(54) **Title**: RECOVERY FROM BEAM FAILURE

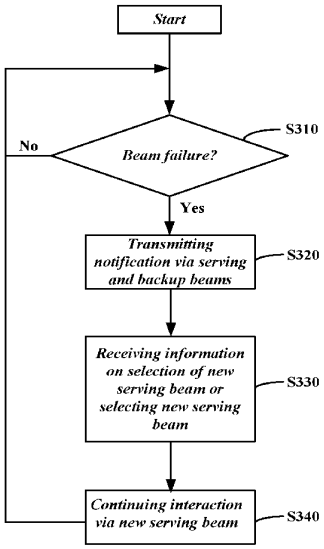

Fig. 3

(57) **Abstract**: The present invention generally relates to wireless communication, more particularly, relates to recovery from beam failure in a wireless access network where beamforming technique is used in communication between network elements. According to one aspect of the present invention, there is provided a method for recovery from beam failure in a wireless access network accessed by a user equipment (UE). The method comprises: at the wireless access network, determining whether the beam failure occurs on the basis of presence of a response from the UE during communicating between the wireless access network and the UE via a first beam; and if it is determined that the beam failure occurs, communicating with the UE via an available beam selected from the first beam and one or more second beams.

WO 2017/024516 A1

RECOVERY FROM BEAM FAILURE

TECHNICAL FIELD

[001] The present invention generally relates to wireless communication, more particularly, relates to recovery from beam failure in a wireless access network where beamforming technique is used in communication between network elements.

BACKGROUND

[002] The ultimate goal of mobile broadband should be the ubiquitous and sustainable provision of non-limiting data rates to everyone and everything at every time. Along this path, Ultra-Dense Network (UDN) is an important next step following the successful introduction of LTE for wide-area and local-area access.

[003] Ultra-dense network (UDN) is envisioned to provide ubiquitous mobile broadband with access-node densities considerably higher than the current densest cellular networks. UDN can be deployed in areas with high traffic consumption. Through overprovision and related low average loads in an access network, UDN creates ubiquitous access opportunities which – even under realistic assumptions on user density and traffic – provide users with the desired data rates.

[004] Overprovisioning is achieved by an extremely dense grid of access nodes; inter-access-node distances in the order of tens of meters and below are envisioned. For in-indoor deployments, one or even multiple access nodes are conceivable in each room. Additionally, in order to increase network capacity, densification – via reduced transmit powers – also offers access to vast spectrum holdings in the millimeter-wave bands and thus higher data rates.

[005] Beamforming for concentrating transmitted energy on an intended receiver plays a critical role for UDN. However, using more narrow transmission beams also makes a wireless system more susceptible to sudden coverage loss due to beam failure. In light of the above, an

efficient and reliable recovery from the beam failure constitutes an urgent issue to be addressed.

SUMMARY OF THE INVENTION

[006] According to one aspect of the present invention, there is provided a method for recovery from beam failure in a wireless access network accessed by a user equipment (UE). The method comprises: at the wireless access network, determining whether the beam failure occurs on the basis of presence of a response from the UE during communication between the wireless access network and the UE via a first beam; and if it is determined that the beam failure occurs, communicating with the UE via an available beam selected from the first beam and one or more second beams.

[007] According to the above aspect of the present invention, the beam failure can be effectively detected by a feedback-based determination without always-on reference signal. This is especially advantageous for a UE specific beam-based system such as UDN.

[008] In an embodiment according to the present invention, the response is one selected from a group consisting of: an acknowledgment(ACK) message or a negative Acknowledgment(NACK) message responding to a data message transmitted from an AN of the wireless access network on a downlink associated with the first beam, and a data message responding to a grant message transmitted from an AN of the wireless access network on a downlink associated with the first beam.

[009] In an embodiment according to the present invention, the selection of the available beam is on the basis of radio link quality for downlinks associated with the first beam and the one or more second beams.

[010] In an embodiment according to the present invention, the step of communicating with the UE via the available beam comprises: upon determining that the beam failure occurs, transmitting to the UE a message from one or more ANs of the wireless access network via the first beam and the one or more second beams; receiving information on the selection of the available beam from the UE; and using the selected available beam

during communication with the UE.

[011] In an embodiment according to the present invention, the step of communicating with the UE via the available beam comprises: upon determining that the beam failure occurs, transmitting to the UE a message from a first AN and a second AN of the wireless access network, wherein the message from the first AN is transmitted via the first beam and the message from the second AN is transmitted via the one or more second beams; receiving information on the selection of the available beam from the UE; and using the selected available beam during communication with the UE.

[012] In an embodiment according to the present invention, the step of communicating with the UE via the available beam comprises: upon determining that the beam failure occurs, transmitting a message from a first AN and second AN of the wireless access network, wherein the message from the first AN is transmitted via the first beam and at least one of the second beams and the message from the second AN is transmitted via the other of the second beams; receiving information on the selection of the available beam from the UE; and using the selected available beam during communication with the UE.

[013] According to another aspect of the present invention, there is provided a method for recovery from beam failure for a user equipment (UE) accessing a wireless access network. The method comprises: at the UE, determining whether the beam failure occurs on the basis of presence of a response from the wireless access network during communication between the wireless access network and the UE via a first beam; and if it is determined that the beam failure occurs, communicating with the wireless access network via an available beam selected from the first beam and one or more second beams.

[014] In an embodiment according to the present invention, the response is one selected from a group consisting of: a grant message responding to a service request transmitted from the UE on an uplink associated with the first beam and an random access response message responding to a random access request transmitted from the UE on an uplink associated with the first beam.

[015] In an embodiment according to the present invention, the selection of the available beam is on the basis of radio link quality for uplinks associated with the first beam and the one or more second beams.

[016] In an embodiment according to the present invention, the step of communicating with the wireless access network via the available beam comprises: upon determining that the beam failure occurs, transmitting to one or more ANs of the wireless access network a message from the UE via the first beam and the one or more second beams; receiving information on the selection of the available beam from the one or more ANs of the wireless access network; and using the selected available beam during communication with the wireless access network.

[017] According to another aspect of the present invention, there is provided an access node (AN) capable of communicating with a user equipment (UE). The AN is configured to: determine whether beam failure occurs on the basis of presence of a response from the UE during communication between the AN and the UE via a first beam; and if it is determined that the beam failure occurs, communicate with the UE via an available beam selected from the first beam and one or more second beams, or transfer to another AN communication with the UE, the communication being made via the available beam.

[018] According to another aspect of the present invention, there is provided a user equipment (UE) capable of communicating with a wireless access network. The UE is configured to: determine whether the beam failure occurs on the basis of presence of a response from the wireless access network during commnication between the wireless access network and the UE via a first beam; and if it is determined that the beam failure occurs, communicate with the wireless access network via an available beam selected from the first beam and one or more second beams.

[019] According to another aspect of the present invention, there is provided a user equipment (UE) capable of interacting with a wireless access network. The UE comprises: a determining unit configured to determine whether the beam failure occurs on the basis of presence of a response from the wireless access network during communication between the wireless access network and the UE via a first beam; and a transceiver configured to communicate with the wireless access network via an available beam selected from the first beam and one or more second beams if determining that the beam failure occurs.

[020] In an embodiment according to the present invention, for communicating with the wireless access network via the available beam, the transceiver is configured to: transmit to one or more ANs of the wireless access network a message from the UE via the first beam and the one or more second beams if determining that the beam failure occurs; receive information on the selection of the available beam from the one or more ANs of the wireless access network; and use the selected available beam to communicate with the wireless access network.

[021] According to another aspect of the present invention, there is provided an access node (AN) capable of communicating with a user equipment (UE). The AN comprises: a determining unit configured to determine whether beam failure occurs on the basis of presence of a response from the UE during communication between the AN and the UE via a first beam; and a transceiver configured to, if the determining unit determines that the beam failure occurs, communicate with the UE via an available beam selected from the first beam and one or more second beams, or transfer to another AN communication with the UE, the communication being made via the available beam.

BRIEF DESCRIPTION OF THE DRAWINGS

[022] The invention is herein described, by way of example only, with reference to the accompanying drawings. With specific reference now to the drawings in detail, it is stressed that the particulars shown are by way of example and for purposes of illustrative discussion of the preferred embodiments of the present invention only, and are presented in order to provide what is believed to be the most useful and readily understood description of the principles and conceptual aspects of the invention. In this regard, no attempt is made to show structural details of the invention in more detail than is necessary for a fundamental understanding of the invention, the description taken with the drawings making apparent to those skilled in the art how the several forms of the invention may be embodied in practice.

[023] In the drawings:

[024] Fig. 1 is a schematic diagram depicting an Ultra-dense network (UDN) architecture.

[027] Fig. 4 is a process flow diagram of a method for recovery from beam failure in a wireless access network according to another exemplary embodiment of the present invention.

[028] Fig. 5 is a block diagram illustrating a user equipment (UE) having recovery capability from beam failure according to another exemplary embodiment of the present invention.

[029] Fig. 6 is a block diagram illustrating an access node (AN) having recovery capability from beam failure according to another exemplary embodiment of the present invention.

DETAILED DESCRIPTION

[030] The principles and operation of the present invention may be better understood with reference to the drawings and accompanying description.

[031] Before explaining at least one embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of construction and the arrangement of the components set forth in the following description or illustrated in the drawings. The invention is capable of being implemented by other embodiments or of being practiced or carried out in various ways. Also, it is to be understood that the phraseology and terminology employed herein is for the purpose of description and should not be regarded as limiting.

[032] All references to "a/an/the element, apparatus, component, means, step, etc." are to be interpreted as referring to at least one instance of the element, apparatus, component, means, step, etc., unless explicitly stated otherwise. The steps of any method disclosed herein do not have to be performed in the exact order disclosed, unless explicitly stated. The

discussion above and below in respect of any of the aspects of the present disclosure is also in applicable parts relevant to any other aspect of the present disclosure.

[033] Generally, all terms used in the claims and the description are to be interpreted according to their ordinary meaning in the technical field, unless explicitly defined otherwise herein. For example, the term "user equipment (UE)" may refer to any suitable terminal capable of wireless communication, such as a mobile phone or a portable computer. Likewise, the term "access node (AN)" may refer to any suitable intermediary devices providing wireless communication, such as a relay node, a router, an access point, a base station or a base site, which is capable of connecting a user equipment to another wireless access node or connecting a user equipment to a core network. The term "wireless link" or "radio link" may refer to a radio channel connecting wireless communication devices such as UEs and ANs with each other, and thus may refer to anyone of an uplink (UL), a downlink (DL), a forward link (FL) and a reverse link (RL).

[034] Beamforming is a signal processing technique used for directional signal transmission or reception. Beamforming can be used at both transmitting and receiving sides in order to achieve spatial selectivity. In a typical beamforming configuration, a transmitter with an antenna array amplifies a signal by different "weights" at the respective antennas, and thus the signal experiences constructive interference at particular directions or sectors and destructive interference at other directions or sectors. As a result, it can have a desired sensitivity pattern where a main lobe, serving as a beam for transmitting the signal to a receiver, is produced together with nulls and side lobes. By adjusting the main lobe width and the side lobe levels, the position of a null can be controlled. This is useful to ignore noise or jammers in one particular direction, while listening for events in other directions. A similar result can be obtained on reception. The details on beamforming are described in, e.g., IEEE 802.11ad, which is incorporated herein by reference in its entirety.

[035] Beam failure, as discussed throughout the present disclosure, refers

to such a situation where a beam currently being used for communication between a transceiver and a receiver becomes unavailable due to e.g., deteriorative radio link quality. A variety of events such as UE mobility, appearance of obstacle and orientation change for a UE may deteriorate the radio link quality.

[036] Fig. 1 is a schematic diagram depicting an Ultra-dense network (UDN) architecture. Referring to Fig. 1, a wireless network, e.g., UDN 110 herein, comprises ANs 111A-111G, which are configured to provide UEs 112A-112B with wireless access within their respective coverages by beamforming technique. For illustrative purpose, UEs 112A and 112B are communicatively coupled to ANs 111E and 111G, respectively. On the other hand, ANs 111A-111G are communicatively coupled with each other. In particular, as shown in Fig. 1, ANs 111A and 111C are connected together via a fixed backhaul link, and other ANs 111B, 111D-111G are connected to AN 111A or 111C via wireless links. As a result, ANs 111A-111G are either directly connected to fixed transport backhaul or wirelessly backhauled by other ANs. Moreover, these ANs are coupled to a transport aggregation node 113, over which they can communicate with an operator core network 120 or an external data network 130, e.g., internet.

[037] As stated above, it has a correlation between the beam failure and the deteriorated radio link quality. Therefore, one can determine whether the beam failure occurs on the basis of the radio link quality. However, this heavily relies on an always-on common reference signal on uplinks or downlinks and thus is not attainable for a typical UDN radio access configuration where beamforming is used widely to compensate the limited link budget in high-frequency spectrum and thus transmission is UE specific rather than UE common, i.e., reference signals are transmitted only when a UE is expected to receive them.

[038] According to one aspect of the present invention, a transmitter utilizes a feedback or response from a receiver to determine the occurrence of the beam failure. For example, in the UDN as shown Fig. 1, assuming that AN 111E and UE 112A communicate with each other via beam E1. In

a session, AN 111E transmits to UE 112A a data message via beam E1 and then waits for an acknowledgment(ACK) message or a negative Acknowledgment(NACK) message from UE 112A. If AN 111E receives neither the ACK message nor the NACK message via beam E1 within a predetermined time interval, it will determine the occurrence of the beam failure for beam E1. As another example, UE 112A transmits a service request to AN 111E via beam E1 and then waits for a grant message from AN 111E. If UE 112A fails to receive the grant message via beam E1 within a predetermined time interval, it will determine the occurrence of the beam failure for beam E1.

[039] It shall be noted that the feedback-based determination as described above is also applicable to other message types. For example, at AN side, the determination may be established on a data message responding to a grant message transmitted from AN 111E; and at UE side, one can make the determination on the basis of an random access response message responding to a random access request transmitted from UE 112A.

[040] With the feedback-based determination, the always-on reference signal is not necessary and thus the beam failure can be effectively detected in a UE specific beam-based system such as UDN.

[041] Typically, for communication between a UE and a wireless access network, two or more beams are available and one of them may be selected for serving the communication. For example, in the UDN as shown in Fig. 1, UE 112A and AN 111E can communicate with each other via beams E1, E2 and E4. These beams are collectively referred to be "candidate beam" hereinafter. Among the candidate beams, one currently serving the communication or interaction is referred to as "serving beam" or "first beam" hereinafter; and other candidate beam(s) are referred to as "backup beam" or "second beam" hereinafter. One way to recover from beam failure is to use one of the backup beams to take over the coverage in case of the sudden beam loss of the serving beam. Note that the candidate beams is unnecessarily limited to only a pair of a UE and a specific AN. As described below, for the candidate beams, some of them

may belong to the UE and one AN and the others may belong to the UE and another AN.

[042] According to another aspect of the present invention, a UE (UE side) and a wireless access network (network side) reach pre-agreement on which beams qualify as the backup beams for a serving beam. The pre-agreement may be periodically carried out between these participators, or carried out at the beginning of establishing connection between them. In one embodiment, the UE side or the network side as a transmitter side (Tx side), transmits to the network side or the UE side as a receiver side (Rx side) a reference signal in different directions or via different beams associated with uplinks or downlinks. The receiver side reports the beam(s) via which the reference signal is received, preferably along with radio link quality associated with them. Therefore, for each beam being as a serving beam, one or more backup beams are identified by the participators. For example, assuming the Tx side transmits the reference signal to the Rx side via beams X1, ... Xn, wherein n represents the number of the transmitting beams. If the Rx side receives the reference signal via beams X1, X3 and Xi, beams X3 and Xi are identified as the backup beams for beam X1, beams X1 and Xi are identified as the backup beams for beam X3, and beams X1 and X3 are identified as the backup beams for beam Xi.

[043] Preferably, in case of a plurality of backup beams for a serving beam, one is designated as a primary backup beam, which will be firstly selected as a new serving beam if the beam failure occurs. More preferably, the designation is made at the receiver side and is based on the radio link quality of the forward links associated with the backup beams. The radio link quality may be obtained from RSRP or SINR measurements at the receiver side. More preferably, the primary backup beam corresponds to one forward link having the best radio link quality.

[044] In case of the network or AN side being as the transmitter side, the designation is made at the UE side. Since the network side does not dominate the designation of the primary backup beam associated with the downlink, it takes a risk that no radio resources are available when the beam failure occurs or the utilization of radio resources is not optimum. In

one embodiment, the designation is always dominated at the network side so as to avoid the above defects. Particularly, the network side designates the primary backup beam based on, e.g., the radio link quality measurement made by the UE side and the current load distribution around the UE side. In one embodiment, the network side indicates the primary backup beam in each downlink transmission, e.g., as additional information in a Scheduling Assignment (SA) or as a MAC Control Element (MAC CE) in a MAC Protocol Data Unit (MAC PDU) carrying data. Alternatively, the network side may send a separate indicator on the primary backup beams by using a MAC CE, e.g., in a MAC PDU without higher layer data, or Radio Resources Control (RRC) signaling. In another embodiment, the primary backup beam is determined in a hybrid mode. As described above, the pre-agreement is periodically carried out between a UE side and a network side. At the beginning of the current pre-agreement cycle, the UE side, being as a receiver side, designates the backup beam corresponding to one forward link having the best radio link quality as the primary backup beam. However, the designation is changeable by the network side during the current pre-agreement cycle. For example, the network side may send a command for changing the primary backup beam in a downlink transmission, either in conjunction with data transmission or as a separate signaling message. Alternatively, the changed primary backup beam is valid until the next sending of the command. In other words, whatever measurements for radio link quality vary from one cycle to another cycle, the primary backup beam will be kept unchanged until the network side sends the command again.

[045] According to another aspect of the present invention, the identified backup beams are mapped into specific downlink and uplink resources. The specific uplink resources may be UL PHY resources, e.g., random access channel resources or scheduling request resources, and the specific downlink resources may be DL PHY resources, e.g., downlink control channel resources according to a Discontinuous Reception (DRX) pattern.

[046] As a result, a transmitter side (e.g., network or AN side in case of DL and UE side in case of UL) will notify the occurrence of beam failure

for a serving beam via both of the current serving beam and the backup beam(s), or only via the backup beam(s), and a receiver side (e.g., network side in case of UL and UE side in case of DL) will recognize the beam failure by monitoring the mapped radio link resources. For UL, the AN side is ready for uplink reception on the mapped resources associated with the backup beams. If the AN side receives a request for transmission resources through a Scheduling Request (SR), e.g., on Physical Downlink Control Channel (PDCCH) resources or through a random access procedure initiated on a Random Access Channel (RACH) mapped to the resources associated with one of the backup beams, it recognizes that this backup beam is in use for the reselection of the serving beam. On the other hand, for DL, the UE side is ready for downlink reception on the mapped resources associated with the backup beams. If the UE receives SA on PDCCH of the mapped downlink resources associated with one of the backup beam, it recognizes that this backup beam is in use for the reselection of the serving beam.

[047] According to another aspect of the present invention, if, at the transmitter side, e.g., at the network or UE side, it determines that the beam failure for the current serving beam occurs, a new serving beam needs to be reselected from the candidate beams, including the current serving beam and the backup beam(s), or only from the backup beam(s). Note that at this time, it has no knowledge on which link (forward link, reverse link, or both) causes the beam failure. Therefore, a transmitter will notify a receiver of the occurrence of the beam failure via the current serving beam and the backup beam(s), or only via the backup beam(s). The notification may be transmitted in a forward link transmission, either in conjunction with data transmission or as a separate signaling message. Note that the explicit notification is unnecessary and the receiver side can recognize the beam failure only from the event that the data transmission is performed via the backup beam(s). At the receiver side, e.g., the network side or UE side, it monitors the forward links associated with the candidate beams. Upon receiving the notification or the data transmission via the backup beams, the receiver side utilizes an available beam as a new

serving beam to communicate with the transmitter side. The available beam is selected from the serving beam and the backup beam(s), or only from the backup beam(s).

[048] In one embodiment, the selection is made on the basis of the radio link quality. For example, assuming the transmitter side transmits the notification or the data transmission via beams X1, X2, X3 and X4, and at the receiver side, the notification or the data transmission is received via beams X1, X2 and X3. If the forward link associated with beam X2 has the highest link quality, beam X2 is selected as the new serving beam.

[049] Alternatively, in case of the receiver side being the UE side, the new serving beam is selected by the network side. Particularly, upon receiving the notification or the data transmission via beams X1, X2 and X3, the receiver reports the radio link quality for the forward links. Then, at the transmitter, the new serving beam is selected on the basis of the radio link quality measurement made by the UE side and the current load distribution around the UE side.

[050] Preferably, upon receiving the notification or the data transmission via beams X1, X2 and X3, the receiver reports to the transmitter the receipt of the notification or the data transmission via beams X1, X2 and X3. Then, in response to the report from the receiver, the transmitter selects the new serving beam on the basis of the radio link quality for the reverse links associated with beams X1, X2 and X3, and optionally along with the current load distribution around the UE side. In another embodiment, the new serving beam may be the primary backup beam designated in the manner as described above.

[051] As a result, the communication continues between the transmitter side and the receiver side via the new serving beam. The new serving beam may be the serving beam previously in use or a backup beam.

[052] Fig. 2 is a process flow diagram of a method for reaching pre-agreement on backup beam(s) according to one exemplary embodiment of the present invention. For illustrative purpose, the following depiction is made in the context of the above architecture as

shown in Fig. 1. However, one skilled artisan in the art would recognize that the present invention is applicable to other architectures. Moreover, one skilled artisan will recognize that all of the aspects of the present invention as described above are applicable to the present exemplary embodiment.

[053] With reference to Fig. 2, at step S210, it determines whether a routine for reaching pre-agreement on backup beams for the current serving beams shall be initiated. Note that the routine may be triggered periodically or by the occurrence of a predefined event, e.g., establishment of connection between UE 112A and AN 111E. If the routine shall be initiated, the process proceeds to step S220; otherwise, the process continues to determine whether the routine shall be initiated at step S210.

[054] At step S220, the routine for reaching pre-agreement on backup beams for the current serving beam is initiated. The initiator for the routine may be either UE 112A or AN 111E. For example, as a initiator, AN 111E initiates the routine by transmitting to UE 112A a reference signal via beams E1, E2, E3 and E4 associated with downlinks.

[055] Assuming UE 112A receives the reference signal via downlinks associated with beams E1, E2 and E4. Thus, at step S230, UE112A will respond to AN 111E via uplinks associated with beams E1, E2 and E4. Preferably, the response to AN 111E may include radio link quality for the downlinks associated with these beams. As a result, the participants will identify backup beams for each beam. In particular, beams E2 and E4 are identified as the backup beams for beam E1, beams E1 and E4 as the backup beams for beam E2, and beams E1 and E2 as the backup beams for beam E4. The identified backup beams are mapped into specific downlink and uplink resources and thus the receiver side can recognize the beam failure by monitoring the mapped specific radio link resources.

[056] At UE 112A, one of beams E2 and E4 may be designated as a primary backup beam based on the radio link quality of the downlinks associated with these backup beams. Alternatively, the designation is performed by UE 111E on the basis of the radio link quality and the current load distribution around UE 112A.

[057] After step S230, the process proceeds to step S210.

[058] Fig. 3 is a process flow diagram of a method for recovery from beam failure in a wireless access network according to another exemplary embodiment of the present invention. For illustrative purpose, the following depiction is made in the context of the above architecture as shown in Fig. 1. However, one skilled artisan in the art would recognize that the present invention is applicable to other architectures. Moreover, one skilled artisan will recognize that all of the aspects of the present invention as described above are applicable to the present exemplary embodiment.

[059] For illustrative purpose, in the present exemplary embodiment, it assumes that UE 112A accesses to UDN 110 through AN 111E via beam E1, which is taken as the current serving beam at the beginning of the process, and under pre-agreement, beams E2 and E4 are taken as the backup beams for beam E1.

[060] At step S310, UE 112A or AN 111E determines whether beam failure for the current serving beam, i.e., beam E1, occurs. The determination may be the feedback-based determination as described above. In particular, UE 112A or AN 111E may utilize a feedback or response from a receiver to determine the occurrence of the beam failure. If it determines the beam failure occurs, the process proceeds to step S320; otherwise, the process continues to determine whether the beam failure occurs at step S310.

[061] For illustrative purpose, it assumes that the beam failure is determined at AN 111E. Then at step S320, AN 111E transmits notification of the occurrence of the beam failure to UE 112A via the current serving beam E1 and the backup beams E2 and E4. Alternatively, the notification may be transmitted only via the backup beams E2 and E4. Likewise, the notification may be transmitted either in conjunction with data transmission or as a separate signaling message.

[062] As described above, upon receiving the notification or the data transmission via the backup beams, the receiver side utilizes an available

beam as a new serving beam to communicate with the transmitter side. The available beam is selected from the serving beam and the backup beams, or only from the backup beams. Therefore, at step S330, AN 111E receives from UE 112A information on the selection of the available beam or the new serving beam. For illustrative purpose, assuming beam E4 is selected as the new serving beam.

[063] Alternatively, instead of selecting a new serving beam, the receiver side may send to the transmitter side a report on the beams via which the notification or the data transmission is received. For example, it assumes the notification or the data transmission is received via beams E1 and E4 at the receiver side. Thus, it will be reported that the notification or the data transmission is received via beams E1 and E4. Accordingly, at step S330, upon receiving the report from the receiver side, the transmitter side selects a new serving beam based on the radio link quality for the forward links associated with the reported beams, i.e., beams E1 and E4. For illustrative purpose, assuming that the forward link associated with beam E4 has the best radio link quality, As a result, beam E4 is selected as the new serving beam at the transmitter side.

[064] At step S340, AN 111E continues the interaction or communication with UE 112A via beam E4 and then returns step S310.

[065] In case the beam failure is determined at UE 112A, UE 112A transmits notification of the occurrence of the beam failure to AN 111E via beams E1, E2 and E4 or only via beams E2 and E4 at step S320. Then at step S330, UE 112A receives from AN 111E information on the selection of the available beam or the new serving beam. The process proceeds to step S340, where UE 112A continues the communication with AN 111E via beam E4 and then returns step S310.

[066] In the above embodiments, it assumes that the backup beams belong to the same AN. However, this assumption is not necessary and the present invention may be extended to such a scenario where, for a serving beam, some or all of the backup beams belong to an AN different from the AN of the serving beam. For example, as shown in Fig. 1, UE 112B can access to AN 111G via beams G1 or G2, or to AN 111F via beam F2.

Therefore, for serving beam G1(G2), besides backup beam G2(G1) in AN 111G, beam F2 in AN 111F can be also used as a backup beam; likewise, for serving beam F2, beams G1 and G2 can be used as backup beams. The above configuration enhances recovery capability from beam failure, especially when all of the beams within an AN are unavailable.

[067] In case the backup beams involve with multiple ANs, it is advantageous to introduce inter-AN coordination between the involved ANs in the pre-agreement on the backup beams and the selection of the new serving beam. Preferably, the inter-AN coordination is performed via an intermediate node, e.g., a control node acting as a cluster head for controlling a cluster comprising the involved ANs. Alternatively, the inter-AN coordination may be performed directly between the involved ANs.

[068] Fig. 4 is a process flow diagram of a method for recovery from beam failure in a wireless access network according to another exemplary embodiment of the present invention. For illustrative purpose, the following depiction is made in the context of the above architecture as shown in Fig. 1. However, one skilled artisan in the art would recognize that the present invention is applicable to other architectures. Moreover, one skilled artisan will recognize that all of the aspects of the present invention as described above are applicable to the present exemplary embodiment.

[069] For illustrative purpose, in the present exemplary embodiment, it assumes that UE 112B access to UDN 110 through AN 111G (referred to be "serving node" hereinafter) via beam G1, which is taken as the current serving beam at the beginning of the process, and between AN 111G, AN 111F (referring to as "neighboring node" hereinafter) and UE 112B, it reaches pre-agreement that beams G2 and F2 are backup beams for beam G1. As described above, an intermediate node such as a cluster head, e.g., transport aggregation node 113 as shown in Fig. 1, coordinates the pre-agreement on the backup beams. Likewise, the pre-agreement may be updated periodically or by the occurrence of a predefined event, e.g., establishment of connection between UE 112B and AN 111E. The

identified backup beams G2 and F2 are mapped into specific downlink and uplink resources and thus the receiver side can recognize the beam failure by monitoring the mapped specific radio link resources.

[070] With reference to Fig. 4, at step S410, UE 112B determines that beam failure for the current serving beam, i.e., beam G1, occurs. Likewise, the determination may be the feedback-based determination as described above. For example, if UE 112B fails to receive a follow-up DL signaling after an UL transmission, e.g., an Ack/Nack feedback, it determines the beam failure for beam G1 occurs.

[071] Then at step S420, UE 112B initiates multiple transmission e.g., by sending a backup beam activation command via uplinks associated with both of the serving and backup beams, i.e., beams G2 and F2. The backup beam activation command may be in the form of a SR.

[072] The serving and neighboring nodes, i.e., AN 111G and AN 111F, keep on monitoring the mapped specific uplink resources, e.g., the SR resources. Assuming that beam F2 is designated as a primary backup beam for beam G1, or the radio link quality for beam F2 is superior to G2, or beams failure for beam G2 also occurs. Thus, with the inter-AN coordination by the cluster head, beam F2 is selected as the new serving beam. As a result, at step S430, the neighboring node returns a UL grant to UE 112B to confirm the activation of the backup beam, i.e., beam F2. Then at step S440, AN 111F and UE 112B start to communicate with each other.

[073] At step S450, with the inter-AN coordination by the cluster head, the serving node notifies the neighboring node of the deactivation of beam G1, which was previously taken as the serving beam. Afterwards, at step S460, the neighboring node transmits DL signaling, e.g., a beam deactivation command to UE 112B to confirm the deactivation of previous serving beam G1.

[074] In the above embodiment, a third node such as a cluster head participates in the inter-AN coordination. As described above, however, the inter-AN coordination may be performed directly between the serving

node and the neighboring node.

[075] Fig. 5 is a block diagram illustrating a user equipment (UE) having recovery capability from beam failure according to another exemplary embodiment of the present invention. For illustrative purpose, the present embodiment is described in the context of the UDN architecture as discussed with reference to Fig1. However, one skilled artisan in the art would recognize that the present invention is applicable to other wireless access networks. Moreover, one skilled artisan will recognize that the aspects of the present invention as described above are applicable to the present exemplary embodiment.

[076] With reference to Fig. 5, in the present embodiment, a UE 500 comprises a transceiver 510 and a determining unit 520 coupled to each other.

[077] The transceiver 510 is configured to interact with one or more ANs in a wireless access network, e.g., ANs 111A-111G in UDN 110 as shown in Fig. 1. For example, the transceiver 510 is able to communicate or interact with AN 111E via beams E1, E2 and E4. Assuming beam E1 is selected as a current serving beam and beams E2 and E4 are selected as backup beams. As an example, the transceiver 510 transmits a service request or a random access request on an uplink associated with beam E1 and waits for a response responding to the service request or the random access request on a downlink associated with beam E1. Meanwhile, the transceiver 510 monitors the mapped specific radio link resources associated with beams E2 and E4.

[078] The determining unit 520 is configured to determine whether beam failure for the current serving beam, i.e., beam E1, occurs. The determination may be the feedback-based determination as described above. If determining the beam failure occurs, the determining unit 520 instructs the transceiver 510 to transmit notification of the occurrence of the beam failure to AN 111E via uplinks associated with the current serving beam E1 and the backup beams E2 and E4. Alternatively, the notification may be transmitted only via uplinks associated with the backup beams E2 and E4.

[079] When the transceiver 510 receives from AN 111E information on the selection of the available beam or the new serving beam, e.g., beam E2, the determining unit 520 will instruct the transceiver 510 to continue the communication or interaction with AN 111E via the new serving beam. Note that the information may be sent via downlinks associated with the new serving beam only, or associated with all of the beams linked to the mapped specific radio link resources.

[080] Note that in case the backup beams involve with multiple ANs, the determining unit 520 is further configured to instruct the transceiver 510 to transmit the notification to all involved ANs, and the transceiver 510 is configured to communicate or interact with the wireless access network via the new serving beam selected with an inter-AN coordination.

[081] Fig. 6 is a block diagram illustrating an access node (AN) having recovery capability from beam failure according to another exemplary embodiment of the present invention. For illustrative purpose, the present embodiment is described in the context of the UDN architecture as discussed with reference to Fig 1. However, one skilled artisan in the art would recognize that the present invention is applicable to other wireless access networks. Moreover, one skilled artisan will recognize that the aspects of the present invention as described above are applicable to the present exemplary embodiment.

[082] With reference to Fig. 6, in the present embodiment, an AN 600, e.g., anyone of ANs 111A-111G as shown in Fig.1, comprises a transceiver 610 and a determining unit 620 coupled to each other.

[083] The transceiver 610 is configured to interact with a UE, e.g., UE 112A or 112B as shown in Fig. 1, and other ANs in a wireless access network, e.g., UDN 110 as shown in Fig. 1. For example, the transceiver 610, e.g., in AN 111G, is able to interact with UE 112B via beams G1 and G2, and is connected to AN 111F directly or via a third node(s). Assuming beam G1 is selected as a current serving beam and beams G2 and F2 are selected as backup beams. As an example, the transceiver 610, e.g., in AN 111G transmits a data message or a grant message on a downlink associated with beam G1, and then waits for an acknowledgment(ACK)

message or a negative Acknowledgment(NACK) message to the data message, or a data message to the grant message on a downlink associated with beam G1. Meanwhile, with a pre-agreement, the transceivers 610, e.g., in AN 111G and AN 111F monitor the mapped specific radio link resources associated with beams G2 and F2, respectively.

[084] The determining unit 620, e.g., in AN 111G is configured to determine whether beam failure for the current serving beam, i.e., beam G1, occurs. The determination may be also the feedback-based determination as described above. If determining the beam failure occurs, in AN 111G, the determining unit 620 instructs the transceiver 610 to transmit notification of the occurrence of the beam failure to UE 112B via uplinks associated with the current serving beam G1 and the backup beams G2. Moreover, with an inter-AN coordination, the transceiver 610 in AN 111F transmits the notification to UE 112B via an uplink associated with beams F2. Alternatively, the notification may be transmitted only via uplinks associated with the backup beams G2 and F2.

[085] Assuming beam F2 is the primary backup beam as designated or is selected as a new serving beam by UE 112B. Thus, UE 112B will send information on the new serving beam, e.g., beam F2. At AN 111F, if the transceiver 610 receives the information from UE 112B, the determining unit 620 will instruct the transceiver 610 to communicate or interact with UE 112B via the new serving beam.

[086] In the exemplary embodiment described with reference to Figs. 5 and 6, the determining unit can be implemented as a processor or part of the processor to perform various tasks as discussed above. The processor can include a microprocessor, microcontroller, processor module or subsystem, programmable integrated circuit, programmable gate array, or another control or computing device.

[087] It should be noted that the aforesaid embodiments are illustrative of this invention instead of restricting this invention, substitute embodiments may be designed by those skilled in the art without departing from the scope of the claims enclosed. The wordings such as “include”, “including”, “comprise” and “comprising” do not exclude elements or

steps which are present but not listed in the description and the claims. It also shall be noted that as used herein and in the appended claims, the singular forms “a”, “an”, and “the” include plural referents unless the context clearly dictates otherwise. This invention can be achieved by means of hardware including several different elements or by means of a suitably programmed computer. In the unit claims that list several means, several ones among these means can be specifically embodied in the same hardware item. The use of such words as first, second, third does not represent any order, which can be simply explained as names.

What is claimed is:

1. A user equipment (UE) capable of communicating with a wireless access network, comprising:

a determining unit configured to determine whether beam failure occurs on the basis of presence of a response from the wireless access network during communication between the wireless access network and the UE via a first beam; and

a transceiver configured to communicate with the wireless access network via an available beam selected from the first beam and one or more second beams if the determined unit determines that the beam failure occurs.

2. The UE according to claim 1, wherein the response is one selected from a group consisting of: a grant message responding to a service request transmitted from the UE on an uplink associated with the first beam and an random access response message responding to a random access request transmitted from the UE on an uplink associated with the first beam.

3. The UE according to claim 1 or 2, wherein the selection of the available beam is on the basis of radio link quality for uplinks associated with the first beam and the one or more second beams.

4. The UE according to claim 1, wherein for communicating with the wireless access network via the available beam, the transceiver is configured to:

transmit to one or more ANs of the wireless access network a message from the UE via the first beam and the one or more second beams if determining that the beam failure occurs;

receive information on the selection of the available beam from the one or more ANs of the wireless access network; and

use the selected available beam during communication with the wireless access network.

5. An access node (AN) capable of communicating with a user equipment (UE), comprising:

a determining unit configured to determine whether beam failure occurs on the basis of presence of a response from the UE during an interaction between the AN and the UE via a first beam; and

a transceiver configured to, if the determining unit determines that the beam failure occurs, communicatewith the UE via an available beam selected from the first beam and one or more second beams, or transfer to another AN communication with the UE, the communication being made via the available beam.

6. The AN according to claim 5, wherein the response is one selected from a group consisting of: an acknowledgment(ACK) message or a negative Acknowledgment(NACK) message responding to a data message transmitted from the AN on a downlink associated with the first beam, and a data message responding to a grant message transmitted from the AN on a downlink associated with the first beam.

7. The AN according to claim 5 or 6, wherein the selection of the available beam is on the basis of radio link quality for downlinks associated with the first beam and the one or more second beams.

8. A user equipment (UE) capable of communicating with a wireless access network, configured to:

determine whether beam failure occurs on the basis of presence of a response from the wireless access network during communication between the wireless access network and the UE via a first beam; and

if it is determined that the beam failure occurs, communicate with the wireless access network via an available beam selected from the first beam and one or more second beams.

9. An access node (AN) capable of communicating with a user equipment (UE), configured to:

determine whether beam failure occurs on the basis of presence of a response from the UE during an interaction between the AN and the UE via a first beam; and

if it is determined that the beam failure occurs, communicate with the UE via an available beam selected from the first beam and one or more second beams, or transfer to another AN communication with the UE, the communication being made via the available beam.

10. A method for recovery from beam failure in a wireless access network accessed by a user equipment (UE), comprising:

at the wireless access network, determining whether beam failure occurs on the basis of presence of a response from the UE during communication between the wireless access network and the UE via a first beam; and

if it is determined that the beam failure occurs, communicating with the UE via an available beam selected from the first beam and one or more second beams.

11. The method according to claim 10, wherein the response is one selected from a group consisting of: an acknowledgment(ACK) message or a negative Acknowledgment(NACK) message responding to a data message transmitted from an AN of the wireless access network on a downlink associated with the first beam, and a data message responding to a grant message transmitted from an AN of the wireless access network on a downlink associated with the first beam.

12. The method according to claim 10 or 11, wherein the selection of the available beam is on the basis of radio link quality for downlinks associated with the first beam and the one or more second beams.

13. The method according to claim 10, wherein the step of communicating with the UE via the available beam comprising:

upon determining that the beam failure occurs, transmitting to the UE a message from one or more ANs of the wireless access network via the first beam and the one or more second beams;

receiving information on the selection of the available beam from the UE; and

using the selected available beam during communication with the UE.

14. The method according to claim 10, wherein the step of communicating with the UE via the available beam comprising:

upon determining that the beam failure occurs, transmitting to the UE a message from a first AN and a second AN of the wireless access network, wherein the message from the first AN is transmitted via the first beam and the message from the second AN is transmitted via the one or more second beams;

receiving information on the selection of the available beam from the UE; and

using the selected available beam during communication with the UE.

15. The method according to claim 10, wherein the step of communicating with the UE via the available beam comprising:

upon determining that the beam failure occurs, transmitting a message from a first AN and second AN of the wireless access network, wherein the message from the first AN is transmitted via the first beam and at least one of the second beams and the message from the second AN is transmitted via the other of the second beams;

receiving information on the selection of the available beam from the UE; and

using the selected available beam during communication with the UE.

16. A method for recovery from beam failure for a user equipment (UE) accessing a wireless access network, comprising:

at the UE, determining whether beam failure occurs on the basis of presence of a response from the wireless access network during communication between the wireless access network and the UE via a first beam; and

if it is determined that the beam failure occurs, communicating with the wireless access network via an available beam selected from the first beam and one or more second beams.

17. The method according to claim 15, wherein the response is one selected from a group consisting of: a grant message responding to a service request transmitted from the UE on an uplink associated with the first beam and an random access response message responding to a random access request transmitted from the UE on an uplink associated with the first beam.

18. The method according to claim 16 or 17, wherein the selection of the available beam is on the basis of radio link quality for uplinks associated with the first beam and the one or more second beams.

19. The method according to claim 16, wherein the step of communicating with the wireless access network via the available beam comprising:

upon determining that the beam failure occurs, transmitting to one or more ANs of the wireless access network a message from the UE via the first beam and the one or more second beams;

receiving information on the selection of the available beam from the one or more ANs of the wireless access network; and

using the selected available beam during communication with the wireless access network.

or a beam failure recovery request response. By using the embodiment of the present invention, the network device may perform beam recovery processing on multiple requests which are used for recovering a beam that are sent by the same terminal device, and beam recovery efficiency is increased.

(57) 摘要：本发明实施例公开了波束恢复方法及装置，所述方法包括：终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，用于恢复波束的请求为调度请求或者波束失败恢复请求；终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。采用本发明实施例，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

波束恢复方法及装置

技术领域

本申请涉及通信技术领域，尤其涉及波束恢复方法及装置。

背景技术

波束(beam)是一种通信资源，不同的波束可以认为是不同的通信资源。在移动通信系统中使用波束进行信息传输，即通过在空间上朝向特定的方向发送信号，可以实现更高的天线阵列增益。发射波束可以是指信号经天线发射出去后在空间不同方向上形成的信号强度的分布，接收波束可以是指从天线上接收到的无线信号在空间不同方向上的信号强度分布。一个波束对通常包括一个发送端的发射波束和一个接收端的接收波束。当下行控制信道关联的波束的性能下降到某个门限值时，该波束失效，即无法使用该波束进行信息传输，一旦波束失效，将触发波束恢复机制。

在长期演进（Long Term Evolution，LTE）系统中，在建立无线链路过程中的初始接入、在无线链路建立失败之后的链路重建或者采用基于上行测量的定位方法以进行定位等过程中可以采用随机接入方案，具体可以为：终端设备向网络设备发送调度请求（Scheduling Request，SR），以通知网络设备有终端设备试图接入；终端设备在预先配置的时间窗内监测控制信道，以接收网络设备下发的随机接入响应（Random Access Response，RAR）。上述随机接入方案仅针对网络设备接收到同一终端设备发送的一个 SR 的场景。

当下行链路（Down Link，DL）的波束对（Beam Pair Link，BPL）失效时，为了充分利用现有的资源，以及波束失效的持续时间远小于无线链路失效（Radio Link Failure，RLF）的时间窗长度，终端设备可以利用随机接入信道（Random Access Channel，RACH）资源在不同方向的多个波束上发射 SR，则网络设备在时间窗内可以接收到来自同一终端设备的多个 SR。而传统 LTE 中随机接入的处理流程仅针对网络设备收到同一终端设备发送的一个 SR 的场景，在网络设备收到同一终端设备发送的多个 SR 时如何进行随机接入处理，是目前亟需解决的问题。

发明内容

本发明实施例所要解决的技术问题在于，提供波束恢复方法及装置，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

第一方面，本发明实施例提供了一种波束恢复方法，终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求；终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应。

其中，用于恢复波束的请求可以为调度请求或者波束失败恢复请求（beam failure recovery request）。

其中，用于波束恢复请求的响应可以为调度请求响应或者波束失败恢复请求响应。

例如，当用于恢复波束的请求为调度请求时，用于波束恢复请求的响应可以为调度请求响应；当用于恢复波束的请求为波束失败恢复请求时，用于波束恢复请求的响应可以为

波束失败恢复请求响应。

其中，第一时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第一时间窗可以包括 3 个符号或者 7 个符号等。

可选的，第一时间窗所包含的第一个符号可以为第一个配置有随机接入信道（Random Access Channel，RACH）资源的符号。

在该技术方案中，终端设备可以使用至少一个波束向网络设备发送用于恢复波束的请求，终端设备还可以在第一时间窗内使用上述至少一个波束接收网络设备发送的用于波束恢复请求的响应，则终端设备向网络设备发送的用于恢复波束的请求可以包括多个，以便提高波束恢复效率。

可选的，终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求。

其中，第一波束可以是网络设备对终端设备配置的一个波束。

例如，终端设备可以在第一时间窗所包含的一个符号上，使用一个第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括 3 个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的一个符号为第一符号，则终端设备可以在第一时间窗所包含的第一符号上，使用第一波束向网络设备发送用于恢复波束的请求。

又如，终端设备可以在第一时间窗所包含的一个符号上，使用多个相同的第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括 3 个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的一个符号为第一符号，则终端设备可以在第一时间窗所包含的第一符号上，在不同方向上使用第一波束向网络设备发送用于恢复波束的请求。

又如，终端设备可以在第一时间窗所包含的多个符号上，使用一个第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括 3 个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的多个符号包括第二符号和第三符号，则终端设备可以在第一时间窗所包含的第二符号上，使用第一波束向网络设备发送用于恢复波束的请求，且在第一时间窗所包含的第三符号上，使用第一波束向网络设备发送用于恢复波束的请求。

又如，终端设备可以在第一时间窗所包含的多个符号上，使用多个相同的第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括 3 个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的多个符号包括第二符号和第三符号，则终端设备可以在第一时间窗所包含的第二符号上，使用第一波束向网络设备发送用于恢复波束的请求，且在第一时间窗所包含的第三符号上，使用第一波束向网络设备发送用于恢复波束的请求。

在该技术方案中，终端设备可以在一个符号上使用多个相同的第一波束向网络设备发送用于恢复波束的请求，或者在多个符号上使用一个或者多个相同的第一波束向网络设备发送用于恢复波束的请求，以实现同一终端设备向网络设备发送多个用于恢复波束的请求。

可选的，终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，具体可以为：终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

在该技术方案中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求之后，可以在第一时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应，可确保发送用于波束恢复的请求的波束和接收用于波束恢复请求的响应的波束为同一波束。

可选的，第一时间窗可以包括第一单元时间窗和第二单元时间窗，则终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求。

其中，第一单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第一单元时间窗可以包括 3 个符号或者 4 个符号等。

其中，第二单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第二单元时间窗可以包括 4 个符号或者 5 个符号等。

其中，第二单元时间窗所包含的第一个符号为第一单元时间窗所包含的最后一个符号之后的第一个符号。例如第一单元时间窗包括 4 个符号，分别为符号 0、符号 1、符号 2 以及符号 3，符号 3 之后的第一个符号为符号 4，则终端设备可以确定第二单元时间窗所包含的第一个符号为符号 4。需要说明的是，本发明实施例中的第一单元时间窗包含但不限定 4 个符号，第一单元时间窗的长度和第二单元时间窗的长度可以相同，也可以不相同，具体不受本发明实施例的限定。

可选的，终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，具体可以为：终端设备在第二单元时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

在该技术方案中，终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求之后，终端设备可以在第二单元时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应，可确保发送用于波束恢复的请求的波束和接收用于波束恢复请求的响应的波束为同一波束。

可选的，当在第一时间窗内未接收到用于波束恢复请求的响应时，终端设备可以确定网络设备对终端设备配置的第三时间窗，并在第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向网络设备发送用于恢复波束的请求。

其中，第三时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第三时间窗可以包括 3 个符号或者 5 个符号等。

在该技术方案中，终端设备在第一时间窗未检测到用于波束恢复请求的响应时，终端设备可以在第三时间窗使用第一波束以外的其他波束重新向网络设备发送用于恢复波束的请求，若终端设备在第三时间窗所包含的至少一个符号上使用第二波束接收到网络设备发送的用于波束恢复请求的响应，则可实现波束恢复，可提高波束恢复的可靠性。

可选的，第一时间窗可以包括第三单元时间窗和第四单元时间窗，则终端设备在第一

时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求。

其中，第三单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第一单元时间窗可以包括 3 个符号或者 5 个符号等。

其中，第四单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第二单元时间窗可以包括 4 个符号或者 5 个符号等。

其中，第四单元时间窗所包含的第一个符号可以为第三单元时间窗所包含的最后一个符号之后的第一个符号。例如第三单元时间窗包括 4 个符号，分别为符号 0、符号 1、符号 2 以及符号 3，符号 3 之后的第一个符号为符号 4，则终端设备可以确定第四单元时间窗所包含的第一个符号为符号 4。需要说明的是，本发明实施例中的第三单元时间窗包含但不限定 4 个符号，第三单元时间窗的长度和第四单元时间窗的长度可以相同，也可以不相同，具体不受本发明实施例的限定。

其中，网络设备可以对终端设备配置最大波束数量，例如允许终端设备发送用于恢复波束的请求时所使用的波束的数量可以小于等于 5。需要说明的是，本发明实施例中的最大波束数量包含但不限于 5，例如，最大波束数量可以为 3，等等，具体不受本发明实施例的限制。

其中，第三单元时间窗所包含的符号的数量总和可以是根据网络设备对终端设备配置的最大波束数量确定的。例如，第三单元时间窗所包含的符号的数量总和与最大波束数量之间可以呈正比例关系。示例性的，最大波束数量为 5，则第三单元时间窗所包含的符号的数量总和可以为 5，即第三单元时间窗包含 5 个符号。

例如，终端设备可以在第三单元时间窗所包含的一个符号上，使用一个波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括 5 个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的一个符号为第一符号，则终端设备可以在第三单元时间窗所包含的第一符号上，使用波束 1 向网络设备发送用于恢复波束的请求。波束 1 可以为终端设备确定得到的一个波束，其中该波束可以是网络设备对终端设备配置的。

又如，终端设备可以在第三单元时间窗所包含的一个符号上，使用多个不同波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括 5 个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的一个符号为第一符号，则终端设备可以在第三单元时间窗所包含的第一符号上，在不同方向上分别使用波束 1~波束 5 中的多个波束向网络设备发送用于恢复波束的请求。其中，若网络设备对终端设备配置的最大波束数量为 5，则终端设备在第三单元时间窗所包含的第一符号上，可以使用大于等于 2 个且小于等于 5 个波束向网络设备发送用于恢复波束的请求。

又如，终端设备可以在第三单元时间窗所包含的多个符号上，使用一个波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括 5 个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的多

个符号包括第二符号和第三符号，则终端设备可以在第三单元时间窗所包含的第二符号上，使用波束 1 向网络设备发送用于恢复波束的请求，且在第三单元时间窗所包含的第三符号上，使用波束 1 向网络设备发送用于恢复波束的请求。

又如，终端设备可以在第三单元时间窗所包含的多个符号上，使用多个不同波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括 5 个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的多个符号包括第二符号和第三符号，则终端设备可以在第三单元时间窗所包含的第二符号上，在不同方向上分别使用波束 1~波束 5 中的多个波束向网络设备发送用于恢复波束的请求，且在第三单元时间窗所包含的第三符号上，在不同方向上分别使用波束 1~波束 5 中的多个波束向网络设备发送用于恢复波束的请求。

在该技术方案中，终端设备可以在一个符号上使用多个不同波束向网络设备发送用于恢复波束的请求，或者在多个符号上使用一个或者多个不同波束向网络设备发送用于恢复波束的请求，以实现同一终端设备向网络设备发送多个用于恢复波束的请求。

可选的，终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，具体可以为：终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收用于波束恢复请求的响应。

在该技术方案中，终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同波束向网络设备发送用于恢复波束的请求之后，终端设备可以在第四单元时间窗所包含的至少一个符号上，使用上述至少一个不同的波束接收用于波束恢复请求的响应，可确保发送用于波束恢复的请求的波束和接收用于波束恢复请求的响应的波束为同一波束。

可选的，终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备基于网络设备对终端设备配置的波束请求指示信息，在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，波束请求指示信息用于指示用于恢复波束的请求的发送方式。

例如，当波束请求指示信息用于指示用于恢复波束的请求的发送方式为在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束发送时，终端设备可以在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，并在第一时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

又如，当波束请求指示信息用于指示用于恢复波束的请求的发送方式为在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束发送时，终端设备可以在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，并在第二单元时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

又如，当波束请求指示信息用于指示用于恢复波束的请求的发送方式为在第三单元时间窗所包含的至少一个符号上，使用至少一个不同波束发送时，终端设备可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求，并在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收用

于波束恢复请求的响应。

第二方面，本发明实施例提供了一种波束恢复方法，网络设备接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，并使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应。

在该技术方案中，网络设备可以接收终端设备发送的多个用于恢复波束的请求，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，并使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

可选的，网络设备在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：网络设备响应在第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求。

例如，若终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定质量最好的波束所承载的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

又如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定质量最好的波束所承载的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

可选的，网络设备在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：网络设备响应在第二时间窗内接收到的第一个用于恢复波束的请求。

例如，若终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定最先接收到的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

又如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定最先接收到的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

又如，若终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定最先接收到的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

可选的，网络设备使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应，具体可以为：网络设备在第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应。

可选的，网络设备使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应，具体可以为：网络设备在第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应。

第三方面，本发明实施例提供一种计算机存储介质，所述计算机存储介质存储有程序，所述程序执行时包括本发明实施例第一方面提供的波束恢复方法中全部或部分的步骤。

第四方面，本发明实施例提供一种计算机存储介质，所述计算机存储介质存储有程序，所述程序执行时包括本发明实施例第二方面提供的波束恢复方法中全部或部分的步骤。

第五方面，本发明实施例提供一种波束恢复装置，该波束恢复装置包括用于执行本发明实施例第一方面公开的波束恢复方法的模块。

第六方面，本发明实施例提供一种波束恢复装置，该波束恢复装置包括用于执行本发明实施例第二方面公开的波束恢复方法的模块。

第七方面，本发明实施例提供一种终端设备，其特征在于，包括处理器、存储器以及收发器，存储器中存储一组程序代码，且处理器调用存储器中存储的程序代码，用于执行以下操作：

在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求；在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应。

第八方面，本发明实施例提供一种网络设备，其特征在于，包括处理器、存储器以及收发器，存储器中存储一组程序代码，且处理器调用存储器中存储的程序代码，用于执行以下操作：

接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求；在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应。

第九方面，本发明实施例提供一种波束恢复系统，包括本发明实施例第七方面公开的终端设备和本发明实施例第八方面公开的网络设备。

第十方面，本申请实施例提供了一种通信芯片，其中存储有指令，当其在终端设备上运行时，使得所述通信芯片执行上述第一方面的方法。

第十一方面，本申请实施例提供了一种通信芯片，其中存储有指令，当其在网络设备上运行时，使得所述通信芯片执行上述第二方面的方法。

附图说明

具体实施方式

下面结合本发明实施例中的附图对本发明实施例进行描述。

为了更好的理解本发明实施例公开的一种波束恢复方法及装置，下面首先对本发明实施例适用的网络架构进行描述。请参见图 1，图 1 是本发明实施例公开的一种波束恢复系统的架构示意图。如图 1 所示，该波束恢复系统可以包括终端设备 10 以及网络设备 20。其中，终端设备 10 与网络设备 20 之间可以通过通信连接进行数据传输。

本发明实施例中的终端设备 10 可以称为用户设备（User Equipment，UE）、移动台、接入终端、用户单元、用户站、移动站、远方站、远程终端、移动设备、终端、无线通信设备、用户代理或用户装置等，其具体可以是 WLAN 中的站点（Station，ST）、蜂窝电话、无绳电话、会话启动协议（Session Initiation Protocol，SIP）电话、无线本地环路（Wireless Local Loop，WLL）站、个人数字处理（Personal Digital Assistant，PDA）、具有无线通信功能的手持设备、计算设备、连接到无线调制解调器的其它处理设备、车载设备、可穿戴设备、未来 5G 网络中的移动台以及未来演进的公共陆地移动网络（Public Land Mobile Network，PLMN）网络中的终端设备等中的任意一种。

本发明实施例中的网络设备 20 可以是能和终端设备 10 通信的设备。网络设备 20 可以是基站、中继站或接入点。基站可以是全球移动通信系统（Global System for Mobile Communication，GSM）或码分多址（Code Division Multiple Access，CDMA）网络中的基

站收发信台（Base Transceiver Station，BTS），也可以是宽带码分多址（Wideband Code Division Multiple Access，WCDMA）中的NB（NodeB），还可以是长期演进（Long Term Evolution，LTE）中的eNB或eNodeB（Evolutional NodeB）。网络设备20还可以是云无线接入网络（Cloud Radio Access Network，CRAN)场景下的无线控制器。网络设备20还可以是未来5G网络中的网络设备或者未来演进的PLMN网络中的网络设备。网络设备20还可以是可穿戴设备或车载设备。

应理解，本发明实施例的技术方案可以应用于各种通信系统，例如：GSM系统、CDMA系统、WCDMA系统、通用分组无线业务（General Packet Radio Service，GPRS）、LTE系统、LTE频分双工（Frequency Division Duplex，FDD）系统、LTE时分双工（Time Division Duplex，TDD）、通用移动通信系统（Universal Mobile Telecommunication System，UMTS）或全球互联微波接入（Worldwide Interoperability for Microwave Access，WiMAX）通信系统等。

本发明实施例中，能够和基站进行数据通信的设备均可以理解为终端设备10，本发明实施例将以一般意义上的终端设备来介绍；本发明实施例中，网络设备20可以通过信令对终端设备10配置允许的最大波束数量，则终端设备10可以使用小于等于最大波束数量的波束向网络设备20发送用于波束恢复的请求；本发明实施例中，网络设备20可以对终端设备10配置第一时间窗，其中第一时间窗可以包括一个子帧、一个时隙以及一个或多个符号中的任意一种，则终端设备10可以在第一时间窗使用至少一个波束向网络设备20发送用于波束恢复的请求；本发明实施例中，网络设备20可以对终端设备10配置第三时间窗，其中第三时间窗可以包括一个子帧、一个时隙以及一个或多个符号中的任意一种，则终端设备10在第一时间窗使用至少一个第一波束向网络设备20发送用于波束恢复的请求之后，当在第一时间窗内未接收到网络设备20发送的用于波束恢复请求的响应时，终端设备10可以在第三时间窗使用至少一个第二波束向网络设备发送用于恢复波束的请求；本发明实施例中，网络设备20可以配置网络设备20侧的第二时间窗，其中第二时间窗可以包括一个子帧、一个时隙以及一个或多个符号中的任意一种，则网络设备20接收到终端设备10在第一时间窗使用至少一个波束发送的用于波束恢复的请求之后，可以在第二时间窗，在接收到的用于波束恢复的请求中确定一个用于波束恢复的请求。

本发明实施例中，终端设备10至少有两种发送方式向网络设备20发送用于波束恢复的请求，以实现波束恢复。

第一种发送方式可以为：终端设备10在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备20发送用于恢复波束的请求，并在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备20发送的用于波束恢复请求的响应。

以图2A所示的信息传输的示意图为例，终端设备10在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束B4'向网络设备20发送用于恢复波束的请求。网络设备20按照接收RACH波束扫描方式检测终端设备10发送的用于恢复波束的请求，当网络设备20在第二时间窗内接收到终端设备10发送的用于波束恢复的请求时，网络设备20可以通过物理下行控制信道（Physical Downlink Control Channel，PDCCH）对该用于波束恢复的请求进行响应。当终端设备10在第一时间窗内未接收到网络设备20发送的用于恢

复波束请求的响应时，终端设备 10 可以在第二时间窗所包含的至少一个符号上，使用至少一个相同的第二波束 B5'向网络设备发送用于恢复波束的请求，当终端设备 10 在第二时间窗接收到网络设备 20 发送的用于波束恢复请求的响应时，终端设备 10 可以确定实现了波束恢复。

第二种发送方式可以为：若第一时间窗包括第三单元时间窗和第四单元时间窗，终端设备 10 可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备 20 发送用于恢复波束的请求，并在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备 20 发送的用于波束恢复请求的响应。

以图 2B 所示的信息传输的示意图为例，终端设备 10 在第三单元时间窗所包含的至少一个符号上，使用多个不同的波束向网络设备 20 发送用于恢复波束的请求，网络设备 20 在第二时间窗内接收到终端设备 10 发送的多个用于恢复波束的请求之后，可以在多个用于恢复波束的请求中确定一个用于恢复波束的请求，网络设备 20 可以使用确定得到的一个用于恢复波束的请求对应的波束，向终端设备 10 发送用于波束恢复请求的响应。终端设备 10 可以按照波束扫描方式检测网络设备 20 发送的用于波束恢复请求的响应，当终端设备 10 接收到网络设备 20 发送的用于波束恢复请求的响应时，终端设备 10 可以确定实现了波束恢复。

相对第一种发送方式，本发明实施例通过第二种发送方式可以使用多个不同的波束向网络设备 20 发送用于恢复波束的请求，可减小时延，提高波束恢复效率。

基于图 1 所示的波束恢复系统的架构示意图，请参见图 3，图 3 是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

步骤 S301：终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。

具体地，当下行链路（Down Link，DL）的波束失效时，终端设备可以在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束 1。

例如，终端设备可以在第一时间窗中选取一个符号（例如符号 3），并在符号 3 上使用一个波束 1 向网络设备发送调度请求。又如，终端设备可以在第一时间窗中选取一个符号（例如符号 3），并在符号 3 上使用多个波束 1 向网络设备发送调度请求，即终端设备在符号 3 上，在不同方向上使用波束 1 向网络设备发送调度请求。又如，以图 4 所示的信息传输的示意图为例，终端设备可以在第一时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用一个波束 1 向网络设备发送调度请求，并在符号 4 上使用一个波束 1 向网络设备发送调度请求。又如，终端设备可以在第一时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用多个波束 1 向网络设备发送调度请求，并在符号 4 上使用多个波束 1 向网络设备发送调度请求。

本发明实施例中，终端设备在第一时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送调度请求，可加大子载波间隔。

本发明实施例中，网络设备可以对终端设备配置第一时间窗。其中，第一时间窗的起

始时刻可以是配置有RACH资源的第一个符号，以图4所示的信息传输的示意图为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第一时间窗的起始时刻为符号3。

其中，第一时间窗的长度可以是固定长度，例如7个符号，可选的，第一时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

其中，网络设备可以向终端设备发送长度指示信息，以指示第一时间窗的长度。可选的，可以通过直接法指示第一时间窗的长度，例如长度指示信息为5，则终端设备可以确定第一时间窗的长度为5个符号。可选的，可以通过映射方式描述第一时间窗的长度，例如长度指示信息和第一时间窗的映射关系如表一所示：

表一

长度指示信息	第一时间窗的长度
00	3个符号
01	4个符号
10	5个符号
11	7个符号

通过表一可知，当长度指示信息为二进制00时，终端设备可以确定第一时间窗的长度为3个符号；当长度指示信息为二进制11时，终端设备可以确定第一时间窗的长度为7个符号。需要说明的是，本发明实施例中的长度指示信息和第一时间长度的映射关系包含但不局限于上述方式，研发人员可以结合不同场景进行修改，具体不受本发明实施例的限制。

其中，网络设备可以通过信令对终端设备配置第一时间窗，例如无线资源控制协议（Radio Resource Control，RRC）、媒体介入控制-控制元素协议（Media Access Control-Control Element，MAC-CE）或者下行控制信息协议（Downlink Control Information，DCI）等。

其中，网络设备可以通过向终端设备发送长度指示信息的方式，通知终端设备配置了第一时间窗。

步骤S302：网络设备确定在第二时间窗内接收到的第一个调度请求。

具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的调度请求，并确定在第二时间窗内接收到的第一个调度请求。

其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一单元时间窗所包含的第一个符号相同。

其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

步骤S303：网络设备在第二时间窗内使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应。

具体实现中，网络设备可以获取承载确定得到的调度请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗内使用确定得到的波束向终端设备发送调度请求响应。其中，波束对可以包括一个发送端的发射波束和一个接收端的接收波束。例如承载确

定得到的调度请求的波束为波束 1，波束 1 与波束 3 构成一个波束对，则网络设备可以在第二时间窗内使用波束 3 向终端设备发送调度请求响应。

以图 4 所示的信息传输的示意图为例，网络设备可以在第二时间窗所包含的符号 0 上，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应。

可选的，网络设备可以通过 PDCCH 向终端设备发送调度请求响应。例如，终端设备可以在同一子帧接收多个承载在不同 PDCCH 上的 DCI 消息。对于一个 PDCCH 所承载的 DCI 消息，每个 DCI 消息上可以附着一个 CRC。终端设备的 C-RNTI 可以被包含在 CRC 计算之中并隐式传输。则网络设备可以根据该终端设备的 C-RNTI，确定包含该 C-RNTI 的 CRC 所属的 DCI，进而确定承载该 DCI 的 PDCCH，通过确定得到的 PDCCH 向终端设备发送调度请求响应。其中，DCI 可以包括下行调度分配、上行调度请求、功率控制等。

可选的，网络设备可以通过 MAC-CE 向终端设备发送调度请求响应。例如，网络设备可以定义一个新的 MAC-CE，将该 MAC-CE 发送给终端设备，其中该 MAC-CE 可以携带调度请求响应。

可选的，网络设备可以通过 RRC 向终端设备发送调度请求响应。例如，网络设备可以定义一个新的 RRC IE，将该 RRC IE 发送给终端设备，其中该 RRC IE 可以携带调度请求响应。

可选的，网络设备可以通过物理下行共享信道（Physical Downlink Shared Channel，PDSCH）向终端设备发送调度请求响应。

步骤 S304：终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应。

终端设备可以在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应。例如，若终端设备在第一时间窗所包含的至少一个符号上，使用波束 1 向网络设备发送调度请求，则终端设备可以在第一时间窗所包含的至少一个符号上，使用波束 1 接收网络设备发送的调度请求响应。

相对传统的波束恢复方法中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔最多第一时间窗，例如 7 个符号，可降低延迟，提高波束恢复的效率。

在图 3 所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求，网络设备确定在第二时间窗内接收到的第一个调度请求，网络设备在第二时间窗内使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应，则终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应，可实现网络设备针对同一终端设备发送的多个调度请求的波束恢复处理，提高波束恢复效率。

基于图 1 所示的波束恢复系统的架构示意图，请参见图 5，图 5 是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

步骤 S501：终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第

一波束向网络设备发送波束失败恢复请求。

具体地，当 DL 波束失效时，终端设备可以在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束 1。

例如，终端设备可以在第一时间窗中选取一个符号（例如符号 3），并在符号 3 上使用一个波束 1 向网络设备发送波束失败恢复请求。又如，终端设备可以在第一时间窗中选取一个符号（例如符号 3），并在符号 3 上使用多个波束 1 向网络设备发送波束失败恢复请求，即终端设备在符号 3 上，在不同方向上使用波束 1 向网络设备发送波束失败恢复请求。又如，以图 4 所示的信息传输的示意图为例，终端设备可以在第一时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用一个波束 1 向网络设备发送波束失败恢复请求，并在符号 4 上使用一个波束 1 向网络设备发送波束失败恢复请求。又如，终端设备可以在第一时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用多个波束 1 向网络设备发送波束失败恢复请求，并在符号 4 上使用多个波束 1 向网络设备发送波束失败恢复请求。

本发明实施例中，终端设备在第一时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送波束失败恢复请求，可加大子载波间隔。

本发明实施例中，网络设备可以对终端设备配置第一时间窗。其中，第一时间窗的起始时刻可以是配置有 RACH 资源的第一个符号，以图 4 所示的信息传输的示意图为例，配置有 RACH 资源的第一个符号为符号 3，则终端设备可以确定第一时间窗的起始时刻为符号 3。

其中，第一时间窗的长度可以是固定长度，例如 7 个符号，可选的，第一时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，网络设备可以向终端设备发送长度指示信息，以指示第一时间窗的长度。可选的，可以通过直接法指示第一时间窗的长度，例如长度指示信息为 5，则终端设备可以确定第一时间窗的长度为 5 个符号。可选的，可以通过映射方式描述第一时间窗的长度，例如长度指示信息和第一时间窗的映射关系如表一所示。通过表一可知，当长度指示信息为二进制 00 时，终端设备可以确定第一时间窗的长度为 3 个符号；当长度指示信息为二进制 11 时，终端设备可以确定第一时间窗的长度为 7 个符号。需要说明的是，本发明实施例中的长度指示信息和第一时间长度的映射关系包含但不局限于上述方式，研发人员可以结合不同场景进行修改，具体不受本发明实施例的限制。

其中，网络设备可以通过信令对终端设备配置第一时间窗，例如无线资源控制协议（Radio Resource Control，RRC）、媒体介入控制-控制元素协议（Media Access Control-Control Element，MAC-CE）或者下行控制信息协议（Downlink Control Information，DCI）等。

其中，网络设备可以通过向终端设备发送长度指示信息的方式，通知终端设备配置了第一时间窗。

步骤 S502：网络设备确定在第二时间窗内接收到的第一个波束失败恢复请求。

具体地，网络设备可以按照接收 RACH 波束扫描方式在第二时间窗内接收终端设备发送的波束失败恢复请求，并确定在第二时间窗内接收到的第一个波束失败恢复请求。

其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一单元时间窗所包含的第一个符号相同。

其中，第二时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

步骤 S503：网络设备在第二时间窗内使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应。

具体实现中，网络设备可以获取承载确定得到的波束失败恢复请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗内使用确定得到的波束向终端设备发送波束失败恢复请求响应。例如承载确定得到的波束失败恢复请求的波束为波束 1，波束 1 与波束 3 构成一个波束对，则网络设备可以在第二时间窗内使用波束 3 向终端设备发送波束失败恢复请求响应。

以图 4 所示的信息传输的示意图为例，网络设备可以在第二时间窗所包含的符号 0 上，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 PDCCH 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 MAC-CE 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 RRC 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 PDSCH 向终端设备发送波束失败恢复请求响应。

步骤 S504：终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应。

终端设备可以在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应。例如，若终端设备在第一时间窗所包含的至少一个符号上，使用波束 1 向网络设备发送波束失败恢复请求，则终端设备可以在第一时间窗所包含的至少一个符号上，使用波束 1 接收网络设备发送的波束失败恢复请求响应。

相对传统的波束恢复方法中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔最多第一时间窗，例如 7 个符号，可降低延迟，提高波束恢复的效率。

在图 5 所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求，网络设备确定在第二时间窗内接收到的第一个波束失败恢复请求，网络设备在第二时间窗内使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应，则终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

基于图 1 所示的波束恢复系统的架构示意图，请参见图 6，图 6 是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

步骤 S601：终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同

的第一波束向网络设备发送调度请求。

具体地，当 DL 波束失效时，终端设备可以在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束 1。

例如，终端设备可以在第一单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用一个波束 1 向网络设备发送调度请求。又如，终端设备可以在第一单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用多个波束 1 向网络设备发送调度请求，即终端设备在符号 3 上，在不同方向上使用波束 1 向网络设备发送调度请求。又如，以图 7 所示的信息传输的示意图为例，终端设备可以在第一单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用一个波束 1 向网络设备发送调度请求，并在符号 4 上使用一个波束 1 向网络设备发送调度请求。又如，终端设备可以在第一单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用多个波束 1 向网络设备发送调度请求，并在符号 4 上使用多个波束 1 向网络设备发送调度请求。

本发明实施例中，终端设备在第一单元时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送调度请求，可加大子载波间隔。

本发明实施例中，网络设备可以对终端设备配置第一单元时间窗。其中，第一单元时间窗的起始时刻可以是配置有 RACH 资源的第一个符号，以图 7 所示的信息传输的示意图为例，配置有 RACH 资源的第一个符号为符号 3，则终端设备可以确定第一单元时间窗的起始时刻为符号 3。

本发明实施例中，网络设备可以对终端设备配置第二单元时间窗。其中，第二单元时间窗所包含的第一个符号为第一单元时间窗所包含的最后一个符号之后的第一个符号，以图 7 所示的信息传输的示意图为例，第一单元时间窗所包含的最后一个符号为符号 6，则终端设备可以确定第二单元时间窗所包含的第一个符号为符号 0。

其中，第一单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第一单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，第二单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，网络设备可以向终端设备发送第一长度指示信息，以指示第一单元时间窗的长度。可选的，可以通过直接法指示第一单元时间窗的长度。可选的，可以通过映射方式描述第一单元时间窗的长度。

其中，网络设备可以向终端设备发送第二长度指示信息，以指示第二单元时间窗的长度。可选的，可以通过直接法指示第二单元时间窗的长度。可选的，可以通过映射方式描述第二单元时间窗的长度。

其中，网络设备可以通过信令对终端设备配置第一单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过信令对终端设备配置第二单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过向终端设备发送第一长度指示信息的方式，通知终端设备配

置了第一单元时间窗。

其中，网络设备可以通过向终端设备发送第二长度指示信息的方式，通知终端设备配置了第二单元时间窗。

步骤 S602：网络设备在第二时间窗内，在接收到的调度请求中确定一个调度请求。

具体地，网络设备可以按照接收 RACH 波束扫描方式在第二时间窗内接收终端设备发送的调度请求，并在接收到的调度请求中确定一个调度请求。

可选的，网络设备可以确定在第二时间窗内接收到的第一个调度请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的调度请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的调度请求。

其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一单元时间窗所包含的第一个符号相同。

其中，第二时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

步骤 S603：网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应。

具体实现中，网络设备可以获取承载确定得到的调度请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送调度请求响应。例如承载确定得到的调度请求的波束为波束 1，波束 1 与波束 3 构成一个波束对，则网络设备可以在第二时间窗之后使用波束 3 向终端设备发送调度请求响应。

以图 7 所示的信息传输的示意图为例，终端设备可以在第二时间窗之后的第一个符号，即符号 0，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应。

可选的，网络设备可以通过 PDCCH 向终端设备发送调度请求响应。

可选的，网络设备可以通过 MAC-CE 向终端设备发送调度请求响应。

可选的，网络设备可以通过 RRC 向终端设备发送调度请求响应。

可选的，网络设备可以通过 PDSCH 向终端设备发送调度请求响应。

步骤 S604：终端设备在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的调度请求响应。

终端设备可以在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的调度请求响应。例如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用波束 1 向网络设备发送调度请求，则终端设备可以在第二单元时间窗所包含的至少一个符号上，使用波束 1 接收网络设备发送的调度请求响应。

相对传统的波束恢复方法中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔最多第一时间窗，例如 7 个符号，可降低延迟，提高波束恢复的效率。

在图 6 所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少

一个相同的第一波束向网络设备发送调度请求，网络设备确定在第一时间窗内接收到的第一个调度请求，网络设备在第一时间窗内使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应，则终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应，可实现网络设备针对同一终端设备发送的多个调度请求的波束恢复处理，提高波束恢复效率。

基于图 1 所示的波束恢复系统的架构示意图，请参见图 8，图 8 是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

步骤 S801：终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。

具体地，当 DL 波束失效时，终端设备可以在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束 1。

例如，终端设备可以在第一单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用一个波束 1 向网络设备发送波束失败恢复请求。又如，终端设备可以在第一单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用多个波束 1 向网络设备发送波束失败恢复请求，即终端设备在符号 3 上，在不同方向上使用波束 1 向网络设备发送波束失败恢复请求。又如，以图 7 所示的信息传输的示意图为例，终端设备可以在第一单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用一个波束 1 向网络设备发送波束失败恢复请求，并在符号 4 上使用一个波束 1 向网络设备发送波束失败恢复请求。又如，终端设备可以在第一单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用多个波束 1 向网络设备发送波束失败恢复请求，并在符号 4 上使用多个波束 1 向网络设备发送波束失败恢复请求。

本发明实施例中，终端设备在第一单元时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送波束失败恢复请求，可加大子载波间隔。

本发明实施例中，网络设备可以对终端设备配置第一单元时间窗。其中，第一单元时间窗的起始时刻可以是配置有 RACH 资源的第一个符号，以图 7 所示的信息传输的示意图为例，配置有 RACH 资源的第一个符号为符号 3，则终端设备可以确定第一单元时间窗的起始时刻为符号 3。

本发明实施例中，网络设备可以对终端设备配置第二单元时间窗。其中，第二单元时间窗所包含的第一个符号为第一单元时间窗所包含的最后一个符号之后的第一个符号，以图 7 所示的信息传输的示意图为例，第一单元时间窗所包含的最后一个符号为符号 8，则终端设备可以确定第二单元时间窗所包含的第一个符号为符号 0。

其中，第一单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第一单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，第二单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，网络设备可以向终端设备发送第一长度指示信息，以指示第一单元时间窗的长

度。可选的，可以通过直接法指示第一单元时间窗的长度。可选的，可以通过映射方式描述第一单元时间窗的长度。

其中，网络设备可以向终端设备发送第二长度指示信息，以指示第二单元时间窗的长度。可选的，可以通过直接法指示第二单元时间窗的长度。可选的，可以通过映射方式描述第二单元时间窗的长度。

其中，网络设备可以通过信令对终端设备配置第一单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过信令对终端设备配置第二单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过向终端设备发送第一长度指示信息的方式，通知终端设备配置了第一单元时间窗。

其中，网络设备可以通过向终端设备发送第二长度指示信息的方式，通知终端设备配置了第二单元时间窗。

步骤 S802：网络设备在第二时间窗内，在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

具体地，网络设备可以按照接收 RACH 波束扫描方式在第二时间窗内接收终端设备发送的波束失败恢复请求，并在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

可选的，网络设备可以确定在第二时间窗内接收到的第一个波束失败恢复请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的波束失败恢复请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的波束失败恢复请求。

其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一时间窗所包含的第一个符号相同。

其中，第二时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

步骤 S803：网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应。

具体实现中，网络设备可以获取承载确定得到的波束失败恢复请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送波束失败恢复请求响应。例如承载确定得到的波束失败恢复请求的波束为波束 1，波束 1 与波束 3 构成一个波束对，则网络设备可以在第二时间窗之后使用波束 3 向终端设备发送波束失败恢复请求响应。

以图 7 所示的信息传输的示意图为例，终端设备可以在第二时间窗之后的第一个符号上，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 PDCCH 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 MAC-CE 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 RRC 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 PDSCH 向终端设备发送波束失败恢复请求响应。

步骤 S804：终端设备在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的波束失败恢复请求响应。

终端设备可以在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的波束失败恢复请求响应。例如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用波束 1 向网络设备发送波束失败恢复请求，则终端设备可以在第二单元时间窗所包含的至少一个符号上，使用波束 1 接收网络设备发送的波束失败恢复请求响应。

相对传统的波束恢复方法中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔最多第一时间窗，例如 7 个符号，可降低延迟，提高波束恢复的效率。

在图 8 所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求，网络设备确定在第一时间窗内接收到的第一个波束失败恢复请求，网络设备在第一时间窗内使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应，则终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

基于图 1 所示的波束恢复系统的架构示意图，请参见图 9，图 9 是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

步骤 S901：终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送调度请求。

具体地，当 DL 波束失效时，终端设备可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送调度请求。其中，网络设备可以对终端设备配置允许的最大波束数量，则终端设备可以使用小于等于最大波束数量的波束向网络设备发送调度请求。

例如，终端设备可以在第三单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用一个波束 1 向网络设备发送调度请求。又如，终端设备可以在第三单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用多个不同波束向网络设备发送调度请求，示例性的，终端设备在符号 3 上，分别使用波束 1 和波束 2 向网络设备发送调度请求。又如，以图 10 所示的信息传输的示意图为例，终端设备可以在第三单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用一个波束 1 向网络设备发送调度请求，并在符号 4 上使用一个波束 1 向网络设备发送调度请求。又如，终端设备可以在第三单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用多个不同波束向网络设备发送调度请求，并在符号 4 上使用多个不同波束向网络设备发送调度请求。

本发明实施例中，终端设备在第三单元时间窗所包含的至少一个符号上，使用多个不

同波束向网络设备发送调度请求，可加大子载波间隔。

本发明实施例中，网络设备可通过 RRC、MAC-CE 或者 DCI 等信令对终端设备配置允许的最大波束数量。其中，同一小区所有终端设备可以配置相同的最大波束数量，或者终端设备集群所包含的所有终端设备可以配置相同的最大波束数量，或者不同终端设备可配置不同的最大波束数量，当不同终端设备配置不同的最大波束数量时，该终端设备需要向网络设备上报该终端设备的能力。其中，可以通过直接法指示最大波束数量。可选的，可以通过映射方法描述最大波束数量。

本发明实施例中，网络设备可以对终端设备配置第三单元时间窗。其中，第三单元时间窗的起始时刻可以是配置有 RACH 资源的第一个符号，以图 10 所示的信息传输的示意图为例，配置有 RACH 资源的第一个符号为符号 3，则终端设备可以确定第三单元时间窗的起始时刻为符号 3。

本发明实施例中，网络设备可以对终端设备配置第四单元时间窗。其中，第四单元时间窗所包含的第一个符号为第三单元时间窗所包含的最后一个符号之后的第一个符号，以图 10 所示的信息传输的示意图为例，第三单元时间窗所包含的最后一个符号为符号 6，则终端设备可以确定第四单元时间窗所包含的第一个符号为符号 0。

其中，第三单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第三单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，第四单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第四单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，网络设备可以向终端设备发送第三长度指示信息，以指示第三单元时间窗的长度。可选的，可以通过直接法指示第三单元时间窗的长度。可选的，可以通过映射方式描述第三单元时间窗的长度。

其中，网络设备可以向终端设备发送第四长度指示信息，以指示第四单元时间窗的长度。可选的，可以通过直接法指示第四单元时间窗的长度。可选的，可以通过映射方式描述第四单元时间窗的长度。

其中，网络设备可以通过信令对终端设备配置第三单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过信令对终端设备配置第四单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过向终端设备发送第三长度指示信息的方式，通知终端设备配置了第三单元时间窗。

其中，网络设备可以通过向终端设备发送第四长度指示信息的方式，通知终端设备配置了第四单元时间窗。

步骤 S902：网络设备在第二时间窗内，在接收到的调度请求中确定一个调度请求。

具体地，网络设备可以按照接收 RACH 波束扫描方式在第二时间窗内接收终端设备发送的调度请求，并在接收到的调度请求中确定一个调度请求。

可选的，网络设备可以确定在第二时间窗内接收到的第一个调度请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所

承载的调度请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的调度请求。

其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第三单元时间窗所包含的第一个符号相同。

其中，第二时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

步骤 S903：网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应。

具体实现中，网络设备可以获取承载确定得到的调度请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送调度请求响应。例如承载确定得到的调度请求的波束为波束 1，波束 1 与波束 3 构成一个波束对，则网络设备可以在第二时间窗之后使用波束 3 向终端设备发送调度请求响应。

以图 10 所示的信息传输的示意图为例，终端设备可以在第二时间窗之后的第一个符号，即符号 0，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应，终端设备还可以在第二时间窗之后的第二个符号，即符号 1，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应。

可选的，网络设备可以通过 PDCCH 向终端设备发送调度请求响应。

可选的，网络设备可以通过 MAC-CE 向终端设备发送调度请求响应。

可选的，网络设备可以通过 RRC 向终端设备发送调度请求响应。

可选的，网络设备可以通过 PDSCH 向终端设备发送调度请求响应。

步骤 S904：终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的调度请求响应。

终端设备可以在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的调度请求响应。例如，若终端设备在第三单元时间窗所包含的至少一个符号上，分别使用波束 1 和波束 2 向网络设备发送调度请求，则终端设备可以在第四单元时间窗所包含的至少一个符号上，分别使用波束 1 和波束 2 接收网络设备发送的调度请求响应。

相对传统的波束恢复方法中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔最多第一时间窗，例如 7 个符号，可降低延迟，提高波束恢复的效率。

在图 9 所描述的方法中，终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送调度请求，网络设备在第二时间窗内，在接收到的调度请求中确定一个调度请求，网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应，终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的调度请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

基于图 1 所示的波束恢复系统的架构示意图，请参见图 11，图 11 是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

步骤 S1101：终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送波束失败恢复请求。

具体地，当 DL 波束失效时，终端设备可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送波束失败恢复请求。其中，网络设备可以对终端设备配置允许的最大波束数量，则终端设备可以使用小于等于最大波束数量的波束向网络设备发送波束失败恢复请求。

例如，终端设备可以在第三单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用一个波束 1 向网络设备发送波束失败恢复请求。又如，终端设备可以在第三单元时间窗中选取一个符号（例如符号 3），并在符号 3 上使用多个不同波束向网络设备发送波束失败恢复请求，示例性的，终端设备在符号 3 上，分别使用波束 1 和波束 2 向网络设备发送波束失败恢复请求。又如，以图 10 所示的信息传输的示意图为例，终端设备可以在第三单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用一个波束 1 向网络设备发送波束失败恢复请求，并在符号 4 上使用一个波束 1 向网络设备发送波束失败恢复请求。又如，终端设备可以在第三单元时间窗中选取多个符号（例如符号 3，符号 4），在符号 3 上使用多个不同波束向网络设备发送波束失败恢复请求，并在符号 4 上使用多个不同波束向网络设备发送波束失败恢复请求。

本发明实施例中，终端设备在第三单元时间窗所包含的至少一个符号上，使用多个不同波束向网络设备发送波束失败恢复请求，可加大子载波间隔。

本发明实施例中，网络设备可通过 RRC、MAC-CE 或者 DCI 等信令对终端设备配置允许的最大波束数量。其中，同一小区所有终端设备可以配置相同的最大波束数量，或者终端设备集群所包含的所有终端设备可以配置相同的最大波束数量，或者不同终端设备可配置不同的最大波束数量，当不同终端设备配置不同的最大波束数量时，该终端设备需要向网络设备上报该终端设备的能力。其中，可以通过直接法指示最大波束数量。可选的，可以通过映射方法描述最大波束数量。

本发明实施例中，网络设备可以对终端设备配置第三单元时间窗。其中，第三单元时间窗的起始时刻可以是配置有 RACH 资源的第一个符号，以图 10 所示的信息传输的示意图为例，配置有 RACH 资源的第一个符号为符号 3，则终端设备可以确定第三单元时间窗的起始时刻为符号 3。

本发明实施例中，网络设备可以对终端设备配置第四单元时间窗。其中，第四单元时间窗所包含的第一个符号为第三单元时间窗所包含的最后一个符号之后的第一个符号，以图 10 所示的信息传输的示意图为例，第三单元时间窗所包含的最后一个符号为符号 6，则终端设备可以确定第四单元时间窗所包含的第一个符号为符号 0。

其中，第三单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第三单元时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，第四单元时间窗的长度可以是固定长度，例如 4 个符号，可选的，第四单元时

间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

其中，网络设备可以向终端设备发送第三长度指示信息，以指示第三单元时间窗的长度。可选的，可以通过直接法指示第三单元时间窗的长度。可选的，可以通过映射方式描述第三单元时间窗的长度。

其中，网络设备可以向终端设备发送第四长度指示信息，以指示第四单元时间窗的长度。可选的，可以通过直接法指示第四单元时间窗的长度。可选的，可以通过映射方式描述第四单元时间窗的长度。

其中，网络设备可以通过信令对终端设备配置第三单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过信令对终端设备配置第四单元时间窗，例如 RRC、MAC-CE 或者 DCI 等。

其中，网络设备可以通过向终端设备发送第三长度指示信息的方式，通知终端设备配置了第三单元时间窗。

其中，网络设备可以通过向终端设备发送第四长度指示信息的方式，通知终端设备配置了第四单元时间窗。

步骤 S1102：网络设备在第二时间窗内，在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

具体地，网络设备可以按照接收 RACH 波束扫描方式在第二时间窗内接收终端设备发送的波束失败恢复请求，并在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

可选的，网络设备可以确定在第二时间窗内接收到的第一个波束失败恢复请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的波束失败恢复请求。

可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的波束失败恢复请求。

其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第三单元时间窗所包含的第一个符号相同。

其中，第二时间窗的长度可以是固定长度，例如 4 个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如 3 个符号或者 5 个符号等。

步骤 S1103：网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应。

具体实现中，网络设备可以获取承载确定得到的波束失败恢复请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送波束失败恢复请求响应。例如承载确定得到的波束失败恢复请求的波束为波束 1，波束 1 与波束 3 构成一个波束对，则网络设备可以在第二时间窗之后使用波束 3 向终端设备发送波束失败恢复请求响应。

以图 10 所示的信息传输的示意图为例，终端设备可以在第二时间窗之后的第一个符号，即符号 0，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应，终端设备还可以在第二时间窗之后的第二个符号，即符号 1，使用第一波束所

属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 PDCCH 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 MAC-CE 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 RRC 向终端设备发送波束失败恢复请求响应。

可选的，网络设备可以通过 PDSCH 向终端设备发送波束失败恢复请求响应。

步骤 S1104：终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的波束失败恢复请求响应。

终端设备可以在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的波束失败恢复请求响应。例如，若终端设备在第三单元时间窗所包含的至少一个符号上，分别使用波束 1 和波束 2 向网络设备发送波束失败恢复请求，则终端设备可以在第四单元时间窗所包含的至少一个符号上，分别使用波束 1 和波束 2 接收网络设备发送的波束失败恢复请求响应。

相对传统的波束恢复方法中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔最多第一时间窗，例如 7 个符号，可降低延迟，提高波束恢复的效率。

在图 11 所描述的方法中，终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送波束失败恢复请求，网络设备在第二时间窗内，在接收到的波束失败恢复请求中确定一个波束失败恢复请求，网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应，终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的波束失败恢复请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

上述详细阐述了本发明实施例的方法，下面提供了本发明实施例的装置。

请参见图 12，图 12 是本发明实施例提供的一种波束恢复装置的结构示意图，该波束恢复装置可以包括发送模块 1201 以及接收模块 1202，其中，各个模块的详细描述如下。

发送模块 1201，用于在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

接收模块 1202，用于在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

可选的，所述发送模块 1201，具体用于在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

可选的，所述接收模块 1202，具体用于在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

可选的，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块 1201，具体用于在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

可选的，所述接收模块 1202，具体用于在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

可选的，本发明实施例中的波束恢复装置还可以包括：

确定模块 1203，用于当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述波束恢复装置确定所述网络设备对所述波束恢复装置配置的第三时间窗；

所述发送模块 1201，还用于在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

可选的，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块 1201，具体用于在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

可选的，所述接收模块 1202，具体用于在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

可选的，所述发送模块 1201，具体用于基于所述网络设备对所述波束恢复装置配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

可选的，所述第一时间窗所包含的第一个符号为第一个配置有 RACH 资源的符号。

可选的，所述第一时间窗的长度是所述网络设备配置的。

可选的，所述第一时间窗所包含的符号的数量总和是根据所述网络设备对所述波束恢复装置配置的最大波束数量确定的。

需要说明的是，本发明实施例可具体参见图 3、5、6、8、9、11 所示实施例的相关描述，不再赘述。

本发明实施例中的波束恢复装置和方法实施例中的终端设备完全对应，由相应的模块执行相应的步骤，例如发送模块 1201 执行方法实施例中发送的步骤，接收模块 1202 执行方法实施例中接收的步骤，除发送接收外的其它步骤可以由确定模块 1203 或处理器执行。具体模块的功能可以参考相应的方法实施例，不再详述。

在图 12 所描述的波束恢复装置中，发送模块 1201 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，接收模块 1202 在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，可实现网络设备针对同一波束恢复装置发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

请参见图 13，图 13 是本发明实施例提供的一种终端设备，该终端设备包括处理器 1301、存储器 1302 以及收发器 1303，所述处理器 1301、存储器 1302 以及收发器 1303 通过总线相互连接。

存储器 1302 包括但不限于是随机存储记忆体（Random Access Memory，RAM）、只读

存储器（Read-Only Memory，ROM）、可擦除可编程只读存储器（Erasable Programmable Read Only Memory，EPROM）、或便携式只读存储器（Compact Disc Read-Only Memory，CD-ROM），该存储器 1302 用于存储相关指令及数据，例如用于恢复波束的请求等。收发器 1303 用于接收和发送数据，例如使用至少一个波束向网络设备发送用于恢复波束的请求，或者使用至少一个波束接收网络设备发送的用于波束恢复请求的响应等。存储器 1302 可以是一个单独的器件，也可以集成在处理器 1301 中。

处理器 1301 可以是一个或多个中央处理器（Central Processing Unit，CPU），或者一个或多个微控制单元（Microcontroller Unit，MCU）。在处理器 1301 是一个 CPU 的情况下，该 CPU 可以是单核 CPU，也可以是多核 CPU。其中，处理器 1301 可结合图 12 所示的波束恢复装置。

应理解，上述的收发器 1303 可以包括发射机和接收机。收发器 1303 还可以进一步包括天线，天线的数量可以为一个或多个。

上述的各个器件或部分器件可以集成到芯片中实现，如集成到基带芯片中实现。

该终端设备中的处理器 1301 用于读取所述存储器 1302 中存储的程序代码，执行以下操作：

通过收发器 1303 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

通过收发器 1303 在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

可选的，处理器 1301 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

可选的，处理器 1301 在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，具体可以为：

在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

可选的，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

处理器 1301 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

可选的，处理器 1301 在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，具体可以为：

在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

可选的，处理器 1301 还可以执行以下操作：

当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，确定所述网络设备对所述终端设备配置的第三时间窗；

在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

可选的，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

处理器 1301 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

可选的，处理器 1301 在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，具体可以为：

在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

可选的，处理器 1301 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

可选的，所述第一时间窗所包含的第一个符号为第一个配置有 RACH 资源的符号。

可选的，所述第一时间窗的长度是所述网络设备配置的。

可选的，所述第一时间窗所包含的符号的数量总和是根据所述网络设备对所述终端设备配置的最大波束数量确定的。

需要说明的是，本发明实施例可具体参见图 3、5、6、8、9、11 所示实施例的相关描述，不再赘述。

在图 13 所描述的终端设备中，处理器 1301 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，并在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

请参见图 14，图 14 是本发明实施例提供的一种波束恢复装置的结构示意图，该波束恢复装置可以包括接收模块 1401、确定模块 1402 以及发送模块 1403，其中，各个模块的详细描述如下。

接收模块 1401，用于接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

确定模块 1402，用于在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

发送模块 1403，用于使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

可选的，所述确定模块 1402，具体用于响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

可选的，所述确定模块 1402，具体用于响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

可选的，所述发送模块 1403，具体用于在所述第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

可选的，所述发送模块 1403，具体用于在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

需要说明的是，本发明实施例可具体参见图 3、5、6、8、9、11 所示实施例的相关描述，不再赘述。

本发明实施例中的波束恢复装置和方法实施例中的终端设备完全对应，由相应的模块执行相应的步骤，例如发送模块 1403 执行方法实施例中发送的步骤，接收模块 1401 执行方法实施例中接收的步骤，除发送接收外的其它步骤可以由确定模块 1402 或处理器执行。具体模块的功能可以参考相应的方法实施例，不再详述。

在图 14 所描述的波束恢复装置中，接收模块 1401 接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，确定模块 1402 在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，发送模块 1403 使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应，可实现网络设备针对同一波束恢复装置发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

请参见图 15，图 15 是本发明实施例提供的一种网络设备，该网络设备包括处理器 1501、存储器 1502 以及收发器 1503，所述处理器 1501、存储器 1502 以及收发器 1503 通过总线相互连接。

存储器 1502 包括但不限于是 RAM、ROM、EPROM、或 CD-ROM，该存储器 1502 用于存储相关指令及数据，例如用于恢复波束的请求等。收发器 1503 用于接收和发送数据，例如接收终端设备使用至少一个波束发送的用于恢复波束的请求，或者使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应等。存储器 1502 可以是一个单独的器件，也可以集成在处理器 1501 中。

