeutic space. Here we present a computational network biol. approach, based on pathway cross-talk inhibition, to discover new synergistic drug combinations for breast cancer treatment. In silico anal. identified 390 novel anticancer drug pairs belonging to 10 drug classes that are likely to diminish pathway cross-talk and display synergistic antitumor effects. Ten novel drug combinations were validated exptl., and seven of these exhibited synergy in human breast cancer cell lines. In particular, we found that one novel combination, pairing the estrogen response modifier raloxifene with the c-Met/VEGFR2 kinase inhibitor cabozantinib, dramatically potentiated the drugs' individual antitumor effects in a mouse model of breast cancer. When compared with high-throughput combinatorial studies without computational prioritization, our approach offers a significant advance capable of uncovering broad-spectrum utility across many cancer types. AB Triple-neg. breast cancer (TNBC) remains an aggressive disease without effective targeted therapies. In this study, we addressed this challenge by testing 128 FDA-approved or investigational drugs as either single agents or in 768 pairwise drug combinations in TNBC cell lines to identify synergistic combinations tractable to clin. translation. Medium-throughput results were scrutinized and extensively analyzed for sensitivity patterns, synergy, anticancer activity, and were validated in low-throughput expts. Principal component anal. revealed that a fraction of all upregulated or downregulated genes of a particular targeted pathway could partly explain cell sensitivity toward agents targeting that pathway. Combination therapies deemed immediately tractable to translation included ABT-263/crizotinib, ABT-263/paclitaxel, paclitaxel/JQ1, ABT-263/XL-184, and paclitaxel/nutlin-3, all of which exhibited synergistic antiproliferative and apoptotic activity in multiple TNBC backgrounds. Mechanistic investigations of the ABT-263/crizotinib combination offering a potentially rapid path to clinic demonstrated RTK blockade, inhibition of mitogenic signaling, and proapoptotic signal induction in basal and mesenchymal stem-like TNBC. Our findings provide preclin. proof of concept for several combination treatments of TNBC, which offer near-term prospects for clin. translation. Cancer Res; 77(2); 566-78. ©2016 AACR.

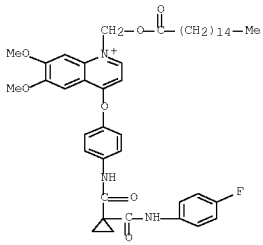
II



AB The invention relates to ethylene oxide deriatives of formula I, method for their preparation and their use as anticancer agents. Compds. of formula I, wherein, R1-R4 are independently H and C1-6alkyl, which can be substituted with 0-4 of F, Cl, Br and I; X1 is (CX1aX1b)1-6, CO, or absent; X2 is CO, CONH, O, S, etc.; X3 and X4 are independently O, S, NH, etc. X1a, X1b are independently H, F, Br, C1-6alkyl, etc.; ring A and B are independently C6-14 carbon ring or 5- to 15-membered heterocycle; ring C is absent, C6-14 carbon ring and 5- to 15-membered heterocycle, their pharmaceutically acceptable salts, are claimed. Example compound II was prepared via a multistep procedure (procedure given). All the invention compds. were evaluated for their anticancer activity. From the assay, it was determined that example compound II exhibited IC50 value of 0.00147 μM and 0.010 μM towards A431 and NCI-H1975 cell line resp.

AB Background: Cabozantinib is an orally available inhibitor of tyrosine kinases including VEGFR2 and c-MET. We performed a post hoc anal. to find assocns. between select plasma biomarkers and treatment response in patients (pts) with metastatic castration resistant prostate cancer (mCRPC) who received cabozantinib 100 mg daily as part of a phase 2 non-randomized expansion cohort (NCT00940225). Methods: Plasma samples were collected at baseline, 6 wk and at time of maximal response from 81 mCRPC pts with bone metastases, of which 33 also had measurable soft-tissue disease. Levels of 27 biomarkers were measured in duplicate using ELISA. Spearman correlation coeffs. were calculated for the association between biomarker levels or their change on treatment and either bone scan response (BSR) or soft tissue response according to RECIST. Results: A BSR and RECIST response were seen in 66/81 pts (81 %) and 6/33 pts (18 %) resp. No significant assocns. were found between any biomarker at any time point and either type of response. Plasma concns. of VEGFA, FLT3L, c-MET, AXL, Gas6A, bone-specific alkaline phosphatase, interleukin-8 and the hypoxia markers CA9 and clusterin significantly increased during treatment with cabozantinib irresp. of response. The plasma concns. of VEGFR2, Trap5b, Angiopoietin-2, TIMP-2 and TIE-2 significantly decreased during treatment with cabozantinib. Conclusions: Our data did not reveal plasma biomarkers associated with response to cabozantinib. The observed alterations in several biomarkers during treatment with cabozantinib may provide insights on the effects of cabozantinib on tumor cells and on tumor micro-environment and may help point to potential co-targeting approaches.