处理器 1501 可以是一个或多个 CPU，或者一个或多个 MCU。在处理器 1501 是一个 CPU 的情况下，该 CPU 可以是单核 CPU，也可以是多核 CPU。其中，处理器 1501 可结合图 14 所示的波束恢复装置。

应理解，上述的收发器 1503 可以包括发射机和接收机。收发器 1503 还可以进一步包括天线，天线的数量可以为一个或多个。

该网络设备中的处理器 1501 用于读取所述存储器 1502 中存储的程序代码，执行以下

操作：

通过收发器 1503 接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

通过收发器 1503 使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

可选的，处理器 1501 在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：

响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

可选的，处理器 1501 在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：

响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

可选的，处理器 1501 使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，具体可以为：

在所述第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

可选的，处理器 1501 使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，具体可以为：

在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

在图 15 所描述的网络设备中，处理器 1501 接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，并使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

请参见图 16，图 16 是本发明实施例提供的一种波束恢复系统，该波束恢复系统可以包括图 13 所示的终端设备 1601 和图 15 所示的网络设备 1602，具体可以参见图 15、16 的描述，本发明实施例不再赘述。

本申请实施例还提供了一种通信芯片，其中存储有指令，当其在终端设备 1601 上运行时，使得所述通信芯片执行上述图 13 中的各种实现方式中终端设备对应的方法。

本申请实施例还提供了一种通信芯片，其中存储有指令，当其在网络设备 1602 上运行时，使得所述通信芯片执行上述图 15 中的各种实现方式中终端设备对应的方法。

上述各个方案的网络设备及终端设备具有实现上述方法中网络设备及终端设备执行的相应步骤的功能；所述功能可以通过硬件实现，也可以通过硬件执行相应的软件实现。所

述硬件或软件包括一个或多个与上述功能相对应的模块；例如发送模块可以由发射机替代，接收模块可以由接收机替代，其它模块，如处理模块等可以由处理器替代，分别执行各个方法实施例中的发送操作、接收操作以及相关的处理操作。

本领域普通技术人员可以理解实现上述实施例方法中的全部或部分流程，该流程可以由计算机程序来指令相关的硬件完成，该程序可存储于计算机可读取存储介质中，该程序在执行时，可包括如上述各方法实施例的流程。而前述的存储介质包括：ROM 或随机存储记忆体 RAM、磁碟或者光盘等各种可存储程序代码的介质。

在上述实施例中，可以全部或部分地通过软件、硬件、固件或者其任意组合来实现。当使用软件实现时，可以全部或部分地以计算机程序产品的形式实现。所述计算机程序产品包括一个或多个计算机指令。在计算机上加载和执行所述计算机程序指令时，全部或部分地产生按照本申请实施例所述的流程或功能。所述计算机可以是通用计算机、专用计算机、计算机网络、或者其他可编程装置。所述计算机指令可以存储在计算机可读存储介质中，或者从一个计算机可读存储介质向另一个计算机可读存储介质传输，例如，所述计算机指令可以从一个网站站点、计算机、服务器或数据中心通过有线（例如同轴电缆、光纤、数字用户线（DSL））或无线（例如红外、无线、微波等）方式向另一个网站站点、计算机、服务器或数据中心进行传输。所述计算机可读存储介质可以是计算机能够存取的任何可用介质或者是包含一个或多个可用介质集成的服务器、数据中心等数据存储设备。所述可用介质可以是磁性介质，(例如，软盘、硬盘、磁带)、光介质(例如，DVD)、或者半导体介质（例如固态硬盘 Solid State Disk (SSD)）等。

权 利 要 求

1、一种波束恢复方法，其特征在于，所述方法包括：

终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

2、如权利要求 1 所述的方法，其特征在于，所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

3、如权利要求 2 所述的方法，其特征在于，所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，包括：

所述终端设备在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

4、如权利要求 1 所述的方法，其特征在于，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

5、如权利要求 4 所述的方法，其特征在于，所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，包括：

所述终端设备在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

6、如权利要求 2~5 任一项所述的方法，其特征在于，所述方法还包括：

当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述终端设备确定所述网络设备对所述终端设备配置的第三时间窗；

所述终端设备在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

7、如权利要求 1 所述的方法，其特征在于，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

8、如权利要求 7 所述的方法，其特征在于，所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，包括：

所述终端设备在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

9、如权利要求 1~8 任一项所述的方法，其特征在于，所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

10、一种波束恢复方法，其特征在于，所述方法包括：

网络设备接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

所述网络设备在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

所述网络设备使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

11、如权利要求 10 所述的方法，其特征在于，所述网络设备在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，包括：

所述网络设备响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

12、如权利要求 10 所述的方法，其特征在于，所述网络设备在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，包括：

所述网络设备响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

13、如权利要求 10~12 任一项所述的方法，其特征在于，所述网络设备使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，包括：

所述网络设备在所述第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

14、如权利要求 10~12 任一项所述的方法，其特征在于，所述网络设备使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，包括：

所述网络设备在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

15、一种波束恢复装置，其特征在于，所述装置包括：

发送模块，用于在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

接收模块，用于在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

16、如权利要求 15 所述的装置，其特征在于，所述发送模块，具体用于：

在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

17、如权利要求 16 所述的装置，其特征在于，

所述接收模块，具体用于在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

18、如权利要求 15 所述的装置，其特征在于，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块，具体用于在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

19、如权利要求 18 所述的装置，其特征在于，

所述接收模块，具体用于在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

20、如权利要求 16~19 任一项所述的装置，其特征在于，所述装置还包括：

确定模块，用于当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述终端设备确定所述网络设备对所述终端设备配置的第三时间窗；

所述发送模块，还用于在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

21、如权利要求 15 所述的装置，其特征在于，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块，具体用于在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

22、如权利要求 21 所述的装置，其特征在于，

所述接收模块，具体用于在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

23、如权利要求 15~22 任一项所述的装置，其特征在于，

所述发送模块，具体用于基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

24、一种波束恢复装置，其特征在于，所述装置包括：

接收模块，用于接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

确定模块，用于在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

发送模块，用于使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

25、如权利要求 24 所述的装置，其特征在于，

所述确定模块，具体用于响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

26、如权利要求 24 所述的装置，其特征在于，

所述确定模块，具体用于响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

27、如权利要求 24~26 任一项所述的装置，其特征在于，

所述发送模块，具体用于在所述第二时间窗内使用确定得到的用于恢复波束的请求对

应的波束，向所述终端设备发送用于波束恢复请求的响应。

28、如权利要求 24~26 任一项所述的装置，其特征在于，

所述发送模块，具体用于在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

经修改的权利要求
国际局收到日：2018年08月17日（17.08.2018）

1、一种波束恢复方法，其特征在于，所述方法包括：

终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

2、如权利要求 1 所述的方法，其特征在于，所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

3、如权利要求 2 所述的方法，其特征在于，所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，包括：

所述终端设备在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

4、如权利要求 1 所述的方法，其特征在于，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

5、如权利要求 4 所述的方法，其特征在于，所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，包括：

所述终端设备在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

6、如权利要求 2~5 任一项所述的方法，其特征在于，所述方法还包括：

当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述终端设备确定所述网络设备对所述终端设备配置的第三时间窗；

所述终端设备在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

7、如权利要求 1 所述的方法，其特征在于，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

8、如权利要求 7 所述的方法，其特征在于，所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，包括：

所述终端设备在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

9、如权利要求 1~8 任一项所述的方法，其特征在于，所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，包括：

所述终端设备基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

10、一种波束恢复方法，其特征在于，所述方法包括：

网络设备接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

所述网络设备在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

所述网络设备使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

11、如权利要求 10 所述的方法，其特征在于，所述网络设备在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，包括：

所述网络设备响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

12、如权利要求 10 所述的方法，其特征在于，所述网络设备在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，包括：

所述网络设备响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

13、如权利要求 10~12 任一项所述的方法，其特征在于，所述网络设备使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，包括：

所述网络设备在所述第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

14、如权利要求 10~12 任一项所述的方法，其特征在于，所述网络设备使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，包括：

所述网络设备在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

15、一种波束恢复装置，其特征在于，所述装置包括：

发送模块，用于在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

接收模块，用于在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

16、如权利要求 15 所述的装置，其特征在于，所述发送模块，具体用于：

在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

17、如权利要求 16 所述的装置，其特征在于，

所述接收模块，具体用于在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

18、如权利要求 15 所述的装置，其特征在于，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块，具体用于在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

19、如权利要求 18 所述的装置，其特征在于，

所述接收模块，具体用于在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

20、如权利要求 16~19 任一项所述的装置，其特征在于，所述装置还包括：

确定模块，用于当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述终端设备确定所述网络设备对所述终端设备配置的第三时间窗；

所述发送模块，还用于在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

21、如权利要求 15 所述的装置，其特征在于，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块，具体用于在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

22、如权利要求 21 所述的装置，其特征在于，

所述接收模块，具体用于在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

23、如权利要求 15~22 任一项所述的装置，其特征在于，

所述发送模块，具体用于基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

24、一种波束恢复装置，其特征在于，所述装置包括：

接收模块，用于接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

确定模块，用于在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

发送模块，用于使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

25、如权利要求 24 所述的装置，其特征在于，

所述确定模块，具体用于响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

26、如权利要求 24 所述的装置，其特征在于，

所述确定模块，具体用于响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

27、如权利要求 24~26 任一项所述的装置，其特征在于，

所述发送模块，具体用于在所述第二时间窗内使用确定得到的用于恢复波束的请求对

应的波束，向所述终端设备发送用于波束恢复请求的响应。

28、如权利要求 24~26 任一项所述的装置，其特征在于，

所述发送模块，具体用于在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

29、如权利要求 1 至 9 任一项所述的方法，其特征在于，所述用于恢复波束的请求通过随机接入信道 RACH 资源发送。

30、如权利要求 1 至 9 任一项所述的方法，其特征在于，所述用于波束恢复请求的响应通过物理下行控制信道 PDCCH 发送，所述 PDCCH 的循环冗余校验 CRC 由小区无线网络临时标识 C-RNTI 加扰。

31、如权利要求 4 或 5 所述的方法，其特征在于，所述第一单元时间窗的起始时刻是配置有 RACH 资源的第一个符号。

32、如权利要求 1 至 9 任一项所述的方法，其特征在于，该方法之前还包括：终端设备获取网络设备配置的用于发送恢复波束的请求时所使用的最大波束数量。

33、如权利要求 10 至 14 任一项所述的方法，其特征在于，该方法之前还包括：网络设备为终端设备配置用于发送恢复波束的请求时所使用的最大波束数量。

34、如权利要求 10 至 14 任一项所述的方法，其特征在于，所述用于恢复波束的请求通过随机接入信道 RACH 资源发送。

35、如权利要求 10 至 14 任一项所述的方法，其特征在于，所述用于波束恢复请求的响应通过物理下行控制信道 PDCCH 发送，所述 PDCCH 的循环冗余校验 CRC 由小区无线网络临时标识 C-RNTI 加扰。

36、如权利要求 15 至 23 任一项所述的装置，其特征在于，所述用于恢复波束的请求通过随机接入信道 RACH 资源发送。

37、如权利要求 15 至 23 任一项所述的装置，其特征在于，所述用于波束恢复请求的响应通过物理下行控制信道 PDCCH 发送，所述 PDCCH 的循环冗余校验 CRC 由小区无线网络临时标识 C-RNTI 加扰。

38、如权利要求 18 或 19 所述的装置，其特征在于，所述第一单元时间窗的起始时刻是配置有 RACH 资源的第一个符号。

39、如权利要求 15 至 13 任一项所述的装置，其特征在于，所述接收模块还用于：获取网络设备配置的用于发送恢复波束的请求时所使用的最大波束数量。

40、如权利要求 24 至 28 任一项所述的装置，其特征在于，所述确定模块还用于：为终端设备配置用于发送恢复波束的请求时所使用的最大波束数量。

41、如权利要求 24 至 28 任一项所述的装置，其特征在于，所述用于恢复波束的请求通过随机接入信道 RACH 资源发送。

42、如权利要求 24 至 28 任一项所述的装置，其特征在于，所述用于波束恢复请求的响应通过物理下行控制信道 PDCCH 发送，所述 PDCCH 的循环冗余校验 CRC 由小区无线网络临时标识 C-RNTI 加扰。

43、一种波束恢复装置，其特征在于，包括：存储器和处理器；所述处理器被配置为支持所述装置执行如权利要求 1 至 9 或 29-32 任一项所述的方法的功能，所述存储器用于保存所述装置的程序和数据。

44、一种波束恢复装置，其特征在于，包括：存储器和处理器；所述处理器被配置为支持所述装置执行如权利要求 10 至 14 或 33-35 任一项所述的方法的功能，所述存储器用于保存所述装置的程序和数据。

45、一种芯片系统，其特征在于，包括：处理器，所述处理器被配置为支持终端设备执行如权利要求 1 至 9 或 29-32 任一项所述的方法的功能。

46、如权利要求 45 所述的芯片系统，其特征在于，所述芯片系统还包括存储器，所述存储器用于保存所述终端设备的程序指令和数据。

47、一种芯片系统，其特征在于，包括：处理器，所述处理器被配置为支持网络设备执行如权利要求 10 至 14 或 33-35 任一项所述的方法的功能。

48、如权利要求 47 所述的芯片系统，其特征在于，所述芯片系统还包括存储器，所述存储器用于保存所述网络设备的程序指令和数据。

49、一种计算机存储介质，其特征在于，用于存储计算机程序，当所述计算机程序在终端设备上运行时，使得所述终端设备执行如权利要求 1 至 9 或 29-32 任一项所述的方法。

50、一种计算机存储介质，其特征在于，用于存储计算机程序，当所述计算机程序在

网络设备上运行时，使得所述网络设备执行如权利要求 10 至 14 或 33-35 任一项所述的方法。

51、一种计算机程序产品，其特征在于，当所述计算机程序产品在终端设备上运行时，使得所述终端设备执行如权利要求 1 至 9 或 29-32 任一项所述的方法。

52、一种计算机程序产品，其特征在于，当所述计算机程序产品在网络设备上运行时，使得所述网络设备执行如权利要求 10 至 14 或 33-35 任一项所述的方法。

53、一种波束恢复系统，其特征在于，所述波束恢复系统包括如权利要求 43 所述的波束恢复装置和如权利要求 44 所述的波束恢复装置。

54、一种波束恢复装置，用于实现如权利要求 1 至 9 或 29-32 任一项所述的方法步骤。

55、一种波束恢复装置，用于实现如权利要求 10 至 14 或 33-35 任一项所述的方法步骤。

INTERNATIONAL SEARCH REPORT

International application No.
PCT/CN2018/085733

A. CLASSIFICATION OF SUBJECT MATTER

H04B 7/0408 (2017.01) i; H04W 72/04 (2009.01) i; H04L 5/00 (2006.01) i

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

H04B, H04W, H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

CNABS; CNTXT; CNKI; VEN; USTXT; WOTXT; EPTXT; XP3GPP: 波束, 恢复, 时间窗, 调度请求, 响应; beam, recover, time 1w window, scheduling 1w request, SR, response

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	QUALCOMM INCORPORATED, Beam Recovery Request, 3GPP TSG-RAN WG 2 Meeting #97bis, R2-1703562, 07 April 2017 (07.04.2017), sections 1-2	1-28
Y	QUALCOM INCORPORATED, Beam Management, 3GPP TSG-RAN WG 2 Meeting #97bis, R2-1703564, 07 April 2017 (07.04.2017), sections 2.1-2.2	1-28
A	INTEL CORPORATION, Radio Link Monitoring, Beam Failure and Radio Link Failure, 3GPP TSG RAN WG 2 Meeting #97bis, R2-1703423, 07 April 2017 (07.04.2017), entire document	1-28
A	WO 2017022902 A1 (SAMSUNG ELECTRONICS CO., LTD.), 09 February 2017 (09.02.2017), entire document	1-28

☐ Further documents are listed in the continuation of Box C. ☒ See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search	Date of mailing of the international search report

* 引用文件的具体类型:

"A" 认为不特别相关的表示了现有技术一般状态的文件

"E" 在国际申请日的当天或之后公布的在先申请或专利

"L" 可能对优先权要求构成怀疑的文件，或为确定另一篇引用文件的公布日而引用的或者因其他特殊理由而引用的文件(如具体说明的)

"O" 涉及口头公开、使用、展览或其他方式公开的文件

"P" 公布日先于国际申请日但迟于所要求的优先权日的文件

"T" 在申请日或优先权日之后公布，与申请不相抵触，但为了理解发明之理论或原理的在后文件

"X" 特别相关的文件，单独考虑该文件，认定要求保护的发明不是新颖的或不具有创造性

"Y" 特别相关的文件，当该文件与另一篇或者多篇该类文件结合并且这种结合对于本领域技术人员为显而易见时，要求保护的发明不具有创造性

EXAMINER SIGNATURE

Examiner Signature		Date Considered	

*EXAMINER: Initial if reference considered, whether or not citation is in conformance with MPEP 609. Draw line through a citation if not in conformance and not considered. Include copy of this form with next communication to applicant.

[1] See Kind Codes of USPTO Patent Documents at www.USPTO.GOV or MPEP 901.04. [2] Enter office that issued the document, by the two-letter code (WIPO Standard ST.3). [3] For Japanese patent documents, the indication of the year of the reign of the Emperor must precede the serial number of the patent document. [4] Kind of document by the appropriate symbols as indicated on the document under WIPO Standard ST.16 if possible. [5] Applicant is to place a check mark here if English language translation is attached.

This collection of information is required by 37 CFR 1.97 and 1.98. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 1 hour to complete, including gathering, preparing and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these record s.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

Description

TECHNICAL FIELD

[0001] The present invention relates to the field of communications technologies, and in particular, to a method and an apparatus for measuring communication quality.

BACKGROUND

[0002] In the field of communications technologies, signals may usually be classified into two types: one type of signal carries information from a higher layer; the other type of signal does not carry information from a higher layer, and this type of signal is usually used for assisting in or indicating reception of the former type of signal. A transmit power of a signal is a very important parameter for both types of signals above. For example, a power of a reference signal may be used for deriving a path loss estimation value, and the path loss estimation value may be used as a part of open-loop control to implement uplink power control, or may be used as a basis for selecting a cell (or a transmit node, or a receive node). A power ratio of a physical downlink shared channel (PDSCH) signal to a reference signal (for example, a cell-specific reference signal (CRS) or a channel state information reference signal (CSI-RS)) may be used for deriving channel state information (CSI), thereby facilitating implementation of scheduling and link adaptation.

[0003] In existing Long Term Evolution (LTE) Releases R8-R11, a power-related parameter is determined on a base station side or a network side, and is notified to user equipment (UE) by using higher layer signaling. Because a conventional base station antenna configuration has a fixed downtilt, and an uplink and a downlink undergo similar path losses, so that a downlink path loss can be desirably used for estimating an uplink path loss. Therefore, distinguishing of antenna ports can be omitted in the power-related parameter sent by the base station side or the network side, and especially in a case of multiple antenna ports. If antenna ports are not distinguished, a downlink path loss can be desirably used for estimating an uplink path loss. The technology is desirably applicable to the conventional base station antenna configuration, especially if transmit powers of antenna ports are the same. In another aspect, a reference signal received power (RSRP), of a current cell/node or an adjacent cell/node, reported by user equipment (UE) may be used by a base station or an evolved node B (eNB) to select a serving cell or node for the UE. In the prior art, the RSRP is an estimation obtained by performing averaging on different antenna ports.

[0004] To lower a system cost and at the same time reach a higher system capacity and coverage requirement, active antenna systems (AAS) have been widely deployed in practice. At present, the LTE R12 standard that is about to be launched is considering enhancement of communication performance after introduction of an AAS system. Different from a conventional base station antenna, an AAS further provides design flexibility in a vertical direction of an antenna, where independent downtilts may be used in an uplink and a downlink, and powers of different antenna ports may be different. In addition, for AAS base stations, even if the AAS base stations have a same quantity of antenna ports, antenna array structures of the AAS base stations may also be different. Therefore, antenna ports having a same sequence number may also have different transmit powers in different array structures. In such a case, in the prior art, power control is implemented based on a downlink reference signal received power, or a method for selecting a cell/node is no longer effective. In the prior art, correct distinguishing cannot be performed if transmit powers of antenna ports are different, and a technical solution that accurately and effectively estimates an uplink path loss and estimates channel state information cannot be provided.

[0005] US 2012/176939 A1 discloses a communications system and a method for performing communications, wherein User Equipments (UEs) are provided with UE-specific configuration information, such as CSI-RS (Channel Status Indication-Reference Signal) patterns, antenna port groupings, reference signal configurations, subframe configurations, and/or scrambling codes.

[0006] WO 2013/081368 A1 discloses a method and apparatus for transmitting a reference signal and discloses an uplink transmission method and apparatus using the same. The method of transmitting a reference signal in a Cooperative Multi-Point (CoMP) system includes sending configuration information on the reference signal and sending the reference signal based on the configuration information on the reference signal, wherein the configuration information on the reference signal indicates Energy Per Resource Element (EPRE), used to transmit the reference signal, for each of transmission points that participate in the transmission of the reference signal.

SUMMARY

[0007] Embodiments of the present invention provide methods for measuring communication quality, thereby overcoming a problem in the prior art that accurate signal quality measurement information cannot be acquired in a multi-antenna system.

[0008] An aspect provides a method for measuring communication quality, including:

receiving reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group;

obtaining reference signal port information in at least one port group according to the reference signal port configuration information; and

acquiring signal quality measurement information according to the reference signal port information in the at least one port group;

wherein the reference signal resource configuration information further includes: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups,

wherein the acquiring the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups includes:

obtaining, according to the reference signal port configuration information, signal quality measurement information corresponding to the at least two port groups;

performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information, wherein the performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information includes:

obtaining the signal quality measurement information according to a formula

$$SQ = \left(\sum_{g=0}^{n-1} p_g \cdot SQ_g \right) \Big/ \left(\sum_{g=0}^{n-1} p_g \right),$$

where

SQ_g is signal quality measurement information of a specified port group, g is a sequence number of a specified port group, n is a quantity of specified port groups, $n \geq 2$, and p_g is a reference signal power of a specified port group, where the reference signal power of the specified port group is obtained according to the reference signal power information of the at least two port groups.

[0009] In a first possible implementation manner with reference to the above aspect, the reference signal power information of the at least two port groups includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or

a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0010] According to the method for measuring communication quality provided in the embodiments of the present invention, reference signal resource configuration information is sent to UE on a user side, and the UE may perform processing according to reference signal quality, of one port group or multiple port groups, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. Therefore, UE is enabled to acquire signal quality measurement information, so that the UE can perform more accurate cell selection and uplink power control.

BRIEF DESCRIPTION OF DRAWINGS

[0011] To describe the technical solutions in the embodiments of the present invention or in the prior art more clearly, the following briefly introduces the accompanying drawings required for describing the embodiments or the prior art. Apparently, the accompanying drawings in the following description show merely some embodiments of the present invention, and a person of ordinary skill in the art may still derive other drawings from these accompanying drawings

without creative efforts. It has to be noted that Embodiment 2 described below is an embodiment of the present invention as defined in the claims, while Embodiment 1 and 3-12 are examples not covered by the claims.

FIG. 1 is a flowchart of a method for measuring communication quality according to Embodiment 1 of the present invention;
FIG. 2 is a flowchart of a method for measuring communication quality according to Embodiment 2 of the present invention;
FIG. 3 is a brief schematic diagram of different uniform linear array antenna array configurations;
FIG. 4 is a brief schematic diagram of different cross-polarization antenna array configurations;
FIG. 5 is a flowchart of a method for measuring communication quality according to Embodiment 3 of the present invention;
FIG. 6 is a flowchart of a method for measuring communication quality according to Embodiment 4 of the present invention;
FIG. 7 is a brief schematic diagram of a network side apparatus according to Embodiment 5 of the present invention;
FIG. 8 is a brief schematic diagram of user equipment according to Embodiment 6 of the present invention;
FIG. 9 is a brief schematic diagram of a network side apparatus according to Embodiment 7 of the present invention;
FIG. 10 is a brief schematic diagram of user equipment according to Embodiment 8 of the present invention;
FIG. 11 is a brief schematic diagram of a network side apparatus according to Embodiment 9 of the present invention;
FIG. 12 is a brief schematic diagram of user equipment according to Embodiment 10 of the present invention;
FIG. 13 is a brief schematic diagram of a network side apparatus according to Embodiment 11 of the present invention; and
FIG. 14 is a brief schematic diagram of user equipment according to Embodiment 12 of the present invention.

DESCRIPTION OF EMBODIMENTS

[0012] The following clearly and completely describes the technical solutions in the embodiments of the present invention with reference to the accompanying drawings in the embodiments of the present invention. Apparently, the described embodiments are merely some but not all of the embodiments of the present invention. All other embodiments obtained by a person of ordinary skill in the art based on the embodiments of the present invention without creative efforts shall fall within the protection scope of the present invention.

Embodiment 1

[0013] An embodiment of the present invention provides a method for measuring communication quality. As shown in FIG. 1, the method includes:

Step S01: Determine reference signal resource configuration information, where the reference signal resource configuration information includes: reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping between the reference signal port and a port group.

[0014] The operation may specifically be executed on a base station side or a network side (for example, a Universal Terrestrial Radio Access Network (UTRAN)), or an evolved UTRAN, or an evolved node B.

[0015] When the reference signal resource configuration information includes the reference signal port configuration information, and optionally, the reference signal resource configuration information may further include reference signal power information of at least one port group, the reference signal resource configuration information is sent to user equipment (UE), so that the user equipment acquires signal quality measurement information according to the reference signal resource configuration information. Because reference signal ports are allocated to multiple groups, the UE may perform processing according to reference signal quality, of one port group or multiple port groups, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. Therefore, the signal quality measurement information acquired in the solution enables the UE to perform more accurate cell selection and uplink power control.

[0016] It should be further understood that for detailed description of the reference signal port configuration information included in the reference signal resource configuration information, reference may be made to the description of step 101 in Embodiment 2.

[0017] Further, the reference signal resource configuration information may further include: any one of a reference signal configuration and a reference signal subframe configuration. Therefore, the UE can receive a reference signal according to the information. It should be understood that, however, this embodiment of the present invention does not limit that any one of the reference signal configuration and the reference signal subframe configuration is necessarily delivered to the UE by using the reference signal resource configuration information, and may also be delivered to the

UE in a form of other information. It should be pointed out that the reference signal configuration or the reference signal subframe configuration may also be predefined, or is implicitly derived according to a parameter, for example, a cell ID or a UE ID, that is known in advance, and is known to both a base station and the UE, which is not limited in this embodiment of the present invention.

[0018] Step S02: Send the determined reference signal resource configuration information to user equipment, so that the user equipment acquires signal quality measurement information according to the reference signal port configuration information.

[0019] Specifically, the foregoing signal quality measurement information may include:
any one or any combination of a reference signal received power RSRP, a reference signal received quality RSRQ, and a reference signal strength indicator RSSI.

[0020] According to the method described in Embodiment 1 above, in the method, reference signal resource configuration information is determined on a network side, and the reference signal resource configuration information is sent to a user side, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping between the reference signal port and a port group. In the method, it can be avoided that reference signal power related information is indicated port by port, so as to reduce a signaling overhead; further, a uniform power indicator is used for ports in a port group, and for different port groups, power related information of the port groups may be indicated independently, so that full use of an antenna configuration or an antenna array structure is made, thereby enabling a system to flexibly select reference signal power related information according to the antenna configuration or the antenna array structure; because an antenna array may have symmetric weights, by means of the symmetry of the weights, design complexity in beamforming or side lobe suppression can be reduced.

[0021] Further, the reference signal resource configuration information is sent to UE on the user side, and the UE may perform processing according to reference signal quality of at least one port group in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. The UE is enabled to acquire signal quality measurement information, so that the UE can perform more accurate cell selection and uplink power control.

[0022] Optionally, the method further includes:
Step S03: Receive the signal quality measurement information sent by the user equipment.

[0023] Optionally, when the signal quality measurement information is a reference signal received power RSRP, the method further includes:
Step S04: Send, to the user equipment, filter coefficient information that is used by the user equipment to perform, based on the filter coefficient information, filtering on the reference signal received power RSRP and obtain a path loss estimation value.

[0024] Specifically, the filter coefficient information may be sent to the user equipment at a same time when the determined reference signal resource configuration information is sent to the user equipment in step S02, for example, the filter coefficient information and the determined reference signal resource configuration information are sent in a same subframe; or may be sent before or after the determined reference signal resource configuration information is sent to the user equipment in step S02. The filter coefficient information and the reference signal resource configuration information may be sent in an information element (IE) of same or different higher layer signaling such as RRC signaling, or same or different downlink control information (DCI).

[0025] Optionally, the method further includes:
Step S05: Receive an uplink physical channel or an uplink physical signal sent by the user equipment, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation by the user equipment according to the path loss estimation value.

[0026] Optionally, the reference signal resource configuration information further includes: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups; and
the reference signal power information of the at least two port groups includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or
a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0027] Optionally, the reference signal port configuration information is a single index, or is a double index, or is an index after combined coding.

[0028] Optionally, the reference signal power information of the port group at least includes: reference signal powers of ports in one port group are the same.

[0029] The first port group is one port group among the at least one port group.

Embodiment 2

[0030] This embodiment of the present invention provides a method for measuring communication quality. As shown in FIG. 2, the method includes:

Step 101: Receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group.

[0031] Specifically, UE receives the reference signal resource configuration information, which may be that the UE receives, by using higher layer signaling (for example, radio resource control (RRC) signaling) or dynamic signaling (for example, downlink control information (DCI), the reference signal resource configuration information notified by an eNB, or obtains, based on a cell identity (ID), the reference signal resource configuration information. The higher layer signaling may be sent by using a data channel such as a physical downlink shared channel (PDSCH for short). The dynamic signaling, for example, the DCI, is sent by using a control channel such as a physical downlink control channel (PDCCH) or an enhanced PDCCH (ePDCCH).

[0032] It should be understood that the reference signal port configuration information is used for indicating a mapping between a reference signal port and a port group. The mapping relationship between a reference signal port and a port group may be predefined, and is known to both the base station and the user equipment. Therefore, a base station side and a user equipment side can both find the reference signal port configuration message by means of identification.

[0033] It should be further understood that according to information about a mapping relationship between a reference signal port group and a corresponding port, and a mapping index of the port group, a port included in the port group may be uniquely determined. As shown in Tables 1 to 3, after learning the information about the mapping relationship between a reference signal port group and a corresponding port, and the mapping index of the port group, a device can learn a port in the corresponding port group. Ports included in the port group may be predefined, and for a different index, a predefined port group may be obtained according to planning. It should be noted that one reference signal port corresponds to one antenna port, and one antenna port corresponds to one reference signal port. Channel information of an antenna signal port is obtained by means of measurement of a reference signal port. Therefore, usually the predefined port group may be obtained according to planning of an antenna port array configuration.

[0034] One reference signal port or antenna port usually corresponds to one physical antenna or one virtual antenna, where the virtual antenna may be obtained by means of weighted combination of multiple physical antennas. An actual antenna deployment may have a different antenna configuration and antenna port array form. For example, FIG. 3 shows different uniform linear array (ULA) antenna port array configurations. An antenna port array A is a 2-row 4-column uniform linear array, an antenna port array B is a 2-row 8-column uniform linear array, and an antenna port array C is a 4-row 4-column uniform linear array. Although both the antenna port array B and the antenna port array C have 16 ports, array forms of the antenna port array B and the antenna port array C are also different. For another example, FIG. 4 shows different cross-polarization (XPO) antenna array configurations. An antenna port array A is a 2-row 2-column cross-polarization antenna array, an antenna port array B is a 2-row 4-column uniform linear array, and an antenna port array C is a 4-row 2-column uniform linear array. Different polarization antennas may be located in a same column. Although both the antenna port array B and the antenna port array C have 16 ports, array forms of the antenna port array B and the antenna port array C are also different. The antenna port array is referred to as an antenna array for short below.

[0035] Optionally, as another embodiment, the reference signal port configuration information includes a quantity of reference signal ports and a mapping index, where the mapping index is used for indicating a mapping between a reference signal port group and a corresponding port. 8-antenna arrays represented by the antenna array A shown in FIG. 3 and the antenna array A shown in FIG. 4 are used as examples. The reference signal port configuration information includes: a quantity of reference signal ports is 8 and a mapping index is 0 or 1. The predefined mapping relationship between a reference signal port and a port group may be defined by using a function, or may be regulated by using a predefined table. For example, as shown in Table 1, the first row may be the reference signal port configuration information of the antenna array A in FIG. 3, and the mapping indication information includes: a quantity of reference signal ports is 8, a mapping index is 0, and two port groups are a port group 0 and a port group 1. The second row in Table 1 may be the reference signal port configuration information of the antenna array A in FIG. 4, and the mapping indication information includes: a quantity of reference signal ports is 8, a mapping index is 1, and two port groups are a port group 0 and a port group 1. It should be pointed out that, in this embodiment, a reference signal port and a reference signal port group may be interchangeable with an antenna port and an antenna port group.

Table 1-Mapping between a port and a port group

Index	Mapping between a port and a port group

0	0, 3, 4, 7	1, 2, 5, 6
1	0, 1, 4, 5	2, 3, 6, 7

[0036] Further, when a mapping index value is 0, the port group 0 includes reference signal ports (or antenna ports) 0, 3, 4, and 7, the port group 1 includes reference signal ports (or antenna ports) 1, 2, 5, and 6; when a mapping index value is 1, the port group 0 includes reference signal ports (or antenna ports) 0, 1, 4, and 5, the port group 1 includes reference signal ports (or antenna ports) 2, 3, 6, and 7.

[0037] 16-antenna arrays represented by the antenna array B or the antenna array C shown in FIG. 3 and the antenna array B or the antenna array C shown in FIG. 4 are used as examples. The reference signal port configuration information includes: a quantity of reference signal ports is 16, and a mapping index is 0 or 1 or 2 or 3. The predefined mapping relationship between a reference signal port and a port group may be defined by using a function, or may be regulated by using a predefined table, for example, as shown in Table 2:

Table 2-Mapping between a port and a port group

Index	Mapping between a port and a port group			
	0	1	2	3
0	0, 3, 8, 11	4, 7, 12, 15	1, 2, 9, 10	5, 6, 13, 14
1	0, 1, 12, 13	2,3, 14, 15	4, 5, 8, 9	6, 7, 10, 11
2	0, 7, 8, 15	1, 6, 9, 14	2, 5, 10, 13	3, 4, 11, 12
3	0, 3, 12, 15	1,2, 13, 14	4, 7, 8, 11	5, 6, 9, 10

[0038] It may be assumed that the antenna array B in FIG. 3 is the first row in Table 2, that is, a mapping index value is 0, a port group 0 includes reference signal ports (or antenna ports) 0, 3, 8, and 11, a port group 1 includes reference signal ports (or antenna ports) 4, 7, 12, and 15, a port group 2 includes reference signal ports (or antenna ports) 1, 2, 9, and 10, and a port group 3 includes reference signal ports (or antenna ports) 5, 6, 13, and 14. When the mapping index value is 1 or 2 or 3, reference signal ports included in each port group may be sequentially obtained by analogy from the foregoing Table.

[0039] Optionally, as another embodiment, the reference signal port configuration information may include a port group mapping double index (m, n). In this case, the predefined mapping relationship between a reference signal port and a port group may be defined by using a function, or may be regulated by using a predefined table, for example, as shown in Table 3:

Table 3-Mapping between a port and a port group

Double index (m, n)	Mapping between a port and a port group			
	0	1	2	3
(2, 4)	0, 1, 4, 5	2, 3, 6, 7	-	-
(2, 8)	0, 3, 8, 11	4, 7, 12, 15	1, 2, 9, 10	6, 7, 10, 11
(4, 4)	0, 1, 12, 13	2, 3, 14, 15	4, 5, 8, 9	6, 7, 10, 11

[0040] Optionally, the double index (m, n) may indicate that a quantity of reference signal ports is a product of m and n.

[0041] Further, combined coding may be performed on the double index information. For example, combined coding of the double index in Table 3 above is shown in Table 3a or 3b.

Table 3a-Mapping between a port and a port group

Combined coding of a double index (m, n)	Double index (m, n)	Mapping between a port and a port group			
		0	1	2	3
0	(2, 4)	0, 1, 4, 5	2, 3, 6, 7	-	-
1	(2, 8)	0, 3, 8, 11	4, 7, 12, 15	1, 2, 9, 10	6, 7, 10, 11
2	(4, 4)	0, 1, 12, 13	2, 3, 14, 15	4, 5, 8, 9	6, 7, 10, 11

or

Table 3b-Mapping between a port and a port group

Mapping index	Double index (m, n)	Mapping between a port and a port group			
		0	1	2	3
0	(2, 4)	0, 1, 4, 5	2, 3, 6, 7	-	-
1	(2, 8)	0, 3, 8, 11	4, 7, 12, 15	1, 2, 9, 10	6, 7, 10, 11
2	(4, 4)	0, 1, 12, 13	2, 3, 14, 15	4, 5, 8, 9	6, 7, 10, 11

[0042] Optionally, grouping of port groups may be that 4 reference signal ports (or antenna ports) are used as one port group.

[0043] It should be further pointed out that grouping of port groups may also be not limited to a port group including 4 reference signal ports, or may be a port group having 2 or 8 ports or in another formation. In addition, a number of a reference signal port included in each port group is also not limited to the foregoing value, and may be flexibly selected according to an actual antenna configuration or deployment. The foregoing predefined port group mapping and mapping indication information may enable a system to adapt to more antenna configurations and antenna array deployments.

[0044] Optionally, the reference signal resource configuration information may further include: any one of a reference signal configuration and a reference signal subframe configuration. The reference signal configuration may include: any one of a subcarrier used by a reference signal port, an orthogonal frequency division multiplexing (OFDM) symbol, and a code resource. The reference signal subframe configuration may include: any one of a subframe position occupied by a reference signal port, a subframe period, and a subframe offset. It should be pointed out that the reference signal configuration or the reference signal subframe configuration may also be predefined, or is implicitly derived according to a parameter, for example, a cell ID or a UE ID, that is known in advance, and is known to both the base station and the UE, which is not limited in this embodiment of the present invention.

[0045] Step 102: Obtain reference signal port information in at least one port group according to the reference signal port configuration information.

[0046] Step 103: Acquire signal quality measurement information according to the reference signal port information in the at least one port group.

[0047] Specifically, the reference signal or signal may specifically include a cell-specific reference signal CSR, or a channel state information reference signal (CSI-RS), or a demodulation reference signal (DMRS), but is not limited to current examples.

[0048] The signal quality measurement information may be a reference signal received power (RSRP) or a reference signal received quality (RSRQ) or a reference signal strength indicator (RSSI), or may also be other signal quality measurement information defined based on a reference signal.

[0049] In this embodiment, a reference signal received power RSRP is used as an example and one implementation is described in detail. This solution is not limited to another implementation solution, and a solution of acquiring other signal quality measurement information is also not limited.

[0050] Optionally, the obtaining reference signal port information in at least one port group according to the reference signal port configuration information in step 102 may include:

obtaining reference signal port information in one specified port group according to the reference signal port configuration information; and

the acquiring signal quality measurement information according to the reference signal port information in the at least one port group in step 103 includes:

acquiring the signal quality measurement information according to the reference signal port information in the one

specified port group.

[0051] For example, a mapping index in Table 2 is 0, and in this case, reference signal ports included in a port group 0 are 0, 3, 8, and 11. Complex RSRP measurement of each antenna port may be correlation between two adjacent reference signal resource elements (RE, Resource Element). The two adjacent REs herein may refer to two adjacent REs in a frequency domain, or two adjacent REs in a time domain, or two adjacent REs in a time-frequency domain.

$$RSRP(r,p)=\frac{1}{K_s-1}\sum_{m=0}^{K_s-1}\hat{h}_p(m)\cdot\hat{h}_p(m+1),p=0,3,8,11 \quad (1)$$

where $\hat{h}_p(m)$ is a channel estimation on a reference signal RE whose label number is m, K_s is a total sample quantity of usable reference signal REs in measurement bandwidth, p is a number of a reference signal port in the one specified port group, and r is an index of a receive antenna. An RSRP corresponding to the antenna port group 0 may be obtained by combining (combine) *RSRP*(*r*,*p*). Specifically, a reference signal received power *RSRP*(*r*,*p*) of a pth port of an rth receive antenna is obtained and the RSRP is obtained by combining *RSRP*(*r*,*p*). For example, for *RSRP*(*r*,*p*) above, linear (correlated or uncorrelated) averaging is performed on ports p and receive antennas, and then an absolute value is taken, to obtain the RSRP corresponding to the port group 0. Alternatively, for *RSRP*(*r*,*p*) above, linear (correlated or uncorrelated) averaging is performed on one port p and receive antennas, and then an absolute value is taken, to obtain the RSRP corresponding to the port group 0. By means of sequential analogy, the RSRP may also be obtained by using reference signals of another port group.

[0052] In step 103 in this embodiment, the port group used for obtaining an RSRP and a port in the port group may be predefined (for example, the port group 0, and the port 0 in the port group 0, or the ports 0 and 3 in the port group 0, or all the ports in the port group 0, or others) or notified by a base station eNB by using higher layer signaling such as RRC signaling or by using downlink control information. In the foregoing, an RSRP is obtained based on one port group or some or all ports in one port group, and RSRPs do not need to be measured port by port, so that implementation complexity in measuring an RSRP by UE can be reduced; at the same time, a port group is predefined or notified, so that the UE and the eNB have consistent understanding of measurement, thereby ensuring consistency in measurement of RSRPs. At the same time, for different port groups, powers of the port groups may be independently indicated, and full use of antenna configurations and antenna array structures shown in FIG. 3 and FIG. 4 is made, so as to adapt to changes in an antenna structure to perform flexible indication, thereby ensuring that the base station eNB can adapt to multiple antenna configurations and antenna arrays.

[0053] Optionally, reference signal power information, of one or more port groups, included in the reference signal resource configuration information received by the UE in step 101 is used for indicating a reference signal power of ports in a corresponding port group.

[0054] 16 reference signal ports are used as an example, and reference signal powers of 4 port groups may be shown in Table 4:

Table 4-Table of reference signal powers of port groups

Port group number	0	1	2	3
Reference signal power	p0	p1	p2	p3

[0055] In this case, a power of a reference signal port included in a port group 0 is p0, and powers of reference signal ports included in port groups 1, 2, and 3 may be sequentially obtained by analogy, which are respectively p1, p2, and p3.

[0056] Alternatively, reference signal power information of the foregoing one or more port groups may also be jointly represented by using a reference signal power of one port group (for example, the port group 0) among the one or more port groups and a ratio of a reference signal power of another port group (for example, the port group 1) to the reference signal power of the port group (for example, the port group 0) or ratios of reference signal powers of multiple port groups (for example, the port groups 1, 2, and 3) to the reference signal power of the port group (for example, the port group 0). For example, the reference signal power of the port group 0 is p0, the ratios of the reference signal powers of the port groups 1, 2, and 3 to the reference signal power of the port group 0 are respectively ρ1, ρ2, and ρ3. In this case, the UE may obtain that the reference signal powers of the port groups 1, 2, and 3 are respectively p0*ρ1, p0*ρ2, and p0*ρ3.

[0057] In addition, reference signal power information of the one or more port groups may also be represented by using a reference signal power of one port group (for example, the port group 0) among the one or more port groups and a differential between a reference signal power of another port group (for example, the port group 1) and the reference signal power of the port group (for example, the port group 0) or differentials between reference signal powers of multiple

port groups (for example, the port groups 1, 2, and 3) and the reference signal power of the port group (for example, the port group 0). For example, the reference signal power of the port group 0 is p0, the differentials between the reference signal powers of the port groups 1, 2, and 3 and the reference signal power of the port group 0 are respectively d1, d2, and d3. In this case, the UE may obtain that the reference signal powers of the port groups 1, 2, and 3 are respectively p0+d1, p0+d2, and p0+d3.

[0058] It is used above that reference signal power information is separately indicated for port groups, and it can be avoided that reference signal powers are indicated port by port, so as to reduce a signaling overhead; further, a uniform power indicator is used for ports in a port group, and for different port groups, different port groups powers may be independently indicated, so that full use of an antenna configuration or an antenna array structure is made, thereby enabling a system to flexibly select a reference signal power according to the antenna configuration or the antenna array structure. In addition, it should be further pointed that that grouping of port groups is not limited to a port group including 4 reference signal ports, and the grouping of port groups and the formation of the ports in Tables 1, 2, and 3 above may further enable the antenna arrays in FIG. 3 or FIG. 4 to have powers symmetric about array structures, that is, the ports may have symmetric weights relative to the array, and by means of the symmetry of the weights, design complexity in beamforming or side lobe suppression can be reduced.

[0059] Further, the reference signal power above may also be represented by using an energy per resource element (EPRE).

[0060] Optionally, reference signal power information of at least two port groups includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or
a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0061] Optionally, the foregoing acquiring the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups includes:

obtaining, according to the reference signal port configuration information, signal quality measurement information corresponding to the at least two port groups; and
performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information.

[0062] Specifically, the signal quality measurement information may be obtained by combining reference signal received powers of more than one port group.

[0063] For example, there are 4 port groups in total: port groups 0, 1, 2, and 3. Based on the foregoing method for obtaining an RSRP of one port group, reference signal received powers $RSRP_g$ corresponding to the port groups 0, 1, 2, and 3 may be separately obtained, where $g = 0,1,2,3$. The reference signal resource configuration information received according to step 101 further includes: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups.

[0064] The performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information includes:

according to a formula

$$SQ = \left(\sum_{g=0}^{n-1} p_g \cdot SQ_g \right) \Big/ \left(\sum_{g=0}^{n-1} p_g \right) \quad (2)$$

obtaining the signal quality measurement information, where
SQ_g is signal quality measurement information of a specified port group, g is a sequence number of a specified port group, n is a quantity of specified port groups, $n \geq 2$, and p_g is a reference signal power of a specified port group, where the reference signal power of the specified port group is obtained according to the reference signal power information of the at least two port groups.

[0065] The multiple port groups above may be all port groups, or may be some port groups. Therefore, preset port information may be information about all port groups, or may be information about some port groups. The some port groups may be agreed in advance (for example, the port group 0 and the port group 1) or notified by the base station eNB by using higher layer signaling such as RRC signaling or by using downlink control information. In the foregoing, RSRPs of the multiple port groups are obtained, and processing such as smoothing or filtering may be performed on the RSRP obtained for each port group, so as to further increase precision of measuring an RSRP; at the same time, it is avoided that the UE performs calculation port by port, thereby lowering implementation complexity. In addition, a configuration of a port group can ensure that the base station eNB can adapt to multiple antenna configurations and antenna arrays.

[0066] Likewise, a similar method is used. Based on the reference signal port configuration information in the reference signal resource configuration information and a reference signal configuration or a subframe configuration, a reference signal sent by the base station is received, and the UE may further obtain signal quality measurement information, such as a reference signal received quality (RSRQ) or a reference signal strength indicator (RSSI), of one or more port groups. The RSSI is a received total wideband power, including a power of interference and a power of thermal noise, and the RSRQ is a ratio of an RSRP to the RSSI.

[0067] Further, the method for measuring communication quality may further include:

[0068] Step 104: The UE reports, to a base station eNB, the channel quality measurement information, for example, an RSRP, so as to help implement cell selection or cell handover.

[0069] Optionally, when the signal quality measurement information is the reference signal received power RSRP, the method for measuring communication quality may further include:

Step 105: Receive filter coefficient information sent by the base station.

[0070] Step 106: Perform, based on the filter coefficient information, filtering on the reference signal received power RSRP, and obtain a path loss estimation value.

[0071] Specifically, the user equipment may receive filter coefficient information sent by the base station at the same time when the reference signal resource configuration information is received in step 101, for example, the filter coefficient information and the reference signal resource configuration information are received in a same subframe. The filter coefficient information sent by the base station may also be received before or after the reference signal resource configuration information is received in step 101. The filter coefficient information and the reference signal resource configuration information may be received in an information element (IE) of same or different higher layer signaling such as RRC signaling, or same or different downlink control information (DCI).

[0072] Specifically, for the method in step 103, a reference signal received power of one or more port groups may be obtained, for example, reference signal received powers $RSRP_g$ corresponding to port groups 0, 1, 2, and 3 maybe obtained, where g = 0,1,2,3.

[0073] The path loss estimation may be obtained based on a reference signal received power of one port group and a corresponding reference signal power:

$$PL(g) = \text{a reference signal power of a port group g} - \text{a higher layer filtered RSRP of the port group g.}$$

where $PL(g)$ represents the PL estimation obtained based on the port group g, where a higher layer filtering parameter is notified by using higher layer signaling. A PL estimation may be obtained by using a PL of one port group, for example, the port group 0. The higher layer filtered RSRP of the port group g is obtained by performing filtering on the RSRP of the port group g by using the higher layer filter parameter notified by using the higher layer signaling.

[0074] The foregoing port group for obtaining a PL estimation may be predefined (for example, the port group 0) or notified by the base station eNB by using higher layer signaling such as RRC signaling or by using downlink control information. A PL estimation is obtained above based on one port group, which can reduce implementation complexity of PL estimation by UE, and ensure consistency of PL estimation. In addition, a configuration of a port group can ensure that the base station eNB can adapt to multiple antenna configurations and antenna arrays.

[0075] The path loss estimation may also be obtained based on reference signal received powers of multiple port groups and corresponding reference signal powers. Specifically, the PL estimation may be a linear average of PL estimations obtained for the multiple port groups.

[0076] The multiple port groups above may be all port groups, or may be some port groups. The some port groups may be agreed in advance (for example, the port group 0 and the port group 1) or notified by the base station eNB by using higher layer signaling such as RRC signaling or by using downlink control information. In the foregoing, PL estimations are obtained for multiple port groups, which can further increase precision of PL estimation, and avoid excessively high complexity of implementation by UE. In addition, a configuration of a port group can ensure that the base station

eNB can adapt to multiple antenna configurations and antenna arrays.

[0077] Further, the method for measuring communication quality may further include:

Step 107: Send an uplink physical channel or an uplink physical signal to the base station, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation according to the path loss estimation value.

[0078] The physical channel may be a physical uplink control channel PUCCH, a physical uplink shared channel PUSCH, or the like. The physical signal may be a sounding reference signal (SRS) or a demodulation reference signal (DMRS) that is used for the uplink physical channel.

[0079] Specifically, according to the foregoing obtained path loss estimation, a setting of the transmit power of the physical uplink control channel PUCCH may be defined as the following formula (3):

$$P_{\mathrm{PUCCH}}(i) = \min\left\{P_{\mathrm{CMAX,c}}(i), P_{\mathrm{O_PUCCH}} + PL_c + h\left(n_{CQI}, n_{HARQ}, n_{SR}\right) + \Delta_{\mathrm{F_PUCCH}}(F) + \Delta_{TxD}(F') + g(i)\right\}$$

where $P_{\mathrm{CMAX,c}}(i)$ is a maximum transmit power configured on UE in a subframe i of a serving cell c, and $P_{\mathrm{O_PUCCH}}$ is a parameter formed by the sum of a cell-specific parameter $P_{\mathrm{O_NOMINAL_PUCCH}}$ provided by a higher layer and a UE specific parameter $P_{\mathrm{O_UE_PUCCH}}$. $h(n_{CQI},n_{HARQ},n_{SR})$ is a value dependent on a PUCCH format, where n_{CQI} corresponds to a quantity of information bits of a CQI. For the parameter n_{SR}, n_{SR} = 1 if subframe i is configured for SR for the UE not having any associated transport block for UL-SCH, or otherwise n_{SR} = 0. The parameter n_{HARQ} is a quantity of HARQ-ACK bits sent in the subframe i. The parameter $\Delta_{\mathrm{F_PUCCH}}(F)$ is provided by a higher layer, and a value of each $\Delta_{\mathrm{F_PUCCH}}(F)$ corresponds to a PUCCH format (F). For the parameter $\Delta_{TxD}(F')$, if the UE is configured by a higher layer to transmit a PUCCH on two antenna ports, a value of $\Delta_{TxD}(F')$ is provided by a higher layer, where each PUCCH format F' is predefined; otherwise, $\Delta_{TxD}(F') = 0$. $g(i)$ is a current PUCCH power control state of the UE. PL_c is an estimation value, of a path loss, obtained for the cell C by the UE by using the method in step 104.

[0080] For another example, according to the foregoing obtained path loss estimation, a setting of the transmit power of the physical uplink shared channel PUSCH may be defined as the following formula (4):

$$P_{\mathrm{PUSCH,c}}(i) = \min\left\{P_{\mathrm{CMAX,c}}(i), 10\log_{10}\left(M_{\mathrm{PUSCH,c}}(i)\right) + P_{\mathrm{O_PUSCH,c}}(j) + \alpha_c(j)\cdot PL_c + \Delta_{\mathrm{TF,c}}(i) + f_c(i)\right\}$$

where $P_{\mathrm{CMAX,c}}(i)$ is a maximum transmit power configured on UE in a subframe i of a serving cell c; $M_{\mathrm{PUSCH,c}}(i)$ is the bandwidth of the PUSCH resource assignment expressed in number of resource blocks valid for subframe i and serving cell c. $P_{\mathrm{O_PUSCH,c}}(j)$ is a parameter formed by a component $P_{\mathrm{O_NOMINAL_PUSCH,c}}(j)$ and a component $P_{\mathrm{O_UE_PUSCH,c}}(j)$ that are provided by a higher layer, where j=0, 1. $\alpha_c \in \{0,0.4,0.5,0.6,0.7,0.8,0.9,1\}$ is a 3-bit parameter, and is provided by a higher layer. $\Delta_{TF,c}(i)$ is a parameter that is determined by using higher layer signaling and related to a transmission format. $f_c(i)$ is a current PUSCH power control adjustment state of the UE. PL_c is an estimation value, of a path loss, obtained for the cell C by the UE by using the method in step 104.

[0081] For still another example, according to the foregoing obtained path loss estimation, a setting of a transmit power of a sounding reference signal SRS may be defined as the following formula:

$$P_{\mathrm{SRS,c}}(i) = \min\left\{P_{\mathrm{CMAX,c}}(i), P_{\mathrm{SRS_OFFSET,c}}(m) + 10\log_{10}\left(M_{\mathrm{SRS,c}}\right) + P_{\mathrm{O_PUSCH,c}}(j) + \alpha_c(j)\cdot PL_c + f_c(i)\right\} \quad ,$$

where $P_{\mathrm{SRS_OFFSET,c}}(m)$ is a parameter semi-statically configured by a higher layer for a serving cell c, where m=0 and m=1. For SRS transmission, if a trigger type is 0, m=0; if a trigger type 1, m=1. $M_{\mathrm{SRS,c}}$ is bandwidth of SRS transmission of a subframe i of the serving cell c. $f_c(i)$ is a current PUSCH power control adjustment state of the serving cell c. $P_{\mathrm{O_PUSCH,c}}(j)$ and $\alpha_c(j)$ are predefined parameters, for example, it is defined in Section 5.1.1.1 in LTE 36.213 that j=1. PL_c is an estimation value, of a path loss, obtained for the cell C by the UE by using the method in step 104.

[0082] The above path loss estimation is used for open-loop control of an uplink channel, which can further improve reliability of power control, and ensure that the base station eNB can adapt to multiple antenna configurations and antenna arrays.

Embodiment 3

[0083] This embodiment of the present invention provides a method for measuring communication quality. As shown in FIG. 5, the method includes:

Step S21: Determine reference signal resource configuration information, and send the reference signal resource configuration information to user equipment, where the reference signal resource configuration information includes: refer-

ence signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal.

[0084] When the reference signal resource configuration information includes: the reference signal port configuration information and the power ratio information, the reference signal resource configuration information is sent to the user equipment (UE), so that the user equipment acquires channel state information CSI according to the reference signal resource configuration information. Because reference signal ports are allocated to multiple groups, the UE may perform processing according to reference signal quality, of one port group or multiple port groups, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. Therefore, channel state information acquired in the solution may enable the UE to perform more accurate modulation and coding scheme (MCS) selection or scheduling, thereby increasing a throughput of a system.

[0085] Step S22: Receive channel state information CSI sent by the user equipment, where the CSI is obtained by the user equipment according to the reference signal port configuration information and the power ratio information.

[0086] The channel state information CSI includes: any one or any combination of a channel quality indicator CQI, a precoding matrix indicator PMI, and a rank indicator RI.

[0087] According to the method described in Embodiment 3 above, in the method, reference signal resource configuration information is determined on a network side, and the reference signal resource configuration information is sent to a user side, where the reference signal resource configuration information at least includes: reference signal power related information of a port group, and reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping between the reference signal port and a port group. In the method, it can be avoided that reference signal power related information is indicated port by port, so as to reduce a signaling overhead; further, a uniform power indicator is used for ports in a port group, and for different port groups, power related information of the port groups may be indicated independently, so that full use of an antenna configuration or an antenna array structure is made, thereby enabling a system to flexibly select reference signal power related information according to the antenna configuration or the antenna array structure; because an antenna array may have symmetric weights, by means of the symmetry of the weights, design complexity in beamforming or side lobe suppression can be reduced.

[0088] Further, the reference signal resource configuration information is sent to UE on the user side, and the UE may perform processing according to reference signal quality, of one port group or multiple port groups, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. The UE is enabled to acquire channel state information, so that the UE can perform more accurate modulation and coding scheme (MCS) selection or scheduling, thereby increasing a throughput of a system.

[0089] Optionally, the reference signal port configuration information is a single index, or is a double index, or is an index after combined coding. Refer to Embodiment 1 for the detailed description, which is no longer repeated herein.

[0090] Optionally, in step S21, in the power ratio information:

power ratios of data channels on antenna ports in each port group among the at least one port group to a reference signal are the same; or

power ratios of data channels on ports in one port group among the at least one port group and data channels on ports in another port group to a reference signal are the same.

[0091] Optionally, the power ratio information is used for indicating multiple sets of power ratios of data channels of the at least one port group to a reference signal; and

the receiving channel state information CSI sent by the user equipment includes: receiving multiple sets of channel state information CSI that are sent by the user equipment, where each set of channel state information CSI is obtained by the user equipment according to one set of power ratios among the multiple sets of power ratios.

[0092] The "multiple sets" in this embodiment refers to use of multiple sets of values. For the multiple sets of values, multiple sets of signaling having a same format may be used. For example,

a signaling format is: power ratios of data channels on ports in at least one port group to a reference signal are the same, that is, powers of ports in a port group are the same; and

another signaling format is: power ratios of data channels on ports in one port group and data channels on ports in another port group to a reference signal are the same; however, powers of ports in a port group are different.

[0093] Two different signaling formats are listed as examples in the foregoing, and they may be understood as specific examples of this embodiment, and should not be construed as limitations to this embodiment.

Embodiment 4

[0094] This embodiment of the present invention provides a method for measuring communication quality. The method is similar to Embodiment 2 above, and a difference lies in that, after receiving reference signal resource configuration information sent by a network side, UE on a user side uses the information to acquire channel state information, so that the UE can perform corresponding modulation and coding scheme MCS selection or resource scheduling according to the channel state information.

[0095] As shown in FIG. 6, the method includes:

Step 201: Receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal.

[0096] For detailed description of the reference signal port configuration information included in the reference signal resource configuration information, reference may be made to the description of the reference signal port configuration information in step 101. That is, the reference signal port configuration information is used for indicating the mapping between a reference signal port and a port group, and the mapping relationship between a reference signal port and a port group is predefined.

[0097] The data channel may be a physical downlink shared channel (PDSCH), or may be a channel used for transmitting control information. A power of a data channel may be an energy per resource element (EPRE).

[0098] Specifically, the UE receives a reference signal resource configuration, which may be that the UE receives, by using higher layer signaling such as radio resource control (RRC) signaling or dynamic signaling such as downlink control information (DCI), the reference signal resource configuration notified by an eNB, or obtains, based on a cell identity ID, the reference signal resource configuration.

[0099] Specifically, the reference signal port configuration information is used for indicating the mapping between the reference signal port and a port group.

[0100] One reference signal port usually corresponds to one physical antenna or one virtual antenna, where the virtual antenna may be obtained by means of weighted combination of multiple physical antennas. An actual antenna deployment may have a different antenna configuration and an antenna array form. It should be pointed out that, in this embodiment, a reference signal port and a reference signal port group may be interchangeable with an antenna port and an antenna port group.

[0101] Optionally, the reference signal port configuration information is used for indicating the mapping relationship between the reference signal port and a port group, and may include a quantity of reference signal ports and a mapping index, where the mapping index is used for indicating a mapping between a reference signal port group and a corresponding port. 8-antenna arrays represented by an antenna array A shown in FIG. 3 and an antenna array A shown in FIG. 4 are used as examples, and the reference signal port configuration information includes: a quantity of reference signal ports is 8 and a mapping index is 0 or 1. The predefined mapping relationship between a reference signal port and a port group may be defined by using a function, or may be regulated by using a predefined table, as shown in Table 1.

[0102] 16-antenna arrays represented by an antenna array B or an antenna array C shown in FIG. 3 and an antenna array B or an antenna array C shown in FIG. 4 are used as examples, and the reference signal port configuration information includes: a quantity of reference signal ports is 16 and a mapping index is 0 or 1 or 2 or 3. The predefined mapping relationship between a reference signal port and a port group may be defined by using a function, or may be regulated by using a predefined table, as shown in Table 2.

[0103] Specifically, the reference signal port configuration information may include a double index (m, n). In this case, the predefined mapping relationship between a reference signal port and a port group may be defined by using a function, or may be regulated by using a predefined table, as shown in Table 3.

[0104] Further, the double index (m, n) may indicate that a quantity of reference signal ports is a product of m and n.

[0105] Further, for the double index information, combined coding may be performed, for example, combined coding of the double index in Table 3 above is shown in Table 3a or 3b.

[0106] Optionally, grouping of port groups may be that 4 reference signal ports/antenna ports form one port group.

[0107] It should be further pointed out that grouping of port groups is not limited to a port group including 4 reference signal ports, or may be a port group having 2 or 8 ports or in another formation. In addition, a number of a reference signal port included in each port group is also not limited to the foregoing value, and may be flexibly selected according to an actual antenna configuration or deployment. The foregoing predefined port group mapping and mapping indication information may enable a system to adapt to more antenna configurations and antenna array deployments.

[0108] In the power ratio information in step 201, power ratios of data channels on antenna ports in each port group among the at least one port group to a reference signal are the same. 16 reference signal ports are used as an example, and it is assumed that a data channel is a PDSCH, and a power corresponds to an EPRE, so that a signal power ratio

of a 4-port group may be:

Table 4-Power ratio

Port group number	0	1	2	3
A ratio of an EPRE of a PDSCH to an EPRE of a reference signal	$\rho 0$	$\rho 1$	$\rho 2$	$\rho 3$

[0109] Further, power ratios of data channels on each antenna port in the at least one port group to a reference signal are equal. Table 4 is used as an example, where power ratios of data channels on ports in a port group 0 to a reference signal may be equal.

[0110] Optionally, as another embodiment, in the power ratio information in step 201, power ratios of data channels on ports in one port group among the at least one port group and data channels on ports in another port group to a reference signal are the same.

[0111] Specifically, a port group having 4 ports is used as an example. For example, ports of a port group 0 are 0, 1, 4, and 5, and ports of a port group 1 are 2, 3, 6, and 7. Power ratios of data channels in the port group 0 to a reference signal are shown in Table 4a.

Table 4a-Power ratio of a port group 0

Port number	0	1	4	5
A ratio of an EPRE of a PDSCH to an EPRE of a reference signal	$\rho 0$	$\rho 1$	$\rho 2$	$\rho 3$

[0112] The power ratios of data channels, corresponding to the ports in the port group 0 and the ports in the port group 1, to a reference signal are the same; that is, power ratios of data channels, corresponding to the ports 2, 3, 6, and 7 in the port group 1, to a reference signal are respectively $\rho 0$, $\rho 1$, $\rho 2$, and $\rho 3$.

[0113] Optionally, as another embodiment, the power ratio of the data channel in the one or more port groups to the reference signal in step 201 may include multiple sets of values. The sets of values may be values shown in Table 4 or 4a.

[0114] In addition, the reference signal resource configuration information may further include: any one of a reference signal configuration and a reference signal subframe configuration. The reference signal configuration may include a subcarrier used by a reference signal port or an OFDM symbol or a code resource. The reference signal subframe configuration may include a subframe position occupied by a reference signal port, a subframe period or a subframe offset. It should be pointed out that the reference signal configuration or the reference signal subframe configuration may also be predefined, or is implicitly derived according to a parameter, for example, a cell ID or a UE ID, that is known in advance, and is known to both the base station and the UE, which is not limited in this embodiment of the present invention.

[0115] Step 202: Obtain a power ratio of a data channel on each antenna port in the at least one port group to a reference signal according to the reference signal port configuration information and the power ratio information.

[0116] Step 203: Obtain channel state information CSI according to the power ratio of the data channel on each antenna port to the reference signal.

[0117] Specifically, the obtaining channel state information CSI according to the power ratio of the data channel on each antenna port to the reference signal may include:

obtaining, according to the reference signal on each antenna port, a channel measurement value corresponding to each antenna port;

obtaining a channel estimation value of the data channel on each antenna port according to the channel measurement value corresponding to each antenna port and the power ratio of the data channel on each antenna port to the reference signal; and

obtaining the channel state information CSI according to the channel estimation value of the data channel on each antenna port.

[0118] It should be pointed out that the present invention does not limit an execution sequence of obtaining a channel measurement value corresponding to each reference signal port in the at least one port group and obtaining a power ratio of a data channel, corresponding to each antenna port in the at least one port group, to a reference signal.

[0119] Specifically, the reference signal may specifically include a cell-specific reference signal CSR, or a received channel state information reference signal (CSI-RS), or a demodulation reference signal (DMRS).

[0120] The channel state information (CSI) may be a channel quality indicator (CQI) or a precoding matrix indicator (PMI) or a rank indicator (RI); or may be other channel state information such as a precoding type indicator (PTI).

[0121] Specifically, when calculating channel state information based on a ratio of an EPRE of a PDSCH signal to an EPRE of a channel state information reference signal (CSI-RS), the UE obtains a transmit power of a corresponding PDSCH on an antenna port.

[0122] 16 reference signal ports are used as an example, and it is assumed that the reference signal port configuration information notified in step 201 includes: a quantity of reference signal ports is 16 and a mapping index is 1; a mapping relationship is shown in Table 2, and power ratios are shown in Table 4. It can be known according to Table 2 and Table 4 that:

EPRE or power ratios of PDSCHs, corresponding to reference signal ports 0, 1, 12, and 13, to a reference signal are $\rho 0$;
EPRE or power ratios of PDSCHs, corresponding to reference signal ports 2,3,14, and 15, to a reference signal are $\rho 1$;
EPRE or power ratios of PDSCHs, corresponding to reference signal ports 4, 5, 8, and 9, to a reference signal are $\rho 2$; and
EPRE or power ratios of PDSCHs, corresponding to reference signal ports 6, 7, 10, and 11, to a reference signal are $\rho 3$.

[0123] It should be noted that the reference signal ports correspond to the antenna ports on a one-to-one basis.

[0124] In addition, the UE receives a reference signal according to the reference signal resource configuration information, and a channel measurement value corresponding to each antenna port may be obtained as follows:

$$\mathbf{H} = \begin{bmatrix} \mathbf{h}_0 & \mathbf{h}_1 & \cdots & \mathbf{h}_{15} \end{bmatrix}$$

where $\mathbf{h}_p$,p= 0,...,15 is a channel measurement value corresponding to an antenna port p, and the measurement value may be obtained based on a manner such as the least square method according to a specific reference signal such as a CSI RS, which is the prior art and is not further elaborated.

[0125] According to the foregoing channel measurement value corresponding to each antenna port, the UE may obtain a channel measurement value or channel estimation value of a data channel PDSCH on each antenna port according to an EPRE or power ratio of the PDSCH to a reference signal, as follows:

$$\hat{\mathbf{H}} = \begin{bmatrix} \hat{\mathbf{h}}_0 & \hat{\mathbf{h}}_1 & \cdots & \hat{\mathbf{h}}_{15} \end{bmatrix}$$

where a channel measurement value or channel estimation value $\hat{\mathbf{h}}_p$ of a data channel PDSCH on the antenna port p is:

$$\hat{\mathbf{h}}_p = \sqrt{\rho_p}\mathbf{h}_p$$

where p is an index of the antenna port, ρ_p is a power ratio of the data channel on the antenna port p to a reference signal, $\mathbf{h}_p$ is a channel measurement value corresponding to the antenna port p, and $\hat{\mathbf{h}}_p$ is a channel estimation value of the data channel on the antenna port p; that is,

$$\hat{\mathbf{h}}_p = \begin{cases} \sqrt{\rho 0}\mathbf{h}_p, p = 0,1,12,13 \\ \sqrt{\rho 1}\mathbf{h}_p, p = 2,3,14,15 \\ \sqrt{\rho 2}\mathbf{h}_p, p = 4,5,8,9 \\ \sqrt{\rho 3}\mathbf{h}_p, p = 6,7,10,11 \end{cases}$$

the UE may calculate channel state information CSI based on the following equation (5):

$$\mathrm{y} = \hat{\mathrm{H}}\mathrm{Ps} + \mathrm{n} \qquad (5)$$

where **P** is a precoding matrix, and for a non-precoding system, P is a unit array; **S** is a sent information symbol, for example, a modulation symbol; **n** is interference and noise vectors; and **y** is a received signal.

[0126] The channel state information, for example, any one or any combination of a channel quality indicator (CQI) or a precoding matrix indicator (PMI)/a rank indicator (RI) is obtained according to the equation (5) above. A specific process of obtaining channel state information, for example, a CQI or a PMI or an RI according to the equation (5) above is the prior art, which is no longer further elaborated herein.

[0127] Optionally, as another embodiment, the power ratio information is used for indicating multiple sets of power ratios of data channels of the at least one port group to a reference signal.

[0128] 16 reference signal ports are used as an example, and it is assumed that the reference signal port configuration information notified in step 201 includes: a quantity of reference signal ports is 16 and a mapping index is 1; a mapping relationship is shown in Table 2, and power ratios are shown in Table 4b. It can be known according to Table 2 and Table 4b that:

EPRE ratios or a first set of power ratios of PDSCHs, corresponding to reference signal ports 0, 1, 12, and 13, to a reference signal are x0;
EPRE ratios or a first set of power ratios of PDSCHs, corresponding to reference signal ports 2, 3, 14, and 15, to a reference signal are x1;
EPRE ratios or a first set of power ratios of PDSCHs, corresponding to reference signal ports 4, 5, 8, and 9, to a reference signal are x2;
EPRE ratios or a first set of power ratios of PDSCHs, corresponding to reference signal ports 6, 7, 10, and 11, to a reference signal are x3;
EPRE ratios or a second set of power ratios of PDSCHs, corresponding to reference signal ports 0, 1, 12, and 13, to a reference signal are y0;
EPRE ratios or a second set of power ratios of PDSCHs, corresponding to reference signal ports 2, 3, 14, and 15, to a reference signal are y1;
EPRE ratios or a second set of power ratios of PDSCHs, corresponding to reference signal ports 4, 5, 8, and 9, to a reference signal are y2; and
EPRE ratios or a second set of power ratios of PDSCHs, corresponding to reference signal ports 6, 7, 10, and 11, to a reference signal are y3.

Table 4b-Multiple sets of power ratios of a port group 0

Port number	0	1	4	5
A first ratio of an EPRE of a PDSCH to an EPRE of a reference signal	x0	x1	x2	x3
A second ratio of an EPRE of a PDSCH to an EPRE of a reference signal	y0	y1	y2	y3

[0129] Step 204: Send the channel state information CSI to the base station.

[0130] Specifically, the channel state information may be sent to the base station by using a physical uplink control channel PUCCH or a physical uplink shared channel PUSCH.

[0131] Optionally, the sending the channel state information CSI to the base station includes: sending multiple sets of channel state information CSI to the base station, where each set of channel state information CSI is obtained according to one set of power ratios among the multiple sets of power ratios.

[0132] 16 reference signal ports are used as an example, and it is assumed that the reference signal port configuration information notified in step 201 includes: a quantity of reference signal ports is 16 and a mapping index is 1; a mapping relationship is shown in Table 2, and power ratios are shown in Table 4b. It can be known according to Table 2 and Table 4b that UE sends two sets of channel state information CSI to the base station. The first set of CSI is calculated according to a first set of power ratios in Table 4c below:

Table 4c-First set of power ratios of a port group 0

Port number	0	1	4	5
A ratio of an EPRE of a PDSCH to an EPRE of a reference signal	x0	x1	x2	x3

[0133] The second set of CSI is calculated according to a second set of power ratios in Table 4d:

Table 4d-Second set of power ratios of a port group 0

Port number	0	1	4	5
A ratio of an EPRE of a PDSCH to an EPRE of a reference signal	y0	y1	y2	y3

[0134] In the foregoing, a port group is used to separately indicate a ratio of a power of a data channel to a power of a reference signal, which can reduce a signaling overhead and enable a system to flexibly configure a signal power according to an antenna configuration or an antenna array structure. In addition, it should be further pointed out that although grouping of a port group is not limited to a port group including 4 reference signal ports, grouping of port groups and formation of ports in Tables 1, 2, and 3 above may further enable the antenna arrays in FIG. 3 or FIG. 4 to have powers symmetric about array structures, that is, the ports may have symmetric weights relative to the array, so as to implement beamforming or side lobe suppression.

Embodiment 5

[0135] This embodiment of the present invention provides a network side apparatus. As shown in FIG. 7, the apparatus includes: a determining unit 601 and a first sending unit 602.

[0136] The determining unit 601 is configured to determine reference signal resource configuration information, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group.

[0137] The first sending unit 602 is configured to send, to user equipment, the reference signal resource configuration information determined by the determining unit 601, so that the user equipment acquires signal quality measurement information according to the reference signal port configuration information.

[0138] The network side apparatus described in this embodiment may be a base station on a network side, and reference may be made to the description of the corresponding steps in Embodiment 1 for implementation of functions of units of the network side apparatus, which is no longer repeated herein.

[0139] In the apparatus described in Embodiment 5 above, reference signal resource configuration information is determined on a network side, and the reference signal resource configuration information is sent to a user side, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group. The apparatus can avoid that reference signal power related information is indicated port by port, so as to reduce a signaling overhead; further, a uniform power indicator is used for ports in a port group, and for different port groups, power related information of the port groups may be indicated independently, so that full use of an antenna configuration or an antenna array structure is made, thereby enabling a system to flexibly select reference signal power related information according to the antenna configuration or the antenna array structure; because an antenna array may have symmetric weights, by means of the symmetry of the weights, design complexity in beamforming or side lobe suppression can be reduced.

[0140] Further, the reference signal resource configuration information is sent to UE on the user side, and the UE may perform processing according to reference signal quality, of at least one port group, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. The UE is enabled to acquire signal quality measurement information, so that the UE can perform more accurate cell selection and uplink power control.

[0141] Optionally, the reference signal resource configuration information determined by the determining unit 601 further includes: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups; and
the reference signal power information of the at least two port groups includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or
a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0142] Optionally, when the signal quality measurement information is a reference signal received power RSRP, the

first sending unit 602 is further configured to send, to the user equipment, filter coefficient information that is used by the user equipment to perform, based on the filter coefficient information, filtering on the reference signal received power RSRP and obtain a path loss estimation value.

[0143] Optionally, the apparatus further includes:

a first receiving unit 603, configured to receive an uplink physical channel or an uplink physical signal sent by the user equipment, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation by the user equipment according to the path loss estimation value.

[0144] Optionally, the signal quality measurement information includes:

any one or any combination of a reference signal received power RSRP, a reference signal received quality RSRQ, and a reference signal strength indicator RSSI.

[0145] Optionally, the apparatus further includes: a second receiving unit 604, where

the second receiving unit 604 is configured to receive the signal quality measurement information sent by the user equipment.

[0146] The first receiving unit 603 and the second receiving unit 604 may be integrated in a same physical module, or may be regarded as being implemented by using a same module; the description of the first receiving unit and the second receiving unit is used for better understanding of connection relationships among modules in the network side apparatus.

Embodiment 6

[0147] This embodiment of the present invention provides user equipment. As shown in FIG. 8, the user equipment includes: a third receiving unit 701, a first acquiring unit 702, and a second acquiring unit 703.

[0148] The third receiving unit 701 is configured to receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group.

[0149] The first acquiring unit 702 is configured to obtain reference signal port information in at least one port group according to the reference signal port configuration information received by the third receiving unit 701.

[0150] The second acquiring unit 703 is configured to acquire signal quality measurement information according to the reference signal port information, in the at least one port group, obtained by the first acquiring unit 702.

[0151] For the user equipment described in this embodiment, reference may be made to the description of the corresponding steps in Embodiment 2 for implementation of functions of units of the user equipment, which is no longer repeated herein.

[0152] The apparatus described in Embodiment 6 above receives reference signal resource configuration information determined on a network side, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group. The apparatus can avoid that reference signal power related information is indicated port by port, so as to reduce a signaling overhead; further, a uniform power indicator is used for ports in a port group, and for different port groups, power related information of the port groups may be indicated independently, so that full use of an antenna configuration or an antenna array structure is made, thereby enabling a system to flexibly select reference signal power related information according to the antenna configuration or the antenna array structure; because an antenna array may have symmetric weights, by means of the symmetry of the weights, design complexity in beamforming or side lobe suppression can be reduced.

[0153] Further, the reference signal resource configuration information is sent to UE on a user side, and the UE may perform processing according to reference signal quality, of at least one port group, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. The UE is enabled to acquire signal quality measurement information, so that the UE can perform more accurate cell selection and uplink power control.

[0154] Optionally, the first acquiring unit 702 is specifically configured to obtain reference signal port information in one specified port group according to the reference signal port configuration information received by the third receiving unit 701.

[0155] The second acquiring unit 703 is specifically configured to acquire the signal quality measurement information according to the reference signal port information, in the one specified port group, obtained by the first acquiring unit 702.

[0156] Optionally, when the signal quality measurement information is a reference signal received power RSRP, the second acquiring unit 703 is specifically configured to:

obtain reference signal received power $RSRP(r,p)$ of a pth port of an rth receive antenna according to a formula

$$RSRP(r,p)=\frac{1}{K_s-1}\sum_{m=0}^{K_s-1}\hat{h}_p(m)\cdot\hat{h}_p(m+1)$$ and obtain the RSRP by combining $RSRP(r,p)$, where $\hat{h}_p(m)$ is a channel estimation on a reference signal RE whose label number is m, K_s is a total sample quantity of usable reference signal REs in measurement bandwidth, p is a number of a reference signal port in the one specified port group, and r is an index of a receive antenna.

[0157] Optionally, the reference signal resource configuration information received by the third receiving unit 701 further includes: reference signal power information of at least two port groups.

[0158] The second acquiring unit 703 is further configured to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups.

[0159] Optionally, the second acquiring unit 703 is specifically configured to:

obtain, according to the reference signal port configuration information, signal quality measurement information corresponding to the at least two port groups; and
perform, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information.

[0160] Optionally, the performing, by the second acquiring unit 703, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information includes:

obtaining the signal quality measurement information according to a formula

$$SQ=\left(\sum_{g=0}^{n-1}p_g\cdot SQ_g\right)\Big/\left(\sum_{g=0}^{n-1}p_g\right),$$

where
SQ_g is signal quality measurement information of a specified port group, g is a sequence number of a specified port group, n is a quantity of specified port groups, $n \geq 2$, and p_g is a reference signal power of a specified port group, where the reference signal power of the specified port group is obtained according to the reference signal power information of the at least two port groups.

[0161] Optionally, the reference signal power information, of the at least two port groups, received by the third receiving unit 701 includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or
a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0162] Optionally, the user equipment further includes: a second sending unit 704, configured to send the signal quality measurement information to the base station.

[0163] Optionally,
the third receiving unit 701 is further configured to: when the signal quality measurement information is a reference signal received power RSRP, receive filter coefficient information sent by the base station; and
the user equipment further includes: a third acquiring unit 705, where
the third acquiring unit 705 is configured to perform, based on the filter coefficient information received by the third receiving unit 701, filtering on the reference signal received power RSRP, and obtain a path loss estimation value.

[0164] Optionally, the user equipment further includes: a third sending unit 706, where
the third sending unit 706 is further configured to send an uplink physical channel or an uplink physical signal to the base station, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation according to the path loss estimation value.

[0165] The third sending unit 706 and the second sending unit 704 may be implemented by using a same physical module, and this time are described separately for ease of understanding.

[0166] Optionally, the signal quality measurement information includes: a reference signal received power RSRP, a reference signal strength indicator RSSI, or a reference signal received quality RSRQ.

Embodiment 7

[0167] This embodiment of the present invention provides a network side apparatus. As shown in FIG. 9, the apparatus includes: a fourth sending unit 801 and a fourth receiving unit 802.

[0168] The fourth sending unit 801 is configured to send reference signal resource configuration information to user equipment, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal.

[0169] The fourth receiving unit 802 is configured to receive channel state information CSI sent by the user equipment, where the CSI is obtained by the user equipment according to the reference signal port configuration information and the power ratio information.

[0170] The network side apparatus described in Embodiment 7 above determines reference signal resource configuration information by using a network side, and sends the reference signal resource configuration information to a user side, where the reference signal resource configuration information includes reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal. The apparatus can avoid that reference signal power related information is indicated port by port, so as to reduce a signaling overhead; further, a uniform power indicator is used for ports in a port group, and for different port groups, power related information of the port groups may be indicated independently, so that full use of an antenna configuration or an antenna array structure is made, thereby enabling a system to flexibly select reference signal power related information according to the antenna configuration or the antenna array structure; because an antenna array may have symmetric weights, by means of the symmetry of the weights, design complexity in beamforming or side lobe suppression can be reduced.

[0171] Further, the reference signal resource configuration information is sent to UE on the user side, and the UE may perform processing according to reference signal quality, of one port group or multiple port groups, in the reference signal resource configuration information to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. The UE is enabled to acquire channel state information, so that the UE can perform more accurate modulation and coding scheme (MCS) selection or scheduling, thereby increasing a throughput of a system.

[0172] Optionally, in the power ratio information:

power ratios of data channels on antenna ports in each port group among the at least one port group to a reference signal are the same; or

power ratios of data channels on ports in one port group among the at least one port group and data channels on ports in another port group to a reference signal are the same.

[0173] Optionally, the power ratio information is used for indicating multiple sets of power ratios of data channels of the at least one port group to a reference signal; and

the fourth receiving unit 802 is specifically configured to receive multiple sets of channel state information CSI that are sent by the user equipment, where each set of channel state information CSI is obtained by the user equipment according to one set of power ratios among the multiple sets of power ratios.

[0174] Optionally, the channel state information CSI received by the fourth receiving unit 802 includes: any one or any combination of a channel quality indicator CQI, a precoding matrix indicator PMI, and a rank indicator RI.

[0175] The network side apparatus provided in this embodiment may be a base station on a network side, and reference may be made to the description of the corresponding steps in Embodiment 3 for implementation of functions of units of the network side apparatus, which is no longer repeated herein.

Embodiment 8

[0176] This embodiment of the present invention provides user equipment. As shown in FIG. 10, the user equipment includes: a fifth receiving unit 901, a fourth acquiring unit 902, a fifth acquiring unit 903, and a fifth sending unit 904.

[0177] The fifth receiving unit 901 is configured to receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal.

[0178] The fourth acquiring unit 902 is configured to obtain a power ratio of a data channel on each antenna port in the at least one port group to a reference signal according to the reference signal port configuration information and the power ratio information that are received by the fifth receiving unit 901.

[0179] The fifth acquiring unit 903 is configured to obtain channel state information CSI according to the power ratio, of the data channel on each antenna port to the reference signal, obtained by the fourth acquiring unit 902.

[0180] The fifth sending unit 904 is configured to send, to the base station, the channel state information CSI obtained by the fifth acquiring unit 903.

[0181] This embodiment of the present invention provides user equipment. The apparatus may perform processing according to reference signal quality of one port group or multiple port groups to obtain final signal quality measurement information, so that a UE side can distinguish ports according to different port groups, which differs from a case in which transmit powers of different ports cannot be distinguished in the prior art. The UE is enabled to acquire channel state information, so that the UE can perform more accurate modulation and coding scheme (MCS) selection or scheduling, thereby increasing a throughput of a system.

[0182] Optionally, the fifth acquiring unit 903 is specifically configured to:

obtain, according to the reference signal on each antenna port, a channel measurement value corresponding to each antenna port;
obtain a channel estimation value of the data channel on each antenna port according to the channel measurement value corresponding to each antenna port and the power ratio of the data channel on each antenna port to the reference signal; and
obtain the channel state information CSI according to the channel estimation value of the data channel on each antenna port.

[0183] Optionally, the obtaining, by the fifth acquiring unit 903, a channel estimation value of the data channel on each antenna port according to the channel measurement value corresponding to each antenna port and the power ratio of the data channel on each antenna port to the reference signal includes:
obtaining a channel estimation value of a data channel on an antenna port p according to a formula

$$\hat{\mathbf{h}}_p = \sqrt{\rho_p}\mathbf{h}_p,$$

where
p is an index of the antenna port, ρ_p is a power ratio of the data channel on the antenna port p to a reference signal, $\mathbf{h}_p$ is a channel measurement value corresponding to the antenna port p, and $\hat{\mathbf{h}}_p$ is a channel estimation value of the data channel on the antenna port p.

[0184] Optionally, in the power ratio information:

power ratios of data channels on antenna ports in each port group among the at least one port group to a reference signal are the same; or
power ratios of data channels on ports in one port group among the at least one port group and data channels on ports in another port group to a reference signal are the same.

[0185] Optionally, the reference signal resource configuration information received by the fifth receiving unit 901 includes: the reference signal port configuration information and the power ratio information.

[0186] The power ratio information is used for indicating multiple sets of power ratios of data channels of the at least one port group to a reference signal; and
the fifth sending unit 904 is specifically configured to:
send multiple sets of channel state information CSI to the base station, where each set of channel state information CSI is obtained according to one set of power ratios among the multiple sets of power ratios.

[0187] Optionally, the channel state information CSI obtained by the fifth acquiring unit 903 includes: any one or any combination of a channel quality indicator CQI, a precoding matrix indicator PMI, and a rank indicator RI.

[0188] For the user equipment provided in this embodiment, reference may be made to the description of the corre-

sponding steps in Embodiment 4 for implementation of functions of units of the user equipment, which is no longer repeated herein.

Embodiment 9

[0189] A network side apparatus is provided and can support a radio communications technology. Transmission of a data packet can be performed based on the method described in Embodiment 1 among units in a communications device in this embodiment. A schematic structural diagram is shown in FIG. 11, and the network side apparatus includes: a processor 21, a receiver 23, and a transmitter 24 that are separately connected to a bus.

[0190] Optionally, the shown network side apparatus may further include: a memory 20.

[0191] Where:

the memory 20 is configured to store data input from the receiver 23, and may further store information such as a necessary file for the processor 21 to process data; and the receiver 23 and the transmitter 24 are ports by using which a communications device communicates with another device.

[0192] The processor 21 is configured to determine reference signal resource configuration information, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group.

[0193] The transmitter 24 is configured to send the reference signal resource configuration information to user equipment, so that the user equipment acquires signal quality measurement information according to the reference signal port configuration information.

[0194] Optionally, the reference signal resource configuration information determined by the processor 21 further includes: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups.

[0195] The reference signal power information of the at least two port groups includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or

a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0196] Optionally, when the signal quality measurement information is a reference signal received power RSRP, the transmitter 24 is further configured to send, to the user equipment, filter coefficient information that is used by the user equipment to perform, based on the filter coefficient information, filtering on the reference signal received power RSRP and obtain a path loss estimation value.

[0197] Optionally, the receiver 23 is configured to receive an uplink physical channel or an uplink physical signal sent by the user equipment, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation by the user equipment according to the path loss estimation value.

[0198] Optionally, the signal quality measurement information includes:

any one or any combination of a reference signal received power RSRP, a reference signal received quality RSRQ, and a reference signal strength indicator RSSI.

[0199] Optionally, the receiver 23 is further configured to receive the signal quality measurement information sent by the user equipment.

[0200] The network side apparatus described in this embodiment may be a base station on a network side, and reference may be made to the description of the corresponding steps in Embodiment 1 for implementation of functions of units of the network side apparatus, which is no longer repeated herein.

Embodiment 10

[0201] This embodiment provides user equipment, which can support a radio communications technology. Transmission of a data packet can be performed based on the method described in Embodiment 2 among units in a communications device in this embodiment. A schematic structural diagram is shown in FIG. 12, and the user equipment includes: a processor 31, a receiver 33, and a transmitter 34 that are separately connected to a bus.

[0202] Optionally, the shown network side apparatus may further include: a memory 30.

[0203] The memory 30 is configured to store data input from the receiver 33, and may further store information such as a necessary file for the processor 31 to process data; and the receiver 33 and the transmitter 34 are ports by using which a communications device communicates with another device.

[0204] The receiver 33 is configured to receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group.

[0205] The processor 31 is configured to obtain reference signal port information in at least one port group according to the reference signal port configuration information; and acquire signal quality measurement information according to the reference signal port information in the at least one port group.

[0206] Optionally, the processor 31 is specifically configured to:

obtain reference signal port information in one specified port group according to the reference signal port configuration information; and
acquire the signal quality measurement information according to the reference signal port information in the one specified port group.

[0207] Optionally, when the signal quality measurement information is a reference signal received power RSRP, the acquiring, by the processor 31, the signal quality measurement information according to the reference signal port information in the one specified port group includes:
obtaining a reference signal received power $RSRP(r,p)$ of a pth port of an rth receive antenna according to a formula

$$RSRP(r,p)=\frac{1}{K_s-1}\sum_{m=0}^{K_s-1}\hat{h}_p(m)\cdot\hat{h}_p(m+1)$$

and obtaining the RSRP by combining $RSRP(r,p)$, where $\hat{h}_p(m)$ is a channel estimation on a reference signal RE whose label number is m, K_s is a total sample quantity of usable reference signal REs in measurement bandwidth, p is a number of a reference signal port in the one specified port group, and r is an index of a receive antenna.

[0208] Optionally, the reference signal resource configuration information received by the receiver 33 further includes: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups.

[0209] Optionally, the acquiring, by the processor 31, the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups includes:

obtaining, according to the reference signal port configuration information, signal quality measurement information corresponding to the at least two port groups; and
performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information.

[0210] Optionally, the performing, by the processor 31, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information includes:
obtaining the signal quality measurement information according to a formula

$$SQ=\left(\sum_{g=0}^{n-1}p_g\cdot SQ_g\right)\Big/\left(\sum_{g=0}^{n-1}p_g\right),$$

where
SQ_g is signal quality measurement information of a specified port group, g is a sequence number of a specified port group, n is a quantity of specified port groups, $n\geq 2$, and p_g is a reference signal power of a specified port group, where the reference signal power of the specified port group is obtained according to the reference signal power information of the at least two port groups.

[0211] Optionally, the reference signal power information, of the at least two port groups, received by the receiver 33 includes:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or
a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

[0212] Optionally, the transmitter 34 is configured to send the signal quality measurement information to the base station.

[0213] Optionally, when the signal quality measurement information is a reference signal received power RSRP, the receiver 33 is further configured to receive filter coefficient information sent by the base station; and
the processor 31 is further configured to perform, based on the filter coefficient information, filtering on the reference signal received power RSRP, and obtain a path loss estimation value.

[0214] Optionally, the transmitter 34 is further configured to send an uplink physical channel or an uplink physical signal to the base station, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation according to the path loss estimation value.

[0215] Optionally, the signal quality measurement information includes: a reference signal received power RSRP, a reference signal strength indicator RSSI, or a reference signal received quality RSRQ.

Embodiment 11

[0216] A network side apparatus is provided and can support a radio communications technology. Transmission of a data packet can be performed based on the method described in Embodiment 3 among units in a communications device in this embodiment. A schematic structural diagram is shown in FIG. 13, and the network side apparatus includes: a processor 41, a receiver 43, and a transmitter 44 that are separately connected to a bus.

[0217] Optionally, the shown network side apparatus may further include: a memory 40.

[0218] The memory 40 is configured to store data input from the receiver 43, and may further store information such as a necessary file for the processor 41 to process data; and the receiver 43 and the transmitter 44 are ports by using which a communications device communicates with another device.

[0219] The transmitter 44 is configured to send reference signal resource configuration information to user equipment, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal; and
the receiver 43 is configured to receive channel state information CSI sent by the user equipment, where the CSI is obtained by the user equipment according to the reference signal port configuration information and the power ratio information.

[0220] Optionally, in the power ratio information:

power ratios of data channels on antenna ports in each port group among the at least one port group to a reference signal are the same; or
power ratios of data channels on ports in one port group among the at least one port group and data channels on ports in another port group to a reference signal are the same.

[0221] Optionally, the power ratio information is used for indicating multiple sets of power ratios of data channels of the at least one port group to a reference signal; and
the receiving, by the receiver 33, channel state information CSI sent by the user equipment includes: receiving multiple sets of channel state information CSI that are sent by the user equipment, where each set of channel state information CSI is obtained by the user equipment according to one set of power ratios among the multiple sets of power ratios.

[0222] Optionally, the channel state information CSI received by the receiver 33 includes: any one or any combination of a channel quality indicator CQI, a precoding matrix indicator PMI, and a rank indicator RI.

[0223] The network side apparatus provided in this embodiment may be a base station on a network side, and reference may be made to the description of the corresponding steps in Embodiment 3 for implementation of functions of units of the network side apparatus, which is no longer repeated herein.

Embodiment 12

[0224] This embodiment provides user equipment, which can support a radio communications technology. Transmission of a data packet can be performed based on the method described in Embodiment 4 among units in a communications device in this embodiment. A schematic structural diagram is shown in FIG. 14, and the user equipment includes: a

processor 51, a receiver 53, and a transmitter 54 that are separately connected to a bus.

[0225] Optionally, the shown network side apparatus may further include: a memory 50.

[0226] The memory 50 is configured to store data input from the receiver 53, and may further store information such as a necessary file for the processor 51 to process data; and the receiver 53 and the transmitter 54 are ports by using which a communications device communicates with another device.

[0227] The receiver 53 is configured to receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal.

[0228] The processor 51 is configured to obtain a power ratio of a data channel on each antenna port in the at least one port group to a reference signal according to the reference signal port configuration information and the power ratio information, and obtain channel state information CSI according to the power ratio of the data channel on each antenna port to the reference signal.

[0229] The transmitter 54 is configured to send the channel state information CSI to the base station.

[0230] Optionally, the obtaining, by the processor 51, channel state information CSI according to the power ratio of the data channel on each antenna port to the reference signal includes:

obtaining, according to the reference signal on each antenna port, a channel measurement value corresponding to each antenna port;
obtaining a channel estimation value of the data channel on each antenna port according to the channel measurement value corresponding to each antenna port and the power ratio of the data channel on each antenna port to the reference signal; and
obtaining the channel state information CSI according to the channel estimation value of the data channel on each antenna port.