AB Background. Platelet-derived growth factor receptor A is altered by amplification and/or mutation in diffuse intrinsic pontine glioma (DIPG). We explored in vitro on new DIPG models the efficacy of dasatinib, a multi-tyrosine kinase inhibitor targeting this receptor. Gene expression profiles were generated from 41 DIPGs biopsied at diagnosis and compared with the signature associated with sensitivity/resistance to dasatinib. A panel of 12 new DIPG cell lines were established from biopsy at diagnosis, serially passaged, and characterized by gene expression analyses. Effects of dasatinib (1-10 μ M) on proliferation, invasion, and cytotoxicity were determined on 4 of these cell lines using live-cell imaging and flow cytometry assays. Downstream signaling and receptor tyrosine kinases (RTKs) were assessed by western blot and phospho-RTK array. The effect of the combination with the c-Met inhibitor cabozantinib was studied on cellular growth and invasion analyzed by the Chou-Talaly method. DIPG primary tumors and cell lines exhibited the gene expression signature of sensitivity to dasatinib. Dasatinib reduced proliferation (half-maximal inhibitory concentration = 10-100 nM) and invasion (30%-60% reduction) at 100 nM in 4/4 cultures and induced apoptosis in 1 of 4 DIPG cell lines. Activity of downstream effectors of dasatinib targets including activin receptor 1 was strongly reduced. Since multiple RTKs were activated simultaneously in DIPG cell lines, including c-Met, which can be also amplified in DIPG, the benefit of the combination of dasatinib with cabozantinib was explored for its synergistic effects on proliferation and migration/invasion in these cell lines. Conclusion. Dasatinib exhibits antitumor effects in vitro that could be increased by the combination with another RTK inhibitor targeting c-Met.

AB : Agents that target the vascular endothelial growth factor (VEGF) or mammalian target of rapamycin (mTOR) pathway as well as the PD-1 checkpoint inhibitor nivolumab are standard therapies for advanced renal cell carcinoma (RCC). Recently, cabozantinib, an inhibitor of MET, VEGF receptors, and AXL, was approved by the FDA and European Commission based on improved progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) compared to standard of care treatment with everolimus in a randomized phase 3 trial in advanced RCC after prior VEGFR-tyrosine kinase inhibitor (TKI) therapy. The preclin. development and scientific rationale, pharmacokinetics, and clin. efficacy and safety of cabozantinib for the treatment of advanced RCC are reviewed. The use of cabozantinib in clin. practice with the growing number of available treatments for advanced RCC is discussed.: Cabozantinib is the only therapy for advanced RCC that has improved PFS, ORR, and OS in a pivotal phase 3 trial after prior antiangiogenic therapy. While no clin. trials have been published comparing cabozantinib with another TKI, available clin. data suggest it could be the most efficacious TKI for second-line therapy. Preliminary encouraging results have also been reported in a phase 2 trial in untreated poor- and intermediate- risk patients with RCC, indicating that treatment with cabozantinib may also be beneficial in the first-line setting.