[0231] Optionally, the obtaining, by the processor 51, a channel estimation value of the data channel on each antenna port according to the channel measurement value corresponding to each antenna port and the power ratio of the data channel on each antenna port to the reference signal includes:
obtaining a channel estimation value of a data channel on an antenna port p according to a formula

$$\hat{\mathbf{h}}_p = \sqrt{\rho_p}\mathbf{h}_p,$$

where
p is an index of the antenna port, ρ_p is a power ratio of the data channel on the antenna port p to a reference signal, $\mathbf{h}_p$ is a channel measurement value corresponding to the antenna port p, and $\hat{\mathbf{h}}_p$ is a channel estimation value of the data channel on the antenna port p.

[0232] Optionally, in the power ratio information:

power ratios of data channels on antenna ports in each port group among the at least one port group to a reference signal are the same; or
power ratios of data channels on ports in one port group among the at least one port group and data channels on ports in another port group to a reference signal are the same.

[0233] Optionally, the power ratio information is used for indicating multiple sets of power ratios of data channels of the at least one port group to a reference signal; and
the transmitter 54 is specifically configured to:
send multiple sets of channel state information CSI to the base station, where each set of channel state information CSI is obtained according to one set of power ratios among the multiple sets of power ratios.

[0234] Optionally, the channel state information CSI obtained by the processor 51 includes: any one or any combination of a channel quality indicator CQI, a precoding matrix indicator PMI, and a rank indicator RI.

[0235] A person of ordinary skill in the art may understand that all or a part of the steps of the methods in the embodiments may be implemented by a program instructing relevant hardware. The program may be stored in a computer readable storage medium. The storage medium may include: a ROM, a RAM, a magnetic disk, or an optical disc.

[0236] The method and the apparatus for measuring communication quality provided in the embodiments of the present invention are introduced above in detail. In this specification, specific examples are used to describe the principle and

implementation manners of the present invention, and the description of the embodiments is only intended to help understand the method and core idea of the present invention defined by the scope of the appended claims. Meanwhile, a person of ordinary skill in the art may, based on the idea of the present invention, make modifications with respect to the specific implementation manners. Therefore, the content of this specification shall not be construed as a limitation to the present invention, which is defined by the scope of the appended claims.

Claims

1. A method for measuring communication quality in an active antenna system performed by a user equipment, comprising:

receiving (101) reference signal resource configuration information sent by a base station, wherein the reference signal resource configuration information comprises reference signal port configuration information, wherein the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group, wherein the port group is a group of ports of an antenna port array;
obtaining (102) reference signal port information in at least one port group according to the reference signal port configuration information; and
acquiring (103) signal quality measurement information according to the reference signal port information in the at least one port group; wherein the reference signal resource configuration information further comprises: reference signal power information of at least two port groups that is used by the user equipment to acquire the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups,
characterized in,
that the acquiring the signal quality measurement information according to the reference signal port configuration information and in combination with the reference signal power information of the at least two port groups comprises:

obtaining, according to the reference signal port configuration information, signal quality measurement information corresponding to the at least two port groups; and
performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information,

wherein the performing, according to the reference signal power information of the at least two port groups, weighted averaging on the obtained signal quality measurement information corresponding to the at least two port groups in accordance with a port group power, to obtain the signal quality measurement information comprises:
obtaining the signal quality measurement information according to a formula

$$SQ = \left(\sum_{g=0}^{n-1} p_g \cdot SQ_g \right) \Big/ \left(\sum_{g=0}^{n-1} p_g \right),$$

wherein
SQ_g is signal quality measurement information of a specified port group, g is a sequence number of a specified port group, n is a quantity of specified port groups, $n \geq 2$, and p_g is a reference signal power of a specified port group, wherein the reference signal power of the specified port group is obtained according to the reference signal power information of the at least two port groups.

2. The method according to claim 1, wherein the reference signal power information of the at least two port groups comprises:

a reference signal power of a first port group, and a ratio of a reference signal power of each port group among the rest port groups to the reference signal power of the first port group; or
a reference signal power of a first port group, and a differential between a reference signal power of each port group among the rest port groups and the reference signal power of the first port group.

Patentansprüche

1. Verfahren zum Messen der Kommunikationsqualität in einem aktiven Antennensystem, durchgeführt von einem Benutzergerät, das Folgendes umfasst:

   Empfangen (101) der von einer Basisstation gesendeten Referenzsignal-Ressourcenkonfigurationsinformationen, wobei die Referenzsignal-Ressourcenkonfigurationsinformationen Referenzsignal-Anschlusskonfigurationsinformationen umfassen, wobei die Referenzsignal-Anschlusskonfigurationsinformationen zum Angeben einer Zuordnungsbeziehung zwischen einem Referenzsignalanschluss und einer Anschlussgruppe verwendet werden, wobei die Anschlussgruppe eine Gruppe von Anschlüssen eines Antennenanschlussarrays ist;
   Erhalten (102) von Referenzsignal-Anschlussinformationen in mindestens einer Anschlussgruppe gemäß den Referenzsignal-Anschlusskonfigurationsinformationen; und
   Erfassen (103) von Signalqualitätsmessungsinformationen gemäß den Referenzsignal-Anschlussinformationen in der mindestens einen Anschlussgruppe; wobei die Referenzsignal-Ressourcenkonfigurationsinformationen ferner Folgendes umfassen: Referenzsignal-Leistungsinformationen von mindestens zwei Anschlussgruppen, die von dem Benutzergerät verwendet werden, um die Signalqualitätsmessungsinformationen gemäß den Referenzsignal-Anschlusskonfigurationsinformationen und in Kombination mit den Referenzsignal-Leistungsinformationen der mindestens zwei Anschlussgruppen zu erfassen,
   gekennzeichnet dadurch,
   dass das Erfassen der Signalqualitätsmessungsinformationen gemäß den Referenzsignal-Anschlusskonfigurationsinformationen und in Kombination mit den Referenzsignal-Leistungsinformationen der mindestens zwei Anschlussgruppen Folgendes umfasst:

      Erhalten, gemäß den Referenzsignal-Anschlusskonfigurationsinformationen, von Signalqualitätsmessungsinformationen, die den mindestens zwei Anschlussgruppen entsprechen; und
      Durchführen, gemäß den Referenzsignal-Leistungsinformationen der mindestens zwei Anschlussgruppen, einer gewichteten Mittelung an den erhaltenen Signalqualitätsmessungsinformationen, die den mindestens zwei Anschlussgruppen entsprechen, im Einklang mit einer Anschlussgruppenleistung, um die Signalqualitätsmessungsinformationen zu erhalten,

   wobei das Durchführen, gemäß den Referenzsignal-Leistungsinformationen der mindestens zwei Anschlussgruppen, einer gewichteten Mittelung an den erhaltenen Signalqualitätsmessungsinformationen, die den mindestens zwei Anschlussgruppen entsprechen, im Einklang mit einer Anschlussgruppenleistung, um die Signalqualitätsmessungsinformationen zu erhalten, Folgendes umfasst:
   Erhalten der Signalqualitätsmessungsinformationen gemäß einer Formel

$$= (\sum_{g=0}^{n-1} Pg \cdot SQg)/(\sum_{g=0}^{n-1} Pg),$$

   wobei
   SQg die Signalqualitätsmessungsinformationen einer angegebenen Anschlussgruppe sind, g eine Folgenummer einer angegebenen Anschlussgruppe ist, n eine Menge von angegebenen Anschlussgruppen ist, $n \geq 2$ ist, und Pg eine Referenzsignalleistung einer angegebenen Anschlussgruppe ist, wobei die Referenzsignalleistung der angegebenen Anschlussgruppe gemäß den Referenzsignal-Leistungsinformationen der mindestens zwei Anschlussgruppen erhalten wird.

2. Verfahren gemäß Anspruch 1, wobei die Referenzsignal-Leistungsinformationen der mindestens zwei Anschlussgruppen Folgendes umfassen:

   eine Referenzsignalleistung einer ersten Anschlussgruppe und ein Verhältnis einer Referenzsignalleistung jeder Anschlussgruppe unter den restlichen Anschlussgruppen zu der Referenzsignalleistung der ersten Anschlussgruppe; oder
   eine Referenzsignalleistung einer ersten Anschlussgruppe und eine Differenz zwischen einer Referenzsignalleistung jeder Anschlussgruppe unter den restlichen Anschlussgruppen und der Referenzsignalleistung der ersten Anschlussgruppe.

Revendications

1. Procédé de mesure d'une qualité de communication dans un système d'antenne actif exécuté par un équipement utilisateur, consistant à :

recevoir (101) des informations de configuration de ressources de signal de référence envoyées par une station de base, dans lequel les informations de configuration de ressources de signal de référence comprennent des informations de configuration de ports de signal de référence, dans lequel les informations de configuration de ports de signal de référence sont utilisées pour indiquer un rapport de mappage entre un port de signal de référence et un groupe de ports, le groupe de ports étant un groupe de ports d'un ensemble de ports d'antennes ;
obtenir (102) des informations de ports de signal de référence dans au moins un groupe de ports en fonction des informations de configuration de ports de signal de référence ; et
acquérir (103) des informations de mesures de qualité de signal en fonction des informations de ports de signal de référence dans l'au moins un groupe de ports ; les informations de configuration de ressources de signal de référence comprenant en outre : des informations de puissance de signal de référence d'au moins deux groupes de ports qui sont utilisées par l'équipement utilisateur pour acquérir les informations de mesures de qualité de signal en fonction des informations de configuration de ports de signal de référence et en combinaison avec les informations de puissance de signal de référence des au moins deux groupes de ports,
caractérisé en ce que
l'acquisition des informations de mesures de qualité de signal en fonction des informations de configuration de ports de signal de référence et en combinaison avec les informations de puissance de signal de référence des au moins deux groupes de ports consiste à :

obtenir, en fonction des informations de configuration de ports de signal de référence, des informations de mesures de qualité de signal correspondant aux au moins deux groupes de ports ; et
exécuter, en fonction des informations de puissance de signal de référence des au moins deux groupes de ports, un moyennage pondéré sur les informations de mesures de qualité de signal obtenues correspondant aux au moins deux groupes de ports en fonction d'une puissance des groupes de ports, pour obtenir les informations de mesures de qualité de signal,

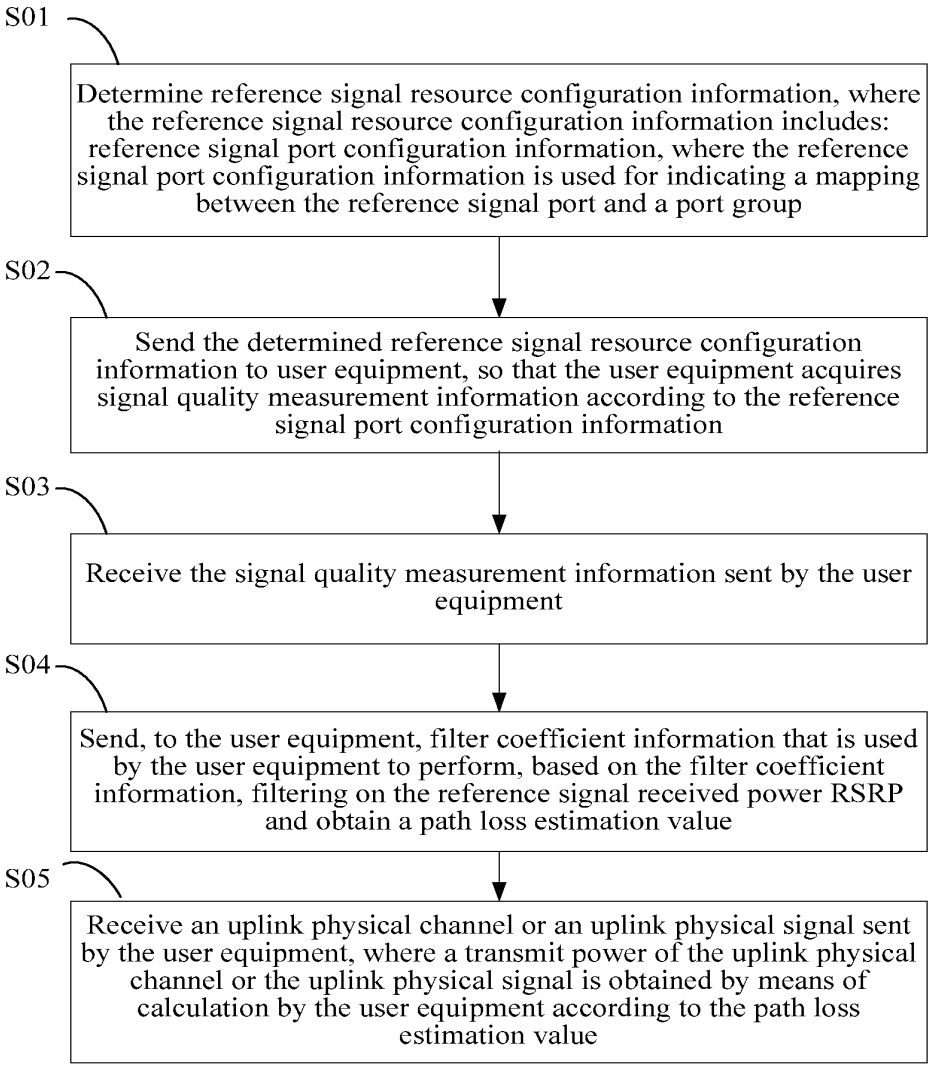
dans lequel l'exécution, en fonction des informations de puissance de signal de référence des au moins deux groupes de ports, du moyennage pondéré sur les informations de mesures de qualité de signal obtenues correspondant aux au moins deux groupes de ports en fonction d'une puissance des groupes de ports, pour obtenir les informations de mesures de qualité de signal consiste à :
obtenir les informations de mesures de qualité de signal selon une formule

$$SQ = \left(\sum_{g=0}^{n-1} p_g \cdot SQ_g \right) \Big/ \left(\sum_{g=0}^{n-1} p_g \right),$$

dans laquelle
SQg représente les informations de mesures de qualité de signal d'un groupe de ports spécifié, g est un numéro de séquence d'un groupe de ports spécifié, n est une quantité de groupes de ports spécifiés, $n \geq 2$, et Pg représente une puissance de signal de référence d'un groupe de ports spécifiés, la puissance de signal de référence du groupe de ports spécifié étant obtenue en fonction des informations de puissance de signal de référence des au moins deux groupes de ports.

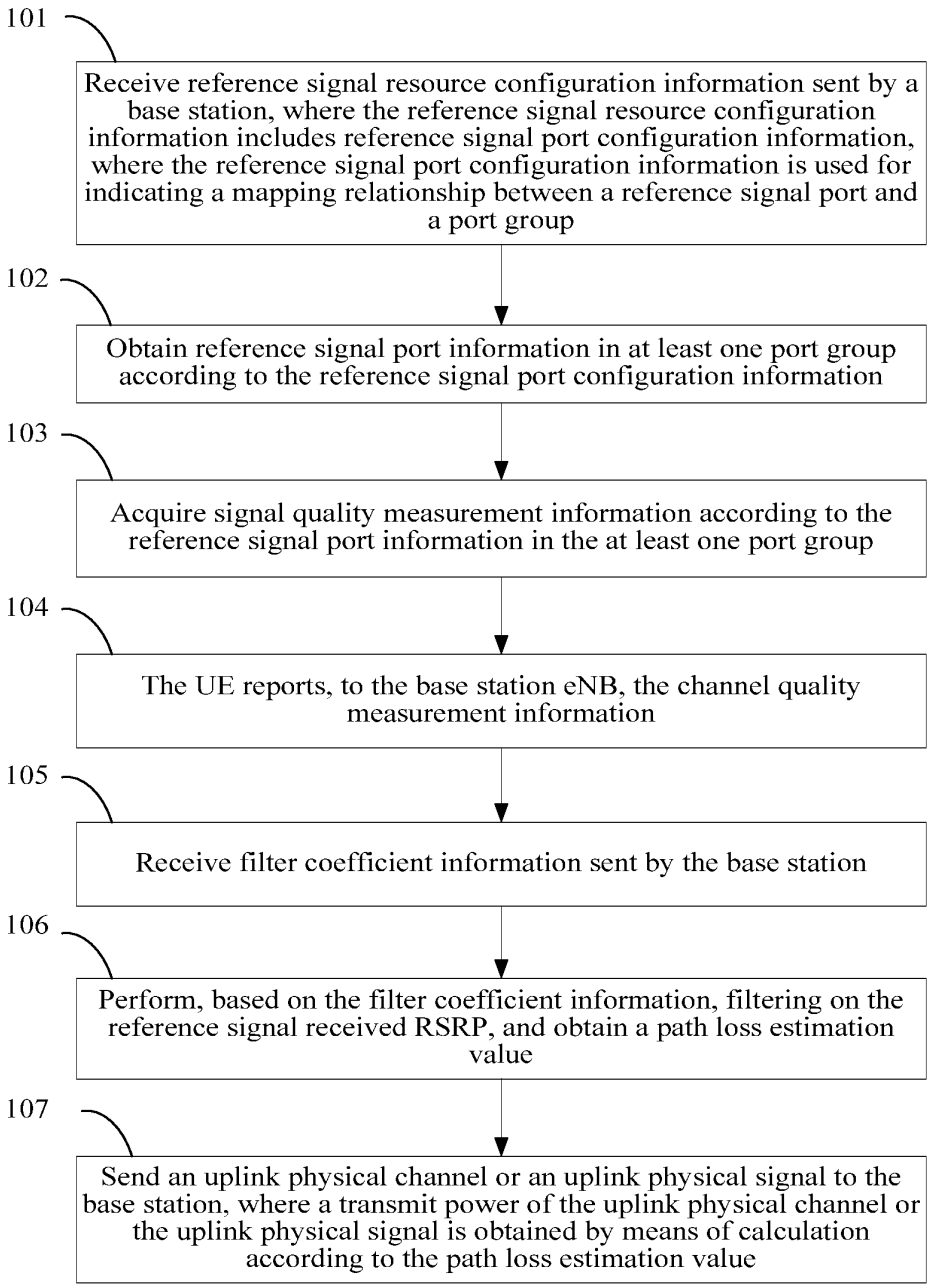
2. Procédé selon la revendication 1, dans lequel les informations de puissance de signal de référence des au moins deux groupes de ports comprennent :

une puissance de signal de référence d'un premier groupe de ports, et un rapport d'une puissance de signal de référence de chaque groupe de ports parmi les groupes de ports restants par rapport à la puissance de signal de référence du premier groupe de ports ; ou
une puissance de signal de référence d'un premier groupe de ports, et un différentiel entre une puissance de signal de référence de chaque groupe de ports parmi les groupes de ports restants et la puissance de signal de référence du premier groupe de ports.



S01
Determine reference signal resource configuration information, where the reference signal resource configuration information includes: reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping between the reference signal port and a port group
S02
Send the determined reference signal resource configuration information to user equipment, so that the user equipment acquires signal quality measurement information according to the reference signal port configuration information
S03
Receive the signal quality measurement information sent by the user equipment
S04
Send, to the user equipment, filter coefficient information that is used by the user equipment to perform, based on the filter coefficient information, filtering on the reference signal received power RSRP and obtain a path loss estimation value
S05
Receive an uplink physical channel or an uplink physical signal sent by the user equipment, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation by the user equipment according to the path loss estimation value

FIG. 1



101
Receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes reference signal port configuration information, where the reference signal port configuration information is used for indicating a mapping relationship between a reference signal port and a port group
102
Obtain reference signal port information in at least one port group according to the reference signal port configuration information
103
Acquire signal quality measurement information according to the reference signal port information in the at least one port group
104
The UE reports, to the base station eNB, the channel quality measurement information
105
Receive filter coefficient information sent by the base station
106
Perform, based on the filter coefficient information, filtering on the reference signal received RSRP, and obtain a path loss estimation value
107
Send an uplink physical channel or an uplink physical signal to the base station, where a transmit power of the uplink physical channel or the uplink physical signal is obtained by means of calculation according to the path loss estimation value

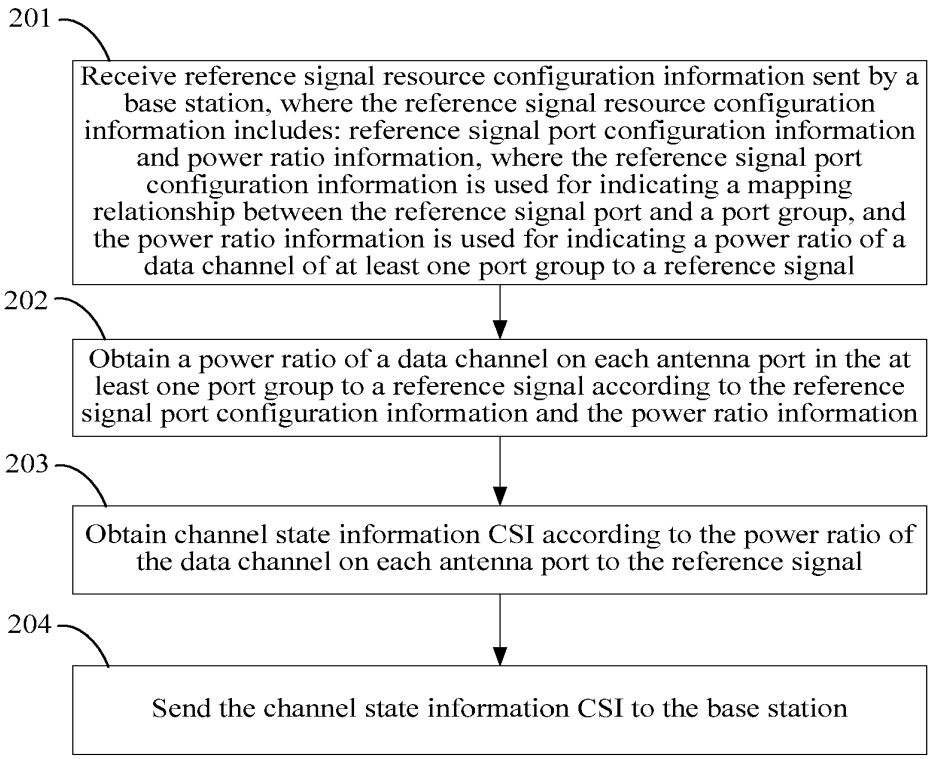
Determine reference signal resource configuration information, and send the reference signal resource configuration information to user equipment, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal
S22
Receive channel state information CSI sent by the user equipment, where the CSI is obtained by the user equipment according to the reference signal port configuration information and the power ratio information

FIG. 5



201
Receive reference signal resource configuration information sent by a base station, where the reference signal resource configuration information includes: reference signal port configuration information and power ratio information, where the reference signal port configuration information is used for indicating a mapping relationship between the reference signal port and a port group, and the power ratio information is used for indicating a power ratio of a data channel of at least one port group to a reference signal
202
Obtain a power ratio of a data channel on each antenna port in the at least one port group to a reference signal according to the reference signal port configuration information and the power ratio information
203
Obtain channel state information CSI according to the power ratio of the data channel on each antenna port to the reference signal
204
Send the channel state information CSI to the base station

Beam recovery method and device

Abstract

The embodiment of the invention discloses a beam recovery method and device, and the method comprises the steps that terminal device uses at least one beam in a first time window to send a request forrecovering a beam to network equipment, and the request for recovering the beam is a scheduling request or a beam failure recovery request; and the terminal device uses at least one beam in the firsttime window to receive a response for the beam recovery request sent by the network device, wherein the response for the beam recovery request is a scheduling request response or a beam failure recovery request response. By adopting the embodiment of the invention, the wave beam recovery processing of a plurality of wave beam recovery requests sent by the same terminal equipment by the network equipment can be realized, and the wave beam recovery efficiency is improved.

波束恢复方法及装置

(57)摘要

本发明实施例公开了波束恢复方法及装置，所述方法包括：终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，用于恢复波束的请求为调度请求或者波束失败恢复请求；终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。采用本发明实施例，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

CN 110062398 A

1.一种波束恢复方法,其特征在于,所述方法包括:

终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求,所述用于恢复波束的请求为调度请求或者波束失败恢复请求;

所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应,所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

2.如权利要求1所述的方法,其特征在于,所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求,包括:

所述终端设备在所述第一时间窗所包含的至少一个符号上,使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

3.如权利要求2所述的方法,其特征在于,所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应,包括:

所述终端设备在所述第一时间窗所包含的至少一个符号上,使用所述第一波束接收所述用于波束恢复请求的响应。

4.如权利要求1所述的方法,其特征在于,所述第一时间窗包括第一单元时间窗和第二单元时间窗,所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号;

所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求,包括:

所述终端设备在所述第一单元时间窗所包含的至少一个符号上,使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

5.如权利要求4所述的方法,其特征在于,所述终端设备在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应,包括:

所述终端设备在所述第二单元时间窗所包含的至少一个符号上,使用所述第一波束接收所述用于波束恢复请求的响应。

6.如权利要求2～5任一项所述的方法,其特征在于,所述方法还包括:

当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时,所述终端设备确定所述网络设备对所述终端设备配置的第三时间窗;

所述终端设备在所述第三时间窗所包含的至少一个符号上,使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

7.如权利要求1～6任一项所述的方法,其特征在于,所述终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求,包括:

所述终端设备基于所述网络设备对所述终端设备配置的波束请求指示信息,在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求,所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

8.如权利要求1～7任一项所述的方法,其特征在于,所述用于恢复波束的请求通过随机接入信道RACH资源发送。

9.如权利要求1-7任一项所述的方法,其特征在于,所述用于波束恢复请求的响应通过物理下行控制信道PDCCH发送,所述PDCCH的循环冗余校验CRC由小区无线网络临时标识C-

RNTI加扰。

10.一种波束恢复装置，其特征在于，所述装置包括：

发送模块，用于在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

接收模块，用于在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

11.如权利要求10所述的装置，其特征在于，所述发送模块，具体用于：

在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

12.如权利要求11所述的装置，其特征在于，

所述接收模块，具体用于在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

13.如权利要求10所述的装置，其特征在于，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

所述发送模块，具体用于在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

14.如权利要求13所述的装置，其特征在于，

所述接收模块，具体用于在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

15.如权利要求10～14任一项所述的装置，其特征在于，所述装置还包括：

确定模块，用于当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述终端设备确定所述网络设备对所述终端设备配置的第三时间窗；

所述发送模块，还用于在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

16.如权利要求10～15任一项所述的装置，其特征在于，

所述发送模块，具体用于基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

17.如权利要求10～16任一项所述的装置，其特征在于，所述用于恢复波束的请求通过随机接入信道RACH资源发送。

18.如权利要求10～16任一项所述的装置，其特征在于，所述用于波束恢复请求的响应通过物理下行控制信道PDCCH发送，所述PDCCH的循环冗余校验CRC由小区无线网络临时标识C-RNTI加扰。

19.一种计算机存储介质，所述计算机存储介质存储有程序，所述程序被执行时实现如权利要求1-9任意一项的方法。

20.一种波束恢复装置，其特征在于，包括处理器、存储器，所述存储器中存储有程序代码，所述处理器调用存储器中存储的程序代码，实现如权利要求1-9任意一项的方法。

波束恢复方法及装置

技术领域

[0001] 本申请涉及通信技术领域，尤其涉及波束恢复方法及装置。

背景技术

[0002] 波束(beam)是一种通信资源，不同的波束可以认为是不同的通信资源。在移动通信系统中使用波束进行信息传输，即通过在空间上朝向特定的方向发送信号，可以实现更高的天线阵列增益。发射波束可以是指信号经天线发射出去后在空间不同方向上形成的信号强度的分布，接收波束可以是指从天线上接收到的无线信号在空间不同方向上的信号强度分布。一个波束对通常包括一个发送端的发射波束和一个接收端的接收波束。当下行控制信道关联的波束的性能下降到某个门限值时，该波束失效，即无法使用该波束进行信息传输，一旦波束失效，将触发波束恢复机制。

[0003] 在长期演进(Long Term Evolution，LTE)系统中，在建立无线链路过程中的初始接入、在无线链路建立失败之后的链路重建或者采用基于上行测量的定位方法以进行定位等过程中可以采用随机接入方案，具体可以为：终端设备向网络设备发送调度请求(Scheduling Request，SR)，以通知网络设备有终端设备试图接入；终端设备在预先配置的时间窗内监测控制信道，以接收网络设备下发的随机接入响应(Random Access Response，RAR)。上述随机接入方案仅针对网络设备接收到同一终端设备发送的一个SR的场景。

[0004] 当下行链路(Down Link，DL)的波束对(Beam Pair Link，BPL)失效时，为了充分利用现有的资源，以及波束失效的持续时间远小于无线链路失效(Radio Link Failure，RLF)的时间窗长度，终端设备可以利用随机接入信道(Random Access Channel，RACH)资源在不同方向的多个波束上发射SR，则网络设备在时间窗内可以接收到来自同一终端设备的多个SR。而传统LTE中随机接入的处理流程仅针对网络设备收到同一终端设备发送的一个SR的场景，在网络设备收到同一终端设备发送的多个SR时如何进行随机接入处理，是目前亟需解决的问题。

发明内容

[0005] 本发明实施例所要解决的技术问题在于，提供波束恢复方法及装置，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

[0006] 第一方面，本发明实施例提供了一种波束恢复方法，终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求；终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应。

[0007] 其中，用于恢复波束的请求可以为调度请求或者波束失败恢复请求(beam failure recovery request)。

[0008] 其中，用于波束恢复请求的响应可以为调度请求响应或者波束失败恢复请求响应。

[0009] 例如，当用于恢复波束的请求为调度请求时，用于波束恢复请求的响应可以为调度请求响应；当用于恢复波束的请求为波束失败恢复请求时，用于波束恢复请求的响应可以为波束失败恢复请求响应。

[0010] 其中，第一时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第一时间窗可以包括3个符号或者7个符号等。

[0011] 可选的，第一时间窗所包含的第一个符号可以为第一个配置有随机接入信道(Random Access Channel，RACH)资源的符号。

[0012] 在该技术方案中，终端设备可以使用至少一个波束向网络设备发送用于恢复波束的请求，终端设备还可以在第一时间窗内使用上述至少一个波束接收网络设备发送的用于波束恢复请求的响应，则终端设备向网络设备发送的用于恢复波束的请求可以包括多个，以便提高波束恢复效率。

[0013] 可选的，终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求。

[0014] 其中，第一波束可以是网络设备对终端设备配置的一个波束。

[0015] 例如，终端设备可以在第一时间窗所包含的一个符号上，使用一个第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括3个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的一个符号为第一符号，则终端设备可以在第一时间窗所包含的第一符号上，使用第一波束向网络设备发送用于恢复波束的请求。

[0016] 又如，终端设备可以在第一时间窗所包含的一个符号上，使用多个相同的第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括3个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的一个符号为第一符号，则终端设备可以在第一时间窗所包含的第一符号上，在不同方向上使用第一波束向网络设备发送用于恢复波束的请求。

[0017] 又如，终端设备可以在第一时间窗所包含的多个符号上，使用一个第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括3个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的多个符号包括第二符号和第三符号，则终端设备可以在第一时间窗所包含的第二符号上，使用第一波束向网络设备发送用于恢复波束的请求，且在第一时间窗所包含的第三符号上，使用第一波束向网络设备发送用于恢复波束的请求。

[0018] 又如，终端设备可以在第一时间窗所包含的多个符号上，使用多个相同的第一波束向网络设备发送用于恢复波束的请求。示例性的，第一时间窗包括3个符号，分别为第一符号、第二符号以及第三符号，若终端设备在第一时间窗中确定的多个符号包括第二符号和第三符号，则终端设备可以在第一时间窗所包含的第二符号上，使用第一波束向网络设备发送用于恢复波束的请求，且在第一时间窗所包含的第三符号上，使用第一波束向网络设备发送用于恢复波束的请求。

[0019] 在该技术方案中，终端设备可以在一个符号上使用多个相同的第一波束向网络设备发送用于恢复波束的请求，或者在多个符号上使用一个或者多个相同的第一波束向网络

设备发送用于恢复波束的请求，以实现同一终端设备向网络设备发送多个用于恢复波束的请求。

[0020] 可选的，终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，具体可以为：终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

[0021] 在该技术方案中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求之后，可以在第一时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应，可确保发送用于波束恢复的请求的波束和接收用于波束恢复请求的响应的波束为同一波束。

[0022] 可选的，第一时间窗可以包括第一单元时间窗和第二单元时间窗，则终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求。

[0023] 其中，第一单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第一单元时间窗可以包括3个符号或者4个符号等。

[0024] 其中，第二单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第二单元时间窗可以包括4个符号或者5个符号等。

[0025] 其中，第二单元时间窗所包含的第一个符号为第一单元时间窗所包含的最后一个符号之后的第一个符号。例如第一单元时间窗包括4个符号，分别为符号0、符号1、符号2以及符号3，符号3之后的第一个符号为符号4，则终端设备可以确定第二单元时间窗所包含的第一个符号为符号4。需要说明的是，本发明实施例中的第一单元时间窗包含但不限定4个符号，第一单元时间窗的长度和第二单元时间窗的长度可以相同，也可以不相同，具体不受本发明实施例的限定。

[0026] 可选的，终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，具体可以为：终端设备在第二单元时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

[0027] 在该技术方案中，终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求之后，终端设备可以在第二单元时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应，可确保发送用于波束恢复的请求的波束和接收用于波束恢复请求的响应的波束为同一波束。

[0028] 可选的，当在第一时间窗内未接收到用于波束恢复请求的响应时，终端设备可以确定网络设备对终端设备配置的第三时间窗，并在第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向网络设备发送用于恢复波束的请求。

[0029] 其中，第三时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第三时间窗可以包括3个符号或者5个符号等。

[0030] 在该技术方案中，终端设备在第一时间窗未检测到用于波束恢复请求的响应时，终端设备可以在第三时间窗使用第一波束以外的其他波束重新向网络设备发送用于恢复波束的请求，若终端设备在第三时间窗所包含的至少一个符号上使用第二波束接收到网络设备发送的用于波束恢复请求的响应，则可实现波束恢复，可提高波束恢复的可靠性。

[0031] 可选的，第一时间窗可以包括第三单元时间窗和第四单元时间窗，则终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求。

[0032] 其中，第三单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第三单元时间窗可以包括3个符号或者5个符号等。

[0033] 其中，第四单元时间窗可以是网络设备对终端设备配置的时间窗，示例性的，第四单元时间窗可以包括4个符号或者5个符号等。

[0034] 其中，第四单元时间窗所包含的第一个符号可以为第三单元时间窗所包含的最后一个符号之后的第一个符号。例如第三单元时间窗包括4个符号，分别为符号0、符号1、符号2以及符号3，符号3之后的第一个符号为符号4，则终端设备可以确定第四单元时间窗所包含的第一个符号为符号4。需要说明的是，本发明实施例中的第三单元时间窗包含但不限定4个符号，第三单元时间窗的长度和第四单元时间窗的长度可以相同，也可以不相同，具体不受本发明实施例的限定。

[0035] 其中，网络设备可以对终端设备配置最大波束数量，例如允许终端设备发送用于恢复波束的请求时所使用的波束的数量可以小于等于5。需要说明的是，本发明实施例中的最大波束数量包含但不限于5，例如，最大波束数量可以为3，等等，具体不受本发明实施例的限制。

[0036] 其中，第三单元时间窗所包含的符号的数量总和可以是根据网络设备对终端设备配置的最大波束数量确定的。例如，第三单元时间窗所包含的符号的数量总和与最大波束数量之间可以呈正比例关系。示例性的，最大波束数量为5，则第三单元时间窗所包含的符号的数量总和可以为5，即第三单元时间窗包含5个符号。

[0037] 例如，终端设备可以在第三单元时间窗所包含的一个符号上，使用一个波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括5个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的一个符号为第一符号，则终端设备可以在第三单元时间窗所包含的第一符号上，使用波束1向网络设备发送用于恢复波束的请求。波束1可以为终端设备确定得到的一个波束，其中该波束可以是网络设备对终端设备配置的。

[0038] 又如，终端设备可以在第三单元时间窗所包含的一个符号上，使用多个不同波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括5个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的一个符号为第一符号，则终端设备可以在第三单元时间窗所包含的第一符号上，在不同方向上分别使用波束1～波束5中的多个波束向网络设备发送用于恢复波束的请求。其中，若网络设备对终端设备配置的最大波束数量为5，则终端设备在第三单元时间窗所包含的第一符号上，可以使用大于等于2个且小于等于5个波束向网络设备发送用于恢复波束的请求。

[0039] 又如，终端设备可以在第三单元时间窗所包含的多个符号上，使用一个波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括5个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的

多个符号包括第二符号和第三符号，则终端设备可以在第三单元时间窗所包含的第二符号上，使用波束1向网络设备发送用于恢复波束的请求，且在第三单元时间窗所包含的第三符号上，使用波束1向网络设备发送用于恢复波束的请求。

[0040] 又如，终端设备可以在第三单元时间窗所包含的多个符号上，使用多个不同波束向网络设备发送用于恢复波束的请求。示例性的，第三单元时间窗包括5个符号，分别为第一符号、第二符号、第三符号、第四符号以及第五符号，若终端设备在第三单元时间窗中确定的多个符号包括第二符号和第三符号，则终端设备可以在第三单元时间窗所包含的第二符号上，在不同方向上分别使用波束1～波束5中的多个波束向网络设备发送用于恢复波束的请求，且在第三单元时间窗所包含的第三符号上，在不同方向上分别使用波束1～波束5中的多个波束向网络设备发送用于恢复波束的请求。

[0041] 在该技术方案中，终端设备可以在一个符号上使用多个不同波束向网络设备发送用于恢复波束的请求，或者在多个符号上使用一个或者多个不同波束向网络设备发送用于恢复波束的请求，以实现同一终端设备向网络设备发送多个用于恢复波束的请求。

[0042] 可选的，终端设备在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，具体可以为：终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收用于波束恢复请求的响应。

[0043] 在该技术方案中，终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同波束向网络设备发送用于恢复波束的请求之后，终端设备可以在第四单元时间窗所包含的至少一个符号上，使用上述至少一个不同的波束接收用于波束恢复请求的响应，可确保发送用于波束恢复的请求的波束和接收用于波束恢复请求的响应的波束为同一波束。

[0044] 可选的，终端设备在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：终端设备基于网络设备对终端设备配置的波束请求指示信息，在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，波束请求指示信息用于指示用于恢复波束的请求的发送方式。

[0045] 例如，当波束请求指示信息用于指示用于恢复波束的请求的发送方式为在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束发送时，终端设备可以在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，并在第一时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

[0046] 又如，当波束请求指示信息用于指示用于恢复波束的请求的发送方式为在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束发送时，终端设备可以在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，并在第二单元时间窗所包含的至少一个符号上，使用第一波束接收用于波束恢复请求的响应。

[0047] 又如，当波束请求指示信息用于指示用于恢复波束的请求的发送方式为在第三单元时间窗所包含的至少一个符号上，使用至少一个不同波束发送时，终端设备可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求，并在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接

收用于波束恢复请求的响应。

[0048] 第二方面，本发明实施例提供了一种波束恢复方法，网络设备接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，并使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应。

[0049] 在该技术方案中，网络设备可以接收终端设备发送的多个用于恢复波束的请求，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，并使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

[0050] 可选的，网络设备在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：网络设备响应在第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求。

[0051] 例如，若终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定质量最好的波束所承载的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

[0052] 又如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定质量最好的波束所承载的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

[0053] 可选的，网络设备在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：网络设备响应在第二时间窗内接收到的第一个用于恢复波束的请求。

[0054] 例如，若终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定最先接收到的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

[0055] 又如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定最先接收到的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

[0056] 又如，若终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送用于恢复波束的请求，则网络设备可以在第二时间窗内接收到的用于恢复波束的请求中确定最先接收到的用于恢复波束的请求，并对确定得到的用于恢复波束的请求进行响应。

[0057] 可选的，网络设备使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应，具体可以为：网络设备在第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应。

[0058] 可选的，网络设备使用确定得到的用于恢复波束的请求对应的波束，向终端发送用于波束恢复请求的响应，具体可以为：网络设备在第二时间窗之外使用确定得到的用于

恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应。

[0059] 第三方面，本发明实施例提供一种计算机存储介质，所述计算机存储介质存储有程序，所述程序执行时包括本发明实施例第一方面提供的波束恢复方法中全部或部分的步骤。

[0060] 第四方面，本发明实施例提供一种计算机存储介质，所述计算机存储介质存储有程序，所述程序执行时包括本发明实施例第二方面提供的波束恢复方法中全部或部分的步骤。

[0061] 第五方面，本发明实施例提供一种波束恢复装置，该波束恢复装置包括用于执行本发明实施例第一方面公开的波束恢复方法的模块。

[0062] 第六方面，本发明实施例提供一种波束恢复装置，该波束恢复装置包括用于执行本发明实施例第二方面公开的波束恢复方法的模块。

[0063] 第七方面，本发明实施例提供一种终端设备，其特征在于，包括处理器、存储器以及收发器，存储器中存储一组程序代码，且处理器调用存储器中存储的程序代码，用于执行以下操作：

[0064] 在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求；在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应。

[0065] 第八方面，本发明实施例提供一种网络设备，其特征在于，包括处理器、存储器以及收发器，存储器中存储一组程序代码，且处理器调用存储器中存储的程序代码，用于执行以下操作：

[0066] 接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求；在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应。

[0067] 第九方面，本发明实施例提供一种波束恢复系统，包括本发明实施例第七方面公开的终端设备和本发明实施例第八方面公开的网络设备。

[0068] 第十方面，本申请实施例提供了一种通信芯片，其中存储有指令，当其在终端设备上运行时，使得所述通信芯片执行上述第一方面的方法。

[0069] 第十一方面，本申请实施例提供了一种通信芯片，其中存储有指令，当其在网络设备上运行时，使得所述通信芯片执行上述第二方面的方法。

附图说明

具体实施方式

[0088] 下面结合本发明实施例中的附图对本发明实施例进行描述。

[0089] 为了更好的理解本发明实施例公开的一种波束恢复方法及装置，下面首先对本发明实施例适用的网络架构进行描述。请参见图1，图1是本发明实施例公开的一种波束恢复系统的架构示意图。如图1所示，该波束恢复系统可以包括终端设备10以及网络设备20。其中，终端设备10与网络设备20之间可以通过通信连接进行数据传输。

[0090] 本发明实施例中的终端设备10可以称为用户设备(User Equipment，UE)、移动台、接入终端、用户单元、用户站、移动站、远方站、远程终端、移动设备、终端、无线通信设备、用户代理或用户装置等，其具体可以是WLAN中的站点(Station，ST)、蜂窝电话、无绳电话、会话启动协议(Session Initiation Protocol，SIP)电话、无线本地环路(Wireless Local Loop，WLL)站、个人数字处理(Personal Digital Assistant，PDA)、具有无线通信功能的手持设备、计算设备、连接到无线调制解调器的其它处理设备、车载设备、可穿戴设备、未来5G网络中的移动台以及未来演进的公共陆地移动网络(Public Land Mobile Network，PLMN)网络中的终端设备等中的任意一种。

[0091] 本发明实施例中的网络设备20可以是能和终端设备10通信的设备。网络设备20可以是基站、中继站或接入点。基站可以是全球移动通信系统(Global System for Mobile Communication，GSM)或码分多址(Code Division Multiple Access，CDMA)网络中的基站收发信台(Base Transceiver Station，BTS)，也可以是宽带码分多址(Wideband Code Division Multiple Access，WCDMA)中的NB(NodeB)，还可以是长期演进(Long Term Evolution，LTE)中的eNB或eNodeB(Evolutional NodeB)。网络设备20还可以是云无线接入网络(Cloud Radio Access Network，CRAN)场景下的无线控制器。网络设备20还可以是未来5G网络中的网络设备或者未来演进的PLMN网络中的网络设备。网络设备20还可以是可穿戴设备或车载设备。

[0092] 应理解，本发明实施例的技术方案可以应用于各种通信系统，例如：GSM系统、CDMA系统、WCDMA系统、通用分组无线业务(General Packet Radio Service，GPRS)、LTE系统、LTE频分双工(Frequency Division Duplex，FDD)系统、LTE时分双工(Time Division Duplex，TDD)、通用移动通信系统(Universal Mobile Telecommunication System，UMTS)或全球互联微波接入(Worldwide Interoperability for Microwave Access，WiMAX)通信

系统等。

[0093] 本发明实施例中，能够和基站进行数据通信的设备均可以理解为终端设备10，本发明实施例将以一般意义上的终端设备来介绍；本发明实施例中，网络设备20可以通过信令对终端设备10配置允许的最大波束数量，则终端设备10可以使用小于等于最大波束数量的波束向网络设备20发送用于波束恢复的请求；本发明实施例中，网络设备20可以对终端设备10配置第一时间窗，其中第一时间窗可以包括一个子帧、一个时隙以及一个或多个符号中的任意一种，则终端设备10可以在第一时间窗使用至少一个波束向网络设备20发送用于波束恢复的请求；本发明实施例中，网络设备20可以对终端设备10配置第三时间窗，其中第三时间窗可以包括一个子帧、一个时隙以及一个或多个符号中的任意一种，则终端设备10在第一时间窗使用至少一个第一波束向网络设备20发送用于波束恢复的请求之后，当在第一时间窗内未接收到网络设备20发送的用于波束恢复请求的响应时，终端设备10可以在第三时间窗使用至少一个第二波束向网络设备发送用于恢复波束的请求；本发明实施例中，网络设备20可以配置网络设备20侧的第二时间窗，其中第二时间窗可以包括一个子帧、一个时隙以及一个或多个符号中的任意一种，则网络设备20接收到终端设备10在第一时间窗使用至少一个波束发送的用于波束恢复的请求之后，可以在第二时间窗，在接收到的用于波束恢复的请求中确定一个用于波束恢复的请求。

[0094] 本发明实施例中，终端设备10至少有两种发送方式向网络设备20发送用于波束恢复的请求，以实现波束恢复。

[0095] 第一种发送方式可以为：终端设备10在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备20发送用于恢复波束的请求，并在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备20发送的用于波束恢复请求的响应。

[0096] 以图2A所示的信息传输的示意图为例，终端设备10在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束B4'向网络设备20发送用于恢复波束的请求。网络设备20按照接收RACH波束扫描方式检测终端设备10发送的用于恢复波束的请求，当网络设备20在第二时间窗内接收到终端设备10发送的用于波束恢复的请求时，网络设备20可以通过物理下行控制信道(Physical Downlink Control Channel，PDCCH)对该用于波束恢复的请求进行响应。当终端设备10在第一时间窗内未接收到网络设备20发送的用于恢复波束请求的响应时，终端设备10可以在第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束B5'向网络设备发送用于恢复波束的请求，当终端设备10在第三时间窗接收到网络设备20发送的用于波束恢复请求的响应时，终端设备10可以确定实现了波束恢复。

[0097] 第二种发送方式可以为：若第一时间窗包括第三单元时间窗和第四单元时间窗，终端设备10可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备20发送用于恢复波束的请求，并在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备20发送的用于波束恢复请求的响应。

[0098] 以图2B所示的信息传输的示意图为例，终端设备10在第三单元时间窗所包含的至少一个符号上，使用多个不同的波束向网络设备20发送用于恢复波束的请求，网络设备20在第二时间窗内接收到终端设备10发送的多个用于恢复波束的请求之后，可以在多个用于恢复波束的请求中确定一个用于恢复波束的请求，网络设备20可以使用确定得到的一个用于恢复波束的请求对应的波束，向终端设备10发送用于波束恢复请求的响应。终端设备10

可以按照波束扫描方式检测网络设备20发送的用于波束恢复请求的响应，当终端设备10接收到网络设备20发送的用于波束恢复请求的响应时，终端设备10可以确定实现了波束恢复。

[0099] 相对第一种发送方式，本发明实施例通过第二种发送方式可以使用多个不同的波束向网络设备20发送用于恢复波束的请求，可减小时延，提高波束恢复效率。

[0100] 基于图1所示的波束恢复系统的架构示意图，请参见图3，图3是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

[0101] 步骤S301：终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。

[0102] 具体地，当下行链路(Down Link，DL)的波束失效时，终端设备可以在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束1。

[0103] 例如，终端设备可以在第一时间窗中选取一个符号(例如符号3)，并在符号3上使用一个波束1向网络设备发送调度请求。又如，终端设备可以在第一时间窗中选取一个符号(例如符号3)，并在符号3上使用多个波束1向网络设备发送调度请求，例如：终端设备在符号3上，在不同方向上使用波束1向网络设备发送调度请求。又如，以图4所示的信息传输的示意图为例，终端设备可以在第一时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用一个波束1向网络设备发送调度请求，并在符号4上使用一个波束1向网络设备发送调度请求。又如，终端设备可以在第一时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用多个波束1向网络设备发送调度请求，并在符号4上使用多个波束1向网络设备发送调度请求。

[0104] 本发明实施例中，终端设备在第一时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送调度请求，可加大子载波间隔。

[0105] 本发明实施例中，网络设备可以对终端设备配置第一时间窗。其中，第一时间窗的起始时刻可以是配置有RACH资源的第一个符号，以图4所示的信息传输的示意图为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第一时间窗的起始时刻为符号3。

[0106] 其中，第一时间窗的长度可以是固定长度，例如7个符号，可选的，第一时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0107] 其中，网络设备可以向终端设备发送长度指示信息，以指示第一时间窗的长度。可选的，可以通过直接法指示第一时间窗的长度，例如长度指示信息为5，则终端设备可以确定第一时间窗的长度为5个符号。可选的，可以通过映射方式描述第一时间窗的长度，例如长度指示信息和第一时间窗的映射关系如表一所示：

[0108] 表一

[0109]

长度指示信息	第一时间窗的长度
00	3个符号
01	4个符号
10	5个符号
11	7个符号

[0110] 通过表一可知，当长度指示信息为二进制00时，终端设备可以确定第一时间窗的长度为3个符号；当长度指示信息为二进制11时，终端设备可以确定第一时间窗的长度为7个符号。需要说明的是，本发明实施例中的长度指示信息和第一时间窗长度的映射关系包含但不局限于上述方式，研发人员可以结合不同场景进行修改，具体不受本发明实施例的限制。

[0111] 其中，网络设备可以通过信令对终端设备配置第一时间窗，例如无线资源控制协议(Radio Resource Control，RRC)、媒体介入控制-控制元素协议(Media Access Control-Control Element，MAC-CE)或者下行控制信息协议(Downlink Control Information，DCI)等。

[0112] 其中，网络设备可以通过向终端设备发送长度指示信息的方式，通知终端设备配置了第一时间窗。

[0113] 步骤S302：网络设备确定在第二时间窗内接收到的第一个调度请求。

[0114] 具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的调度请求，并确定在第二时间窗内接收到的第一个调度请求。

[0115] 其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一单元时间窗所包含的第一个符号相同。

[0116] 其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0117] 步骤S303：网络设备在第二时间窗内使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应。

[0118] 具体实现中，网络设备可以获取承载确定得到的调度请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗内使用确定得到的波束向终端设备发送调度请求响应。其中，波束对可以包括一个发送端的发射波束和一个接收端的接收波束。例如承载确定得到的调度请求的波束为波束1，波束1与波束3构成一个波束对，则网络设备可以在第二时间窗内使用波束3向终端设备发送调度请求响应。

[0119] 以图4所示的信息传输的示意图为例，网络设备可以在第二时间窗所包含的符号0上，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应。

[0120] 可选的，网络设备可以通过PDCCH向终端设备发送调度请求响应。例如，终端设备可以在同一子帧接收多个承载在不同PDCCH上的DCI消息。对于一个PDCCH所承载的DCI消息，每个DCI消息上可以附着一个CRC。终端设备的C-RNTI可以被包含在CRC计算之中并隐式传输。则网络设备可以根据该终端设备的C-RNTI，确定包含该C-RNTI的CRC所属的DCI，进而确定承载该DCI的PDCCH，通过确定得到的PDCCH向终端设备发送调度请求响应。其中，DCI可以包括下行调度分配、上行调度请求、功率控制等。

[0121] 可选的，网络设备可以通过MAC-CE向终端设备发送调度请求响应。例如，网络设备可以定义一个新的MAC-CE，将该MAC-CE发送给终端设备，其中该MAC-CE可以携带调度请求响应。

[0122] 可选的，网络设备可以通过RRC向终端设备发送调度请求响应。例如，网络设备可以定义一个新的RRC IE，将该RRC IE发送给终端设备，其中该RRC IE可以携带调度请求响应。

[0123] 可选的，网络设备可以通过物理下行共享信道(Physical Downlink Shared Channel，PDSCH)向终端设备发送调度请求响应。

[0124] 步骤S304：终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应。

[0125] 终端设备可以在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应。例如，若终端设备在第一时间窗所包含的至少一个符号上，使用波束1向网络设备发送调度请求，则终端设备可以在第一时间窗所包含的至少一个符号上，使用波束1接收网络设备发送的调度请求响应。

[0126] 相对传统的波束恢复方法中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔最多第一时间窗，例如7个符号，可降低延迟，提高波束恢复的效率。

[0127] 在图3所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求，网络设备确定在第二时间窗内接收到的第一个调度请求，网络设备在第二时间窗内使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应，则终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应，可实现网络设备针对同一终端设备发送的多个调度请求的波束恢复处理，提高波束恢复效率。

[0128] 基于图1所示的波束恢复系统的架构示意图，请参见图5，图5是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

[0129] 步骤S501：终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。

[0130] 具体地，当DL波束失效时，终端设备可以在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束1。

[0131] 例如，终端设备可以在第一时间窗中选取一个符号(例如符号3)，并在符号3上使用一个波束1向网络设备发送波束失败恢复请求。又如，终端设备可以在第一时间窗中选取一个符号(例如符号3)，并在符号3上使用多个波束1向网络设备发送波束失败恢复请求，例如：终端设备在符号3上，在不同方向上使用波束1向网络设备发送波束失败恢复请求。又如，以图4所示的信息传输的示意图为例，终端设备可以在第一时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用一个波束1向网络设备发送波束失败恢复请求，并在符号4上使用一个波束1向网络设备发送波束失败恢复请求。又如，终端设备可以在第一时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用多个波束1向网络设备发送波束失败恢复请求，并在符号4上使用多个波束1向网络设备发送波束失败恢复请求。

[0132] 本发明实施例中，终端设备在第一时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送波束失败恢复请求，可加大子载波间隔。

[0133] 本发明实施例中，网络设备可以对终端设备配置第一时间窗。其中，第一时间窗的起始时刻可以是配置有RACH资源的第一个符号，以图4所示的信息传输的示意图为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第一时间窗的起始时刻为符号3。

[0134] 其中，第一时间窗的长度可以是固定长度，例如7个符号，可选的，第一时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0135] 其中，网络设备可以向终端设备发送长度指示信息，以指示第一时间窗的长度。可选的，可以通过直接法指示第一时间窗的长度，例如长度指示信息为5，则终端设备可以确定第一时间窗的长度为5个符号。可选的，可以通过映射方式描述第一时间窗的长度，例如长度指示信息和第一时间窗的映射关系如表一所示。通过表一可知，当长度指示信息为二进制00时，终端设备可以确定第一时间窗的长度为3个符号；当长度指示信息为二进制11时，终端设备可以确定第一时间窗的长度为7个符号。需要说明的是，本发明实施例中的长度指示信息和第一时间窗长度的映射关系包含但不局限于上述方式，研发人员可以结合不同场景进行修改，具体不受本发明实施例的限制。

[0136] 其中，网络设备可以通过信令对终端设备配置第一时间窗，例如无线资源控制协议(Radio Resource Control，RRC)、媒体介入控制-控制元素协议(Media Access Control-Control Element，MAC-CE)或者下行控制信息协议(Downlink Control Information，DCI)等。

[0137] 其中，网络设备可以通过向终端设备发送长度指示信息的方式，通知终端设备配置了第一时间窗。

[0138] 步骤S502：网络设备确定在第二时间窗内接收到的第一个波束失败恢复请求。

[0139] 具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的波束失败恢复请求，并确定在第二时间窗内接收到的第一个波束失败恢复请求。

[0140] 其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一单元时间窗所包含的第一个符号相同。

[0141] 其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0142] 步骤S503：网络设备在第二时间窗内使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应。

[0143] 具体实现中，网络设备可以获取承载确定得到的波束失败恢复请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗内使用确定得到的波束向终端设备发送波束失败恢复请求响应。例如承载确定得到的波束失败恢复请求的波束为波束1，波束1与波束3构成一个波束对，则网络设备可以在第二时间窗内使用波束3向终端设备发送波束失败恢复请求响应。

[0144] 以图4所示的信息传输的示意图为例，网络设备可以在第二时间窗所包含的符号0上，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应。

[0145] 可选的，网络设备可以通过PDCCH向终端设备发送波束失败恢复请求响应。

[0146] 可选的，网络设备可以通过MAC-CE向终端设备发送波束失败恢复请求响应。

[0147] 可选的，网络设备可以通过RRC向终端设备发送波束失败恢复请求响应。

[0148] 可选的，网络设备可以通过PDSCH向终端设备发送波束失败恢复请求响应。

[0149] 步骤S504：终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应。

[0150] 终端设备可以在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设

备发送的波束失败恢复请求响应。例如，若终端设备在第一时间窗所包含的至少一个符号上，使用波束1向网络设备发送波束失败恢复请求，则终端设备可以在第一时间窗所包含的至少一个符号上，使用波束1接收网络设备发送的波束失败恢复请求响应。

[0151] 相对传统的波束恢复方法中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔最多第一时间窗，例如7个符号，可降低延迟，提高波束恢复的效率。

[0152] 在图5所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求，网络设备确定在第二时间窗内接收到的第一个波束失败恢复请求，网络设备在第二时间窗内使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应，则终端设备在第一时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

[0153] 基于图1所示的波束恢复系统的架构示意图，请参见图6，图6是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

[0154] 步骤S601：终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。

[0155] 具体地，当DL波束失效时，终端设备可以在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束1。

[0156] 例如，终端设备可以在第一单元时间窗中选取一个符号(例如符号3)，并在符号3上使用一个波束1向网络设备发送调度请求。又如，终端设备可以在第一单元时间窗中选取一个符号(例如符号3)，并在符号3上使用多个波束1向网络设备发送调度请求，例如：终端设备在符号3上，在不同方向上使用波束1向网络设备发送调度请求。又如，以图7所示的信息传输的示意图为例，终端设备可以在第一单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用一个波束1向网络设备发送调度请求，并在符号4上使用一个波束1向网络设备发送调度请求。又如，终端设备可以在第一单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用多个波束1向网络设备发送调度请求，并在符号4上使用多个波束1向网络设备发送调度请求。

[0157] 本发明实施例中，终端设备在第一单元时间窗所包含的至少一个符号上，使用多个相同的第一波束向网络设备发送调度请求，可加大子载波间隔。

[0158] 本发明实施例中，网络设备可以对终端设备配置第一单元时间窗。其中，第一单元时间窗的起始时刻可以是配置有RACH资源的第一个符号，以图7所示的信息传输的示意图为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第一单元时间窗的起始时刻为符号3。

[0159] 本发明实施例中，网络设备可以对终端设备配置第二单元时间窗。其中，第二单元时间窗所包含的第一个符号为第一单元时间窗所包含的最后一个符号之后的第一个符号，以图7所示的信息传输的示意图为例，第一单元时间窗所包含的最后一个符号为符号6，则

终端设备可以确定第二单元时间窗所包含的第一个符号为符号0。

[0160] 其中，第一单元时间窗的长度可以是固定长度，例如4个符号，可选的，第一单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0161] 其中，第二单元时间窗的长度可以是固定长度，例如4个符号，可选的，第二单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0162] 其中，网络设备可以向终端设备发送第一长度指示信息，以指示第一单元时间窗的长度。可选的，可以通过直接法指示第一单元时间窗的长度。可选的，可以通过映射方式描述第一单元时间窗的长度。

[0163] 其中，网络设备可以向终端设备发送第二长度指示信息，以指示第二单元时间窗的长度。可选的，可以通过直接法指示第二单元时间窗的长度。可选的，可以通过映射方式描述第二单元时间窗的长度。

[0164] 其中，网络设备可以通过信令对终端设备配置第一单元时间窗，例如RRC、MAC-CE或者DCI等。

[0165] 其中，网络设备可以通过信令对终端设备配置第二单元时间窗，例如RRC、MAC-CE或者DCI等。

[0166] 其中，网络设备可以通过向终端设备发送第一长度指示信息的方式，通知终端设备配置了第一单元时间窗。

[0167] 其中，网络设备可以通过向终端设备发送第二长度指示信息的方式，通知终端设备配置了第二单元时间窗。

[0168] 步骤S602：网络设备在第二时间窗内，在接收到的调度请求中确定一个调度请求。

[0169] 具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的调度请求，并在接收到的调度请求中确定一个调度请求。

[0170] 可选的，网络设备可以确定在第二时间窗内接收到的第一个调度请求。

[0171] 可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的调度请求。

[0172] 可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的调度请求。

[0173] 其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一单元时间窗所包含的第一个符号相同。

[0174] 其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0175] 步骤S603：网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应。

[0176] 具体实现中，网络设备可以获取承载确定得到的调度请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送调度请求响应。例如承载确定得到的调度请求的波束为波束1，波束1与波束3构成一个波束对，则网络设备可以在第二时间窗之后使用波束3向终端设备发送调度请求响应。

[0177] 以图7所示的信息传输的示意图为例，网络设备可以在第二时间窗之后的第一个符号，即符号0，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响

应。

[0178] 可选的，网络设备可以通过PDCCH向终端设备发送调度请求响应。

[0179] 可选的，网络设备可以通过MAC-CE向终端设备发送调度请求响应。

[0180] 可选的，网络设备可以通过RRC向终端设备发送调度请求响应。

[0181] 可选的，网络设备可以通过PDSCH向终端设备发送调度请求响应。

[0182] 步骤S604：终端设备在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的调度请求响应。

[0183] 终端设备可以在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的调度请求响应。例如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用波束1向网络设备发送调度请求，则终端设备可以在第二单元时间窗所包含的至少一个符号上，使用波束1接收网络设备发送的调度请求响应。

[0184] 相对传统的波束恢复方法中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔最多第一时间窗，例如7个符号，可降低延迟，提高波束恢复的效率。

[0185] 在图6所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送调度请求，网络设备确定在第二时间窗内接收到的第一个调度请求，网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应，则终端设备在第二单元时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的调度请求响应，可实现网络设备针对同一终端设备发送的多个调度请求的波束恢复处理，提高波束恢复效率。

[0186] 基于图1所示的波束恢复系统的架构示意图，请参见图8，图8是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

[0187] 步骤S801：终端设备在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。

[0188] 具体地，当DL波束失效时，终端设备可以在第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求。其中，第一波束可以是网络设备对终端设备配置的波束，例如波束1。

[0189] 例如，终端设备可以在第一单元时间窗中选取一个符号(例如符号3)，并在符号3上使用一个波束1向网络设备发送波束失败恢复请求。又如，终端设备可以在第一单元时间窗中选取一个符号(例如符号3)，并在符号3上使用多个波束1向网络设备发送波束失败恢复请求，例如：终端设备在符号3上，在不同方向上使用波束1向网络设备发送波束失败恢复请求。又如，以图7所示的信息传输的示意图为例，终端设备可以在第一单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用一个波束1向网络设备发送波束失败恢复请求，并在符号4上使用一个波束1向网络设备发送波束失败恢复请求。又如，终端设备可以在第一单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用多个波束1向网络设备发送波束失败恢复请求，并在符号4上使用多个波束1向网络设备发送波束失败恢复请求。

[0190] 本发明实施例中，终端设备在第一单元时间窗所包含的至少一个符号上，使用多

个相同的第一波束向网络设备发送波束失败恢复请求，可加大子载波间隔。

[0191] 本发明实施例中，网络设备可以对终端设备配置第一单元时间窗。其中，第一单元时间窗的起始时刻可以是配置有RACH资源的第一个符号，以图7所示的信息传输的示意图为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第一单元时间窗的起始时刻为符号3。

[0192] 本发明实施例中，网络设备可以对终端设备配置第二单元时间窗。其中，第二单元时间窗所包含的第一个符号为第一单元时间窗所包含的最后一个符号之后的第一个符号，以图7所示的信息传输的示意图为例，第一单元时间窗所包含的最后一个符号为符号8，则终端设备可以确定第二单元时间窗所包含的第一个符号为符号0。

[0193] 其中，第一单元时间窗的长度可以是固定长度，例如4个符号，可选的，第一单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0194] 其中，第二单元时间窗的长度可以是固定长度，例如4个符号，可选的，第二单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0195] 其中，网络设备可以向终端设备发送第一长度指示信息，以指示第一单元时间窗的长度。可选的，可以通过直接法指示第一单元时间窗的长度。可选的，可以通过映射方式描述第一单元时间窗的长度。

[0196] 其中，网络设备可以向终端设备发送第二长度指示信息，以指示第二单元时间窗的长度。可选的，可以通过直接法指示第二单元时间窗的长度。可选的，可以通过映射方式描述第二单元时间窗的长度。

[0197] 其中，网络设备可以通过信令对终端设备配置第一单元时间窗，例如RRC、MAC-CE或者DCI等。

[0198] 其中，网络设备可以通过信令对终端设备配置第二单元时间窗，例如RRC、MAC-CE或者DCI等。

[0199] 其中，网络设备可以通过向终端设备发送第一长度指示信息的方式，通知终端设备配置了第一单元时间窗。

[0200] 其中，网络设备可以通过向终端设备发送第二长度指示信息的方式，通知终端设备配置了第二单元时间窗。

[0201] 步骤S802：网络设备在第二时间窗内，在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

[0202] 具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的波束失败恢复请求，并在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

[0203] 可选的，网络设备可以确定在第二时间窗内接收到的第一个波束失败恢复请求。

[0204] 可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的波束失败恢复请求。

[0205] 可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的波束失败恢复请求。

[0206] 其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第一时间窗所包含的第一个符号相同。

[0207] 其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0208] 步骤S803：网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应。

[0209] 具体实现中，网络设备可以获取承载确定得到的波束失败恢复请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送波束失败恢复请求响应。例如承载确定得到的波束失败恢复请求的波束为波束1，波束1与波束3构成一个波束对，则网络设备可以在第二时间窗之后使用波束3向终端设备发送波束失败恢复请求响应。

[0210] 以图7所示的信息传输的示意图为例，网络设备可以在第二时间窗之后的第一个符号上，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应。

[0211] 可选的，网络设备可以通过PDCCH向终端设备发送波束失败恢复请求响应。

[0212] 可选的，网络设备可以通过MAC-CE向终端设备发送波束失败恢复请求响应。

[0213] 可选的，网络设备可以通过RRC向终端设备发送波束失败恢复请求响应。

[0214] 可选的，网络设备可以通过PDSCH向终端设备发送波束失败恢复请求响应。

[0215] 步骤S804：终端设备在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的波束失败恢复请求响应。

[0216] 终端设备可以在第二单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束接收网络设备发送的波束失败恢复请求响应。例如，若终端设备在第一单元时间窗所包含的至少一个符号上，使用波束1向网络设备发送波束失败恢复请求，则终端设备可以在第二单元时间窗所包含的至少一个符号上，使用波束1接收网络设备发送的波束失败恢复请求响应。

[0217] 相对传统的波束恢复方法中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔最多第一时间窗，例如7个符号，可降低延迟，提高波束恢复的效率。

[0218] 在图8所描述的方法中，终端设备在第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向网络设备发送波束失败恢复请求，网络设备确定在第二时间窗内接收到的第一个波束失败恢复请求，网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应，则终端设备在第二单元时间窗所包含的至少一个符号上，使用第一波束接收网络设备发送的波束失败恢复请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

[0219] 基于图1所示的波束恢复系统的架构示意图，请参见图9，图9是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

[0220] 步骤S901：终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送调度请求。

[0221] 具体地，当DL波束失效时，终端设备可以在第三单元时间窗所包含的至少一个符

号上，使用至少一个不同的波束向网络设备发送调度请求。其中，网络设备可以对终端设备配置允许的最大波束数量，则终端设备可以使用小于等于最大波束数量的波束向网络设备发送调度请求。

[0222] 例如，终端设备可以在第三单元时间窗中选取一个符号(例如符号3)，并在符号3上使用一个波束1向网络设备发送调度请求。又如，终端设备可以在第三单元时间窗中选取一个符号(例如符号3)，并在符号3上使用多个不同波束向网络设备发送调度请求，示例性的，终端设备在符号3上，分别使用波束1和波束2向网络设备发送调度请求。又如，以图10所示的信息传输的示意图为例，终端设备可以在第三单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用一个波束1向网络设备发送调度请求，并在符号4上使用一个波束2向网络设备发送调度请求。又如，终端设备可以在第三单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用多个不同波束向网络设备发送调度请求，并在符号4上使用多个不同波束向网络设备发送调度请求。

[0223] 本发明实施例中，终端设备在第三单元时间窗所包含的至少一个符号上，使用多个不同波束向网络设备发送调度请求，可加大子载波间隔。

[0224] 本发明实施例中，网络设备可通过RRC、MAC-CE或者DCI等信令对终端设备配置允许的最大波束数量。其中，同一小区所有终端设备可以配置相同的最大波束数量，或者终端设备集群所包含的所有终端设备可以配置相同的最大波束数量，或者不同终端设备可配置不同的最大波束数量，当不同终端设备配置不同的最大波束数量时，该终端设备需要向网络设备上报该终端设备的能力。其中，可以通过直接法指示最大波束数量。可选的，可以通过映射方法描述最大波束数量。

[0225] 本发明实施例中，网络设备可以对终端设备配置第三单元时间窗。其中，第三单元时间窗的起始时刻可以是配置有RACH资源的第一个符号，以图10所示的信息传输的示意图为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第三单元时间窗的起始时刻为符号3。

[0226] 本发明实施例中，网络设备可以对终端设备配置第四单元时间窗。其中，第四单元时间窗所包含的第一个符号为第三单元时间窗所包含的最后一个符号之后的第一个符号，以图10所示的信息传输的示意图为例，第三单元时间窗所包含的最后一个符号为符号6，则终端设备可以确定第四单元时间窗所包含的第一个符号为符号0。

[0227] 其中，第三单元时间窗的长度可以是固定长度，例如4个符号，可选的，第三单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0228] 其中，第四单元时间窗的长度可以是固定长度，例如4个符号，可选的，第四单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0229] 其中，网络设备可以向终端设备发送第三长度指示信息，以指示第三单元时间窗的长度。可选的，可以通过直接法指示第三单元时间窗的长度。可选的，可以通过映射方式描述第三单元时间窗的长度。

[0230] 其中，网络设备可以向终端设备发送第四长度指示信息，以指示第四单元时间窗的长度。可选的，可以通过直接法指示第四单元时间窗的长度。可选的，可以通过映射方式描述第四单元时间窗的长度。

[0231] 其中，网络设备可以通过信令对终端设备配置第三单元时间窗，例如RRC、MAC-CE

或者DCI等。

[0232] 其中，网络设备可以通过信令对终端设备配置第四单元时间窗，例如RRC、MAC-CE或者DCI等。

[0233] 其中，网络设备可以通过向终端设备发送第三长度指示信息的方式，通知终端设备配置了第三单元时间窗。

[0234] 其中，网络设备可以通过向终端设备发送第四长度指示信息的方式，通知终端设备配置了第四单元时间窗。

[0235] 步骤S902：网络设备在第二时间窗内，在接收到的调度请求中确定一个调度请求。

[0236] 具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的调度请求，并在接收到的调度请求中确定一个调度请求。

[0237] 可选的，网络设备可以确定在第二时间窗内接收到的第一个调度请求。

[0238] 可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的调度请求。

[0239] 可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的调度请求。

[0240] 其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第三单元时间窗所包含的第一个符号相同。

[0241] 其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0242] 步骤S903：网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应。

[0243] 具体实现中，网络设备可以获取承载确定得到的调度请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送调度请求响应。例如承载确定得到的调度请求的波束为波束1，波束1与波束3构成一个波束对，则网络设备可以在第二时间窗之后使用波束3向终端设备发送调度请求响应。

[0244] 以图10所示的信息传输的示意图为例，网络设备可以在第二时间窗之后的第一个符号，即符号0，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应，网络设备还可以在第二时间窗之后的第二个符号，即符号1，使用第一波束所属波束对所包含的另一波束向终端设备发送调度请求响应。

[0245] 可选的，网络设备可以通过PDCCH向终端设备发送调度请求响应。

[0246] 可选的，网络设备可以通过MAC-CE向终端设备发送调度请求响应。

[0247] 可选的，网络设备可以通过RRC向终端设备发送调度请求响应。

[0248] 可选的，网络设备可以通过PDSCH向终端设备发送调度请求响应。

[0249] 步骤S904：终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的调度请求响应。

[0250] 终端设备可以在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的调度请求响应。例如，若终端设备在第三单元时间窗所包含的至少一个符号上，分别使用波束1和波束2向网络设备发送调度请求，则终端设备可以在第四单元时间窗所包含的至少一个符号上，分别使用波束1和波束2接收网络设备发送的调度请

求响应。

[0251] 相对传统的波束恢复方法中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收调度请求响应的接收时间与发送调度请求的发送时间间隔最多第一时间窗，例如7个符号，可降低延迟，提高波束恢复的效率。

[0252] 在图9所描述的方法中，终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送调度请求，网络设备在第二时间窗内，在接收到的调度请求中确定一个调度请求，网络设备在第二时间窗之后使用确定得到的调度请求对应的波束，向终端设备发送调度请求响应，终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的调度请求响应，可实现网络设备针对同一终端设备发送的多个调度请求的波束恢复处理，提高波束恢复效率。

[0253] 基于图1所示的波束恢复系统的架构示意图，请参见图11，图11是本发明实施例提供的一种波束恢复方法的流程示意图，该方法包括但不限于如下步骤：

[0254] 步骤S1101：终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送波束失败恢复请求。

[0255] 具体地，当DL波束失效时，终端设备可以在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送波束失败恢复请求。其中，网络设备可以对终端设备配置允许的最大波束数量，则终端设备可以使用小于等于最大波束数量的波束向网络设备发送波束失败恢复请求。

[0256] 例如，终端设备可以在第三单元时间窗中选取一个符号(例如符号3)，并在符号3上使用一个波束1向网络设备发送波束失败恢复请求。又如，终端设备可以在第三单元时间窗中选取一个符号(例如符号3)，并在符号3上使用多个不同波束向网络设备发送波束失败恢复请求，示例性的，终端设备在符号3上，分别使用波束1和波束2向网络设备发送波束失败恢复请求。又如，以图10所示的信息传输的示意图为例，终端设备可以在第三单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用一个波束1向网络设备发送波束失败恢复请求，并在符号4上使用一个波束2向网络设备发送波束失败恢复请求。又如，终端设备可以在第三单元时间窗中选取多个符号(例如符号3，符号4)，在符号3上使用多个不同波束向网络设备发送波束失败恢复请求，并在符号4上使用多个不同波束向网络设备发送波束失败恢复请求。

[0257] 本发明实施例中，终端设备在第三单元时间窗所包含的至少一个符号上，使用多个不同波束向网络设备发送波束失败恢复请求，可加大子载波间隔。

[0258] 本发明实施例中，网络设备可通过RRC、MAC-CE或者DCI等信令对终端设备配置允许的最大波束数量。其中，同一小区所有终端设备可以配置相同的最大波束数量，或者终端设备集群所包含的所有终端设备可以配置相同的最大波束数量，或者不同终端设备可配置不同的最大波束数量，当不同终端设备配置不同的最大波束数量时，该终端设备需要向网络设备上报该终端设备的能力。其中，可以通过直接法指示最大波束数量。可选的，可以通过映射方法描述最大波束数量。

[0259] 本发明实施例中，网络设备可以对终端设备配置第三单元时间窗。其中，第三单元时间窗的起始时刻可以是配置有RACH资源的第一个符号，以图10所示的信息传输的示意图

为例，配置有RACH资源的第一个符号为符号3，则终端设备可以确定第三单元时间窗的起始时刻为符号3。

[0260] 本发明实施例中，网络设备可以对终端设备配置第四单元时间窗。其中，第四单元时间窗所包含的第一个符号为第三单元时间窗所包含的最后一个符号之后的第一个符号，以图10所示的信息传输的示意图为例，第三单元时间窗所包含的最后一个符号为符号6，则终端设备可以确定第四单元时间窗所包含的第一个符号为符号0。

[0261] 其中，第三单元时间窗的长度可以是固定长度，例如4个符号，可选的，第三单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0262] 其中，第四单元时间窗的长度可以是固定长度，例如4个符号，可选的，第四单元时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0263] 其中，网络设备可以向终端设备发送第三长度指示信息，以指示第三单元时间窗的长度。可选的，可以通过直接法指示第三单元时间窗的长度。可选的，可以通过映射方式描述第三单元时间窗的长度。

[0264] 其中，网络设备可以向终端设备发送第四长度指示信息，以指示第四单元时间窗的长度。可选的，可以通过直接法指示第四单元时间窗的长度。可选的，可以通过映射方式描述第四单元时间窗的长度。

[0265] 其中，网络设备可以通过信令对终端设备配置第三单元时间窗，例如RRC、MAC-CE或者DCI等。

[0266] 其中，网络设备可以通过信令对终端设备配置第四单元时间窗，例如RRC、MAC-CE或者DCI等。

[0267] 其中，网络设备可以通过向终端设备发送第三长度指示信息的方式，通知终端设备配置了第三单元时间窗。

[0268] 其中，网络设备可以通过向终端设备发送第四长度指示信息的方式，通知终端设备配置了第四单元时间窗。

[0269] 步骤S1102：网络设备在第二时间窗内，在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

[0270] 具体地，网络设备可以按照接收RACH波束扫描方式在第二时间窗内接收终端设备发送的波束失败恢复请求，并在接收到的波束失败恢复请求中确定一个波束失败恢复请求。

[0271] 可选的，网络设备可以确定在第二时间窗内接收到的第一个波束失败恢复请求。

[0272] 可选的，网络设备可以确定在第二时间窗内接收到的质量大于预设质量阈值的波束所承载的波束失败恢复请求。

[0273] 可选的，网络设备可以确定在第二时间窗内接收到的质量最好的波束所承载的波束失败恢复请求。

[0274] 其中，网络设备可以配置网络设备侧的第二时间窗，第二时间窗所包含的第一个符号可以和第三单元时间窗所包含的第一个符号相同。

[0275] 其中，第二时间窗的长度可以是固定长度，例如4个符号，可选的，第二时间窗的长度也可以是网络设备配置的，例如3个符号或者5个符号等。

[0276] 步骤S1103：网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应

的波束，向终端设备发送波束失败恢复请求响应。

[0277] 具体实现中，网络设备可以获取承载确定得到的波束失败恢复请求的波束，确定该波束所属波束对所包含的另一波束，在第二时间窗之后使用确定得到的波束向终端设备发送波束失败恢复请求响应。例如承载确定得到的波束失败恢复请求的波束为波束1，波束1与波束3构成一个波束对，则网络设备可以在第二时间窗之后使用波束3向终端设备发送波束失败恢复请求响应。

[0278] 以图10所示的信息传输的示意图为例，网络设备可以在第二时间窗之后的第一个符号，即符号0，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应，网络设备还可以在第二时间窗之后的第二个符号，即符号1，使用第一波束所属波束对所包含的另一波束向终端设备发送波束失败恢复请求响应。

[0279] 可选的，网络设备可以通过PDCCH向终端设备发送波束失败恢复请求响应。

[0280] 可选的，网络设备可以通过MAC-CE向终端设备发送波束失败恢复请求响应。

[0281] 可选的，网络设备可以通过RRC向终端设备发送波束失败恢复请求响应。

[0282] 可选的，网络设备可以通过PDSCH向终端设备发送波束失败恢复请求响应。

[0283] 步骤S1104：终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的波束失败恢复请求响应。

[0284] 终端设备可以在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的波束失败恢复请求响应。例如，若终端设备在第三单元时间窗所包含的至少一个符号上，分别使用波束1和波束2向网络设备发送波束失败恢复请求，则终端设备可以在第四单元时间窗所包含的至少一个符号上，分别使用波束1和波束2接收网络设备发送的波束失败恢复请求响应。

[0285] 相对传统的波束恢复方法中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔至少两个子帧，本发明实施例中终端设备接收波束失败恢复请求响应的接收时间与发送波束失败恢复请求的发送时间间隔最多第一时间窗，例如7个符号，可降低延迟，提高波束恢复的效率。

[0286] 在图11所描述的方法中，终端设备在第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向网络设备发送波束失败恢复请求，网络设备在第二时间窗内，在接收到的波束失败恢复请求中确定一个波束失败恢复请求，网络设备在第二时间窗之后使用确定得到的波束失败恢复请求对应的波束，向终端设备发送波束失败恢复请求响应，终端设备在第四单元时间窗所包含的至少一个符号上，使用至少一个不同的波束接收网络设备发送的波束失败恢复请求响应，可实现网络设备针对同一终端设备发送的多个波束失败恢复请求的波束恢复处理，提高波束恢复效率。

[0287] 上述详细阐述了本发明实施例的方法，下面提供了本发明实施例的装置。

[0288] 请参见图12，图12是本发明实施例提供的一种波束恢复装置的结构示意图，该波束恢复装置可以包括发送模块1201以及接收模块1202，其中，各个模块的详细描述如下。

[0289] 发送模块1201，用于在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

[0290] 接收模块1202，用于在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波

束失败恢复请求响应。

[0291] 可选的，所述发送模块1201，具体用于在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

[0292] 可选的，所述接收模块1202，具体用于在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

[0293] 可选的，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

[0294] 所述发送模块1201，具体用于在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

[0295] 可选的，所述接收模块1202，具体用于在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

[0296] 可选的，本发明实施例中的波束恢复装置还可以包括：

[0297] 确定模块1203，用于当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，所述波束恢复装置确定所述网络设备对所述波束恢复装置配置的第三时间窗；

[0298] 所述发送模块1201，还用于在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

[0299] 可选的，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

[0300] 所述发送模块1201，具体用于在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

[0301] 可选的，所述接收模块1202，具体用于在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

[0302] 可选的，所述发送模块1201，具体用于基于所述网络设备对所述波束恢复装置配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

[0303] 可选的，所述第一时间窗所包含的第一个符号为第一个配置有RACH资源的符号。

[0304] 可选的，所述第一时间窗的长度是所述网络设备配置的。

[0305] 可选的，所述第一时间窗所包含的符号的数量总和是根据所述网络设备对所述波束恢复装置配置的最大波束数量确定的。

[0306] 需要说明的是，本发明实施例可具体参见图3、5、6、8、9、11所示实施例的相关描述，不再赘述。

[0307] 本发明实施例中的波束恢复装置和方法实施例中的终端设备完全对应，由相应的模块执行相应的步骤，例如发送模块1201执行方法实施例中发送的步骤，接收模块1202执行方法实施例中接收的步骤，除发送接收外的其它步骤可以由确定模块1203或处理器执行。具体模块的功能可以参考相应的方法实施例，不再详述。

[0308] 在图12所描述的波束恢复装置中，发送模块1201在第一时间窗内使用至少一个波

束向网络设备发送用于恢复波束的请求，接收模块1202在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，可实现网络设备针对同一波束恢复装置发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

[0309] 请参见图13，图13是本发明实施例提供的一种终端设备，该终端设备包括处理器1301、存储器1302以及收发器1303，所述处理器1301、存储器1302以及收发器1303通过总线相互连接。

[0310] 存储器1302包括但不限于是随机存储记忆体(Random Access Memory，RAM)、只读存储器(Read-Only Memory，ROM)、可擦除可编程只读存储器(Erasable Programmable Read Only Memory，EPROM)、或便携式只读存储器(Compact Disc Read-Only Memory，CD-ROM)，该存储器1302用于存储相关指令及数据，例如用于恢复波束的请求等。收发器1303用于接收和发送数据，例如使用至少一个波束向网络设备发送用于恢复波束的请求，或者使用至少一个波束接收网络设备发送的用于波束恢复请求的响应等。存储器1302可以是一个单独的器件，也可以集成在处理器1301中。

[0311] 处理器1301可以是一个或多个中央处理器(Central Processing Unit，CPU)，或者一个或多个微控制单元(Microcontroller Unit，MCU)。在处理器1301是一个CPU的情况下，该CPU可以是单核CPU，也可以是多核CPU。其中，处理器1301可结合图12所示的波束恢复装置。

[0312] 应理解，上述的收发器1303可以包括发射机和接收机。收发器1303还可以进一步包括天线，天线的数量可以为一个或多个。

[0313] 上述的各个器件或部分器件可以集成到芯片中实现，如集成到基带芯片中实现。

[0314] 该终端设备中的处理器1301用于读取所述存储器1302中存储的程序代码，执行以下操作：

[0315] 通过收发器1303在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

[0316] 通过收发器1303在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

[0317] 可选的，处理器1301在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

[0318] 在所述第一时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

[0319] 可选的，处理器1301在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，具体可以为：

[0320] 在所述第一时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

[0321] 可选的，所述第一时间窗包括第一单元时间窗和第二单元时间窗，所述第二单元时间窗所包含的第一个符号为所述第一单元时间窗所包含的最后一个符号之后的第一个符号；

[0322] 处理器1301在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的

请求，具体可以为：

[0323] 在所述第一单元时间窗所包含的至少一个符号上，使用至少一个相同的第一波束向所述网络设备发送所述用于恢复波束的请求。

[0324] 可选的，处理器1301在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，具体可以为：

[0325] 在所述第二单元时间窗所包含的至少一个符号上，使用所述第一波束接收所述用于波束恢复请求的响应。

[0326] 可选的，处理器1301还可以执行以下操作：

[0327] 当在所述第一时间窗内未接收到所述用于波束恢复请求的响应时，确定所述网络设备对所述终端设备配置的第三时间窗；

[0328] 在所述第三时间窗所包含的至少一个符号上，使用至少一个相同的第二波束向所述网络设备发送所述用于恢复波束的请求。

[0329] 可选的，所述第一时间窗包括第三单元时间窗和第四单元时间窗，所述第四单元时间窗所包含的第一个符号为所述第三单元时间窗所包含的最后一个符号之后的第一个符号；

[0330] 处理器1301在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

[0331] 在所述第三单元时间窗所包含的至少一个符号上，使用至少一个不同的波束向所述网络设备发送所述用于恢复波束的请求。

[0332] 可选的，处理器1301在所述第一时间窗内使用所述至少一个波束接收所述网络设备发送的用于波束恢复请求的响应，具体可以为：

[0333] 在所述第四单元时间窗所包含的至少一个符号上，使用所述至少一个不同的波束接收所述用于波束恢复请求的响应。

[0334] 可选的，处理器1301在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，具体可以为：

[0335] 基于所述网络设备对所述终端设备配置的波束请求指示信息，在所述第一时间窗内使用所述至少一个波束向所述网络设备发送所述用于恢复波束的请求，所述波束请求指示信息用于指示所述用于恢复波束的请求的发送方式。

[0336] 可选的，所述第一时间窗所包含的第一个符号为第一个配置有RACH资源的符号。

[0337] 可选的，所述第一时间窗的长度是所述网络设备配置的。

[0338] 可选的，所述第一时间窗所包含的符号的数量总和是根据所述网络设备对所述终端设备配置的最大波束数量确定的。

[0339] 需要说明的是，本发明实施例可具体参见图3、5、6、8、9、11所示实施例的相关描述，不再赘述。

[0340] 在图13所描述的终端设备中，处理器1301在第一时间窗内使用至少一个波束向网络设备发送用于恢复波束的请求，并在第一时间窗内使用至少一个波束接收网络设备发送的用于波束恢复请求的响应，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

[0341] 请参见图14，图14是本发明实施例提供的一种波束恢复装置的结构示意图，该波

束恢复装置可以包括接收模块1401、确定模块1402以及发送模块1403，其中，各个模块的详细描述如下。

[0342] 接收模块1401，用于接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

[0343] 确定模块1402，用于在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

[0344] 发送模块1403，用于使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

[0345] 可选的，所述确定模块1402，具体用于响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

[0346] 可选的，所述确定模块1402，具体用于响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

[0347] 可选的，所述发送模块1403，具体用于在所述第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

[0348] 可选的，所述发送模块1403，具体用于在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

[0349] 需要说明的是，本发明实施例可具体参见图3、5、6、8、9、11所示实施例的相关描述，不再赘述。

[0350] 本发明实施例中的波束恢复装置和方法实施例中的终端设备完全对应，由相应的模块执行相应的步骤，例如发送模块1403执行方法实施例中发送的步骤，接收模块1401执行方法实施例中接收的步骤，除发送接收外的其它步骤可以由确定模块1402或处理器执行。具体模块的功能可以参考相应的方法实施例，不再详述。

[0351] 在图14所描述的波束恢复装置中，接收模块1401接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，确定模块1402在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，发送模块1403使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应，可实现网络设备针对同一波束恢复装置发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

[0352] 请参见图15，图15是本发明实施例提供的一种网络设备，该网络设备包括处理器1501、存储器1502以及收发器1503，所述处理器1501、存储器1502以及收发器1503通过总线相互连接。

[0353] 存储器1502包括但不限于是RAM、ROM、EPROM、或CD-ROM，该存储器1502用于存储相关指令及数据，例如用于恢复波束的请求等。收发器1503用于接收和发送数据，例如接收终端设备使用至少一个波束发送的用于恢复波束的请求，或者使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应等。存储器1502可以是一个单独的器件，也可以集成在处理器1501中。

[0354] 处理器1501可以是一个或多个CPU，或者一个或多个MCU。在处理器1501是一个CPU

的情况下，该CPU可以是单核CPU，也可以是多核CPU。其中，处理器1501可结合图14所示的波束恢复装置。

[0355] 应理解，上述的收发器1503可以包括发射机和接收机。收发器1503还可以进一步包括天线，天线的数量可以为一个或多个。

[0356] 该网络设备中的处理器1501用于读取所述存储器1502中存储的程序代码，执行以下操作：

[0357] 通过收发器1503接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，所述用于恢复波束的请求为调度请求或者波束失败恢复请求；

[0358] 在第二时间窗内，在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求；

[0359] 通过收发器1503使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，所述用于波束恢复请求的响应为调度请求响应或者波束失败恢复请求响应。

[0360] 可选的，处理器1501在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：

[0361] 响应在所述第二时间窗内接收到的质量最好的波束所承载的用于恢复波束的请求，所述第二时间窗所包含的第一个符号与所述第一时间窗所包含的第一个符号相同。

[0362] 可选的，处理器1501在所述接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，具体可以为：

[0363] 响应在所述第二时间窗内接收到的第一个用于恢复波束的请求。

[0364] 可选的，处理器1501使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，具体可以为：

[0365] 在所述第二时间窗内使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

[0366] 可选的，处理器1501使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应，具体可以为：

[0367] 在所述第二时间窗之外使用确定得到的用于恢复波束的请求对应的波束，向所述终端设备发送用于波束恢复请求的响应。

[0368] 在图15所描述的网络设备中，处理器1501接收终端设备在第一时间窗内使用至少一个波束发送的用于恢复波束的请求，在第二时间窗内，在接收到的用于恢复波束的请求中确定一个用于恢复波束的请求，并使用确定得到的用于恢复波束的请求对应的波束，向终端设备发送用于波束恢复请求的响应，可实现网络设备针对同一终端设备发送的多个用于恢复波束的请求的波束恢复处理，提高波束恢复效率。

[0369] 请参见图16，图16是本发明实施例提供的一种波束恢复系统，该波束恢复系统可以包括图13所示的终端设备1601和图15所示的网络设备1602，具体可以参见图13、15的描述，本发明实施例不再赘述。

[0370] 本申请实施例还提供了一种通信芯片，其中存储有指令，当其在终端设备1601上运行时，使得所述通信芯片执行上述图13中的各种实现方式中终端设备对应的方法。

[0371] 本申请实施例还提供了一种通信芯片，其中存储有指令，当其在网络设备1602上

运行时，使得所述通信芯片执行上述图15中的各种实现方式中终端设备对应的方法。

[0372] 上述各个方案的网络设备及终端设备具有实现上述方法中网络设备及终端设备执行的相应步骤的功能；所述功能可以通过硬件实现，也可以通过硬件执行相应的软件实现。所述硬件或软件包括一个或多个与上述功能相对应的模块；例如发送模块可以由发射机替代，接收模块可以由接收机替代，其它模块，如处理模块等可以由处理器替代，分别执行各个方法实施例中的发送操作、接收操作以及相关的处理操作。

[0373] 本领域普通技术人员可以理解实现上述实施例方法中的全部或部分流程，该流程可以由计算机程序来指令相关的硬件完成，该程序可存储于计算机可读取存储介质中，该程序在执行时，可包括如上述各方法实施例的流程。而前述的存储介质包括：ROM或随机存储记忆体RAM、磁碟或者光盘等各种可存储程序代码的介质。

[0374] 在上述实施例中，可以全部或部分地通过软件、硬件、固件或者其任意组合来实现。当使用软件实现时，可以全部或部分地以计算机程序产品的形式实现。所述计算机程序产品包括一个或多个计算机指令。在计算机上加载和执行所述计算机程序指令时，全部或部分地产生按照本申请实施例所述的流程或功能。所述计算机可以是通用计算机、专用计算机、计算机网络、或者其他可编程装置。所述计算机指令可以存储在计算机可读存储介质中，或者从一个计算机可读存储介质向另一个计算机可读存储介质传输，例如，所述计算机指令可以从一个网站站点、计算机、服务器或数据中心通过有线(例如同轴电缆、光纤、数字用户线(DSL))或无线(例如红外、无线、微波等)方式向另一个网站站点、计算机、服务器或数据中心进行传输。所述计算机可读存储介质可以是计算机能够存取的任何可用介质或者是包含一个或多个可用介质集成的服务器、数据中心等数据存储设备。所述可用介质可以是磁性介质，(例如，软盘、硬盘、磁带)、光介质(例如，DVD)、或者半导体介质(例如固态硬盘Solid State Disk(SSD))等。

Message decoding method, sending end and receiving end

Abstract

The invention provides a message decoding method, a sending end and a receiving end. The method comprises the following steps: a receiving end receives a second message sent by a sending end and associated with the first message; the receiving end determines a target receiver parameter for decoding the first message according to the second message; and the receiving end decodes the first message sent by the sending end according to the target receiver parameter. Through the message decoding method provided by the embodiment of the invention, the receiving end can determine the receiver parameter according to the second message associated with the first message, and the message transmission performance can be improved.