AB In the majority of gastrointestinal stromal tumors (GIST), oncogenic signaling is driven by KIT mutations. Advanced GIST is treated with tyrosine kinase inhibitors (TKI) such as imatinib. Acquired resistance to TKI is mainly caused by secondary KIT mutations, but can also be attributed to a switch of KIT dependency to another receptor tyrosine kinase (RTK). We tested the efficacy of cabozantinib, a novel TKI targeting KIT, MET, AXL, and vascular endothelial growth factor receptors (VEGFR), in patient-derived xenograft (PDX) models of GIST, carrying different KIT mutations. NMRI nu/nu mice (n = 52) were bilaterally transplanted with human GIST: UZLX-GIST4 (KIT exon 11 mutation, imatinib sensitive), UZLX-GIST2 (KIT exon 9, imatinib dose-dependent resistance), or UZLX-GIST9 (KIT exon 11 and 17 mutations, imatinib resistant). Mice were grouped as control (untreated), imatinib (50 mg/kg/bid), and cabozantinib (30 mg/kg/qd) and treated orally for 15 days. Cabozantinib resulted in significant tumor regression in UZLX-GIST4 and -GIST2 and delayed tumor growth in -GIST9. In all three models, cabozantinib inhibited the proliferative activity, which was completely absent in UZLX-GIST4 and significantly reduced in -GIST2 and -GIST9. Increased apoptotic activity was observed only in UZLX-GIST4. Cabozantinib inhibited the KIT signaling pathway in UZLX-GIST4 and -GIST2. In addition, compared with both control and imatinib, cabozantinib significantly reduced microvessel d. in all models. In conclusion, cabozantinib showed antitumor activity in GIST PDX models through inhibition of tumor growth, proliferation, and angiogenesis, in both imatinib-sensitive and imatinib-resistant models. AB Hepatocellular carcinoma is among the leading causes of cancer-related deaths worldwide, and the development of new treatment regimens is urgently needed to improve therapeutic approach. In our study, we found that the combination of a Met inhibitor, cabozantinib, and a novel FAK inhibitor, CT-707, exerted synergistic antitumor effects against hepatocellular carcinoma in vitro and in vivo. Interestingly, further studies showed that therapeutic concns. of cabozantinib increased the phosphorylation of FAK, which might attenuate the antitumor activity of cabozantinib. The simultaneous exposure to CT-707 effectively inhibited the activation of FAK that was induced by cabozantinib, which contributes to the synergistic effect of the combination. Furthermore, cabozantinib increased the mRNA and protein levels of integrin α5, which is a canonical upstream of FAK, and the introduction of cilengitide to block integrin function could abrogate FAK activation by cabozantinib, indicating that cabozantinib upregulated the phosphorylation of FAK in an integrin-dependent manner. Similar synergy was also observed on PHA-665752, another selective MET inhibitor, indicating that this observation might be a common characteristic of MET-targeting strategies. Our findings not only favor the development of the novel FAK inhibitor CT-707 as a therapeutic agent against hepatocellular carcinoma but also provide a new strategy of combining MET and FAK inhibitors to potentiate the anticancer activities of these two types of agents for treating hepatocellular carcinoma patients. AB Cancer cell line panels are important tools to characterize the in vitro activity of new investigational drugs. Here, we present the inhibition profiles of 122 anticancer agents in proliferation assays with 44 or 66 genetically characterized cancer cell lines from diverse tumor tissues (Oncolines). The library includes 29 cytotoxics, 68 kinase inhibitors, and 11 epigenetic modulators. For 38 compds. this is the first comparative profiling in a cell line panel. By strictly maintaining optimized assay protocols, biol. variation was kept to a min. Replicate profiles of 16 agents over three years show a high average Pearson correlation of 0.8 using IC50 values and 0.9 using GI50 values. Good correlations were observed with other panels. Curve fitting appears a large source of variation. Hierarchical clustering revealed 44 basic clusters, of which 26 contain compds. with common mechanisms of action, of which 9 were not reported before, including TTK, BET and two clusters of EZH2 inhibitors. To investigate unexpected clusterings, sets of BTK, Aurora and PI3K inhibitors were profiled in biochem. enzyme activity assays and surface plasmon resonance binding assays. The BTK inhibitor ibrutinib clusters with EGFR inhibitors, because it cross-reacts with EGFR. Aurora kinase inhibitors sep. into two clusters, related to Aurora A or pan-Aurora selectivity. Similarly, 12 inhibitors in the PI3K/AKT/mTOR pathway separated into different clusters, reflecting biochem. selectivity (pan-PI3K, PI3Kβγδ-isoform selective or mTOR-selective). Of these, only allosteric mTOR inhibitors preferentially targeted PTEN-mutated cell lines. This shows that cell line profiling is an excellent tool for the unbiased classification of antiproliferative compds. Mol Cancer Ther; 15(12); 3097-109. ©2016 AACR.

AB The discovery of a novel potent type II ABL/c-KIT dual kinase inhibitor compound 34 (CHMFL-ABL/KIT-155), which utilized a hydrogen bond formed by NH on the kinase backbone and carbonyl oxygen of 34 as a unique hinge binding, is described. 34 potently inhibited purified ABL (IC50: 46 nM) and c-KIT kinase (IC50: 75 nM) in the biochem. assays and displayed high selectivity (S Score (1) = 0.03) at the concentration of 1 μM among 468 kinases/mutants in KINOMEscan assay. It exhibited strong antiproliferative activities against BCR-ABL/c-KIT driven CML/GISTs cancer cell lines through blockage of the BCR-ABL/c-KIT mediated signaling pathways, arresting cell cycle progression and induction of apoptosis. 34 possessed a good oral PK property and effectively suppressed the tumor progression in the K562 (CML) and GIST-T1 (GISTs) cells mediated xenograft mouse model. The distinct hinge-binding mode of 34 provided a novel pharmacophore for expanding the chemical structure diversity for the type II kinase inhibitors discovery.

AB Purpose Cabozantinib is an inhibitor of kinases, including MET and vascular endothelial growth factor receptors,and has shown activity in men with previously treated metastatic castration-resistant prostate cancer(mCRPC). This blinded phase III trial compared cabozantinib with prednisone in patients with mCRPC. Patients and Methods Men with progressive mCRPC after docetaxel and abiraterone and/or enzalutamide were randomlyassigned at a two-to-one ratio to cabozantinib 60 mg once per day or prednisone 5 mg twice per day.The primary end point was overall survival (OS). Bone scan response (BSR) at week 12 as assessedby independent review committee was the secondary end point; radiog. progression-freesurvival (rPFS) and effects on circulating tumor cells (CTCs), bone biomarkers, serum prostatespecificantigen (PSA), and symptomatic skeletal events (SSEs) were exploratory assessments. Results A total of 1,028 patients were randomly assigned to cabozantinib (n = 682) or prednisone (n = 346).Median OS was 11.0 mo with cabozantinib and 9.8 mo with prednisone (hazard ratio, 0.90;95% CI, 0.76 to 1.06; stratified log-rank P =.213). BSR at week 12 favored cabozantinib (42% v 3%;stratified Cochran-Mantel-Haenszel P <.001). rPFS was improved in the cabozantinib group(median, 5.6 v 2.8 mo; hazard ratio, 0.48; 95% CI, 0.40 to 0.57; stratified log-rank P<.001).Cabozantinib was associated with improvements in CTC conversion, bone biomarkers, andpost-random assignment incidence of SSEs but not PSA outcomes. Grade 3 to 4 adverse eventsand discontinuations because of adverse events were higher with cabozantinib than with prednisone(71% v 56% and 33% v 12%, resp.). Conclusion Cabozantinib did not significantly improve OS compared with prednisone in heavily treated patientswith mCRPC and progressive disease after docetaxel and abiraterone and/or enzalutamide.Cabozantinib had some activity in improving BSR, rPFS, SSEs, CTC conversions, and bone biomarkersbut not PSA outcomes.

AB The present invention relates to a method for detg. or predicting the response of a patient diagnosed with melanoma to targeted pharmacotherapy. The present invention also aims to provide methods and devices for predicting the response of patients diagnosed with melanoma to specific medicaments. More specifically, the present invention provides methods which measure kinase activity by studying phosphorylation levels and profiles and inhibitions thereof by drugs in samples of said patients.

AB The present invention relates to a method for the prognosis of bone metastasis in cancer which comprises using a probe to determine if a gene of interest is amplified in a primary tumor sample. Likewise, the invention also relates to a method for determining the tendency to develop bone metastasis with respect to metastasis in other organs, which comprise using a probe to determine the expression level of a gene of interest, or the amplification or translocation of a gene of interest. The invention also relates to a method for predicting early bone metastasis in a subject suffering cancer. The invention also relates to a c-MAF inhibitor as therapeutic agent for use in the treatment of cancer metastasis. The invention relates to kits for predicting bone metastasis and predicting the clin. outcome of a subject suffering from bone metastasis. Finally, the invention relates to a method for typing of a subject suffering cancer and for classifying a subject from cancer into a cohort.