一种消息解码方法、发送端和接收端

(57)摘要

本发明提供一种消息解码方法、发送端和接收端，该方法可包括：接收端接收发送端发送的与第一消息关联的第二消息；所述接收端根据所述第二消息，确定解码所述第一消息的目标接收器参数；所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。这样本发明实施例可以实现接收端根据与第一消息关联的第二消息确定接收器参数，且还可以提高消息传输性能。

CN 108809488 A

1.一种消息解码方法，其特征在于，包括：

接收端接收发送端发送的与第一消息关联的第二消息；

所述接收端根据所述第二消息，确定解码所述第一消息的目标接收器参数；

所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。

2.如权利要求1所述的方法，其特征在于，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

3.如权利要求2所述的方法，其特征在于，所述接收端默认的接收器参数包括：

所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

4.如权利要求2所述的方法，其特征在于，所述参数指示信息显式或者隐式指示所述目标接收器参数。

5.如权利要求4所述的方法，其特征在于，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

6.如权利要求1-5中任一项所述的方法，其特征在于，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

7.如权利要求6所述的方法，其特征在于，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

8.如权利要求1-5中任一项所述的方法，其特征在于，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前，所述接收端根据所述目标接收器参数对所述第一消息进行解码，包括：

若所述第二消息包括参数指示信息，则所述接收端根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

若所述第二消息包括参数指示信息，则所述接收端丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

若所述第二消息包括参数指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

若所述第二消息不包括波束指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码；或者

若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

若所述第二消息包括参数指示字段，且所述参数指示字段指示没有参数指示信息或者没有参数改变，则所述接收端根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

9.如权利要求1-5中任一项所述的方法，其特征在于，所述方法还包括：

所述接收端接收所述发送端发送的第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

10.如权利要求9所述的方法，其特征在于，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

11.如权利要求1-5中任一项所述的方法，其特征在于，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

12.如权利要求11所述的方法，其特征在于，所述空域的接收器参数包括所述接收端的接收波束。

13.一种消息解码方法，其特征在于，包括：

发送端向接收端发送与第一消息关联的第二消息，所述第二消息用于所述接收端确定解码所述第一消息的目标接收器参数；

所述发送端向所述接收端发送所述第一消息。

14.如权利要求13所述的方法，其特征在于，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

15.如权利要求14所述的方法，其特征在于，所述接收端默认的接收器参数包括：

所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

16.如权利要求14所述的方法，其特征在于，所述参数指示信息显式或者隐式指示所述目标接收器参数。

17.如权利要求16所述的方法，其特征在于，若所述参数指示信息隐式指示所述目标接

收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

18.如权利要求13-17中任一项所述的方法，其特征在于，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

19.如权利要求18所述的方法，其特征在于，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

20.如权利要求13-17中任一项所述的方法，其特征在于，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

21.如权利要求13-17中任一项所述的方法，其特征在于，所述方法还包括：

所述发送端向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

22.如权利要求21所述的方法，其特征在于，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

23.如权利要求13-17中任一项所述的方法，其特征在于，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

24.如权利要求23所述的方法，其特征在于，所述空域的接收器参数包括所述接收端的接收波束。

25.一种接收端，其特征在于，包括：

第一接收模块，用于接收发送端发送的与第一消息关联的第二消息；

确定模块，用于根据所述第二消息，确定解码所述第一消息的目标接收器参数；

解码模块，用于根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。

26.如权利要求25所述的接收端，其特征在于，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

27.如权利要求25或26所述的接收端，其特征在于，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

28.如权利要求25或26所述的接收端，其特征在于，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前；

所述解码模块用于若所述第二消息包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息不包括波束指示信息，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

所述解码模块用于若所述第二消息包括参数指示字段，且所述参数指示字段指示没有参数指示信息或者没有参数改变，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

29.如权利要求25或26所述的接收端，其特征在于，所述接收端还包括：

第二接收模块，用于接收所述发送端发送的第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

30.一种发送端，其特征在于，包括：

第一发送模块，用于发送端向接收端发送与第一消息关联的第二消息，所述第二消息用于所述接收端确定解码所述第一消息的目标接收器参数；

第二发送模块，用于向所述接收端发送所述第一消息。

31.如权利要求30所述的发送端，其特征在于，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

32.如权利要求30或31所述的发送端，其特征在于，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

33.如权利要求30或31所述的发送端，其特征在于，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

34.如权利要求30或31所述的发送端，其特征在于，所述发送端还包括：

第二发送模块，用于向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

一种消息解码方法、发送端和接收端

技术领域

[0001] 本发明涉及通信技术领域，特别涉及一种消息解码方法、发送端和接收端。

背景技术

[0002] 随着通信技术的发展，目前通信设备均支持多天线系统，例如：支持高达128、256或者512个天线单元，以及高达128、256或者512个收发单元，每个天线单元连接一个收发单元。且目前通信设备还支持多波束，不同的波束的覆盖范围可以不同。这样发送端(例如：网络侧设备)在发送消息时，就可以在多个发送器参数(例如：发送波束)中选择相应的发送器参数进行发送，以提高通信性能。而接收端(例如：用户终端)如何选择相应的接收器参数(例如：接收波束)对发送端发送的消息进行解码目前还未明确。可见，接收端如何选择相应的接收器参数对发送端发送的消息进行解码是当前急需解决的技术问题。

发明内容

[0003] 本发明的目的在于提供一种消息解码方法、发送端和接收端，以解决接收端如何选择相应的接收器参数对发送端发送的消息进行解码的问题。

[0004] 为了达到上述目的，本发明实施例提供一种消息解码方法，包括：

[0005] 接收端接收发送端发送的与第一消息关联的第二消息；

[0006] 所述接收端根据所述第二消息，确定解码所述第一消息的目标接收器参数；

[0007] 所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。

[0008] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0009] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0010] 可选的，所述接收端默认的接收器参数包括：

[0011] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0012] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0013] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0014] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0015] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所

述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0016] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0017] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0018] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前，所述接收端根据所述目标接收器参数对所述第一消息进行解码，包括：

[0019] 若所述第二消息包括参数指示信息，则所述接收端根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0020] 若所述第二消息包括参数指示信息，则所述接收端丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0021] 若所述第二消息包括参数指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0022] 若所述第二消息不包括波束指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码；或者

[0023] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0024] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0025] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0026] 若所述第二消息包括参数指示字段，且所述参数指示字段指示没有参数指示信息或者没有参数改变，则所述接收端根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

[0027] 可选的，所述方法还包括：

[0028] 所述接收端接收所述发送端发送的第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0029] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0030] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0031] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0032] 本发明实施例还提供一种消息解码方法，包括：

[0033] 发送端向接收端发送与第一消息关联的第二消息，所述第二消息用于所述接收端确定解码所述第一消息的目标接收器参数；

[0034] 所述发送端向所述接收端发送所述第一消息。

[0035] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0036] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0037] 可选的，所述接收端默认的接收器参数包括：

[0038] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0039] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0040] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0041] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0042] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0043] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0044] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0045] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

[0046] 可选的，所述方法还包括：

[0047] 所述发送端向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0048] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0049] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0050] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0051] 本发明实施例还提供一种接收端，包括：

[0052] 第一接收模块，用于接收发送端发送的与第一消息关联的第二消息；

[0053] 确定模块，用于根据所述第二消息，确定解码所述第一消息的目标接收器参数；

[0054] 解码模块，用于根据所述目标接收器参数对所述发送端发送的所述第一消息进行

解码。

[0055] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0056] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0057] 可选的，所述接收端默认的接收器参数包括：

[0058] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0059] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0060] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0061] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0062] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0063] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0064] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0065] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前；

[0066] 所述解码模块用于若所述第二消息包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0067] 所述解码模块用于若所述第二消息包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0068] 所述解码模块用于若所述第二消息包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0069] 所述解码模块用于若所述第二消息不包括波束指示信息，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码；或者

[0070] 所述解码模块用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0071] 所述解码模块用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接

收器参数对所述第二部分内容进行解码;或者

[0072] 所述解码模块用于若所述第二消息包括参数指示字段,且所述参数指示字段包括参数指示信息,则根据默认的接收器参数对所述第一部分内容进行解码,以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码;或者

[0073] 所述解码模块用于若所述第二消息包括参数指示字段,且所述参数指示字段指示没有参数指示信息或者没有参数改变,则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

[0074] 可选的,所述接收端还包括:

[0075] 第二接收模块,用于接收所述发送端发送的第三消息,所述第三消息用于指示所述第二消息是否包括参数指示信息,且若所述第三消息指示所述第二消息包括参数指示信息,则所述第二消息与所述第一消息之间存在间隙,若所述第三消息指示所述第二消息不包括参数指示信息,则所述第二消息与所述第一消息之间不存在间隙。

[0076] 可选的,所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息,所述M为大于或者等于1的整数,所述M个时间单位连续或者不连续。

[0077] 可选的,所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0078] 可选的,所述空域的接收器参数包括所述接收端的接收波束。

[0079] 本发明实施例还提供一种发送端,包括:

[0080] 第一发送模块,用于发送端向接收端发送与第一消息关联的第二消息,所述第二消息用于所述接收端确定解码所述第一消息的目标接收器参数;

[0081] 第二发送模块,用于向所述接收端发送所述第一消息。

[0082] 可选的,若所述第二消息包括参数指示信息,则所述目标接收器参数为所述参数指示信息指示的接收器参数;

[0083] 若所述第二消息不包括参数指示信息,则所述目标接收器参数为所述接收端默认的接收器参数。

[0084] 可选的,所述接收端默认的接收器参数包括:

[0085] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0086] 可选的,所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0087] 可选的,若所述参数指示信息隐式指示所述目标接收器参数,则所述参数指示信息包括所述发送端选择的发送器参数,所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0088] 可选的,若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的,则所述第二消息包括参数指示信息,且所述第二消息与所述第一消息之间存在间隙;

[0089] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的,则所述第二消息不包括参数指示信息,且所述第二消息与所述第一消息之间不存在间隙。

[0090] 可选的,所述参数切换指示集对应的调度时间单位在时域上周期存在;和\或

[0091] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置,并

通知所述接收端。

[0092] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

[0093] 可选的，所述发送端还包括：

[0094] 第二发送模块，用于向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0095] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0096] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0097] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0098] 本发明实施例还提供一种接收端，其特征在于，包括：处理器、收发机、存储器、用户接口和总线接口，其中：

[0099] 所述处理器，用于读取所述存储器中的程序，执行本发明实施例提供的接收端侧对应的消息解码方法中的步骤。

[0100] 本发明实施例还提供一种发送端，其特征在于，包括：处理器、收发机、存储器、用户接口和总线接口，其中：

[0101] 所述处理器，用于读取所述存储器中的程序，执行本发明实施例提供的发送侧对应的消息解码方法的步骤。

[0102] 本发明的上述技术方案至少具有如下有益效果：

[0103] 本发明实施例，接收端接收发送端发送的与第一消息关联的第二消息；所述接收端根据所述第二消息，确定解码所述第一消息的目标接收器参数；所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。这样可以实现接收端根据与第一消息关联的第二消息确定接收器参数，且还可以提高消息传输性能。

具体实施方式

[0117] 为使本发明要解决的技术问题、技术方案和优点更加清楚，下面将结合附图及具体实施例进行详细描述。

[0118] 参见图1，图1为本发明实施例可应用的网络结构示意图，如图1所示，包括发送端11和接收端12，其中，发送端11可以是基站或者终端，而接收端12也可以是终端或者基站，例如：发送端11为基站，接收端12为终端，则可以实现终端与基站之间的通信，又或者发送端11为终端，则接收端12为基站，也可以实现终端与基站之间的通信，又或者发送端11为基站，接收端12也为基站，则可以实现基站与基站之间的通信，又或者发送端11为终端，接收端12也为终端，则可以实现终端与终端之间的通信。当然，本发明实施例中，并不限定发送端11只能是终端或者基站，例如：发送端11还可以是其他的网络侧设备，同理，接收端12也并不限定只是终端或者设备，例如：接收端12还可以是其他的网络侧设备，对此本发明实施例不作限定。其中，附图1，以发送端11为基站，接收端12为终端进行举例示意。终端可以是用户终端(User Equipment，UE)，例如：可以是手机、平板电脑(Tablet Personal Computer)、膝上型电脑(Laptop Computer)、个人数字助理(personal digital assistant，简称PDA)、移动上网装置(Mobile Internet Device，MID)或可穿戴式设备(Wearable Device)等终端侧设备，需要说明的是，在本发明实施例中并不限定终端的具体类型。基站可以是宏站，如LTE eNB、5G NR NB等；也可以是小站，如低功率节点(LPN：low power node)pico、femto等小站，或者可以是接入点(AP，access point)；基站也可以是中央单元(CU，central unit)与其管理和控制的多个传输接收点(TRP，Transmission Reception Point)共同组成的网络节点。另外，一个基站下有一个或多个小区(例如：不同的频点或扇区分裂)。需要说明的是，在本发明实施例中并不限定基站的具体类型。

[0119] 请参考图2，图2是本本发明实施例提供一种消息解码方法的流程图，如图2所示，包括以下步骤：

[0120] 201、接收端接收发送端发送的与第一消息关联的第二消息；

[0121] 202、所述接收端根据所述第二消息，确定解码所述第一消息的目标接收器参数；

[0122] 203、所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。

[0123] 其中，上述第一消息可以是发送端需要向接收端发送的信号，例如：数据和/或控制消息等等，如上述第一消息可以是下行链路信号。另外，本发明实施例中，可以将第一消息定义为msg1。而上述第二消息可以理解为用于通知接收端接收器参考的消息，例如：控制消息或者调度消息等等，另外，本发明实施例中第二消息可以定义为msg2。

[0124] 上述根据所述第二消息，确定解码所述第一消息的目标接收器参数可以是，若上述第二消息中包括了参数指示信息，则确定该参数指示信息指示的接收器参数作为上述目标器参数，若上述第二消息中不包括参数指示信息，则确定默认的接收器参数作为上述目标器参数。即本发明实施例中，上述第二消息可以存在两种情况，一种是存在参数指示信息，该情况下接收端可能需要进行接收器参数切换，再对发送端发送的消息进行解码。另一

种是不存在参数指示信息，该情况下接收端可能不需要进行波束接收器参数切换，直接对接收端发送的消息进行解码。另外，目标接收器参数可以是接收端中接收器的相关参数，例如：接收波束、均衡器和接收滤波器等参数中的至少一项，对此本发明实施例不作限定。例如：以目标接收器参数为目标接收波束为例，上述确定解码所述第一消息的目标接收波束还可以是在接收端的多个接收波束(Rx波束)中选择一个或者多个接收波束。且接收端的多个接收器参数可以是与发送端无关的，或者接收端的多个接收器参数对于发送端来说也可以是已知的，例如：通过预配置或反馈通知发送端，对此本发明实施例不作限定。

[0125] 本发明实施例中，通过上述步骤就可以实现通过专门的第二消息向接收端通知发送端发送的第一消息的接收波束，从使接收端和发送端获得更准确的波束组合信息，支持多波束传输，以及提高波束传输性能。另外，本发明实施例可以用于在无线通信系统中的接收端的模拟波束切换，以及还可以用于接收端的数字波束切换等，对此本发明实施例不作限定。

[0126] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0127] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0128] 该实施方式中，可以实现上述第二消息中包括或者不包括参数指示信息，若包括，则将参数指示信息指示的接收器参数作为上述目标接收器参数。其中，参数指示信息指示接收波束可以是与接收端当前使用的接收器参数为不同的接收器参数，这时接收端需要进行接收器参数切换。而使用默认的接收器参数，可以不进行切换，例如：默认的接收器参数就可以是接收端当前使用的接收器参数，以快速对发送端发送的消息进行解码。另外，本发明实施例中，第二消息中的参数指示信息可以是，第二消息中的参数指示字段，即第二消息中可以存在或者不存在该参数指示字段。

[0129] 例如：所述接收端默认的接收器参数包括：

[0130] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0131] 该实施方式中，通过上述默认波束可以减少接收器参数的切换，例如：减少接收波束的切换，以提高传输性能，例如：第二消息与第一消息之间可以不存在间隙。

[0132] 另外，本发明实施例中，上述参数指示信息可以显式或者隐式指示所述目标接收器参数。例如：显式或者隐式指示所述目标接收波束。

[0133] 其中，显式指示可以理解为直接指示，例如：以接收波束举例，接收端具有一组L个预配置的接收波束，这些对于发送端可以是已知的。这样上述参数指示信息就式携带Log_2(L)位的字段，以指示接收端的推荐接收波束。在接收到第二消息后，接收端就可以机确定对应的接收波束用于解码msg1。而上述隐式指示可以理解为间接指示，例如：上述参数指示信息可以是指示发送波束(Tx波束)，通过指示的发送波束隐式指示该发送波束对应的接收波束。该实施方式中，通过上述显式或者隐式的方式可以实现灵活地向接收端指示接收波束，以提高系统的灵活性。

[0134] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信

息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0135] 该实施方式中，可以实现通过发送器参数来隐式指示接收器参数，例如：以目标接收器参数为目标波束举例，发送端可以具有用于下行链路传输的M个候选发送波束。发送端配置M个参考符号(RS)资源，并将每个发送波束应用于相应的RS资源。对于每个RS资源，接收端可以测试一组候选接收波束，并确定每个RS资源(例如发送波束)的最佳接收波束。优选的，接收端可以将至少推荐的发送波束的信息反馈给发送端，例如，以推荐的RS资源的形式，但这一步是可选的。在发送第一消息之前，发送端以第二消息的方式发送其选定的发送波束的指示。接收端接收到第二消息后，获得所使用的发送波束的信息，并获得最佳的接收波束作为上述目标接收波束，该最佳的接收波束可以是从先前的测量已知并保存在接收端中。

[0136] 该实施方式中，可以实现通过发送器参数来隐式指示接收器参数，从而有利于接收端与发送端之间的传输。当然，在一些实施方式中，发送端可以是根据接收端返回的推荐信息自主选择相应的发送器参数，例如：发送波束。

[0137] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0138] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0139] 该实施方式中，上述参数切换指示集(BSIS)对应的调度时间单位可以是子帧或者时隙(slots)等时间单位。且发送端和接收端对BSIS可以具有一致的认识。只有在BSIS对应的slot(这里以slot为例)中，第二消息才可能会携带参数指示信息，否则第二消息不携带波束指示信息。这意味着在BSIS对应的时隙之外的所有时隙中可以不执行接收器参数切换，例如：接收波束切换，而仅在周期性的选定时隙(例如BSIS中的时隙)中执行接收器参数切换。

[0140] 另外，由于第二消息包括参数指示信息时，所述第二消息与所述第一消息之间存在间隙，这样接收端可以是在该间隙切换进行接收器参数切换，例如：接收波束切换，从而不影响消息的传输。而所述第二消息不包括参数指示信息时，所述第二消息与所述第一消息之间可以不存在间隙，这样可以节约传输资源，因为该情况下，接收端可能是不需要进行接收器参数切换，例如：接收波束切换，进而第二消息和第一消息连续传输也不会影响接收端的解码。且上述第二消息和第一消息可以采用相同的频域资源发送的，或者采用相同的信道发送等，对此本发明实施例不作限定。

[0141] 例如：对于在BSIS中的时隙中发送的第二消息，携带波束指示信息。在这种情况下，同一时隙中的第一消息和第二消息之间有切换时间。否则对于BSIS外的时隙中的第二消息传输，发送端发送第二消息，而不携带波束指示字段。在这种情况下，接收端可以准备在第二消息之后立即接收第一消息(没有间隙)。例如：图3所示的第二个slot。另外，当尝试在每个时隙中接收到第二消息或者第一消息时，接收端可以根据假定存在或者不存在波束指示信息来解码第二消息。换句话说，在BSIS中的时隙中，第二消息可以携带参数指示信息，接收端尝试解码第二消息，假设有一个参数指示信息。在其他时隙中，接收器解码第二

消息，假设没有参数指示信息。在第二消息不携带参数指示信息的时隙中，接收端仍然可以选择一个接收器参数(例如：接收波束)来解码第一消息。接收端可以使用在最新的携带参数指示字段的第二消息中指示的接收器参数。如果没有接收到参数指示信息，则接收机可以使用默认的接收器参数来解码第一消息。

[0142] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0143] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续(semi-persistent)配置，并通知所述接收端。

[0144] 其中，上述参数切换指示集对应的调度时间单位在时域上周期存在可以是，上述参数切换指示集对应的调度时间单位具有周期性，例如：参数切换指示集在时域中可以周期性地具有预配置的周期和定时偏移，其中，该定时偏移可以是相对于另一个定时参考的偏移，如帧边界。例如，参数切换指示集可以具有10ms的周期，其指示在10个slots中的1个中发送的第二消息可能会携带参数指示信息，而其他9个slots中的第二消息不携带参数指示信息。上述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端可以是，发送端半静态或半持续配置，并通知接收端参数切换指示集的集合，即指示多个参数切换指示集。或者上述参数切换指示集可以由接收端获得，并作为推荐被反馈给发送端。发送端可以使用接收端推荐的参数切换指示集，或覆盖接收端推荐的参数切换指示集，并选择一个新的参数切换指示集。发送端可以需要向接收端指示是否确认接收端推荐的参数切换指示集，或者将其选择的参数切换指示集指示给接收端。

[0145] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前，所述接收端根据所述目标接收器参数对所述第一消息进行解码，包括：

[0146] 若所述第二消息包括参数指示信息，则所述接收端根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0147] 若所述第二消息包括参数指示信息，则所述接收端丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0148] 若所述第二消息包括参数指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0149] 若所述第二消息不包括波束指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

[0150] 该实施方式中，所述第一消息分为时域上连续的第一部分内容和第二部分内容可以是接收端将第一消息分为两个部分，这里分为可以理解为将第一消息看作两个部分，因为，此时接收端还未接收到第一消息，不能对其进行拆分。

[0151] 例如：发送端可以发送携带与接收第一消息有关的下行调度信息的第二消息。第二消息可以携带或不携带参数指示信息，对此接收端可以没有先验知识。如果第二消息没有参数指示信息，则第二消息的有效载荷较小(表示为A位)。如果第二消息具有参数指示信息，则第二消息的有效载荷较大(表示为B位，其中B>A)。在发送端发送第二消息后，接收端可以尝试用盲解码第二消息。因为，接收端没有关于第二消息的有效载荷的先验信息，因此

需要基于不同的可能的第二消息有效载荷来执行盲解码。例如，接收端将执行假设有效载荷A位的第二消息的一次盲解码，以及假设B位的有效载荷的另一个第二消息的盲解码。这样根据第二消息的实际有效负载，两个盲解码之一将成功解码第二消息。之后，接收端就可以将第一消息分为第一部分内容和第二部分内容(part1and part 2)，第一部分内容在第二部分内容前面，并且在时域中为时分复用(TDM)。第一消息的第一部分部分紧随着第二消息，即两者没有间隙，第一消息的第二部分内容紧邻第一部分内容，例如：图4所示的第二个slot。

[0152] 另外，由于第一部分内容和第二部分内容属于同一消息，从而接收端可以分别对第一部分内容和第二部分内容执行符号级处理。

[0153] 该实施方式中，由于若所述第二消息包括参数指示信息时，则所述接收端使用所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码，其中，所述发送端未发送所述第一部分内容。例如：图4所示的第一个slot。这样可以提高接收端解码的准确性。

[0154] 另外，由于第二消息包括参数指示信息时，可以丢弃所述第一部分内容，以及使用所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码。即可以丢弃图4所示的第二个slot的第一部分内容，同样能够保证发送端与接收端之间的性能，因为，在该情况下发送端可以在第一部分内容中传输非重要信息，而在第二部分内容中传输重要信息。

[0155] 另外，由于第二消息包括参数指示信息时，可以使用默认的接收器参数对所述第一部分内容进行解码，以及使用所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码。这样可以实现接收到准备地解码第一部分部分和第二部分内容。

[0156] 另外，由于第二消息不包括参数指示信息，可以实现使用默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。即图4所示的第三个slot。

[0157] 另外，发送端和接收端可以将其对接收端上确切的第一消息解码行为的理解对齐。这可以由网络半静态地或半持续地配置给接收端，或者使用另一个动态控制消息动态地指示给接收端。

[0158] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前，所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码，包括：

[0159] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0160] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0161] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则所述接收端根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0162] 若所述第二消息包括参数指示字段，且所述参数指示字段指示没有参数指示信息或者没有参数改变，则所述接收端根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

[0163] 该实施方式中，可以实现第二消息终具有参数指示字段，例如：波束指示字段，例如S比特位。且参数指示字段具有至少一个状态指示，即没有参数指示信息或者没有参数改变的状态指示，以及还可以指示用于解码第一消息的接收器参数的其他状态。因此，第二消息的有效载荷预先已知到发送端和接收端。例如对应于4个可能的接收器参数指示状态的S＝2。一个状态向接收机指示存在“没有参数指示信息或者没有参数改变”，而其他3个状态指示到接收机的接收器参数。

[0164] 另外，该实施方式中，关于第一消息的第一部分内容和第二部分内容可以参考上一实施方式中的相应描述，此处不作赘述。

[0165] 且关于第二消息中是否包括参数指示信息的情况，如何对第一部分内容和第二部分内容的解码，可以参见上述实施方式的相应描述，此处不作赘述，且可以达到相同的有益效率。

[0166] 可选的，所述方法还包括：

[0167] 所述接收端接收所述发送端发送的第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0168] 其中，上述第三消息可以定义为msg3，该实施方式中，通过第三消息通知接收端第二消息是否包括参数指示信息，更为具体的可以指示第二消息指示的接收器参数对于接收端是否存在接收器参数改变，这样可以实现当不存在接收器参数改变或者不包括参数指示信息时，接收端甚至可以不接收第二消息，直接使用当前的接收器参数对第一消息进行解码。另外，在一些实施方式中，第三消息可以具有固定有效载荷，其中第二消息中的参数指示信息的存在或者不存在对应于第三消息中的两个不同状态。例如，第三消息有1位表示第二消息是否携带参数指示信息。

[0169] 另外，本发明实施例中，上述第三消息可以对应于一个第二消息，即一个第三消息指示一个第二消息，例如：如图5所示。且第三消息、第二消息可以是以相同的调度时间单位(例如，时隙)发送，其中图5给出了一个示例。可以以不同的调度时间单位发送的第三消息和第二消息。如果第二消息有参数指示信息，第一消息和第二消息之间可以有一个间隙。如果第二消息没有参数指示，第一消息和第二消息之间可以没有间隙。

[0170] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0171] 该实施方式中，可以实现通过第三消息指示多个第二消息，例如：第三消息用于指示M个时隙中的M个第二消息是否包括参数指示信息，这样可以节省消息开销。另外，上述M的值和M个第二消息的时间位置可以预定义的半静态或半持续配置的，并且对发送端和接收端均是已知的。其中，图6示出了一个例子，其中M＝3。一旦接收到第三消息，该第三消息就向接收端指示相应的M个时隙中的第二消息是否携带参数指示信息。

[0172] 另外，第三消息可以是可以在每个调度时间单位(例如slots)或在由发送端预配

置的时隙的子集(例如,具有预先配置的传输周期和偏移)中被发送。对于后一种情况,发送端可以事先向接收端指示第三消息的发生。

[0173] 可选的,本发明实施例中,目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0174] 这样可以实现根据发送端的第二消息灵活选择时域、频域和空域中的至少一项的接收器参数,对第一消息进行解码。优先的,所述空域的接收器参数包括所述接收端的接收波束。这样可以实现接收端根据与第一消息关联的第二消息确定接收波束,且还可以提高波束传输性能。

[0175] 需要说明的是,本发明实施例介绍的多种可选的实施方式均可以相互结合实现,也可以单独实现,对此本发明实施例不作限定。

[0176] 本发明实施例,接收端接收发送端发送的与第一消息关联的第二消息;所述接收端根据所述第二消息,确定解码所述第一消息的目标接收器参数;所述接收端根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。这样可以实现接收端根据与第一消息关联的第二消息确定接收器参数,且还可以提高消息传输性能。

[0177] 请参阅图7,图7是本发明实施例提供的另一种消息解码方法的流程图,如图7所示,包括以下步骤:

[0178] 701、发送端向接收端发送与第一消息关联的第二消息,所述第二消息用于所述接收端确定解码所述第一消息的目标接收器参数;

[0179] 702、所述发送端向所述接收端发送所述第一消息。

[0180] 可选的,若所述第二消息包括参数指示信息,则所述目标接收器参数为所述参数指示信息指示的接收器参数;

[0181] 若所述第二消息不包括参数指示信息,则所述目标接收器参数为所述接收端默认的接收器参数。

[0182] 可选的,所述接收端默认的接收器参数包括:

[0183] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0184] 可选的,所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0185] 可选的,若所述参数指示信息隐式指示所述目标接收器参数,则所述参数指示信息包括所述发送端选择的发送器参数,所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0186] 可选的,若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的,则所述第二消息包括参数指示信息,且所述第二消息与所述第一消息之间存在间隙;

[0187] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的,则所述第二消息不包括参数指示信息,且所述第二消息与所述第一消息之间不存在间隙。

[0188] 可选的,所述参数切换指示集对应的调度时间单位在时域上周期存在;和\或

[0189] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置,并通知所述接收端。

[0190] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

[0191] 可选的，所述方法还包括：

[0192] 所述发送端向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0193] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0194] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0195] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0196] 需要说明的是，本实施例作为与图2所示的实施例中对应的发送端的实施方式，其具体的实施方式可以参见图2所示的实施例的相关说明，为了避免重复说明，本实施例不再赘述，且还可以达到相同有益效果。

[0197] 请参考图8，图8是本发明实施例提供一种接收端的结构图，如图8所示，接收端800包括：

[0198] 第一接收模块801，用于接收发送端发送的与第一消息关联的第二消息；

[0199] 确定模块802，用于根据所述第二消息，确定解码所述第一消息的目标接收器参数；

[0200] 解码模块803，用于根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。

[0201] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0202] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0203] 可选的，所述接收端默认的接收器参数包括：

[0204] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0205] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0206] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0207] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0208] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0209] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0210] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0211] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前；

[0212] 所述解码模块803用于若所述第二消息包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0213] 所述解码模块803用于若所述第二消息包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0214] 所述解码模块803用于若所述第二消息包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0215] 所述解码模块803用于若所述第二消息不包括波束指示信息，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码；或者

[0216] 所述解码模块803用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0217] 所述解码模块803用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0218] 所述解码模块803用于若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0219] 所述解码模块803用于若所述第二消息包括参数指示字段，且所述参数指示字段指示没有参数指示信息或者没有参数改变，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

[0220] 可选的，如图9所示，所述接收端800还包括：

[0221] 第二接收模块804，用于接收所述发送端发送的第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0222] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0223] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0224] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0225] 需要说明的是，本实施例中上述接收端800可以是本发明实施例中方法实施例中任意实施方式的接收端，本发明实施例中方法实施例中接收端的任意实施方式都可以被本

实施例中的上述接收端800所实现，以及达到相同的有益效果，此处不再赘述。

[0226] 请参阅图10，图10是本发明实施例提供的一种发送端的结构图，如图10所示，发送端1000包括：

[0227] 第一发送模块1001，用于发送端向接收端发送与第一消息关联的第二消息，所述第二消息用于所述接收端确定解码所述第一消息的目标接收器参数；

[0228] 第二发送模块1002，用于向所述接收端发送所述第一消息。

[0229] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0230] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0231] 可选的，所述接收端默认的接收器参数包括：

[0232] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0233] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0234] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0235] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0236] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0237] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0238] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0239] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

[0240] 可选的，如图11所示，所述发送端还包括：

[0241] 第二发送模块1003，用于向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0242] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0243] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0244] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0245] 需要说明的是，本实施例中上述发送端1000可以是本发明实施例中方法实施例中

任意实施方式的发送端，本发明实施例中方法实施例中发送端的任意实施方式都可以被本实施例中的上述发送端1000所实现，以及达到相同的有益效果，此处不再赘述。

[0246] 请参考图12，图12是本发明实施例提供的另一种接收端的结构图，如图12所示，该接收端包括：处理器1200、收发机1210、存储器1220、用户接口1230和总线接口，其中：

[0247] 处理器1200，用于读取存储器1220中的程序，执行下列过程：

[0248] 通过收发机1210接收端接收发送端发送的与第一消息关联的第二消息；

[0249] 根据所述第二消息，确定解码所述第一消息的目标接收器参数；

[0250] 根据所述目标接收器参数对所述发送端发送的所述第一消息进行解码。

[0251] 其中，收发机1210，用于在处理器1200的控制下接收和发送数据。

[0252] 在图12中，总线架构可以包括任意数量的互联的总线和桥，具体由处理器1200代表的一个或多个处理器和存储器1220代表的存储器的各种电路链接在一起。总线架构还可以将诸如外围设备、稳压器和功率管理电路等之类的各种其他电路链接在一起，这些都是本领域所公知的，因此，本文不再对其进行进一步描述。总线接口提供接口。收发机1210可以是多个元件，即包括发送机和接收机，提供用于在传输介质上与各种其他装置通信的单元。针对不同的用户设备，用户接口1230还可以是能够外接内接需要设备的接口，连接的设备包括但不限于小键盘、显示器、扬声器、麦克风、操纵杆等。

[0253] 处理器1200负责管理总线架构和通常的处理，存储器1220可以存储处理器1200在执行操作时所使用的数据。

[0254] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0255] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0256] 可选的，所述接收端默认的接收器参数包括：

[0257] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0258] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0259] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0260] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0261] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0262] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0263] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0264] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述

第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前，所述根据所述目标接收器参数对所述第一消息进行解码，包括：

[0265] 若所述第二消息包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0266] 若所述第二消息包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0267] 若所述第二消息包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0268] 若所述第二消息不包括波束指示信息，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码；或者

[0269] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0270] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则丢弃所述第一部分内容，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0271] 若所述第二消息包括参数指示字段，且所述参数指示字段包括参数指示信息，则根据默认的接收器参数对所述第一部分内容进行解码，以及根据所述参数指示信息指示的所述目标接收器参数对所述第二部分内容进行解码；或者

[0272] 若所述第二消息包括参数指示字段，且所述参数指示字段指示没有参数指示信息或者没有参数改变，则根据默认的接收器参数对所述第一部分内容和所述第二部分内容进行解码。

[0273] 可选的，处理器1200还用于：

[0274] 通过收发机1210接收所述发送端发送的第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0275] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0276] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0277] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0278] 需要说明的是，本实施例中上述接收端可以是图1-图7所示的实施例中的终端，图1-图7所示实施例中接收端的任意实施方式都可以被本实施例中的上述接收所实现，以及达到相同的有益效果，此处不再赘述。

[0279] 请参考图13，图13是本发明实施提供的另一种发送端的结构图，如图13所示，该发送端包括：处理器1300、收发机1310、存储器1320、用户接口1330和总线接口，其中：

[0280] 处理器1300，用于读取存储器1320中的程序，执行下列过程：

[0281] 通过收发机1310向接收端发送与第一消息关联的第二消息，所述第二消息用于所

述接收端确定解码所述第一消息的目标接收器参数；

[0282] 通过收发机1310向所述接收端发送所述第一消息。

[0283] 其中，收发机1310，用于在处理器1300的控制下接收和发送数据。

[0284] 在图13中，总线架构可以包括任意数量的互联的总线和桥，具体由处理器1300代表的一个或多个处理器和存储器1320代表的存储器的各种电路链接在一起。总线架构还可以将诸如外围设备、稳压器和功率管理电路等之类的各种其他电路链接在一起，这些都是本领域所公知的，因此，本文不再对其进行进一步描述。总线接口提供接口。收发机1310可以是多个元件，即包括发送机和接收机，提供用于在传输介质上与各种其他装置通信的单元。针对不同的用户设备，用户接口1330还可以是能够外接内接需要设备的接口，连接的设备包括但不限于小键盘、显示器、扬声器、麦克风、操纵杆等。

[0285] 处理器1300负责管理总线架构和通常的处理，存储器1320可以存储处理器1300在执行操作时所使用的数据。

[0286] 可选的，若所述第二消息包括参数指示信息，则所述目标接收器参数为所述参数指示信息指示的接收器参数；

[0287] 若所述第二消息不包括参数指示信息，则所述目标接收器参数为所述接收端默认的接收器参数。

[0288] 可选的，所述接收端默认的接收器参数包括：

[0289] 所述接收端当前使用的接收器参数、所述接收端接收到的时间最近的第二消息指示的接收器参数、预先定义的接收器参数或者所述接收端向所述发送端上报时间最近的发送器参数对应的接收器参数。

[0290] 可选的，所述参数指示信息显式或者隐式指示所述目标接收器参数。

[0291] 可选的，若所述参数指示信息隐式指示所述目标接收器参数，则所述参数指示信息包括所述发送端选择的发送器参数，所述接收端将预先为所述发送器参数选择的接收器参数作为所述目标接收器参数。

[0292] 可选的，若所述第二消息是在预先确定的参数切换指示集对应的调度时间单位内接收到的，则所述第二消息包括参数指示信息，且所述第二消息与所述第一消息之间存在间隙；

[0293] 若所述第二消息是在所述参数切换指示集对应的调度时间单位外接收到的，则所述第二消息不包括参数指示信息，且所述第二消息与所述第一消息之间不存在间隙。

[0294] 可选的，所述参数切换指示集对应的调度时间单位在时域上周期存在；和\或

[0295] 所述参数切换指示集对应的调度时间单位由所述发送端半静态或半持续配置，并通知所述接收端。

[0296] 可选的，所述第一消息分为时域上连续的第一部分内容和第二部分内容，且所述第一部分内容在所述第二部分内容的前面，以及所述第一部分内容与所述第二消息在时域连续，所述第二消息在所述第一部分内容之前。

[0297] 可选的，处理器1300还用于：

[0298] 通过收发机1310向所述接收端发送第三消息，所述第三消息用于指示所述第二消息是否包括参数指示信息，且若所述第三消息指示所述第二消息包括参数指示信息，则所述第二消息与所述第一消息之间存在间隙，若所述第三消息指示所述第二消息不包括参数

指示信息，则所述第二消息与所述第一消息之间不存在间隙。

[0299] 可选的，所述第三消息用于指示M个时间单位内的第二消息是否包括参数指示信息，所述M为大于或者等于1的整数，所述M个时间单位连续或者不连续。

[0300] 可选的，所述目标接收器参数包括时域、频域和空域中的至少一项的接收器参数。

[0301] 可选的，所述空域的接收器参数包括所述接收端的接收波束。

[0302] 需要说明的是，本实施例中上述发送端可以是图1-图7所示的实施例中的发送端，图1-图7所示实施例中发送端的任意实施方式都可以被本实施例中的上述发送端所实现，以及达到相同的有益效果，此处不再赘述。

[0303] 在本申请所提供的几个实施例中，应该理解到，所揭露方法和装置，可以通过其它的方式实现。例如，以上所描述的装置实施例仅仅是示意性的，例如，所述单元的划分，仅仅为一种逻辑功能划分，实际实现时可以有另外的划分方式，例如多个单元或组件可以结合或者可以集成到另一个系统，或一些特征可以忽略，或不执行。另一点，所显示或讨论的相互之间的耦合或直接耦合或通信连接可以是通过一些接口，装置或单元的间接耦合或通信连接，可以是电性，机械或其它的形式。

[0304] 另外，在本发明各个实施例中的各功能单元可以集成在一个处理单元中，也可以是各个单元单独物理包括，也可以两个或两个以上单元集成在一个单元中。上述集成的单元既可以采用硬件的形式实现，也可以采用硬件加软件功能单元的形式实现。

[0305] 上述以软件功能单元的形式实现的集成的单元，可以存储在一个计算机可读取存储介质中。上述软件功能单元存储在一个存储介质中，包括若干指令用以使得一台计算机设备(可以是个人计算机，服务器，或者网络设备等)执行本发明各个实施例所述收发方法的部分步骤。而前述的存储介质包括：U盘、移动硬盘、只读存储器(Read-Only Memory，简称ROM)、随机存取存储器(Random Access Memory，简称RAM)、磁碟或者光盘等各种可以存储程序代码的介质。

[0306] 以上所述是本发明的优选实施方式，应当指出，对于本技术领域的普通技术人员来说，在不脱离本发明所述原理的前提下，还可以作出若干改进和润饰，这些改进和润饰也应视为本发明的保护范围。

Channel transmission method and network device

Abstract

Embodiments of the invention disclose a channel transmission method and a network device. The method includes steps: a first network device determines a search space of at least two downlink control channels; the first network device respectively determines resources occupied by the at least two downlink control channels in the search space, wherein the resources scheduled by the at least two downlink control channels belong to one carrier; and the first network device obtains the at least two downlink control channels by employing the resources. By adopting the method and the device, data ofone carrier can be scheduled through a plurality of downlink control channels so that the efficiency and the reliability of information transmission are improved.

(54)发明名称

一种信道传输方法及网络设备

(57)摘要

本发明实施例公开了一种信道传输方法及网络设备。其中，该方法包括：第一网络设备确定至少两个下行控制信道的搜索空间；所述第一网络设备在所述搜索空间中分别确定出所述至少两个下行控制信道占用的资源，所述至少两个下行控制信道调度的资源属于一个载波；所述第一网络设备使用所述资源获取所述至少两个下行控制信道。采用本发明实施例，能够实现通过多个下行控制信道调度一个载波的数据，从而提升了信息传输的效率及可靠性。

CN 108633047 B

1.一种信道传输方法,其特征在于,包括:

用户设备确定至少两个下行控制信道的搜索空间;

所述用户设备在所述搜索空间中分别确定出所述至少两个下行控制信道占用的资源,所述至少两个下行控制信道调度的数据所占的资源属于一个载波;

所述用户设备使用所述至少两个下行控制信道占用的资源,获取所述至少两个下行控制信道。

2.根据权利要求1所述的方法,其特征在于,所述至少两个下行控制信道的搜索空间相同;所述用户设备确定至少两个下行控制信道的搜索空间,包括:

所述用户设备基于第一参数确定至少两个下行控制信道的搜索空间;其中,所述第一参数包括控制信道元素CCE个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项;

所述至少两个下行控制信道的搜索空间的CCE的个数相同;或,

所述至少两个下行控制信道的第一时间单元的标识是基于所述至少两个下行控制信道占用的资源的子载波间隔确定的;或,

所述至少两个下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与所述至少两个下行控制信道的第一时间单元对应的时间单元的标识确定的;或,

所述至少两个下行控制信道的候选位置不同,所述至少两个下行控制信道的候选位置是基于第二参数确定的,所述第二参数包括设备类型、设备标识、聚合等级中的至少一项。

3.根据权利要求1所述的方法,其特征在于,所述至少两个下行控制信道的搜索空间不同;所述用户设备确定至少两个下行控制信道的搜索空间,包括:

所述用户设备分别确定至少两个下行控制信道的搜索空间占用的资源,所述至少两个下行控制信道的搜索空间占用的资源不同,其中,所述至少两个下行控制信道的搜索空间占用的资源包括频域资源或时域资源;

所述用户设备基于所述至少两个下行控制信道的搜索空间占用的资源分别确定所述至少两个下行控制信道的搜索空间。

4.根据权利要求3所述的方法,其特征在于,所述用户设备分别确定至少两个下行控制信道的搜索空间占用的资源,包括:

所述用户设备确定第一资源配置信息,并基于所述第一资源配置信息确定至少两个下行控制信道的搜索空间占用的资源;

其中,所述第一资源配置信息包括所述至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息,且所述至少两个下行控制信道对应的搜索空间的个数与控制信道资源集合的个数相同。

5.根据权利要求3所述的方法,其特征在于,所述用户设备分别确定至少两个下行控制信道的搜索空间占用的资源,包括:

所述用户设备确定第二资源配置信息,并基于所述第二资源配置信息确定至少两个下行控制信道的搜索空间占用的资源;

其中,所述第二资源配置信息包括所述至少两个下行控制信道的搜索空间所在的至少两个控制信道资源集合占用的资源信息、所述至少两个控制信道资源集合的标识以及第一偏移值中的至少一项,所述第一偏移值是基于所述至少两个控制信道资源集合的标识确定

出的，且所述至少两个控制信道资源集合占用的资源相重叠。

6.根据权利要求3所述的方法，其特征在于，所述用户设备分别确定至少两个下行控制信道的搜索空间占用的资源，包括：

所述用户设备确定第三资源配置信息，并基于所述第三资源配置信息确定至少两个下行控制信道的搜索空间占用的资源；

其中，所述第三资源配置信息包括所述至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息、所述至少两个下行控制信道的搜索空间的标识以及第二偏移值中的至少一项，所述第二偏移值是基于所述至少两个下行控制信道的搜索空间的标识确定出的，且所述至少两个下行控制信道对应的搜索空间所在的控制信道资源集合相同。

7.根据权利要求3所述的方法，其特征在于，所述至少两个下行控制信道的搜索空间占用的资源包括时域资源；所述方法还包括：

所述用户设备接收至少一个第二网络设备发送的通知消息，所述通知消息包括所述至少两个下行控制信道的搜索空间占用的第二时间单元的标识。

8.一种信道传输方法，其特征在于，包括：

第一网络设备在第一搜索空间中确定第一下行控制信道占用的第一资源；

第二网络设备在第二搜索空间中确定第二下行控制信道占用的第二资源，所述第一下行控制信道调度的资源和所述第二下行控制信道调度的数据所占的资源属于一个载波；

所述第一网络设备使用所述第一资源向用户设备发送所述第一下行控制信道；

所述第二网络设备使用所述第二资源向所述用户设备发送所述第二下行控制信道。

9.根据权利要求8所述的方法，其特征在于，所述第一搜索空间和所述第二搜索空间相同；所述方法还包括：

所述第一网络设备或所述第二网络设备基于第一参数确定所述第一搜索空间；

其中，所述第一参数包括控制信道元素CCE的个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项；

所述第一网络设备对应的第一参数包括的CCE的个数和所述第二网络设备对应的第一参数包括的CCE的个数相同；或，

所述第一下行控制信道的第一时间单元的标识或所述第二下行控制信道的第一时间单元的标识是基于所述第一资源和第二资源的子载波间隔确定的；或，

所述第一下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与所述第一下行控制信道的第一时间单元对应的时间单元的标识确定的，所述第二下行控制信道的第一时间单元的标识是根据所述预设子载波间隔下的时间单元中与所述第二下行控制信道的第一时间单元对应的时间单元的标识确定出的；或，

所述第一下行控制信道的候选位置与所述第二下行控制信道的候选位置不同，所述第一下行控制信道或所述第二下行控制信道的候选位置是基于第二参数确定的，所述第二参数包括设备类型、设备标识、聚合等级中的至少一项。

10.根据权利要求8所述的方法，其特征在于，所述第一搜索空间和所述第二搜索空间不同；所述方法还包括：

所述第一网络设备确定第一搜索空间占用的第三资源；其中，所述第三资源包括频域资源或时域资源；

所述第一网络设备基于所述第三资源确定所述第一搜索空间。

11.根据权利要求10所述的方法，其特征在于，所述第一网络设备基于所述第三资源确定所述第一搜索空间，包括：

所述第一网络设备确定第一资源配置信息，并基于所述第一资源配置信息确定所述第一搜索空间，所述第一资源配置信息包括所述第一搜索空间所在的控制信道资源集合占用的资源信息。

12.根据权利要求10所述的方法，其特征在于，所述第一网络设备基于所述第三资源确定所述第一搜索空间，包括：

所述第一网络设备确定第二资源配置信息，并基于所述第二资源配置信息确定所述第一搜索空间，所述第二资源配置信息包括所述第一搜索空间所在的控制信道资源集合占用的资源信息、所述控制信道资源集合的标识以及第一偏移值中的至少一项，所述第一偏移值是基于所述控制信道资源集合的标识确定出的。

13.根据权利要求10所述的方法，其特征在于，所述第一网络设备基于所述第三资源确定所述第一搜索空间，包括：

所述第一网络设备确定第三资源配置信息，并基于所述第三资源配置信息确定所述第一搜索空间，所述第三资源配置信息包括所述第一搜索空间所在的控制信道资源集合占用的资源信息、所述第一搜索空间的标识以及第二偏移值中的至少一项，所述第二偏移值是基于所述第一搜索空间的标识确定出的。

14.根据权利要求10所述的方法，其特征在于，所述第三资源包括时域资源；所述方法还包括：

所述第一网络设备向所述用户设备发送通知消息，所述通知消息包括所述第一搜索空间占用的第二时间单元的标识。

15.根据权利要求8所述的方法，其特征在于，所述方法还包括：

所述第一网络设备基于第三参数确定所述第一搜索空间，其中，所述第一搜索空间包括至少一个控制信道元素CCE，所述第三参数包括CCE的个数或CCE的标识。

16.一种用户设备，其特征在于，包括：

确定模块，用于确定至少两个下行控制信道的搜索空间；

所述确定模块，还用于在所述搜索空间中分别确定出所述至少两个下行控制信道占用的资源，所述至少两个下行控制信道调度的数据所占的资源属于一个载波；

通信模块，用于使用所述至少两个下行控制信道占用的资源获取所述至少两个下行控制信道。

17.根据权利要求16所述的用户设备，其特征在于，所述至少两个下行控制信道的搜索空间相同；所述确定模块在确定至少两个下行控制信道的搜索空间时，具体用于：

基于第一参数确定至少两个下行控制信道的搜索空间；其中，所述第一参数包括控制信道元素CCE个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项；

所述至少两个下行控制信道的搜索空间的CCE的个数相同；或，

所述至少两个下行控制信道的第一时间单元的标识是基于所述至少两个下行控制信道占用的资源的子载波间隔确定的；或，

所述至少两个下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间

单元中与所述至少两个下行控制信道的第一时间单元对应的时间单元的标识确定的；或，

所述至少两个下行控制信道的候选位置不同，所述至少两个下行控制信道的候选位置是基于第二参数确定的，所述第二参数包括设备类型、设备标识、聚合等级中的至少一项。

18.根据权利要求16所述的用户设备，其特征在于，所述至少两个下行控制信道的搜索空间不同；所述确定模块在确定至少两个下行控制信道的搜索空间时，具体用于：

分别确定至少两个下行控制信道的搜索空间占用的资源，所述至少两个下行控制信道的搜索空间占用的资源不同，其中，所述至少两个下行控制信道的搜索空间占用的资源包括频域资源或时域资源；

基于所述至少两个下行控制信道的搜索空间占用的资源分别确定所述至少两个下行控制信道的搜索空间。

19.根据权利要求18所述的用户设备，其特征在于，所述确定模块在分别确定至少两个下行控制信道的搜索空间占用的资源时，具体用于：

确定第一资源配置信息，并基于所述第一资源配置信息确定至少两个下行控制信道的搜索空间占用的资源；

其中，所述第一资源配置信息包括所述至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息，且所述至少两个下行控制信道对应的搜索空间的个数与控制信道资源集合的个数相同。

20.根据权利要求18所述的用户设备，其特征在于，所述确定模块在分别确定至少两个下行控制信道的搜索空间占用的资源时，具体用于：

确定第二资源配置信息，并基于所述第二资源配置信息确定至少两个下行控制信道的搜索空间占用的资源；

其中，所述第二资源配置信息包括所述至少两个下行控制信道的搜索空间所在的至少两个控制信道资源集合占用的资源信息、所述至少两个控制信道资源集合的标识以及第一偏移值中的至少一项，所述第一偏移值是基于所述至少两个控制信道资源集合的标识确定出的，且所述至少两个控制信道资源集合占用的资源相重叠。

21.根据权利要求18所述的用户设备，其特征在于，所述确定模块在分别确定至少两个下行控制信道的搜索空间占用的资源时，具体用于：

确定第三资源配置信息，并基于所述第三资源配置信息确定至少两个下行控制信道的搜索空间占用的资源；

其中，所述第三资源配置信息包括所述至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息、所述至少两个下行控制信道的搜索空间的标识以及第二偏移值中的至少一项，所述第二偏移值是基于所述至少两个下行控制信道的搜索空间的标识确定出的，且所述至少两个下行控制信道对应的搜索空间所在的控制信道资源集合相同。

22.根据权利要求18所述的用户设备，其特征在于，所述至少两个下行控制信道的搜索空间占用的资源包括时域资源；

所述通信模块，还用于接收至少一个另一网络设备发送的通知消息，所述通知消息包括所述至少两个下行控制信道的搜索空间占用的第二时间单元的标识。

23.一种网络设备，其特征在于，包括：

第一确定模块，用于在第一搜索空间中确定第一下行控制信道占用的第一资源；

第二确定模块，用于在第二搜索空间中确定第二下行控制信道占用的第二资源，所述第一下行控制信道调度的资源和所述第二下行控制信道调度的数据所占的资源属于一个载波；

第一通信模块，用于使用所述第一资源向用户设备发送所述第一下行控制信道；

第二通信模块，用于使用所述第二资源向所述用户设备发送所述第二下行控制信道。

24.根据权利要求23所述的网络设备，其特征在于，所述第一搜索空间和所述第二搜索空间相同；

所述第一确定模块，还用于基于第一参数确定所述第一搜索空间；

所述第二确定模块，还用于基于第一参数确定所述第一搜索空间；其中，所述第一参数包括控制信道元素CCE的个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项；

所述第一确定模块确定出的第一参数包括的CCE的个数和所述第二确定模块确定出的第一参数包括的CCE的个数相同；或，

所述第一下行控制信道的第一时间单元的标识或所述第二下行控制信道的第一时间单元的标识是基于所述第一资源和第二资源的子载波间隔确定的；或，

所述第一下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与所述第一下行控制信道的第一时间单元对应的时间单元的标识确定的，所述第二下行控制信道的第一时间单元的标识是根据所述预设子载波间隔下的时间单元中与所述第二下行控制信道的第一时间单元对应的时间单元的标识确定出的；或，

所述第一下行控制信道的候选位置与所述第二下行控制信道的候选位置不同，所述第一下行控制信道或所述第二下行控制信道的候选位置是基于第二参数确定的，所述第二参数包括设备类型、设备标识、聚合等级中的至少一项。

25.根据权利要求23所述的网络设备，其特征在于，所述第一搜索空间和所述第二搜索空间不同；

所述第一确定模块，还用于确定第一搜索空间占用的第三资源，并基于所述第三资源确定所述第一搜索空间；其中，所述第三资源包括频域资源或时域资源。

26.根据权利要求25所述的网络设备，其特征在于，所述第一确定模块在基于所述第三资源确定所述第一搜索空间时，具体用于：

确定第一资源配置信息，并基于所述第一资源配置信息确定所述第一搜索空间，所述第一资源配置信息包括所述第一搜索空间所在的控制信道资源集合占用的资源信息。

27.根据权利要求25所述的网络设备，其特征在于，所述第一确定模块在基于所述第三资源确定所述第一搜索空间时，具体用于：

确定第二资源配置信息，并基于所述第二资源配置信息确定所述第一搜索空间，所述第二资源配置信息包括所述第一搜索空间所在的控制信道资源集合占用的资源信息、所述控制信道资源集合的标识以及第一偏移值中的至少一项，所述第一偏移值是基于所述控制信道资源集合的标识确定出的。

28.根据权利要求25所述的网络设备，其特征在于，所述第一确定模块在基于所述第三资源确定所述第一搜索空间时，具体用于：

确定第三资源配置信息，并基于所述第三资源配置信息确定所述第一搜索空间，所述

第三资源配置信息包括所述第一搜索空间所在的控制信道资源集合占用的资源信息、所述第一搜索空间的标识以及第二偏移值中的至少一项，所述第二偏移值是基于所述第一搜索空间的标识确定出的。

29.根据权利要求25所述的网络设备，其特征在于，所述第三资源包括时域资源；

所述第一通信模块，还用于向所述用户设备发送通知消息，所述通知消息包括所述第一搜索空间占用的第二时间单元的标识。

30.根据权利要求23所述的网络设备，其特征在于，

所述第一确定模块，还用于基于第三参数确定所述第一搜索空间，其中，所述第一搜索空间包括至少一个控制信道元素CCE，所述第三参数包括CCE的个数或CCE的标识。

一种信道传输方法及网络设备

技术领域

[0001] 本申请涉及通信技术领域，尤其涉及一种信道传输方法及网络设备。

背景技术

[0002] 目前，基站和用户设备(英文:User Equipment，缩写:UE)之间可采用多点协作传输(英文:Coordinated Multiple Points Transmission/Reception，缩写:CoMP)技术进行信息传输，CoMP主要是指使用地理位置上分离的多个基站，协同参与为一个UE的物理下行共享信道(英文:Physical Downlink Sharing Channel，缩写:PDSCH)数据进行传输，或者联合接收一个UE发送的物理上行共享信道(英文:Physical Uplink Sharing Channel，缩写:PUSCH)数据，以提升UE的覆盖性能。现有的长期演进(英文:Long Term Evolution，缩写:LTE)系统中一个小区中的物理下行控制信道(英文:Physical Downlink Control Channel，缩写:PDCCH)的发送是采用全带宽的方式，在一个子帧中通过不同的载波协作传输一个UE的多个PDCCH，不同的PDCCH用于调度不同载波的数据。从而UE能够使用自身的无线网络临时标识(英文:RNTI Radio Network Tempory Identity，缩写:RNTI)对该子帧包括的所有PDCCH进行尝试解码，基于该RNTI解码得到属于自己的PDCCH，并基于该PDCCH进行信息发送或者接收。然而，对于同一个UE，目前一个子帧中只能携带该UE调度的一个载波的一个PDCCH，传输效率较低。而且，在协作传输的场景下，多基站是可以进行独立调度的，仅发送一个PDCCH往往会存在时延问题，导致发送该PDCCH前获知的信道状态信息(英文:Channel State Information，缩写:CSI)可能失效，进而导致导致PDCCH携带的信息不能适用于真正的信道状况，使得基于该PDCCH的信息传输不可靠。

发明内容

[0003] 本发明实施例提供了一种信道传输方法及网络设备，能够实现在通过多个下行控制信道调度一个载波的数据，从而提升了信息传输的效率及可靠性。

[0004] 第一方面，本发明实施例提供了一种信道传输方法，包括：

[0005] 第一网络设备确定至少两个下行控制信道的搜索空间，在该搜索空间中分别确定出该至少两个下行控制信道占用的资源，并使用该资源获取该至少两个下行控制信道。

[0006] 其中，该至少两个下行控制信道调度的资源属于一个载波。该下行控制信道可以包括下行调度信息，也可以包括上行调度信息。

[0007] 可选的，该至少两个下行控制信道可以是一个网络设备发送给该第一网络设备的，也可以是多个网络设备发送给该第一网络设备的。该第一网络设备可以为基站，也可以为用户设备。

[0008] 进一步可选的，该至少两个下行控制信道的搜索空间可以相同也可以不同。

[0009] 在一些可能的实现中，该至少两个下行控制信道的搜索空间可以相同，该第一网络设备确定至少两个下行控制信道的搜索空间时，可基于第一参数确定至少两个下行控制信道的搜索空间。

[0010] 其中，该第一参数可包括控制信道元素(英文：Control Channel Element，缩写：CCE)个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项。可选的，该第一参数可以是该第一网络设备确定出的；该第一参数也可以是发送该至少两个下行控制信道的网络设备发送给该第一网络设备的，从而该第一网络设备可接收至少一个网络设备发送的该第一参数，以基于该第一参数确定出该至少两个下行控制信道的搜索空间。

[0011] 在一些可能的实现中，该至少两个下行控制信道的搜索空间的CCE的个数相同；或，该至少两个下行控制信道的第一时间单元的标识是基于该至少两个下行控制信道占用的资源的子载波间隔确定的；或，该至少两个下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与该至少两个下行控制信道的第一时间单元对应的时间单元的标识确定的；或，该至少两个下行控制信道的候选位置不同，该至少两个下行控制信道的候选位置是基于第二参数确定的，该第二参数包括设备类型、设备标识、聚合等级中的至少一项。

[0012] 在一些可能的实现中，该第一网络设备还可基于至少两个下行控制信道的时间单元信息确定该至少两个下行控制信道的搜索空间对应的CCE的个数；其中，该时间单元信息包括第二时间单元的个数或第二时间单元的标识。也就是说，该第一网络设备还可以基于该至少两个下行控制信道(或其搜索空间)所在的第二时间单元的个数或标识确定出该至少两个下行控制信道的搜索空间的CCE个数，或该至少两个下行控制信道的搜索空间所在的控制信道资源集合的CCE个数，以确定出该至少两个下行控制信道的搜索空间。可选的，该第二时间单元对应的时间单位和该第一时间单元对应的时间单位可以相同也可以不同。

[0013] 在一些可能的实现中，该至少两个下行控制信道的搜索空间也可以不同；该第一网络设备确定至少两个下行控制信道的搜索空间时，可以具体为：第一网络设备分别确定至少两个下行控制信道的搜索空间占用的资源，该至少两个下行控制信道的搜索空间占用的资源不同，并基于该资源分别确定该至少两个下行控制信道的搜索空间。其中，该资源可以包括频域资源或时域资源。

[0014] 也就是说，当第一网络设备接收的多个下行控制信道的搜索空间不同时，该第一网络设备在确定该多个下行控制信道的搜索空间时，可分别确定该多个下行控制信道的搜索空间占用的时域资源和/或频域资源，并基于该资源分别确定该多个下行控制信道的搜索空间。

[0015] 在一些可能的实现中，该第一网络设备分别确定至少两个下行控制信道的搜索空间占用的资源，可以具体为：第一网络设备确定第一资源配置信息，并基于该第一资源配置信息确定至少两个下行控制信道的搜索空间占用的资源。其中，该第一资源配置信息包括该至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息，且该至少两个下行控制信道对应的搜索空间的个数与控制信道资源集合的个数相同。也就是说，该至少两个下行控制信道对应的至少两个搜索空间可以处于至少两个控制信道资源集合中，该至少两个控制信道资源集合的频域资源不重叠，也即该至少两个下行控制信道的搜索空间所在的控制信道资源集合不同。

[0016] 在一些可能的实现中，该第一网络设备分别确定至少两个下行控制信道的搜索空间占用的资源，可以具体为：第一网络设备确定第二资源配置信息，并基于该第二资源配置信息确定至少两个下行控制信道的搜索空间占用的资源。其中，该第二资源配置信息包括

该至少两个下行控制信道的搜索空间所在的至少两个控制信道资源集合占用的资源信息、该至少两个控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值是基于该至少两个控制信道资源集合的标识确定出的，且该至少两个控制信道资源集合占用的资源相重叠。也就是说，该至少两个下行控制信道对应的至少两个搜索空间可以处于至少两个控制信道资源集合中，该至少两个控制信道资源集合的频域资源可以完全重叠，且该至少两个下行控制信道对应的搜索空间的个数与该控制信道资源集合的个数相同。

[0017] 在一些可能的实现中，该第一网络设备分别确定至少两个下行控制信道的搜索空间占用的资源，可以具体为：第一网络设备确定第三资源配置信息，并基于该第三资源配置信息确定至少两个下行控制信道的搜索空间占用的资源。其中，该第三资源配置信息包括该至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息、该至少两个下行控制信道的搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该至少两个下行控制信道的搜索空间的标识确定出的，且该至少两个下行控制信道对应的搜索空间所在的控制信道资源集合相同。也就是说，该至少两个下行控制信道对应的搜索空间可以处于一个控制信道资源集合中。

[0018] 可选的，该第一资源配置信息或该第二资源配置信息或该第三资源配置信息中还可携带CCE标识等信息，以结合该CCE标识进一步确定该搜索空间。

[0019] 进一步可选的，该第一资源配置信息或该第二资源配置信息或该第三资源配置信息还可以是至少一个第二网络设备发送给该第一网络设备的，比如通过某一通知消息指示该第一资源配置信息或该第二资源配置信息或该第三资源配置信息。其中，该第二网络设备可以是发送该至少两个下行控制信道中的一个或多个下行控制信道的网络设备。

[0020] 在一些可能的实现中，该资源可包括时域资源；则该第一网络设备还可接收该至少一个第二网络设备发送的通知消息，该通知消息可用于指示该至少两个下行控制信道的搜索空间占用的第三时间单元的标识，比如该通知消息中可以携带该第三时间单元的标识。可选的，该第三时间单元对应的时间单位可以与该第一时间单元对应的时间单位相同，也可以不同；该第三时间单元对应的时间单位可以与该第二时间单元对应的时间单位相同，也可以不同，本申请不做限定。

[0021] 在一些可能的实现中，第一网络设备确定至少两个下行控制信道的搜索空间，可以具体为：第一网络设备基于第三参数确定该至少两个下行控制信道的搜索空间。其中，该搜索空间包括至少一个CCE，该第三参数包括CCE的个数或CCE的标识。从而第一网络设备可基于该CCE个数或CCE标识确定出该搜索空间。

[0022] 进一步可选的，该第一网络设备还可接收该至少一个第二网络设备发送的第一消息，该第一消息用于指示发送的下行控制信道的个数，从而该第一网络设备可基于该个数获取下行控制信道，在获取的下行控制信道的个数达到该第一消息指示的个数之后即可停止盲检，从而减少了盲检次数，降低了设备开销。或者，该第一网络设备还可以向该至少一个第二网络设备发送第二消息，该第二消息用于指示第一网络设备支持接收的下行控制信道的个数，从而第二网络设备可以基于该第二消息指示的个数进行下行控制信道的发送，其发送的下行控制信道的个数不超过该第二消息指示的个数。可选的，该第一消息或第二消息指示的个数的值可以与该第一网络设备的接收能力相关，或者与当前的信道条件相关，接收能力越强，个数越大，信道条件越好，个数越大，等等，本申请不做限定。进一步可选

的，该搜索空间还可以是基于聚合级别、控制信息的格式、控制信息的大小以及搜索空间的个数中的至少一项确定出的。从而能够减少盲检次数，降低系统开销。

[0023] 第二方面，本发明实施例提供了一种信道传输方法，包括：

[0024] 第一网络设备在第一搜索空间中确定第一下行控制信道占用的第一资源；

[0025] 第二网络设备在第二搜索空间中确定第二下行控制信道占用的第二资源；

[0026] 第一网络设备使用该第一资源向发送该第一下行控制信道；

[0027] 第二网络设备使用该第二资源向该第三网络设备发送该第二下行控制信道。

[0028] 其中，该第一下行控制信道调度的资源和该第二下行控制信道调度的资源属于一个载波。

[0029] 在一些可能的实现中，该第一网络设备可确定该第一搜索空间；该第二网络设备确定该第二搜索空间。可选的，该第一网络设备和第二网络设备可以是相同的网络设备，即通过同一个网络设备给第三网络设备即其他网络设备发送多个下行控制信道；或者，该第一网络设备和第二网络设备还可以是不同的网络设备，即实现通过一个或多个网络设备向第三网络设备发送多个下行控制信道。其中，该第一网络设备和第二网络设备可以是基站，也可以是用户设备；该第三网络设备可以是用户设备，也可以是基站。该第一网络设备和第二网络设备可以和上述第一方面的信道传输方法中的至少一个第二网络设备相对应，该第三网络设备可以和上述第一方面的信道传输方法中的第一网络设备相对应。

[0030] 可选的，该至少两个下行控制信道的搜索空间可以相同也可以不同。

[0031] 在一些可能的实现中，该第一搜索空间和该第二搜索空间可以相同，则该第一网络设备可基于第一参数确定该第一搜索空间。进一步可选的，该第二网络设备可基于第二参数确定该第二搜索空间。其中，该第一参数或该第二参数可包括CCE的个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项。

[0032] 可选的，该第一参数包括的CCE的个数和该第二参数包括的CCE的个数相同；或，该第一下行控制信道的第一时间单元的标识或该第二下行控制信道的第一时间单元的标识是基于该第一资源和第二资源的子载波间隔确定的；或，该第一下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与该第一下行控制信道的第一时间单元对应的时间单元的标识确定的，该第二下行控制信道的第一时间单元的标识是根据该预设子载波间隔下的时间单元中与该第二下行控制信道的第一时间单元对应的时间单元的标识确定出的；或，该第一下行控制信道的候选位置与该第二下行控制信道的候选位置不同，该第一下行控制信道或该第二下行控制信道的候选位置是基于第三参数确定的，该第三参数可包括设备类型、设备标识、聚合等级中的至少一项。

[0033] 在一些可能的实现中，该第一网络设备或该第二网络设备还可向该第三网络设备发送该第一参数和/或第二参数和/或第三参数。

[0034] 在一些可能的实现中，该第一搜索空间和该第二搜索空间不同；该第一网络设备确定该第一搜索空间，可以具体为：第一网络设备确定第一搜索空间占用的第三资源，并基于该第三资源确定该第一搜索空间。其中，该第三资源可包括频域资源或时域资源。

[0035] 在一些可能的实现中，该第二网络设备确定该第二搜索空间，可以具体为：该第二网络设备确定第二搜索空间占用的第四资源，并基于该第四资源确定该第二搜索空间。其中，该第四资源可包括频域资源或时域资源；

[0036] 在一些可能的实现中，该第一网络设备基于该第三资源确定该第一搜索空间，可以具体为：第一网络设备确定第一资源配置信息，并基于该第一资源配置信息确定该第一搜索空间，该第一资源配置信息包括该第一搜索空间所在的控制信道资源集合占用的资源信息。相应的，该第二网络设备基于该第四资源确定该第二搜索空间，可以具体为：第二网络设备确定第四资源配置信息，并基于该第四资源配置信息确定该第二搜索空间，该第四资源配置信息包括该第二搜索空间所在的控制信道资源集合占用的资源信息。

[0037] 在一些可能的实现中，该第一网络设备基于该第三资源确定该第一搜索空间，可以具体为：该第一网络设备确定第二资源配置信息，并基于该第二资源配置信息确定该第一搜索空间，该第二资源配置信息包括该第一搜索空间所在的控制信道资源集合占用的资源信息、该控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值是基于该控制信道资源集合的标识确定出的。相应的，该第二网络设备基于该第四资源确定该第一搜索空间，可以具体为：该第二网络设备确定第五资源配置信息，并基于该第五资源配置信息确定该第二搜索空间，该第五资源配置信息包括该第二搜索空间所在的控制信道资源集合占用的资源信息、该控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值是基于该控制信道资源集合的标识确定出的。

[0038] 在一些可能的实现中，该第一网络设备基于该第三资源确定该第一搜索空间，可以具体为：该第一网络设备确定第三资源配置信息，并基于该第三资源配置信息确定该第一搜索空间，该第三资源配置信息包括该第一搜索空间所在的控制信道资源集合占用的资源信息、该第一搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该第一搜索空间的标识确定出的。相应的，该第二网络设备基于该第四资源确定该第一搜索空间，可以具体为：该第二网络设备确定第六资源配置信息，并基于该第六资源配置信息确定该第二搜索空间，该第六资源配置信息包括该第二搜索空间所在的控制信道资源集合占用的资源信息、该第二搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该第二搜索空间的标识确定出的。

[0039] 在一些可能的实现中，该第一网络设备还可向该第三网络设备发送通知消息，该通知消息用于指示第一资源配置信息或第二资源配置信息或第三资源配置信息。也就是说，第一网络设备在确定出第一资源配置信息之后，还可向第三网络设备发送用于指示该第一资源配置信息的通知消息，以告知第三网络设备该第一资源配置信息，以使该第三网络设备基于该第一资源配置信息确定搜索空间以获取下行控制信道。进一步的，该第一网络设备还可在确定出第二资源配置信息之后，还可向第三网络设备发送用于指示该第二资源配置信息的通知消息，在确定出第三资源配置信息之后，还可向第三网络设备发送用于指示该第三资源配置信息的通知消息，此处不赘述。进一步的，该第二网络设备还可向该第三网络设备发送通知消息，该通知消息用于指示第四资源配置信息或第五资源配置信息或第六资源配置信息。

[0040] 在一些可能的实现中，该第三资源可包括时域资源；则该第一网络设备还可向第三网络设备发送通知消息，该通知消息包括该第一搜索空间占用的第二时间单元的标识。相应的，该第二网络设备还可向第三网络设备发送通知消息，该通知消息包括该第二搜索空间占用的第二时间单元的标识。

[0041] 在一些可能的实现中，该第一网络设备还可以向该第三网络设备发送第一消息，

该第一消息用于指示发送的下行控制信道的个数(还可以指示搜索空间的个数),从而第三网络设备可以基于该第一消息指示的个数进行下行控制信道的接收,在接收的下行控制信道的个数达到该第一消息指示的个数之后即可停止盲检,从而减少了盲检次数,降低了设备开销。该第一网络设备还可接收该第三网络设备发送的第二消息,该第二消息用于指示第三网络设备支持接收的下行控制信道的个数(还可以指示搜索空间的个数),从而该第一网络设备可基于该个数发送下行控制信道,其发送的下行控制信道的个数可不超过该第二消息指示的个数。可选的,该第一消息或第二消息指示的个数的值可以与该第三网络设备的接收能力相关,或者与当前的信道条件相关,接收能力越强,个数越大,信道条件越好,个数越大,等等,本申请不做限定。进一步可选的,该搜索空间可以是基于聚合级别、控制信息的格式、控制信息的大小以及搜索空间的个数中的至少一项确定出的。从而能够减少盲检次数,降低系统开销。

[0042] 在一些可能的实现中,该第一网络设备还可基于第四参数确定该第一搜索空间,其中,该第一搜索空间包括至少一个控制信道元素CCE,该第四参数可包括CCE的个数或CCE的标识等等。相应的,该第二网络设备还可基于第五参数确定该第二搜索空间,其中,该第二搜索空间包括至少一个CCE,该第五参数可包括CCE的个数或CCE的标识等等。

[0043] 第三方面,本申请还提供了一种网络设备,该网络设备包括:确定模块和通信模块,该网络设备通过上述模块实现上述第一方面的信道传输方法中的第一网络设备的部分或全部步骤。所述模块可以是软件和/或是硬件。

[0044] 第四方面,本申请还提供了一种网络设备,该网络设备包括:第一确定模块、第二确定模块、第一通信模块和第二通信模块,该网络设备通过上述模块实现上述第二方面的信道传输方法中的第一网络设备或第二网络设备的部分或全部步骤。该模块可以是软件和/或是硬件。

[0045] 第五方面,本申请还提供了一种计算机存储介质,该计算机存储介质存储有程序,该程序执行时包括上述第一方面的信道传输方法的部分或全部的步骤。

[0046] 第六方面,本申请还提供了一种计算机存储介质,该计算机存储介质存储有程序,该程序执行时包括上述第二方面的信道传输方法的部分或全部的步骤。

[0047] 第七方面,本申请还提供了一种网络设备,包括:通信接口、存储器和处理器,该处理器分别与该通信接口及该存储器连接;其中,

[0048] 该存储器用于存储程序指令;

[0049] 该处理器用于调用该存储器中的程序指令执行上述第一方面的信道传输方法的部分或全部的步骤。

[0050] 第八方面,本申请还提供了一种网络设备,包括:通信接口、存储器和处理器,该处理器分别与该通信接口及该存储器连接;其中,

[0051] 该存储器用于存储程序指令;

[0052] 该处理器用于调用该存储器中的程序指令执行上述第二方面的信道传输方法的部分或全部步骤。

[0053] 第九方面,本申请还提供了一种信道传输系统,包括第一网络设备和至少一个第二网络设备;其中,该第一网络设备用于执行上述第一方面的信道传输方法的部分或全部步骤;该第二网络设备用于执行上述第二方面的信道传输方法的部分或全部步骤。

[0054] 本申请的又一方面提供了一种包含指令的计算机程序产品，当其在计算机上运行时，使得计算机执行上述各方面所述的方法。

[0055] 在本申请提供的技术方案中，网络设备能够通过确定调度的资源属于一个载波的多个下行控制信道如PDCCH的搜索空间，并进一步在该搜索空间中分别确定出该多个PDCCH占用的资源，以使用该资源传输该多个PDCCH，从而使得一个网络设备能够接收一个或多个其他网络设备发送的多个PDCCH，并通过该多个PDCCH调度一个载波的数据，这就提升了信息传输的效率，并提升了信息传输的可靠性。

附图说明

[0056] 为了更清楚地说明本发明实施例或背景技术中的技术方案，下面将对本发明实施例或背景技术中所需要使用的附图进行说明。

具体实施方式

[0078] 下面结合本发明实施例中的附图对本发明实施例进行描述。

[0079] 应理解，本申请的技术方案可具体应用于各种通信系统中，例如：全球移动通讯系统(Global System of Mobile communication，缩写：GSM)，码分多址(英文：Code Division Multiple Access，缩写：CDMA)、宽带码分多址(英文：Wideband Code Division Multiple Access，缩写：WCDMA)、时分同步码分多址(英文：Time Division-Synchronous

Code Division Multiple Access,缩写:TD-SCDMA)、通用移动通信系统(英文:Universal Mobile Telecommunication System,缩写:UMTS)、长期演进(英文:Long Term Evolution,缩写:LTE)系统等,随着通信技术的不断发展,本申请的技术方案还可用于未来网络,如第五代移动通信技术(英文:The Fifth Generation Mobile Communication Technology,缩写:5G)系统,也可以称为NR(英文:New Radio,缩写:NR)系统,或者可用于D2D(device to device)系统,M2M(machine to machine)系统等等。

[0080] 本申请结合网络设备进行描述,其中,网络设备可以是基站,也可以是用户设备。示例的,本申请中涉及的通信既可以是基站和用户设备之间的,也可以是基站和基站之间的,比如宏基站和小基站之间的,还可以是用户设备和用户设备之间的,比如D2D网络中的通信。

[0081] 在本申请中,用户设备(英文:User Equipment,缩写:UE)还可称之为终端(terminal)、移动台(英文:Mobile Station,缩写:MS)、移动终端(mobile terminal)、订户单元(英文:Subscriber Unit;缩写:SU)、订户站(英文:Subscriber Station;缩写:SS),移动站(英文:Mobile Station;缩写:MB)、远程站(英文:Remote Station;缩写:RS)、接入点(英文:Access Point;缩写:AP)、远程终端(英文:Remote Terminal;缩写:RT)、接入终端(英文:Access Terminal;缩写:AT)、用户终端(英文:User Terminal;缩写:UT)、用户代理(英文:User Agent;缩写:UA)、终端设备(英文:User Device;缩写:UD)或用户装备(英文:User Equipment;缩写:UE)等,本申请不做限定。该用户设备可以是指无线终端、有线终端。该无线终端可以是指向用户提供语音和/或数据连通性的设备,具有无线连接功能的手持式设备、或连接到无线调制解调器的其他处理设备,其可以经无线接入网(如RAN,radio access network)与一个或多个核心网进行通信。例如,该用户设备可以是移动终端,如移动电话(或称为"蜂窝"电话)和具有移动终端的计算机,还可以是便携式、袖珍式、手持式、计算机内置的或者车载的移动装置,如个人通信业务(英文:Personal Communication Service;缩写:PCS)电话、无绳电话、会话发起协议(英文:Session Initiation Protocol;缩写:SIP)话机、无线本地环路(英文:Wireless Local Loop;缩写:WLL)站、个人数字助理(英文:Personal Digital Assistant;缩写:PDA)等,它们与无线接入网交换语言和/或数据。

[0082] 在本申请中,基站可以是指接入网中在空中接口上通过一个或多个扇区与用户设备通信的设备,其可协调对空中接口的属性管理。例如,该基站可以是如GSM或CDMA中的基站,如基站收发台(base transceiver station,缩写:BTS),也可以是WCDMA中的基站,如NodeB,还可以是LTE中的演进型基站,如eNB或e-NodeB(evolutional Node B),还可以是5G系统中的基站,如gNB,或未来网络中的基站,或者可以是传输点(英文:Transmission point,缩写:TP)、收发点(英文:transmission and receiver point,缩写:TRP)、中继设备,或者具备基站功能的其他网络设备等等,本申请不做限定。

[0083] 本申请中涉及的控制信道主要用于承载资源调度信息和其他控制信息,例如该控制信道可以是物理下行控制信道(英文:Physical Downlink Control Channel,缩写:PDCCH)、增强物理下行控制信道(英文:Enhanced Physical Downlink Control Channel,缩写:EPDCCH)、新空口物理下行控制信道(英文:New Radio Physical Downlink Control Channel,缩写:NR-PDCCH)以及随着网络演变而定义的具有上述功能的其他下行信道,或者

可以为上行控制信道，比如物理上行控制信道为(Physical Uplink Control CHannel，缩写：PUCCH)等等，本申请以PDCCH为例进行说明。在本申请中，信道也可以叫做信号或者其余名称，本申请不做限定。

[0084] 在本申请中，时间单元是指一种时间单位对应的一个单元。该时间单位是指用于进行信息传输的时域内的时间单位或者调度单位，该时间单元时域内包含整数个符号，如该时间单位可以是指子帧，也可以是指时隙(slot)，还可是指无线帧、微时隙(mini slot或sub slot)、多个聚合的时隙、多个聚合的子帧、符号等等，还可以是指传输时间间隔(英文：Transmission Time Interval，缩写：TTI)，本申请不做限定。其中，一种时间单位的一个或多个时间单元时域内可包含整数个另一种时间单位的时间单元，或者，一种时间单位的一个或多个时间单元时域内长度等于整数个另一种时间单位的时间单元长度和，例如，一个微时隙/时隙/子帧/无线帧内包含整数个符号，一个时隙/子帧/无线帧内包含整数个微时隙，一个子帧/无线帧内包含整数个时隙，一个无线帧包含整数个子帧等，也可以存在其余包含举例，本申请不做限定。

[0085] 下面对本申请的应用场景进行介绍，本申请以基站和UE之间的通信为例进行描述。请参见图1，图1是本发明实施例提供的一种通信系统的架构图。具体的，如图1所示，该通信系统中包括至少一个基站(图1中示出2个基站)和UE，基站与UE之间可采用各种通信系统进行通信，如上述无线通信系统中的5G系统，也可以称为NR系统，又如LTE系统等，从而实现信息传输。

[0086] 在基站和UE进行信息传输时，UE需要监听并尝试解码一个时间单元如子帧中的所有PDCCH候选位置(候选资源)，该候选资源上包括需要监听的一个或多个PDCCH。本申请能够通过在一个时间单元上通过不同的PDCCH搜索空间(Search Space)配置同一UE的多个PDCCH，或者通过相同的PDCCH搜索空间配置同一UE的多个PDCCH。可选的，该多个PDCCH可以通过相同的波束发送(即通过一个波束发送)，也可以通过不同的波束发送。使得一个UE能够接收到多个PDCCH，并基于接收的多个PDCCH调度一个载波的数据，以进行信息传输。其中，该多个PDCCH中的每个PDCCH可包括下行调度信息，也可以包括上行调度信息。在本申请中，PDCCH搜索空间由至少一个CCE组成，具体可包括一个时间单元如子帧中的控制区域的CCE的总数。CCE是控制信道资源的基本单位，CCE可由一个或者多个资源元素组(英文：Resource Element Group，缩写：REG)组成，REG是由一个或者多个资源元素RE组成，RE为基本的资源单位，比如LTE中一个RE为频域上的一个子载波和时域上的一个符号。进一步的，搜索空间中可以包括一个或者多个PDCCH候选资源，该候选资源可以与聚合级别有关，聚合级别可以是指一个PDCCH是由几个CCE传输，或者承载在几个CCE资源上。

[0087] 本申请公开了一种信道传输方法、网络设备及系统，能够实现通过多个下行控制信道调度一个载波的数据，从而提升了信息传输的效率及可靠性。在本申请中，UE可通过分别确定调度的资源属于一个载波的至少两个PDCCH在PDCCH搜索空间占用的资源，以使用该资源获取该至少两个PDCCH，从而实现一个UE对多个PDCCH的接收。其中，该调度的资源可以是指下行控制信道中调度的数据所占的资源。下面以UE接收两个PDCCH，如接收第一基站发送的第一PDCCH和第二基站发送的第二PDCCH为例进行详细说明。

[0088] 请参见图2，图2是本发明实施例提供的一种信道传输方法的交互示意图。具体的，如图2所示，本发明实施例的所述信道传输方法包括以下步骤：

[0089] 101、第一基站在第一搜索空间中确定第一PDCCH占用的第一资源。

[0090] 102、第二基站在第二搜索空间中确定第二PDCCH占用的第二资源，该第一搜索空间和该第二搜索空间相同。

[0091] 其中，该第一PDCCH调度的资源和第二PDCCH调度的资源属于一个载波，该调度的资源可以是指PDCCH中调度的数据所占的资源。可选的，传输该第一PDCCH和第二PDCCH的资源可以在一个载波上，即在相同的载波，也可以是在不同的载波。

[0092] 可选的，该第一基站和第二基站可以是相同的基站，即通过同一个基站给一个UE发送多个PDCCH；或者，该第一基站和第二基站还可以是不同的基站。进一步可选的，系统中还可存在第三基站、第四基站等等，每个基站可向同一个UE发送一个或多个PDCCH，即实现通过一个或多个基站向一个UE发送多个PDCCH，本发明实施例不做限定。

[0093] 可选的，系统中的多个基站向UE发送多个PDCCH时，可先确定出发送的PDCCH的搜索空间（又称“PDCCH搜索空间”），进而在该搜索空间中确定PDCCH占用的资源。也即，在本发明实施例中，该第一基站可确定该第一PDCCH搜索空间（即第一搜索空间），该第二基站可确定该第二PDCCH搜索空间（即第二搜索空间）。

[0094] 其中，该多个PDCCH的搜索空间可以相同也可以不同。也即，该第一PDCCH搜索空间和该第二PDCCH搜索空间可以相同，也可以不同。

[0095] 可选的，当该第一PDCCH搜索空间和该第二PDCCH搜索空间相同时，该第一基站在确定该第一PDCCH搜索空间时，可基于第一参数确定该第一PDCCH搜索空间；其中，该第一参数可包括CCE的个数、第一时间单元的标识以及PDCCH候选位置中的至少一项。相应的，该第二基站确定该第二PDCCH搜索空间时，也可基于第一参数确定该第一PDCCH搜索空间，该第一基站对应的第一参数和第二基站对应的第一参数的参数值可以相同也可以不同。也就是说，基站在确定PDCCH搜索空间时，可以是基于CCE的个数、第一时间单元的标识以及PDCCH候选位置等参数确定出的。进一步可选的，该CCE的个数可以是指PDCCH搜索空间的CCE的个数或该PDCCH搜索空间所在的控制信道资源集合（control resource set）包括的CCE的个数。

[0096] 具体的，基站在UE相同的搜索空间中发送PDCCH时，可先确定出control resource set，即PDCCH的搜索空间的所在的资源位置，包括时频资源位置。比如频域可以是一段带宽，也可以是连续的资源块（英文：Resource Block，缩写：RB）资源或者不连续的RB资源，或者一个或者多个子带，或者子带部分等；时域可以是时间单元的个数，如子帧或者时隙或者微时隙中的符号个数（比如可默认前几个符号），或者可以是时间单元的标识，如具体的一个或者多个符号位置。其中，RB是时频资源大小的一种衡量单位，比如LTE中的一个RB在频域上为12个子载波以及在时域上为一个时隙。随着系统的不断发展，RB资源块可以重新定义，本发明实施例不做限定。从而UE可在control resource set中进行PDCCH搜索空间的确定以及盲检。该确定方式有多种，本发明实施例按照如下方式进行举例说明。

[0097] 基站或UE在确定PDCCH搜索空间$S_k^{(L)}$时，可以按照以下公式确定出该搜索空间$S_k^{(L)}$：

[0098] $$L\left\{(Y_k+m')\bmod\left\lfloor N_{CCE,k}/L\right\rfloor\right\}+i$$

[0099] 其中，L为聚合级别（Aggregation level）的大小，其取值可以为1、2、4或8，或者还可以取其他值，L可表示用于传输该PDCCH的资源CCE个数。$N_{CCE,k}$为时间单元k如子帧k时包含

的控制区域(即控制信道资源集合)的CCE个数(Size),i=,0,…L1-且m=0,…,$M^{(L)}$-1。$M^{(L)}$为给定的搜索空间内需要监听的PDCCH candidate数目,即需要监听的PDCCH候选数目。例如,该L、$N_{CCE,k}$和$M^{(L)}$的对应关系可以如下表一所示。

[0100] 表一

[0101]

Search space $S_k^{(L)}$			Number of PDCCH candidates $M^{(L)}$
Type	Aggregation level L	Size [in CCEs]	
UE-specific	1	6	6
	2	12	6
	4	8	2
	8	16	2
Common	4	16	4
	8	16	2

[0102] 具体的,PDCCH搜索空间可分为公共搜索空间(Common)和用户搜索空间(UE-specific,即UE特定的搜索空间)。对于公共搜索空间,m′=m,Y_k为0。对于用户搜索空间,Y_k定义为:$Y_k=(A\cdot Y_{k-1})\ \mathrm{mod}D$,其中,$Y_{-1}=n_{RNTI}\neq 0$,A=39827,D=65537,$k=\lfloor n_s/2\rfloor$,$n_s$为一个无线帧中的时隙(slot)编号(取值范围可以为0～19)。可选的,该搜索空间还可以基于其他方式确定出,本发明实施例不做限定。

[0103] 也就是说,为了确保第一基站和第二基站也即多个基站在UE相同的PDCCH搜索空间中发送PDCCH,则该多个基站需确保该PDCCH搜索空间对应的时间单位(比如子帧,时隙,微时隙)上总的CCE个数相同,即搜索空间的CCE个数相同;和/或,还需该多个基站对于相同时域上的时间单元的标识相同;和/或,需要确保该发送的多个PDCCH在不同的PDCCH候选位置。

[0104] 具体的,该第一基站对应的第一参数包括的CCE的个数和该第二基站对应的第一参数包括的CCE的个数相同。假设分配频域资源为全带宽或者部分带宽或者子带等等,为第一基站和第二基站的分配的频域资源相同,当第一基站和第二基站的PDCCH搜索空间(控制区域)的时间单元如符号数相同时,若控制区域的符号上没有参考信号(英文:Reference Signal,缩写:RS),则可以确保PDCCH搜索空间对应的CCE个数相同;若该控制区域的符号上有RS,但该控制区域的导频图案(pattern)或者RE相同,则可以保证CCE相同。例如,第一基站和第二基站的该RS可以码分,此时第一基站和第二基站需要分别通知UE具体的导频序列,也即,针对一个PDCCH搜索空间所在的control resource set通知2种导频序列,使得UE能够根据该两种导频序列估计到两个基站的信道情况,进而进行信道估计以解码得到该PDCCH搜索空间中的多个PDCCH。若该控制区域的符号上有RS,且该控制区域的pattern或者RE不同,也可以保证CCE相同。例如,该第一基站和第二基站的该RS可以时分或者频分,此时需要通知UE具体的RS位置,也即,针对一个PDCCH搜索空间所在的control resource set通知2种RS的pattern或者RE,使得UE能够根据每种RS pattern确定出参考信号位置,进而进

行信道估计以解码得到该PDCCH搜索空间中的多个PDCCH。如图3所示，左图为时分方案，右图为频分方案，每个基站的RS占用不同的符号位置。可选的，对于不同基站的RS的位置按照以下两种处理方法：在第一基站的RS位置，第二基站不发送任何信号，该方式保证了基站间导频没有任何干扰，提高了解调性能；或者，在第一基站的RS位置，第二基站正常发送信号，这就使得UE可以在RS的位置先解RS，后续消除RS，再解有用信号，从而提升了信息传输的可靠性。

[0105] 进一步可选的，该第一基站还可向第二基站发送指示消息，该指示消息用于指示该第一PDCCH对应的第一时间单元信息；第二基站还可向第一基站发送指示消息，以指示该第二PDCCH对应的第二时间单元信息；该第一基站接收该第二基站发送的第二时间单元信息，该第二时间单元信息为该第二PDCCH对应的时间单元信息；该第一基站可基于该第一时间单元信息和该第二时间单元信息确定第一PDCCH搜索空间对应的CCE的个数；第二基站可基于该第一时间单元信息和该第二时间单元信息确定第二PDCCH搜索空间对应的CCE的个数。其中，该第一时间单元信息或该第二时间单元信息包括第二时间单元的个数或第二时间单元的标识。

[0106] 可选的，本发明实施例涉及的消息如该指示消息可以为高层信息，比如系统消息，或者无线资源控制(英文：Radio Resource Control，缩写：RRC)信令，或者媒体接入控制(英文：Medium Access Control，缩写：MAC)信令。或者，可选的，该指示消息还可以为物理层信令，比如物理层下行控制信息(英文：Downlink Control Information，缩写：DCI)信息，等等，本发明实施例不做限定。

[0107] 也就是说，当第一基站和第二基站的PDCCH搜索空间(控制区域)的符号数不同时，基站间可交互各自的符号数或符号标识等时间单元信息，以确保对于为UE分配的总体CCE相同。例如，该第一基站和该第二基站可以取两个基站符号数较小者作为确定CCE个数的符号数。

[0108] 可选的，在统一多个基站对于时间单元的标识的规则的理解时，该第一PDCCH的时间单元的标识或该第二PDCCH的时间单元的标识可以是基于该第一资源和第二资源的子载波间隔确定的。或者，该第一PDCCH的时间单元的标识还可以是根据预设子载波间隔下的时间单元中与该第一PDCCH的时间单元对应的时间单元的标识确定的，该第二PDCCH的时间单元的标识是根据该预设子载波间隔下的时间单元中与该第二PDCCH的时间单元对应的时间单元的标识确定出的。从而确保信道传输系统中的多个基站即协作的多个基站在相同时域上的时间单元的标识相同。

[0109] 具体的，由于不同的基站在不同的子帧上采用的帧结构可能是不同的，其结构与子载波间隔有关。如图4所示，分别为15kHz，30kHz，60kHz子载波间隔下子帧示意图。由此，在确定控制区域的时间单元的标识如时隙的编号时，可采用各自子载波间隔下的时隙号，因不同的子载波间隔下的时域长度成比例关系，因此，针对不同的子载波间隔下的时隙号，可以进行同样的处理：比如子载波间隔15kHz时，时间变量为$k=\lfloor n_s/2 \rfloor$；若子载波间隔为15*2nkHz，则时间变量为$k=\lfloor n_s/(2n) \rfloor$；若子载波间隔为$15*2^n$kHz，则时间变量为$k=\lfloor n_s/2^n \rfloor$，其中，$n_s$可以为时隙号或者微时隙号。或者，在确定时隙号时，可直接采用预设子载波间隔比如15kHz子载波间隔下的时隙编号，若一个时隙中有多个微时隙，则可按照15kHz子载波

间隔下的微时隙号(n_{mini_s})来确定搜索搜索空间。

[0110] 进一步可选的，该第一基站还可以向该UE发送该第一参数，该第二基站还可以向该UE发送该第一参数，以使UE快速确定出需要接收的PDCCH的搜索空间。

[0111] 可选的，该第一PDCCH的候选位置与该第二PDCCH的候选位置不同，该第一PDCCH或该第二PDCCH的候选位置是基于候选位置参数即第二参数确定的，该第二参数可包括基站类型、基站标识、聚合等级中的至少一项。

[0112] 具体的，在确保不同的基站在UE相同的PDCCH搜索空间中发送PDCCH时，第一基站和第二基站在决策时还需确保不在同一候选位置发送PDCCH。可选的，该第一基站和第二基站之间可交互或者预定义REG到CCE的映射，以及CCE到搜索空间候选的映射。其中，每个CCE可以包括4～8个REG，或者其他数目，REG到CCE可以是集中式映射也可以是分布式映射，REG到CCE的映射可以是先频域再时域，也可以先时域再频域，CCE到搜索空间的映射可以是先频域再时域，也可以先时域再频域，本发明实施例不做限定。

[0113] 进一步的，该第一PDCCH和该第二PDCCH的聚合级别可以相同也可以不同。当两个PDCCH的聚合级别相同时，基站之间可按照预定义或者基站交互的方式确定各自占用的候选空间(候选位置)。例如，可预定义为：第一基站(TP1，如服务基站)占前半部分，第二基站(TP2，如协作基站)占后半部分，如图5a所示；或者，可预定义为：交叉的方式，第一基站占候选1、3、5，第二基站占候选2、4、6等等，如图5b所示。或者，可按照基站编号(比如第一基站编号0，第二基站编号1)，编号小的用前半部分，编号大的用后半部分。或者，基站之间可以交互所使用的候选空间。当两个PDCCH的聚合级别不同时，可以预定义低聚合级别(Lower L)采用前半部分候选空间，高聚合级别(Higher L)采用后半部分候选空间，如图5c所示；或者预定义为低聚合级别采用后半部分候选空间，高聚合级别采用前半部分候选空间，或者基站间可交互各自采用的候选空间，等等。其中，该聚合级别L的高低可以是基站间交互或者预定义得到的，比如可定义L＝1，2代表低聚合级别，L＝4，8代表高聚合级别；或者可定义L＝1，2，4代表低聚合级别，L＝8，16，32为高聚合级别等。进一步可选的，若2个基站的信道特性差异比较大，则基站可以提前通知UE，2个PDCCH的聚合级别不同。其中，图5a或图5b或图5c中的方框可代表一个CCE。