AB Erlotinib is approved for the treatment of all patients with advanced non-small-cell lung cancer (NSCLC), but is most active in the treatment of EGFR mutant NSCLC. Cabozantinib, a small mol. tyrosine kinase inhibitor, targets MET, VEGFR, RET, ROS1, and AXL, which are implicated in lung cancer tumorigenesis. We compared the efficacy of cabozantinib alone or in combination with erlotinib vs. erlotinib alone in patients with EGFR wild-type NSCLC. This three group, randomised, controlled, open-label, multicentre, phase 2 trial was done in 37 academic and community oncol. practices in the USA. Patients were eligible if they had received one or two previous treatments for advanced non-squamous, EGFR wild-type, NSCLC. Patients were stratified by performance status and line of therapy, and randomly assigned using permuted blocks within strata to receive open-label oral daily dosing of erlotinib (150 mg), cabozantinib (60 mg), or erlotinib (150 mg) and cabozantinib (40 mg). Imaging was done every 8 wk. At the time of radiog. progression, there was optional crossover for patients in either single-drug group to receive combination treatment. The primary endpoint was to compare progression-free survival in patients given erlotinib alone vs. cabozantinib alone, and in patients given erlotinib alone vs. the combination of erlotinib plus cabozantinib. We assessed the primary endpoint in the per-protocol population, which was defined as all patients who were eligible, randomly assigned, and received at least one dose of treatment. The safety anal. population included all patients who received study treatment irresp. of eligibility. This trial is registered with ClinicalTrials.gov, number NCT01708954. Between Feb 7, 2013, and July 1, 2014, we enrolled and randomly assigned 42 patients to erlotinib treatment, 40 patients to cabozantinib treatment, and 43 patients to erlotinib plus cabozantinib treatment, of whom 111 (89%) in total were included in the primary anal. (erlotinib [n=38], cabozantinib [n=38], erlotinib plus cabozantinib [n=35]). Compared with erlotinib alone (median 1·8 mo [95% CI 1·7-2·2]), progression-free survival was significantly improved in the cabozantinib group (4·3 mo [3·6-7·4]; hazard ratio [HR] 0·39, 80% CI 0·27-0·55; one-sided p=0·0003) and in the erlotinib plus cabozantinib group (4·7 mo [2·4-7·4]; HR 0·37, 0·25-0·53; one-sided p=0·0003). Among participants included in the safety anal. of the erlotinib (n=40), cabozantinib (n=40), and erlotinib plus cabozantinib (n=39) groups, the most common grade 3 or 4 adverse events were diarrhoea (three [8%] cases in the erlotinib group vs three [8%] in the cabozantinib group vs 11 [28%] in the erlotinib plus cabozantinib group), hypertension (none vs ten [25%] vs one [3%]), fatigue (five [13%] vs six [15%] vs six [15%]), oral mucositis (none vs four [10%] vs one [3%]), and thromboembolic event (none vs three [8%] vs two [5%]). One death due to respiratory failure occurred in the cabozantinib group, deemed possibly related to either drug, and one death due to pneumonitis occurred in the erlotinib plus cabozantinib group, deemed related to either drug or the combination. Despite its small sample size, this trial showed that, in patients with EGFR wild-type NSCLC, cabozantinib alone or combined with erlotinib has clin. meaningful, superior efficacy to that of erlotinib alone, with addnl. toxicity that was generally manageable. Cabozantinib-based regimens are promising for further investigation in this patient population. ECOG-ACRIN Cancer Research Group, National Cancer Institute of the National Institutes of Health.

AB RET rearrangements are found in 1-2% of non-small-cell lung cancers. Cabozantinib is a multikinase inhibitor with activity against RET that produced a 10% overall response in unselected patients with lung cancers. To assess the activity of cabozantinib in patients with RET-rearranged lung cancers, we did a prospective phase 2 trial in this mol. subgroup. We enrolled patients in this open-label, Simon two-stage, single-center, phase 2, single-arm trial in the USA if they met the following criteria: metastatic or unresectable lung cancer harbouring a RET rearrangement, Karnofsky performance status higher than 70, and measurable disease. Patients were given 60 mg of cabozantinib orally per day. The primary objective was to determine the overall response (Response Criteria Evaluation in Solid Tumors version 1.1) in assessable patients; those who received at least one dose of cabozantinib, and had been given CT imaging at baseline and at least one protocol-specified follow-up timepoint. We did safety analyses in the modified intention-to-treat population who received at least one dose of cabozantinib. The accrual of patients with RET-rearranged lung cancer to this protocol has been completed but the trial is still ongoing because several patients remain on active treatment. This study was registered with ClinicalTrials.gov, number NCT01639508. Between July 13, 2012, and Apr. 30, 2016, 26 patients with RET-rearranged lung adenocarcinomas were enrolled and given cabozantinib; 25 patients were assessable for a response. KIF5B-RET was the predominant fusion type identified in 16 (62%) patients. The study met its primary endpoint, with confirmed partial responses seen in seven of 25 response-assessable patients (overall response 28%, 95% CI 12-49). Of the 26 patients given cabozantinib, the most common grade 3 treatment-related adverse events were lipase elevation in four (15%) patients, increased alanine aminotransferase in two (8%) patients, increased aspartate aminotransferase in two (8%) patients, decreased platelet count in two (8%) patients, and hypophosphatemia in two (8%) patients. No drug-related deaths were recorded but 16 (62%) patients died during the course of follow-up. 19 (73%) patients required dose redns. due to drug-related adverse events. The reported activity of cabozantinib in patients with RET-rearranged lung cancers defines RET rearrangements as actionable drivers in patients with lung cancers. An improved understanding of tumor biol. and novel therapeutic approaches will be needed to improve outcomes with RET-directed targeted treatment. Exelixis, National Institutes of Health and National Cancer Institute Cancer Center Support Grant P30 CA008748.

AB BACKGROUND : Erlotinib is a std. first-line therapy for patients who have metastatic nonsmall cell lung cancer (NSCLC) with epidermal growth factor receptor (EGFR) mutations. The recommended dose of 150 mg daily is the maximum tolerated dose (MTD). Few clin. data are available regarding its efficacy at doses less than the MTD. METHODS : An institutional database was queried for patients with advanced NSCLC who were pos. for EGFR L858R mutations or exon 19 deletions and had received treatment with erlotinib. The treatment course, including the erlotinib dose at initiation of treatment, at 4 mo into therapy, and at disease progression, was retrospectively studied. Progression-free survival (PFS) was compared between patients who received the MTD (150 mg) and those who received reduced-dose erlotinib (≤100 mg). RESULTS : In total, 198 eligible patients were identified. Thirty-one patients (16%) were initiated on reduced-dose erlotinib; they were older (P = .001) and had lower performance status (P = .01) compared with those who were initiated on erlotinib at the MTD. The response rate to reduced-dose erlotinib was 77%. The median PFS of patients initiated on reduced-dose erlotinib was 9.6 mo vs. 11.4 mo for those initiated at the MTD, a difference that was not statistically significant (hazard ratio, 0.81; 95% confidence interval, 0.54-1.21; P = .30). There was a nonsignificant trend toward higher rates of progression within the central nervous system with reduced-dose erlotinib. CONCLUSIONS : At doses below the MTD, erlotinib treatment results in a high response rate and a prolonged median PFS. Review of the literature indicates that 15 of 30 small-mol. inhibitors that are approved or in late-stage development for cancer therapy have recommended doses below the MTD. When the toxicities of MTD dosing are a concern, an investigation of small-mol. inhibitors at doses below the MTD is warranted. Cancer 2016;122:3456-63. © 2016 American Cancer Society.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT
AB Disclosed are compns. and methods related to the use of kinase inhibitors in treating macular degeneration and/or retinal vein occlusion. In some aspects, the invention relates to sustained-release drug delivery devices that can deliver effective intraocular concns. of the kinase inhibitor, while delivering low systemic concns. of the kinase inhibitor, e.g., to reduce the risk of toxicity or other undesirable side effects.

AB Renal-cell carcinoma (RCC) affects over 330,000 new patients every year, of whom 1/3 present with metastatic RCC (mRCC) at diagnosis. Most mRCC patients treated with a firstline agent relapse within 1 yr and need second-line therapy. The present study aims to compare overall survival (OS) between nivolumab and cabozantinib from two recent pivotal studies comparing, resp., each one of the two emerging treatments against everolimus in patients who relapse following first-line treatment. Comparison is traditionally carried out using the Bucher method, which assumes proportional hazard. Since OS curves intersected in one of the pivotal studies, models not assuming proportional hazards were also considered to refine the comparison. Four Bayesian parametric survival network meta-anal. models were implemented on overall survival (OS) data digitized from the Kaplan- Meier curves reported in the studies. Three models allowing hazard ratios (HR) to vary over time were assessed against a fixed-HR model. The Bucher method favored cabozantinib, with a fixed HR for OS vs. nivolumab of 1.09 (95% confidence interval: [0.77, 1.54]). However, all models with time-varying HR showed better fits than the fixed-HR model. The loglogistic model fitted the data best, exhibiting a HR for OS initially favoring cabozantinib, the trend inverting to favor nivolumab after month 5 (95% credible interval <1 from 10 mo). The initial probability of cabozantinib conferring superior OS was 54%, falling to 41.5% by month 24. Numerical differences in study-adjusted OS ests. between the two treatments remained small. This study evidences that HR for OS of nivolumab vs. cabozantinib varies over time, favoring cabozantinib in the first months of treatment but nivolumab afterwards, a possible indication that patients with poor prognosis benefit more from cabozantinib in terms of survival, nivolumab benefiting patients with better prognosis. More evidence, including real-world observational data, is needed to compare effectiveness between cabozantinib and nivolumab.