[0114] 进一步可选的，该第一基站和第二基站还可以向该UE发送第二参数，即告知UE该第一基站和第二基站的基站类型、基站标识、聚合等级等参数。从而UE在基于该基站类型、基站标识、聚合等级等参数行盲检时，UE检测到一个PDCCH后，另一个PDCCH的盲检范围可以减小，进而减小盲检次数，降低UE开销。

[0115] 103、第一基站使用第一资源向UE发送所述第一PDCCH。

[0116] 104、第二基站使用第二资源向该UE发送所述第二PDCCH。

[0117] 其中，该第一资源可以是指时频域资源(时域资源和/或频域资源)，也可以是指码分资源。可选的，该第一PDCCH和第二PDCCH可以通过相同的波束发送，或者可以通过不同的波束发送，本发明实施例不做限定。

[0118] 进一步可选的，该一个或多个基站还可以分别通知UE需要接收的PDCCH的个数或搜索空间的个数，以便于UE基于该个数接收PDCCH(接收的PDCCH的个数不超过该通知的个数)；或者，该多个基站可接收用于指示UE发送的能够接收的PDCCH的个数或检查的搜索空间的个数的消息，以使基站基于该个数进行PDCCH的发送(发送的PDCCH的个数不超过该消

息指示的个数)。进一步的,该多个基站还可基于该个数进行交互,以确定各基站发送的PDCCH的个数,进而进行PDCCH的搜索空间配置,从而减小UE的盲检次数,降低UE开销,并提升PDCCH传输的可靠性。

[0119] 105、UE确定第一PDCCH的第一搜索空间和第二PDCCH的第二搜索空间。

[0120] 106、UE在该第一搜索空间中确定出该第一PDCCH占用的第一资源,以及在该第二搜索空间中确定出该第二PDCCH占用的第二资源。

[0121] 具体的,UE在确定PDCCH搜索空间时,UE可确定PDCCH搜索空间所在的控制信道资源集合control resource set,即传输控制信道的资源位置,包括时频资源位置。比如频域可以是整个带宽,也可以是连续的RB资源或者不连续的RB资源,或者一个或者多个子带,或者子带部分等;时域可以是时间单元如子帧或者时隙或者微时隙中的符号个数(如默认前几个符号),或者具体的一个或者多个符号位置。进而UE可在control resource set中进行PDCCH的搜索空间的确定以及盲检。可选的,基站在确定出control resource set之后,还可向UE发送该control resource set的配置信息,以指示该control resource set的位置。UE可接收该配置信息以确定该control resource set,或者,该control resource set可以是预定义得到的。

[0122] 可选的,UE在确定至少两个PDCCH的PDCCH搜索空间如该第一PDCCH搜索空间和该第二PDCCH搜索空间时,该UE可基于第一参数确定该第一PDCCH搜索空间和该第二PDCCH搜索空间;其中,该第一参数可包括CCE个数、第一时间单元的标识以及PDCCH的候选位置中的至少一项。可选的,该第一参数可以是至少一个基站发送给UE的,比如UE可接收第一基站发送的用于指示该第一PDCCH搜索空间的第一参数,UE还可接收第二基站发送的用于指示该第二PDCCH搜索空间的第一参数;或者,该第一参数也可以是UE按照预设规则确定的;或者,该第一参数还可以是基站和UE预先协商确定的,本发明实施例不做限定。

[0123] 可选的,为了确保该第一PDCCH搜索空间和该第二PDCCH搜索空间相同,则该第一PDCCH搜索空间的CCE的个数和该第二PDCCH搜索空间的CCE个数相同;或,该第一PDCCH的时间单元的标识和该第二PDCCH的时间单元的标识分别是基于该第一PDCCH和该第二PDCCH占用的资源的子载波间隔确定的;或,该第一PDCCH的时间单元的标识还可以是根据预设子载波间隔下的时间单元中与该第一PDCCH的时间单元对应的时间单元的标识确定的,该第二PDCCH的时间单元的标识是根据该预设子载波间隔下的时间单元中与该第二PDCCH的时间单元对应的时间单元的标识确定出的;或,该第一PDCCH和该第二PDCCH的候选位置不同,该候选位置可以是基于候选位置参数即第二参数确定的,该第二参数可包括基站类型、基站标识、聚合等级中的至少一项。

[0124] 具体的,该第一PDCCH的候选位置与该第二PDCCH的候选位置不同,从而UE可以根据各PDCCH的候选位置来进行盲检。例如,针对如图5a或5c所示的对半分的方案,如果UE在前半部分检测到一个PDCCH,接下来UE可以仅检测后半部分候选区域即可;如果UE在后半部分检测到一个PDCCH,接下来可以仅检测前半部分候选区域即可。再如,针对如图5b交叉分的方案,如果在第1、3、5...个候选区域检测到一个PDCCH,则接下来可以仅检测第2、4、6...个候选区域即可。又如,对于低聚合级别,UE可仅检测前半部分搜索空间候选;对于高聚合级别下,UE可仅检测后半部分搜索空间候选;再如,两个PDCCH搜索空间的聚合级别相同的情况下,UE可再按照基站的编号(比如第一基站编号0,第二基站编号1),编号小的检测前半

部分，编号大的检测后半部分，等等。从而UE在进行盲检时，UE在检测到一个PDCCH后，另一个PDCCH的盲检范围可以减小，进而可以减小盲检次数，降低UE开销。

[0125] 107、UE使用该第一资源获取第一PDCCH，并使用该第二资源获取第二PDCCH。

[0126] 可选的，可以设置一个最大盲检次数，当UE达到最大盲检次数停止盲检。从而能够进一步减小盲检次数，降低UE开销。可选的，该最大盲检次数可以协议预定义的，或者是由UE自定义设置得到，或者由基站通知得到，等等，本发明实施例不做限定。

[0127] 进一步可选的，该搜索空间可以是基于聚合级别、PDCCH的个数、控制信息的格式、控制信息的大小以及搜索空间的个数中的至少一项确定出的。比如该聚合级别、PDCCH的个数、控制信息格式、控制信息大小以及搜索空间的个数可以是基站通知给UE的，如在基站确定control resource set时通知给UE的(如可携带于control resource set的配置信息中)。其中，该控制信息可以是指下行控制信道如本发明实施例中的PDCCH承载的控制信息，如DCI。

[0128] 举例来说，第一基站或第二基站可以是在配置(确定)control resource set时可通知UE一个或者多个聚合级别。比如第一基站或第二基站可以配置聚合级别为4，则UE在监测时仅检测聚合级别为4的候选即可；或者第一基站或第二基站可以配置为4、8、16等多个聚合级别，则UE在监测时仅检测指示的聚合级别对应的候选即可，从而能够降低盲检次数。

[0129] 又例如，第一基站或第二基站可以通知UE针对该control resource set需要监测的PDCCH的个数。比如如果配置UE监测1个PDCCH，则UE监测到一个PDCCH或者到达最大盲检次数后停止监测；如果配置UE监测2个PDCCH，则UE监测到2个PDCCH或者到达最大盲检次数后停止监测。

[0130] 再例如，第一基站或第二基站可以通知UE针对该control resource set需要监测的PDCCH的个数以及对应的聚合级别。比如配置UE检测1个PDCCH而且对应的聚合级别为4，则UE仅针对聚合级别为4的候选进行监测，而且当UE监测到一个PDCCH或者到达最大盲检次数后停止监测；或者配置UE检测1个PDCCH而且对应的聚合级别为4、8、16等多个聚合级别，则UE仅针对指示的聚合级别的候选进行监测，当UE监测到一个PDCCH或者到达最大盲检次数后停止监测；或者，第一基站或第二基站可配置UE检测2个PDCCH，且两个对应的聚合级别相同，比如分别对应的聚合级别为4，则UE可仅针对聚合级别为4的候选进行监测，而且当UE监测到2个PDCCH或者到达最大盲检次数后停止监测；或者配置UE检测2个PDCCH而且两个对应的聚合级别相同，比如分别对应的聚合级别为4、8、16等多个聚合级别，则UE仅针对指示的聚合级别的候选进行监测，而且当UE监测到2个PDCCH或者到达最大盲检次数后停止监测；或者，第一基站或第二基站可配置UE检测2个PDCCH而且两个对应的聚合级别不同，比如第一个PDCCH对应的聚合级别为4，第二个PDCCH对应的聚合级别为8，则UE对于第一个PDCCH仅针对聚合级别为4的候选进行监测，而且当UE监测到1个PDCCH或者到达最大盲检次数后再进行第二个PDCCH的监测，针对第二个PDCCH，则UE仅针对聚合级别为8的候选进行监测，当UE检测到1个PDCCH或者达到最大盲检次数后停止监测；其中，第一PDCCH和第二PDCCH的检测顺序可以不分先后。或者，第一基站或第二基站可配置UE检测2个PDCCH，且两个对应的聚合级别不同，比如第一PDCCH对应的聚合级别为4、8、16等多个聚合级别，第二PDCCH对应的聚合级别为8、16、32等多个聚合级别，则UE可对于第一PDCCH仅针对指示的聚合级别比如4、8、16等的候选进行监测，而且当UE监测到1个PDCCH或者到达最大盲检次数后再进行第二

个PDCCH的监测，针对第二PDCCH，则UE仅针对指示的聚合级别比如8、16、32等的候选进行监测，当UE检测到1个PDCCH或者达到最大盲检次数后停止监测；其中，第一PDCCH和第二PDCCH的检测顺序可以不分先后，或者可以同时进行检测，比如在两者的聚合级别相同时，可以同时进行2个PDCCH的检测，本发明实施例不做限定。

[0131] 进一步可选的，第一基站或第二基站还可以通知UE针对该control resource set的控制信息格式或者控制信息大小中的至少一项。比如配置UE检测控制信息格式DCI format 2D或者检测控制信息大小为A的PDCCH，A的取值可以为20bit或者40bit或者其他数值。可选的，第一基站或第二基站可以针对多个搜索空间或者多个PDCCH配置多个控制信息个数或者控制信息大小的信息，或者可以针对多个搜索空间或者多个PDCCH配置一个控制信息个数或者控制信息大小的信息，或者可以针对一个搜索空间或者一个PDCCH配置多个控制信息个数或者控制信息大小的信息，或者该控制信息个数或者控制信息大小为预定义的，本发明实施例不做限定。从而UE能够快速进行PDCCH的检测和解码。

[0132] 进一步可选的，第一基站或第二基站还可以通知UE针对该control resource set的搜索空间个数，该一个搜索空间可以包括一个或者多个PDCCH。进一步的，第一基站或第二基站还可以通知针对搜索空间的PDCCH的个数以及对应的聚合级别、控制信息格式、控制信息大小，等等，具体请参考上述描述，此处不赘述。

[0133] 也就是说，UE在确定出每个PDCCH的搜索空间之后，即可在该搜索空间进行盲检，进一步在该搜索空间中确定出该PDCCH占用的资源，从而能够使用该资源获取该PDCCH。

[0134] 在本发明实施例中，多个基站能够在UE相同的PDCCH搜索空间中向UE发送多个PDCCH，从而UE能够接收多个PDCCH，并通过该多个PDCCH调度一个载波的数据，这就提升了信息传输的效率，并提升了信息传输的可靠性。本发明实施例通过设计多个PDCCH的搜索空间候选，设计多个PDCCH的CCE不重叠，解决了现有技术无法支持多个PDCCH传输的问题，并降低了UE盲检次数，提升了UE盲检效率。

[0135] 请参见图6，图6是本发明实施例提供的另一种信道传输方法的交互示意图。具体的，如图6所示，本发明实施例的所述信道传输方法包括以下步骤：

[0136] 201、第一基站在第一搜索空间中确定第一PDCCH占用的第一资源。

[0137] 202、第二基站在第二搜索空间中确定第二PDCCH占用的第二资源，该第一搜索空间和该第二搜索空间不同。

[0138] 其中，该第一PDCCH调度的资源和第二PDCCH调度的资源属于一个载波，该调度的资源可以是指PDCCH中调度的数据所占的资源。可选的，传输第一PDCCH和第二PDCCH的资源可以在一个载波上，即在相同的载波，也可以是在不同的载波。

[0139] 可选的，通信系统中的多个基站向UE发送多个PDCCH时，可先确定出发送的PDCCH的搜索空间，进而在该搜索空间中确定PDCCH占用的资源。也即，在本发明实施例中，该第一基站可确定该第一PDCCH搜索空间(即第一搜索空间)，该第二基站可确定该第二PDCCH搜索空间(即第二搜索空间)。

[0140] 其中，该多个PDCCH的搜索空间可以相同也可以不同。也即，该第一PDCCH搜索空间和该第二PDCCH搜索空间可以相同，也可以不同。

[0141] 可选的，当该第一PDCCH搜索空间和该第二PDCCH搜索空间不同时，该第一基站确定该第一PDCCH搜索空间时，可确定第一PDCCH搜索空间占用的第三资源，并基于该第三资

源确定该第一PDCCH搜索空间。相应的，该第二基站确定该第二PDCCH搜索空间时，可确定第二PDCCH搜索空间占用的第四资源，并基于该第四资源确定该第二PDCCH搜索空间。其中，该PDCCH搜索空间占用的资源即上述的第三资源和/或第四资源可包括频域资源或时域资源。从而能够在不同的时域资源或频域资源上发送不同的PDCCH，以实现UE进行多PDCCH的接收。

[0142] 进一步可选的，当该第一PDCCH搜索空间和该第二PDCCH搜索空间不同时，第一PDCCH和第二PDCCH可以从频域资源区分，如第一PDCCH搜索空间和第二PDCCH搜索空间可分别为不同的频域资源，如图7所示。

[0143] 作为一种可选的实施方式，该第一基站基于该第三资源确定该第一PDCCH搜索空间时，可确定第一资源配置信息，并基于该第一资源配置信息确定该第一PDCCH搜索空间，该第一资源配置信息可包括该第一PDCCH搜索空间所在的控制信道资源集合占用的资源信息。相应的，该第二基站基于该第四资源确定该第二PDCCH搜索空间时，也可确定第四资源配置信息，并基于该第四资源配置信息确定该第二PDCCH搜索空间，该第四资源配置信息包括该第二PDCCH搜索空间所在的控制信道资源集合占用的资源信息。进一步可选的，该第一资源配置信息和/或该第四资源配置信息中还可包括该CCE标识如CCE编号信息。

[0144] 进一步可选的，该第一基站还可向UE发送该第一通知消息，该第一通知消息用于指示该第一资源配置信息，该第二基站还可向UE发送该第四通知消息，该第四通知消息用于指示第四资源配置信息。从而UE能够根据该第一资源配置信息和该第四资源配置信息确定出两个PDCCH搜索空间。进一步的，该第一通知消息或第四通知消息可以是第一基站或第二基站在配置control resource set时发送给UE的，比如该第一资源配置信息或第四资源配置信息可以携带在control resource set的配置信息中发送给UE。该control resource set的配置信息还可包括PDCCH的个数、搜索空间的个数、聚合等级、控制信息格式、控制信息大小等信息。具体的配置方法如上述实施例所述，在此不做赘述。

[0145] 具体的，该第一PDCCH搜索空间和第二PDCCH搜索空间可以处于两个control resource set，两个set的频域资源不重叠，即两个PDCCH搜索空间所在的control resource set不同。进一步的，各自set的CCE编号可以分别编号，比如从0开始，如图8a所示，第一基站在control resource set1(控制信道资源集合1)中发送PDCCH(搜索空间1)，第二基站在control resource set2(控制信道资源集合2)中发送PDCCH(搜索空间2)。从而UE可基于该编号计算搜索空间位置，进行搜索空间候选的盲检测。或者，该两个control resource set中的CCE编号也可以是联合编号的，对于该control resource set的个数和CCE编号方式，本发明实施例不做限定。

[0146] 作为一种可选的实施方式，该第一基站基于该第三资源确定该第一PDCCH搜索空间时，可确定第二资源配置信息，并基于该第二资源配置信息确定该第一PDCCH搜索空间，该第二资源配置信息可包括该第一PDCCH搜索空间所在的控制信道资源集合占用的资源信息、该控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值可以是基于该控制信道资源集合的标识确定出的。相应的，该第二基站基于该第四资源确定该第二PDCCH搜索空间时，也可确定第五资源配置信息，并基于该第五资源配置信息确定该第二PDCCH搜索空间，该第五资源配置信息包括该第二PDCCH搜索空间所在的控制信道资源集合占用的资源信息、该控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移

值可以是基于该控制信道资源集合的标识确定出的。进一步可选的，该第二资源配置信息和/或该第五资源配置信息中还可包括该CCE标识如CCE编号信息。

[0147] 进一步可选的，该第一基站还可向UE发送该第二通知消息，该第二通知消息用于指示第二资源配置信息，该第二基站还可向UE发送该第五通知消息，该第五通知消息用于指示第五资源配置信息。从而UE能够根据该第二资源配置信息和该第五资源配置信息确定出两个PDCCH搜索空间。进一步的，该第二通知消息或第五通知消息可以是第一基站或第二基站在配置control resource set时发送给UE的，比如该第二资源配置信息或第五资源配置信息可以携带在control resource set的配置信息中发送给UE。该control resource set的配置信息还可包括PDCCH的个数、搜索空间的个数、聚合等级、控制信息格式、控制信息大小等信息。具体的配置方法如上述实施例所述，在此不做赘述。

[0148] 具体的，该第一PDCCH搜索空间和第二PDCCH搜索空间可以处于两个control resource set，即control resource set1(控制信道资源集合1)和control resource set2(控制信道资源集合2)，两个set的资源可以完全重叠。进一步的，PDCCH搜索空间的CCE编号可以与set编号相关，比如可以配置一个第一偏移值offset1，则第一个set对应的第一PDCCH搜索空间的CCE编号可按公式确定出，第二个set对应的PDCCH搜索空间的CCE编号可增加offset1值。比如第一个set的某个CCE编号为1，则第二个set计算的CCE编号可以为1+offset1。其中，offset1可以为固定的值或者基站信令通知给UE，比如该offset1可以为8、16、32、64或其他整数。进一步的，offset1也可以是根据set编号确定的，比如offset1＝N*M，其中，N为set编号，M为偏移差值，比如8、16、32、64或其他整数。如图8b所示，最大圆圈指示了control resource set1的资源位置，也即control resource set2的资源位置，上面的圆圈指示了control resource set1的搜索空间(搜索空间1)即第一PDCCH搜索空间的CCE位置，下面的圆圈指示了control resource set2的搜索空间(搜索空间1)即第二PDCCH搜索空间的CCE的位置，其CCE编号增加了offset1值。

[0149] 作为一种可选的实施方式，该第一基站基于该第三资源确定该第一PDCCH搜索空间时，可确定第三资源配置信息，并基于该第三资源配置信息确定该第一PDCCH搜索空间，该第三资源配置信息包括该第一PDCCH搜索空间所在的控制信道资源集合占用的资源信息、该第一PDCCH搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该第一PDCCH搜索空间的标识确定出的。相应的，该第二基站基于该第四资源确定该第二PDCCH搜索空间时，也可确定第六资源配置信息，并基于该第六资源配置信息确定该第二PDCCH搜索空间，该第六资源配置信息包括该第二PDCCH搜索空间所在的控制信道资源集合占用的资源信息、该第二PDCCH搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该第二PDCCH搜索空间的标识确定出的。进一步可选的，该第三资源配置信息和/或该第六资源配置信息中还可包括该CCE标识如CCE编号信息。

[0150] 进一步可选的，该第一基站还可向UE发送该第三通知消息，该第三通知消息用于指示第三资源配置信息，该第二基站还可向UE发送该第六通知消息，该第六通知消息用于指示第六资源配置信息。从而UE能够根据该第三资源配置信息和该第六资源配置信息确定出该两个PDCCH搜索空间。进一步的，该第三通知消息或第六通知消息可以是第一基站或第二基站在配置control resource set时发送给UE的，比如该第三资源配置信息或第六资源配置信息可以携带在control resource set的配置信息中发送给UE，或者，该第三资源配

置信息或第六资源配置信息可以携带搜索空间的配置信息中(如第一搜索空间的配置信息携带该第三资源配置信息,第二搜索空间的配置信息携带该第六资源配置信息)。进一步可选的,该control resource set的配置信息或搜索空间的配置信息还可包括PDCCH的个数、搜索空间的个数、搜索空间的编号、聚合等级、控制信息格式、控制信息大小等信息。具体的配置方法如上述实施例所述,在此不做赘述。

[0151] 具体的,该第一PDCCH搜索空间(search space 1,即搜索空间1)和第二PDCCH搜索空间(search space 2,即搜索空间2)可以处于一个control resource set(control resource set1,即控制信道资源集合1)中。进一步的,PDCCH搜索空间的CCE编号可以与搜索空间的编号相关,比如针对搜索空间配置信息中可以配置一个第二偏移值offset2,具体的比如针对第一个搜索空间的offset2配置为0,的针对第二个搜索空间的offset2配置为offset2的值,则第一PDCCH搜索空间的CCE编号可按公式确定出,第二PDCCH搜索空间的CCE编号可增加offset2值。比如第一PDCCH搜索空间计算的某个CCE编号为1,则第二PDCCH搜索空间的CCE编号可以为1+offset2。其中,offset2可以为固定的值或者基站信令通知给UE,比如该offset2可以为8、16、32、64或其他整数,offset2可与PDCCH搜索空间编号相关,比如offset2=N*M,其中N为搜索空间search space的编号,M为偏移差值,比如8、16、32、64或其他整数。如图8c所示,最大圆圈指示了control resource set1的资源位置,上面的圆圈指示了control resource set1的search space 1的CCE位置,下面的圆圈指示了control resource set1的search space 2的CCE的位置,其CCE编号增加了offset2值。

[0152] 进一步可选的,针对不同的control resource set,第一基站或第二基站可以进行REG到CCE的映射,以及CCE到搜索空间候选的映射,该映射可以是集中式映射或者分布式映射。

[0153] 可选的,则该第一基站还可向UE发送第七通知消息,该第七通知消息包括该第一PDCCH搜索空间占用的第三时间单元的标识,该第二基站还可向UE发送第八通知消息,该第八通知消息包括该第二PDCCH搜索空间占用的第四时间单元的标识。

[0154] 也就是说,该第三资源可包括时域资源;当该第一PDCCH搜索空间和该第二PDCCH搜索空间不同时,第一PDCCH搜索空间和第二PDCCH搜索空间还可以从时域资源区分,如第一PDCCH搜索空间和第二PDCCH搜索空间可分别为不同的时域资源。如图9所示,可以将第一PDCCH搜索空间或第一PDCCH(PDCCH1)使用的时间单元的位置和第二PDCCH搜索空间或第二PDCCH(PDCCH2)使用的时间单元位置区分开,该时间单元对应的时间单位可以是子帧、时隙、微时隙、符号等等,图9中以时间单位为符号为例,比如第一PDCCH搜索空间占用第一个符号的资源,第二PDCCH搜索空间占用第二和第三个符号的资源。可选的,针对不同的时域资源,第一基站或第二基站可以进行REG到CCE的映射,以及CCE到搜索空间候选的映射,该映射可以是集中式映射或者分布式映射。

[0155] 举例来说,第一基站和第二基站可分别指示PDCCH1和PDCCH2的时间单元的标识如符号编号信息,比如在control resource set中指示PDCCH1和PDCCH2的符号编号信息。可选的,该符号编号信息可以用2个bit表示,比如00代表第一个符号,01代表第二个符号,10代表第三个符号,11代表第四个符号;或者,该符号编号信息可以采用bitmap的形式,用4个bit表示,比如1100代表使用第一个和第二个符号,0011代表使用第三个和第四个符号,1010代表使用第一个和第三个符号,0101代表使用第二个和第四个符号,等等;或者,该符

号编号信息也可以使用其他的bit个数或者bit含义指示，此处不一一列举；或者，该符号编号信息还可以直接指示，比如符号#0，#1可以表示使用符号编号为0和1的符号位置等等，本发明实施例不做限定。

[0156] 又例如，该第一基站和第二基站也可以先指示小区级的符号个数，再指示UE级的符号位置。从而第一基站和第二基站可通知各自小区内所有UE的可用符号个数，比如第一基站通知小区内UE的可用符号个数为2个，第二基站通知小区内UE的可用符号个数为3个，并能够进一步通知UE可用的符号编号，比如第一基站通知该UE该PDCCH1的可用符号编号为0，第二基站通知该UE该PDCCH2的可用符号编号为2。或者，第一基站和第二基站也可直接指示UE级的符号位置，比如第一基站和第二基站可通知UE可用的符号编号，如第一基站通知该UE该PDCCH1的可用符号编号为0，第二基站通知该UE该PDCCH2的可用符号编号为2。

[0157] 可选的，若PDCCH1和PDCCH2分别为不同的时域资源，在进行CCE编号时，CCE编号可以都从0开始。如图10a所示，假设针对两个control resource set，符号0代表第一个control resource set，符号1和2代表第二个control resource set，两个control resource set都从0开始编号。此时，若其他UE分配的也是1个符号或者2个符号，则可以将每个control resource set进行独立CCE编号，UE检索时按照每个Control resource set的总的N_{CCE}计算的盲检的CCE。从而能够避免不同符号间的交织情况。其中，该符号编号可在指示control resource set时携带。

[0158] 可选的，若PDCCH1和PDCCH2分别为不同的时域资源，在进行CCE编号时，可以根据符号所在位置，进行连续编号。如图10b所示，假设针对两个control resource set，符号0代表第一个control resource set，符号1和2代表第二个control resource set时，两个control resource set的编号与所在符号位置相关，比如位于符号0的control resource set的CCE可以从0开始编号，而位于符号1的control resource set的CCE从N开始编号。其中，N为第一个符号上包含的总的CCE个数。

[0159] 进一步可选的，该符号位置的信息可以携带于control resource set的配置信息发送给UE。比如第一基站或第二基站还可以配置一个control resource set，并且在该control resource set的配置信息中携带2种符号位置(符号位置可以是符号个数及符号编号的至少一项)的信息，该2种符号位置可分别对应2个搜索空间。或者，第一基站或第二基站可以配置2个control resource set，每个control resource set中可以携带一个符号位置的信息，等等，本发明实施例不做限定。

[0160] 203、第一基站使用第一资源向UE发送所述第一PDCCH。

[0161] 204、第二基站使用第二资源向该UE发送所述第二PDCCH。

[0162] 进一步的，第一基站和第二基站在确定PDCCH的资源位置之后，即可在该资源位置发送该PDCCH。其中，该第一资源可以是时频域资源，也可以是码分资源。

[0163] 进一步的，在可选的实施例中，该步骤203和204可以均执行或者仅执行一项，比如第一基站和第二基站都为UE的协作基站时，在不同的时刻传输数据的基站可以不同，如在时刻1第一基站和第二基站都需要发送下行控制信息(信道)对该UE进行数据调度时，则步骤203和步骤204可以都执行。又如在时刻2仅有第一基站需要发送下行控制信息对该UE进行数据调度时，则仅需要执行步骤203。又如在时刻3仅有第二基站需要发送下行控制信息对该UE进行数据调度时，则仅需要执行步骤204。具体哪一个或者哪几个基站对该UE进行数

据调度，可以取决于信道状况以及基站的调度决策等调度相关信息。其中时刻1、2、3可以是具体的时间单元的标识，比如该时间单元对应的时间单位可以是无线帧、子帧、时隙、微时隙、符号等等。

[0164] 205、UE确定第一PDCCH的第一搜索空间和第二PDCCH的第二搜索空间。

[0165] 具体的，当UE接收的多个PDCCH的PDCCH搜索空间不同时，该UE在确定该多个PDCCH的PDCCH搜索空间时，可分别确定该多个PDCCH的PDCCH搜索空间占用的资源，并基于该资源分别确定该多个PDCCH的PDCCH搜索空间。其中，该资源可包括频域资源，也可以包括时域资源。

[0166] 可选的，该UE分别确定该多个PDCCH的PDCCH搜索空间占用的资源时，可按照一定的规则确定该多个PDCCH的PDCCH搜索空间占用的资源，或者多个基站发送的通知消息来确定该多个PDCCH的PDCCH搜索空间占用的资源。比如UE可接收至少一个基站如该第一基站发送的用于指示第一资源配置信息的第一通知消息以及第二基站发送的用于指示第四资源配置信息的第四通知消息，并可基于该第一资源配置信息和第四资源配置信息确定该多个PDCCH的PDCCH搜索空间占用的资源。其中，该第一资源配置信息和第四资源配置信息可包括该多个PDCCH的PDCCH搜索空间所在的控制信道资源集合占用的资源信息。在本发明实施例中，该第一资源配置信息和第四资源配置信息可以是第一基站和第二基站分别发送的各自的资源配置信息，即该第一资源配置信息可包括该第一PDCCH搜索空间所在的控制信道资源集合占用的资源信息，该第四资源配置信息可包括该第二PDCCH搜索空间所在的控制信道资源集合占用的资源信息，即该控制信道集合的个数为2，即该多个PDCCH对应的PDCCH搜索空间的个数与控制信道资源集合的个数相同。进一步可选的，该第一资源配置信息和/或该第四资源配置信息中还可包括该CCE标识如CCE编号信息。UE可通过接收第一基站或第二基站发送的control resource set的配置信息获取该第一资源配置信息或第四资源配置信息。也即，该第一资源配置信息或该第四资源配置信息可以为基站发送的control resource set的配置信息。

[0167] 具体的，该第一PDCCH搜索空间和第二PDCCH搜索空间可以处于两个control resource set，两个set的频域资源不重叠，即两个PDCCH搜索空间所在的control resource set不同。进一步的，各自set的CCE编号可以从0开始，如图8a所示，从而UE可在control resource set1和control resource set2中基于该CCE编号计算搜索空间位置，进行搜索空间候选的盲检测。

[0168] 可选的，该UE分别确定该多个PDCCH的PDCCH搜索空间占用的资源时，还可接收第一基站发送的用于指示第二资源配置信息的第二通知消息以及第二基站发送的用于指示第五资源配置信息的第五通知消息，并基于该第二资源配置信息和第五资源配置信息确定第一PDCCH搜索空间和第二PDCCH搜索空间占用的资源。其中，该第二资源配置信息和该第五资源配置信息可包括该第一PDCCH搜索空间和该第二PDCCH所在的两个控制信道资源集合占用的资源信息，该两个控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值可以是基于该两个控制信道资源集合的标识确定出的(或者该第一偏移值还可由UE确定出，或者偏移值是预定义的)，且该两个控制信道资源集合占用的资源相重叠。进一步可选的，该第二资源配置信息和/或该第五资源配置信息中还可包括该CCE标识如CCE编号信息。UE可通过接收第一基站或第二基站发送的control resource set的配置信息获取

该第二资源配置信息或第五资源配置信息。也即，该第二资源配置信息或该第五资源配置信息可以为基站发送的control resource set的配置信息。

[0169] 具体的，该第一PDCCH搜索空间和第二PDCCH搜索空间可以处于两个control resource set，即control resource set1和control resource set2，两个set的资源可以完全重叠。进一步的，PDCCH搜索空间的CCE编号可以与set编号相关，比如可以配置一个第一偏移值offset1，则第一个set对应的第一PDCCH搜索空间的CCE编号可按公式确定出，第二个set对应的PDCCH搜索空间的CCE编号可增加offset1值。比如第一个set的某个CCE编号为1，则第二个set计算的CCE编号可以为1+offset1。其中，offset1可以为固定的值或者基站信令通知给UE，此处不赘述。如图8b所示，UE即可在control resource set1和control resource set2中基于该CCE编号计算搜索空间位置，进行搜索空间候选的盲检测。

[0170] 可选的，该UE分别确定该多个PDCCH的PDCCH搜索空间占用的资源时，还可接收第一基站发送的用于指示第三资源配置信息的第三通知消息以及第二基站发送的用于指示第六资源配置信息的第六通知消息，并基于该第三资源配置信息和第六资源配置信息确定第一PDCCH搜索空间和第二PDCCH搜索空间占用的资源。其中，该第三资源配置信息和该第六资源配置信息可以是第一基站和第二基站分别发送的各自的资源配置信息，该第三资源配置信息可包括该第一PDCCH搜索空间所在的控制信道资源集合占用的资源信息，该第一PDCCH搜索空间的标识以及第二偏移值中的至少一项，该第六资源配置信息可包括该第二PDCCH搜索空间所在的控制信道资源集合占用的资源信息，该第二PDCCH搜索空间的标识以及第二偏移值中的至少一项。该第二偏移值是基于该第一PDCCH搜索空间的标识和该第二PDCCH搜索空间的标识确定出的(该第二偏移值还可由UE确定出)，且该第一PDCCH搜索空间和该第二PDCCH搜索空间所在的控制信道资源集合相同。进一步可选的，该第三资源配置信息和/或该第六资源配置信息中还可包括该CCE标识如CCE编号信息。UE可通过接收第一基站或第二基站发送的control resource set的配置信息或搜索空间的配置信息以获取该第三资源配置信息或第六资源配置信息。也即，该第三资源配置信息或该第六资源配置信息可以为基站发送的control resource set的配置信息或搜索空间的配置信息。

[0171] 具体的，该第一PDCCH搜索空间(search space 1)和第二PDCCH搜索空间(search space 2)可以处于一个control resource set(control resource set1)中。进一步的，PDCCH搜索空间的CCE编号可以与搜索空间的编号相关，比如可以配置一个第二偏移值offset2，则第一PDCCH搜索空间的CCE编号可按公式确定出，第二PDCCH搜索空间的CCE编号可增加offset2值。比如第一PDCCH搜索空间计算的某个CCE编号为1，则第二PDCCH搜索空间的CCE编号可以为1+offset2。其中，offset2可以为固定的值或者基站信令通知给UE，此处不赘述。如图8c所示，UE即可在control resource set1和control resource set2中基于该CCE编号计算搜索空间位置，进行搜索空间候选的盲检测。

[0172] 进一步可选的，该资源可包括时域资源；则UE还可接收该第一基站和该第二基站发送的通知消息，如上述的第七通知消息和第八通知消息。该通知消息分别包括该第一PDCCH搜索空间占用的第三时间单元的标识和该第二PDCCH搜索空间占用的第四时间单元的标识。从而第一PDCCH搜索空间和第二PDCCH搜索空间可以从时域资源区分，如图9所示。UE即可基于各PDCCH搜索空间占用的时间单元的标识如符号编号去确定搜索空间并进行盲检。

[0173] 也就是说，该搜索空间可以是基于聚合级别、PDCCH的个数、控制信息的格式、控制信息的大小以及搜索空间的个数中的至少一项确定出的。比如该聚合级别、PDCCH的个数、控制信息的格式、控制信息的大小以及搜索空间的个数可以是基站通知给UE的，如在基站确定control resource set时通知给UE的。

[0174] 举例来说，第一基站或第二基站可以是在配置(确定)control resource set时可通知UE一个或者多个聚合级别。比如第一基站或第二基站可以配置聚合级别为4，则UE在监测时仅检测聚合级别为4的候选即可；或者第一基站或第二基站可以配置为4、8、16等多个聚合级别，则UE在监测时仅检测指示的聚合级别对应的候选即可，从而能够降低盲检次数。或者，第一基站或第二基站可以通知UE针对该control resource set需要监测的PDCCH的个数。比如如果配置UE监测1个PDCCH，则UE监测到一个PDCCH或者到达最大盲检次数后停止监测；如果配置UE监测2个PDCCH，则UE监测到2个PDCCH或者到达最大盲检次数后停止监测。

[0175] 又例如，第一基站或第二基站可以通知UE针对该control resource set需要监测的PDCCH的个数以及对应的聚合级别。比如配置UE检测1个PDCCH而且对应的聚合级别为4，则UE仅针对聚合级别为4的候选进行监测，而且当UE监测到一个PDCCH或者到达最大盲检次数后停止监测；或者配置UE检测1个PDCCH而且对应的聚合级别为4、8、16等多个聚合级别，则UE仅针对指示的聚合级别的候选进行监测，当UE监测到一个PDCCH或者到达最大盲检次数后停止监测；或者，第一基站或第二基站可配置UE检测2个PDCCH而且两个对应的聚合级别相同，比如分别对应的聚合级别为4，则UE可仅针对聚合级别为4的候选进行监测，而且当UE监测到2个PDCCH或者到达最大盲检次数后停止监测；或者配置UE检测2个PDCCH而且两个对应的聚合级别相同，比如分别对应的聚合级别为4、8、16等多个聚合级别，则UE仅针对指示的聚合级别的候选进行监测，而且当UE监测到2个PDCCH或者到达最大盲检次数后停止监测；或者，第一基站或第二基站可配置UE检测2个PDCCH而且两个对应的聚合级别不同，比如第一个PDCCH对应的聚合级别为4，第二个PDCCH对应的聚合级别为8，则UE对于第一个PDCCH仅针对聚合级别为4的候选进行监测，而且当UE监测到1个PDCCH或者到达最大盲检次数后再进行第二个PDCCH的监测，针对第二个PDCCH，则UE仅针对聚合级别为8的候选进行监测，当UE检测到1个PDCCH或者达到最大盲检次数后停止监测；其中，第一PDCCH和第二PDCCH的检测顺序可以不分先后。或者，第一基站或第二基站可配置UE检测2个PDCCH而且两个对应的聚合级别不同，比如第一PDCCH对应的聚合级别为4、8、16等多个聚合级别，第二PDCCH对应的聚合级别为8、16、32等多个聚合级别，则UE可对于第一PDCCH仅针对指示的聚合级别比如4、8、16等的候选进行监测，而且当UE监测到1个PDCCH或者到达最大盲检次数后再进行第二个PDCCH的监测，针对第二PDCCH，则UE仅针对指示的聚合级别比如8、16、32等的候选进行监测，当UE检测到1个PDCCH或者达到最大盲检次数后停止监测；其中，第一PDCCH和第二PDCCH的检测顺序可以不分先后，或者可以同时进行检测，比如在两者的聚合级别相同时，可以同时进行2个PDCCH的检测，本发明实施例不做限定。

[0176] 进一步可选的，第一基站或第二基站可以通知UE针对该control resource set的控制信息格式或者控制信息大小中的至少一项。比如配置UE检测控制信息格式DCI format 2D或者检测控制信息大小为A的PDCCH，A的取值为20bit或者40bit或者其他数值。可以针对多个搜索空间或者多个PDCCH配置多个控制信息个数或者控制信息大小的信息。或者可以针对多个搜索空间或者多个PDCCH配置一个控制信息个数或者控制信息大小的信息。或者

可以针对一个搜索空间或者一个PDCCH配置多个个控制信息个数或者控制信息大小的信息。或者控制信息个数或者控制信息大小为预定义。采用该方案，便于UE进行PDCCH的正确检测和解码。

[0177] 进一步可选的，第一基站或第二基站可以通知UE针对该control resource set的搜索空间个数，一个搜索空间可以包括一个或者多个PDCCH，进一步还可以通知针对搜索空间的PDCCH的个数以及对应的聚合级别、控制信息的格式、控制信息的大小，此处不赘述。

[0178] 206、UE在该第一搜索空间中确定出该第一PDCCH占用的第一资源，以及在该第二搜索空间中确定出该第二PDCCH占用的第二资源。

[0179] 207、该UE使用该第一资源获取第一PDCCH，并使用该第二资源获取第二PDCCH。

[0180] 进一步的，UE在确定出每个PDCCH的搜索空间之后，即可确定出每个PDCCH在该PDCCH搜索空间中占用的资源，并使用该资源获取该PDCCH，该资源包括时频资源或码分得到的资源，从而UE可在确定出的时频资源上获取该PDCCH，或者在确定出的码分资源上获取该PDCCH。

[0181] 在本发明实施例中，多个基站能够在UE不同的PDCCH搜索空间中向UE发送多个PDCCH，从而UE能够接收多个PDCCH，并通过该多个PDCCH调度一个载波的数据，这就提升了信息传输的效率，并提升了信息传输的可靠性。本发明实施例能够根据时频资源配置不同的control resource set及search space，并通过设计多个PDCCH的搜索空间候选，确保了多个PDCCH的CCE不重叠，从而解决了现有技术无法支持多个PDCCH传输的问题，并能够提升协作传输下分布式MIMO多流传输的性能，且降低了UE盲检次数，提升了UE盲检效率。

[0182] 请参见图11，图11是本发明实施例提供的又一种信道传输方法的交互示意图。具体的，如图11所示，本发明实施例的所述信道传输方法包括以下步骤：

[0183] 301、第一基站确定协作的第一搜索空间。

[0184] 302、第二基站确定协作的第二搜索空间。

[0185] 可选的，该第一基站确定该第一PDCCH搜索空间(即第一搜索空间)时，还可以是基于第三参数确定该第一PDCCH搜索空间。相应的，该第二基站在确定该第二PDCCH搜索空间(即第二搜索空间)时，还可以是基于第三参数确定该第二PDCCH搜索空间，其中，该第一PDCCH搜索空间或第二PDCCH搜索空间可包括至少一个CCE，该第三参数包括CCE的个数或CCE的标识。进一步可选的，该第一PDCCH搜索空间对应的第三参数和该第二PDCCH搜索空间对应的第三参数包括的CCE个数(或标识)可以相同，也可以不同。

[0186] 也就是说，该协作的第一PDCCH搜索空间或第二PDCCH搜索空间是指用于协作传输的专用搜索空间(又称“协作的搜索空间”)，该第一PDCCH搜索空间和该第二PDCCH搜索空间可以是预定义得到的。可选的，该协作的第一PDCCH搜索空间和该第二PDCCH搜索空间可以是为UE配置的搜索空间，也可以是为基站统一配置的搜索空间，也可以是为不同的基站分别配置的搜索空间，等等，本发明实施例不做限定。

[0187] 例如，对于为UE配置协作的搜索空间的方式，可以预定义该协作的搜索空间的大小和位置，并将该协作的搜索空间与UE的标识相关联。比如将时隙的前16个CCE作为该UE的协作搜索空间，该方式下，该第一PDCCH搜索空间和该第二PDCCH搜索空间相同。可选的，对于配置了协作的搜索空间的UE，可以按照一定的规则盲检PDCCH，比如搜索空间的确定与是否为协作控制信道相关，如果是协作控制信道，则将用于确定搜索空间的Y_k取值为固定的

值，比如将Y_k取值1或2等。或者令$Y_k'=Y_k+ID_{TP}$，并可将该Y_k'作为Y_k代入到上面的公式来确定搜索空间。其中，ID_{TP}可以表示协作的小区的标识，该标识可以是小区编号或者其他标识。进一步的，如果协作的搜索空间有空余，则正常UE的搜索空间与协作UE的搜索空间可以重叠，即正常UE也可以使用该协作的搜索空间，以避免资源浪费。例如，某个UE的RNTI模$\lfloor N_{CCE,k}/L \rfloor$等于1时，则该UE的搜索空间可以与协作的搜索空间全部或部分重叠，在该协作的搜索空间存在空余时可以传输该UE的PDCCH。

[0188] 又例如，协作的搜索空间可以由基站统一配置，如基站可通过RRC或MAC层信令配置第一配置信息，以基于该第一配置信息确定共用的协作搜索空间。可选的，该第一配置信息可包括以下至少一项：coordinated search space-config，用于指示协作的搜索空间的配置，也可以是协作的控制信道资源集合的配置；subframe pattern，用于指示时域资源的配置信息，比如可以是子帧、时隙、微时隙等等；symbol number，用于指示协作控制信道资源占用的符号个数；symbol Index，用于指示协作控制信道资源（该协作控制信道资源可以是协作的搜索空间或协作的控制信道资源集合）占用的符号所在的编号信息；CCE_number，用于指示协作的搜索空间占用的CCE的个数，或者是CCE的位置信息，比如可默认为某个时间单元中的前面几个CCE等；Yk_value，用于指示协作的搜索空间计算相关的变量值；frequencyResource，用于指示协作控制信道资源占用的频域资源位置信息。该方式下，不同基站共用一个协作的搜索空间，基站可以按照上述搜索空间相同的场景进行不同基站间的CCE的分配，此处不赘述。例如，该第一配置信息可以按照如下所示：

[0189]

```
Coordinated search space-Config ::=        SEQUENCE{
        subframePattern          MeasSubframePattern          OPTIONAL, -- Need ON
        SymbolNumber-r11         INTEGER (1..4)               OPTIONAL, -- Need OP
        SymbolIndex-r11          BIT STRING (size(4)) or INTEGER (1..4)
                                                              OPTIONAL, -- Need OP
        CCE_number               ENUMERATED {16,32,64}        OPTIONAL,-- Need ON
        Yk_value                 INTEGER (0,1..4)             OPTIONAL-- Need ON
        frequencyResource        ENUMERATED {16,32,64} or BIT STRING
                                     (size(4))or INTEGER (1..4)  OPTIONAL,-- Need ON
        }
    }
}
```

[0190] 又例如，不同的基站可以配置不同的协作搜索空间，此时，一个基站或者不同的基站可通过RRC或MAC层信令配置至少两个第二配置信息，每个第二配置信息可携带协作的搜索空间标识。可选的，该第二配置信息包括以下至少一项：coordinated search space-config，用于指示协作的搜索空间的配置，也可以是协作的控制信道资源集合配置；Coordinated search space_ID，用于指示协作的搜索空间的配置标识，也可以是协作的控制信道资源集合的配置标识；subframe pattern，用于指示时域资源的配置信息，比如可以是子帧，时隙，微时隙等等；symbol number，用于指示协作控制信道资源占用的符号个数；symbol Index，用于指示协作控制信道资源占用的符号所在的编号信息；CCE_number，用于指示协作的搜索空间占用的CCE的个数，或者是CCE的位置信息，比如可默认前面的CCE等；

Yk_value，用于指示协作的搜索空间计算相关的变量值；frequencyResource，用于指示协作控制信道资源占用的频域资源位置信息；Coordinated search space_ID，用于指示协作的搜索空间配置标识，也可以是协作控制信道资源集合配置标识；Coordinated search space_ID_List，用于指示协作的搜索空间的配置标识列表，也可以是协作的控制信道资源集合的配置标识列表；symbol Index_List，用于指示协作控制信道资源占用的符号所在的编号信息列表；CCE_index_List，用于指示协作的搜索空间占用的CCE的情况列表，或者是CCE个数列表，或者是CCE的位置信息列表；frequencyResource_List，用于指示协作控制信道资源占用的频域资源位置信息列表。从而UE能够通过该第二配置信息区分出多个基站的协作的搜索空间的CCE，以进行PDCCH盲检，而且不影响正常UE的接收。例如，该第二配置信息可以按照如下所示：

[0191]

```
Coordinated search space_ID      INTEGER (1..4)
subframePattern                  MeasSubframePattern-r10      OPTIONAL, -- Need ON
SymbolNumber                     INTEGER (1..4)               OPTIONAL, -- Need OP
SymbolIndex                      BIT STRING (size(4))    or INTEGER (1..4)
                                                              OPTIONAL, -- Need OP
CCE_index                        ENUMERATED {0~16,16~32,32~64}
                                                              OPTIONAL, -- Need ON
Yk_value                         INTEGER (0,1..4)             OPTIONAL, -- Need ON
frequencyResource                ENUMERATED {16,32,64}or BIT STRING (size(4))or
                                 INTEGER (1..4)               OPTIONAL, -- Need ON
        }
    }
}
```

[0192] 又如，该第二配置信息还可以按照如下所示：

[0193]

```
Coordinated search space-Config::=      SEQUENCE{
    Coordinated search space_ID_LIST    INTEGER (1..4)
    symbol Index_List                   SEQUENCE{ SIZE OF ENUMERATED
                                        {0,0~1,0~2,1~2,,1,2}} OPTIONAL -- Need ON
    CCE_index_List                      SEQUENCE{ SIZE OF ENUMERATED
                                        {0~16,16~32,32~64}} OPTIONAL -- Need ON
  frequencyResource_List                SEQUENCE{ ENUMERATED {16,32,64}or BIT
                                        STRING (size(4))or INTEGER (1..4) }
                                                              OPTIONAL, -- Need ON
```

[0194]

```
}
```

[0195] 303、第一基站在第一搜索空间中的第一资源向该UE发送第一PDCCH。

[0196] 304、第二基站在第二搜索空间中的第二资源向该UE发送第二PDCCH。

[0197] 305、UE确定该第一搜索空间和该第二搜索空间。

[0198] 306、UE使用该第一搜索空间中的第一资源获取该第一PDCCH，以及使用该第二搜索空间中的第二资源获取该第二PDCCH。

[0199] 具体的，该UE在确定第一PDCCH搜索空间和第二PDCCH搜索空间时，仍可基于第一

基站和第二基站发送的包括CCE的个数或CCE的标识的参数信息，或者预定义的CCE的个数或CCE的标识等参数信息，来确定该协作的第一PDCCH搜索空间和第二PDCCH搜索空间，从而在该确定出的PDCCH搜索空间上进行盲检，以获取得到第一PDCCH和第二PDCCH。

[0200] 可选的，该第一搜索空间和该第二搜索空间可以相同，也可以不同。该第一基站或第二基站确定PDCCH占用的资源，以及UE获取PDCCH的方式可以参照上述实施例中的描述，此处不赘述。

[0201] 进一步可选的，该第一基站或第二基站还可通知UE聚合级别和/或PDCCH的个数和/或搜索空间的个数和/或控制信息格式和/或控制信息大小，从而UE可基于该聚合级别和/或PDCCH的个数和/或搜索空间的个数和/或控制信息格式和/或控制信息大小来进行搜索空间的确定，具体可参照上述实施例中的描述，此处不赘述。

[0202] 在本发明实施例中，多个基站能够通过设计的协作的搜索空间向UE发送属于多个PDCCH，从而UE能够接收多个PDCCH，并通过该多个PDCCH调度一个载波的数据，本发明实施例通过设计多个PDCCH的搜索空间候选，确保了多个PDCCH的CCE不重叠，从而解决了现有技术无法支持多个PDCCH传输以调度一个载波的数据的问题，从而提升了信息传输的效率，并提升了信息传输的可靠性，且降低了UE盲检次数，提升了UE盲检效率。

[0203] 请参见图12，图12是本发明实施例提供的一种网络设备的结构示意图。具体的，如图12所示，本发明实施例的该网络设备可包括确定模块11和通信模块模块12。其中，

[0204] 确定模块11，用于确定至少两个下行控制信道的搜索空间；

[0205] 该确定模块11，还用于在该搜索空间中分别确定出该至少两个下行控制信道占用的资源，该至少两个下行控制信道调度的资源属于一个载波；

[0206] 通信模块12，用于使用该资源获取该至少两个下行控制信道。

[0207] 可选的，该至少两个下行控制信道的搜索空间可以相同，则该确定模块11在确定至少两个下行控制信道的搜索空间时，可具体用于：

[0208] 基于第一参数确定至少两个下行控制信道的搜索空间；其中，该第一参数包括控制信道元素CCE个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项。

[0209] 进一步可选的，该至少两个下行控制信道的搜索空间的CCE的个数相同；或，该至少两个下行控制信道的第一时间单元的标识是基于该至少两个下行控制信道占用的资源的子载波间隔确定的；或，该至少两个下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与该至少两个下行控制信道的第一时间单元对应的时间单元的标识确定的；或，该至少两个下行控制信道的候选位置不同，该至少两个下行控制信道的候选位置是基于第二参数确定的，该第二参数包括设备类型、设备标识、聚合等级中的至少一项。

[0210] 可选的，该至少两个下行控制信道的搜索空间也可以不同，则该确定模块11在确定至少两个下行控制信道的搜索空间时，可具体用于：

[0211] 分别确定至少两个下行控制信道的搜索空间占用的资源，该至少两个下行控制信道的搜索空间占用的资源不同，并基于该资源分别确定该至少两个下行控制信道的搜索空间。其中，该确定的资源可包括频域资源或时域资源。

[0212] 进一步可选的，该确定模块11在分别确定至少两个下行控制信道的搜索空间占用的资源时，可具体用于：

[0213] 确定第一资源配置信息，并基于该第一资源配置信息确定至少两个下行控制信道的搜索空间占用的资源。其中，该第一资源配置信息可包括该至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息，且该至少两个下行控制信道对应的搜索空间的个数与控制信道资源集合的个数相同。

[0214] 进一步可选的，该确定模块11在分别确定至少两个下行控制信道的搜索空间占用的资源时，可具体用于：

[0215] 确定第二资源配置信息，并基于该第二资源配置信息确定至少两个下行控制信道的搜索空间占用的资源。其中，该第二资源配置信息可包括该至少两个下行控制信道的搜索空间所在的至少两个控制信道资源集合占用的资源信息、该至少两个控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值是基于该至少两个控制信道资源集合的标识确定出的，且该至少两个控制信道资源集合占用的资源相重叠。

[0216] 进一步可选的，该确定模块11在分别确定至少两个下行控制信道的搜索空间占用的资源时，可具体用于：

[0217] 确定第三资源配置信息，并基于该第三资源配置信息确定至少两个下行控制信道的搜索空间占用的资源。其中，该第三资源配置信息包括该至少两个下行控制信道的搜索空间所在的控制信道资源集合占用的资源信息、该至少两个下行控制信道的搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该至少两个下行控制信道的搜索空间的标识确定出的，且该至少两个下行控制信道对应的搜索空间所在的控制信道资源集合相同。

[0218] 进一步可选的，该资源可包括时域资源；

[0219] 该通信模块11，还可用于接收至少一个另一网络设备发送的通知消息，该通知消息包括该至少两个下行控制信道的搜索空间占用的第二时间单元的标识。

[0220] 可选的，该网络设备可通过上述模块实现上述图2至图11对应实施例中的信道传输方法中用户设备执行的部分或全部步骤。应理解，本发明实施例是对应方法实施例的装置实施例，对方法实施例的描述，也适用于本发明实施例。

[0221] 请参见图13，图13是本发明实施例提供的另一种网络设备的结构示意图。具体的，如图13所示，本发明实施例的该网络设备包括第一确定模块21、第二确定模块22、第一通信模块23和第二通信模块24。其中，

[0222] 第一确定模块21，用于在第一搜索空间中确定第一下行控制信道占用的第一资源；

[0223] 第二确定模块22，用于在第二搜索空间中确定第二下行控制信道占用的第二资源，该第一下行控制信道调度的资源和该第二下行控制信道调度的资源属于一个载波；

[0224] 第一通信模块23，用于使用该第一资源向另一网络设备发送该第一下行控制信道；

[0225] 第二通信模块24，用于使用该第二资源向该另一网络设备发送该第二下行控制信道。

[0226] 可选的，该第一确定模块21、第一通信模块23和该第二确定模块22、第二通信模块24可以设置于同一网络设备中，也可以设置于不同的网络设备中，本发明实施例不做限定。

[0227] 其中，该第一搜索空间和该第二搜索空间可以相同也可以不同。

[0228] 可选的，该第一搜索空间和该第二搜索空间可以相同；

[0229] 第一确定模块21，还用于基于第一参数确定该第一搜索空间；

[0230] 第二确定模块22，还用于基于第一参数确定该第一搜索空间；其中，该第一参数包括CCE的个数、第一时间单元的标识以及下行控制信道的候选位置中的至少一项。

[0231] 进一步可选的，该第一确定模块21确定出的第一参数包括的CCE的个数和该第二确定模块22确定出的第一参数包括的CCE的个数相同；或，该第一下行控制信道的第一时间单元的标识或该第二下行控制信道的第一时间单元的标识是基于该第一资源和第二资源的子载波间隔确定的；或，该第一下行控制信道的第一时间单元的标识是根据预设子载波间隔下的时间单元中与该第一下行控制信道的第一时间单元对应的时间单元的标识确定的，该第二下行控制信道的第一时间单元的标识是根据该预设子载波间隔下的时间单元中与该第二下行控制信道的第一时间单元对应的时间单元的标识确定出的；或，该第一下行控制信道的候选位置与该第二下行控制信道的候选位置不同，该第一下行控制信道或该第二下行控制信道的候选位置是基于第二参数确定的，该第二参数包括设备类型、设备标识、聚合等级中的至少一项。

[0232] 可选的，该第一搜索空间和该第二搜索空间也可以不同；

[0233] 第一确定模块21，还可用于确定第一搜索空间占用的第三资源，并基于该第三资源确定该第一搜索空间。其中，该第三资源可包括频域资源或时域资源。

[0234] 进一步可选的，该第一确定模块21在基于该第三资源确定该第一搜索空间时，可具体用于：

[0235] 确定第一资源配置信息，并基于该第一资源配置信息确定该第一搜索空间。其中，该第一资源配置信息包括该第一搜索空间所在的控制信道资源集合占用的资源信息。

[0236] 进一步可选的，该第一确定模块21在基于该第三资源确定该第一搜索空间时，可具体用于：

[0237] 确定第二资源配置信息，并基于该第二资源配置信息确定该第一搜索空间。其中，该第二资源配置信息包括该第一搜索空间所在的控制信道资源集合占用的资源信息、该控制信道资源集合的标识以及第一偏移值中的至少一项，该第一偏移值是基于该控制信道资源集合的标识确定出的。

[0238] 进一步可选的，该第一确定模块21在基于该第三资源确定该第一搜索空间时，可具体用于：

[0239] 确定第三资源配置信息，并基于该第三资源配置信息确定该第一搜索空间。其中，该第三资源配置信息包括该第一搜索空间所在的控制信道资源集合占用的资源信息、该第一搜索空间的标识以及第二偏移值中的至少一项，该第二偏移值是基于该第一搜索空间的标识确定出的。

[0240] 进一步可选的，该第一搜索空间和该第二搜索空间也可以不同；第二确定模块22，还可用于确定第二搜索空间占用的第四资源，并基于该第四资源确定该第一搜索空间。具体的，该第二确定模块22基于该第四资源确定该第二搜索空间与该第一确定模块21基于该第三资源确定该第一搜索空间的方式相同，此处不赘述。

[0241] 可选的，该第三资源可包括时域资源；

[0242] 该第一通信模块23，还用于向该另一网络设备发送通知消息，该通知消息包括该

第一搜索空间占用的第二时间单元的标识。

[0243] 可选的，该第一确定模块21，还用于基于第三参数确定该第一搜索空间。其中，该第一搜索空间包括至少一个CCE，该第三参数包括CCE的个数或CCE的标识。

[0244] 具体的，该第一通信模块23和第二通信模块24在第二搜索空间中确定第二下行控制信道占用的第二资源的方式以及发送第二下行控制信道的方式与该第一确定模块21和第二确定模块22在第一搜索空间中确定第一下行控制信道占用的第一资源的方式以及发送第一下行控制信道的方式类似，此处不赘述。

[0245] 可选的，该网络设备可通过上述模块实现上述图2至图11对应实施例中的信道传输方法中基站执行的部分或全部步骤。应理解，本发明实施例是对应方法实施例的装置实施例，对方法实施例的描述，也适用于本发明实施例。

[0246] 在本发明实施例中，能够通过设计多个下行控制信道的搜索空间候选，实现多个下行控制信道的CCE不重叠，从而解决了现有技术无法支持多个PDCCH传输以调度一个载波的数据的问题，并降低了用户设备盲检次数，提升了盲检效率。

[0247] 请参见图14，图14是本发明实施例提供的一种信道传输系统的结构示意图。具体的，如图14所示，本发明实施例的信息传输系统可包括第一网络设备1、第二网络设备2和第三网络设备3。其中，

[0248] 第一网络设备1，用于在第一搜索空间中确定第一下行控制信道占用的第一资源，并使用该第一资源向第三网络设备3发送该第一下行控制信道；

[0249] 第二网络设备2，用于在第二搜索空间中确定第二下行控制信道占用的第二资源，并使用该第二资源向该第三网络设备3发送该第二下行控制信道；其中，该第一下行控制信道调度的资源和该第二下行控制信道调度的资源属于一个载波；

[0250] 第三网络设备3，用于确定该第一下行控制信道的第一搜索空间和该第二下行控制信道的第二搜索空间，在第一搜索空间中确定该第一下行控制信道占用的第一资源，在第二搜索空间中确定该第二下行控制信道占用的第二资源，使用该第一资源获取该第一下行控制信道以及使用该第二资源获取该第二下行控制信道。

[0251] 可选的，该第一搜索空间和第二搜索空间可以相同也可以不同。该网络设备如上述的第一网络设备、第二网络设备或第三网络设备可以是基站，也可以是用户设备。该第一网络设备和第二网络设备可以是相同的网络设备，即通过同一个网络设备如基站给另一个网络设备如用户设备发送多个下行控制信道；或者，该第一网络设备和第二网络设备还可以是不同的网络设备，本发明实施例不做限定。

[0252] 具体的，该第一网络设备和该第二网络设备可参照上述图2至图11对应实施例中的基站的相关描述，该第三网络设备可参照上述图2至图11对应实施例中的用户设备的相关描述，此处不赘述。

[0253] 请参见图15，图15是本发明实施例提供的又一种网络设备的结构示意图。具体的，如图15所示，本发明实施例的所述网络设备可包括：通信接口300、存储器200和处理器100，所述处理器100分别与所述通信接口300及所述存储器200连接。

[0254] 所述通信接口300、存储器200以及处理器100之间可以通过总线进行数据连接，也可以通过其他方式数据连接。本实施例中以总线连接进行说明。

[0255] 所述处理器100可以是中央处理器(英文：Central Processing Unit，缩写：CPU)，

网络处理器(英文:Network Processor,缩写:NP)或CPU和NP的组合。

[0256] 所述处理器100还可以进一步包括硬件芯片。上述硬件芯片可以是专用集成电路(英文:Application-Specific Integrated Circuit,缩写:ASIC),可编程逻辑器件(英文:Programmable Logic Device,缩写:PLD)或其组合。上述PLD可以是复杂可编程逻辑器件(英文:Complex Programmable Logic Device,缩写:CPLD),现场可编程逻辑门阵列(英文:Field-Programmable Gate Array,缩写:FPGA),通用阵列逻辑(英文:Generic Array Logic,缩写:GAL)或其任意组合。

[0257] 所述存储器200可以包括易失性存储器(英文:Volatile Memory),例如随机存取存储器(英文:Random-Access Memory,缩写:RAM);存储器也可以包括非易失性存储器(英文:non-volatile memory),例如快闪存储器(英文:flash memory),硬盘(英文:Hard Disk Drive,缩写:HDD)或固态硬盘(英文:Solid-State Drive,缩写:SSD);存储器200还可以包括上述种类的存储器的组合。

[0258] 其中,该网络设备可以是用户设备,也可以是基站。可选的,存储器200可以用于存储程序指令,该处理器100调用该存储器200中存储的程序指令,可以执行图2至图11所示实施例中的一个或多个步骤,或其中可选的实施方式,使得该网络设备实现上述方法中的功能。例如,该网络设备可通过上述模块实现上述图2至图11对应实施例中的信道传输方法中的网络设备如用户设备执行的部分或全部步骤。

[0259] 请参见图16,图16是本发明实施例提供的又一种网络设备的结构示意图。具体的,如图16所示,本发明实施例的网络设备可包括:通信接口600、存储器500和处理器400,该处理器400分别与通信接口600及存储器500连接。

[0260] 所述通信接口600、存储器500以及处理器400之间可以通过总线进行数据连接,也可以通过其他方式数据连接。本实施例中以总线连接进行说明。

[0261] 所述处理器400可以是CPU,NP或CPU和NP的组合。

[0262] 所述处理器400还可以进一步包括硬件芯片。上述硬件芯片可以是ASIC,PLD或其组合。上述PLD可以是CPLD,FPGA,GAL或其任意组合。

[0263] 所述存储器500可以包括易失性存储器(英文:Volatile Memory),例如RAM;存储器也可以包括非易失性存储器(英文:non-volatile memory),例如快闪存储器(英文:flash memory),HDD或SSD;存储器500还可以包括上述种类的存储器的组合。

[0264] 其中,该网络设备可以是基站,也可以是用户设备。可选的,存储器500可以用于存储程序指令,该处理器400调用该存储器500中存储的程序指令,可以执行图2至图11所示实施例中的一个或多个步骤,或其中可选的实施方式,使得该网络设备实现上述方法中的功能。例如,该网络设备可通过上述模块实现上述图2至图11对应实施例中的信道传输方法中的网络设备如基站执行的部分或全部步骤。

[0265] 在上述实施例中,可以全部或部分地通过软件、硬件、固件或者其任意组合来实现。当使用软件实现时,可以全部或部分地以计算机程序产品的形式实现。所述计算机程序产品包括一个或多个计算机指令。在计算机上加载和执行所述计算机程序指令时,全部或部分地产生按照本发明实施例所述的流程或功能。所述计算机可以是通用计算机、专用计算机、计算机网络、或者其他可编程装置。所述计算机指令可以存储在计算机可读存储介质中,或者从一个计算机可读存储介质向另一个计算机可读存储介质传输,例如,所述计算机

指令可以从一个网站站点、计算机、服务器或数据中心通过有线(例如同轴电缆、光纤、数字用户线(DSL))或无线(例如红外、无线、微波等)方式向另一个网站站点、计算机、服务器或数据中心进行传输。所述计算机可读存储介质可以是计算机能够存取的任何可用介质或者是包含一个或多个可用介质集成的服务器、数据中心等数据存储设备。所述可用介质可以是磁性介质,(例如,软盘、硬盘、磁带)、光介质(例如,DVD)、或者半导体介质(例如固态硬盘Solid State Disk(SSD))等。

(54) Title: BEAMFORMING METHODS AND METHODS FOR USING BEAMS

(57) Abstract: A method, apparatus, system, and computer readable medium may be used to perform beamforming. The method may include a first communication device sending a first plurality of beamforming training frames to a second communication device using a first beamforming weight vector; the first communication device receiving from the second communication device a second beamforming weight vector; and the first communication device sending a second plurality of beamforming training frames to the second communication device using the second beamforming weight vector. The apparatus, method, system, and computer readable media may use spatial diversity with beam switching, spatial diversity with a single beam, weighted multipath beamforming training, single user spatial multiplexing, and beamforming training for beam division multiple access (BDMA).

WO 2014/074894 A1

BEAMFORMING METHODS AND METHODS FOR USING BEAMS

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Application No. 61/724,679 filed on November 9, 2012, the contents of which are hereby incorporated by reference.

BACKGROUND

[0002] Some wireless communication networks support operation at very high and even extremely high carrier frequencies such as 60 GHz and millimeter wave (mmW) frequency bands. These extremely high carrier frequencies may support very high throughput such as up to 6 gigabits per second (Gbps). One of the challenges for wireless communication at very high or extremely high carrier frequencies is that a significant propagation loss may occur due to the high carrier frequency. As the carrier frequency increases, the carrier wavelength may decrease, and the propagation loss may increase as well.

[0003] At mmW frequency bands, the propagation loss may be severe. For example, the propagation loss may be on the order of 22 to 27 dB, relative to that observed in either the 2.4 GHz, or 5 GHz bands. Since the available spectrum is limited, however, and since users continue to demand more bandwidth, there is a need for effectively using very high and extremely high carrier frequencies for communication networks.

[0033] FIG. 24 is a diagram of an example multi-beam multi-DMG antenna SLS feedback method.

SUMMARY

[0034] A first communication device for beamforming may include a plurality of antennas and a processor. The processor may be configured to partition the antenna into at least a first group of antennas and a second group of antennas. The processor may be further configured to send a plurality of beamforming training frames to a second communication device using the

first group of antennas and the second group of antennas. The processor and/or a receiver may be configured to receive, from the second communication device, a first beamforming weight vector for sending signals on the first group of antennas and to receive a second beamforming weight vector for sending signals on the second group of antennas.

[0035] A method of beamforming training for beam division multiple access (BDMA) may include an AP transmitting Nt sequences modulated using Nt beamforming vectors. A first station may use a first previous beamforming vector to receive the Nt sequences and determine a first transmit beamforming weight from the AP to the first station based on the first previous beamforming vector and the received Nt sequences. The first station may send the determined first transmit beamforming weight to the AP. A second station may use a second previous beamforming vector to receive the Nt sequences and determine a second transmit beamforming weight from the AP to the first station based on the second previous beamforming vector and the received Nt sequences. The second station may send the determined second transmit beamforming weight to the AP, and the AP may transmit one or more sequences modulated based on the first transmit beamforming weight and the second transmit beamforming weight.

[0036] A method and apparatus may be used for spatial diversity with beam switching, spatial diversity with a single beam, weighted multipath beamforming training, single user spatial multiplexing, and for reduced beamforming training overhead.

DETAILED DESCRIPTION

[0037] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, such as voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources,

including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0038] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, 102d, a radio access network (RAN) 104, a core network 106, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include user equipment (UE), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0039] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to one or more communication networks, such as the core network 106, the Internet 110, and/or the networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0040] The base station 114a may be part of the RAN 104, which may also include other base stations and/or network elements (not shown), such as

a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In another embodiment, the base station 114a may employ multiple-input multiple output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0041] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 116, which may be any suitable wireless communication link (e.g., radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 116 may be established using any suitable radio access technology (RAT).

[0042] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, such as CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 104 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 116 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0043] In another embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 116 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0044] In other embodiments, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), and the like.

[0045] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, such as a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In another embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet another embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (e.g., WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106.

[0046] The RAN 104 may be in communication with the core network 106, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, such as user authentication. Although not shown in FIG. 1A, it will be appreciated that the RAN 104 and/or the core network 106 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 104 or a different RAT. For example, in addition to

being connected to the RAN 104, which may be utilizing an E-UTRA radio technology, the core network 106 may also be in communication with another RAN (not shown) employing a GSM radio technology.

[0047] The core network 106 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, such as the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include another core network connected to one or more RANs, which may employ the same RAT as the RAN 104 or a different RAT.

[0048] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0049] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 106, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment.

[0050] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0051] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (e.g., the base station 114a) over the air interface 116. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In another embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet another embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0052] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (e.g., multiple antennas) for transmitting and receiving wireless signals over the air interface 116.

[0053] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, such as UTRA and IEEE 802.11, for example.

[0054] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (e.g., a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, such as the non-removable memory 106 and/or the removable memory 132. The non-removable memory 106 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In other embodiments, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, such as on a server or a home computer (not shown).

[0055] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (e.g., nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0056] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (e.g., longitude and

latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 116 from a base station (e.g., base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0057] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0058] FIG. 1C is a system diagram of the RAN 104 and the core network 106 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 106.

[0059] The RAN 104 may include eNode-Bs 140a, 140b, 140c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 140a, 140b, 140c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 140a, 140b, 140c may implement MIMO technology. Thus, the eNode-B 140a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0060] Each of the eNode-Bs 140a, 140b, 140c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1C, the eNode-Bs 140a, 140b, 140c may communicate with one another over an X2 interface.

[0061] The core network 106 shown in FIG. 1C may include a mobility management gateway (MME) 142, a serving gateway 144, and a packet data network (PDN) gateway 146. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0062] The MME 142 may be connected to each of the eNode-Bs 142a, 142b, 142c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 142 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 142 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, such as GSM or WCDMA.

[0063] The serving gateway 144 may be connected to each of the eNode Bs 140a, 140b, 140c in the RAN 104 via the S1 interface. The serving gateway 144 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 144 may also perform other functions, such as anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0064] The serving gateway 144 may also be connected to the PDN gateway 146, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices. An access router (AR) 150 of a wireless local area network (WLAN)

155 may be in communication with the Internet 110. The AR 150 may facilitate communications between APs 160a, 160b, and 160c. The APs 160a, 160b, and 160c may be in communication with STAs 170a, 170b, and 170c.

[0065] The core network 106 may facilitate communications with other networks. For example, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 106 may include, or may communicate with, an IP gateway (e.g., an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 106 and the PSTN 108. In addition, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0066] Fig. 1D is a diagram of an example use of beamforming in a WLAN 185. The WLAN 185 may include an AP 190 and an STA 192 forming a BSS. Fig. 1E is a diagram of an example use of beamforming using spatial diversity or multipath diversity in the WLAN 185. The WLAN 185 may include an AP 190 and an STA 192 forming a BSS. A WLAN in a Infrastructure Basic Service Set (BSS) mode has an Access Point (AP) 190 for the BSS and one or more stations (STAs) 192 associated with the AP. The AP 190 may have an access, or interface, to a Distribution System (DS) 195, or another type of wired/wireless network that carries traffic in and out of the BSS. Traffic to STAs that originates from outside the BSS may arrive through the AP to be delivered to the STAs. Traffic originating from STAs to destinations outside the BSS may be sent to the AP to be delivered to the respective destinations. Traffic between STAs within the BSS may also be sent through the AP where the source STA may send traffic to the AP and the AP may deliver the traffic to the destination STA. Such traffic between STAs within a BSS may be peer-to-peer traffic. Such peer-to-peer traffic may also be sent directly between the source and destination STAs with a direct link setup

(DLS) using an 802.11e DLS or an 802.11z tunneled DLS (TDLS). A WLAN using an Independent BSS (IBSS) mode has no AP, and/or STAs, communicating directly with each other. This mode of communication may be referred to as an "ad-hoc" mode of communication.

[0067] As used herein an STA 192 may include, but is not limited to, a WTRU 102, an AP, or a communication device. Using the 802.11 infrastructure mode of operation, the AP 190 may transmit a beacon on a fixed channel, usually the primary channel. This channel may be 20 MHz wide, and may be the operating channel of the BSS. This channel may also be used by the STAs to establish a connection with the AP. The fundamental channel access mechanism in an 802.11 system may be Carrier Sense Multiple Access with Collision Avoidance (CSMA/CA). In this mode of operation, every STA, including the AP, may sense the primary channel. If the channel is detected to be busy, the STA may back off. Hence only one STA may transmit at any given time in a given BSS.

[0068] In an 802.11n example, High Throughput (HT) STAs may also use a 40 MHz wide channel for communication. This 40 MHz wide channel may be achieved by combining the primary 20 MHz channel, with an adjacent 20 MHz channel to form a 40 MHz wide contiguous channel. 802.11n may operate on the 2.4 GHz, and 5 GHz ISM bands.

[0069] In an 802.11ac example, Very High Throughput (VHT) STAs may support 20 MHz, 40 MHz, 80 MHz, and 160 MHz wide channels. The 40 MHz, and 80 MHz, channels may be formed by combining contiguous 20 MHz channels similar to 802.11n described above. A 160 MHz channel may be formed either by combining 8 contiguous 20 MHz channels, or by combining two non-contiguous 80 MHz channels, this may also be referred to as an 80+80 configuration. For the 80+80 configuration, the data, after channel encoding, is passed through a segment parser that may divide it into two streams. IFFT and time domain processing are done on each stream separately. The streams may then be mapped on two channels, and the data may be transmitted. At the receiver, this process may be reversed, and the combined data may be sent

to the MAC. 802.11ac may operate only on the 5 GHz ISM band, and consequently may not be backward compatible with 802.11n modes of operation in the 2.4 GHz ISM band. For the examples described herein, any combination of channels may be used, and should not be limited to contiguous and non-contiguous channels.

[0070] Sub 1 GHz modes of operation may be supported by 802.11af, and 802.11ah. For these specifications the channel operating bandwidths may be reduced relative to those used in 802.11n, and 802.11ac. 802.11af may support 5 MHz, 10 MHz and 20 MHz bandwidths in the TV White Space (TVWS) spectrum, and 802.11ah may support 1 MHz, 2 MHz, 4 MHz, 8 MHz, and 16 MHz bandwidths using a non-TVWS spectrum. A possible use case for 802.11ah may support Meter Type Control (MTC) devices in a macro coverage area. MTC devices may have limited capabilities including only support for limited bandwidths, but also may include a requirement for a very long battery life. 802.11ah may also be used for macro coverage as support for cellular offload to WiFi.

[0071] In 802.11ad, wide bandwidth spectrum at 60 GHz may be available, thus enabling very high throughput operation. 802.11ad may support up to 2 GHz operating bandwidths and the data rate may reach up to 6 Gbps. Since the propagation loss at 60 GHz may be more significant than at the 2.4 GHz, and 5 GHz bands, beamforming may be adopted in 802.11ad as a means to extend the coverage range. To support the receiver requirements for this band, the 802.11ac MAC layer may be modified in several areas. An important modification for the 802.11ad MAC layer may include procedures that allow channel estimation and training. These procedures may include omni, and beamformed modes of operation which do not exist in 802.11ac.

[0072] WLAN systems that support multiple channels and channel widths, such as 802.11n, 802.11ac, 802.11af, and 802.11ah, may include a channel designated as the primary channel. The primary channel may, but not necessarily, have a bandwidth equal to the largest common operating bandwidth supported by all STAs in the BSS. The bandwidth of the primary

channel may therefore be limited by the STA, of all the STAs operating in a BSS, which supports or enables the use of the smallest bandwidth operating mode. In the example of 802.11ah, the primary channel may be 1 MHz wide if there are STAs, for example, MTC type devices that only support a 1 MHz mode, even if the AP, and other STAs in the BSS, may support a 2 MHz, 4 MHz, 8 MHz, 16 MHz, or other channel bandwidth operating modes. All carrier sensing and NAV settings may depend on the status of the primary channel. For example, if the primary channel is busy due to a STA supporting only a 1 MHz operating mode, then the entire available frequency bands may be considered busy even though a majority of the frequency bands remain idle and available.

[0073] In the United States, for example, the available frequency bands that may be used by 802.11ah are from 902 MHz to 928 MHz. In Korea, for example, the available frequency bands may be from 917.5 MHz to 923.5 MHz, and in Japan, it may be from 916.5 MHz to 927.5 MHz. The total bandwidth available for 802.11ah may be 6 MHz to 26 MHz depending on the country.

[0074] One of the challenges for wireless communication over 60 GHz may include significant propagation loss due to the high frequency. As the wavelength decreases, the free space propagation loss may increase. To address the range limitation due to this propagation loss, 802.11ad may use beamforming to increase the Effective Radiated Power (ERP) of the transmissions. Since the wavelength is small, it may be possible to use a large antenna array to get a very high beamformed antenna gain. The beam in 802.11ad may be electronically steered to a particular STA, or group of STAs, during association with the STAs.

[0075] In order to support beamforming, the 802.11ad PHY and MAC specifications may be modified to support directional transmissions, and millimeter wave (mmW) antenna training procedures. A comprehensive beamforming training protocol may be defined in 802.11ad. The beamforming training protocol may include two components, for example a sector level sweep (SLS) procedure and a beam refinement protocol (BRP) procedure. The

SLS procedure may be used for transmit beamforming training. The BRP procedure may enable receive beamforming training and iterative refinement of both the transmit and receive beams.

[0076] In order to reduce implementation complexity, 802.11ad may support beam switching at both the AP and the STA. The beam switching at both the AP and the STA may be in contrast to more advanced multi-antenna schemes, and may assume that a single RF front-end is available at both ends. Problems related to link robustness and spectral efficiency may be of importance for enabling 802.11ad+ to address the current trend for a Carrier Grade WiFi service. A Carrier Grade WiFi service may be referred to as 5G Carrier Grade WiFi, may provide high air interference efficiency for multiple users, and a stable "cellular-like" quality. A 5G Carrier Grade WiFi system may support robust and dynamic deployments, for example dense deployments and flash crowds.

[0077] Although 802.11ad may address the need for a very high peak throughput, limitations due to the propagation environment are not adequately addressed in 802.11ad.

[0078] For mmW communications it may be necessary to handle a propagation loss due in part to the high free space propagation loss which may occur at mmW frequencies. For example, blockage of transmissions by the human body may attenuate a signal by 15 to 25 dB for hundreds of milliseconds.

[0079] While propagation loss of walls and other indoor obstacles may prevent the propagation of mmW through them, indoor Line of Site (LOS) propagation may occur indoors. LOS propagation may occur indoors either due to a direct line of sight transmission, or due to reflections off walls and other obstacles. It should be noted that non-negligible propagation loss at mmW frequencies may occur due to walls and other environmental factors. Beam switching may be used in 802.11ad to utilize signal diversity due to these reflections.

[0080] Some mmW communications may utilize a single beam for communications, for example, in 802.11ad. MIMO techniques, such as spatial multiplexing, may be employed to improve the spectral efficiency of the system, however it may be difficult to use these techniques in mmW systems due to the need for multiple symbol generation. Methods that improve the spectral efficiency of mmW systems, such as methods that enable the use of spatial multiplexing, may be needed in future mmW specifications which for example may be based on 802.11ad, and/or in mmW systems in general.

[0081] Beamforming training protocols, such as SLS and BRP, may be used to perform transmit/receive beamforming training and iterative beam refinement training. The beamforming training overhead and latency of these procedures, however, may be significant. For example, with the transmit beamforming training defined in SLS, the transmitter may need to transmit multiple sector sweep (SSW) frames that may be modulated by different beamforming sectors. Each device may have up to 64 different beam sectors. Each SSW frame may include a full PLCP header, which may include a preamble, one or more header blocks, and a MAC frame. In order to fully exploit the beamforming gain, transmit and receive training procedures at both peer devices may be required, and an iterative beam refinement may also be needed. These procedures may represent a significant overhead and hence methods that reduce this overhead may be needed in part to allow for a better user experience in mmW systems.

[0082] Referring back to FIGS. 1D and 1E, multipath propagation may be common in indoor communications links. Beam switching based beamforming algorithms utilized in the current 802.11ad specification may attempt to point the beam to the strongest path. As shown in FIG. 1D, a LOS path and a strong reflection path may exist between AP 190 and STA 192. After the beamforming training procedure, the beam with the best channel gain may be selected. This beam may be formed towards the strongest path among multiple propagation paths. However, human blockage may introduce an average 20 dB loss for 230 ms, which may prevent the 60GHz radio to

provide multi-Gigabit/sec data transmissions. It is therefore highly likely that the beamformed link may be dropped, and hence the transmitted packet during this period would be lost. Moreover, due to the loss of the packet, the system may have to repeat the beamforming training and then retransmit the packet over a potentially new beam.

[0083] Example beamforming schemes may exploit the spatial diversity such that the transmission is not dependent on only the strongest path. As shown in FIG. 1E, with two strong propagation paths, for example, a LOS path and a strong reflection path, a number of solutions may be possible including fast beam switching, wider beam and multi-beam methods.

[0084] Spatial diversity may be achieved with fast beam switching. In order to accomplish fast beam switching when the channel condition changes, it may be necessary that both AP and STA have an available list of weight vectors/beam identifiers. Example methods for obtaining a list of weight vectors/beam identifiers are disclosed below. There may be two possibilities for fast-beam switching including in-band signaling and out-of-band signaling. In-band beam switching may be used in some examples.

[0085] In an in-band beam switching example, the AP may be communicating with the STA using a beam set (Tx and Rx beams) B1. The AP and STA may have prioritized the beam sets according to the received SNR, or SINR, during the SLS and BRP phases. The STA may monitor one or more of the received SNR, SINR, Bit-Error-Rate (BER) or Packet Error Rate (PER), acknowledgement (ACK) statistics or a combination of these parameters. If, at the end of a packet reception, the STA determines that the channel quality is deteriorating, it may append a message to the ACK packet requesting the AP to switch to the next best beam set, for example B2, for the next transmitted packet. The assumption here is that the channel condition may be deteriorating, but not to the point that the data packet cannot be decoded correctly and hence an ACK may be sent.

[0086] In another example, alternative beam retransmission methods may be used. In 802.11 systems, and mmW systems in particular, if no ACK

is received, the data packet may be retransmitted. This retransmission may use the same beam that was used in the prior transmission. An example for an alternative procedure may be that if the AP does not receive an ACK, the AP may retransmit the data packet using the beam set B2 instead of the beam set B1. Since these beam sets may have been defined prior to this procedure, possibly during association of the STA with the AP, the procedure at the STA may use the corresponding receive beam set B2 for reception of the retransmission from the AP. In an example procedure, the AP and the STA may define an association of indices to beam sets, and subsequently use the beam set indices for identification of beam sets in the aforementioned procedures.

[0087] In an alternative, or additional example, the AP may cycle the data packet through the N best beam-sets. The STA may then perform a procedure wherein it receives N packets from the AP, and perform maximum-ratio-combining, selection combining, or a similar receive algorithm, on these packets. An ACK may then be determined and sent to the AP, for example, after all N transmissions have occurred, or as soon as the packet has been successfully received and decoded.

[0088] In an alternative, or additional example, the AP may also transmit the data packet through all of, or a subset of, the N beam-sets simultaneously. The remainder of the procedure described in the previous paragraph may then follow in a similar way.

[0089] A beam set may include the identification of a primary beam within the beam set. The primary beam may be used by transmission procedures at the AP, STA, or both, as the beam to be used for initial attempts at wireless communication. Alternatively, the primary beam may be used exclusively for transmission of control or scheduling information. More than one primary beam may be used for more than one STA wherein each primary beam may be associated with a particular STA.

[0090] In an alternative, or in addition to, the AP may also cycle through different modes of MIMO operation for each beam set, prior to

proceeding to the next beam set. For example, if the AP does not receive an ACK on beam set B1 it may select a more robust form of operation such as Space Time Block Coding (STBC), Space Frequency Block Coding (SFBC), or Cyclic Delay Diversity (CDD), before proceeding to transmit on the remaining beam sets B2 through BN.

[0091] In some examples, a first and second best beam transmission method may be used. For example, the STA may determine the two best beams, B1, B2, using a procedure similar to the above, and recommend these beam indices to the AP. In this example, for the remainder of the communication interval, the AP and the STA may assume that either, or both, beam indices may be used for wireless communication.

[0092] The AP may then determine to transmit on either beam during a particular transmission time interval (TTI) based on one or more criteria determined by the AP. Example criteria may include one or more of the received SNR, or SINR, Bit-Error-Rate (BER), or Packet Error Rate (PER), acknowledgement (ACK) statistics, or a combination of these criteria. The STA may respond to a message from the AP with an indication of the reception quality, or similar metric, for the beam that it used to receive the message from the AP. This indication or metric may be indicated in the response by the beam index.

[0093] Alternatively, if the STA does not provide an indication of the reception quality in its ACK and/or any other packet to the AP, the AP may determine that the reception quality was acceptable for one or more associated beams. If the STA indicates a poor reception quality to the AP for B1, it may assume that the next transmission from the AP will use the second best beam B2.

[0094] During communication with the STA, the AP may store the packet reception quality for each transmission, on each beam, in a memory, while using either beam. If a particular beam in the pair becomes unusable for further communication, the AP may identify a new first, or a second best beam for communication with the STA, while at the same time continuing

communication on the remaining beam of the original beam pair. Other combinations of the procedures described in this example may be possible. The above example is not limited to a pair of beams and may be extended to support any number of beams greater than one that the system may simultaneously support.

[0095] Some examples may use out of band beam switching. For example, the AP and STA may both have multi-band capability. In this example, the AP and the STA may communicate over either a 2.4 GHz or a 5 GHz link in addition to a directional 60 GHz link. The AP and the STA may use one or more of the sub-6 GHz links as an alternate link to signal to each other that the beam set needs to switch to the next best beam set at the beginning of the next data packet. This example procedure may allow for a fast beam switch to occur even if the packet currently being transmitted is not decoded correctly.

[0096] Some examples may implement spatial diversity using a single beam. For example, it may be possible that only one RF chain is available at both transmitter and receiver, such that only one data stream may be transmitted and received at the same time. This RF chain arrangement may be used in mmW systems. With one RF chain, devices may form one beam and transmit the data stream toward the direction specified by the beam. In this example, the devices may forming a beam pointing to a propagation path with the strongest channel gain. Multipath wireless channels, however, may introduce frequency selectivity. A beamforming weight may benefit some frequency tones, however, it may have a detrimental effect for one or more of the other set of frequency tones. Accordingly, there may be no guarantee that the weight pointing to the strongest propagation path will introduce the maximum beamforming gain for the entire frequency channel. Moreover, pointing in one beam direction may increase the system sensitivity to small changes in the multipath environment and may fail to provide robust communication.

[0097] FIG. 2 is a diagram of an example method 200 using two STAs to perform multi-path beamforming. The method may be a multi-stage iterative beamforming method as discussed below, and may include grouping two or more antennas. For example, FIG. 2 shows a first iteration 201 of the method and a second iteration 202 of the method.

[0098] The following articles disclose methods for beamforming. P. Xia, S. K. Yong, J. Oh and C. Ngo, "A practical SDMA protocol for 60GHz millimeter wave communications", Asilomar, 2008; and, P. Xia, S. K. Yong, J. Oh and C. Ngo, "Mulit-stage iterative antenna training for millimeter wave communications", Globecom, 2008, the entire contents of both are incorporated herein by reference.

[0099] Referring to FIG. 2, STA_1 205 and STA_2 210 are respectively shown on two time axes 215 and 220. In this example, STA_1 205 may transmit one or more training beamforming weights, and STA_2 210 may receive training beamforming weights 230, 240, and transmit beamforming weights 235 to STA_1 205. STA_1 205 and STA_2 210 may be, for example, WTRU, stations, electronic communication devices, or access points. The example in FIG. 2 shows STA_1 205 transmitting 230, 240 to only STA_2 210, however there may be more than one STA, which are not shown. STA_1 205 may be an AP or a non-AP STA. STA_2 210 may be an AP or a non-AP STA.

[0100] In each iteration of the method 201, 202, the AP, here STA_1 205, may transmit one or more training sequences over multiple time slots 230 and sweep the transmit beamforming weights. For example, STA_1 205 may be an AP or a non-AP STA. Note that only two iterations of the method 201, 202 are illustrated, but the method may have more than two iterations of the method 201, 202. STA_2 210 may calculate the best transmit beamforming weight vector according to an estimate of the received channel state. Note that the calculated transmit beamforming weight may not be one of the weights the transmitter STA_1 205 originally utilized. The method at STA_2 210 may then feedback this beamforming weight vector 235, or the estimated channel state vector, to the AP, here STA_1 205. The AP, here STA_1 205, may, or may not,

update the transmit beamforming weight it utilizes for a subsequent transmission to STA_2 210. The method may continue until packet transmissions are completed for the associated STAs, STA_2 210.

[0101] The AP, here STA_1 205, may group the antenna array into multiple sub-groups to point the beamforming weight to multiple paths. For example, if there are 36 antenna units and only the two strongest paths are used, then each sub-group may have 18 antenna units. Alternatively, if more antenna gain is anticipated from the strongest path, more antenna units may be assigned to the strongest path. The AP, here STA_1 205, may assign other antenna sub-group partitions depending on the requirements of the system. For example, more than two strongest paths may be used. The method in this example may steer the antenna array in the first sub-group to the strongest path, while the second sub-group may be steered to the second strongest path, and so on. This antenna group partition procedure may be performed by the AP, here STA_1 205, or STA_2 210, or both.

[0102] In another example, antenna group based multi-path beamforming may be performed. In this example, STA_1 205 may have Nt transmit antennas and STA_2 210 may have Nr receive antennas, and only the two strongest paths may be considered.

[0103] The transmitter, for example STA_1 205, may transmit Nt sequences 230. The Nt sequences 230 may be modulated using Nt orthogonal beamforming vectors. STA_1 205 may include a precoder, for example an identity precoder, and may be configured to transmit the first sequence using the first antenna, and transmit the second sequence using the second antenna, and so on. Other orthogonal precoding matrices may be utilized by STA_1 205.

[0104] The receiver, for example STA2 210, may receive the Nt sequences using the receive beamforming vector calculated in the last iteration, W_{i-1}^{r}. In some examples, W_{i-1}^{r} may be set to an initial value. STA2 210 may be configured to determine that the first n time slots correspond to transmit antenna 1 to antenna n, which may correspond to antenna group 1.

STA2 210 may utilize the training sequence transmitted in each time slot to estimate the strongest path of the propagation channel, and may denote the strongest channel path as H1. The received signal from the first n time slots may be expressed as $y_i^{11} = W_{i-1}^r(1:n)Hs + N$, where y may be the received symbol, s may be the sent symbol, N may be the additive Gaussian noise having a variance, and H may be the channel matrix between the transmitter STA1 205 and the receiver STA2 210. The receiver STA2 210 may use the correlation property of the training sequence to estimate the channel corresponding to the strongest propagation path, $\hat{H}_1^1$. Thus, the receiver STA2 210 may determine the best transmit beamforming weight corresponding to antenna group 1 and the strongest path, and may be represented as $(\hat{H}_1^1)'$. The size of the beamforming weight may be $n \times 1$.

[0105] The receiver, STA2 210, may be configured to determine that time slots n+1 to Nt correspond to transmit antenna n+1 to antenna Nt, and may correspond to antenna group 2 of STA1 205. The receiver, STA2 210, may utilize the training sequence transmitted in each time slot to estimate the second strongest path of the propagation channel, and may be denoted as H2. The received signal 245 from the Nt-(n+1)+1 time slots may be expressed as $y_i^{12} = W_{i-1}^r(n+1:Nt)Hs + N$. Since the signal may be transmitted using a sequence with a zero auto correlation (ZAC) property, STA2 210 may use a Rake receiver like method, where the strongest path may be removed, and the channel of the second strongest path may be determined. The second strongest path may be represented by $\hat{H}_2^1$. Thus the best transmit beamforming weight corresponding to antenna group 2 and the second strongest path may be $(\hat{H}_2^1)'$. The size of the transmit beamforming weight may be $(Nt - n) \times 1$.

[0106] The updated transmit beamforming weight for iteration i may be expressed as $W_i^t = [\hat{H}_1^1, \hat{H}_2^1]'$. STA2 210 may transmit W_i^t back to STA1 205 at 235. STA1 205 may use the received W_i^t to transmit 240 another set of beamforming training frames. STA1 205 may transmit Nr repetition of

training frames, where Nr may be the number of antenna(s) at STA2 205. STA2 205 may be configured to use this set of training frames to update the received beamforming weight. STA2 210 may use Nr antennas to receive the training frames sequentially. STA2 210 may also use other orthogonal beamforming weights to receive the Nr training frames. In this example, at STA2 210, antenna 1 to m may belong to the first antenna group, and may be used to point to the strongest propagation path, while antenna m+1 to Nr may belong to antenna group 2, and may correspond to the second strongest propagation path.

[0107] In one example, STA1 205 may use a mixed mode to transmit Nr repetitions of training frames with weight W_i^t. This example mixed mode method is shown in FIG. 2 as 202. The received signal through the Nr time slot may be expressed as $y_i = HW_i^t s + n$. The received signal from antenna group 1 may be $y_i^{21} = y_i(1:m)$. STA2 210 may use the correlation property of the training sequence to estimate the channel with the strongest propagation path, $\hat{H}_1^2$. The received signal from antenna group 2 may be $y_i^{22} = y_i(m+1:Nr)$, and STA2 210 may use correlation detection to remove the strongest path. STA2 210 may accordingly determine the estimated channel for the second strongest path, $\hat{H}_2^2$. STA2 210 may update the receive beamforming weight, which may be represented as $W_i^r = [\hat{H}_1^2, \hat{H}_2^2]'$. In FIG. 2, the reception of the signals is shown in dashed lines as an example illustration of the receiver operation while receiving a packet.

[0108] Alternatively, or in addition to, STA1 205 may use a sequential mode. STA1 205 may transmit m repetitions of training frames with antenna group 1, i.e., $W_1^{t1} = [\hat{H}_1^1, 0]'$. During the m training time slot, the receiver, for example STA2 210, may utilize antenna group 1 to receive the training frames. For example, STA2 210 may utilize antenna 1 to receive the first training frame, and antenna m to receive the mth training frame. The

received signal from these m frames may be expressed as $y_i^{21} = HW_i^{t1}s + n$. STA2 210 may estimate the channel corresponding to the strongest propagation path $\hat{H}_1^2$. STA1 205 may transmit Nr-m repetitions of training frames with antenna group 2 only, for example, $W_1^{t2} = [0, \hat{H}_2^1]'$. STA2 210 may utilize its antenna group 2 to receive the training frames. The received signal may be $y_i^{22} = HW_i^{t2}s + n$. STA2 210 may use a correlation method to determine the channel corresponding to the second strongest path, $\hat{H}_2^2$. STA2 210 may update the receive beamforming weight $W_i^r = [\hat{H}_1^2, \hat{H}_2^2]'$. In some examples, feedback channels corresponding to the strongest paths may be used directly by STA2 210 or STA1 205. Note that this mode is not illustrated in FIG. 2.