AB A review. Thyroid cancer is the most common endocrine malignancy. Differentiated thyroid cancer (DTC) with the two subtypes, papillary thyroid cancer (PTC) and follicular thyroid cancer (FTC), is the most frequent subtype of thyroid cancer; more rare subtypes are medullary thyroid cancer (MTC) and anaplastic thyroid cancer (ATC). The incidence of DTC has increased rapidly in recent years due to the more frequent use of imaging methods such as ultrasound of the neck and fine-needle aspiration (FNA) of thyroid nodules. After total thyroidectomy and radioiodine treatment, DTC remains an indolent and curable disease in most patients, whereas the cure rate in MTC is lower and depends on early diagnosis. Most ATCs are incurable. In recent years, there has been great progress in identifying genetic changes in thyroid cancer, and genetic testing of FNA samples or blood samples provides useful information for clin. decision making. Tumor staging, either postoperatively or by imaging, and measuring the tumor markers thyroglobulin for DTC and calcitonin for MTC, allow for dynamic risk-adapted stratification for follow-up procedures. In advanced metastatic thyroid cancer, mol. targeted therapy using tyrosine kinase receptor inhibitors, including sorafenib, lenvantinib, vandetanib, and cabozantinib, helps control tumor progression and prolongs progression-free survival. Using a dynamic risk-stratified approach to manage thyroid cancer, the outcomes for most thyroid cancer patients are excellent compared with those for other cancers. The major challenge in the future is to identify high-risk patients and to treat and monitor them appropriately. Clin Cancer Res; 22(20); 5012-21.

AB The application relates to novel combinations of at least two components, component A, an interleukin-1 receptor-associated kinase 4 (IRAK4) inhibiting compound of formula I, and component B, a Bruton tyrosine kinase (BTK) inhibiting compound, or a pharmaceutically acceptable salt thereof; and, optionally, one or more components C which are pharmaceutical products; in which one or two of the above-defined compds. A and B are optionally present in pharmaceutical formulations ready for simultaneous, sep. or sequential administration, for treatment and/or prophylaxis of diseases such as endometriosis, lymphoma, macular degeneration, COPD, neoplastic disorders and psoriasis. A pharmaceutical combination comprising a BTK inhibiting compound and I [wherein R1 = (un)substituted C1-6 alkyl, -CH2CH2S(O2)CH3, -CH2CH2CH2CF3, etc.; R2 = R3 = H or C1-6 alkyl; R4 = halo, cyano, (un)substituted C1-6 alkyl, etc.; R5 = H, halo, or (un)substituted C1-6 alkyl] or a diastereomer, enantiomer, metabolite, salt, or solvate thereof, and optionally a third pharmaceutical product is claimed and exemplified. II was prepared via the reduction of the corresponding Me carboxylate intermediate with lithium aluminum hydride. I were evaluate for IRAK-4-inhibitory activity using the TR-FRET anal. (data provided).

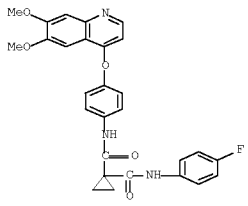
AB RET fusions have been found in lung adenocarcinoma, of which KIF5B-RET is the most prevalent. We established inducible KIF5B-RET transgenic mice and KIF5B-RET-dependent cell lines for preclin. modeling of KIF5B-RET-associated lung adenocarcinoma. Doxycycline-induced CCSP-rtTA/tetO-KIF5B-RET transgenic mice developed invasive lung adenocarcinoma with desmoplastic reaction. Tumors regressed upon suppression of KIF5B-RET expression. By culturing KIF5B-RET-dependent BaF3 (B/KR) cells with increasing concns. of cabozantinib or vandetanib, we identified cabozantinib-resistant RETV804L mutation and vandetanib-resistant-RETG810A mutation. Among cabozantinib, lenvatinib, ponatinib, and vandetanib, ponatinib was identified as the most potent inhibitor against KIF5B-RET and its drug-resistant mutants. Interestingly, the vandetanib-resistant KIF5B-RETG810A mutant displayed gain-of-sensitivity (GOS) to ponatinib and lenvatinib. Treatment of doxycycline-induced CCSP-rtTA/tetO-KIF5B-RET bitransgenic mice with ponatinib effectively induced tumor regression. These results indicate that KIF5B-RET-associated lung tumors are addicted to the fusion oncogene and ponatinib is the most effective inhibitor for targeting KIF5B-RET in lung adenocarcinoma. Moreover, this study finds a novel vandetanib-resistant



RETG810A mutation and identifies lenvatinib and ponatinib as the secondary drugs to overcome this vandetanib resistance mechanism. Mol Cancer Ther; 15(10); 2521-9.

AB The invention is about a cancer obliterator that contains anticancer drug enriched by H5WYG peptides containing several histidine with a property escaping from endosomes; and solves the problem of the vasoactive intestinal peptides and drug-loaded nanoparticles taken into the cell (which play a role in endocytose process and specifically bind to the receptors on cancer cell membranes) not being released into the cytosol by being held by endosomes.