[0109] STA2 210 may send $W_i^r = [\hat{H}_1^2, \hat{H}_2^2]'$ to STA1 205 (not illustrated). In addition, the method may repeat for a number of times up to a threshold or until the method converges which may be determined by comparing a next value of the beamforming weights with a previous value of the beamforming weights and determining if the difference is less than a threshold value.

[0110] The initial beamforming weights for STA1 205 and STA2 210 may be set to initial values prior to beginning the method. STA1 205 and STA2 210 may determine the initial values in order to reduce the number iterations needed for the method to converge. The example method shown in FIG. 2 may be used for determining the two strongest paths. However, in other example embodiments, more than two paths may be determined by the STA1 205 and STA2 210.

[0111] Existing protocols may be modified to perform multi-path beamforming methods. For example, a multi-path beamforming method may be used in 802.11 and 802.11ad. For example, the multi-path beamforming method may be used in 802.11ad by using a modification of the beam refinement protocol (BRP) as disclosed in IEEE P802.11ad™/D9.0: Part 11, "Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) specifications," the entire contents of which are herein incorporated by

reference. The multi-path beamforming method may be a multi-iteration multi-path beamforming training method.

[0112] A beam refinement transaction may be a set of BRP frames that include one or more beam refinement requests and responses. The multi-path beamforming method may be implemented by modifying current beamforming refinement protocols.

[0113] FIG. 3 is a diagram of an example of one iteration of the multi-path beamforming method 300 using BRP transactions. The beamforming initiator, STA1 305, may transmit a BRP frame 315 that indicates that the BRP frame 315 is a Transmit BRP Request frame. This indication may be performed by setting a field, for example, TX-TRN-REQ=1. A BRP frame with TX-TRN-REQ=1 315 may include a transmit training subfield (TRN-T) 320 appended to it. The responder, STA2 310 may reply with a Transmit BRP Feedback 325, for example, by setting TX-TRN-RSP=1. Moreover, STA2 310 may request a receive beamforming training by indicating Receive BRP Request frame in the same BRP frame, for example, by setting L_RX>0. In this example, the Receive BRP Request frame may be piggybacked on the Transmit BRP Response frame. L_RX may be a signal field used to indicate that the receiver requests a receive BRP training, and the transmitter may respond with a BRP train response followed by a TRN-R training field. STA1 305 may transmit a BRP frame 330 with a BRP train response, for example, by setting RX-TRN-RSP to 1. A BRP frame that includes an RX-Train-response that equals 1 may include a receive training subfield (TRN-R) 335 appended to it.

[0114] FIG. 4 is a diagram of an example frame format for a BRP packet 402. The BRP packet 402 may include a short training field (STF) 404, a channel estimation (CE) field 406, a Header field 408 and a data field 410. A training field 416 may be appended/prepended to the BRP packet 402 and may include an AGC training field 412 and a receiver/transmitter training subfield (TRN-R/T) 414. A BRP packet 402 may be transmitted using control PHY. Prior to the RTN-R/T training, there may be a signaling exchange to aid the

training procedure. This is the purpose of field 404, 406, 408, 410. A Packet Type field may be included in the PHY header, and it may indicate whether a TRN-R or a TRN-T subfield 414 is appended to the frame 402. A BRP frame 402 with a TRN-R/T 414 field appended may be referred to as a BRP-RX/TX packet 402. In a BRP-TX packet 402, the transmitter may change the TX beamforming weight configuration at the beginning of each AGC subfield 412. The set of beamforming weights used for the AGC subfields 412 may be the same as that used for the TRN-T subfield 414. In a BRP-RX packet 402, the transmitter may use the same transmit beamforming weight as in the preamble and data fields of the transmission data packet. The BRP frame may be an Action No ACK frame.

[0115] FIG. 5 is a diagram of an example format of a BRP frame Action field. The BRP frame Action field 500 may include a Category field 510, an Unprotected DMG Action field 520, a Dialog Token field 530, a BRP Request field 540, a DMG Beam Refinement element 550, and one or more Channel Measurement Feedback elements 5601…560n.

[0116] An 802.11ad beam refinement protocol may be modified as follows in order to accommodate a multi-path beamforming algorithm. For example, an initiator may determine the capabilities of the responder prior to initiating beamforming training with the responder. The multi-path multi-stage iterative beamforming training capability may be indicated in a DMG Capabilities element. A DMG Capabilities element may be present in Association Request, Association Response, Reassociation Request, Reassociation Response, Probe Request and Probe Response frames and may be present in DMG Beacon and Information request and response frames. A DMG Antenna Array Support field may include one or more bits that indicate that the STA is capable of forming sub-antenna groups and capable of performing the multi-path multi-stage beamforming training method.

[0117] Partitioning of antenna sub-groups at both initiator and responder may be signaled. Depending on the antenna grouping method, the

signaling may be different. For example, the antenna grouping may be performed uniformly or non-uniformly.

[0118] In a uniform antenna grouping example, assuming the total number of antennas is even, each antenna sub-group may have the same number of antenna elements, and hence only the number of antenna groups is required to indicate the partition of antenna sub-groups. For example if there are four antennas, and two groups, the number of groups, in this example two, may be sent back since the number of antennas per group will be known. The mapping between antenna element indices and sub-group indices may be predetermined and transmitted explicitly in a field of the BRP frame, for example, a BRP Request field. If the mapping is explicitly indicated in the BRP frame, the antenna sub-group index may be assigned to each antenna element.

[0119] In a non-uniform antenna grouping example, each antenna sub-group may have a different number of antenna elements. For example, the system may assign more antenna elements for the strongest path, so that the antenna gain from this sub-group may be larger. The mapping between antenna element indices and sub-group indices may be predetermined and transmitted explicitly in a field of the BRP frame, for example, in a BRP Request field.

[0120] Mapping between antenna sub-groups and channel propagation paths/taps may be predetermined. For example, antenna sub-group 1 may always map to the strongest path, and so on. Alternatively, the mapping may be defined in the BRP Request field.

[0121] The precoding matrix used by the initiator, for example, STA1 205, in the first part of each iteration may be predetermined and agreed by both initiator and responder. The first part of each iteration may be referred to as the transmit beamforming training part. In one example, a set of unitary precoding matrices may be predetermined. In this example, the initiator and responder may negotiate which matrix is utilized before performing the

beamforming training. For example, the precoding matrix index may be predetermined and transmitted in the BRP Request field.

[0122] The number of antennas at both initiator and responder side may be signaled. Number of antennas may be signaled, for example, in the PHY header, MAC header or BRP Request field.

[0123] FIG. 6 is a diagram of an example modified channel measurement feedback element 600. The channel measurement feedback element may include a signal-to-noise ratio (SNR) subfield 610, a channel measurement subfield 620, a tap delay subfield 630, and a sector ID order subfield 640. The presence of these subfields may depend on the values defined in the DMG Beam Refinement element. For example, the channel measurement subfield may be used to feed back up to Ntap channel measurements that correspond to a common set of relative tap delays defined in the tap delay subfield. Without the presence of the tap delay subfield, for example, the Ntaps channel taps may be interpreted as contiguous time samples, separated by Tc, where Tc may be the SC PHY chip time, and may be 0.57ns. In these exemplary multi-path beamforming methods, the channel measurements of the strongest propagation paths may be sent to STA1. In the example shown in FIG. 2, the strongest path/tap may be assigned for the first antenna sub-group, and the second strongest path/tap may be assigned for the second antenna sub-group and so on. If the multi-path beamforming method is indicated in the PHY header, MAC header or MAC body, the interpretation of the channel measurement may be modified when the tap delay subfield is not present. Therefore, protocols may be modified to accommodate examples of the multi-path beamforming method disclosed herein.

[0124] Weighted multi-path beamforming training methods may be performed. For example, a beamforming method for steering the beam towards multiple propagation paths may be performed. The strongest propagation paths/taps may be determined by a STA, and one or more beamforming weights may be determined to point to one or more of the propagation paths/taps. The beamforming weight for the kth strongest

propagation path may be represented as Wk, and the final beamforming weight may be expressed as $W = \sum_{k=1}^{K} \alpha_k W_k$, where K may be the number of channel propagation paths and α_k may be the weight, with $\sum \alpha_k = 1$.

[0125] Different methods may be used by the STA selecting α_k in one of the following ways. For example, propagation path selection may be based on: $\alpha_k = \begin{cases} 1 & k = m \\ 0 & k \neq m \end{cases}$. By this selection, the final beamforming weight vector may equal the weight vector directed towards the mth propagation path.

[0126] In an 802.11ad example, the channel propagation taps may be measured and fed back to the beamforming initiator, which may be STA1 205. According to the channel measurement of each tap, a channel gain may be estimated by the STA. Channel gain of the kth propagation path/tap may be represented as β_k. α_k may be represented as $\alpha_k = \lambda - \frac{1}{\beta_k}$, so that $\sum \alpha_k = 1$, $\lambda = \frac{1 + \sum 1/\beta_k}{K}$ may be satisfied. The propagation path with the larger channel gain may have a larger weight and may be determined by the STA to be the strongest propagation path.

[0127] A single data stream transmission may be performed with multi-beam capability devices. For example, multiple RF chains may be available at the AP. Accordingly, the AP may form multiple beams simultaneously. In this example, the STA may form only one RF chain. The AP and the STA may be configured to use an Nx1 virtual MIMO channel. The AP and the STA may be configured to use diversity methods, such as, for example, STBC, SFBC and CDD. These example methods may be performed by more than one AP and more than one STA. In addition, a STA may be an AP.

[0128] There may be at least two possible transmission procedures that implement RF front-end beamforming with digital domain STBC. One example transmission procedure may use full size beamforming with STBC.

Another example transmission procedure may use partial size beamforming with STBC.

[0129] FIG. 7 is a diagram of an example AP 700 configured to perform a transmission using full size beamforming with STBC. The AP 700 may include a coding/modulation unit 702, an STBC encoder 706, a plurality of DAC/upconverters 708, 710, and a plurality of antennas 716. In this example, the coding/modulation unit 702 may perform modulation and coding and pass the modulation symbols 704 to the STBC encoder 706. The STBC encoder 706 may generate two data streams 718, 720. The two data streams 718, 720 then be processed through two RF chains at the plurality of DAC/upconverters 708, 710, which may separately perform DAC and up conversion to the operating frequency band. At the RF front-end, two beamforming weight vectors W1 712 and W2 714 may be generated by AP. Each weight-vector may be of size Nt x 1. The first data stream 718 may be multiplied with the first weight vector W1 712, and the second data stream 720 may be multiplied with the second weight vector W2 514. The two data streams 718, 720 may then be summed together and transmitted through the Nt antennas 716. In some embodiments, the AP may be configured with more than two RF chains.

[0130] FIG. 8 is a diagram of an example AP 800 configured to perform a transmission using partial size beamforming with STBC. The AP 800 may include a coding/modulation unit 802, an STBC encoder 806, a plurality of DAC/upconverters 808, 810, and a plurality of sets of antennas 816, 817. In this example, the coding/modulation unit 802 may perform modulation and coding and pass the modulation symbols 804 to the STBC encoder 806. The STBC encoder 806 may generate two data streams 818, 820. The two data streams 818, 820 may then be processed through two RF chains at the plurality of DAC/upconverters 808, 810, which may separately perform DAC and up conversion to the operating frequency band. At the RF front-end, two beamforming weight vectors W1 812 and W2 814 may be generated. Each weight vector may be of size Nt/2 x 1. The first data stream 818 may be multiplied with the first weight vector W1 812, and the second data stream

820 may be multiplied with the second weight vector W2 814. The first data stream 818 may be transmitted through the first set of Nt/2 antennas 816 and the second data stream may be transmitted through the second set of Nt/2 antennas 817. In embodiments, AP may be configured with more than two RF chains.

[0131] The AP and/or the STA may be configured to send and receive multiple data streams. For example, the AP and/or the STA may be configured with multiple RF chains. In these examples, the AP may be configured to communicate with multiple STAs simultaneously. The AP may be configured to distinguish the multiple STAs by spatial domain beams, thus the method may be referred to as Beam Division Multiple Access (BDMA). The AP may need multiple RF chains to perform BDMA. For example, the AP may be configured to use spatial multiplexing methods for single STA transmission. The AP and STA may be configured to send more than one data stream at a time, which may increase the spectral efficiency of the system. Multiple RF chains may be needed at both AP and STA side.

[0132] FIG. 9 is a diagram of an example of transceiver architecture 900. The AP and/or STA may be configured as follows. The transceiver architecture 900 may include a transmitter side 902 and a receiver side 904. The transmitter side 902 may include one or more coding/modulation units 903, a plurality of DAC/upconverters 912, 914, a digital controller 917, one or more power amplifiers (PA)s 920, and a plurality of Nt antennas 925. Multiple data streams may be modulated and coded at baseband, and then converted from a digital domain to an analog domain through the digital controller 917. The streams 908, 910 may be upconverted to operation frequency band by the DAC/upconverters 912, 914. Two sets of DACs and upconverters are illustrated here, which implies that up to two data streams may be supported by the transmitter. Beamforming weights 915, 916 may be applied prior to applying the streams to the PAs 920. The beamforming weights 915, 916 may be prepared in a digital domain.

[0133] The transmitter 902, may be an AP or STA, an may be configured with Nt antennas 925. The Nt antennas 925 may be shared by two or more RF chains. When the transmitter 902 has two data streams $\{s_1, s_2\}$ to transmit, it may generate two beamforming weights $V^1 = (V_1^1, V_2^1, ..., V_{Nt}^1)^T$ 916 and $V^2 = (V_1^2, V_2^2, ..., V_{Nt}^2)^T$ 915. The two signal streams may be combined and transmitted through Nt transmit antennas 925, $s = V^1 s_1 + V^2 s_2$. The AP and STA may be similarly configured on the receiver side if multiple RF chains are presented. The receiver 904 may generate two sets of receive beamforming weights $U^1 = (U_1^1, U_2^1, ..., U_{Nr}^1)^T$ 936 and $U^2 = (U_1^2, U_2^2, ..., U_{Nr}^2)^T$ 935 and apply them in an analog domain. The weighted streams may be applied to a respective ADC/downconverter. The downconverted streams 908', 910' may be decoded and demodulated.

[0134] Communication devices, which may be, for example, APs or STAs, with the transceiver embodiment illustrated in FIG. 9 may be referred to as Type I. In some embodiments, the AP and/or STA may be configured with more than two RF chains where FIG. 9 may be extended to accommodate the more than two RF chains.

[0135] FIG. 10 is a diagram of another example transceiver architecture 1000. The transceiver architecture 1000 may include a transmitter side 1002 and a receiver side 1004. In this example, the AP and or the STA may be configured as follows. Each RF chain may have its own set of antennas 1048, 1050, respectively. The antennas may be deemed to have been partitioned or split into sub-groups based on the number of RF chains. Compared to Type I devices, in order to achieve the same antenna gain, N antenna elements may be required. Here N may be the number of RF chains. Communication devices, which may be, for example, APs or STA, with the transceiver architecture illustrated in FIG. 10 may be referred to as Type II. The beamforming weights in FIG. 10, may be tuned as a group by the digital controller logic, as indicated by the dashed lines.

[0136] FIG. 11 is a diagram of an example of beam division multiple access (BDMA) architecture 1100. The AP 1102 may be configured to transmit two packets to STA1 1106 and STA2 1104 simultaneously. The STAs 1106, 1104 may be configured to share the time-frequency resource by different RF front-end beams.

[0137] The AP 1102 may be configured to prepare MAC packets for both STA1 1106 and STA2 1104. The AP 1102 may encode and modulate the MAC packets and form separate PHY packets and up convert them to 60 GHz through separate RF chains. At the RF front-end, the AP 1102 may apply beamforming weight vector W1 to the first data stream and W2 to the second data stream. The AP transmits a combination of the two data streams. In this way, multiple RF chains may share the same set of antennas as shown in FIG. 9. Alternatively, the AP 1102 may be configured to implementation BDMA by dividing, grouping, or partitioning the set of antennas to sub-groups, and each RF chain control may be sent by the AP 1102 on one antenna sub-group as shown in FIG. 10.

[0138] The AP and STA may be configured to perform a beamforming training method for BDMA. The AP and/or STA may be configured to perform the beamforming training method sequentially with one or more STAs in communication with one another. The example beamforming training methods may be standardized, for example, and may be used in 802.11ad. The AP and/or STA may be configured to use orthogonality between training beams.

[0139] FIG. 12 is a diagram of an example beamforming training method 1200 for BDMA. This example may use a multi-stage iterative beamforming training algorithm for BDMA. In the example illustrated, the AP 1202 has Nt antennas, STA1 1204 has M1 antennas and STA2 1206 has M2 antennas.

[0140] The beamforming training method for BDMA may be performed iteratively. The AP 1202 may transmit Nt sequences 1208. The Nt sequences 1208 maybe modulated using Nt orthogonal beamforming vectors. The

example shown in FIG. 12 may be performed using a precoder, for example, an identity precoder. In this example, the first sequence may be transmitted using a first antenna ("Ant 1") 1208, and a second sequence may be transmitted using the second antenna, and so on until the Nt antenna ("Ant Nt") 1210. The AP 1202 may be configured to use other orthogonal precoding matrices, such as, for example, the Walsh Hadamard matrix or FFT matrix.

[0141] STA1 1204 may be configured to utilize the best receive beamforming vector 1212 calculated through the last iteration, W_{i-1}^{r1}, to receive the signals. In FIG. 12, the reception of the signals is shown in dashed lines as an example illustration of the receiver operation while receiving a packet. For example, the dashed box W_{i-1}^{r1} may indicate that the STA1 1204 should use receive beamforming vector W_{i-1}^{r1} to perform receive beamforming. Since the AP 1202 may have transmitted the signal through each antenna sequentially, STA1 1204 may receive a Nt x 1 effective MISO channel between AP 1202 and STA1 1204, $W_{i-1}^{r1}H_1$ at the end of the transmission due to the use of the receive beamformer. Equivalently, the received signal may be expressed in a matrix format: $y_{11} = W_{i-1}^{r1}H_1 s + n$, where y may be the received signal, s may be the sent signal, n may be Gaussian noise, W may be the weight used by STA1 1204, and H may be the channel matrix between AP 1202 and STA1 1204. Based on the received signal, STA1 1204 may calculate or determine the best transmit beamforming weight from AP 1202 to STA1 1204 which may be represented as $V_i^{r1} = \frac{y_{11}s'}{\|y_{11}s'\|}$.

[0142] Similarly, STA2 1206 may be configured to utilize W_{i-1}^{r2} to receive the signals, and the received signal may be expressed as $y_{12} = W_{i-1}^{r2}H_2 s + n$. The best transmit beamforming weight from AP 1202 to STA2 1206 may be represented as $V_i^{r2} = \frac{y_{12}s'}{\|y_{12}s'\|}$, which STA2 1206 may be configured to determine.

[0143] The method may continue with STA1 1204 sending V_i^{r1} 1222 to the AP 1202. STA2 1206 may send V_i^{r2} 1220 to the AP 1202. STA2 1206 may transmit the packet immediately after the transmission of STA1 1204, or STA2 1206 may wait for a polling frame transmitted from the AP 1202 (not illustrated) before transmitting the packet.

[0144] The method may continue with the AP 1202 calculating MU-MIMO weight W_i^{t1} and W_i^{t2} based on V_i^{r1} and V_i^{r2}. The AP 1202 may then implement a linear or non-linear MU-MIMO precoding algorithm for this weight update 1209.

[0145] The method may continue with the AP 1202 transmitting 1230 again with the best beamforming weights and each STA 1204, 1206 receiving with multiple receive antennas.

[0146] The method may continue with one of the following alternatives. In a first alternative, as illustrated in FIG. 12, the AP 1202 may transmit $W_i^{t1}s_1 + W_i^{t2}s_2$ for Max(M1,M2) times 1230. s_1 and s_2 may be orthogonal sequences, and may be known at AP 1202, STA1 1204 and STA2 1206. The AP 1202 may signal STA1 1204 and STA2 1206 about the assignment of s_1 and s_2. STA1 1204 may be configured to switch receive antennas to train the best receive beamforming weight W_i^{r1}. Similarly, STA2 1206 may train the best receive beamforming weight W_i^{r2}. STA1 1204 may use the orthogonal sequences to estimate the current signal (via cross correlation with s_1) and the current interference (via cross correlation with s_2). Thus, STA1 1204 may train its receive beamforming vectors by nulling the interference. Similarly, STA2 1206 may use the orthogonal sequences to estimate the current signal (via cross correlation with s_2) and the current interference (via cross correlation with s_1). Then, STA2 1206 may train its receive beamforming vectors by nulling the interference.

[0147] In a second alternative, the AP 1202 may transmit $W_i^{t1}s$ for M1 repetitions. STA1 1204 may switch between its M1 antennas to receive $W_i^{t1}s$, and at the same time, STA2 may monitor the transmission of $W_i^{t1}s$. AP 1202 may transmit $W_i^{t2}s$ for M2 repetitions and STA2 may switch between its M2 antennas to receive $W_i^{t2}s$ while STA1 1204 monitors the transmission of $W_i^{t2}s$.

[0148] The example beamforming training method for BDMA may not be successful. If the correlation between two STAs 1204, 1206 is high, the two STAs 1204, 1206 may not be distinguished by beams. This may lead to an unsuccessful beamforming training for BDMA. In this example, the AP 1202, and or STAs 1204, 1206, may be configured to provide information if BDMA may or may not be supported with the current configuration. The STAs 1204, 1206 may include the report of beamforming gain when they report V_i^{r1} and V_i^{r2} to the AP 1002. The beamforming gain may be defined as $\|y_{11}s'\|^2$ and $\|y_{12}s'\|^2$. Alternatively, or in addition, the STAs 1204, 1206 may report signal to interference ratio (SIR) during or at the end of the method. The STAs 1004, 1006 may determine or calculate the desired signal strength and interference signal strength with both example alternatives.

[0149] The BDMA training method may include performing BDMA training on each STA 1204, 1206 sequentially. This example method may be extended for more than two STAs.

[0150] Examples of the BDMA training method may be standardized. For example, the BDMA training method may be used with IEEE 802.11ad. In these examples, a service period (SP) may be a time period scheduled for service from one device to another device. The transmission during an SP duration may be scheduled by an AP. The BDMA training method may be scheduled by the AP if it is allocated in an SP duration. Examples of the BDMA training method may be used by modifying the BRP procedures.

[0151] FIG. 13 is a diagram of an example modified BRP procedure to implement a multi-stage iterative beamforming training method for BDMA 1300. In this example, AP 1302 may transmit a BRP frame 1320 that indicates a Transmit BDMA BRP Request. A Transmit BDMA BRP Request subfield may be defined in BRP Request field, and may indicate that the BRP frame is for transmit BDMA BRP training. Alternatively, a Transmit BRP Request may be used with TX-TRN-REQ=1 to indicate that the BRP frame is for transmit BRP training. A frame that is utilized for single user beamforming training or BDMA training may be indicated implicitly or explicitly in the MAC frame or PHY header.

[0152] STA1 1304 may reply with a Transmit BRP Feedback frame 1322 by setting TX-train-response=1. STA1 1304 may also request a receive beamforming training by indicating Receive BRP Request in the same Transmit BRP Feedback frame 1322 by setting L_RX>0.

[0153] AP 1302 may transmit a Polling frame 1324 to STA2 1304 to request BRP feedback. This step may be skipped if the frame length of BRP feedback frame is fixed and known by all the devices.

[0154] STA2 1306 may reply with a Transmit BRP Feedback frame 1326 by setting TX-train-response=1. STA2 1306 may also request a receive beamforming training by indicating Receive BRP Request in the same Transmit BRP Feedback frame 1326 by setting L_RX>0.

[0155] AP 1302 may transmit a BDMA BRP frame 1328 indicating a BRP train response by setting RX-Train-response to 1. A BRP frame with RX-Train-response equal to 1 may include a receive training subfield TRN-R 1330 appended to it. A BDMA BRP frame 1328 may indicate multiple receivers explicitly or implicitly in PHY header or MAC body.

[0156] The example in FIG. 13 shows that one AP 1302 may transmit to two STAs 1304, 1306. However, the BDMA transmission may be from one device to two devices irrespective of whether they are APs or STAs. Moreover, the AP 1302 may transmit to two or more STAs.

[0157] Examples of the method in FIG. 13 may include BDMA protection mechanisms. The feedback frame 1322 may include not only the best beam, but also the achievable SINR. If after a certain number of iterations, the achievable SINR is less than the target SNR, the BDMA method may be aborted. The number of iterations may be predetermined, determined statically, dynamically determined based on previous methods running, or in another way.

[0158] BDMA grouping may be indicated in some examples. The following examples may enable an indication of BDMA grouping by one or more communication devices. Using an SP, the BDMA grouping information may be indicated in an allocation field in an Extended Schedule Element. The Extended Schedule Element may be transmitted in a Beacon frame. The tuple, Source AID, Destination AID and Allocation ID may uniquely identify the allocation. The Source AID field may be set to the AID of the STA an may initiate channel access during the SP. The Destination AID field may indicate the AID of a STA that may be expected to communicate with the source STA during the allocation. The Allocation ID may identify an airtime allocation from a Source AID to a Destination AID. With BDMA transmission, more than one receiver may be indicated. One method may be to group BDMA transmitters and receivers, and assign each group a unique BDMA ID. Each STA corresponding to a BDMA ID may be assigned a User Position Array that may be used to distinguish the role of the STA. Therefore, the Destination AID may be replaced by the BDMA ID for BDMA transmissions. Alternatively, more than one Destination AID may be included in the allocation field. In this way, the order of the Destination AIDs may imply the role of one or more STAs in the BDMA transmission.

[0159] Since the BDMA transmission may be within the SP time slot, the communication device may not need to signal the BDMA transmission in the PHY header or MAC header. The MCS levels and Length field for each BDMA receiver may be signaled in PHY Header.

[0160] FIG. 14 is a diagram of an example PHY layer frame format 1400 that may be used in a BDMA transmission. N may represent the number of BDMA communication devices that may be signaled in the allocation field in Extended Schedule Element. The example PHY layer frame format 1400 may include an STF field 1410, one or more CE fields 1420, a header 1430, and a data field 1440. The one or more CE fields 1420 may be transmitted with a weight and a P matrix. The weight for the one or more CE fields may range from W1 to WN, for example, the first field may be transmitted with a weight W1, and the last CE field may be transmitted with a weight WN. The header 1430 and data field 1440 may be transmitted using BDMA and with all of the weights from W1 to WN.

[0161] Example embodiments may include performing BDMA in a contention based access period. For example, BDMA transmission protocols may be used by the communication device. Performing a BDMA transmission in a contention based access period may utilize the NDP announcement (NDPA) and NDP sequences for beamforming training. BDMA transmission may be performed after the NDP sequence exchanges. Alternatively, or in addition, the BDMA transmission may be delayed until the BDMA initiator, which may be a STA or an AP, acquires the media again.

[0162] In one example BDMA transmission procedure, one or more of the communication devices may be configured to use an NDPA period. In this example, an AP may transmit a message that indicates which STAs should participate in BDMA training. The NDPA frame may contain a STA info field to indicate the individual STA information. The NDPA frame may reserve a TXOP until the end of BDMA beamforming training by setting the duration period accordingly. Alternatively, the NDPA frame may reserve a TXOP until the end of the BDMA transmission.

[0163] In another example, an NDP period may be configured to allow training of transmit antennas at the AP. In this example, the STAs may perform measurements. In another example, a feedback period may be configured to allow STAs to take turns to feedback the best beam vectors as

well as the achievable SINRs. Moreover, STAs may also feedback the measured channels or the calculated transmit beamforming weight vectors.

[0164] In another example, a receiver training period may be configured to allow an AP to set its beamforming vectors. In this example, STAs may train their receive antennas.

[0165] In another example, the NDP period, feedback period, and receiver training period may be repeated for a number of iterations. A number of stopping criteria may be applied in this example. For example, if the achievable SINR meets expectation, the iteration may stop early. In these examples, BDMA transmissions may begin a certain inter-frame spacing after training is performed. ACK1 and ACK 2 may each be followed by a SIFs duration after BDMA transmission is performed.

[0166] In another example, one or more communication devices may be configured to indicate BDMA grouping. The following is an example of indicating grouping. BDMA grouping with contention based access period (CBAP) may be performed by using a BDMA ID. A BDMA ID management frame may be transmitted from an AP to a STA to indicate whether the STA belongs to one of the BDMA groups and the user position of the STA. The BDMA ID management frame may contain a Membership Status Array field and a User Position Array field. The BDMA ID may be included in BDMA related frames, such as BDMA training frames, BDMA transmission frames, or other similar frames.

[0167] One or more communication devices may be configured to perform a BDMA transmission method for CBAP that may be similar to that defined for SP. The BDMA transmission may be performed after the BDMA initiator, for example the AP, acquires a TXOP in the CBAP. The PHY layer frame format may be the same as illustrated FIG. 14. The transmission of BDMA in CBAP may not be scheduled by the AP. Accordingly, the BDMA ID may be included in the PHY header. The number of users or communication devices, N, may be indicated in the sequence exchange to acquire the TXOP

before a BDMA transmission. Alternatively, it may be implicitly indicated using a short training field (STF) and/or a channel estimation (CE) field.

[0168] In some examples, the communication devices may be configured to perform single user spatial multiplexing. In order to perform spatial multiplexing, both transmitter and receiver may have multiple RF chains. FIG. 9 and FIG. 10 are example transceiver configurations to perform single user spatial multiplexing. A communication device with the transceiver configuration shown in FIG. 9 may be referred to as a Type I device, i.e., where multiple RF chains share the same set of antenna elements. A communication device with the transceiver configuration shown in FIG. 10 may be referred to as a Type II communication device, i.e., where the antenna elements may be split into sub-groups, and each sub-group may correspond to one RF chain.

[0169] The communication devices may be configured to perform beamforming methods for spatial multiplexing. In this example, several beamforming methods may be used to perform spatial multiplexing transmission between a pair of communication devices. Two types of example beamforming methods may be used. The first example method may be referred to as Eigen-Beamforming based spatial multiplexing. In this example, the initiator/responder may estimate the channel over the air and calculate beamforming weights accordingly. The second example method may be referred to as beam sweep based spatial multiplexing. With this method, both initiator and responder may transmit and receive using pre-defined beam sectors. The beamforming beams may then be selected from these beam sectors.

[0170] The communication devices may be configured to perform an Eigen-Beamforming based spatial multiplexing method, where the communication devices may be configured as Type I devices with calibration. Type I devices may have multiple RF chains sharing the same set of antennas as discussed in conjunction with FIG. 9. If the communication devices are configured to calibrate the multiple transmit RF chains, the communication

devices may determine that the multiple RF chains are identical. Examples of non-calibrated or identical RF chains are discussed below.

[0171] FIG. 15 is a diagram of an example beamforming training procedure 1500 using Eigen-beamforming based spatial multiplexing where the Type I communication devices may be configured to calibrate the multiple transmit RF chains. An iterative example with two RF chains at both initiator and responder is shown in FIG. 15, however, the method may be extended to any number of RF chains. In this example, the transmitter (STA1) 1502 may have Nt antenna elements, and the receiver side (STA2) 1504 may have Nr antenna elements.

[0172] The beamforming training method may be performed iteratively. In each iteration, the transmit beamforming training may be performed and then the receive beamforming training may be performed. An example of a detailed method for Type I devices with calibration is described below.

[0173] For iteration i, STA1 1502 may act as an initiator, and may transmit Nt training sequences 1506 sweeping all the transmit antenna elements. The transmission may be performed using the first transmit RF chain (TX1) or the second transmit RF chain (TX2) of STA1 1502. In some examples, the two RF chains may be identical or differ by a scalar, or, in other examples, the two TX chains may be calibrated. Alternatively, STA1 1502 may also use an orthogonal precoding matrix to transmit the Nt training sequences.

[0174] STA2 (responder) 1504 may have two receive beamforming weights trained from previous iterations, and may be represented by W_{i-1}^{r1} and W_{i-1}^{r2}. If this is the first iteration of the method, STA2 1504 may randomly select two beamforming weights, or use Omni weights, or may determine the two beamforming weights in an alternate method. The first RF chain (RX1) may receive a signal that is the weighted combination of signals received from all the receive antenna elements. This weight may be the first receive beamforming weight W_{i-1}^{r1}. Similarly, the second RF chain (RX2) may receive a

signal that is the weighted combination of signals received from all the receive antenna elements. This weight may be the second receive beamforming weight W_{i-1}^{r2}. In FIG. 15, the reception of the signals is shown in dashed lines as an example illustration of the receiver operation while receiving a packet. For example, the dashed box W_{i-1}^{r1} may indicate that the STA1 1504 should use receive beamforming vector W_{i-1}^{r1} to perform receive beamforming. After conversion to the digital domain, STA2 1504 may estimate the effective channel by comparing the received sequence with the known transmitted sequence. For time slot k, STA2 1504 may estimate two channels using two RF chains $\begin{bmatrix} G_{k1} \\ G_{k2} \end{bmatrix}$. With Nt time slots, STA2 1504 may receive $\begin{bmatrix} G_{11} & \dots & G_{Nt1} \\ G_{12} & \dots & G_{Nt2} \end{bmatrix}$. Applying the inverse of the orthorgonal precoding matrix, STA2 1504 may obtain the channel from Nt transmit antenna elements to two RF chains as $H = \begin{bmatrix} H_{11} & \dots & H_{Nt1} \\ H_{12} & \dots & H_{Nt2} \end{bmatrix}$.

[0175] STA2 1504 may feedback the channel information or beamforming weights for multiple data streams to STA1 1502. STA2 1504 may calculate the transmit beamforming weights for spatial multiplexing and feedback 1508 the weights to STA1 1502. STA2 1504 may feedback the channel H to STA1 1502, and STA1 1502 then may determine or calculate the transmit beamforming weights 1510.

[0176] In some examples, the transmit beamforming weight method may be implementation dependent. For example, STA1 1502 and/or STA2 1504 may use linear or non-linear procoding algorithms.

[0177] The updated transmit beamforming weights for the ith iteration may be denoted as (W_i^{t1}, W_i^{t2}). STA1 1502 may transmit a training sequence Nr times with beamforming weight W_i^{t1} 1512. STA2 1504 may sweep through Nr receive antennas 1514, or apply an orthorgonal matrix. STA2 1504 then passes the received signal through the two RF chains. STA1 1502 may

transmit training sequences again Nr times with beamforming weight W_i^{t2} 1516. STA2 1504 may repeat a similar procedure with both RF chains 1518. The sweeping of the Nr receive antennas 1514 and 1518 is shown in dashed lines as an example illustration of receiver operation. For example, to receive Nr packets from the transmitter, the receiver may receive a first packet with the first receive antenna, a second packet with the second receive antenna, and so on, until it receives a last packet with the last receive antenna. STA2 1504 may estimate the channel and update the receive beamforming weight accordingly (not shown). The receive beamforming weight method may be implementation dependent.

[0178] The above method may be repeated until the method converges or certain criteria have been met that indicate that spatial multiplexing is not suitable for the pair of devices, for example, a set of failure criteria). There may be several ways to define failure criteria that indicate that the pair of devices are not suitable for spatial multiplexing. A first example of failure criteria may be that STA2 monitors the rank or condition number of a channel matrix while selecting a beamforming weight, and may feedback this information to STA1. A second example of failure criteria may be that STA2 monitors the rank or condition number of channel matrix while sweeping through Nr receive antennas or applying an orthogonal matrix, and feeds back this information to STA1. If the rank is less than the number of data streams expected to be supported, or the condition number is greater than a certain threshold, both STA1 and STA2 may determine that the maximum number of data streams supported may not meet the desired number. In this example, the pair of devices may determine to complete the training procedure, and perform RF selection at both transmitter and receiver later. For example, the pair of devices may terminate the training with a full set of RF chains, and return to perform beamforming training with a lesser number of RF chains. For example, after training, the devices may transmit with a lesser number of spatial streams.

[0179] A method of Eigen-beamforming for spatial multiplexing may be performed. The method may be for communication devices that are of Type I or Type II as discussed in conjunction with FIG. 9.

[0180] Type I devices may perform transmit RF chain training sequentially if the RF chains are not calibrated. Even though the RF chains share the same set of antenna elements and the physical channels over the air may be the same, the effective channels, which may be the combination of channel over the air and transmit/receive RF chains, may be measured and estimated.

[0181] Type II devices may split the antenna elements into sub-groups, and each sub-group has an RF chain. In these examples, there may be two RF chains and two sub-groups of antennas. The physical channel corresponding to RF chain 1 may be transmitted with antenna sub-group I, which may be different from that corresponding to RF chain 2 that may be transmitted with the other antenna sub-group. Because of this, the training for multiple transmit RF chains may be performed sequentially.

[0182] FIG. 16 is a diagram of an example beamforming training method 1600 for Eigen-beamforming based spatial multiplexing for Type I devices and for Type II devices without calibration. For iteration i, STA1 1602 (initiator) may transmit Nt repetitions of training sequences sweeping all the transmit antenna elements in a first antenna sub-group using the first transmit RF chain (TX1) 1606. Then STA1 1602 may transmit Nt repetitions of training sequences sweeping all the transmit antenna elements in the second antenna sub-group using the first transmit RF chain (TX2) 1608. STA1 1602 may also use an orthorgonal precoding matrix to transmit the Nt repetitions of training sequences. The first antenna sub-group may be the same as the second antenna sub-group for Type I devices, STA1 1602; while for Type II devices, STA1 1602, they may correspond to different antenna elements.

[0183] STA2 (responder) 1604 may have the two receive beamforming weights trained from the previous iterations. If this is the first iteration,

STA2 1604 may randomly select two beamforming weights, use Omni weights, or select the weights in an alternate manner. The first receive RF chain (RX1) may obtain a signal as the weighted combination of signals received from all antenna elements. The weight may be the first receive beamforming weight W_{i-1}^{r1}. Similarly, the second receive RF chain (RX2) may obtain a signal as the weighted combination of signals received from all the antenna elements. The weight may be the second receive beamforming weight W_{i-1}^{r2}. The sweeping of the Nr receive antennas 1616 and 1618 is shown in dashed lines as an example illustration of receiver operation. For example, to receive Nr packets from the transmitter, the receiver may receive a first packet with the first receive antenna, a second packet with the second receive antenna, and so on, until it receives a last packet with the last receive antenna. After converting them to baseband and digital domain, STA2 1604 may estimate the effective channel by comparing the received sequence with the known transmitted sequence. For time slot k, STA2 1604 may estimate two channels using two RF chains $\begin{bmatrix} G_{k1} \\ G_{k2} \end{bmatrix}$. With 2Nt time slot, STA2 may receive $\begin{bmatrix} G_{11} & \dots & G_{2Nt1} \\ G_{12} & \dots & G_{2Nt2} \end{bmatrix}$. The first half of the G matrix, $G_{TX1} = \begin{bmatrix} G_{11} & \dots & G_{Nt1} \\ G_{12} & \dots & G_{Nt2} \end{bmatrix}$, may correspond to TX1, and the second half of the G matrix, $G_{TX2} = \begin{bmatrix} G_{(Nt+1)1} & \dots & G_{2Nt1} \\ G_{(Nt+1)2} & \dots & G_{2Nt2} \end{bmatrix}$, may correspond to TX2. Applying the inverse of the orthorgonal precoding matrix to the first half and second half of G matrix respectively, STA2 1604 may obtain the channel from Nt transmit antenna elements with two transmit RF chains to two receive RF chains $H = \begin{bmatrix} H_{11} & \dots & H_{2Nt1} \\ H_{12} & \dots & H_{2Nt2} \end{bmatrix}$.

[0184] STA2 1604 may transmit channel information or beamforming weights for multiple data streams 1610 to STA1 1602. STA2 1604 may calculate the transmit beamforming weights to perform spatial multiplexing for STA1 1602, and transmit the weights 1610 to STA1 1602. STA2 1604 may

transmit the channel H 1610 to STA1 1602, and STA1 1602 then may determine or calculate the transmit beamforming weights for itself 1620.

[0185] For example, the transmit beamforming weight method may be implementation dependent, and linear or non-linear procoding methods may be used. The updated transmit beamforming weights for ith iteration may be denoted as (W_i^{t1}, W_i^{t2}). STA1 1602 may transmit training sequences Nr times with beamforming weight W_i^{t1} 1612. STA2 1604 may sweep through Nr receive antennas 1616, or apply an orthorgonal matrix. STA2 1604 may pass the received signal to two RF chains. STA1 1602 may transmit training sequences 1614 again for Nr times with beamforming weight W_i^{t2}. STA2 1604 may repeat the same procedure with both RF chains 1618. The sweeping of the Nr receive antennas 1616 and 1618 is shown in dashed lines as an example illustration of receiver operation. For example, to receive Nr packets from the transmitter, the receiver may receive a first packet with the first receive antenna, a second packet with the second receive antenna, and so on, until it receives a last packet with the last receive antenna. STA2 1604 may estimate the channel and update the receive beamforming weight 1622 accordingly.

[0186] For example, the receive beamforming weight method may be implementation dependent, and may be repeated for several iterations until the algorithm converges or certain criteria have been met that indicate that spatial multiplexing is not suitable for the pair of devices, STA1 1602 and STA2 1604.

[0187] There may be several ways to define failure criteria to indicate that the pair of devices are not suitable for spatial multiplexing. For example, the failure criteria may include STA2 monitoring the rank or condition number of channel matrix when selecting beamforming weights, and feeding back this information to STA1. A second example of a failure criteria may include STA2 monitoring the rank or condition number of channel matrix

while sweeping through Nr receive antennas or applying an orthogonal matrix, and feeding back this information to STA1.

[0188] If the rank is less than the number of data streams expected to be supported, or the condition number is greater than a certain threshold, both STA1 and STA2 may determine that the maximum number of data streams that may be supported does not meet the requirements. In this example, the pair of devices may determine to complete the training procedure, and perform RF selection at both transmitter and receiver later. Alternatively, the pair of devices may terminate the training with full set of RF chains, and return to performing beamforming training with a fewer number of RF chains. After training, they may transmit with a fewer number of spatial streams.

[0189] In some examples, methods for beam sweep based spatial multiplexing for Type I devices with calibration may be performed. For example, the method of beam sweep based spatial multiplexing may be similar to Eigen-Beamforming based spatial multiplexing. Examples using Eigen-Beamforming based spatial multiplexing may require that the channel estimate and the transmit/receive weights for spatial multiplexing may be determined based on the estimated channel, which may not necessarily be the same as one of the beams used for beamforming training. In beam sweep based spatial multiplexing, there may be no requirement for channel estimation. The device may select one or multiple beams from the set of beams used for beam sweep training. For example, implementation of beam sweep based beamforming may be easier than Eigen-Beamforming based beamforming. The performance of the beam sweep based methods may be sub-optimum compared to the Eigen-beamforming based methods.

[0190] FIG. 17 is a diagram of an example beamforming training method 1700 for beam sweep based spatial multiplexing for Type I devices with calibration between two TX chains. Referring to FIG. 17, for iteration i, STA1 (initiator) 1702 may transmit N repetitions of training sequences 1706 sweeping the transmit beams it intends to train. In these examples, N may

not necessarily be related to the number of transmit antennas. The transmission 1706 may be performed using the first transmit RF chain (TX1) or the second transmit RF chain (TX2). The two RF chains may be identical or different by a scalar. In some examples, the two TX chains may have been calibrated.

[0191] STA2 (responder) 1704 may have the two receive beams trained from the previous iterations. If this is the first iteration, STA2 1704 may randomly select two beams, use Omni weights, or select initial values in an alternate manner. The first receive RF chain (RX1) of STA2 1704 may obtain a signal as the weighted combination of signals received from all antenna elements. The weight may be the first receive beamforming weight W_{i-1}^{r1}. Similarly, the second receive RF chain (RX2) of STA2 1704 may obtain a signal as the weighted combination of signals received from all the antenna elements. The weight may be the second receive beamforming weight W_{i-1}^{r2}. $\{W_{i-1}^{r1}, W_{i-1}^{r2}\}$ may be the weights corresponding to beam indices $\{ID_{i-1}^{r1}, ID_{i-1}^{r2}\}$. After converting them to baseband and digital domain, STA2 1704 may measure the effective SNR or equivalent parameters. For time slot k, STA2 1704 may perform SNR measurements using two receive RF chains $\begin{bmatrix} SNR_{k1} \\ SNR_{k2} \end{bmatrix}$. With N time slots, STA2 1704 may receive $\begin{bmatrix} SNR_{11} & \dots & SNR_{N1} \\ SNR_{12} & \dots & SNR_{N2} \end{bmatrix}$. In FIG. 17, the reception of the signals is shown in dashed lines as an example illustration of the receiver operation while receiving a packet.

[0192] STA2 1704 may feedback two beam indices to STA1 1702. The beam selection method may be implementation dependent. For example, the STA2 1704 may choose the pair of indices (ID_i^{t1}, ID_i^{t2}) which may satisfy $ID_i^{t1} = \arg\max_k (SNR_{k1}^{TX} - SNR_{k2}^{TX})$, and $ID_i^{t2} = \arg\max_k (SNR_{k2}^{TX} - SNR_{k1}^{TX})$.

[0193] The updated transmit beam indices for the ith iteration may be (ID_i^{t1}, ID_i^{t2}). STA1 1702 may transmit a training sequence for M times with

beam ID_i^{t1} 1720. STA2 1704 may sweep through M receive beams with both receive RF chains (RX1 and RX2) 1722. STA1 1702 may transmits a training sequence again for M times with beamforming weight ID_i^{t2} 1724. STA2 1704 may repeat the similar procedure with both RF chains 1726. The sweeping of the receive antennas 1722 and 1726 is shown in dashed lines as an example illustration of receiver operation. For example, to receive packets from the transmitter, the receiver may receive a first packet with the first receive antenna, a second packet with the second receive antenna, and so on, until it receives a last packet with the last receive antenna. STA2 1704 may measure the SNR or equivalent parameters and update the receive beam index accordingly. The receive beam selection method may be implementation dependent. For example, M may be the number of receive beams STA2 1704 intends to train and it may not necessarily be related to a number of receive antennas at STA2 1704. The method may be repeated until the method converges or certain criteria have been met that indicates that spatial multiplexing is not suitable for the pair of devices.

[0194] Failure criteria may be defined in several different ways. For example, failure criteria may indicate that the pair of devices is not suitable for spatial multiplexing. In one example, the failure criteria may be defined as when STA2 1704 may record $\Delta_{11}^{SNR} = \max_k (SNR_{k1}^{TX} - SNR_{k2}^{TX})$ and $\Delta_{12}^{SNR} = \max_k (SNR_{k2}^{TX} - SNR_{k1}^{TX})$ when selecting beams, and feedback this information to STA1 1702. In another example, STA2 1704 may record $\Delta_{21}^{SNR} = \max_{1 \le k \le N} (SNR_{k1}^{RX} - SNR_{k2}^{RX})$ and $\Delta_{22}^{SNR} = \max_{N < k \le 2N} (SNR_{k2}^{RX} - SNR_{k1}^{RX})$ when sweeping beams, and feedback this information to STA1 1702.

[0195] If Δ_{ij}^{SNR} is smaller than a certain threshold, both STA1 1702 and STA2 1704 may determine that the channel cannot provide enough spatial diversity to support two data streams. In this example, STA1 1702 and STA2 1704 may determine to complete the training procedure, and perform RF selection at both transmitter and receiver. STA1 1702 and STA2 1704 may

terminate the training with two RF chains, and return to performing beamforming training with one RF chain. After training, they may transmit with a fewer number of spatial streams. For example, more than two data streams may be determined.

[0196] Beam sweep based spatial multiplexing for Type II devices and Type I devices without calibration may be performed. FIG. 18 is a diagram of an example beamforming training method 1800 for beam sweep based spatial multiplexing Type II devices and Type I devices without calibration.

[0197] For iteration i, STA1 (initiator) 1802 may transmit N repetition of training sequences sweeping all the transmit beams it intends to train using the first transmit RF chain (TX1) 1806. Then STA1 1802 may repeat the same procedure with the second RF chain (TX2) 1808. N may not necessarily be related to the number of transmit antennas. For example, the beam pattern used for TX1 may not be the same as that for TX2.

[0198] STA2 (responder) 1804 may have the two receive beams trained from the previous iterations. If this is the first iteration, STA2 1804 may randomly select two beams, use Omni weights, or select the two beams in a different way. The first receive RF chain (RX1) 1810 may obtain a signal as the weighted combination of signals received from all antenna elements. The weight may be the first receive beamforming weight W_{i-1}^{r1}. The second receive RF chain (RX2) 1812 may obtain a signal as the weighted combination of signals received from all the antenna elements. The weight may be the second receive beamforming weight W_{i-1}^{r2}. For example, $\{W_{i-1}^{r1}, W_{i-1}^{r2}\}$ may be the weights that correspond to beam indices $\{ID_{i-1}^{r1}, ID_{i-1}^{r2}\}$. After converting them to baseband and digital domain, STA2 1804 may measure the effective SNR or equivalent parameters. For time slot k, STA2 1804 may perform SNR measurements using two receive RF chains $\begin{bmatrix} SNR_{k1} \\ SNR_{k2} \end{bmatrix}$. With the first N time slot, STA2 1804 may receive $\begin{bmatrix} SNR_{11} & \dots & SNR_{N1} \\ SNR_{12} & \dots & SNR_{N2} \end{bmatrix}$, which may correspond to

TX1 of STA1 1802. With the last N time slots, STA2 1804 may receive $\begin{bmatrix} SNR_{(N+1)1} & \dots & SNR_{2N1} \\ SNR_{(N+1)2} & \dots & SNR_{2N2} \end{bmatrix}$, which may correspond to TX2 of STA1 1802. In FIG. 18, the reception of the signals is shown in dashed lines as an example illustration of the receiver operation while receiving a packet.

[0199] STA2 1804 may feedback two beam indices 1814 to STA1 1802. The beam selection method may be implementation dependent. For example, the STA2 1804 may select the pair of indices (ID_i^{t1}, ID_i^{t2}) which may satisfy $ID_i^{t1} = \arg\max_{1 \le k \le N} (SNR_{k1}^{TX} - SNR_{k2}^{TX})$ and $ID_i^{t2} = \arg\max_{N < k \le 2N} (SNR_{k2}^{TX} - SNR_{k1}^{TX})$.

[0200] The updated transmit beam indices for ith iteration may be (ID_i^{t1}, ID_i^{t2}). STA1 1802 may transmit a training sequence M times with beam ID_i^{t1} 1816. STA2 1804 may sweep through M receive beams with both receive RF chains (RX1 and RX2) 1818. STA1 1802 may transmit a training sequence again M times with beamforming weight ID_i^{t2} 1820. STA2 1804 may repeat the same procedure with both RF chains 1822. The sweeping of the receive antennas 1818 and 1822 is shown in dashed lines as an example illustration of receiver operation. For example, to receive packets from the transmitter, the receiver may receive a first packet with the first receive antenna, a second packet with the second receive antenna, and so on, until it receives a last packet with the last receive antenna. STA2 1804 may measure the SNR or equivalent parameters and update the receive beam index accordingly. The receive beam selection method may be implementation dependent. For example, M may be the number of receive beams STA2 1804 intends to train and may not necessarily be related to the number of receive antennas at STA2 1804.

[0201] The procedure may be repeated for several iterations until the method converges or certain criteria have been met that indicates that spatial multiplexing is not suitable for STA1 1802 and STA2 1804.

[0202] There may be several ways to define failure criteria that indicate that the pair of devices are not suitable for spatial multiplexing. For example, the failure criteria may be defined as when STA2 1804 may record $\Delta_{11}^{SNR} = \max_{1 \le k \le N}(SNR_{k1}^{TX} - SNR_{k2}^{TX})$ and $\Delta_{12}^{SNR} = \max_{N < k \le 2N}(SNR_{k2}^{TX} - SNR_{k1}^{TX})$ in when selecting beams, and feedback this information to STA1 1802. In another example failure criteria, STA2 1804 may record $\Delta_{21}^{SNR} = \max_{1 \le k \le N}(SNR_{k1}^{RX} - SNR_{k2}^{RX})$ and $\Delta_{22}^{SNR} = \max_{N < k \le 2N}(SNR_{k2}^{RX} - SNR_{k1}^{RX})$ in when sweeping beams, and feedback this information to STA1 1802.

[0203] If Δ_{ij}^{SNR} is smaller than a threshold, both STA1 1802 and STA2 1804 may determine that the channel cannot provide enough spatial diversity to support two data streams. In this example, the pair of devices may determine to complete the training procedure, and perform RF selection at both transmitter and receiver. Alternatively, the pair of devices may terminate the training with two RF chains, and return to performing beamforming training with one RF chain. After training, the pair of devices may transmit with a fewer number of spatial streams.

[0204] The beam refinement transaction discussed in conjunction with FIG. 3 may be used for Eigen-beamforming based spatial multiplexing methods disclosed above. Modifications may be applied to support spatial multiplexing. For example, a number of spatial streams may be defined. The number of data streams may be defined in a DMG beam refinement element. The FBCK-TYPE subfield in the DMG beam refinement element may be modified.

[0205] FIG. 19 is a diagram of an example modified FBCK-TYPE subfield 1900. The modified FBCK-TYPE subfield 1900 may be included in a DMG refinement element. The modified FBCK-TYPE subfield 1900 may include a SNR present field 1910, a channel measurement present field 1920, a tap delay present field 1930, a number of taps present field 1940, a number of measurement field 1950, a number of spatial streams field 1960, a sector ID order present field 1970, and a number of beams field 1980.

[0206] An initiator may determine the capabilities of the responder prior to initiating beamforming training with the responder by using an Eigen-beamforming based spatial multiplexing capability. The Beam sweep based spatial multiplexing capability may be indicated in a DMG capabilities element. The DMG capabilities element may be present in an association request, association response, re-association request, re-association response, probe request and probe response frames and may be present in DMG beacon and information request and response frames. One bit of Eigen-beamforming based spatial multiplexing indication and one bit of beam sweep spatial multiplexing capability may be used to indicate that the STA is capable of performing Eigen-beamforming based spatial multiplexing.

[0207] The type of beamforming training algorithm, such as Eigen-beamforming based and beam sweep based, may be indicated in DMG beam refinement element. In addition, transceiver architecture type, such as Type I and Type II may be indicated in a DMG capabilities element.

[0208] A precoding matrix utilized by the initiator in the first part of each iteration may be predefined and agreed on by both initiator and responder if Eigen-beamforming based spatial multiplexing is implemented. In this example, the initiator and responder may negotiate which matrix to utilize before the beamforming training. For example, the precoding matrix index may be defined and transmitted in a BRP request field. In addition, a set of unitary precoding matrices may be predetermined.

[0209] A number of antennas at both initiator and responder may be signaled if Eigen-beamforming based spatial multiplexing is implemented. The number of antennas may be signaled in the PHY header, MAC header or a BRP Request field.

[0210] A spatial multiplexing frame format may be implemented. For example, when a packet is transmitted using spatial multiplexing, an indication may be sent to inform the packet recipients that multiple streams were transmitted. The MCS may be redefined for a modulation/coding scheme and the number of spatial streams. In 802.11ad, for example, MCS 0 may be

the Control PHY; MCS 1-12 may be utilized for single carrier (SC) PHY; MCS 13-24 may be for OFDM PHY; and MCS 25-31 may be for low power SC PHY.

[0211] In examples with two data stream transmissions, the following may be defined for use by the communication devices. For example, MCS 32-43 may be for SC PHY, MCS 44-55 may be for OFDM PHY, and 56-62 may be for low power SC PHY. In some examples, the MCS mapping may not be the same as defined above.

[0212] Alternatively, the number of spatial streams may be indicated in a PHY header. In order to support multiple data streams, the PHY layer frame format may need to be modified.

[0213] FIGS. 20A, 20B, and 20C are diagrams of example PHY layer frame formats. With SC PHY, the data field may be composed of symbol blocks, while with OFDM PHY, the data field may be composed of OFDM symbols. The frame may be appended with TRN-T/R subfields, and may be utilized for beam refinement protocol.

[0214] Referring to FIG. 20A, short training field (STF) 2010, channel estimation field (CE) 2020 and PHY headers 2030 may be transmitted with a weight, W1 2040. The number of data streams supported, N, may be indicated in the PHY header. If more than one data stream will be transmitted, additional CE field(s) may be included. With N data streams, an extra N-1 CE field 2050 may be transmitted and weights W2 2060, ..., WN 2070 may be applied to each CE field. An orthogonal mapping matrix, such as the P matrix defined in 802.11n/ac, may be applied. If a cyclic shift delay (CSD) scheme is applied to spatial multiplexing, the same CSD parameters may be applied to the CE fields. The data field 2080 that follows may be transmitted using the spatial multiplexing scheme, and all of the weights (W1,...,WN) 2090 may be applied.

[0215] FIG. 20B is a diagram of another example preamble format for spatial multiplexing transmissions. This format is similar to FIG. 20A except that an AGC field 2015 may be inserted after additional CE fields and before the data field 2080. The AGC field 2015 may use the same sequence as an LTF

field, or it may be redesigned. The purpose of this AGC field 2015 may be for automatic gain control. The transmission of the AGC field 2015 may be in the same format as the data field 2080, i.e., weights (W1,...,WN) 2090 may be applied. The same CSD parameters may be applied to AGC field 2015 if CSD is utilized for data transmissions.

[0216] FIG. 20C is a diagram of another example preamble format for spatial multiplexing transmissions in which the number of data streams may be signaled implicitly. STF 2010 may be transmitted using all the weights (W1,...,WN) 2025. The first CE field 2020 following STF 2010 may be transmitted using the first weight W1 2040. The number of data streams may be implicitly indicated by using STF 2010 and the first CE field 2020. For example, several CE sequences may be defined, and each sequence may correspond to a certain number of data streams. Additional N-1 CE fields 2050 may follow the first CE field 2020 and transmitted with weights W2 2060 to WN 2070. The header 2035 may be transmitted with one of the weights or a combination of the weights similar to STF 2010. The spatial multiplexing transmission may be transmitted following the additional CE fields.

[0217] Beamforming training overhead and latency may be reduced. For example, sector sweep (SSW) frames and related training methods may be modified.

[0218] In the SLS procedures, SSW frames may be utilized for transmit and receive beamforming training. For example, the SSW frames may be transmitted in N time slots. For transmit beamforming training, SSW frames may be transmitted and multiple antenna sectors may be swept. The receiver may receive the SSW frames with the same antenna sector and feedback the best transmit sector ID to the transmitter. For example, for receive beamforming training, the same SSW frames may be repeated N times, and the receiver may sweep over multiple antenna sectors to receive. After the receive beamforming training, the receiver may select the best receive sector.

[0219] Each SSW frame may comprise a full PLCP header that may include a preamble, one or more header blocks, and a MAC frame. Since the

SSW frames may be utilized for beamforming training, they may be transmitted using the lowest data rate, for example, control PHY or MCS0 in 802.11ad. SSW frames may not contain data traffic, therefore SSW frame sequences may be beamforming training overhead.

[0220] FIG. 21 is a diagram of an example modified SSW training frames and sequence 2100. In this example, modified SSW training sequences may be utilized. A SSW announcement (SSWA) frame 2110 may be transmitted at the beginning of the SSW training sequences. The SSWA frame 2110 may contain all the information used to transmit by SSW frames. One or more N null SSW (NSSW) frames 2120 may follow the SSWA frame 2110 with a certain inter-frame spacing. NSSW frames 2120 may contain only preamble and PHY headers, and no MAC frame.

[0221] Figure 22 is a diagram of an example SSWA frame format 2200. The SSWA frame format 2200 may include a frame control field 2205, a duration field 2210, an RA field 2215, a TA field 2220, an SSW field 2225, an SSW feedback (FB) field 2230, and an FCS field 2235. The SSW field 2225 may include a direction subfield 2240, a DMG antenna ID 1 subfield 2245, a sector ID 1 subfield 2250, a sector ID N subfield 2255, a DMG antenna ID 2 subfield 2260, a sector ID 1 subfield 2265, a sector ID N2 subfield 2270, and an RXSS length subfield 2275. In this example, sector ID 1 subfield 2250 may be for DMG antenna ID 1, and sector ID 1 subfield 2265 may be for DMG antenna ID 2.

[0222] The direction subfield 2240 and the RXSS length subfield 2275 may be the same as in IEEE 802.11ad. The direction subfield 2240 may be set to 0 to indicate that the frame is transmitted by the beamforming initiator and set to 1 to indicate that the frame is transmitted by the beamforming responder. The RXSS Length subfield 2275 may be valid only when transmitted in a CBAP and may be reserved otherwise. The RXSS Length subfield 2275 may specify the length of a receive sector sweep as required by the transmitting STA, and may be defined in units of an SSW frame. The value of this field is in the range 0–62, with odd values being reserved.

[0223] DMG Antenna IDs and Sector IDs may be utilized to indicate the antenna pattern for the following NSSW frames. For example, the first NSSW frame may utilize DMG Antenna ID 1 and Sector ID 1 to transmit, and the second NSSW frame may utilize DMG Antenna ID 1 and Sector ID 2 to transmit, and so on. With DMG antenna ID k, there may be Nk sectors swept for this round of beamforming training. The total number of NSSW frames following this SSWA frame may be $\sum_{k=1}^{K} N_k$. K may be the number of DMG antennas trained with these SSWA-NSSW sequences.

[0224] The SSWA may be transmitted as follows. For example, the SSWA frame may carry all the MAC information necessary for beamforming training. It may be important that the receiver decodes the SSWA frame correctly. The SSWA frame may be transmitted using one of the following methods. For example, if the beamforming training is between two non-AP/PCP devices, the SSWA frame may be transmitted from AP to the two devices. In another example, if both the beamforming initiator and responder are multi-band capable, they may operate on multiple frequency bands simultaneously, and the SSWA frame may be transmitted on another frequency band. The SSWA frame may be transmitted with low data rate, spreading codes, or repetition schemes.

[0225] Some examples may use sub-optimum SLS training methods. In these examples, SLS training methods may be terminated early.

[0226] FIG. 23 is a diagram of an example early termination of the SLS training procedure. In this example, the initiator 2302 may have 4 beam sectors to train, and the countdown (CDOWN) number may equal 3 in the first training frame. In this example, sector 3 is shaded to illustrate that the initiator may use sector 3 for transmission in a first period, and sector 4 is shaded to illustrate that the initiator may use sector 4 for transmission in the second period. The initiator 2302 may continue transmitting training frames which are separated by inter-frame space duration 2T, for example. The responder 2304 may monitor the received training frames 2306. The dashed

"omni" circles in FIG. 23 are shown to illustrate that the receiver/responder may be in an omni-receiving mode. An omni-receiving mode may be enabled by an omni-directional receiving antenna. The first two "omni" circles are shown in dashed lines to illustrate that they are example receiver operations. The last "omni" circle is shown in indicating solid line to illustrate that this is an example transmitter operation, i.e., the feedback packet may be transmitted in an omni-transmitting mode, which may be enabled by an omni-directional transmitting antenna. Once the received SNR (or other parameters) is greater than a certain threshold, the responder 2304 may determine to terminate the training procedure by transmitting a feedback frame 2308. The feedback frame 2308 may be transmitted after a T duration from the end of a training frame transmitted by the initiator 2302. Thus the initiator 2302 may detect the transmission of this feedback and stop transmitting more training frames. This example may be used for both transmit and receive beamforming training.

[0227] A group based SLS training method may be performed. In this example, a STA may divide its sectors to groups. The partition of sectors may be implementation dependent. For example, the partition may be based on the direction of the sectors. The beamforming initiator may select one group to perform SLS training and wait for the feedback from the responder. Once the feedback from responder meets the expectation of the initiator, the beamforming initiator may determine to stop the beamforming training. Otherwise, the initiator may select another group to perform SLS training until one beam is selected or all the beams are swept.

[0228] Multi-beam, multi-DMG antenna sector level sweep feedback may be performed. In examples of the sector level sweep method, the receiver STA may report back the best beam only, for example, one sector of one DMG antenna. For example, a list of the best beams, such as multiple beams of multiple antennas may be reported. This may enable the communication link to track the relative performance of the beams over time and, if necessary, switch to a better beam without the need for retraining.

[0229] FIG. 24 is a diagram of an example multi-beam multi-DMG antenna SLS feedback method 2400. The following method 2400 may use a sector level sweep method that may report a list of best beams. In this example, the DMG transmitting STA1 2402 and receiving STA2 2404 may indicate their capability to support multi-sector, multi-DMG antenna Sector Sweep (SSW) feedback. This capability may be indicated by a bit in the DMG STA Capability Information field. STAs that do not have the capability may fall back to legacy transmission.

[0230] The STA initiating the sector sweep, for example STA1 2402, may transmit information to the responder STA, for example STA2 2404, indicating the number of beams to be fed back. The responder STA 2404 may also transmit information to initiator STA 2402 on the number of beams to be fed back. The metric to decide on the best beams may be implementation dependent. One signaling method may use a Transmit Sector Sweep frame for both the initiator and the responder may contain the number of beams to be fed back. A second signaling method may use a DMG beacon that may contain a field that indicates the number of beams to be fed back for all SSW feedback 2420. In a third signaling method, before a Sector Level Sweep procedure, the initiator and responder may exchange SLS setup frames indicating the number of beams to feed back. Quasi-omni may refer to a near omni-directional transmission or reception. For example, quasi-omni transmissions may be enabled by repeatedly transmitting the same information using multiple directional transmissions, as if it were transmitted using an omni-directional transmit antenna. Similarly, quasi-omni receptions may be enabled by repeatedly receiving the same packet using multiple directional receptions, as if it were received using an omni-directional receiving antenna.

[0231] Both STAs may implement the legacy initiator and responder sector level sweep procedures. The transmitter may feedback the best N beams. This may be by one of the following example methods. In a first example method, multiple SSW Feedback fields may be aggregated within an SSW feedback frame 2420. In a second example, a single SSW Feedback field

may be modified to enable feedback of multiple beams and DMG antennas and corresponding SNR Reports. In a third example, the best beam/antenna may be fed back during the SLS procedure and subsequent feedback of the additional N-1 beams with other transmissions, for example an ACK. In these examples, the number of antenna may be larger than the number radio frequency (RF) chains. In some examples, the number of antenna may be much larger than the number of RF chains.

EMBODIMENTS

1. A first communication device comprising:

a plurality of antennas;

a processor configured to partition the plurality of antennas;

a transmitter configured to transmit a plurality of frames to a second communication device;

and a receiver.

2. The first communication device of embodiment 1, wherein the processor is configured to partition the plurality of antennas into at least a first group of antennas and a second group of antennas.

3. The first communication device of embodiment 2, wherein the first group of antennas is associated with a first beam to a first station (STA).

4. The first communication device of embodiment 2 or 3, wherein the second group of antennas is associated with a second beam to a second station (STA).

5. The first communication device of any one of embodiments 2-4, wherein the first group of antennas is associated with a first beam to a first plurality of stations (STAs).

6. The first communication device of any one of embodiments 2-5, wherein the second group of antennas is associated with a second beam to a second plurality of stations (STAs).

7. The first communication device of any preceding embodiment, wherein the plurality of frames transmitted are beamforming training frames.

8. The first communication device of any preceding embodiment, wherein the plurality of frames are transmitted using the first group of antennas.

9. The first communication device of any preceding embodiment, wherein the plurality of frames are transmitted using the second group of antennas.

10. The first communication device of any preceding embodiment, wherein the receiver is configured to receive a first beamforming weight vector from the second communication device.

11. The first communication device of embodiment 10, wherein the first beamforming weight vector is for sending signals on the first group of antennas.

12. The first communication device of any preceding embodiment, wherein the receiver is configured to receive a second beamforming weight vector from the second communication device.

13. The first communication device of embodiment 12, wherein the second beamforming weight vector is for sending signals on the second group of antennas.

14. The first communication device of any one of embodiments 10-13, wherein the first beamforming weight vector is a strongest beam between the first communication device and the second communication device.

15. The first communication device of any one of embodiments 12-14, wherein the second beamforming weight vector is for a second strongest beam between the first communication device and the second communication device.

16. The first communication device of any preceding embodiment, wherein the first communication device is a wireless transmit/receive unit (WTRU).

17. The first communication device of any one of embodiments 1-15, wherein the first communication device is a station (STA).

18. The first communication device of any one of embodiments 1-15, wherein the first communication device is an access point (AP).

19. The first communication device of any one of embodiments 1-15, wherein the first communication device is a base station.

20. The first communication device of any preceding embodiment, wherein the second communication device is a wireless transmit/receive unit (WTRU).

21. The first communication device of any one of embodiments 1-19, wherein the second communication device is a station (STA).

22. The first communication device of any one of embodiments 1-19, wherein the second communication device is an access point (AP).

23. The first communication device of any one of embodiments 1-19, wherein the second communication device is a base station.

24. The first communication device of any one of embodiments 7-23, wherein the beamforming training frames are orthogonal beamforming vectors.

25. The first communication device of any preceding embodiment, wherein the transmitter is further configured to transmit a second set of beamforming training frames.

26. The first communication device of embodiment 25, wherein the second set of beamforming training frames is transmitted using the received first beamforming weight vector.

27. The first communication device of embodiment 25 or 26, wherein the second set of beamforming training frames is transmitted using the received second beamforming weight vector.

28. The first communication device of any preceding embodiment, wherein the receiver is further configured to receive a modified first beamforming weight vector.

29. The first communication device of embodiment 28, wherein the modified first weight vector is for sending signals on the first group of antenna.

30. The first communication device of any preceding embodiment, wherein the receiver is further configured to receive a modified second beamforming weight vector.

31. The first communication device of embodiment 30, wherein the modified second weight vector is for sending signals on the second group of antenna.

32. The first communication device of any preceding embodiment, wherein the first communication device comprises one or more radio frequency (RF) chains.

33. The first communication device of any preceding embodiment, wherein a number of the antenna is larger than a number of one or more radio frequency (RF) chains.

34. A first communication device comprising:

a plurality of antennas;

a receiver configured to receive a set of beamforming training frames;

a processor; and

a transmitter.

35. The first communication device of embodiment 34, wherein the processor is configured to determine a first transmit beamforming weight vector.

36. The first communication device of embodiment 35, wherein the first transmit beamforming weight vector corresponds to a first antenna group.

37. The first communication device of embodiment 36, wherein the first antenna group is for a second communication device.

38. The first communication device of any one of embodiments 34-37, wherein the processor is configured to determine a second transmit beamforming weight vector.

39. The first communication device of embodiment 38, wherein the second transmit beamforming weight vector corresponds to a second antenna group.

40. The first communication device of embodiment 39, wherein the second antenna group is for a second communication device.

41. The first communication device of any one of embodiments 34-40, wherein the transmitter is configured to transmit data using the first transmit beamforming weight vector to the second communication device to the second communication device.

42. The first communication device of any one of embodiments 34-41, wherein the transmitter is configured to transmit data using the second transmit data using the second transmit beamforming weight vector to the second communication device.

43. The first communication device of any one of embodiments 34-42, wherein the first communication device is a wireless transmit/receive unit (WTRU).

44. The first communication device of any one of embodiments 34-42, wherein the first communication device is a station (STA).

45. The first communication device of any one of embodiments 34-42, wherein the first communication device is an access point (AP).

46. The first communication device of any one of embodiments 34-42, wherein the first communication device is a base station.

47. The first communication device of any one of embodiments 34-46, wherein the second communication device is a wireless transmit/receive unit (WTRU).

48. The first communication device of any one of embodiments 34-46, wherein the second communication device is a station (STA).

49. The first communication device of any one of embodiments 34-46, wherein the second communication device is an access point (AP).

50. The first communication device of any one of embodiments 34-46, wherein the second communication device is a base station.

51. The first communication device of any one of embodiments 34-50, wherein the received beamforming training frames are orthogonal beamforming vectors.

52. The first communication device of any one of embodiments 34-51, wherein the transmitted beamforming weight vectors are orthogonal beamforming vectors.

53. A method for beamforming training for beam division multiple access (BDMA), the method comprising:

receiving a first transmit beamforming weight from a first station (STA), and receiving a second transmit beamforming weight from a second (STA);

transmitting Nt sequences modulated using Nt beamforming vectors, wherein the Nt sequences are modulated based on the first transmit beamforming weight and the second transmit beamforming weight.

54. The method of embodiment 53, wherein the Nt beamforming vectors are orthogonal.

55. A method for beamforming training for beam division multiple access (BDMA), the method comprising:

receiving a plurality of Nt sequences using a first previous beamforming vector;

determining a first transmit beamforming weight from an access point (AP) based on the first previous beamforming vector and the received plurality of Nt sequences; and

transmitting the determined first transmit beamforming weight to the AP.

56. A method for beamforming training for spatial multiplexing, the method comprising:

an initiator station having two radio frequency (RF) chains and having transmit antenna elements, the initiator station transmitting Nt known training sequences sweeping the transmit antenna elements;

a responder station having a first and a second RF chain and having receive antenna elements, and having a first and a second receive beamforming weight, the responder station receiving the first RF chain and receiving the second RF chain; and

the responder station estimating at least two channels by comparing the received first RF chain and the second RF chain to the Nt known training sequences.

57. The method of embodiment 56, wherein the first RF chain is the combination of signals received from the receive antenna elements weighted by the first receive beamforming weights

58. The method of embodiment 57, wherein the second RF chain is the combination of signals received from the receive antenna elements weighted by the second receive beamforming weights.

59. The method of any one of embodiments 56-58, wherein the transmitting Nt training sequences further comprises transmitting Nt training sequences over a first RF chain of the initiator.

60. The method of any one of embodiments 56-58, wherein the transmitting Nt training sequences further comprises transmitting Nt training sequences over a second RF chain of the initiator.

61. The method of any one of embodiments 56-58, wherein the transmitting Nt training sequences further comprises transmitting Nt training sequences over the first RF chain and the second RF chain.

62. The method of embodiment 61, wherein the first RF chain and the second RF chain are calibrated.

63. The method of any one of embodiments 56-62, wherein the transmitting Nt known training sequences sweeping the transmit antenna elements comprises the initiator station having two RF chains and having transmit antenna elements, transmitting Nt known training sequences sweeping the transmit antenna elements, wherein a number of the transmit antenna elements is larger than a number of RF chains.

64. The method of any one of embodiments 56-63, wherein the number of transmit antenna elements is at least six times larger than a number of RF chains.

65. The method of any one of embodiments 56-64 further comprising the responder transmitting the estimated two channels to the initiator.

66. A method for beamforming training for spatial multiplexing, the method comprising:

an initiator station having two or more radio frequency (RF) chains and having transmit antenna elements, the initiator station transmitting Nt known sequences sweeping the transmit antenna elements;

a responder station having a first and a second RF chain and having receive antenna elements, and having a first and a second receive beamforming weight, the responder station receiving the first RF chain and receiving the second RF chain; and

the responder estimating at least two channels by comparing the received first RF chain and the second RF chain to the known Nt training sequences.

67. The method of embodiment 66, wherein the first RF chain is a combination of signals received from the receive antenna elements weighted by the first receive beamforming weights.

68. The method of embodiment 66 or 67, wherein the second RF chain is the combination of signals received from the receive antenna elements weighted by the second receive beamforming weights.

69. A method for performing beamforming, the method comprising:

a first communication device transmitting a first plurality of beamforming training frames to a second communication device using a first beamforming vector;

the first communication device receiving from the second communication device a second beamforming weight vector; and

the first communication device transmitting a second plurality of beamforming training frames to the second communication device using the second beamforming vector.

70. The method of embodiment 69, wherein the first communication device transmits the first plurality of beamforming training frames to the second communication device using a first beamforming weight vector.

71. The method of embodiment 69 or 70, wherein the first communication device transmits a first portion of the first plurality of beamforming training frames using a first group of antenna and a first portion of the beamforming weights.

72. The method of any one of embodiments 69-71, wherein the first communication device transmits a second portion of the first plurality of beamforming training frames using a second group of antenna and a second portion of the beamforming weights.

73. A base station configured to perform any one of embodiments 53-72.

74. A base station configured to perform any portion of embodiments 53-72.

75. An integrated circuit configured to perform any one of embodiments 53-72.

76. An integrated circuit configured to perform any portion of embodiments 53-72.

77. A station (STA) configured to perform any one of embodiments 53-72.

78. A station (STA) configured to perform any portion of embodiments 53-72.

79. An access point (AP) configured to perform any one of embodiments 53-72.

80. An access point (AP) configured to perform any portion of embodiments 53-72.

81. A wireless transmit/receive unit (WTRU) configured to perform any one of embodiments 53-72.

82. A wireless transmit/receive unit (WTRU) configured to perform any portion of embodiments 53-72.

[0232] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element can be used alone or in any combination with the other features and elements. In addition, the methods described herein may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, and optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, UE, terminal, base station, RNC, or any host computer.

* * *

CLAIMS

What is claimed is:

1. A first communication device, the first communication device comprising:

a plurality of antennas;

a processor, wherein the processor is configured to partition the plurality of antennas into at least a first group of antennas and a second group of antennas, wherein the first group of antennas is associated with a first beam to a first station (STA) or a first plurality of STAs, and the second group of antennas is associated with a second beam to a second STA or a second plurality of STAs;

a transmitter configured to transmit, to a second communication device, a plurality of beamforming training frames using the first group of antennas and the second group of antennas; and

a receiver configured to receive from the second communication device a first beamforming weight vector for sending signals on the first group of antennas and to receive a second beamforming weight vector for sending signals on the second group of antennas.

2. The first communication device of claim 1, wherein the first beamforming weight vector is a strongest beam between the first communication device and the second communication device, and wherein the second beamforming weight vector is for a second strongest beam between the first communication device and the second communication device.

3. The first communication device of claim 1, wherein the first communication device and the second communication device are one of: a wireless transmit receive unit, a station, an access point, or a base station.

4. The first communication device of claim 1, wherein the beamforming training frames are orthogonal beamforming vectors.

5. The first communication device of claim 1, wherein the transmitter is further configured to transmit a second set of beamforming training frames using the received first beamforming weight vector and the second beamforming weight vector; and wherein the receiver is further configured to receive from the second communication device a modified first beamforming weight vector for sending signals on the first group of antenna and to receive a modified second beamforming weight vector for sending signals on the second group of antenna.

6. The first communication device of claim 1, wherein the first communication device comprises one or more radio frequency (RF) chains and wherein a number of the antenna is larger than a number of the one or more RF chains.

7. A first communication device, the first communication device comprising:

a plurality of antennas; and

a processor, wherein the plurality of antennas are configured to receive a set of beamforming training frames, and wherein the processor is configured to determine a first transmit beamforming weight vector corresponding to a first antenna group of a second communication device, and to determine a second transmit beamforming weight vector corresponding to a second antenna group of the second communication device; and

a transmitter configured to transmit data using the first transmit beamforming weight vector and to send data using the second transmit beamforming weight vector to the second communication device.

8. The first communication device of claim 7, wherein the first communication device and the second communication device are one of: a wireless transmit receive unit, a station, an access point, or a base station.

9. The first communication device of claim 7, wherein the received beamforming training frames are orthogonal beamforming vectors.

10. The first communication device of claim 7, wherein the transmitted beamforming weight vectors are orthogonal beamforming vectors.

11. A method for use in a first communication device, the method comprising:

partitioning, at the first communication device, a plurality of antennas into at least a first group of antennas and a second group of antennas, wherein the first group of antennas is associated with a first beam to a first station (STA) or a first plurality of STAs, and the second group of antennas is associated with a second beam to a second STA or a second plurality of STAs;

transmitting, to a second communication device, a plurality of beamforming training frames using the first group of antennas and the second group of antennas; and

receiving, from the second communication device, a first beamforming weight vector for transmitting signals on the first group of antennas and receiving a second beamforming weight vector for transmitting signals on the second group of antennas.

12. The method of claim 11, wherein the first beamforming weight vector is a strongest beam between the first communication device and the second communication device, and wherein the second beamforming weight vector is for a second strongest beam between the first communication device and the second communication device.

13. The method of claim 11, wherein the first communication device and the second communication device are one of: a wireless transmit receive unit, a STA, an access point (AP), or a base station.

14. The method of claim 11, wherein the beamforming training frames are orthogonal beamforming vectors.

15. The method of claim 11 further comprising:

transmitting a second set of beamforming training frames using the received first beamforming weight vector and the second beamforming weight vector; and

receiving from the second communication device a modified first beamforming weight vector for transmitting signals on the first group of antenna and receiving a modified second beamforming weight vector for transmitting signals on the second group of antenna.

16. The method of claim 11, wherein the first communication device comprises one or more radio frequency (RF) chains and wherein a number of the antenna is larger than a number of the one or more RF chains.

17. A method for use in a first communication device, the method comprising:

receiving a set of beamforming training frames;

determining a first transmit beamforming weight vector corresponding to a first antenna group of a second communication device, and to determining a second transmit beamforming weight vector corresponding to a second antenna group of the second communication device; and

transmitting data using the first transmit beamforming weight vector and transmitting data using the second transmit beamforming weight vector to the second communication device.

18. The method of claim 17, wherein the first communication device and the second communication device are one of: a wireless transmit receive unit, a station (STA), an access point (AP), or a base station.

19. The method of claim 17, wherein the received beamforming training frames are orthogonal beamforming vectors.

20. The method of claim 17, wherein the received beamforming training frames are orthogonal beamforming vectors.

(54) Title: METHOD AND APPARATUS FOR TRANSMITTING PAGING FOR MACHINE TYPE COMMUNICATION USER EQUIPMENT IN WIRELESS COMMUNICATION SYSTEM

[Fig. 7]

(57) Abstract: A method and apparatus for monitoring a paging in a wireless communication system is provided. A user equipment (UE) monitors multiple paging instances at one paging occasion. Specifically, the UE monitors a first paging instance with a first repetition level in a paging occasion, and monitors a second paging instance with a second repetition level, which is higher than the first repetition level, in the paging occasion.

Description

Title of Invention: METHOD AND APPARATUS FOR TRANSMITTING PAGING FOR MACHINE TYPE COMMUNICATION USER EQUIPMENT IN WIRELESS COMMUNICATION SYSTEM

Technical Field

[1] The present invention relates to wireless communications, and more particularly, to a method and apparatus for transmitting a paging for a machine type communication user equipment (MTC UE) in a wireless communication system.

Background Art

[2] 3rd generation partnership project (3GPP) long-term evolution (LTE) is a technology for enabling high-speed packet communications. Many schemes have been proposed for the LTE objective including those that aim to reduce user and provider costs, improve service quality, and expand and improve coverage and system capacity. The 3GPP LTE requires reduced cost per bit, increased service availability, flexible use of a frequency band, a simple structure, an open interface, and adequate power consumption of a terminal as an upper-level requirement.

[3] In the future versions of the LTE-A, it has been considered to configure low-cost/low-end (or, low-complexity) user equipments (UEs) focusing on the data communication, such as meter reading, water level measurement, use of security camera, vending machine inventory report, etc. For convenience, these UEs may be called machine type communication (MTC) UEs. Since MTC UEs have small amount of transmission data and have occasional uplink data transmission/downlink data reception, it is efficient to reduce the cost and battery consumption of the UE according to a low data rate. Specifically, the cost and battery consumption of the UE may be reduced by decreasing radio frequency (RF)/baseband complexity of the MTC UE significantly by making the operating frequency bandwidth of the MTC UE smaller.

[4] Paging is the mechanism in which the network tells UE saying "I have something for you". Then the UE decode the content (paging cause) of the paging message and the UE has to initiate the appropriate procedure. In most cases, this paging process happens while the UE is in idle mode. This means that the UE has to monitor whether the network transmits any paging message to the UE and the UE has to spend some energy (battery) to run this monitoring process. Accordingly, a method for transmitting a paging for MTC UEs efficiently may be required.

Disclosure of Invention

Technical Problem

[5] The present invention provides a method and apparatus for transmitting a paging for a machine type communication user equipment (MTC UE) in a wireless communication system. The present invention provides a method and apparatus for performing periodic reporting triggered by paging for low complexity MTC UEs. The present invention provides a method and apparatus for addressing a paging mechanism for low complexity MTC UEs requiring coverage enhancement via such as repetition.

Solution to Problem

[6] In an aspect, a method for monitoring, by a user equipment (UE), a paging in a wireless communication system is provided. The method includes monitoring a first paging instance with a first repetition level in a paging occasion, and monitoring a second paging instance with a second repetition level, which is higher than the first repetition level, in the paging occasion.

[7] In another aspect, a user equipment (UE) is provided. The UE includes a memory, a transceiver, and a processor coupled to the memory and the transceiver, and configured to monitor a first paging instance with a first repetition level, and monitor a second paging instance with a second repetition level which is higher than the first repetition level.

Advantageous Effects of Invention

[8] MTC UEs can be paged efficiently.

Brief Description of Drawings

[9] FIG. 1 shows a wireless communication system.

[10] FIG. 2 shows structure of a radio frame of 3GPP LTE.

[11] FIG. 3 shows a resource grid for one downlink slot.

[12] FIG. 4 shows structure of a downlink subframe.

[13] FIG. 5 shows structure of an uplink subframe.

[14] FIG. 6 shows an overall paging timing to support coverage enhancement for MTC UEs according to an embodiment of the present invention.

[15] FIG. 7 shows increase of coverage enhancement levels or repetition levels according to an embodiment of the present invention.

[16] FIG. 8 shows a method for monitoring a paging according to an embodiment of the present invention.

[17] FIG. 9 shows a wireless communication system to implement an embodiment of the present invention.

Mode for the Invention

[18] Techniques, apparatus and systems described herein may be used in various wireless

access technologies such as code division multiple access (CDMA), frequency division multiple access (FDMA), time division multiple access (TDMA), orthogonal frequency division multiple access (OFDMA), single carrier frequency division multiple access (SC-FDMA), etc. The CDMA may be implemented with a radio technology such as universal terrestrial radio access (UTRA) or CDMA2000. The TDMA may be implemented with a radio technology such as global system for mobile communications (GSM)/general packet radio service (GPRS)/enhanced data rates for GSM evolution (EDGE). The OFDMA may be implemented with a radio technology such as institute of electrical and electronics engineers (IEEE) 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802-20, evolved-UTRA (E-UTRA) etc. The UTRA is a part of a universal mobile telecommunication system (UMTS). 3rd generation partnership project (3GPP) long term evolution (LTE) is a part of an evolved-UMTS (E-UMTS) using the E-UTRA. The 3GPP LTE employs the OFDMA in downlink (DL) and employs the SC-FDMA in uplink (UL). LTE-advance (LTE-A) is an evolution of the 3GPP LTE. For clarity, this application focuses on the 3GPP LTE/LTE-A. However, technical features of the present invention are not limited thereto.

[19] FIG. 1 shows a wireless communication system. The wireless communication system 10 includes at least one evolved NodeB (eNB) 11. Respective eNBs 11 provide a communication service to particular geographical areas 15a, 15b, and 15c (which are generally called cells). Each cell may be divided into a plurality of areas (which are called sectors). A user equipment (UE) 12 may be fixed or mobile and may be referred to by other names such as mobile station (MS), mobile terminal (MT), user terminal (UT), subscriber station (SS), wireless device, personal digital assistant (PDA), wireless modem, handheld device. The eNB 11 generally refers to a fixed station that communicates with the UE 12 and may be called by other names such as base station (BS), base transceiver system (BTS), access point (AP), etc.

[20] In general, a UE belongs to one cell, and the cell to which a UE belongs is called a serving cell. An eNB providing a communication service to the serving cell is called a serving eNB. The wireless communication system is a cellular system, so a different cell adjacent to the serving cell exists. The different cell adjacent to the serving cell is called a neighbor cell. An eNB providing a communication service to the neighbor cell is called a neighbor eNB. The serving cell and the neighbor cell are relatively determined based on a UE.

[21] This technique can be used for DL or UL. In general, DL refers to communication from the eNB 11 to the UE 12, and UL refers to communication from the UE 12 to the eNB 11. In DL, a transmitter may be part of the eNB 11 and a receiver may be part of the UE 12. In UL, a transmitter may be part of the UE 12 and a receiver may be part of the eNB 11.

[22] The wireless communication system may be any one of a multiple-input multiple-output (MIMO) system, a multiple-input single-output (MISO) system, a single-input single-output (SISO) system, and a single-input multiple-output (SIMO) system. The MIMO system uses a plurality of transmission antennas and a plurality of reception antennas. The MISO system uses a plurality of transmission antennas and a single reception antenna. The SISO system uses a single transmission antenna and a single reception antenna. The SIMO system uses a single transmission antenna and a plurality of reception antennas. Hereinafter, a transmission antenna refers to a physical or logical antenna used for transmitting a signal or a stream, and a reception antenna refers to a physical or logical antenna used for receiving a signal or a stream.

[23] FIG. 2 shows structure of a radio frame of 3GPP LTE. Referring to FIG. 2, a radio frame includes 10 subframes. A subframe includes two slots in time domain. A time for transmitting one subframe is defined as a transmission time interval (TTI). For example, one subframe may have a length of 1ms, and one slot may have a length of 0.5ms. One slot includes a plurality of orthogonal frequency division multiplexing (OFDM) symbols in time domain. Since the 3GPP LTE uses the OFDMA in the DL, the OFDM symbol is for representing one symbol period. The OFDM symbols may be called by other names depending on a multiple-access scheme. For example, when SC-FDMA is in use as a UL multi-access scheme, the OFDM symbols may be called SC-FDMA symbols. A resource block (RB) is a resource allocation unit, and includes a plurality of contiguous subcarriers in one slot. The structure of the radio frame is shown for exemplary purposes only. Thus, the number of subframes included in the radio frame or the number of slots included in the subframe or the number of OFDM symbols included in the slot may be modified in various manners.

[24] The wireless communication system may be divided into a frequency division duplex (FDD) scheme and a time division duplex (TDD) scheme. According to the FDD scheme, UL transmission and DL transmission are made at different frequency bands. According to the TDD scheme, UL transmission and DL transmission are made during different periods of time at the same frequency band. A channel response of the TDD scheme is substantially reciprocal. This means that a DL channel response and a UL channel response are almost the same in a given frequency band. Thus, the TDD-based wireless communication system is advantageous in that the DL channel response can be obtained from the UL channel response. In the TDD scheme, the entire frequency band is time-divided for UL and DL transmissions, so a DL transmission by the eNB and a UL transmission by the UE cannot be simultaneously performed. In a TDD system in which a UL transmission and a DL transmission are discriminated in units of subframes, the UL transmission and the DL transmission are performed in different subframes.

[25] FIG. 3 shows a resource grid for one downlink slot. Referring to FIG. 3, a DL slot includes a plurality of OFDM symbols in time domain. It is described herein that one DL slot includes 7 OFDM symbols, and one RB includes 12 subcarriers in frequency domain as an example. However, the present invention is not limited thereto. Each element on the resource grid is referred to as a resource element (RE). One RB includes 12×7 resource elements. The number N^{DL} of RBs included in the DL slot depends on a DL transmit bandwidth. The structure of a UL slot may be same as that of the DL slot. The number of OFDM symbols and the number of subcarriers may vary depending on the length of a CP, frequency spacing, etc. For example, in case of a normal cyclic prefix (CP), the number of OFDM symbols is 7, and in case of an extended CP, the number of OFDM symbols is 6. One of 128, 256, 512, 1024, 1536, and 2048 may be selectively used as the number of subcarriers in one OFDM symbol.

[26] FIG. 4 shows structure of a downlink subframe. Referring to FIG. 4, a maximum of three OFDM symbols located in a front portion of a first slot within a subframe correspond to a control region to be assigned with a control channel. The remaining OFDM symbols correspond to a data region to be assigned with a physical downlink shared chancel (PDSCH). Examples of DL control channels used in the 3GPP LTE includes a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), a physical hybrid automatic repeat request (HARQ) indicator channel (PHICH), etc. The PCFICH is transmitted at a first OFDM symbol of a subframe and carries information regarding the number of OFDM symbols used for transmission of control channels within the subframe. The PHICH is a response of UL transmission and carries a HARQ acknowledgment (ACK)/non-acknowledgment (NACK) signal. Control information transmitted through the PDCCH is referred to as downlink control information (DCI). The DCI includes UL or DL scheduling information or includes a UL transmit (TX) power control command for arbitrary UE groups.

[27] The PDCCH may carry a transport format and a resource allocation of a downlink shared channel (DL-SCH), resource allocation information of an uplink shared channel (UL-SCH), paging information on a paging channel (PCH), system information on the DL-SCH, a resource allocation of an upper-layer control message such as a random access response transmitted on the PDSCH, a set of TX power control commands on individual UEs within an arbitrary UE group, a TX power control command, activation of a voice over IP (VoIP), etc. A plurality of PDCCHs can be transmitted within a control region. The UE can monitor the plurality of PDCCHs. The PDCCH is transmitted on an aggregation of one or several consecutive control channel elements (CCEs). The CCE is a logical allocation unit used to provide the PDCCH with a coding rate based on a state of a radio channel. The CCE corresponds to a plurality of resource

element groups.

[28] A format of the PDCCH and the number of bits of the available PDCCH are determined according to a correlation between the number of CCEs and the coding rate provided by the CCEs. The eNB determines a PDCCH format according to a DCI to be transmitted to the UE, and attaches a cyclic redundancy check (CRC) to control information. The CRC is scrambled with a unique identifier (referred to as a radio network temporary identifier (RNTI)) according to an owner or usage of the PDCCH. If the PDCCH is for a specific UE, a unique identifier (e.g., cell-RNTI (C-RNTI)) of the UE may be scrambled to the CRC. Alternatively, if the PDCCH is for a paging message, a paging indicator identifier (e.g., paging-RNTI (P-RNTI)) may be scrambled to the CRC. If the PDCCH is for system information (more specifically, a system information block (SIB) to be described below), a system information identifier and a system information RNTI (SI-RNTI) may be scrambled to the CRC. To indicate a random access response that is a response for transmission of a random access preamble of the UE, a random access-RNTI (RA-RNTI) may be scrambled to the CRC.

[29] FIG. 5 shows structure of an uplink subframe. Referring to FIG. 5, a UL subframe can be divided in a frequency domain into a control region and a data region. The control region is allocated with a physical uplink control channel (PUCCH) for carrying UL control information. The data region is allocated with a physical uplink shared channel (PUSCH) for carrying user data. When indicated by a higher layer, the UE may support a simultaneous transmission of the PUSCH and the PUCCH. The PUCCH for one UE is allocated to an RB pair in a subframe. RBs belonging to the RB pair occupy different subcarriers in respective two slots. This is called that the RB pair allocated to the PUCCH is frequency-hopped in a slot boundary. This is said that the pair of RBs allocated to the PUCCH is frequency-hopped at the slot boundary. The UE can obtain a frequency diversity gain by transmitting UL control information through different subcarriers according to time.

[30] UL control information transmitted on the PUCCH may include a HARQ ACK/NACK, a channel quality indicator (CQI) indicating the state of a DL channel, a scheduling request (SR), and the like. The PUSCH is mapped to a UL-SCH, a transport channel. UL data transmitted on the PUSCH may be a transport block, a data block for the UL-SCH transmitted during the TTI. The transport block may be user information. Or, the UL data may be multiplexed data. The multiplexed data may be data obtained by multiplexing the transport block for the UL-SCH and control information. For example, control information multiplexed to data may include a CQI, a precoding matrix indicator (PMI), an HARQ, a rank indicator (RI), or the like. Or the UL data may include only control information.

[31] A radio resource control (RRC) state indicates whether an RRC layer of the UE is logically connected to an RRC layer of the evolved universal terrestrial radio access network (E-UTRAN). The RRC state may be divided into two different states such as an RRC idle state (RRC_IDLE) and an RRC connected state (RRC_CONNECTED). In RRC_IDLE, the UE may receive broadcasts of system information and paging information while the UE specifies a discontinuous reception (DRX) configured by non-access stratum (NAS), and the UE has been allocated an identification (ID) which uniquely identifies the UE in a tracking area and may perform public land mobile network (PLMN) selection and cell re-selection. Also, in RRC_IDLE, no RRC context is stored in the eNB.

[32] In RRC_CONNECTED, the UE has an E-UTRAN RRC connection and a context in the E-UTRAN, such that transmitting and/or receiving data to/from the eNB becomes possible. Also, the UE can report channel quality information and feedback information to the eNB. In RRC_CONNECTED, the E-UTRAN knows the cell to which the UE belongs. Therefore, the network can transmit and/or receive data to/from UE, the network can control mobility (handover and inter-radio access technologies (RAT) cell change order to GSM EDGE radio access network (GERAN) with network assisted cell change (NACC)) of the UE, and the network can perform cell measurements for a neighboring cell.

[33] In RRC_IDLE, the UE specifies the paging DRX cycle. Specifically, the UE monitors a paging signal at a specific paging occasion of every UE specific paging DRX cycle. The paging occasion is a time interval during which a paging signal is transmitted. The UE has its own paging occasion. A paging message is transmitted over all cells belonging to the same tracking area. If the UE moves from one tracking area (TA) to another TA, the UE will send a tracking area update (TAU) message to the network to update its location.

[34] Discontinuous reception for paging is further described. The UE may use DRX in idle mode in order to reduce power consumption. One paging occasion (PO) is a subframe in which there may be P-RNTI transmitted on PDCCH addressing the paging message. One paging frame (PF) is one radio Frame, which may contain one or multiple PO(s). When DRX is used, the UE needs only to monitor one PO per DRX cycle.

[35] The PF and PO is determined by following equations using the DRX parameters provided in system Information. PF is given by Equation 1 below.

[36] <Equation 1>

[37] SFN mod T = (T div N)*(UE_ID mod N)

[38] Index i_s pointing to PO from subframe pattern is derived from Equation 2 below.

[39] <Equation 2>

[40] i_s = floor(UE_ID/N) mod Ns

[41] System information DRX parameters stored in the UE shall be updated locally in the UE whenever the DRX parameter values are changed in system information. If the UE has no international mobile subscriber identity (IMSI), for instance when making an emergency call without universal subscriber identity module (USIM), the UE shall use as default identity UE_ID = 0 in the PF and i_s equations above.

[42] The following parameters are used for the calculation of the PF and i_s, shown in Equation 1 and Equation 2.

[43] - T: DRX cycle of the UE. T is determined by the shortest of the UE specific DRX value, if allocated by upper layers, and a default DRX value broadcast in system information. If UE specific DRX is not configured by upper layers, the default value is applied.

[44] - nB: 4T, 2T, T, T/2, T/4, T/8, T/16, T/32

[45] - N: min(T, nB)

[46] - Ns: max(1, nB/T)

[47] - UE_ID: IMSI mod 1024.

[48] IMSI is given as sequence of digits of type Integer (0..9), and IMSI in the equations above shall be interpreted as a decimal integer number, where the first digit given in the sequence represents the highest order digit. For example, when IMSI = 12 (digit1=1, digit2=2), in the calculations, this shall be interpreted as the decimal integer "12", not "1x16+2 = 18".

[49] Table 1 shows paging subframe patterns for FDD.

[53] In the current LTE specification, all UEs shall support maximum 20MHz system bandwidth, which requires baseband processing capability to support 20MHz

bandwidth. To reduce hardware cost and battery power of the UE used for machine type communication (MTC), reducing bandwidth is a very attractive option. To enable narrow-band MTC UEs, the current LTE specification shall be changed to allow narrow-band UE category. If the serving cell has small system bandwidth (smaller than or equal to bandwidth that narrow-band UE can support), the UE can attach based on the current LTE specification.

[54] In normal MTC, it is expected that UL heavy traffic such as periodic reporting of sensor data is typical. To support a long-battery-life, it is also expected that a UE sleeps a long time and wakes up only for either event-triggered reporting or periodic reporting or sending keep-alive messages. When the UE wakes up, due to a rather long-time sleep, time/frequency tracking of the UE may be inaccurate. Thus, re-synchronization may be necessary. This is also true for UL transmission as well. Thus, transmitting necessary tracking signals such as cell-specific reference signal (CRS) is essential along with any DL data such as paging or wake-up signals. When the UE wakes up from paging or based on event/timer, before it transmits UL data, the UE also needs to transmit physical random access channel (PRACH)-like signals to align UL timing/frequency. To allow multiplexing of UEs, a mechanism to trigger periodic report based on paging may be considered. For example, the eNB may transmit paging to a set of UEs periodically which will be used for UL grants. Further, when a UE experiences limited coverage, it is also necessary to transmit repeated paging (paging re-transmission or repetition) for coverage enhancement (CE). In this case, paging occasion and paging frame definition for a MTC UE needs to be changed. Furthermore, how to repeat paging also need to be clarified.

[55] In order to solve the problem described above, a method for transmitting a paging for MTC UEs according to an embodiment of the present invention may be proposed. Hereinafter, all of a MTC UE, a low cost UE, a low end UE, a low complexity UE, a narrow(er) band UE, a small(er) band UE, or a new category UE may be used mixed with each other. Or, just UE may refer one of UEs described above. In the description below, a case where system bandwidth of available cells is larger than bandwidth that new category narrow-band UEs can support may be assumed. For the new category UE, it may be assumed that only one narrow-band is defined. In other words, all narrow-band UE shall support the same narrow bandwidth smaller than 20MHz. It may be assumed that the narrow bandwidth is larger than 1.4MHz (6 PRBs). However, the present invention may be applied to narrower bandwidth less than 1.4MHz as well (e.g. 200 kHz), without loss of generality. More generally, the present invention may apply to a case where the system has large bandwidth such as 160MHz, whereas the UE may support smaller bandwidth size such as 20MHz as well.

[56] FIG. 6 shows an overall paging timing to support coverage enhancement for MTC

UEs according to an embodiment of the present invention. Referring to FIG. 6, for MTC UEs in coverage enhancement mode, T_{MTC} may be defined in a predetermined value or signaled by SIB/master information block (MIB), which may contain the cycle duration of paging instance to MTC UEs in coverage enhancement mode. This is different from no coverage enhancement where paging frame can occur in every T where T is the default DRX cycle in RRC_IDLE broadcasted by SIB or minimum DRX cycle in RRC_CONNECTED. The cycle duration of paging instance may be defined as overall periodicity of MTC UE reporting such as for smart meter applications. T_{MTC} may be defined in consideration of both periodicity of wake-up or paging and the maximum coverage enhancement level that the network supports. If the network supports e.g. 15dB enhancement and thus may support up to 100 times of repetition of paging, one paging frame occasion for a MTC UE may be larger than 100 subframes. PF_{MTC} may define the number of subframes or the number of radio frames where one paging instance may require. PF_{MTC} may be defined based on the maximum coverage level that the network supports. Within a PF_{MTC}, a set of subframe/radio frames may be allocated for paging purpose in a predetermined or via higher layer signaling such as SIB.

[57] In terms of determining the location of paging/paging frame, the current function may be reused. Since the network may not know the coverage enhancement level that a UE may require, the network may transmit the maximum repetition that the network supports for every UE. Alternatively, the network may use previous coverage enhancement level that the specific UE has been configured/used (which was successful), and if the transmission fails (i.e. no feedback has been received from the UE), the network may increase the coverage enhancement level. However, given that paging may not occur so often particularly for MTC UEs in coverage enhancement mode, it is desirable to always use maximum coverage enhancement mode to support successful transmission. However, a MTC UE may stop monitoring/receiving repletion of paging once it succeeds the reception.

[58] Starting subframe of paging repetition according to an embodiment of the present invention is described. To determine the starting subframe of repeated paging, according to an embodiment of the present invention, paging may be transmitted without PDCCH with preconfigured modulation and coding scheme (MCS) and resource allocation. In this case, the starting position/subframe of the repeated paging may start at PF_{MTC} and the repetition may continue every PO_{MTC} opportunity (i.e. paging occasion configured not only for the given UE as well for other UEs) in each PF_{MTC}. Further, in order to indicate starting set of PF_{MTC} or set of PO_{MTC} where a UE may expect the repeated paging may start. In terms of determining PF_{MTC}, UE-specific or P-RNTI-based function, which is similar to the current function, may be used. In

this case, the first PO within a PF may be used as a starting subframe for the repeated paging transmission. In this case, to determine the paging location for a UE, the following function may be used. PF may be given by Equation 3. Further, PO_{MTC}=0.

[59] <Equation 3>

[60] SFN*M mod T*M = (T*M div N*M)*(UE_ID mod N)

[61] In Equation 3, the following parameters may be used.

[62] - T: Size of one paging cycle (e.g. the number of UEs or the number of P-RNTIs supported in one paging cycle), which is predetermined or higher layer signaled

[63] - M: The number of radio frames within one PF_{MTC}. For example, M=4 may mean that 40 subframes consist one PF_{MTC}.

[64] - nB: 4T, 2T, T, T/2, T/4, T/8, T/16, T/32

[65] - N: min(T, nB)

[66] - Ns: max(1, nB/T)

[67] - UE_ID: IMSI mod 1024.

[68] Alternatively, the starting position/subframe of the repeated paging may start at PF_{MTC}/PO_{MTC} and the repetition may continue in successive DL subframes. In this case, it is desirable that the size of PF_{MTC} is larger than the required number of subframes to transmit repeated/retransmitted paging. One example may be to set the size of PF_{MTC} = 2 * maximum number of repetition (e.g. 100) and PO_{MTC} may be placed only in first half of PF_{MTC} duration such that all UEs can be scheduled with the maximum repetition number within one PF_{MTC}. For this, PF_{MTC} may be determined as the same as the first approach, i.e. by Equation 3 described above. Paging occasion may be determined by Equation 4, which distributes UEs uniformly within one half of PF_{MTC}.

[69] <Equation 4>

[70] i_s = UE_ID mod M*10/2

[71] The set of subframes/radio frames used for paging repetition may be determined based on UE ID or P-RNTI. For example, one PF_{MTC} = PO_{MTC} size * number of UE IDs (or number of P-RNTIs), where the size of PO_{MTC} may be larger than the maximum repetition number for paging. In that case, the starting subframe of repetition may be the first subframe within a PO_{MTC}. This approach is similar to the first approach. The difference is that the paging occasion frame may be determined solely by UE ID or P-RNTI such as K = (UE_ID mod N), where K is the index of PF_{MTC} and N is the maximum number of UE IDs (or number of P-RNTIs) that the system supports.

[72] According to another embodiment of the present invention, paging may be transmitted with PDCCH. In this case, approaches described above for paging without PDCCH may be applied similarly. Once PDCCH is transmitted, in terms of PDSCH, the following options may be considered.

[73] - PDSCH repetition may start at K subframe (e.g. K = 1 or 2) after end of the

PDCCH repetition

[74] - Two separate PF_{MTC}/PO_{MTC} for PDCCH/PDSCH may be defined where the repetition of PDCCH/PDSCH occurs in each set respectively.

[75] - PDCCH may indicate a set of subframes where PDSCH are transmitted.

[76] - Other options used for repeating PDCCH and PDSCH may be also applicable to paging retransmission.

[77] Meanwhile, PDCCH for MTC UEs (hereinafter, M-PDCCH) is used to schedule paging transmission, paging occasion may be configured in consideration of repetition number or aligned with repetition number. The network may configure at least one of the followings via SIB.

[78] - Periodicity of M-PDCCH (the largest repetition number of M-PDCCH): It is generally desirable to have multiple of radio frame for this periodicity, and also, it is desirable that the maximum number of system frame number (SFN) can divide this repetition number.

[79] - (optionally) offset indicating when the period starts

[80] - Repetition number of M-PDCCH

[81] For M-PDCCH used for paging, the repetition may occur only valid subframe configured by SIB1. Further, a set of paging subframe where M-PDCCH and/or paging PDSCH may be transmitted. In terms of paging occasion configuration, the following may be considered. PF may be given by Equation 5.

[82] <Equation 5>

[83] SFN*M mod T*M = (T*M div N*M)*(UE_ID mod floor (N/P)*P)

[84] In Equation 5, the following parameters may be used.

[85] - T: Size of one paging cycle (e.g. the number of UEs or the number of P-RNTIs supported in one paging cycle), which is predetermined or higher layer signaled

[86] - M: The number of radio frames within one PF_{MTC}. For example, M=4 may mean that 40 subframes consist one PF_{MTC}.

[87] - nB: 4T, 2T, T, T/2, T/4, T/8, T/16, T/32

[88] - N: min(T, nB)

[89] - Ns: max(1, nB/T)

[90] - UE_ID: IMSI mod 1024.

[91] - P: the periodicity in radio frame unit.

[92] By this way, paging occasion may be aligned with the starting subframes of M-PDCCH monitoring for paging transmission. Other configuration may be also considered which aligns the starting subframe of M-PDCCH with paging occasion. If paging occasion and starting subframe of M-PDCCH is not aligned, a UE may start monitoring of M-PDCCH monitoring occasions within paging occasion.

[93] In addition to the above configuration, paging duration may be configured in SIB via

some signaling. For example, the paging duration may be multiple of M-PDCCH monitoring window. If a UE is monitoring multiple repetition levels, it will be based on the largest repetition number. Or, separate configuration per each repetition level may be also considered. Further, for PDSCH where paging is transmitted, the PDSH may be scheduled outside of paging occasion. The starting offset of PDSCH may be signaled from M-PDCCH or via SIB.

[94] Handling of dynamic/variable CE/repetition level according to an embodiment of the present invention is described. For a MTC UE in coverage enhancement mode, it is likely that CE/repetition level for paging message may change even though the UE may be static due to channel/environments change. Since paging generally occurs for a UE in RRC_IDLE, tight management of CE/repetition level does not seem to be feasible or feedback from UE regarding CE/repetition level may not be easily assumed. In this case, overall change of CE/repetition level may be performed as described below.

[95] If it is assumed that a mobility management entity (MME) may increase CE/ repetition level in case of retransmission, since the UE may not know whether there is a retransmission or not, the UE may have to monitor multiple resource candidates where paging can be transmitted at one time. Or, multiple resource candidates may be configured such that a UE may monitor different resources with different repetition level at each time. For example, at each paging occasion, instead of a UE monitoring one instance of paging, the UE may monitor multiple paging instances with potentially different repetition level. Specifically, since the UE does not know the CE/repetition level, the UE may monitor paging instances, from the minimum CE/repetition level to the maximum CE/repetition level.

[96] FIG. 7 shows increase of coverage enhancement levels or repetition levels according to an embodiment of the present invention. Referring to FIG. 7, at first, the MME initiates paging with CE level i. The eNB transmits the paging message to the UE with CE level i. However, in spite of repetition, the UE cannot receive the paging message. Accordingly, the MME increases CE level. The eNB transmits the paging message to the UE with CE level i+1. In this case, the UE can receive the paging message via repetition, and can transmit a connection request to the eNB.

[97] As one approach, in order to transmit the paging message with different repetition levels, the paging message may be transmitted by utilizing a control channel format, such as PDCCH or enhanced PDCCH (EPDCCH) or a new control channel format, which allows multiplexing of different aggregation levels where different aggregation levels may be mapped to different CE/repetition levels. In this example, the number of repeated subframes may be fixed where different aggregation levels are used for different CE/repetition levels. In this case, to cover multiple CE/repetition levels, more

aggregation levels may be used, or different aggregation levels may be used. For example, instead that aggregation levels of 1, 2, 4 and 8 is used, aggregation levels of 1, 4, 16, 256, and so on, may be used. The number of repeated PDSCH may be indicated by PDCCH or implicitly mapped to the aggregation level used for control channel or CE/repetition level used for control channel.

[98] As another approach, repetition/CE level may be mapped to a subband or frequency location such that control channel may indirectly indicate CE/repetition level of PDSCH depending on resource allocation or subband allocation. Another approach is to configure the maximum number of repetitions based on the maximum CE/repetition level that the system supports or system supports for the paging, and the network may transmit the paging message with smaller number of repetition if the CE/repetition level used for paging is smaller than the maximum CE/repetition level. In this case, a UE needs to blindly search the end of repetition (e.g. by detecting discontinuous transmission (DTX), etc.). CE/repetition level change/determination mechanisms described here may be applied to other channels such unicast PDSCH or random access response (RAR).

[99] Alternatively, multiple PO and/or PF may be configure for different CE/repetition levels. For example, m different number of PF_{MTC} and/or PO_{MTC} may be configured such that in one instance of paging, the UE may need to monitor multiple occasions with different CE/repetition levels. However, this approach leads higher latency to be able to receive paging with the appropriate CE/repetition level.

[100] FIG. 8 shows a method for monitoring a paging according to an embodiment of the present invention. In step S100, the UE monitors a first paging instance with a first repetition level in a paging occasion. Paging in the first paging instance with the first paging repetition level may be failed. In step S110, the UE monitors a second paging instance with a second repetition level, which is higher than the first repetition level, in the paging occasion. Paging in the second paging instance with the second paging repetition level may be succeed. The first repetition level and the second repetition level may be provided by the MME to the eNB. In this case, the UE may transmit a connection request message to the eNB. The UE may be a low cost machine-type communication UE.

[101] The first repetition level may correspond to a minimum repetition level. The second repetition level may correspond to a maximum repetition level. Monitoring the first paging instance or the second paging instance may comprise monitoring transmission of a paging message from an eNB in the first paging instance or the second paging instance. The paging message may be transmitted with a first aggregation level in the first paging instance, and the paging message may be transmitted with a second aggregation level in the second paging instance. The first repetition level may be mapped

to the first aggregation level, and the second repetition level may be mapped to the second aggregation level.

[102] FIG. 9 shows a wireless communication system to implement an embodiment of the present invention.

[103] An eNB 800 may include a processor 810, a memory 820 and a transceiver 830. The processor 810 may be configured to implement proposed functions, procedures and/or methods described in this description. Layers of the radio interface protocol may be implemented in the processor 810. The memory 820 is operatively coupled with the processor 810 and stores a variety of information to operate the processor 810. The transceiver 830 is operatively coupled with the processor 810, and transmits and/or receives a radio signal.

[104] A MTC UE 900 may include a processor 910, a memory 920 and a transceiver 930. The processor 910 may be configured to implement proposed functions, procedures and/or methods described in this description. Layers of the radio interface protocol may be implemented in the processor 910. The memory 920 is operatively coupled with the processor 910 and stores a variety of information to operate the processor 910. The transceiver 930 is operatively coupled with the processor 910, and transmits and/or receives a radio signal.

[105] The processors 810, 910 may include application-specific integrated circuit (ASIC), other chipset, logic circuit and/or data processing device. The memories 820, 920 may include read-only memory (ROM), random access memory (RAM), flash memory, memory card, storage medium and/or other storage device. The transceivers 830, 930 may include baseband circuitry to process radio frequency signals. When the embodiments are implemented in software, the techniques described herein can be implemented with modules (e.g., procedures, functions, and so on) that perform the functions described herein. The modules can be stored in memories 820, 920 and executed by processors 810, 910. The memories 820, 920 can be implemented within the processors 810, 910 or external to the processors 810, 910 in which case those can be communicatively coupled to the processors 810, 910 via various means as is known in the art.

[106] In view of the exemplary systems described herein, methodologies that may be implemented in accordance with the disclosed subject matter have been described with reference to several flow diagrams. While for purposed of simplicity, the methodologies are shown and described as a series of steps or blocks, it is to be understood and appreciated that the claimed subject matter is not limited by the order of the steps or blocks, as some steps may occur in different orders or concurrently with other steps from what is depicted and described herein. Moreover, one skilled in the art would understand that the steps illustrated in the flow diagram are not exclusive and

other steps may be included or one or more of the steps in the example flow diagram may be deleted without affecting the scope and spirit of the present disclosure.

Claims

[Claim 1] A method for monitoring, by a user equipment (UE), a paging in a wireless communication system, the method comprising:
monitoring a first paging instance with a first repetition level in a paging occasion; and
monitoring a second paging instance with a second repetition level, which is higher than the first repetition level, in the paging occasion.

[Claim 2] The method of claim 1, wherein paging in the first paging instance with the first paging repetition level is failed.

[Claim 3] The method of claim 1, wherein paging in the second paging instance with the second paging repetition level is succeed.

[Claim 4] The method of claim 3, further comprising transmitting a connection request message to an evolved NodeB (eNB).

[Claim 5] The method of claim 1, wherein the first repetition level or the second repetition level is provided by a mobility management entity (MME) to an eNB.

[Claim 6] The method of claim 1, wherein the first repetition level corresponds to a minimum repetition level.

[Claim 7] The method of claim 1, wherein the second repetition level corresponds to a maximum repetition level.

[Claim 8] The method of claim 1, wherein monitoring the first paging instance or the second paging instance comprises monitoring transmission of a paging message from an eNB in the first paging instance or the second paging instance.

[Claim 9] The method of claim 8, wherein the paging message is transmitted with a first aggregation level in the first paging instance, and
wherein the paging message is transmitted with a second aggregation level in the second paging instance.

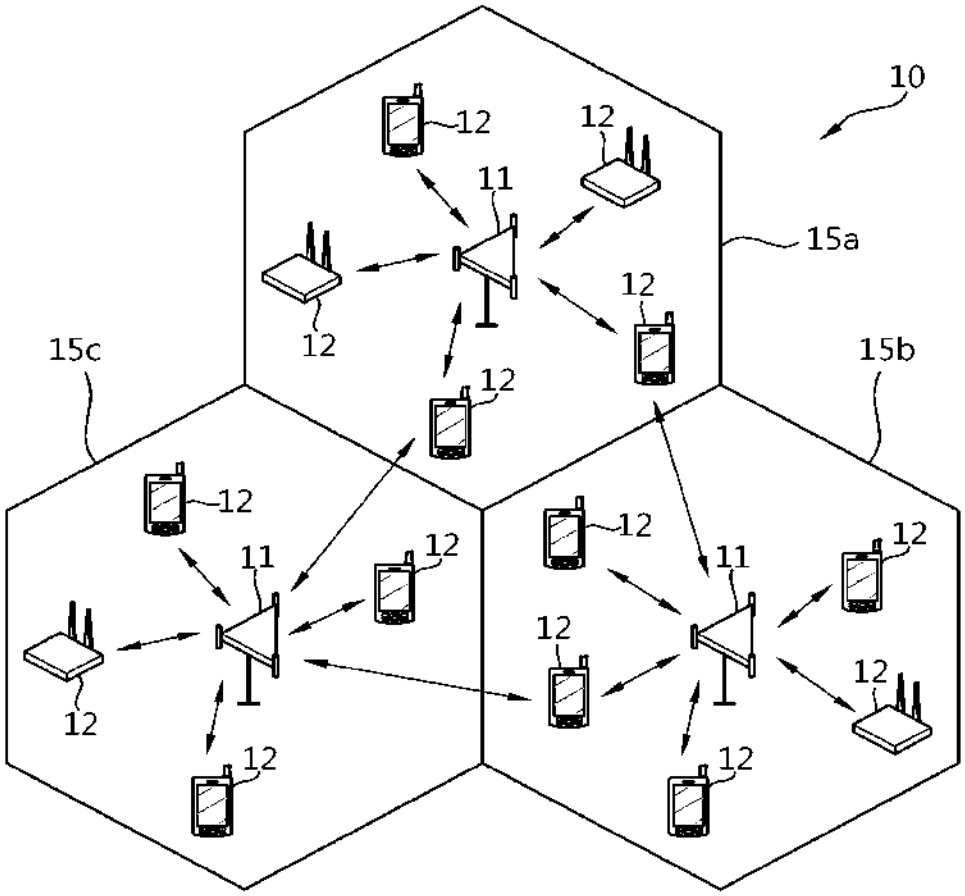
[Claim 10] The method of claim 9, wherein the first repetition level is mapped to the first aggregation level, and
wherein the second repetition level is mapped to the second aggregation level.

[Claim 11] The method of claim 1, wherein the UE is a low cost machine-type communication UE.

[Claim 12] A user equipment (UE) comprising:
a memory;
a transceiver; and

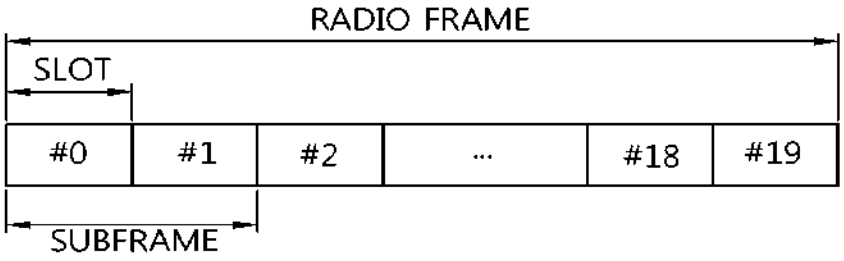
a processor coupled to the memory and the transceiver, and configured to:

monitor a first paging instance with a first repetition level; and



monitor a second paging instance with a second repetition level which is higher than the first repetition level.

[Claim 13] The UE of claim 12, wherein paging in the first paging instance with the first paging repetition level is failed.



[Claim 14] The UE of claim 12, wherein paging in the second paging instance with the second paging repetition level is succeed.

[Claim 15] The UE of claim 12, wherein the first repetition level or the second repetition level is provided by a mobility management entity (MME) to an eNB.

(54) Title: SIGNAL TRANSMISSION METHOD AND ASSOCIATED DEVICE

(54) 发明名称 : 一种信号发送方法及相关设备

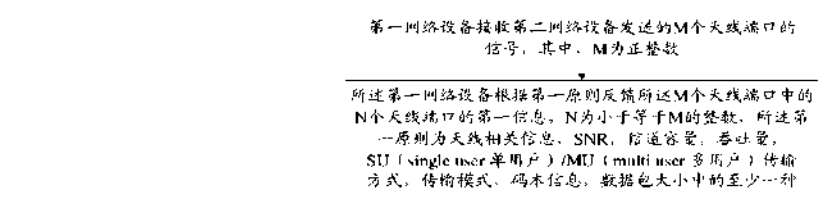

图 1 / Fig. 1

S101 A FIRST NETWORK DEVICE RECEIVES SIGNALS OF M ANTENNA PORTS SENT BY A SECOND NETWORK DEVICE, WHERE M IS A POSITIVE INTEGER

S102 THE FIRST NETWORK DEVICE FEEDS BACK FIRST INFORMATION OF N ANTENNA PORTS IN THE M ANTENNA PORTS ACCORDING TO A FIRST RULE, WHERE N IS AN INTEGER SMALLER THAN OR EQUAL TO M, AND THE FIRST RULE IS AT LEAST ONE OF ANTENNA ASSOCIATED INFORMATION, SNR, CHANNEL CAPACITY, THROUGHPUT, AN SU (SINGLE-USER)/MU (MULTI-USER) TRANSMISSION MANNER, A TRANSMISSION MODE, CODEBOOK INFORMATION AND A DATA PACKET SIZE

(57) Abstract: A signal transmission method and an associated device. The method comprises: a first network device receives signals of M antenna ports sent by a second network device, where M is a positive integer; the first network device feeds back first information of N antenna ports in the M antenna ports according to a first rule, where N is an integer smaller than or equal to M, and the first rule is at least one of antenna associated information, SNR, channel capacity, throughput, an SU (single-user)/MU (multi-user) transmission manner, a transmission mode, codebook information and a data packet size. The present invention performs the optimum antenna configuration according to at least one of antenna associated information, SNR, channel capacity, throughput, an SU/MU transmission manner, a transmission mode, codebook information or a data packet size and carries out more effective antenna selection.

(57) 摘要: 一种信号发送方法及相关设备。其中的方法包括：第一网络设备接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数；所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU(single user 单用户)/MU(multi user 多用户)传输方式，传输模式，码本信息，数据包大小中的至少一种。本发明实施例通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，进行了更有效的天线选择。

一种信号发送方法及相关设备

技术领域

本发明涉及通信技术领域，尤其涉及一种信号发送方法及相关设备。

背景技术

通过发射波束赋形(Beam Forming，BF)/预编码和接收合并，多输入多输出(Multiple-Input Multiple-Output，MIMO)无线系统可以得到分集和阵列增益。利用 BF 或者预编码的典型系统通常可以表示为：

$$\mathbf{y}=\mathbf{HVs}+\mathbf{n}$$

其中 $\mathbf{y}$ 是接收信号矢量，$\mathbf{H}$ 是信道矩阵，$\mathbf{V}$ 是预编码矩阵，$\mathbf{s}$ 是发射的符号矢量，$\mathbf{n}$ 是测量噪声。最优预编码通常需要发射机完全已知信道状态信息（Channel State Information，CSI）。常用的方法是用户设备对瞬时 CSI 进行量化并反馈给基站设备。现有 LTE R8 系统反馈的 CSI 信息包括秩指示（RI）、预编码矩阵指示（PMI）和信道质量指示（CQI）信息等，其中 RI 和 PMI 分别指示使用的层数和预编码矩阵。

现在为了进一步提高小区用户总吞吐率和平均吞吐率，使用动态三维(3 Dimensions，3D)波束赋形技术等 3D 多天线技术。但在现有蜂窝系统中，基站发射端波束仅能在水平维进行调整，而垂直维对每个用户都是固定的下倾角，因此各种波束赋形/预编码技术等均是基于水平维信道信息的。事实上，由于信道是 3D 的，固定下倾角的方法往往不能使系统的吞吐量达到最优。因此在 3D 天线可以通过不同的驱动网络形成对应于不同下倾角的天线端口，即不同的天线端口的天线方向图不同。同时，随着高频技术的演进，将会引入 massive MIMO 技术，massive MIMO 采用大规模天线，不同的天线间的信道特性不会完全相同。

综上所述，3D 多天线，或者大规模天线技术中需要有更有效的天线选择方法。

发明内容

本发明实施例提供一种信号发送方法及相关设备，以进行更有效的天线选择。

第一方面，提供了一种信号发送方法，包括:

第一网络设备接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

在第一种可能的实现方式中，所述第一准则为天线相关信息;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

结合第一方面的第一种可能的实现方式，在第二种可能的实现方式中，所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，具体为:

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面，在第三种可能的实现方式中，所述第一准则为信噪比 SNR;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面，在第四种可能的实现方式中，第一准则为信道容量;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天

线端口的第一信息并进行反馈。

结合第一方面，在第五种可能的实现方式中，第一准则为吞吐量；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面，在第六种可能的实现方式中，第一准则为 SU/MU 传输方式；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择 MU 传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

结合第一方面，在第七种可能的实现方式中，第一准则为传输模式；所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

结合第一方面，在第八种可能的实现方式中，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面，在第九种可能的实现方式中，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面，在第十种可能的实现方式中，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面，在第十一种可能的实现方式中，所述第一准则为数据包信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择传输第一数据包传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第一方面或第一方面的第一种可能的实现方式或第一方面的第二种可能的实现方式或第一方面的第三种可能的实现方式或第一方面的第四种可能的实现方式或第一方面的第五种可能的实现方式或第一方面的第六种可能的实现方式或第一方面的第七种可能的实现方式或第一方面的第八种可能的

实现方式或第一方面的第九种可能的实现方式或第一方面的第十种可能的实现方式或第一方面的第十一种可能的实现方式，在第十二种可能的实现方式中，所述第一准则或者所述第一阈值，第二阈值，第三阈值和第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

结合第一方面或第一方面的第一种可能的实现方式或第一方面的第二种可能的实现方式或第一方面的第三种可能的实现方式或第一方面的第四种可能的实现方式或第一方面的第五种可能的实现方式或第一方面的第六种可能的实现方式或第一方面的第七种可能的实现方式或第一方面的第八种可能的实现方式或第一方面的第九种可能的实现方式或第一方面的第十种可能的实现方式或第一方面的第十一种可能的实现方式或第一方面的第十二种可能的实现方式，在第十三种可能的实现方式中，所述 M 个天线端口对应于 X 个信道状态信息处理进程 CSI process，N 个天线端口对应于所述 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。

结合第一方面或第一方面的第一种可能的实现方式或第一方面的第二种可能的实现方式或第一方面的第三种可能的实现方式或第一方面的第四种可能的实现方式或第一方面的第五种可能的实现方式或第一方面的第六种可能的实现方式或第一方面的第七种可能的实现方式或第一方面的第八种可能的实现方式或第一方面的第九种可能的实现方式或第一方面的第十种可能的实现方式或第一方面的第十一种可能的实现方式或第一方面的第十二种可能的实现方式或第一方面的第十三种可能的实现方式，在第十四种可能的实现方式中，所述第一信息包括天线相关信息，或者所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

第二方面，提供了一种信号发送方法，包括:

第二网络设备向第一网络设备发送 M 个天线端口的信号，其中，M 为正整数;

所述第二网络设备接收所述第一网络设备根据第一准则反馈的所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少

一种。

在第一种可能的实现方式中，所述第一信息包括天线相关信息；

所述方法，还包括：

所述第二网络设备根据所述天线相关信息确定所述 N 个天线端口为所选择的天线端口。

结合第二方面，在第二种可能的实现方式中，所述第一信息包括所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

结合第二方面或第二方面的第一种可能的实现方式或第二方面的第二种可能的实现方式，在第三种可能的实现方式中，所述第二网络设备通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值或者第四阈值。

第三方面，提供了一种第一网络设备，包括：

接收单元，用于接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数；

反馈单元，用于根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

在第一种可能的实现方式中，所述第一准则为天线相关信息；

所述反馈单元具体用于：

根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

结合第三方面的第一种可能的实现方式，在第二种可能的实现方式中，所述反馈单元执行所述根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，的步骤，具体为：

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第三种可能的实现方式中，所述第一准则为信噪比 SNR;

所述反馈单元具体用于:

在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第四种可能的实现方式中，第一准则为信道容量;

所述反馈单元具体用于:

在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第五种可能的实现方式中，第一准则为吞吐量;

所述反馈单元具体用于:

在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第六种可能的实现方式中，第一准则为 SU/MU 传输方式;

所述反馈单元具体用于:

在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择 MU 传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

结合第三方面，在第七种可能的实现方式中，第一准则为传输模式;

所述反馈单元具体用于:

在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端

口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

结合第三方面，在第八种可能的实现方式中，所述第一准则为码本信息；

所述反馈单元具体用于：

在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第九种可能的实现方式中，所述第一准则为码本信息；

所述反馈单元具体用于：

在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第十种可能的实现方式中，所述第一准则为码本信息；

所述反馈单元具体用于：

在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面，在第十一种可能的实现方式中，所述第一准则为数据包信息；

所述反馈单元具体用于：

在 M 个天线端口中选择传输第一数据包传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第三方面或第三方面的第一种可能的实现方式或第三方面的第二种可能的实现方式或第三方面的第三种可能的实现方式或第三方面的第四种可能的实现方式或第三方面的第五种可能的实现方式或第三方面的第六种可能

的实现方式或第三方面的第七种可能的实现方式或第三方面的第八种可能的实现方式或第三方面的第九种可能的实现方式或第三方面的第十种可能的实现方式或第三方面的第十一种可能的实现方式，在第十二种可能的实现方式中，所述第一准则或者所述第一阈值，第二阈值，第三阈值和第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

结合第三方面或第三方面的第一种可能的实现方式或第三方面的第二种可能的实现方式或第三方面的第三种可能的实现方式或第三方面的第四种可能的实现方式或第三方面的第五种可能的实现方式或第三方面的第六种可能的实现方式或第三方面的第七种可能的实现方式或第三方面的第八种可能的实现方式或第三方面的第九种可能的实现方式或第三方面的第十种可能的实现方式或第三方面的第十一种可能的实现方式或第三方面的第十二种可能的实现方式，在第十三种可能的实现方式中，所述 M 个天线端口对应于 X 个信道状态信息处理进程 CSI process，N 个天线端口对应于所述 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。

结合第三方面或第三方面的第一种可能的实现方式或第三方面的第二种可能的实现方式或第三方面的第三种可能的实现方式或第三方面的第四种可能的实现方式或第三方面的第五种可能的实现方式或第三方面的第六种可能的实现方式或第三方面的第七种可能的实现方式或第三方面的第八种可能的实现方式或第三方面的第九种可能的实现方式或第三方面的第十种可能的实现方式或第三方面的第十一种可能的实现方式或第三方面的第十二种可能的实现方式或第三方面的第十三种可能的实现方式，在第十四种可能的实现方式中，所述第一信息包括天线相关信息，或者所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

第四方面，提供了一种第二网络设备，包括:

发送单元，用于向第一网络设备发送 M 个天线端口的信号，其中，M 为正整数;

接收单元，用于接收所述第一网络设备根据第一准则反馈的所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU

（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

在第一种可能的实现方式中，所述第一信息包括天线相关信息；

所述第二网络设备，还包括：

确定单元，用于根据所述天线相关信息确定所述 N 个天线端口为所选择的天线端口。

结合第四方面，在第二种可能的实现方式中，所述第一信息包括所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

结合第四方面或第四方面的第一种可能的实现方式或第四方面的第二种可能的实现方式，在第五种可能的实现方式中，所述发送单元还用于通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值或者第四阈值。

第五方面，提供了一种第一网络设备，包括：接收器和发送器；

接收器，用于接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数；

发送器，用于根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

在第一种可能的实现方式中，所述第一准则为天线相关信息；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

结合第五方面的第一种可能的实现方式，在第二种可能的实现方式中，所述发送器执行所述根据测量的所述 M 个天线端口的天线相关信息，进行小区选择的步骤，具体为：

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一

阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第三种可能的实现方式中，所述第一准则为信噪比 SNR;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第四种可能的实现方式中，第一准则为信道容量;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第五种可能的实现方式中，第一准则为吞吐量;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

所述第一网络设备在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第六种可能的实现方式中，第一准则为 SU/MU 传输方式;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择 MU 传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

结合第五方面，在第七种可能的实现方式中，第一准则为传输模式;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

结合第五方面，在第八种可能的实现方式中，所述第一准则为码本信息;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第九种可能的实现方式中，所述第一准则为码本信息;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第十种可能的实现方式中，所述第一准则为码本信息;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面，在第十一种可能的实现方式中，所述第一准则为数据包信息;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择传输第一数据包传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，例如一定误码率的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

结合第五方面或第五方面的第一种可能的实现方式或第五方面的第二种可能的实现方式或第五方面的第三种可能的实现方式或第五方面的第四种可能的实现方式或第五方面的第五种可能的实现方式或第五方面的第六种可能的实现方式或第五方面的第七种可能的实现方式或第五方面的第八种可能的实现方式或第五方面的第九种可能的实现方式或第五方面的第十种可能的实现方式或第五方面的第十一种可能的实现方式，在第十二种可能的实现方式中，所述第一准则或者所述第一阈值，第二阈值，第三阈值和第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

结合第五方面或第五方面的第一种可能的实现方式或第五方面的第二种可能的实现方式或第五方面的第三种可能的实现方式或第五方面的第四种可能的实现方式或第五方面的第五种可能的实现方式或第五方面的第六种可能的实现方式或第五方面的第七种可能的实现方式或第五方面的第八种可能的实现方式或第五方面的第九种可能的实现方式或第五方面的第十种可能的实现方式或第五方面的第十一种可能的实现方式或第五方面的第十二种可能的实现方式，在第十三种可能的实现方式中，所述 M 个天线端口对应于 X 个信道状态信息处理进程 CSI process，N 个天线端口对应于所述 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。

结合第五方面或第五方面的第一种可能的实现方式或第五方面的第二种可能的实现方式或第五方面的第三种可能的实现方式或第五方面的第四种可能的实现方式或第五方面的第五种可能的实现方式或第五方面的第六种可能的实现方式或第五方面的第七种可能的实现方式或第五方面的第八种可能的

实现方式或第五方面的第九种可能的实现方式或第五方面的第十种可能的实现方式或第五方面的第十一种可能的实现方式或第五方面的第十二种可能的实现方式或第五方面的第十三种可能的实现方式，在第十四种可能的实现方式中，所述第一信息包括天线相关信息，或者所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

第六方面，提供了一种第二网络设备，包括：发送器和接收器；

发送器，用于向第一网络设备发送 M 个天线端口的信号，其中，M 为正整数；

接收器，用于接收所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

在第一种可能的实现方式中，所述第一信息包括天线相关信息；

所述第二网络设备，还包括：控制器；

控制器，用于根据所述天线相关信息确定所述 N 个天线端口为所选择的天线端口。

结合第六方面，在第二种可能的实现方式中，所述第一信息包括所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

结合第六方面或第六方面的第一种可能的实现方式或第六方面的第二种可能的实现方式，在第三种可能的实现方式中，所述发送器还用于通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值或者第四阈值。

可见，根据本发明实施例提供的一种信号发送方法及相关设备，通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，进行了更有效的天线选择。

附图说明

为了更清楚地说明本发明实施例或现有技术中的技术方案，下面将对实施例中所需要使用的附图作简单地介绍，显而易见地，下面描述中的附图仅仅是本发明的一些实施例，对于本领域普通技术人员来讲，在不付出创造性劳动的前提下，还可以根据这些附图获得其他的附图。

图 1 为本发明实施例提供的一种信号发送方法的流程图；

图 2 为示例的有源天线阵列中的多个天线配置示意图；

图 3 为本发明实施例提供的另一种信号发送方法的流程图；

图 4 为本发明实施例提供的又一种信号发送方法的流程图；

图 5 为本发明实施例提供的一种第一网络设备的结构示意图；

图 6 为本发明实施例提供的一种第二网络设备的结构示意图；

图 7 为本发明实施例提供的另一种第二网络设备的结构示意图；

图 8 为本发明实施例提供的另一种第一网络设备的结构示意图；

图 9 为本发明实施例提供的又一种第二网络设备的结构示意图；

图 10 为本发明实施例提供的又一种第二网络设备的结构示意图。

具体实施方式

下面将结合本发明实施例中的附图，对本发明实施例中的技术方案进行清楚、完整地描述，显然，所描述的实施例仅仅是本发明一部分实施例，而不是全部的实施例。基于本发明中的实施例，本领域普通技术人员在没有作出创造性劳动前提下所获得的所有其他实施例，都属于本发明保护的范围。

请参阅图 1，为本发明实施例提供的一种信号发送方法的流程图，该方法包括以下步骤：

步骤 S101，第一网络设备接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数。

在进行天线配置时，第二网络设备给第一网络设备发送 M 个天线端口的配置信息，并将 M 个天线端口的信号发送给第一网络设备，第一网络设备根据配置信息接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数，在本实施例中，第一网络设备可以是用户设备(User Equipment，UE)，第二网络设备可以是基站；或者第一网络设备可以是用户设备，第二网络设备可以是用户设备；或者第一网络设备可以是基站，第二网络设备可以是基站。

所述的基站可以是宏站，低功率节点 pico 或者射频拉远单元 RRH。

M 个天线端口的配置信息包括天线端口的图案，即天线端口的时频资源的位置、天线端口信号的发送周期、功率等信息。

第二网络设备可以只发送一个配置信息给第一网络设备，该配置信息是 M 个天线端口的配置信息，或者将 M 个天线端口分成多个组，以多个配置信息的形式发送给第一网络设备，每个配置信息对应其中一个天线端口组的配置。

步骤 S102，所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

第一网络设备需根据一定的准则从 M 个天线端口中选择 N 个天线端口，并将选择的 N 个天线端口的第一信息通知第二网络设备，在这里，第一信息为 N 个天线端口对应的信道状态信息 CSI 或者 N 个天线端口对应的索引信息；或者将 N 个天线端口的第一信息发送给第二网络设备，由第二网络设备确定该 N 个天线端口，在这里，第一信息为天线相关信息。

下面通过具体的实施方式介绍如何根据各种第一准则反馈 M 个天线端口中的 N 个天线端口的第一信息：

作为一种实施方式，所述第一准则为天线相关信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

现有技术中，进行小区选择仅考虑根据接收信号功率信息例如 RSRP，RSSI，RSRQ 进行选择，本实施例中，还考虑天线相关性进行小区选择，使得用户能根据自己的业务更全面的考虑小区或者传输节点的选择。

具体实现中，所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，具体为：

例如 M=10，对应 5 个小区，每个小区有 2 个天线，小区 1 对应 port0，port1，

小区 1 对应 port2，port3，小区 1 对应 port4，port5，小区 1 对应 port6，port7，小区 1 对应 port8，port9;

UE 测量和这 5 个小区的分别对应的 5 组天线端口，发现小区 1 对应的 port0,1 的接收信号功率最强，例如 RSRP1>RSRP2>RSRP3>RSRP4>RSRP5，RSRP1 代表小区 1 对应的接收信号功率，RSRP2 代表小区 2 对应的接收信号功率，RSRPn 代表小区 n 对应的接收信号功率。但是如果假设第一准则是天线相关信息，并且要求天线相关信息越大越好，则定义天线相关系数为 Cor，例如，小区 1 的天线相关系数 Cor1 为 port0 和 port1 的天线相关性，可以采用信道估计获得 port0 对应的信道系数 H0，port1 对应的信道系数 H1，并计算 H0，H1 的相关来获得 Cor1，例如相关矩阵可以由 $H=[H_0 \quad H_1]$，$R=H^{H}H$ 获得；或者根据 $R_{ik}=\frac{1}{2\Delta}\int_{\theta-\Delta}^{\theta+\Delta}\exp[jz(i-k)\sin\beta]d\beta$ 获得。

其中 i，k 分别为第 i 和第 k 个天线，Δ为角度扩展。

同样方法得到 Cor2，Cor3，Cor4，Cor5，Corn 代表小区 n 对应的天线相关系数。

并且 Cor2> Cor1> Cor3> Cor4> Cor5，则虽然小区 1 的接收信号功率最强，但是综合考虑信号功率和天线相关性，小区 2 最终被 UE 选择，并且驻留在小区 2。

这里第一准则不限定于天线相关性，还可以是 SU/MU,信号传输模式等，并且第一准则可以为预定义的，或者基站广播或者 UE 特定的信令通知。

具体地，所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，具体为：所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

即将 M 个天线端口的相关矩阵或相关系数与设定阈值进行比较，选择相关矩阵或相关系数大于等于或小于等于设定阈值的 N 个天线端口，得到 N 个天线端口对应的信道状态信息(Channel State Singal，CSI)或 N 个天线端口的索引信息，并将这 N 个天线端口对应的 CSI 或 N 个天线端口对应的索引信息通知第二网络设备，以使第二网络设备在该 N 个天线端口给第一网络设备发送数据。

作为另一种实施方式，所述第一准则为信噪比 SNR;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

例如，基站配置给 UE M 个天线端口，如图 2 示例的另一个天线阵列中的多个天线示意图，M=88，UE 在 M 个端口中遍历所有的 N=1 到 N=88 的天线端口组合，对于每个 N 的取值，需要遍历的组合数为 c，例如对于 N=4，组合有组合 1 为 a11，a12，a13，a14，组合 2 为 a12，a13，a14， a15，组合 3 为，a13，a14，a15，a16，组合 4 为 a14，a15，a16，a17，组合 5 为 a15，a16，a17，a18，组合 6 为 b11，b12，b13，b14，...对于每个组合，例如组合 1 a11，a12，a13，a14，UE 通过 a11，a12，a13，a14 得到信道 $H_{N,1}$，然后遍历所有的预编码矩阵 w_i，得到信噪比:

$$SNR_{N,\ m,\ i}=\frac{\left|H_{n,m}W_i\right|^2}{\sigma^2}$$

其中 $H_{N,\ m}$ 表示 N 个天线端口组合情况下的第 m 个配置，Wi 表示第 i 个预编码矩阵，σ^2 为噪声;

遍历所有的 N 端口组合情况下的所有 SNR,找到最大的，例如 max（$SNR_{N,\ m,\ i}, N=4, 1\le m\le C_M^4, 1\le i\le X_4$）=5dB，$X_4$ 表示 N=4 的情况下的预编码矩阵的个数。对于 N=5，采用上述同样的方法进行遍历，max（$SNR_{N,\ m,\ i}, N=5, 1\le m\le C_M^5, 1\le i\le X_5$）=7dB，如果基站通知 UE 天线选择的第一准则为 SNR 要大于等于 6dB 的最少数目的天线，则 N=5 恰巧可以到 6dB，并且是达到 6dB 所需要的天线数目最少的，。因此 UE 可以将 N=5 的达到 7dB 的天线组合的标号，例如，a11，b12，c14，d11，对应的索引反馈给基站。采用 N>5,得到的信噪比会比 N=5 更高，但是对于某些信道，只需达到一定的 SNR 性能要求即可，无需更大的 SNR，采用更多的天线，会导致基站浪费发射功率。

作为又一种实施方式，第一准则为信道容量;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

由于信道容量 C=Blog2(1+SNR)，本实施方式中，根据信道容量进行天线端口的选择的过程与上面实施方式中根据 SNR 进行天线端口的选择的过程类似，在此不再赘述。

作为又一种实施方式，第一准则为吞吐量；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

同样地，本实施方式中，根据吞吐量进行天线端口的选择的过程与上面实施方式中根据 SNR 或信道容量进行天线端口的选择的过程类似，在此不再赘述。

作为又一种实施方式，第一准则为 SU/MU 传输方式；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择 MU 传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

在本实施方式中，例如，基站配置 UE 按照 SU 传输最优的方式选择天线，则 UE 遍历所有天线，根据使得 UE 自己的性能达到最优的方式选择天线，例

如选择了天线 a11，b13，g15，h18，则将 a11，b13，g15，h18 的天线索引信息上报给基站。

又例如，基站配置 UE1 按照 MU 配对最优的方式选择天线，基站可以将配对用户的信息，例如与 UE1 配对的用户 UE2，UE3 的信息，包括 UE2 的，UE3 的天线信息通知给 UE1，UE1 根据使得配对后的所有用户的总的性能最优的方式选择天线，例如选择天线 c13，d12，e11，f18，将其对应的天线索引信息通知给基站。

也可以同时反馈根据 SU 传输最优的一组天线端口的信息和根据 MU 传输最优的一组天线端口的信息。例如 SU 可以选择交叉极化的天线，天线的相关性小，有利于空间复用；而 MU 配对时，每个用户最好选择同极化的天线，有利用每个用户的波束赋型。其中所述的 SU 为用户单独在一个时频资源上发送自己的数据包，MU 为多个用户可以在相同的时频资源上通过空间复用的方式进行发送各自的数据包。

作为又一种实施方式，第一准则为传输模式；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

作为又一种实施方式，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

码本信息是指：包含多个预编码矩阵的信息；

作为又一种实施方式，所述第一准则为码本信息；

例如将M个天线端口分成X组，基站给每组天线端口单独配置一个码本集合。用户设备根据这个配置的码本集合计算SNR，并且反馈给基站设备。例如第一组天线端口对应于天线配置1，包括天线端口port0，port1，基站为天线配置1配置码本集合C1，C1包括的预编码矩阵为（W_{11}, W_{12}, W_{1n}, ...W_{1N}）,第二组天线端口对应与天线配置2，包括天线端口port2，port3，为天线配置2配置码本集合C2，C2包括的预编码矩阵为（W_{21}, W_{22}, W_{2n}, ...W_{2N}），第三组天线端口对应于天线配置3，包括天线端口port4，port5，为天线配置3配置码本集合C3，C3包括的预编码矩阵为（W_{31}, W_{32}, W_{3n}, ...W_{3N}），第四组天线端口对应于天线配置4，包括天线端口port6，port7，为天线配置4配置码本集合C4，C4包括的预编码矩阵为（W_{41}, W_{42}, W_{4n}, ...W_{4N}）。用户设备根据各个天线配置的对应的天线端口在其对应的码本集合Ci内反馈一个最优的秩(rank)，PMI（i）和SNR（i），基站比较各个SNR（i）选择一个最好的天线给用户设备进行配置；或者UE比较各个SNR（i），选择一个最好天线配置并将其对应的第一信息，反馈给基站，第一信息包括天线的索引和或CSI反馈给基站。例如，UE分别测量四组天线端口,得到第三组天线端口port4，port5，在C3包括的预编码矩阵为（W_{31}, W_{32}, W_{3n}, ...W_{3N}）内进行遍历，得到的最优的SNR高于其他三组天线端口，因此UE将第三组天线端口对应的索引反馈给基站。给每组天线端口配置一个码本集合，用户设备根据这个码本集合计算SNR,并且反馈给基站设备。例如给天线配置1配置码本集合C1，给天线配置2配置码本集合C2，给天线配置3配置码本集合C3，给天线配置4配置码本集合C4。用户设备在RRM测量时，根据各个天线配置的导频在其对应的码本集合Ci内，采用随机波束赋形(random beamforming)的方式，计算平均参考信号接收功率(Reference Signal Receiving Power，RSRP)，或者参考信号接收质量(Reference Signal Receiving Quality，RSRQ)进行上报，例如用户设备在天线配置1的导频，采用C1内所有的码本进行随机beamforming的方式，得到RSRP1，天线配置2的导频，采用C2内所有的

码本进行随机beamforming的方式，得到RSRP2，...UE将RSRP最大的天线配置对应的索引反馈给基站。

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

作为又一种实施方式，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

作为又一种实施方式，所述第一准则为数据包信息，所述的数据包信息包括传输块大小，调制编码方式；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择传输第一数据包传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，例如一定误码率的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

需要说明的是，在以上实施例中，第一准则，第一阈值，第二阈值，第三阈值和第四阈值为第二网络设备通过广播信息，高层信令或者动态信令配置

的。

M 个天线端口对应于 X 个信道状态信息处理进程(CSI process)，N 个端口对应于 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。每个 CSI process 对应一定的测量资源，例如每个 CSI process 配置一个信号测量资源和干扰测量资源，UE 根据信号测量资源和干扰测量资源获得 CSI 进行上报。例如，M=20，对应 5 个 CSI process，则每 4 个天线端口对应 1 个 CSI process，N=4。

可见，根据本发明实施例提供的一种信号发送方法，通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，进行了更有效的天线选择。

请参阅图3，为本发明实施例提供的另一种信号发送方法的流程图，该方法包括以下步骤:

步骤S201，第二网络设备向第一网络设备发送M个天线端口的信号，其中，M为正整数。

在进行天线配置时,第二网络设备给第一网络设备发送M个天线端口的配置信息，并将M个天线端口的信号发送给第一网络设备，第一网络设备根据配置信息接收第二网络设备发送的M个天线端口的信号，其中，M为正整数，在本实施例中，第一网络设备可以是用户设备(User Equipment，UE)，第二网络设备可以是基站; 或者第一网络设备可以是用户设备，第二网络设备可以是用户设备; 或者第一网络设备可以是基站，第二网络设备可以是基站。

所述的基站可以是宏站，低功率节点pico或者射频拉远单元RRH。

M个天线端口的配置信息包括天线端口的图案,即天线端口的时频资源的位置、天线端口信号的发送周期、功率等信息。

第二网络设备可以只发送一个配置信息给第一网络设备,该配置信息是M个天线端口的配置信息，或者将M个天线端口分成多个组，以多个配置信息的形式发送给第一网络设备，每个配置信息对应其中一个天线端口组的配置。

步骤S202，所述第二网络设备接收所述第一网络设备根据第一准则反馈的所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单

用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

第一网络设备需根据一定的准则从M个天线端口中选择N个天线端口，并将选择的N个天线端口的第一信息通知第二网络设备，在这里，第一信息为N个天线端口对应的信道状态信息CSI或者N个天线端口对应的索引信息；或者将N个天线端口的第一信息发送给第二网络设备，由第二网络设备确定该N个天线端口，在这里，第一信息为天线相关信息。

第二网络设备通过广播信息、高层信令或动态信令配置第一准则，第一阈值，第二阈值，第三阈值或者第四阈值。

可见，根据本发明实施例提供的一种信号发送方法，第一网络设备通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，将得到的天线相关信息，或者所述N个天线端口对应的信道状态信息CSI，或者所述N个天线端口的索引信息反馈给第二网络设备，使得第一网络设备进行了更有效的天线选择。

请参阅图4，为本发明实施例提供的又一种信号发送方法的流程图，该方法包括以下步骤：

步骤S301，第二网络设备向第一网络设备发送M个天线端口的信号，其中，M为正整数；

步骤S302，所述第二网络设备接收所述第一网络设备根据第一准则反馈的所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种，所述第一信息包括天线相关信息。

步骤S301和步骤S302分别与前述实施例的步骤S201和步骤S202相同，具体地，这里的第一信息包括天线相关信息。

步骤S303，所述第二网络设备根据所述天线相关信息确定所述N个天线端口为所选择的天线端口。

第二网络设备根据天线相关信息确定N个天线端口为所选择的天线端口。

可见，根据本发明实施例提供的一种信号发送方法，第一网络设备通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，将得到的天线相关信息反馈给第二网络设备，由第二网络设备确定选择的天线端口，使得第一网络设备进行了更有效的天线选择。

请参阅图5，为本发明实施例提供的一种第一网络设备的结构示意图，该第一网络设备1000包括:

接收单元11，用于接收第二网络设备发送的M个天线端口的信号，其中，M为正整数。

在进行天线配置时，第二网络设备给第一网络设备发送M个天线端口的配置信息，并将M个天线端口的信号发送给第一网络设备，第一网络设备根据配置信息接收第二网络设备发送的M个天线端口的信号，其中，M为正整数，在本实施例中，第一网络设备可以是用户设备(User Equipment，UE)，第二网络设备可以是基站；或者第一网络设备可以是用户设备，第二网络设备可以是用户设备；或者第一网络设备可以是基站，第二网络设备可以是基站。

所述的基站可以是宏站，低功率节点pico或者射频拉远单元RRH。

M个天线端口的配置信息包括天线端口的图案，即天线端口的时频资源的位置、天线端口信号的发送周期、功率等信息。

第二网络设备可以只发送一个配置信息给第一网络设备，该配置信息是M个天线端口的配置信息，或者将M个天线端口分成多个组，以多个配置信息的形式发送给第一网络设备，每个配置信息对应其中一个天线端口组的配置。

反馈单元12，用于根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

第一网络设备需根据一定的准则从M个天线端口中选择N个天线端口，并将选择的N个天线端口的第一信息通知第二网络设备，在这里，第一信息为N个天线端口对应的信道状态信息CSI或者N个天线端口对应的索引信息；或者将N个天线端口的第一信息发送给第二网络设备，由第二网络设备确定该N个

天线端口，在这里，第一信息为天线相关信息。

下面通过具体的实施方式介绍反馈单元12如何根据各种第一准则反馈M个天线端口中的N个天线端口的第一信息:

作为一种实施方式，所述第一准则为天线相关信息;

反馈单元12具体用于根据测量的所述M个天线端口的天线相关信息，进行小区选择，其中M个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

现有技术中，进行小区选择仅考虑根据接收信号功率信息例如RSRP，RSSI，RSRQ进行选择，本实施例中，还考虑天线相关性进行小区选择，使得用户能根据自己的业务更全面的考虑小区或者传输节点的选择。

具体实现中，所述第一网络设备根据测量的所述M个天线端口的天线相关信息，进行小区选择，具体为:

例如M=10，对应5个小区，每个小区有2个天线，小区1对应port0，port1，小区1对应port2，port3，小区1对应port4，port5，小区1对应port6，port7，小区1对应port8，port9;

UE测量和这5个小区的分别对应的5组天线端口，发现小区1对应的port0,1的接收信号功率最强，例如RSRP1>RSRP2>RSRP3>RSRP4>RSRP5，RSRP1代表小区1对应的接收信号功率，RSRP2代表小区2对应的接收信号功率，RSRPn代表小区n对应的接收信号功率。但是如果假设第一准则是天线相关信息，并且要求天线相关信息越大越好，则定义天线相关系数为Cor，例如，小区1的天线相关系数Cor1为port0和port1的天线相关性，可以采用信道估计获得port0对应的信道系数H0，port1对应的信道系数H1，并计算H0，H1的相关来获得Cor1，例如相关矩阵可以由 $H=[H_0 \quad H_1]$，$R=H^{H}H$ 获得。

或者根据 $R_{ik}=\frac{1}{2\Delta}\int_{\theta-\Delta}^{\theta+\Delta}\exp[jz(i-k)\sin\beta]d\beta$ 获得。

其中i，k分别为第i和第k个天线，Δ为角度扩展。

同样方法得到Cor2，Cor3，Cor4，Cor5，Corn代表小区n对应的天线相关系数。.

并且Cor2> Cor1> Cor3> Cor4> Cor5，则虽然小区1的接收信号功率最强，

但是综合考虑信号功率和天线相关性，小区2最终被UE选择，并且驻留在小区2。

这里第一准则不限定于天线相关性，还可以是SU/MU,信号传输模式等，并且第一准则可以为预定义的，或者基站广播或者UE特定的信令通知。

具体地,反馈单元12执行所述根据测量的所述M个天线端口的天线相关信息，进行小区选择的步骤，具体为：所述第一网络设备根据测量的所述M个天线端口的天线相关信息与第一阈值的比较结果，选择所述N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

即将M个天线端口的相关矩阵或相关系数与设定阈值进行比较,选择相关矩阵或相关系数大于等于或小于等于设定阈值的N个天线端口，得到N个天线端口对应的信道状态信息(Channel State Singal，CSI)或N个天线端口的索引信息,并将这N个天线端口对应的CSI或N个天线端口对应的索引信息通知第二网络设备，以使第二网络设备在该N个天线端口给第一网络设备发送数据。

作为另一种实施方式，所述第一准则为信噪比SNR;

反馈单元12具体用于在M个天线端口中选择使得波束赋型或者发射分集后的SNR小于等于或大于等于第二阈值的天线端口组合中数目最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

例如，基站配置给UE M个天线端口，如图2示例的另一个天线阵列中的多个天线示意图，M=88，UE在M个端口中遍历所有的N=1到N=88的天线端口组合，对于每个N的取值，需要遍历的组合数为c，例如对于N=4，组合有组合1为a11，a12，a13，a14，组合2为a12，a13，a14， a15，组合3为，a13，a14，a15，a16，组合4为a14，a15，a16，a17，组合5为a15，a16，a17，a18，组合6为b11，b12，b13，b14，...对于每个组合，例如组合1 a11，a12，a13，a14，UE通过a11，a12，a13，a14得到信道$H_{N,1}$，然后遍历所有的预编码矩阵w_i，得到信噪比:

$$SNR_{N,\ m,\ i}=\frac{\left|H_{n,m}W_i\right|^2}{\sigma^2}$$

其中$H_{N,\ m}$表示N个天线端口组合情况下的第m个配置，Wi表示第i个预编码矩阵，σ^2为噪声;

遍历所有的N端口组合情况下的所有SNR,找到最大的，例如max（$SNR_{N,m,i}, N=4, 1\le m\le C_M^4, 1\le i\le X_4$）=5dB，$X_4$表示N=4的情况下的预编码矩阵的个数。对于N=5，采用上述同样的方法进行遍历，max（$SNR_{N,m,i}, N=5, 1\le m\le C_M^5, 1\le i\le X_5$）=7dB，如果基站通知UE天线选择的第一准则为SNR要大于等于6dB的最少数目的天线，则N=5恰巧可以到6dB，并且是达到6dB所需要的天线数目最少的，。因此UE可以将N=5的达到7dB的天线组合的标号，例如，a11，b12，c14，d11，对应的索引反馈给基站。采用N>5,得到的信噪比会比N=5更高，但是对于某些信道，只需达到一定的SNR性能要求即可，无需更大的SNR，采用更多的天线，会导致基站浪费发射功率。

作为又一种实施方式，第一准则为信道容量;

反馈单元12具体用于在M个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

由于信道容量C=Blog2(1+SNR)，本实施方式中，根据信道容量进行天线端口的选择的过程与上面实施方式中根据SNR进行天线端口的选择的过程类似，在此不再赘述。

作为又一种实施方式，第一准则为吞吐量;

反馈单元12具体用于在M个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

同样地，本实施方式中，根据吞吐量进行天线端口的选择的过程与上面实施方式中根据SNR或信道容量进行天线端口的选择的过程类似，在此不再赘述。

作为又一种实施方式，第一准则为SU/MU传输方式;

反馈单元12具体用于在M个天线端口中选择SU传输最优的第一组天线端口，所述的第一组天线端口包含N1个天线端口，得到所述N1个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在M个天线端口中选择MU传输最优的第二组天线端口，所述的第二组天线端口包含N2个天线端口，得到所述N2个天线端口的第一信息并进行反馈。

在本实施方式中，例如，基站配置UE按照SU传输最优的方式选择天线，则UE遍历所有天线，根据使得UE自己的性能达到最优的方式选择天线，例如选择了天线a11，b13，g15，h18，则将a11，b13，g15，h18的天线索引信息上报给基站。

又例如，基站配置UE1按照MU配对最优的方式选择天线，基站可以将配对用户的信息，例如与UE1配对的用户UE2，UE3的信息，包括UE2的，UE3的天线信息通知给UE1，UE1根据使得配对后的所有用户的总的性能最优的方式选择天线，例如选择天线c13，d12，e11，f18，将其对应的天线索引信息通知给基站。

也可以同时反馈根据SU传输最优的一组天线端口的信息和根据MU传输最优的一组天线端口的信息。例如SU可以选择交叉极化的天线，天线的相关性小，有利于空间复用；而MU配对时，每个用户最好选择同极化的天线，有利用每个用户的波束赋型。其中所述的SU为用户单独在一个时频资源上发送自己的数据包，MU为多个用户可以在相同的时频资源上通过空间复用的方式进行发送各自的数据包。

作为又一种实施方式，第一准则为传输模式；

反馈单元12具体用于在M个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含N1个天线端口，得到所述N1个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在M个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含N2个天线端口，得到所述N2个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在M个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含N3个天线端口，得到所述N3个天线端口的第一信息并进行反馈。

作为又一种实施方式，所述第一准则为码本信息；

反馈单元12具体用于在M个天线端口中选择采用第一码本信息传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

码本信息是指：包含多个预编码矩阵的信息；

作为又一种实施方式，所述第一准则为码本信息；

例如将M个天线端口分成X组，基站给每组天线端口单独配置一个码本集合。用户设备根据这个配置的码本集合计算SNR，并且反馈给基站设备。例如第一组天线端口对应于天线配置1，包括天线端口port0，port1，基站为天线配置1配置码本集合C1，C1包括的预编码矩阵为（W_{11}, W_{12}, W_{1n}, ...W_{1N}）,第二组天线端口对应与天线配置2，包括天线端口port2，port3，为天线配置2配置码本集合C2，C2包括的预编码矩阵为（W_{21}, W_{22}, W_{2n}, ...W_{2N}），第三组天线端口对应于天线配置3，包括天线端口port4，port5，为天线配置3配置码本集合C3，C3包括的预编码矩阵为（W_{31}, W_{32}, W_{3n}, ...W_{3N}），第四组天线端口对应于天线配置4，包括天线端口port6，port7，为天线配置4配置码本集合C4，C4包括的预编码矩阵为（W_{41}, W_{42}, W_{4n}, ...W_{4N}）。用户设备根据各个天线配置的对应的天线端口在其对应的码本集合Ci内反馈一个最优的秩(rank)，PMI（i）和SNR（i），基站比较各个SNR（i）选择一个最好的天线给用户设备进行配置；或者UE比较各个SNR（i），选择一个最好天线配置并将其对应的第一信息，反馈给基站，第一信息包括天线的索引和或CSI反馈给基站。例如，UE分别测量四组天线端口,得到第三组天线端口port4，port5，在C3包括的预编码矩阵为（W_{31}, W_{32}, W_{3n}, ...W_{3N}）内进行遍历，得到的最优的SNR高于其他三组天线端口，因此UE将第三组天线端口对应的索引反馈给基站。给每组天线端口配置一个码本集合，用户设备根据这个码本集合计算SNR,并且反馈给基站设备。例如给天线配置1配置码本集合C1，给天线配置2配置码本集合C2，给天线配置3配置码本集合C3，给天线配置4配置码本集合C4。用户设备在RRM测量时，根据各个天线配置的导频在其对应的码本集合Ci内，采用随机波束赋形(random beamforming)的方式，计算平均参考信号接收功率(Reference Signal Receiving Power，RSRP)，或者参考信号接收质量(Reference Signal Receiving Quality，RSRQ)进行上报，例如用户设备在天线配置1的导频，采用C1内所有的码本进

行随机beamforming的方式，得到RSRP1，天线配置2的导频，采用C2内所有的码本进行随机beamforming的方式，得到RSRP2，...UE将RSRP最大的天线配置对应的索引反馈给基站。

反馈单元12具体用于在M个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

作为又一种实施方式，所述第一准则为码本信息;

反馈单元12具体用于在M个天线端口中选择轮询第一码本中的所有码字使

得其中最好的信息传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

作为又一种实施方式，所述第一准则为数据包信息，所述的数据包信息包括传输块大小，调制编码方式;

反馈单元12具体用于在M个天线端口中选择传输第一数据包传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在M个天线端口中选择传输第一数据包最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在M个天线端口中选择传输第一数据包达到一定性能要求的最少的N个天线端口，例如一定误码率的最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

需要说明的是，在以上实施例中，第一准则，第一阈值，第二阈值，第三阈值和第四阈值为第二网络设备通过广播信息，高层信令或者动态信令配置的。

M个天线端口对应于X个信道状态信息处理进程(CSI process)，N个端口对应于X个CSI process中的一个CSI process，其中，X为正整数。每个CSI process对应一定的测量资源，例如每个CSI process配置一个信号测量资源和干扰测量

资源，UE根据信号测量资源和干扰测量资源获得CSI进行上报。例如，M=20，对应5个CSI process，则每4个天线端口对应1个CSI process，N=4。

可见，根据本发明实施例提供的一种第一网络设备，通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，进行了更有效的天线选择。

请参阅图6，为本发明实施例提供的一种第二网络设备的结构示意图，该第二网络设备2000包括:

发送单元21，用于向第一网络设备发送M个天线端口的信号，其中，M为正整数。

在进行天线配置时，发送单元21给第一网络设备发送M个天线端口的配置信息，并将M个天线端口的信号发送给第一网络设备，第一网络设备根据配置信息接收发送单元21发送的M个天线端口的信号，其中，M为正整数，在本实施例中，第一网络设备可以是用户设备(User Equipment，UE)，第二网络设备可以是基站；或者第一网络设备可以是用户设备，第二网络设备可以是用户设备；或者第一网络设备可以是基站，第二网络设备可以是基站。

所述的基站可以是宏站，低功率节点pico或者射频拉远单元RRH。

M个天线端口的配置信息包括天线端口的图案，即天线端口的时频资源的位置、天线端口信号的发送周期、功率等信息。

第二网络设备可以只发送一个配置信息给第一网络设备，该配置信息是M个天线端口的配置信息，或者将M个天线端口分成多个组，以多个配置信息的形式发送给第一网络设备，每个配置信息对应其中一个天线端口组的配置。

接收单元22，用于接收所述第一网络设备根据第一准则反馈的所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

第一网络设备需根据一定的准则从M个天线端口中选择N个天线端口，并将选择的N个天线端口的第一信息通知第二网络设备的接收单元22，在这里，第一信息为N个天线端口对应的信道状态信息CSI或者N个天线端口对应的索

引信息；或者将N个天线端口的第一信息发送给第二网络设备，由第二网络设备确定该N个天线端口，在这里，第一信息为天线相关信息。

第二网络设备通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值或者第四阈值。

可见，根据本发明实施例提供的一种第二网络设备，第一网络设备通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，将得到的天线相关信息，或者所述N个天线端口对应的信道状态信息CSI，或者所述N个天线端口的索引信息反馈给第二网络设备，使得第一网络设备进行了更有效的天线选择。

请参阅图7，为本发明实施例提供的另一种第二网络设备的结构示意图，该第二网络设备3000包括：

发送单元31，用于向第一网络设备发送M个天线端口的信号，其中，M为正整数；

接收单元32，用于接收所述第一网络设备根据第一准则反馈的所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种，所述第一信息包括天线相关信息。

发送单元31和接收单元32的功能分别与前述实施例的发送单元21和接收单元22相同，具体地，这里的第一信息包括天线相关信息。

确定单元33，用于根据所述天线相关信息确定所述N个天线端口为所选择的天线端口。

确定单元33根据天线相关信息确定N个天线端口为所选择的天线端口。

可见，根据本发明实施例提供的一种第二网络设备，第一网络设备通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，将得到的天线相关信息反馈给第二网络设备，由第二网络设备确定选择的天线端口，使得第一网络设备进行了更有效的天线选择。

请参阅图8，为本发明实施例提供的另一种第一网络设备的结构示意图，该第一网络设备4000包括：接收器41和发送器42。

接收器41，用于接收第二网络设备发送的M个天线端口的信号，其中，M为正整数；

发送器42，用于根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

在一种实施方式中，所述第一准则为天线相关信息；

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为：

根据测量的所述M个天线端口的天线相关信息，进行小区选择，其中M个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

在另一种实施方式中，所述发送器42执行所述根据测量的所述M个天线端口的天线相关信息，进行小区选择的步骤，具体为：

所述第一网络设备根据测量的所述M个天线端口的天线相关信息与第一阈值的比较结果，选择所述N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在又一种实施方式中，所述第一准则为信噪比SNR；

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为：

在M个天线端口中选择使得波束赋型或者发射分集后的SNR小于等于或大于等于第二阈值的天线端口组合中数目最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在又一种实施方式中，第一准则为信道容量；

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为：

在M个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的N个天线端口，得到所述N个天线端口的第一信息并

进行反馈。

在又一种实施方式中，第一准则为吞吐量;

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为:

所述第一网络设备在M个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在又一种实施方式中，第一准则为SU/MU传输方式;

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为:

在M个天线端口中选择SU传输最优的第一组天线端口，所述的第一组天线端口包含N1个天线端口，得到所述N1个天线端口的第一信息并进行反馈;和/或

在M个天线端口中选择MU传输最优的第二组天线端口，所述的第二组天线端口包含N2个天线端口，得到所述N2个天线端口的第一信息并进行反馈。

在又一种实施方式中，第一准则为传输模式;

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为:

在M个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含N1个天线端口，得到所述N1个天线端口的第一信息并进行反馈;和/或

在M个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含N2个天线端口，得到所述N2个天线端口的第一信息并进行反馈;和/或

在M个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含N3个天线端口，得到所述N3个天线端口的第一信息并进行反馈。

在又一种实施方式中，所述第一准则为码本信息;

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为:

在M个天线端口中选择采用第一码本信息传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在又一种实施方式中，所述第一准则为码本信息；

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为：

在M个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在又一种实施方式中，所述第一准则为码本信息；

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为：

在M个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在又一种实施方式中，所述第一准则为数据包信息；

所述发送器42执行所述根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息的步骤，具体为：

在M个天线端口中选择传输第一数据包传输性能最优的N个天线端口，得到所述N个天线端口的第一信息并进行反馈；和/或

在M个天线端口中选择传输第一数据包最少的N个天线端口，得到所述N个天线端口的第一信息并进行反馈。

在以上各实施例或实施方式中，所述第一准则，所述第一阈值，第二阈值，第三阈值或者第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

在以上各实施例或实施方式中，所述M个天线端口对应于X个信道状态信息处理进程CSI process，N个天线端口对应于所述X个CSI process中的一个CSI process，其中，X为正整数。

在以上各实施例或实施方式中，所述第一信息包括天线相关信息，或者所述N个天线端口对应的信道状态信息CSI，或者所述N个天线端口的索引信息。

可见，根据本发明实施例提供的一种第一网络设备，通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本

信息或数据包大小中的至少一种进行最优天线配置，进行了更有效的天线选择。

请参阅图9，为本发明实施例提供的又一种第二网络设备的结构示意图，该第二网络设备5000包括：发送器和接收器；

发送器51，用于向第一网络设备发送M个天线端口的信号，其中，M为正整数。

接收器52，用于接收所述第一网络设备根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

其中，所述第一信息包括所述N个天线端口对应的信道状态信息CSI，或者所述N个天线端口的索引信息，或天线相关信息。

可见，根据本发明实施例提供的一种第二网络设备，第一网络设备通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，将得到的天线相关信息，或者所述N个天线端口对应的信道状态信息CSI，或者所述N个天线端口的索引信息反馈给第二网络设备，使得第一网络设备进行了更有效的天线选择。

请参阅图10，为本发明实施例提供的又一种第二网络设备的结构示意图，该第二网络设备6000包括：发送器、接收器和控制器。

发送器61，用于向第一网络设备发送M个天线端口的信号，其中，M为正整数。

接收器62，用于接收所述第一网络设备根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种，述第一信息包括天线相关信息。

控制器63，用于根据所述天线相关信息确定所述N个天线端口为所选择的

天线端口。

可见，根据本发明实施例提供的一种第二网络设备，第一网络设备通过根据天线相关信息、SNR、信道容量、吞吐量、单用户/多用户传输方式、传输模式、码本信息或数据包大小中的至少一种进行最优天线配置，将得到的天线相关信息反馈给第二网络设备，由第二网络设备确定选择的天线端口，使得第一网络设备进行了更有效的天线选择。

需要说明的是，对于前述的各方法实施例，为了简单描述，故将其都表述为一系列的动作组合，但是本领域技术人员应该知悉，本发明并不受所描述的动作顺序的限制，因为根据本发明，某些步骤可以采用其他顺序或者同时进行。其次，本领域技术人员也应该知悉，说明书中所描述的实施例均属于优选实施例，所涉及的动作和模块并不一定是本发明所必须的。

在上述实施例中，对各个实施例的描述都各有侧重，某个实施例中没有详述的部分，可以参见其他实施例的相关描述。

通过以上的实施方式的描述，所属领域的技术人员可以清楚地了解到本发明可以用硬件实现，或固件实现，或它们的组合方式来实现。当使用软件实现时，可以将上述功能存储在计算机可读介质中或作为计算机可读介质上的一个或多个指令或代码进行传输。计算机可读介质包括计算机存储介质和通信介质，其中通信介质包括便于从一个地方向另一个地方传送计算机程序的任何介质。存储介质可以是计算机能够存取的任何可用介质。以此为例但不限于：计算机可读介质可以包括随机存取存储器(Random Access Memory，RAM)、只读存储器(Read-Only Memory，ROM)、电可擦可编程只读存储器(Electrically Erasable Programmable Read-Only Memory，EEPROM)、只读光盘(Compact Disc Read-Only Memory，CD-ROM)或其他光盘存储、磁盘存储介质或者其他磁存储设备、或者能够用于携带或存储具有指令或数据结构形式的期望的程序代码并能够由计算机存取的任何其他介质。此外。任何连接可以适当的成为计算机可读介质。例如，如果软件是使用同轴电缆、光纤光缆、双绞线、数字用户线（Digital Subscriber Line，DSL）或者诸如红外线、无线电和微波之类的无线技术从网站、服务器或者其他远程源传输的，那么同轴电缆、光纤光缆、双绞

线、DSL 或者诸如红外线、无线和微波之类的无线技术包括在所属介质的定影中。如本发明所使用的，盘（Disk）和碟（disc）包括压缩光碟（CD）、激光碟、光碟、数字通用光碟（DVD）、软盘和蓝光光碟，其中盘通常磁性的复制数据，而碟则用激光来光学的复制数据。上面的组合也应当包括在计算机可读介质的保护范围之内。

总之，以上所述仅为本发明技术方案的较佳实施例而已，并非用于限定本发明的保护范围。凡在本发明的精神和原则之内，所作的任何修改、等同替换、改进等，均应包含在本发明的保护范围之内。

权 利 要 求

1、一种信号发送方法，其特征在于，包括:

第一网络设备接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

2、根据权利要求 1 所述的方法，其特征在于，所述第一准则为天线相关信息;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

3、根据权利要求 2 所述的方法，其特征在于，所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，具体为:

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

4、根据权利要求 1 所述的方法，其特征在于，所述第一准则为信噪比 SNR;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天

线端口，得到所述 N 个天线端口的第一信息并进行反馈。

5、根据权利要求 1 所述的方法，其特征在于，第一准则为信道容量;

所述第一网络设备根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

6、根据权利要求 1 所述的方法，其特征在于，第一准则为吞吐量;

所述第一网络设备根据第一准则反馈所述M个天线端口中的N个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

7、根据权利要求 1 所述的方法，其特征在于，第一准则为 SU/MU 传输方式;

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈; 和/或

所述第一网络设备在M个天线端口中选择MU传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

8、根据权利要求 1 所述的方法，其特征在于，第一准则为传输模式; 所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为:

所述第一网络设备在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

9、根据权利要求 1 所述的方法，其特征在于，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

10、根据权利要求 1 所述的方法，其特征在于，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

11、根据权利要求 1 所述的方法，其特征在于，所述第一准则为码本信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

12、根据权利要求 1 所述的方法，其特征在于，所述第一准则为数据包信息；

所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，具体为：

所述第一网络设备在 M 个天线端口中选择传输第一数据包传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

所述第一网络设备在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

13、根据权利要求 1~12 所述的方法，其特征在于，所述第一准则或者所述第一阈值，第二阈值，第三阈值和第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

14、根据权利要求 1~13 所述的方法，其特征在于，所述 M 个天线端口对应于 X 个信道状态信息处理进程 CSI process，N 个天线端口对应于所述 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。

15、根据权利要求 1~14 所述的方法，其特征在于，所述第一信息包括天线相关信息，或者所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

16、一种信号发送方法，其特征在于，包括：

第二网络设备向第一网络设备发送 M 个天线端口的信号，其中，M 为正整数；

所述第二网络设备接收所述第一网络设备根据第一准则反馈的所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用

户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

17、如权利要求 16 所述的方法，其特征在于，所述第一信息包括天线相关信息；

所述方法，还包括：

所述第二网络设备根据所述天线相关信息确定所述 N 个天线端口为所选择的天线端口。

18、如权利要求 16 所述的方法，其特征在于，所述第一信息包括所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

19、如权利要求 16-18 任意一项所述的方法，其特征在于，还包括：

所述第二网络设备通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值或者第四阈值。

20、一种第一网络设备，其特征在于，包括：

接收单元，用于接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数；

反馈单元，用于根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

21、根据权利要求 20 所述的第一网络设备，其特征在于，所述第一准则为天线相关信息；

所述反馈单元具体用于：

根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

22、根据权利要求 21 所述的第一网络设备，其特征在于，所述反馈单元执行所述根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，的步骤，具体为：

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

23、根据权利要求 20 所述的第一网络设备，其特征在于，所述第一准则为信噪比 SNR;

所述反馈单元具体用于：

在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

24、根据权利要求 20 所述的第一网络设备，其特征在于，第一准则为信道容量;

所述反馈单元具体用于：

在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

25、根据权利要求 20 所述的第一网络设备，其特征在于，第一准则为吞吐量;

所述反馈单元具体用于：

在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

26、根据权利要求 20 所述的第一网络设备，其特征在于，第一准则为 SU/MU 传输方式;

所述反馈单元具体用于:

在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择 MU 传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

27、根据权利要求 20 所述的第一网络设备，其特征在于，第一准则为传输模式;

所述反馈单元具体用于:

在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

28、根据权利要求 20 所述的第一网络设备，其特征在于，所述第一准则为码本信息;

所述反馈单元具体用于:

在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

29、根据权利要求 20 所述的第一网络设备，其特征在于，所述第一准则为码本信息;

所述反馈单元具体用于:

在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

30、根据权利要求 20 所述的第一网络设备，其特征在于，所述第一准则为码本信息；

所述反馈单元具体用于：

在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

31、根据权利要求 20 所述的第一网络设备，其特征在于，所述第一准则为数据包信息；

所述反馈单元具体用于：

在M个天线端口中选择传输第一数据包传输性能最优的N个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，例如一定误码率的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

32、根据权利要求 20-31 所述的第一网络设备，其特征在于，所述第一准则或者所述第一阈值，第二阈值，第三阈值和第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

33、根据权利要求 20-32 所述的第一网络设备，其特征在于，所述 M 个天线端口对应于 X 个信道状态信息处理进程 CSI process，N 个天线端口对应于所述 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。

34、根据权利要求 20-33 所述的方法，其特征在于，所述第一信息包括

天线相关信息，或者所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

35、一种第二网络设备，其特征在于，包括:

发送单元，用于向第一网络设备发送 M 个天线端口的信号，其中，M 为正整数;

接收单元，用于接收所述第一网络设备根据第一准则反馈的所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

36、如权利要求 35 所述的第二网络设备，其特征在于，所述第一信息包括天线相关信息;

所述第二网络设备，还包括:

确定单元，用于根据所述天线相关信息确定所述 N 个天线端口为所选择的天线端口。

37、如权利要求 35 所述的第二网络设备，其特征在于，所述第一信息包括所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

38、如权利要求 35-37 任意一项所述的第二网络设备，其特征在于，所述发送单元还用于通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值和第四阈值。

39、一种第一网络设备，其特征在于，包括：接收器和发送器;

接收器，用于接收第二网络设备发送的 M 个天线端口的信号，其中，M 为正整数;

发送器，用于根据第一准则反馈所述 M 个天线端口中的 N 个天线端

口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

40、根据权利要求 39 所述的第一网络设备，其特征在于，所述第一准则为天线相关信息；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

根据测量的所述 M 个天线端口的天线相关信息，进行小区选择，其中 M 个天线端口对应至少两个小区或者两个传输节点，每个所述小区或传输节点对应至少两个天线端口。

41、根据权利要求 40 所述的第一网络设备，其特征在于，所述发送器执行所述根据测量的所述 M 个天线端口的天线相关信息，进行小区选择的步骤，具体为：

所述第一网络设备根据测量的所述 M 个天线端口的天线相关信息与第一阈值的比较结果，选择所述 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

42、根据权利要求 39 所述的第一网络设备，其特征在于，所述第一准则为信噪比 SNR；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择使得波束赋型或者发射分集后的 SNR 小于等于或大于等于第二阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

43、根据权利要求 39 所述的第一网络设备，其特征在于，第一准则为信道容量；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天

线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择使得信道容量小于等于或大于等于第三阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

44、根据权利要求 39 所述的第一网络设备，其特征在于，第一准则为吞吐量；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

所述第一网络设备在 M 个天线端口中选择使得吞吐量小于等于或大于等于第四阈值的天线端口组合中数目最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

45、根据权利要求 39 所述的第一网络设备，其特征在于，第一准则为 SU/MU 传输方式；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择 SU 传输最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择 MU 传输最优的第二组天线端口，所述的第二组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈。

46、根据权利要求 39 所述的第一网络设备，其特征在于，第一准则为传输模式；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择传输模式是发射分集传输的最优的第一组天线端口，所述的第一组天线端口包含 N1 个天线端口，得到所述 N1 个天线端

口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输模式是波束赋型传输的最优的第二组天线端口，所述的第一组天线端口包含 N2 个天线端口，得到所述 N2 个天线端口的第一信息并进行反馈；和/或

在 M 个天线端口中选择传输模式是空间复用传输的最优的第三组天线端口，所述的第三组天线端口包含 N3 个天线端口，得到所述 N3 个天线端口的第一信息并进行反馈。

47、根据权利要求 39 所述的第一网络设备，其特征在于，所述第一准则为码本信息；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择采用其对应的第一码本信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

48、根据权利要求 39 所述的第一网络设备，其特征在于，所述第一准则为码本信息；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择轮询第一码本中的所有码字使得平均信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

49、根据权利要求 39 所述的第一网络设备，其特征在于，所述第一准则为码本信息；

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为：

在 M 个天线端口中选择轮询第一码本中的所有码字使得其中最好的信息传输性能最优的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

50、根据权利要求 39 所述的第一网络设备，其特征在于，所述第一准则为数据包信息;

所述发送器执行所述根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息的步骤，具体为:

在M个天线端口中选择传输第一数据包传输性能最优的N个天线端口，得到所述 N 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择传输第一数据包最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈; 和/或

在 M 个天线端口中选择传输第一数据包达到一定性能要求的最少的 N 个天线端口，例如一定误码率的最少的 N 个天线端口，得到所述 N 个天线端口的第一信息并进行反馈。

51、根据权利要求 39-50 所述的第一网络设备，其特征在于，所述第一准则或者所述第一阈值，第二阈值，第三阈值和第四阈值为所述第二网络设备通过广播信息，高层信令或者动态信令配置的。

52、根据权利要求 39-51 所述的第一网络设备，其特征在于，所述 M 个天线端口对应于 X 个信道状态信息处理进程 CSI process，N 个天线端口对应于所述 X 个 CSI process 中的一个 CSI process，其中，X 为正整数。

53、根据权利要求 39-52 所述的第一网络设备，其特征在于，所述第一信息包括天线相关信息，或者所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

54、一种第二网络设备，其特征在于，包括: 发送器和接收器;

发送器，用于向第一网络设备发送 M 个天线端口的信号，其中，M 为正整数;

接收器，用于接收所述第一网络设备根据第一准则反馈所述 M 个天线端口中的 N 个天线端口的第一信息，N 为小于等于 M 的整数，所述第一准则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU

（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种。

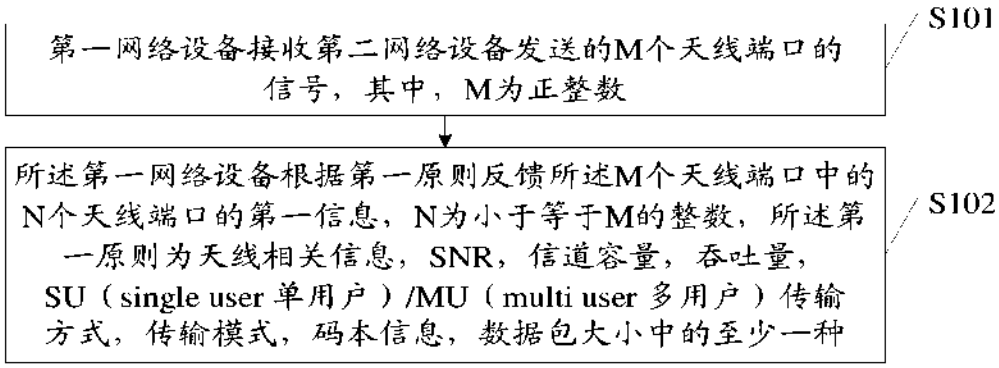
55、如权利要求 54 所述的第二网络设备，其特征在于，所述第一信息包括天线相关信息；

所述第二网络设备，还包括：控制器；

控制器，用于根据所述天线相关信息确定所述 N 个天线端口为所选择的天线端口。

56、如权利要求 54 所述的第二网络设备，其特征在于，所述第一信息包括所述 N 个天线端口对应的信道状态信息 CSI，或者所述 N 个天线端口的索引信息。

57、如权利要求 54-56 任意一项所述的第二网络设备，其特征在于，所述发送器还用于通过广播信息、高层信令或动态信令配置所述第一准则，第一阈值，第二阈值，第三阈值和第四阈值。



第一网络设备接收第二网络设备发送的M个天线端口的信号，其中，M为正整数
S101
所述第一网络设备根据第一原则反馈所述M个天线端口中的N个天线端口的第一信息，N为小于等于M的整数，所述第一原则为天线相关信息，SNR，信道容量，吞吐量，SU（single user 单用户）/MU（multi user 多用户）传输方式，传输模式，码本信息，数据包大小中的至少一种

INTERNATIONAL SEARCH REPORT

International application No.
PCT/CN2014/083479

A. CLASSIFICATION OF SUBJECT MATTER

H04B 7/06 (2006.01) i; H04B 7/08 (2006.01) i

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

H04B; H04W; H04Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

CNPAT, CNKI, WPI, EPODOC: confirm, port, Signal-to-Noise, SNR, codebook, antenna, feedback, feed back, throughput, select+, determin+, capability, group, data packet, mode, way, relate

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	CN 1918817 A (LG ELECTRONICS INC.) 21 February 2007 (21.02.2007) description, page 14, the second paragraph to page 15, the second paragraph, and figures 4-6	1-57
A	CN 101015137 A (SAMSUNG ELECTRONICS CO., LTD. et al.) 08 August 2007 (08.08.2007) the whole document	1-57
A	CN 101359952 A (HUAWEI TECHNOLOGIES CO., LTD.) 04 February 2009 (04.02.2009) the whole document	1-57
A	CN 101013917 A (ZTE CORP.) 08 August 2007 (08.08.2007) the whole document	1-57

☐ Further documents are listed in the continuation of Box C. ☒ See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&"document member of the same patent family

(54) Title: PERFORMING MISSION CRITICAL COMMUNICATIONS AT A USER EQUIPMENT (UE)

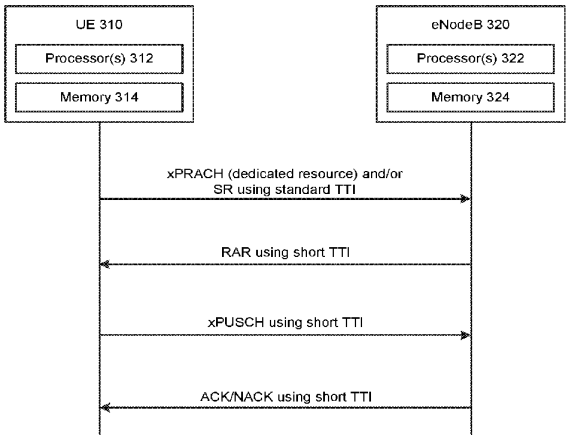

FIG. 3

(57) Abstract: Technology for a user equipment (UE) operable to perform mission critical communications with an eNodeB is disclosed. The UE can transmit a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB. The PRACH signal can be transmitted in accordance with a first transmission time interval (TTI). The UE can receive a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication. The RAR message can be transmitted from the eNodeB using a second TTI. The UE can perform the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message. The mission critical communication can be performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

PERFORMING MISSION CRITICAL COMMUNICATIONS AT A USER EQUIPMENT (UE)

BACKGROUND

[0001] Wireless mobile communication technology uses various standards and protocols to transmit data between a node (e.g., a transmission station) and a wireless device (e.g., a mobile device). Some wireless devices communicate using orthogonal frequency-division multiple access (OFDMA) in a downlink (DL) transmission and single carrier frequency division multiple access (SC-FDMA) in uplink (UL). Standards and protocols that use orthogonal frequency-division multiplexing (OFDM) for signal transmission include the third generation partnership project (3GPP) long term evolution (LTE), the Institute of Electrical and Electronics Engineers (IEEE) 1202.16 standard (e.g., 1202.16e, 1202.16m), which is commonly known to industry groups as WiMAX (Worldwide interoperability for Microwave Access), and the IEEE 1202.11 standard, which is commonly known to industry groups as WiFi.

[0002] In 3GPP radio access network (RAN) LTE systems, the node can be a combination of Evolved Universal Terrestrial Radio Access Network (E-UTRAN) Node Bs (also commonly denoted as evolved Node Bs, enhanced Node Bs, eNodeBs, or eNBs) and Radio Network Controllers (RNCs), which communicates with the wireless device, known as a user equipment (UE). The downlink (DL) transmission can be a communication from the node (e.g., eNodeB) to the wireless device (e.g., UE), and the uplink (UL) transmission can be a communication from the wireless device to the node.