AB Background: Antiangiogenic tyrosine kinase inhibitors (TKIs) are the mainstay of advanced thyroid cancer (TC) treatment. Concern is rising about TKI-related toxicity. Objective: To determine the incidence and to investigate the risk factors of hemoptysis in TC patients during TKI treatment. Methods: We analyzed consecutive TC patients treated with TKI in our center between 2005 and 2013 and performed an independent review of computed tomog. scan images for airway invasion assessment. Occurrence of grade 1-2 or grade 3-5 hemoptysis according to Common Terminol. Criteria for Adverse Events version 4.03 and risk factors for hemoptysis were investigated. Results: A total of 140 patients (89 males; median age, 52 y) with medullary (56%), differentiated (33%), and poorly differentiated (11%) TC were enrolled. Thyroidectomy±neck dissection was performed in 123 patients and neck/mediastinum external-beam radiotherapy in 41 (32% with therapeutic purpose and 68% with adjuvant purpose). Patients received from 1 to 4 lines of TKI (median 1). Median follow-up was 24 mo. Airway invasion was found in 65 (46%) cases. Hemoptysis occurred in 9 patients: grade 1-2 in 7 cases (5%) and grade 3-5 in 2 (1.4%) cases (fatal in 1). Hemoptysis was associated with presence of airway invasion (P = .04), poorly differentiated pathol. (P = .03), history of therapeutic external-beam radiotherapy (P = .003), and thyroidectomy without neck dissection (P = .02). Conclusion: Airway invasion, poorly differentiated pathol., therapeutic external-beam radiotherapy, and thyroidectomy without neck dissection are associated with and increased risk of hemoptysis in TC patients during antiangiogenic TKI treatment. Further research is needed to confirm this data and to sort out interactions between these risk factors. A careful assessment of airway invasion is mandatory before TKI introduction.

AB Purpose: Cabozantinib (XL184), a multi-targeted oral tyrosine kinase inhibitor with activity against MET, VEGFR2, AXL, and other tyrosine kinases, was assessed in a cohort of metastatic breast cancer (MBC) patients in a phase II randomized discontinuation trial (RDT). Methods: Patients received 100 mg cabozantinib daily during a 12-wk lead-in stage. Those with stable disease per modified Response Evaluation Criteria in Solid Tumors version 1.0 at 12 wk were randomized to either continue cabozantinib or receive placebo. Primary endpoints were objective response rate (ORR) during the 12-wk lead-in stage and progression-free survival (PFS) after randomization. Patients were also followed for overall survival (OS). Results: Forty-five patients with MBC and a median of three prior lines of chemotherapy for metastatic disease were enrolled. The ORR during the lead-in stage was 13.6 % (95 % confidence interval [CI] 6-25.7 %), and the disease control rate at week 12 was 46.7 % (95 % CI 31.7-61.6 %). Per the initial RDT study design, patients with stable disease at week 12 were randomized to cabozantinib or placebo. Following a Study Oversight Committee recommendation, randomization was suspended. Patients in the lead-in stage continued on open-label cabozantinib. Patients in the randomization stage were subsequently unblinded. The overall median PFS for all MBC patients was 4.3 mo. Median OS was 11.4 mo (95 % CI 10.5-16.5 mo). The most common grade 3/4 adverse events in the lead-in stage were palmar-plantar erythrodysesthesia (13 %) and fatigue (11 %). One death from respiratory failure was reported as drug-related during the lead-in stage. Conclusions: In heavily pretreated MBC patients, cabozantinib monotherapy demonstrated clin. activity including objective response and disease control.

AB Traditional approaches to evaluating antitumor agents using human tumor xenograft models have generally used cohorts of 8 to 10 mice against a limited panel of tumor models. An alternative approach is to use fewer animals per tumor line, allowing a greater number of models that capture greater mol./genetic heterogeneity of the cancer type. We retrospectively analyzed 67 agents evaluated by the Pediatric Preclin. Testing Program to determine whether a single mouse, chosen randomly from each group of a study, predicted the median response for groups of mice using 83 xenograft models. The individual tumor response from a randomly chosen mouse was compared with the group median response using established response criteria. A total of 2,134 comparisons were made. The single tumor response accurately predicted the group median response in 1,604 comparisons (75.16%). The mean tumor response correct prediction rate for 1,000 single mouse random samples was 78.09%. Models had a range for correct prediction (60%-87.5%). Allowing for misprediction of ± one response category, the overall mean correct single mouse prediction rate was 95.28%, and predicted overall objective response rates for group data in 66 of 67 drug studies. For molecularly targeted agents, occasional exceptional responder models were identified and the activity of that agent confirmed in addnl. models with the same genotype. Assuming that large treatment effects are targeted, this alternate exptl. design has similar predictive value as traditional approaches, allowing for far greater nos. of models to be used that more fully encompass the heterogeneity of disease types.