BRIEF DESCRIPTION OF THE DRAWINGS

[0003] Features and advantages of the disclosure will be apparent from the detailed description which follows, taken in conjunction with the accompanying drawings, which together illustrate, by way of example, features of the disclosure; and, wherein:

[0004] FIG. 1 illustrates a flexible radio access technology (RAT) in accordance with an example;

[0005] FIG. 2 illustrates a subframe structure for low latency applications in accordance

with an example;

[0006] FIG. 3 illustrates a mission critical communication between a user equipment (UE) and an eNodeB in accordance with an example;

[0007] FIG. 4 illustrates a partition of a physical random access channel (PRACH) preamble resource in accordance with an example;

[0008] FIG. 5 illustrates a multiplexing of a physical random access channel (PRACH) signal and a scheduling request (SR) message in a repeated transmission in accordance with an example;

[0009] FIG. 6 illustrates a random access response (RAR) window for repeated transmissions between a user equipment (UE) and an eNodeB in accordance with an example;

[0010] FIGS. 7A to 7C illustrates a resource allocation of a primary partition and a secondary partition within a transmission time interval (TTI) in accordance with an example;

[0011] FIG. 8 illustrates a repeated transmission of a random access response (RAR) message using a short transmission time interval (TTI) in accordance with an example;

[0012] FIG. 9 depicts functionality of a user equipment (UE) operable to perform mission critical communications with an eNodeB in accordance with an example;

[0013] FIG. 10 depicts functionality of a base station operable to receive mission critical communications from a user equipment (UE) in accordance with an example;

[0014] FIG. 11 depicts a flowchart of a machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB in accordance with an example;

[0015] FIG. 12 illustrates a diagram of a wireless device (e.g., UE) in accordance with an example; and

[0016] FIG. 13 illustrates a diagram of a wireless device (e.g., UE) in accordance with an example.

[0017] Reference will now be made to the exemplary embodiments illustrated, and specific language will be used herein to describe the same. It will nevertheless be

understood that no limitation of the scope of the technology is thereby intended.

DETAILED DESCRIPTION

[0018] Before the present technology is disclosed and described, it is to be understood that this technology is not limited to the particular structures, process actions, or materials disclosed herein, but is extended to equivalents thereof as would be recognized by those ordinarily skilled in the relevant arts. It should also be understood that terminology employed herein is used for the purpose of describing particular examples only and is not intended to be limiting. The same reference numerals in different drawings represent the same element. Numbers provided in flow charts and processes are provided for clarity in illustrating actions and operations and do not necessarily indicate a particular order or sequence.

EXAMPLE EMBODIMENTS

[0019] An initial overview of technology embodiments is provided below and then specific technology embodiments are described in further detail later. This initial summary is intended to aid readers in understanding the technology more quickly but is not intended to identify key features or essential features of the technology nor is it intended to limit the scope of the claimed subject matter.

[0020] The field of mobile communications has evolved significantly from early voice systems to today's highly sophisticated integrated communication platform. 4G Long Term Evolution (LTE) networks are deployed in more than 100 countries to provide services in various spectrum band allocations depending on spectrum regime. Recently, significant momentum has started to build around the idea of a next generation, i.e., fifth generation (5G) wireless communications technology.

[0021] A wide range of potential applications and services have been identified for the 5G system. Some examples include (1) enhanced mobile broadband, (2) massive machine type communications (MTC), and (3) ultra-reliable and low latency or mission critical communications. In enhanced mobile broadband, increased data rates is expected to be a key driver in network development and evolution for the 5G system. A peak data rate of more than 10 gigabits per second (Gbps) and a minimum guaranteed user data rate of at

least 100 megabits per second (Mbps) are envisioned for the 5G system. With respect to massive MTC, the support of a massive number of Internet of Things (IoT) or MTC devices is expected to be a key feature for the 5G system. MTC devices can be used for a wide variety of applications. MTC devices use low operational power consumption and are expected to communicate with infrequent small burst transmissions. Finally, with respect to ultra-reliable and low latency or mission critical communications, the support of mission critical MTC applications for the 5G system can necessitate a high level of reliable connectivity with guaranteed low latency, availability and reliability-of-service.

[0022] FIG. 1 illustrates an exemplary flexible radio access technology (RAT). The flexible RAT, also referred to as a 5G xRAT, can function to address the diverse features of the 5G system, such as the enhanced mobile broadband, massive MTC, and ultra-reliable and low latency or mission critical communications. The flexible RAT can define a unified framework that supports these diverse applications and services. In addition, the flexible RAT can support multiple frequency bands, multiple application/services, licensed/unlicensed frequency, and multiple RATs.

[0023] As shown in FIG. 1, the flexible RAT can be represented in two dimensions – frequency and time. Multiple RATs/sub-RATs/partitions or applications in the same frequency resources or frequency bands (or different frequency resources or frequency bands) can be multiplexed using time-division multiplexing (TDM), frequency-division multiplexing (FDM), code-division multiplexing (CDM), or a combination of the above.

[0024] In one example, the flexible RAT can include a medium/high frequency band, as well as a low frequency band. In the low frequency band, there can be a primary partition. The primary partition can be in accordance with a standard transmission time interval (TTI). As an example, the standard TTI can be for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure. The standard TTI can be approximately one millisecond (ms) in duration. Furthermore, in the low frequency band, there can be a first secondary partition and a second secondary partition. The primary partition and the secondary partition can be in both time and frequency. The first secondary partition can be in accordance with a short TTI and the second secondary partition can be in accordance with a long TTI. In general, the short TTI can have a duration that is less than

the standard TTI, and the long TTI can have a duration that is greater than the standard TTI. As non-limiting examples, the short TTI can be approximately 0.1 to 0.2 ms in duration, and the long TTI can be approximately 5 ms in duration. In one example, the primary partition in the flexible RAT can be utilized for non-mission critical communications (e.g., voice, data), and the secondary partition in the flexible RAT can be utilized for mission critical communications.

[0025] In one example, for a carrier frequency below 6 Gigahertz (GHz), the primary partition can reuse existing LTE numerology, while the secondary partition can be designed to support low latency or mission critical MTC applications. In particular, the short TTI can enable the low latency for mission critical MTC communications. In addition, increased subcarrier spacing, e.g., 75 kilohertz (kHz), can be adopted for the secondary partition. In contrast, a 15 KHz subcarrier spacing can be utilized for the primary partition.

[0026] FIG. 2 illustrates an exemplary subframe structure for low latency applications. The subframe structure can be for a secondary partition in a low frequency band, and the secondary partition can be associated with a short TTI of approximately 0.1 to 0.2 ms in duration. In one example, the subframe structure for the secondary partition can be based on an orthogonal frequency division multiplexing (OFDM) waveform.

[0027] In the example shown in FIG. 2, a 0.2ms TTI can be achieved. Within one TTI, 12 OFDM symbols can be grouped together (e.g., symbol 0 to symbol 11). Each OFDM symbol can have a duration of 13.3 micro seconds (us). A cyclic prefix (CP) can be inserted between each OFDM symbol. A CP length can be approximately 3.3 us or 512 samples if a sampling rate is 153.6MHz.

[0028] As described in further detail below, a system and method for mission critical communications in a 5G system is described. The mission critical communication can be performed at a user equipment (UE) in a radio resource control (RRC) idle mode. In one example, the procedure can involve a "keep trying" mechanism in which transmissions are repeated to ensure robust communication. The repeated transmissions can provide the ultra-reliability for the mission critical communication. The procedure can involve using a short transmission time interval (TTI) for signaling between the UE and an eNodeB, thereby providing the low latency for the mission critical communication. In one

example, dedicated resources can be used for a 5G physical random access channel (xPRACH) transmission that triggers or indicates the mission critical communication. The xPRACH transmission can be combined with a contention based scheduling request (SR). In addition, the procedure can involve information content, resource allocation and transmission schemes for random access response (RAR) messages with respect to the mission critical communication.

[0029] FIG. 3 illustrates an exemplary mission critical communication between a user equipment (UE) 310 and an eNodeB 320. In one example, the UE 310 can be a mission critical machine type communication (MTC) device. The UE 310 can initially be in a radio resource control (RRC) idle mode. The UE can include one or more processors 312 and memory 314, and the eNodeB 320 can include one or more processors 322 and memory 324. The mission critical communication between the UE 310 and the eNodeB 320 can include four distinct actions. In a first action, the UE 310 can transmit a fifth generation (5G) physical random access channel (xPRACH) signal to the eNodeB 320 using a dedicated resource to indicate or trigger the mission critical communication. To enable faster uplink access and transmission, the xPRACH signal can be combined together with a scheduling request (SR) message. The xPRACH signal and/or SR message can be transmitted using a standard transmission time interval (TTI) in a primary partition. The standard TTI can be approximately one millisecond (ms) in duration. In addition, the dedicated resource can be represented in the form of an xPRACH preamble signature/sequence, time and frequency resource. In a second action, after successful detection of the xPRACH signal and/or decoding of the SR message, the eNodeB 320 can transmit a random access response (RAR) message using a short TTI in a secondary partition. The short TTI can be approximately 0.1 to 0.2 ms in duration. In general, the short TTI is associated with a time interval that is less than the standard TTI. In one example, the standard TTI can be referred to as a first TTI and the short TTI can be referred to as a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI. The RAR message may include a timing advance (TA), a resource allocation for an uplink transmission, etc. In a third action, after successfully decoding the RAR message, the UE 310 can transmit uplink data (i.e., the mission critical data) to the eNodeB 320 in a 5G physical uplink shared channel (xPUSCH) using the short TTI in the secondary partition. In other words, the mission critical communication

from the UE 310 to the eNodeB 320 is performed using the 5G xPUSCH and the short TTI. The uplink data in the xPUSCH can be transmitted on the allocated resource in the RAR message. In a fourth action, the eNodeB 320 can transmit acknowledgement (ACK) or negative acknowledgement (NACK) information to the UE 310. The ACK/NACK information can be transmitted in a 5G physical downlink control channel (xPDCCH) or a 5G physical hybrid-ARQ indicator channel (xPHICH) using the short TTI in the secondary partition. The four actions involved in performing the mission critical communication are described in further detail below.

[0030] In one configuration, a transmitter (e.g., the UE 310 or the eNodeB 320) can keep transmitting the signal until a response is received from a receiver (e.g., the eNodeB 320 or the UE 310). This "keep trying" mechanism can ensure high robustness of the reception, which is essential for the mission critical communication. For instance, in the first action, the UE 310 can continue transmitting the xPRACH signal on the dedicated resource until the UE 310 receives the RAR message from the eNodeB 320. The "keep trying" mechanism can be viewed as an early termination of a repeated transmission. In other words, the transmitter can terminate the repeated transmission when the transmitter receives a response/feedback from the receiver. In addition, a maximum repetition number for each action (e.g., actions 1-4 as described above) can be predefined or configured by higher layers via a 5G master information block (xMIB), a 5G system information block (xSIB) or dedicated RRC signaling. When the transmission reaches the maximum repetition number, the UE 310 can perform a random back-off on the xPRACH signal to re-initiate the mission critical communication.

[0031] In one configuration, for each action (e.g., actions 1-4 as described above), the transmitter can repeat the transmission using a fixed number of repetitions (K repetitions). The number of repetitions can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling. In one example, the value of K can be configured as 1, which indicates that no repetition is used for the transmission. When the transmission reaches the fixed repetition number, the UE 310 can perform a random back-off on the xPRACH signal to re-initiate the mission critical communication, or the UE 310 can indicate a random access problem to upper layers in order to trigger corresponding procedure(s).

[0032] In one example, a combination of the above options can be considered for the transmission of channels and signals in each action (e.g., actions 1-4 as described above). In particular, the transmitter can keep sending the signal until the transmitter receives the response from the receiver, wherein each transmission occupies K repetitions. Similar to the above option, the number of repetitions (K) in each transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0033] In one configuration, a set of dedicated resources can be allocated for the transmission of the xPRACH signal from the UE to indicate or trigger the mission critical communication. The dedicated xPRACH resources can be multiplexed with resources for other applications (i.e., non-mission critical applications) using TDM or FDM or CDM, or a combination of the above. In addition, the partition of the set of dedicated resources for mission critical communications and the resources for other applications can be predefined or configured by higher layer via the xMIB, the xSIB or dedicated RRC signaling.

[0034] In one example, the xPRACH signal can be transmitted using the standard TTI (e.g., 1 ms duration) on the primary partition. Several options can be utilized to allocate the dedicated resource for the transmission of the xPRACH signal. For example, one or a plurality of signatures can be reserved for the xPRACH signal to indicate or trigger the mission critical communication. In addition, to handle the mission critical communication with different applications/services, one or a plurality of dedicated preamble signatures can be reserved for each specific event.

[0035] FIG. 4 illustrates an exemplary partition of a physical random access channel (PRACH) preamble resource. The PRACH preamble resource can include a fifth generation (5G) xPRACH preamble resource. The partition of the xPRACH preamble resource can be for mission critical applications, as well as other applications (i.e., non-mission critical applications). In other words, the xPRACH preamble resource can include a first resource for other applications and a second resource for mission critical applications. In addition, the partition of the xPRACH preamble resource can be associated with different applications and/or events. For example, the xPRACH preamble resource size or the number of reserved sequences for each event can be different. For instance, event #1 in the resource for mission critical applications can correspond to a

mission critical application for earthquake event, and one preamble signature can be reserved for event #1. Event #2 in the resource for mission critical applications can correspond to a mission-critical Vehicular to Vehicular (V2V) application, and five preamble signatures can be reserved for event #2.

[0036] In one example, one or a plurality of frequency resources can be allocated for the xPRACH signal to trigger the mission critical communication. When the UE transmits the xPRACH signal in the dedicated frequency resource, the eNodeB can transmit the corresponding RAR message using the short TTI on the secondary partition. The eNodeB can transmit the corresponding RAR message upon successful detection of xPRACH signal.

[0037] In one example, one or a plurality of time resources can be allocated for the xPRACH signal to trigger the mission critical communication. For example, the xPRACH signal for other applications (i.e., non-mission critical applications) can be transmitted in subframe 0, 2, 4, 6, 8 within one frame, while the xPRACH signal used to trigger the mission critical communication can be transmitted in subframe 1, 3, 5, 7, 9 within one frame.

[0038] In one example, a combination of TDM and/or FDM and/or CDM based multiplexed schemes can be used to separate the resource for mission critical applications and other applications (i.e., non-mission critical applications). For example, a combination of FDM and CDM multiplexing schemes can be utilized, i.e., one additional frequency resource can be reserved for mission critical applications, and within this dedicated frequency resource, different mission critical applications/services can be separated using different xPRACH preamble signatures.

[0039] In another example, a combination of TDM and CDM multiplexing schemes can be utilized. The xPRACH signal for the other application (i.e., a non-mission critical application) can be transmitted in subframe 0, 2, 4, 6, 8 within one frame, while the xPRACH signal used to trigger the mission critical communication can be transmitted in subframe 1, 3, 5, 7, 9 within one frame. Further, different mission critical applications/services can be separated using different xPRACH preamble signatures.

[0040] In one example, with respect to ultra-reliable and low latency communications, multiple mission critical devices can operate as a “single frequency network” (SFN),

which can improve a link level performance for mission critical communication. In this case, the eNodeB can treat multiple mission critical devices as a single mission critical device. For example, the eNodeB can transmit a single RAR message to multiple UEs, and in response, multiple UEs can transmit uplink data (i.e., mission critical data) simultaneously to the eNodeB on the same time and frequency resource.

[0041] In one example, in order to differentiate a typical operation from a "single frequency network" type of operation, different xPRACH resources can be allocated. For example, one event ID or dedicated xPRACH signature can be allocated for the "single frequency network" type of operation. In addition, when repeated transmissions of the xPRACH preamble are used, a starting subframe of the repeated xPRACH transmission can be predefined or configured by higher layers, thereby causing the eNodeB to perform efficient detection of the repeated xPRACH signal.

[0042] A more detailed description is now provided with respect to the first action shown in FIG. 3, in which the UE can transmit the 5G xPRACH signal and/or SR message to the eNodeB using dedicated resources to indicate or trigger the machine critical communication. The xPRACH signal transmission can be combined with a contention based scheduling request (SR) message to allow uplink access in a reduced amount of time, thereby fulfilling the latency constraints for mission critical communications. The contention based SR message can include the UE ID and buffer status report to enable uplink access in the reduced amount of time.

[0043] For mission critical applications, the SR message can be transmitted from the UE to the eNodeB as part of a random access channel (RACH) procedure, which allows for a reduction in connection establishment delay as compared to existing LTE systems. The SR message can be a fixed size and can include several parameters/fields. The SR message can include a mission critical MTC device ID, which can be the same as the UE ID or a different ID. The SR message can include an event ID to indicate an access cause when a same set of xPRACH sequences are allocated for multiple applications/services. The event ID can be included in the SR message to expedite access for the UE. The SR message can include a mission critical MTC device capability, which can include mission critical specific UE radio access capability information, such as carrier aggregation (CA) capability, i.e., component carrier (CC) index(s) that are supported by the UE (e.g., the

mission critical MTC device), supported multiple input multiple output (MIMO) capability, etc. The SR message can include a resource request and modulation and coding scheme (MCS) for an uplink transmission (e.g., mission critical data) from the UE. For example, the SR message can include the resource request in the time and frequency domain, e.g., physical resource block (PRB) index or numbers within one band, or symbol/slot/subframe/frame index or CC index(s) used for the uplink transmission. Alternatively, the UE can indicate the total amount of data for mission critical application and/or channel state information (CSI)/reference signaling measurements, which can subsequently be used for downlink MCS selection and open loop power control calculation.

[0044] In one example, when the resource request of PRB index and MCS are included in the SR message, the eNodeB can feedback 1 bit ACK/NACK information to the UE (or mission critical MTC device). Upon successful ACK detection, the UE can use the resource indicated in the SR message for uplink data transmission based on a predefined timing following a subframe in which the ACK/NACK information is detected.

[0045] In one example, the "keep trying" mechanism or repeated transmission can be employed when transmitting the xPRACH signal and/or SR message to the eNodeB. The same xPRACH preamble signature and the same SR information can be used for the transmission of the xPRACH signal and the SR message during the repetition, respectively. In addition, the SR message can occupy the resource allocated for the SR transmission to further enhance the link level performance.

[0046] In one example, UEs may not have the xPRACH/SR repetition capability, or the function may not be configured at the UE by the eNodeB. In this case, different xPRACH and/or SR resources can be used with respect to (1) an initial transmission that is shared among all UEs and (2) subsequent repeated transmission that is dedicated for UEs enabled with the xPRACH/SR repetition capability. In one example, the resource for the initial transmission of the xPRACH signal and SR message can be selected by the UE within a contention-based resource region, while the resources for subsequent repeated transmissions can be configured by higher-layers (e.g., broadcasted in the xSIB) within a contention-free resource region on the same partition or a different partition.

[0047] In one example, available sets of xPRACH or SR resources reserved for the UE

(e.g., a mission critical MTC device) can be divided into two different regions – a first region can be used for the xPRACH/SR transmission repetition and the second region can be reserved for the xPRACH/SR transmission without repetition. More specifically, an xPRACH signal or SR message can be repeatedly transmitted on a configurable or fixed consecutive xPRACH or SR resources within the first region according to a known pattern (e.g., TDM, CDM or FDM). The number of repetition times can be predefined or configured by higher layers for an individual UE. In addition, one-to-one mapping between the xPRACH repetition level and the xPRACH/SR resource set can be utilized. The UE can select an xPRACH/SR repetition level based on a measurement, such as a reference signal received power (RSRP), and the UE can transmit the xPRACH/SR using the xPRACH/SR resources set according to the selected xPRACH/SR repetition level.

[0048] FIG. 5 illustrates an exemplary multiplexing of a physical random access channel (PRACH) signal and a scheduling request (SR) message in a repeated transmission. The PRACH signal can include a fifth generation (5G) xPRACH signal. Various multiplexing mechanisms, such as time division multiplexing (TDM) or frequency division multiplexing (FDM), can be applied to the xPRACH signal and the SR message. As shown in FIG. 5, TDM multiplexing can be used for repeated transmissions of the xPRACH signal and the SR message, or FDM multiplexing can be used for repeated transmissions of the xPRACH signal and the SR message. In other words, TDM and FDM based multiplexing mechanisms can be applied to the "keep trying" mechanism for repeated transmissions. In addition, the SR message can be transmitted using all the available resource to achieve ultra-reliable communication.

[0049] In one example, with respect to transmission power control mechanism for the transmission of the xPRACH signal and/or the SR message, several options can be used. In one example, when (re)transmitting the xPRACH signal and/or SR message, a maximum transmit power can be used to ensure robust detection at the eNodeB. In another example, an existing power control mechanism can be applied for the transmission and retransmission of the xPRACH signal and/or SR message. In particular, for an initial transmission, the xPRACH transmission power can be set to an initial PRACH power, while for the retransmission, power ramping can be used to increase the actual transmission power.

[0050] In yet another example with respect to transmission power control, repetition level ramping can be applied for the transmission and retransmission of the xPRACH signal and/or SR message. Further, the repetition level ramping mechanism can be combined in conjunction with power ramping to further improve the performance. In one example, the repetition level can be doubled for each retransmission. In the initial transmission, the repetition level can be defined as K, while in the first retransmission, the repetition level can be set to 2K, etc. Additionally, if power ramping is applied on top of the repetition level ramping, the power ramping can be defined so as to account for an increase in the repetition level. Specifically, the power level for the first attempt at a subsequent repetition level can be reduced by a factor of 10*log(numRepL/numRepL-1), wherein numRepL and numRepL-1 are the number of repetitions configured for repetition levels L and L-1, respectively.

[0051] A more detailed description is now provided with respect to the second action shown in FIG. 3, in which the eNodeB can transmit the RAR message to the UE using the short TTI. After identifying the mission critical event based on detection of the xPRACH signal, the eNodeB can dynamically allocate the resource in a secondary partition, and the eNodeB can transmit the corresponding RAR message using the short TTI.

[0052] For mission critical MTC applications, a fixed relationship can be defined between the time (e.g., a last repetition/retransmission) of the xPRACH transmission and a time of the first transmission of the xPDCCH/xPDSCH signal (either scheduling or carrying the RAR message). Additionally, the frequency resource for the xPDCCH (if xPDCCH is not wideband) or xPDSCH can be determined as a function of at least the preamble sequence of the detected xPRACH signal, and possibly also the frequency location of the detected xPRACH signal. If additional flexibility is desired at the eNodeB, then for time-domain scheduling of the RAR message, a short RAR window can be defined in which the UE monitors for the first transmission of the xPDCCH/xPDSCH signal with the RAR message.

[0053] FIG. 6 illustrates an exemplary random access response (RAR) window for repeated transmissions between a user equipment (UE) and an eNodeB. When repeated transmissions are used for the xPRACH signal and/or SR message, the RAR window can be defined such that the UE (e.g., a mission critical MTC device) can monitor for the

RAR message within the RAR window. As shown in FIG. 6, the xPRACH signal and SR message can be transmitted in an uplink in accordance with a standard TTI (e.g., 1 ms in duration). After transmission of the xPRACH signal and SR message, the RAR window can be defined. During the RAR window, the UE can monitor a downlink for the RAR message. The UE can detect the RAR message during the RAR message, wherein the RAR message is transmitted in accordance with a short TTI. In one example, the position of the RAR window can be predefined or configured by higher layer via the xMIB, the xSIB or dedicated RRC signaling. In addition, the starting position of the RAR window can be defined relative to the starting of the last subframe of the repeated xPRACH signal and/or SR message transmission.

[0054] FIGS. 7A to 7C illustrates exemplary resource allocations of a primary partition and a secondary partition within a transmission time interval (TTI). The TTI can be a standard TTI with a duration of one millisecond (ms). Guard bands can be inserted between the primary and secondary partitions in a frequency domain in order to reduce inter-carrier interference.

[0055] As shown in FIG. 7A, a secondary partition using a short TTI (e.g., 0.1 to 0.2 ms) can be allocated after an xPDCCH region. The xPDCCH region can be in the primary partition using the standard TTI. When different numerologies, e.g., subcarrier spacing, are used for the primary and secondary partitions, a guard time may be inserted between the xPDCCH region using the standard TTI and the secondary partition using the short TTI. This option may avoid traffic interruption for the primary partition, as the eNodeB can schedule the downlink and uplink transmission via the xPDCCH within the primary partition.

[0056] As shown in FIG. 7B, a secondary partition using a short TTI (e.g., 0.1 to 0.2 ms) can be allocated after an xPDCCH region. The xPDCCH region can be in the primary partition using the standard TTI. Further, the secondary partition can occupy a full system bandwidth to enhance the link level performance. In this approach, guard times may not be inserted between the xPDCCH region using the standard TTI and the secondary partition using the short TTI.

[0057] As shown in FIG. 7C, a secondary partition using a short TTI (e.g., 0.1 to 0.2 ms) can span a standard TTI (e.g., 1 ms). In this approach, the secondary partition can occupy

a full system bandwidth to enhance the link level performance. In addition, a guard time may be inserted to reduce interference in a primary partition.

[0058] In one example, the resource allocation for the secondary partition can be predefined, or broadcasted in a mission critical specific xSIB message, or indicated in a downlink control information (DCI) format in the xPDCCH using the standard TTI in the primary partition. In the latter case, the UE (e.g., a mission critical MTC device) can monitor the xPDCCH with a cyclic redundancy check (CRC) scrambled by an existing random-access radio network temporary identifier (RA-RNTI) or a newly defined RA-RNTI for mission critical applications. The RA-RNTI can be predefined in the specification or defined as a function of at least one of: the time index, frequency index, preamble sequence, and repetition level used for the detected xPRACH transmission. Upon successful decoding of the xPDCCH signal, the UE can switch to a short TTI mode and decode the RAR message within the secondary partition.

[0059] FIG. 8 illustrates an exemplary repeated transmission of a random access response (RAR) message using a short transmission time interval (TTI). The "keep trying" mechanism or repeated transmissions of the RAR message can be used to improve the link level performance. The repeated RAR transmissions using the short TTI can occur within a secondary partition used for mission critical communication. As shown in FIG. 8, a preamble can be inserted before each transmission of the RAR message to improve a downlink synchronization accuracy, which is useful in view of the higher sampling rate used for the short TTI with large subcarrier spacing (e.g., 15 KHz). The preamble can utilize similar principles as compared to the 5G downlink synchronization channel (xSCH). To differentiate the preamble from the xSCH, independent root sequences can be employed when Zadoff-Chu (ZC) sequences are used for the xSCH.

[0060] In one example, the RAR message can include various parameters. For example, the RAR message can include a timing advance (TA). The eNodeB can estimate an initial TA from the xPRACH signal sent by the UE. The RAR message can include an UL grant for a subsequent uplink transmission. In addition, the UL grant can include a resource allocation of the secondary partition used for the subsequent uplink transmission. When the UE (e.g., a mission critical MTC device) supports carrier aggregation (CA), the resource allocation for multiple component carriers (CCs) can be included in the uplink

grant. The UL grant can include a modulation and coding scheme (MCS) and a power control parameter for the subsequent uplink transmission, as well as the number of repetitions used for the RAR transmission. In one example, the RAR message can include a mission critical MTC device ID, which can be used for contention resolution. The RAR message can include an event ID, which can be obtained from the SR message and used for contention resolution. In addition, the RAR message can include a random access preamble ID that is useful for contention resolution. The random access preamble ID can include a preamble index for the xPRACH transmission.

[0061] In one example, the RAR message can be transmitted in the secondary partition using the short TTI either: (1) on the xPDSCH scheduled by the xPDCCH, or (2) using the xPDCCH directly, or (3) using the xPDSCH directly. With respect to the first option, the xPDCCH can indicate the resource allocation and MCS for the transmission of the xPDSCH signal, while the xPDSCH carries the RAR message. With respect to the second option, the RAR message can be transmitted via the xPDCCH. In this case, the UE (e.g., a mission critical MTC device) can monitor the xPDCCH with the CRC scrambled by the RA-RNTI. With respect to the third option, the RAR message can be transmitted via the xPDSCH using the short TTI. When repeated transmissions or the "keep trying" mechanism is employed for the RAR message, TTI bundling and a predefined redundancy version (RV) pattern (e.g., [0 2 3 1]) can be used when turbo coding is adopted. Further, a scrambling seed for the transmission of the xPDSCH signal can be defined as a function of the RA-RNTI or a group ID with respect to a "single frequency network" (SFN) type of operation. In one example, the group ID can be specified as the event ID.

[0062] In one example, the UE (e.g., a mission critical MTC device) can monitor for the xPDSCH signal using fixed and known values of the MCS and a transport block size (TBS). If a UE processing complexity increase can be accommodated for mission critical devices, then a limited number of options for MCS and TBS for the xPDSCH can be configured, from which the UE can perform blind detection.

[0063] A more detailed description is now provided with respect to the third action shown in FIG. 3, in which the UE can transmit uplink data (i.e., mission critical data) to the eNodeB using the short TTI. A resource allocation for the uplink data transmission can be

indicated in the RAR message. In particular, the resource allocation can be associated with a secondary partition to be used for the uplink data transmission. Further, a scrambling seed for a transmission of the xPUSCH signal can be defined as a function of a mission critical MTC device ID or a group ID with respect to a "single frequency network" type of operation. In one example, the group ID can be specified as the event ID.

[0064] When the repeated transmission is used for the uplink transmission, a gap between the end of a last RAR transmission and a starting subframe of the uplink transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling. Alternatively, to allow additional flexibility, a delay parameter can be indicated in the UL grant of the RAR message, wherein the delay parameter can be of the order of one or more standard or short TTI(s).

[0065] In one example, to improve the robustness of the uplink transmission, the same information can be transmitted on multiple component carriers (CC) simultaneously, or transmitted repeatedly within a CC to fulfil the reliability constraint of the mission critical communication. Further, TTI bundling with a predefined redundancy version (RV) pattern can be employed for performance enhancement. For mission critical applications with small data packet transmissions, tail biting convolution coding (TBCC) can be used as a forward error correction (FEC) scheme as opposed to turbo coding.

[0066] A more detailed description is now provided with respect to the fourth action shown in FIG. 3, in which the eNodeB can transmit ACK/NACK information to the UE using the short TTI. The ACK/NACK can be transmitted via the xPDCCH or the xPHICH using the short TTI on the secondary partition. When repeated transmission are used for the ACK/NACK transmission, a gap between the end of a last uplink data transmission and a starting subframe of the ACK/NACK transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0067] In one example, when a NACK is received or an ACK is not received, the UE (e.g., a mission critical MTC device) can perform a retransmission of the uplink data. When a maximum number of retransmission is reached, the UE can perform a random back-off and re-initiate the procedure for mission critical communication. Alternatively, assuming that an uplink synchronization has been established via a mission critical

random access procedure, the UE can transmit a scheduling request (SR) using the short TTI on the secondary partition at a next available SR opportunity. In one example, periodically occurring SR opportunities can be defined in the secondary partition. The SR transmission can be based on a physical structure of the xPUSCH or xPUCCH, which are adapted for transmissions using short TTIs. The configuration of the SR opportunities in the secondary partition can be pre-defined or broadcasted using the xSIB. Alternatively, the configuration of the SR opportunities can be indicated via a combination of broadcasted information of system level configurations and UE-specific signaling of the actual configured SR resource periodicity carried in the RAR message.

[0068] In one example, with respect to the "single frequency network (SFN)" type of operation, multiple UEs that are closely co-located (i.e., located within a defined distance from each other) can transmit the xPRACH signal on the same xPRACH resource using the same xPRACH preamble, which can improve the xPRACH detection performance. In response to receiving the xPRACH signal from multiple UEs, the eNodeB can transmit a single RAR message that targets the multiple UEs. In addition, when one or more UEs successfully receive the RAR message, the UEs can transmit the xPUSCH signal simultaneously on the same resource, which can achieve SFN gain.

[0069] In one configuration, a system and method of ultra-reliable and low latency communications for a fifth generation (5G) system is described. A user equipment (UE) can transmit, to an eNodeB, a 5G Physical Random Access Channel (xPRACH) and/or a scheduling request (SR) message to trigger a mission critical communication. The xPRACH and/or SR can be transmitted on a dedicated resource using a standard transmission time interval (TTI) in a primary partition. The UE can receive a random access response (RAR) using a short TTI in a secondary partition. The UE can transmit uplink data to the eNodeB in a 5G physical uplink shared channel (xPUSCH) using the short TTI in the secondary partition. The UE can receive, from the eNodeB, acknowledgement (ACK) or negative acknowledgement (NACK) information in a 5G physical downlink control channel (xPDCCH) or a 5G Physical Hybrid-ARQ Indicator Channel (xPHICH) using the short TTI in the secondary partition.

[0070] In one configuration, a keep trying mechanism is employed between the UE and the eNodeB for ultra-reliable and low latency communication. A transmitter (e.g., the UE

or eNodeB) can keep sending a signal until a response is received from a receiver (e.g., the eNodeB or UE). A maximum repetition number for each transmission can be predefined or configured by higher layers via a 5G master information block (xMIB), a 5G system information block (xSIB) or dedicated RRC signaling.

[0071] In one configuration, a transmitter (e.g., the UE or eNodeB) can repeat the transmission using a fixed number of repetitions. The fixed number of repetitions can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0072] In one configuration, a transmitter (e.g., the UE or eNodeB) can keep sending the signal until a response is received from a receiver (e.g., the eNodeB or UE). In addition, each transmission can occupy K repetitions, and K is predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0073] In one configuration, a set of dedicated xPRACH resources for mission critical communications can be multiplexed with resources for non-mission critical applications using time division multiplexing (TDM) or frequency division multiplexing (FDM) or code division multiplexing (CDM) or a combination of above. In addition, a partition configuration can be predefined or configured by higher layer via the xMIB, the xSIB or dedicated RRC signaling.

[0074] In one configuration, one or more signatures can be reserved for the xPRACH to trigger the mission critical communication.

[0075] In one configuration, one or more time resources can be reserved for the xPRACH to trigger the mission critical communication.

[0076] In one configuration, one or more frequency resources can be reserved for the xPRACH to trigger the mission critical communication.

[0077] In one configuration, one or more xPRACH signatures or time resources or frequency resources can be reserved for "single frequency network" type of operations.

[0078] In one configuration, the SR message can have a fixed size, and the SR can include at least the following parameters or fields: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, a resource request, and a modulation and coding scheme (MCS) for

transmission of the uplink data from the UE to the eNodeB. In addition, the resource request can include a physical resource block (PRB) index or numbers within one band, or symbol/slot/subframe/frame index or component carrier (CC) index(s) used for the transmission of the uplink data.

[0079] In one configuration, a resource for an initial transmission of the xPRACH and SR is selected by a given UE within a contention-based resource region, and resources for subsequent repeated transmissions can be configured by higher-layers (e.g.. broadcasted in the xSIB) within a contention-free resource region on a same partition or a different partition.

[0080] In one configuration, a maximum transmit power can be utilized for the transmission and retransmission of the xPRACH signal and/or SR message.

[0081] In one configuration, existing power control mechanisms can be applied for the transmission and retransmission of the xPRACH signal and/or SR message.

[0082] In one configuration, repetition level ramping can be applied for the transmission and retransmission of the xPRACH signal and/or SR message.

[0083] In one configuration, the UE (e.g., a mission critical MTC device) can monitor a random access response (RAR) message within a RAR window. A position of the RAR window can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0084] In one configuration, a resource allocation of a secondary partition or a RAR transmission is predefined, or broadcasted in a xSIB message, or indicated in a downlink control information (DCI) format in the xPDCCH using a standard TTI in the primary partition.

[0085] In one configuration, the secondary partition can be allocated after the xPDCCH region in the primary partition using the standard TTI (e.g., 1 ms). In addition, the secondary partition can occupy a full system bandwidth.

[0086] In one configuration, the secondary partition can span a standard TTI (e.g., 1 ms). In addition, the secondary partition can occupy a full system bandwidth.

[0087] In one configuration, a preamble can be inserted prior to the transmission of the RAR message. The preamble can be based on a 5G downlink synchronization channel

(xSCH).

[0088] In one configuration, the RAR message can include the following parameters or fields: a timing advance command (TA), an uplink grant, a mission critical MTC device ID, an event ID and a random access preamble ID. The uplink grant can further include a resource allocation of the secondary partition used for a subsequent uplink transmission.

[0089] In one configuration, the RAR message can be transmitted via the xPDSCH using a short TTI. When a repeated transmission mechanism (or "keep trying" mechanism) is employed, TTI bundling and a predefined redundancy version (RV) pattern can be used for the transmission of the RAR message when turbo coding is adopted. In addition, with respect to a "single frequency network" type of operation, a scrambling seed for the transmission of the xPDSCH can be defined as a function of a random access radio network temporary identifier (RA-RNTI), a group ID or an event ID.

[0090] In one configuration, the RAR message can be transmitted via the xPDCCH. The UE (e.g., a mission critical MTC device) can monitor the xPDCCH with a cyclic redundancy check (CRC) scrambled by an RA-RNTI.

[0091] In one configuration, the RAR message can be transmitted via the xPDSCH scheduled by the xPDCCH.

[0092] In one configuration, a gap between an end of a last RAR transmission and a starting subframe of the uplink transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling. In addition, a delay parameter in the order of standard or short TTI can indicated in the UL grant of the RAR message.

[0093] In one configuration, for the uplink transmission, the same information can be transmitted on multiple component carriers (CC) simultaneously or transmitted repeatedly over multiple sets of PRBs within a CC. In one example, TTI bundling with a predefined redundancy version (RV) pattern can be employed for the uplink transmission. In another example, a scrambling seed for the transmission of the xPUSCH can be defined as a function of a mission critical MTC device ID or a group ID for a "single frequency network" type of operation.

[0094] In one configuration, a gap between an end of the uplink data transmission and a starting subframe of the ACK/NACK transmission can be predefined or configured by

higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0095] In one configuration, when a negative acknowledgement (NACK) is received or an acknowledgement (ACK) is not received, the UE (e.g., a mission critical MTC device) can perform a retransmission of the uplink data. When a maximum number of retransmission is reached, the UE can perform a random back-off and re-initiate the procedure for mission critical communication.

[0096] Another example provides functionality 900 of a user equipment (UE) operable to perform mission critical communications with an eNodeB, as shown in the flow chart in FIG. 9. The UE can comprise one or more processors and memory configured to: transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI), as in block 910. The UE can comprise one or more processors and memory configured to: receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI, as in block 920. The UE can comprise one or more processors and memory configured to: decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication, as in block 930. The UE can comprise one or more processors and memory configured to: perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI, as in block 940.

[0097] Another example provides functionality 1000 of a base station operable to receive mission critical communications from a user equipment (UE), as shown in the flow chart in FIG. 10. The base station can comprise one or more processors and memory configured to: receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in

accordance with a first transmission time interval (TTI), as in block 1010. The base station can comprise one or more processors and memory configured to: transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI, as in block 1020. The base station can comprise one or more processors and memory configured to: receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message, as in block 1030. The base station can comprise one or more processors and memory configured to: transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI, as in block 1040.

[0098] Another example provides at least one machine readable storage medium having instructions 1100 embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, as shown in the flow chart in FIG. 11. The instructions can be executed on a machine, where the instructions are included on at least one computer readable medium or one non-transitory machine readable storage medium. The instructions when executed perform: transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI), as in block 1110. The instructions when executed perform: receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI, as in block 1120. The instructions when executed perform: performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation

indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI, as in block 1130. The instructions when executed perform: receiving, using the at least one processor of the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI, as in block 1140.

[0099] FIG. 12 provides an example illustration of a user equipment (UE) device 1200, such as a wireless device, a mobile station (MS), a mobile wireless device, a mobile communication device, a tablet, a handset, or other type of wireless device. The UE device 1200 can include one or more antennas configured to communicate with a node or transmission station, such as a base station (BS), an evolved Node B (eNB), a baseband unit (BBU), a remote radio head (RRH), a remote radio equipment (RRE), a relay station (RS), a radio equipment (RE), a remote radio unit (RRU), a central processing module (CPM), or other type of wireless wide area network (WWAN) access point. The UE device 1200 can be configured to communicate using at least one wireless communication standard including 3GPP LTE, WiMAX, High Speed Packet Access (HSPA), Bluetooth, and WiFi. The UE device 1200 can communicate using separate antennas for each wireless communication standard or shared antennas for multiple wireless communication standards. The UE device 1200 can communicate in a wireless local area network (WLAN), a wireless personal area network (WPAN), and/or a WWAN.

[00100] In some embodiments, the UE device 1200 may include application circuitry 1202, baseband circuitry 1204, Radio Frequency (RF) circuitry 1206, front-end module (FEM) circuitry 1208 and one or more antennas 1210, coupled together at least as shown.

[00101] The application circuitry 1202 may include one or more application processors. For example, the application circuitry 1202 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The processor(s) may include any combination of general-purpose processors and dedicated processors (e.g., graphics processors, application processors, etc.). The processors may be coupled with and/or may include a storage medium 1212, and may be configured to execute instructions stored in the storage medium 1212 to enable various applications and/or operating systems to run on the system.

[00102] The baseband circuitry 1204 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry 1204 may include one or more baseband processors and/or control logic to process baseband signals received from a receive signal path of the RF circuitry 1206 and to generate baseband signals for a transmit signal path of the RF circuitry 1206. Baseband processing circuity 1204 may interface with the application circuitry 1202 for generation and processing of the baseband signals and for controlling operations of the RF circuitry 1206. For example, in some embodiments, the baseband circuitry 1204 may include a second generation (2G) baseband processor 1204a, third generation (3G) baseband processor 1204b, fourth generation (4G) baseband processor 1204c, and/or other baseband processor(s) 1204d for other existing generations, generations in development or to be developed in the future (e.g., fifth generation (5G), 6G, etc.). The baseband circuitry 1204 (e.g., one or more of baseband processors 1204a-d) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry 1206. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some embodiments, modulation/demodulation circuitry of the baseband circuitry 1204 may include Fast-Fourier Transform (FFT), precoding, and/or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry 1204 may include convolution, tail-biting convolution, turbo, Viterbi, and/or Low Density Parity Check (LDPC) encoder/decoder functionality. Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments.

[00103] In some embodiments, the baseband circuitry 1204 may include elements of a protocol stack such as, for example, elements of an evolved universal terrestrial radio access network (EUTRAN) protocol including, for example, physical (PHY), media access control (MAC), radio link control (RLC), packet data convergence protocol (PDCP), and/or radio resource control (RRC) elements. A central processing unit (CPU) 1204e of the baseband circuitry 1204 may be configured to run elements of the protocol stack for signaling of the PHY, MAC, RLC, PDCP and/or RRC layers. In some embodiments, the baseband circuitry may include one or more audio digital signal

processor(s) (DSP) 1204f. The audio DSP(s) 104f may be include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments. Components of the baseband circuitry may be suitably combined in a single chip, a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry 1204 and the application circuitry 1202 may be implemented together such as, for example, on a system on a chip (SOC).

[00104] In some embodiments, the baseband circuitry 1204 may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry 1204 may support communication with an evolved universal terrestrial radio access network (EUTRAN) and/or other wireless metropolitan area networks (WMAN), a wireless local area network (WLAN), a wireless personal area network (WPAN). Embodiments in which the baseband circuitry 1204 is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

[00105] The RF circuitry 1206 may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry 1206 may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry 1206 may include a receive signal path which may include circuitry to down-convert RF signals received from the FEM circuitry 1208 and provide baseband signals to the baseband circuitry 1204. RF circuitry 1206 may also include a transmit signal path which may include circuitry to up-convert baseband signals provided by the baseband circuitry 1204 and provide RF output signals to the FEM circuitry 1208 for transmission.

[00106] In some embodiments, the RF circuitry 1206 may include a receive signal path and a transmit signal path. The receive signal path of the RF circuitry 1206 may include mixer circuitry 1206a, amplifier circuitry 1206b and filter circuitry 1206c. The transmit signal path of the RF circuitry 1206 may include filter circuitry 1206c and mixer circuitry 1206a. RF circuitry 1206 may also include synthesizer circuitry 1206d for synthesizing a frequency for use by the mixer circuitry 1206a of the receive signal path and the transmit signal path. In some embodiments, the mixer circuitry 1206a of the receive signal path

may be configured to down-convert RF signals received from the FEM circuitry 1208 based on the synthesized frequency provided by synthesizer circuitry 1206d. The amplifier circuitry 1206b may be configured to amplify the down-converted signals and the filter circuitry 1206c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals. Output baseband signals may be provided to the baseband circuitry 1204 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals, although this is not a requirement. In some embodiments, mixer circuitry 1206a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

[00107] In some embodiments, the mixer circuitry 1206a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 1206d to generate RF output signals for the FEM circuitry 1208. The baseband signals may be provided by the baseband circuitry 1204 and may be filtered by filter circuitry 1206c. The filter circuitry 1206c may include a low-pass filter (LPF), although the scope of the embodiments is not limited in this respect.

[00108] In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a of the transmit signal path may include two or more mixers and may be arranged for quadrature down-conversion and/or up-conversion respectively. In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a may be arranged for direct down-conversion and/or direct up-conversion, respectively. In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a of the transmit signal path may be configured for super-heterodyne operation.

[00109] In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 1206 may include analog-to-digital converter (ADC) and digital-to-analog

converter (DAC) circuitry and the baseband circuitry 1204 may include a digital baseband interface to communicate with the RF circuitry 1206.

[00110] In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

[00111] In some embodiments, the synthesizer circuitry 1206d may be a fractional-N synthesizer or a fractional N/N+1 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 1206d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

[00112] The synthesizer circuitry 1206d may be configured to synthesize an output frequency for use by the mixer circuitry 1206a of the RF circuitry 1206 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 1206d may be a fractional N/N+1 synthesizer.

[00113] In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO), although that is not a requirement. Divider control input may be provided by either the baseband circuitry 1204 or the applications processor 1202 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the applications processor 1202.

[00114] Synthesizer circuitry 1206d of the RF circuitry 1206 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or N+1 (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into Nd equal packets of phase, where Nd is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

[00115] In some embodiments, synthesizer circuitry 1206d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 1206 may include an IQ/polar converter.

[00116] FEM circuitry 1208 may include a receive signal path which may include circuitry configured to operate on RF signals received from one or more antennas 1210, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 1206 for further processing. FEM circuitry 1208 may also include a transmit signal path which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 1206 for transmission by one or more of the one or more antennas 1210.

[00117] In some embodiments, the FEM circuitry 1208 may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry may include a low-noise amplifier (LNA) to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry 1206). The transmit signal path of the FEM circuitry 1208 may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry 1206), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas 1210.

[00118] FIG. 13 provides an example illustration of the wireless device, such as a user equipment (UE), a mobile station (MS), a mobile wireless device, a mobile communication device, a tablet, a handset, or other type of wireless device. The wireless device can include one or more antennas configured to communicate with a node, macro node, low power node (LPN), or, transmission station, such as a base station (BS), an evolved Node B (eNB), a baseband processing unit (BBU), a remote radio head (RRH), a remote radio equipment (RRE), a relay station (RS), a radio equipment (RE), or other

type of wireless wide area network (WWAN) access point. The wireless device can be configured to communicate using at least one wireless communication standard such as, but not limited to, 3GPP LTE, WiMAX, High Speed Packet Access (HSPA), Bluetooth, and WiFi. The wireless device can communicate using separate antennas for each wireless communication standard or shared antennas for multiple wireless communication standards. The wireless device can communicate in a wireless local area network (WLAN), a wireless personal area network (WPAN), and/or a WWAN. The wireless device can also comprise a wireless modem. The wireless modem can comprise, for example, a wireless radio transceiver and baseband circuitry (e.g., a baseband processor). The wireless modem can, in one example, modulate signals that the wireless device transmits via the one or more antennas and demodulate signals that the wireless device receives via the one or more antennas.

[00119] FIG. 13 also provides an illustration of a microphone and one or more speakers that can be used for audio input and output from the wireless device. The display screen can be a liquid crystal display (LCD) screen, or other type of display screen such as an organic light emitting diode (OLED) display. The display screen can be configured as a touch screen. The touch screen can use capacitive, resistive, or another type of touch screen technology. An application processor and a graphics processor can be coupled to internal memory to provide processing and display capabilities. A non-volatile memory port can also be used to provide data input/output options to a user. The non-volatile memory port can also be used to expand the memory capabilities of the wireless device. A keyboard can be integrated with the wireless device or wirelessly connected to the wireless device to provide additional user input. A virtual keyboard can also be provided using the touch screen.

Examples

[00120] The following examples pertain to specific technology embodiments and point out specific features, elements, or actions that can be used or otherwise combined in achieving such embodiments.

[00121] Example 1 includes an apparatus of a user equipment (UE) operable to perform mission critical communications with an eNodeB, the apparatus comprising one or more processors and memory configured to: transmit, from the UE to the eNodeB, a physical

random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI); receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication; and perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

[00122] Example 2 includes the apparatus of Example 1, further configured to receive, from the eNodeB, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00123] Example 3 includes the apparatus of any of Examples 1-2, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and the second TTI is approximately 0.1 to 0.2 ms.

[00124] Example 4 includes the apparatus of any of Examples 1-3, wherein the first TTI is associated with a first partition of a low band and the second TTI is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00125] Example 5 includes the apparatus of any of Examples 1-4, wherein the UE is configured to: perform repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and perform repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative

acknowledgement (NACK) is received from the eNodeB, wherein a maximum number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling, wherein the UE performs a random back off and reinitiates a procedure for performing the mission critical communication when the maximum number of repetitions for a defined transmission is reached.

[00126] Example 6 includes the apparatus of any of Examples 1-5, wherein the UE is configured to: repeatedly transmit the PRACH signal to the eNodeB in accordance with a fixed number of repetitions; and repeatedly perform the mission critical communication with the eNodeB in accordance with a fixed number of repetitions, wherein the fixed number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

[00127] Example 7 includes the apparatus of any of Examples 1-6, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

[00128] Example 8 includes the apparatus of any of Examples 1-7, wherein a plurality of signatures, time resources and frequency resources are reserved for transmitting the PRACH signal from the UE to trigger the mission critical communication.

[00129] Example 9 includes the apparatus of any of Examples 1-8, wherein the PRACH signal is communicated to the eNodeB with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE.

[00130] Example 10 includes the apparatus of any of Examples 1-9, wherein the PRACH signal is transmitted from the UE to the eNodeB in accordance with a maximum transmit power.

[00131] Example 11 includes the apparatus of any of Examples 1-10, wherein the UE is

configured to receive the RAR message from the eNodeB by monitoring a RAR message window, wherein a position of the RAR message window is configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

[00132] Example 12 includes the apparatus of any of Examples 1-11, further configured to receive a preamble from the eNodeB prior to receiving the RAR message, wherein the preamble functions to improve a downlink synchronization accuracy.

[00133] Example 13 includes the apparatus of any of Examples 1-12, wherein the RAR message received at the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

[00134] Example 14 includes the apparatus of any of Examples 1-13, wherein: the RAR message is received at the UE via a physical downlink control channel (PDCCH), wherein the UE is configured to monitor the PDCCH using a cyclic redundancy check (CRC) scrambled by a random-access radio network temporary identifier (RA-RNTI); or the RAR message is received at the UE via a physical downlink shared channel (PDSCH) that is scheduled by the PDCCH.

[00135] Example 15 includes the apparatus of any of Examples 1-14, wherein: a gap between a last subframe for a RAR message transmission and a starting subframe of the mission critical communication in uplink is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling; and a gap between a last subframe of the mission critical communication in uplink and a starting subframe of an acknowledgement (ACK) or a negative acknowledgement (NACK) transmission is predefined or configured by higher layers via one of: the MIB, the SIB, or dedicated RRC signaling.

[00136] Example 16 includes the apparatus of any of Examples 1-15, wherein the UE includes at least one of an antenna, a touch sensitive display screen, a speaker, a microphone, a graphics processor, an application processor, a baseband processor, an internal memory, a non-volatile memory port, and combinations thereof.

[00137] Example 17 includes an apparatus of a base station operable to receive mission

critical communications from a user equipment (UE), the apparatus comprising one or more processors and memory configured to: receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI); transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message; and transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00138] Example 18 includes the apparatus of Example 17, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00139] Example 19 includes the apparatus of any of Examples 17-18, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

[00140] Example 20 includes the apparatus of any of Examples 17-19, wherein: the PRACH signal is received from the UE with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device

identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE; and the RAR message transmitted to the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

[00141] Example 21 includes the apparatus of any of Examples 17-20, wherein the RAR message is transmitted to the UE via a physical downlink control channel (PDCCH) or a physical downlink shared channel (PDSCH).

[00142] Example 22 includes at least one machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, the instructions when executed perform the following: transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI); receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI; and receiving, using the at least one processor of the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00143] Example 23 includes the at least one machine readable storage medium of Example 22, wherein the UE is configured to initiate performance of the mission critical

communication when in a radio resource control (RRC) idle mode.

[00144] Example 24 includes the at least one machine readable storage medium of any of Examples 22-23, wherein the first TTI is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00145] Example 25 includes the at least one machine readable storage medium of any of Examples 22-24, further comprising instructions which when executed perform the following: performing repeated transmissions of the repeatedly transmit the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and performing repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB.

[00146] Various techniques, or certain aspects or portions thereof, may take the form of program code (i.e., instructions) embodied in tangible media, such as floppy diskettes, compact disc-read-only memory (CD-ROMs), hard drives, non-transitory computer readable storage medium, or any other machine-readable storage medium wherein, when the program code is loaded into and executed by a machine, such as a computer, the machine becomes an apparatus for practicing the various techniques. A non-transitory computer readable storage medium can be a computer readable storage medium that does not include signal. In the case of program code execution on programmable computers, the computing device may include a processor, a storage medium readable by the processor (including volatile and non-volatile memory and/or storage elements), at least one input device, and at least one output device. The volatile and non-volatile memory and/or storage elements may be a random-access memory (RAM), erasable programmable read only memory (EPROM), flash drive, optical drive, magnetic hard drive, solid state drive, or other medium for storing electronic data. The node and wireless device may also include a transceiver module (i.e., transceiver), a counter module (i.e., counter), a processing module (i.e., processor), and/or a clock module (i.e., clock) or timer module (i.e., timer). One or more programs that may implement or utilize

the various techniques described herein may use an application programming interface (API), reusable controls, and the like. Such programs may be implemented in a high level procedural or object oriented programming language to communicate with a computer system. However, the program(s) may be implemented in assembly or machine language, if desired. In any case, the language may be a compiled or interpreted language, and combined with hardware implementations.

[00147] As used herein, the term "circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

[00148] It should be understood that many of the functional units described in this specification have been labeled as modules, in order to more particularly emphasize their implementation independence. For example, a module may be implemented as a hardware circuit comprising custom very-large-scale integration (VLSI) circuits or gate arrays, off-the-shelf semiconductors such as logic chips, transistors, or other discrete components. A module may also be implemented in programmable hardware devices such as field programmable gate arrays, programmable array logic, programmable logic devices or the like.

[00149] Modules may also be implemented in software for execution by various types of processors. An identified module of executable code may, for instance, comprise one or more physical or logical blocks of computer instructions, which may, for instance, be organized as an object, procedure, or function. Nevertheless, the executables of an identified module may not be physically located together, but may comprise disparate instructions stored in different locations which, when joined logically together, comprise the module and achieve the stated purpose for the module.

[00150] Indeed, a module of executable code may be a single instruction, or many instructions, and may even be distributed over several different code segments, among

different programs, and across several memory devices. Similarly, operational data may be identified and illustrated herein within modules, and may be embodied in any suitable form and organized within any suitable type of data structure. The operational data may be collected as a single data set, or may be distributed over different locations including over different storage devices, and may exist, at least partially, merely as electronic signals on a system or network. The modules may be passive or active, including agents operable to perform desired functions.

[00151] Reference throughout this specification to "an example" or “exemplary” means that a particular feature, structure, or characteristic described in connection with the example is included in at least one embodiment of the present technology. Thus, appearances of the phrases "in an example" or the word “exemplary” in various places throughout this specification are not necessarily all referring to the same embodiment.

[00152] As used herein, a plurality of items, structural elements, compositional elements, and/or materials may be presented in a common list for convenience. However, these lists should be construed as though each member of the list is individually identified as a separate and unique member. Thus, no individual member of such list should be construed as a de facto equivalent of any other member of the same list solely based on their presentation in a common group without indications to the contrary. In addition, various embodiments and example of the present technology may be referred to herein along with alternatives for the various components thereof. It is understood that such embodiments, examples, and alternatives are not to be construed as defacto equivalents of one another, but are to be considered as separate and autonomous representations of the present technology.

[00153] Furthermore, the described features, structures, or characteristics may be combined in any suitable manner in one or more embodiments. In the following description, numerous specific details are provided, such as examples of layouts, distances, network examples, etc., to provide a thorough understanding of embodiments of the technology. One skilled in the relevant art will recognize, however, that the technology can be practiced without one or more of the specific details, or with other methods, components, layouts, etc. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid obscuring aspects of the

technology.

[00154] While the forgoing examples are illustrative of the principles of the present technology in one or more particular applications, it will be apparent to those of ordinary skill in the art that numerous modifications in form, usage and details of implementation can be made without the exercise of inventive faculty, and without departing from the principles and concepts of the technology. Accordingly, it is not intended that the technology be limited, except as by the claims set forth below.

CLAIMS

What is claimed is:

1. An apparatus of a user equipment (UE) operable to perform mission critical communications with an eNodeB, the apparatus comprising one or more processors and memory configured to:

transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI);

receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication; and

perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

2. The apparatus of claim 1, further configured to receive, from the eNodeB, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

3. The apparatus of claim 1, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and the second TTI is approximately 0.1 to

0.2 ms.

4. The apparatus of claim 1, wherein the first TTI is associated with a first partition of a low band and the second TTI is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

5. The apparatus of any of claims 1 to 4, wherein the UE is configured to:

perform repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and

perform repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB,

wherein a maximum number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling,

wherein the UE performs a random back off and reinitiates a procedure for performing the mission critical communication when the maximum number of repetitions for a defined transmission is reached.

6. The apparatus of claim 1, wherein the UE is configured to:

repeatedly transmit the PRACH signal to the eNodeB in accordance with a fixed number of repetitions; and

repeatedly perform the mission critical communication with the eNodeB in accordance with a fixed number of repetitions,

wherein the fixed number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

7. The apparatus of claim 1, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

8. The apparatus of claim 1, wherein a plurality of signatures, time resources and frequency resources are reserved for transmitting the PRACH signal from the UE to trigger the mission critical communication.

9. The apparatus of claim 1, wherein the PRACH signal is communicated to the eNodeB with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE.

10. The apparatus of claim 1, wherein the PRACH signal is transmitted from the UE to the eNodeB in accordance with a maximum transmit power.

11. The apparatus of claim 1, wherein the UE is configured to receive the RAR message from the eNodeB by monitoring a RAR message window, wherein a position of the RAR message window is configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

12. The apparatus of claim 1, further configured to receive a preamble from the eNodeB prior to receiving the RAR message, wherein the preamble functions to improve a downlink synchronization accuracy.

13. The apparatus of claim 1, wherein the RAR message received at the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type

communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

14. The apparatus of claim 1, wherein:

the RAR message is received at the UE via a physical downlink control channel (PDCCH), wherein the UE is configured to monitor the PDCCH using a cyclic redundancy check (CRC) scrambled by a random-access radio network temporary identifier (RA-RNTI); or

the RAR message is received at the UE via a physical downlink shared channel (PDSCH) that is scheduled by the PDCCH.

15. The apparatus of any of claims 6 to 14, wherein:

a gap between a last subframe for a RAR message transmission and a starting subframe of the mission critical communication in uplink is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling; and

a gap between a last subframe of the mission critical communication in uplink and a starting subframe of an acknowledgement (ACK) or a negative acknowledgement (NACK) transmission is predefined or configured by higher layers via one of: the MIB, the SIB, or dedicated RRC signaling.

16. The apparatus of claim 1, wherein the UE includes at least one of an antenna, a touch sensitive display screen, a speaker, a microphone, a graphics processor, an application processor, a baseband processor, an internal memory, a non-volatile memory port, and combinations thereof.

17. An apparatus of a base station operable to receive mission critical communications from a user equipment (UE), the apparatus comprising one or more processors and memory configured to:

receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the

eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI);

transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message; and

transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

18. The apparatus of claim 17, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

19. The apparatus of claim 17, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

20. The apparatus of any of claims 17 to 19, wherein:

the PRACH signal is received from the UE with a scheduling request (SR),

wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE; and

the RAR message transmitted to the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

21. The apparatus of claim 17, wherein the RAR message is transmitted to the UE via a physical downlink control channel (PDCCH) or a physical downlink shared channel (PDSCH).

22. At least one machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, the instructions when executed perform the following:

transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI);

receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI; and

receiving, using the at least one processor of the UE, an acknowledgement

(ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

23. The at least one machine readable storage medium of claim 22, wherein the UE is configured to initiate performance of the mission critical communication when in a radio resource control (RRC) idle mode.

24. The at least one machine readable storage medium of claim 22, wherein the first TTI is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

25. The at least one machine readable storage medium of any of claims 22 to 24, further comprising instructions which when executed perform the following:

performing repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and

performing repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB.

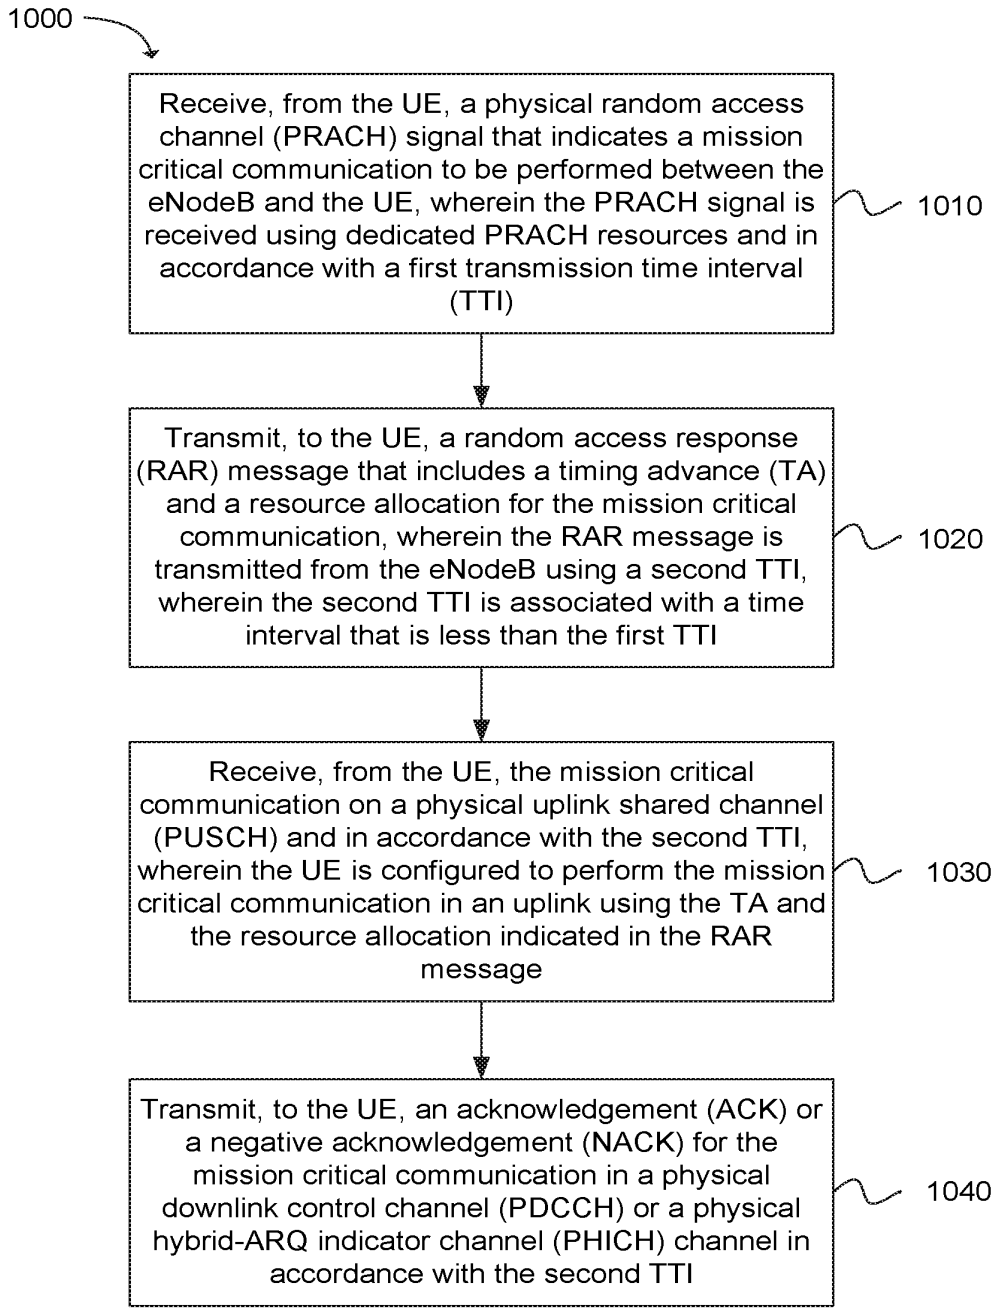
900
Transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI)
910
Receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
920
Decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication
930
Perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI
940

FIG. 9



1000
Receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI)
1010
Transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
1020
Receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message
1030
Transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI

(54) **Title**: BEAMFORMED CSI-RS BASED MEASUREMENT FRAMEWORK

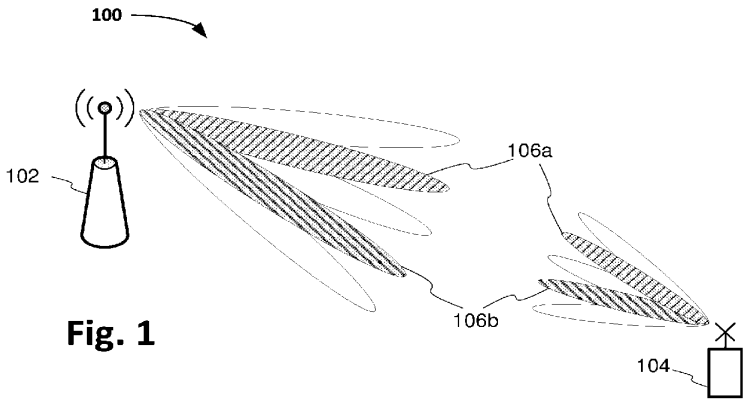

Fig. 1

(57) **Abstract**: There are disclosed methods and apparatus to facilitate beamformed CSI-RS based measurement including an apparatus for use in an eNB in a wireless communication network, the apparatus comprising transmitter circuitry; and control circuitry coupled to the transmitter circuitry, the control circuitry to configure a plurality of channel state information reference signals (CSI-RS), each CSI-RS associated with one of a plurality of virtualized sectors, and cause the transmitter circuitry to transmit the configured CSI-RS, wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

WO 2017/084235 A1

BEAMFORMED CSI-RS BASED MEASUREMENT FRAMEWORK

CROSS REFERENCE TO RELATED APPLICATIONS

The present application claims priority to U.S. Provisional Patent Application No. 62/255,865, filed November 16, 2015, entitled "BEAMFORMED CSI-RS BASED MEASUREMENT FRAMEWORK" the entire disclosure of which is hereby incorporated by reference.

TECHNICAL FIELD

Embodiments described herein generally relate to the field of wireless communications and, more particularly, to methods and apparatus for measurement of channel state information reference signals in beamformed transmit beams.

BACKGROUND

It is becoming more important to be able to provide telecommunication services to fixed and mobile subscribers as efficient and inexpensively as possible. Further, the increased use of mobile applications has resulted in much focus on developing wireless systems capable of delivering large amounts of data at high speed.

One approach under consideration for improving the efficient use of spectral resources is massive Multiple Input and Multiple output (MIMO) which allows reuse of frequencies to communicate with different users in the network through spatial multiplexing.

BRIEF DESCRIPTION OF THE DRAWING.

Aspects, features and advantages of embodiments of the present invention will become apparent from the following description of the invention in reference to the appended drawings in which like numerals denote like elements and in which:

Fig. 1 is diagram of an example wireless network according to various embodiments;

Fig. 2 is a block diagram of the example wireless network of Figure 2 according to various embodiments;

Fig. 3 is a sequence diagram of messaging for beamformed channel state information reference signals (CSI-RS) based measurement according to some embodiments;

Fig. 4 is a block diagram of a method performed in an eNB according to some embodiments;

Fig. 5 is a block diagram of a method performed in a UE according to some embodiments;

Fig. 6 is a block diagram of an example system operable to implement some embodiments; and

DETAILED DESCRIPTION OF EMBODIMENTS

Various aspects of the illustrative embodiments will be described using terms commonly employed by those skilled in the art to convey the substance of their work to others skilled in the art. However, it will be apparent to those skilled in the art that some alternate embodiments may be practiced using with portions of the described aspects. For purposes of explanation, specific numbers, materials, and configurations are set forth in order to provide a thorough understanding of the illustrative embodiments. However, it will be apparent to one skilled in the art that alternate embodiments may be practiced without the specific details. In other instances, well-known features are omitted or simplified in order to not obscure the illustrative embodiments.

Further, various operations will be described as multiple discrete operations, in turn, in a manner that is most helpful in understanding the illustrative embodiments; however, the order of description should not be construed as to imply that these operations are necessarily order dependent. In particular, these operations need not be performed in the order of presentation.

The phrase "in one embodiment" is used repeatedly. The phrase generally does not refer to the same embodiment; however, it may. The terms "comprising," "having," and "including" are synonymous, unless the context dictates otherwise. The phrase "A/B" means "A or B". The phrase "A and/or B" means "(A), (B), or (A and B)". The phrase "at least one of A, B and C" means "(A), (B), (C), (A and B), (A and C), (B and C) or (A, B and C)". The phrase "(A) B" means "(B) or (A B)", that is, A is optional.

Although specific embodiments have been illustrated and described herein, it will be appreciated by those of ordinary skill in the art that a wide variety of alternate and/or equivalent implementations may be substituted for the specific embodiments shown and described, without departing from the scope of the embodiments of the present disclosure. This application is intended to cover any adaptations or variations of the embodiments discussed herein. Therefore, it is manifestly intended that the embodiments of the present disclosure be limited only by the claims and the equivalents thereof.

As used herein, the term "module" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group) and/or memory (shared, dedicated, or group) that execute one or more software or firmware instructions and/or programs, a combinational logic circuit, and/or other suitable components that provide the described functionality.

The following inventive embodiments may be used in a variety of applications including transmitters and receivers of a radio system, although the present invention is not limited in this respect. Radio systems specifically included within the scope of the present invention include, but are not limited to, network interface cards (NICs), network adaptors, fixed or mobile client devices, relays, base stations, femtocells, gateways, bridges, hubs, routers, access points, or other network devices. Further, the radio systems within the scope of the invention may be implemented in cellular radiotelephone systems, satellite systems, two-way radio systems as well as computing devices including such radio systems including personal computers (PCs), tablets and related peripherals, personal digital assistants (PDAs), personal computing accessories, hand-held communication devices and all systems which may be related in nature and to which the principles of the inventive embodiments could be suitably applied.

In a system implementing massive Multiple Input and Multiple output (MIMO), or Full Dimension MIMO (FD-MIMO), a large number of service antennas may be used to provide a number of virtual beams that may provide a high degree of spatial separation between terminals in a wireless network. Thus, using massive MIMO, a system may be able to support a large number of users on the same bandwidth simultaneously.

According to an example massive MIMO implementation, an evolved NodeB ("eNodeB" or "eNB") may transmit a number of analog sector transmitting (Tx) beams, and each sector Tx beam may be generated based on different vertical down tilting angles. That is, a single eNB may provide a plurality of virtualized sectors that are horizontally wide and vertically narrow. The eNB may transmit multiple antenna ports from each sector Tx beam. Within each virtualized sector Tx beam, a digital precoder may be applied to provide further horizontal Tx beamforming.

A user equipment (UE) served by the eNB may select one sector Tx beam and report the Channel State Information (CSI) measured from this sector Tx beam. In particular, the UE may report a Reference Signal Receiving Power (RSRP) of one sector Tx beam. Then the UE may report the CSI for the selected sector Tx beam which may contain a Channel Quality Indicator (CQI), Rank Indicator (RI), and Precoder Matrix Indicator (PMI). The eNB usually relies on the PMI to create a Tx beam for data transmission on the selected sector Tx beam.

However, in systems that implement receiving (Rx) beam beamforming and multiple Rx antenna panels at the UE side, different serving Tx beams for data transmission may be observed from different Rx beams of the same or different antenna panels. In this case, the best Tx beams for data transmission may be within the same or different sector Tx beams.

Figure 1 illustrates one example arrangement of a wireless network 100 including an eNB 102 and a UE 104 configured to use different Tx beam and Rx beam pairs for data transmission. According to the example illustrated in Figure 1, the eNB 102 and UE 104 may have identified a first Tx beam – Rx beam pair 106a for transmission of data and control information, and a second, candidate, Tx beam – Rx beam pair 106b.

As a result of UE rotation, movement, or Doppler Effect, the active antenna panel or active Rx beam on the UE side may change so that the Tx beams for data transmission may need to be updated. The Tx beam change for data transmission may include a sector Tx beam change, horizontal digital Tx beam change within a sector Tx beam, or both. As the CSI-RS may be beamformed within a sector Tx beam, it may be beneficial in some embodiments to measure the receiving power from the narrow vertical and narrow horizontal beams to allow beam switching from any two Tx beams for data transmission from either the same or different sector Tx beams.

Example embodiments provide systems, apparatuses, and methods for beamformed CSI-RS based measurement framework with the UE side Rx beamforming to enable beam mobility in millimeter wave (mmWave) systems.

Figure 2 schematically illustrates the wireless communication network 100 in accordance with various embodiments. Wireless communication network 100 (hereinafter "network 100") may be an access network of a 3rd Generation Partnership Project (3GPP) long-term evolution (LTE), long-term evolution- advanced (LTE-A) network such as an evolved universal mobile telecommunication system (UMTS) terrestrial radio access network (E-UTRAN) or 5G network.

The network 100 may include a base station, e.g., evolved node base station (eNB) 102, configured to wirelessly communicate with one or more mobile device(s) or terminal(s), e.g., user equipment (UE) 104. In various embodiments, the eNB 102 may be a fixed station (e.g., a fixed node) or a mobile station/node.

The eNB 104 may include receiver circuitry 120 with which to receive signals from UE 104 via one or more antennas 130. eNB 104 may include transmitter circuitry 124 with which to transmit signals to UE 104 via one or more antennas 130. eNB 104 may also include controller circuitry 128 in communication with receiver module 120 and transmitter module 124 and configured to encode and decode information communicated by the

signals. Controller module 128 also includes CSI-RS configuration circuitry 126 to facilitate configuration and report processing of beamformed CSI-RS messages in the network 100.

In various embodiments, the control circuitry 128 may be comprised in a separate device from the receiver circuitry 120 and/or the transmitter circuitry 124. For example, the eNB 104 may be implemented as part of a cloud-RAN (C-RAN).

In various embodiments, the UE 104 and/or the eNB 102 may include a plurality of antennas 156, 130 to implement a multiple-input-multiple-output (MIMO) transmission system, which may operate in a variety of MIMO modes, including single-user MIMO (SU-MIMO), multi-user MIMO (MU-MIMO), close loop MIMO, open loop MIMO or variations of smart antenna processing.

In various embodiments, UE 104 comprises transmitter circuitry 148 for transmitting signals to eNB 102 and receiver circuitry 144 for receiving signals from the eNB 102. UE 104 further comprises controller circuitry 152 coupled between receiver circuitry 144 and transmitter circuitry 148 and including communication circuitry 154 to encode and decode information communicated by the signals. Controller circuitry 152 may also include CSI reporting circuitry 158 to facilitate measurement and reporting of channel state information by the UE 102.

According to embodiments, the UE 104 may attempt to receive channel state information reference signals (CSI-RS) for each sector Tx beam using receiver circuitry 144 and then measure a reference signal received power (RSRP) for each sector Tx beam received based on the CSI-RS beamformed within each sector Tx beam. The RSRP may be used as an indication of the signal quality for each sector Tx beam being received by the UE, and therefore the UE may select the sector Tx beam having the highest measured RSRP value. The US 104 may then report the selected Tx beam to the eNB 102, and may include the measured RSRP value associated with the selected sector Tx beam.

According to some embodiments, the UE 104 may report all measured RSRP values and their associated sector Tx beams to the eNB 102, and selection of a sector Tx beam may then be performed in the eNB 102.

Once sector Tx selection has been performed, the UE may then attempt to receive UE specific CSI-RS on the selected sector Tx beam and to determine based on the received CSI-RS a precoder matrix indicator to signal to the eNB 102 a horizontal Tx beam within the selected Tx sector to be used to communicate data.

Based on the information provided by the UE 104 to the eNB 102, a two-dimensional narrow Tx beam may be defined. Further CSI-RS may be transmitted on this two-dimensional narrow beam to allow the UE to determine a channel quality indicator, rank indicator, etc. for the beamformed link.

Thus, the UE 104 may select its sector Tx beam based on the CSI-RS Receiving Power (CSIRS-RP) of each sector Tx beam, as the CSI-RS may be beamformed with different sector Tx beams. The UE may report the horizontal Tx beam directions by the PMI. Then the eNodeB may further transmit one additional beamformed CSI-RS using the Tx beam for data transmission. UE may further measure this additional CSI-RS from this Tx beam to derive CQI RI etc.

At the eNB 102, the active Tx beam may be defined as the one digital narrow beam with the highest reported CQI from the sector Tx beam having highest reported CSIRS-RP. According to some embodiments, a candidate Tx beam can be defined as the digital narrow beam with the highest CQI from the sector beam which is cannot be measured by UE simultaneously as the active Tx beam.

Table 1 illustrates one example for the CSIRS-RPs measured by UE 104 using different Rx beams. In the example of Table 2, Tx beam 2 has the highest reported received power and may be designated to be the active Tx beam and the Tx beam 4 has the second highest reported received power and may be designated to be the candidate Tx beam by the eNB 102.

BRS-RP [dBm]		Sector Tx beam				
		1	2	3	4	5
Rx beam	1				-89	
	2			-88	***-77***	-93
	3		-88		-92	
	4	-83	***-71***	-82		
	5		-80			

Table 1: one example for RSRP measurement result

In some embodiments, the active Tx beam and candidate Tx beam can be the same sector Tx beam.

To support a narrow vertical and horizontal beamformed data transmission within the vertical narrow and horizontal wide beam sector Tx beam, the basic procedure may contain the sector Tx beam selection, digital beam selection and CSIRS-RP measurement and report as illustrated in Figure 3.

According to the method 200 illustrated in the sequence diagram of Figure 3, eNB 102 begins by transmitting 202 multiple CSI-RS(s) on a plurality of vertically narrow, horizontally wide sector Tx beams. These sector Tx beams are monitored by the UE 104,

and RSRP values for one or more sector Tx beams are reported 204 to the eNB to facilitate sector Tx beam selection.

The eNB 102 then transmits 206 UE specific CSI-RS within the selected sector Tx beam. In some embodiments, multiple horizontally narrow beams within the selected sector Tx beam may be used. The UE 104, uses the received CSI-RS information to provide 208 a precoder matrix indicator to the eNB 102 defining a horizontally narrow beam within the Tx sector. The eNB 102 then transmits 210 further UE specific CSI-RS using the defined two-dimensional narrow beam to allow channel state information to be determined by the UE and reported 212 to the eNB 102.

Figure 4 illustrates a method 400 performed by an eNB 102 according to some embodiments. According to the illustrated method, the eNB 102 first configures 402 CSI-RS for each of a number of virtualized, horizontally wide but vertically narrow, sector Tx beams. The eNB 102 then receives 404 at least one RSRP value associated with a sector Tx beam. A selection 406 is then made based on the received RSRP value.

Figure 5 illustrates a method 500 performed at UE 104 according to some embodiments. According to the illustrated method, the UE 104 receives 502 CSI-RS associated with virtualized, horizontally wide but vertically narrow, sector Tx beams. A reference signal received power value is then determined 504 for a virtualized sector based on the associated received CSI-RS. Determined RSRP values are then reported 506 to the eNB 102.

CSIRS-RP Measurement for sector Tx beam selection

According to some embodiments, the UE 104 may need to report an RSRP value for each sector Tx beam, which may help the eNodeB 102 to decide the best sector Tx beam for the UE.

In some embodiments, the UE 104 may maintain two non-simultaneous Rx beam(s), and may report the RSRP value with an indicator to show whether this RSRP value is measured from active Rx beam or candidate Rx beam. A current Rx beam is defined as the Rx beam used for current downlink control and signal receiving. This current Rx beam may switch between active Rx beam and candidate Rx beam according to channel conditions. Hence, in some embodiments, the context for RSRP may contain the following information:

- Cell ID;
- RSRP value;
- Rx beam Indicator;
- Subframe index or CSI-RS process ID; and
- Beam index or CSI-RS port index.

According to some embodiments, the Cell ID may be used to indicate the cell ID which used to generate the CSI-RS. RSRP value may be quantized by several bits. Subframe index may indicate the subframe index for the CSI-RS where the RSRP is measured. The Rx beam indicator may contain 1 bit, where value 0 may indicate the CSIRS-RP is measured from active Rx beam and value 1 may indicate it is measured from candidate Rx beam. Alternatively the Rx beam indicator may not be used and the UE may report two RSRPs values measured from two Rx beams per sector Tx beam to the eNodeB.

The beam index may be equal to the sector Tx beam index. Sometimes, sector Tx beam index is transparent to UE, so CSI-RS port index may be used to implicitly indicate which sector Tx beam is chosen based on the corresponding Rx beam. Two ports may be paired for vertical and horizontal channel measurement, and be equipped with the same sector Tx beam. In this case, report of only one CSI-RS port index may be sufficient. CSI-RS process ID may indicate the RSRP is measured on which CSI-RS symbols.

CSI Feedback for digital beam selection

After sector Tx beam selection, the UE may further select the Tx beam within the selected sector Tx beam. In some embodiments, if more than one simultaneous Rx beam can be applied for CSI-RS receiving, the UE may measure the same CSI-RS in the selected sector Tx beam and report more than one digital beam selection based CSI, e.g. using one PMI for one digital precoder.

According to some embodiments, two PMIs may be restricted to be measured from a rank 1 precoder codebook for N Tx antenna ports based sector Tx beam, where N is equal to the number of antenna ports for sector beam based CSI-RS. The codebook for the two PMIs may be defined by the system.

In embodiments, if the UE cannot use simultaneous Rx beams for receiving the CSI-RS, the PMI for the active Rx beam and candidate Rx beam may be measured in two CSI-RS subframes and reported individually or jointly as in the embodiment above.

CSI-RS Tx beam for CSI measurement

After receiving the PMI for active Rx beam and PMI for candidate Rx beam, the eNodeB may be able to generate the narrow Tx beam based on the feedback PMIs and the sector Tx beam.

In some embodiments, the CSI-RS may be divided into several groups, and each CSI-RS group may include K antenna ports. In one example, K may be equal to 2. Different narrow Tx beams may be applied to different CSI-RS groups. In one example, a narrow Tx beam can be generated as follow.

$$P_{i,j} = P_c^i P_d^j \quad (1)$$

Where P_c^i may indicate the $N_{tx} \times N_p$ analog beamforming weight for sector Tx beam *i*; P_d^j may denote the $N_p \times K$ digital precoder for PMI j; $P_{i,j}$ may refer to the narrow Tx beam for sector *i* and PMI *j*; N_{tx} is the number of Tx antenna; N_p is the number of CSI-RS antenna ports.

The UE may then measure a number of narrow Tx beams of one sector Tx beam in one CSI-RS subframe, and may report the CSI containing the following items:

- Beam Index (BI);
- Rank Indicator (RI);
- Precoding Matrix Indicator (PMI);
- Channel Quality Indicator (CQI); and
- Rx beam Indicator.

In some embodiments, not all the above items in CSI may be transmitted, and the Uplink Control Information (UCI) may contain more than one of the above CSI blocks.

In some embodiments, the UE may measure and report the CSIRS-RP based on each CSI-RS group. Then the UE may report the CSIRS-RP with the following pattern:

- Cell ID;
- RSRP value;
- Rx beam Indicator;
- Subframe index for the measured CSI-RS; and
- Beam index or CSI-RS group index corresponded to active beam.

In another embodiment, the UE may report up to *X* CSIRS-RPs, where *X* can be configured by the system or Radio Resource Control (RRC) signaling, e.g. *X*=8. Further the UE may only include a report for valid beams where a valid beam can be defined as a beam with the following condition in (2) is valid.

$$r_a - r_{c,k} < \Delta \quad (2)$$

Where r_a may indicate the CSIRS-RP measured from active Tx beam with the current Rx beam; $r_{c,k}$ may indicate the CSIRS-RP measured from the Tx beam *c* with Rx beam *k*. The Rx beam *k* can be either the current Rx beam or candidate Rx beam. Threshold Δ denotes the CSIRS-RP threshold, which may be configured via RRC signaling.

Various embodiments have been described in the context of transmit or receive beams that are beamformed to be horizontally and/or vertically narrow as opposed to wide. Such beamforming rely on the use of a plurality of antenna elements with a narrower beam being achievable through the use of a greater number of antenna elements.

According to some embodiments, an antenna port used to transmit a transmit beam for a virtualized sector beamformed to be vertically narrow and horizontally wide is associated with a first number, N_v, of vertical antenna elements and a second number, N_h, of horizontal antenna elements, where N_v is greater than N_h. Furthermore, according to some embodiments N_v is greater than or equal to 8 while N_h is less than or equal to 2.

Throughout the disclosure, the term eNB may loosely refer to a cell or RAN (Radio Access Network) node or transmission point (TP). The relay UE may belong to the same or different eNB or entity. When it belongs to different entity than the direct path of the remote UE, then additional signaling and context transfer might need to happen for the remote UE to switch between the direct path and relay UE path. Furthermore, the remote UE may be receiving data from multiple relay UEs, each associated with the same eNB/entity or different eNB/entity than the remote UE itself.

Embodiments of the technology herein may be described as related to the third generation partnership project (3GPP) long term evolution (LTE) or LTE-advanced (LTE-A) standards. For example, terms or entities such as eNodeB (eNB), mobility management entity (MME), user equipment (UE), etc. may be used that may be viewed as LTE-related terms or entities. However, in other embodiments the technology may be used in or related to other wireless technologies such as the Institute of Electrical and Electronic Engineers (IEEE) 802.16 wireless technology (WiMax), IEEE 802.11 wireless technology (WiFi), various other wireless technologies such as global system for mobile communications (GSM), enhanced data rates for GSM evolution (EDGE), GSM EDGE radio access network (GERAN), universal mobile telecommunications system (UMTS), UMTS terrestrial radio access network (UTRAN), or other 2G, 3G, 4G, 5G, etc. technologies either already developed or to be developed. In those embodiments, where LTE-related terms such as eNB, MME, UE, etc. are used, one or more entities or components may be used that may be considered to be equivalent or approximately equivalent to one or more of the LTE-based terms or entities.

As used herein, the term "circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

Embodiments described herein may be implemented into a system using any suitably configured hardware and/or software. Figure 6 illustrates, for one embodiment, example components of an electronic device 600. In embodiments, the electronic device 600 may

be, implement, be incorporated into, or otherwise be a part of a user equipment (UE), an evolved NodeB (eNB), or any other suitable electronic device. In some embodiments, the electronic device 600 may include application circuitry 602, baseband circuitry 604, Radio Frequency (RF) circuitry 606, front-end module (FEM) circuitry 608 and one or more antennas 610, coupled together at least as shown.

The application circuitry 602 may include one or more application processors. For example, the application circuitry 602 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The processor(s) may include any combination of general-purpose processors and dedicated processors (e.g., graphics processors, application processors, etc.). The processors may be coupled with and/or may include memory/storage and may be configured to execute instructions stored in the memory/storage to enable various applications and/or operating systems to run on the system.

The baseband circuitry 604 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry 604 may include one or more baseband processors and/or control logic to process baseband signals received from a receive signal path of the RF circuitry 606 and to generate baseband signals for a transmit signal path of the RF circuitry 606. Baseband processing circuity 604 may interface with the application circuitry 602 for generation and processing of the baseband signals and for controlling operations of the RF circuitry 606. For example, in some embodiments, the baseband circuitry 604 may include a second generation (2G) baseband processor 604a, third generation (3G) baseband processor 604b, fourth generation (4G) baseband processor 604c, and/or other baseband processor(s) 604d for other existing generations, generations in development or to be developed in the future (e.g., fifth generation (5G), 6G, etc.). The baseband circuitry 604 (e.g., one or more of baseband processors 604a-d) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry 606. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some embodiments, modulation/demodulation circuitry of the baseband circuitry 604 may include Fast-Fourier Transform (FFT), precoding, and/or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry 604 may include convolution, tail-biting convolution, turbo, Viterbi, and/or Low Density Parity Check (LDPC) encoder/decoder functionality. Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments.

In some embodiments, the baseband circuitry 604 may include elements of a protocol stack such as, for example, elements of an evolved universal terrestrial radio access

network (EUTRAN) protocol including, for example, physical (PHY), media access control (MAC), radio link control (RLC), packet data convergence protocol (PDCP), and/or radio resource control (RRC) elements. A central processing unit (CPU) 604e of the baseband circuitry 604 may be configured to run elements of the protocol stack for signaling of the PHY, MAC, RLC, PDCP and/or RRC layers. In some embodiments, the baseband circuitry may include one or more audio digital signal processor(s) (DSP) 604f. The audio DSP(s) 604f may be include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments.

The baseband circuitry 604 may further include memory/storage 604g. The memory/storage 604g may be used to load and store data and/or instructions for operations performed by the processors of the baseband circuitry 604. Memory/storage for one embodiment may include any combination of suitable volatile memory and/or non-volatile memory. The memory/storage 604g may include any combination of various levels of memory/storage including, but not limited to, read-only memory (ROM) having embedded software instructions (e.g., firmware), random access memory (e.g., dynamic random access memory (DRAM)), cache, buffers, etc. The memory/storage 604g may be shared among the various processors or dedicated to particular processors.

Components of the baseband circuitry may be suitably combined in a single chip, a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry 604 and the application circuitry 602 may be implemented together such as, for example, on a system on a chip (SOC).

In some embodiments, the baseband circuitry 604 may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry 604 may support communication with an evolved universal terrestrial radio access network (EUTRAN) and/or other wireless metropolitan area networks (WMAN), a wireless local area network (WLAN), a wireless personal area network (WPAN). Embodiments in which the baseband circuitry 604 is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

RF circuitry 606 may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry 606 may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry 606 may include a receive signal path which may include circuitry to down-convert RF signals received from the FEM circuitry 608 and provide baseband signals to the baseband circuitry 604. RF circuitry 606 may also include a transmit signal path which may include circuitry to up-

convert baseband signals provided by the baseband circuitry 604 and provide RF output signals to the FEM circuitry 608 for transmission.

In some embodiments, the RF circuitry 606 may include a receive signal path and a transmit signal path. The receive signal path of the RF circuitry 606 may include mixer circuitry 606a, amplifier circuitry 606b and filter circuitry 606c. The transmit signal path of the RF circuitry 606 may include filter circuitry 606c and mixer circuitry 606a. RF circuitry 606 may also include synthesizer circuitry 606d for synthesizing a frequency for use by the mixer circuitry 606a of the receive signal path and the transmit signal path. In some embodiments, the mixer circuitry 606a of the receive signal path may be configured to down-convert RF signals received from the FEM circuitry 608 based on the synthesized frequency provided by synthesizer circuitry 606d. The amplifier circuitry 606b may be configured to amplify the down-converted signals and the filter circuitry 606c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals. Output baseband signals may be provided to the baseband circuitry 604 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals, although this is not a requirement. In some embodiments, mixer circuitry 606a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 606a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 606d to generate RF output signals for the FEM circuitry 608. The baseband signals may be provided by the baseband circuitry 604 and may be filtered by filter circuitry 606c. The filter circuitry 606c may include a low-pass filter (LPF), although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 606a of the receive signal path and the mixer circuitry 606a of the transmit signal path may include two or more mixers and may be arranged for quadrature downconversion and/or upconversion respectively. In some embodiments, the mixer circuitry 606a of the receive signal path and the mixer circuitry 606a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 606a of the receive signal path and the mixer circuitry 606a may be arranged for direct downconversion and/or direct upconversion, respectively. In some embodiments, the mixer circuitry 606a of the receive signal path and the mixer circuitry 606a of the transmit signal path may be configured for super-heterodyne operation.

In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input

baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 606 may include analog-to-digital converter (ADC) and digital-to-analog converter (DAC) circuitry and the baseband circuitry 604 may include a digital baseband interface to communicate with the RF circuitry 606.

In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

In some embodiments, the synthesizer circuitry 606d may be a fractional-N synthesizer or a fractional N/N+1 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 606d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

The synthesizer circuitry 606d may be configured to synthesize an output frequency for use by the mixer circuitry 606a of the RF circuitry 606 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 606d may be a fractional N/N+1 synthesizer.

In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO), although that is not a requirement. Divider control input may be provided by either the baseband circuitry 604 or the applications processor 602 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the applications processor 602.

Synthesizer circuitry 606d of the RF circuitry 606 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or N+1 (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into Nd equal packets of phase, where Nd is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

In some embodiments, synthesizer circuitry 606d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times

the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 606 may include an IQ/polar converter.

FEM circuitry 608 may include a receive signal path which may include circuitry configured to operate on RF signals received from one or more antennas 610, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 606 for further processing. FEM circuitry 608 may also include a transmit signal path which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 606 for transmission by one or more of the one or more antennas 610.

In some embodiments, the FEM circuitry 608 may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry may include a low-noise amplifier (LNA) to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry 606). The transmit signal path of the FEM circuitry 608 may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry 606), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas 610.

In some embodiments, the electronic device 600 may include additional elements such as, for example, memory/storage, display, camera, sensor, and/or input/output (I/O) interface.

In some embodiments, the electronic device 600 of Figure 6 may be configured to perform one or more processes, techniques, and/or methods as described herein, or portions thereof. Such processes may include one or more of the following examples.

Figure 7 shows an embodiment in which the electronic device 600 implements a UE 102 in the specific form of a mobile device 700.

In various embodiments, user interfaces could include, but are not limited to, a display 740 (e.g., a liquid crystal display, a touch screen display, etc.), a speaker 730, a microphone 790, one or more cameras 780 (e.g., a still camera and/or a video camera), a flashlight (e.g., a light emitting diode flash), and a keyboard 770.

In various embodiments, the peripheral component interfaces may include, but are not limited to, a non-volatile memory port, an audio jack, and a power supply interface.

In various embodiments, the sensors may include, but are not limited to, a gyro sensor, an accelerometer, a proximity sensor, an ambient light sensor, and a positioning unit. The positioning unit may also be part of, or interact with, a network interface to communicate with components of a positioning network, e.g., a global positioning system (GPS) satellite.

In various embodiments, the electronic device 600 may be a mobile computing device such as, but not limited to, a laptop computing device, a tablet computing device, a netbook, a mobile phone, etc. In various embodiments, system 700 may have more or less components, and/or different architectures.

In embodiments, the implemented wireless network may be a 3rd Generation Partnership Project's long term evolution (LTE) advanced wireless communication standard, which may include, but is not limited to releases 8, 9, 10, 11, 12, 13, and 14 or later, of the 3GPP's LTE-A or 5G standards.

Although certain embodiments have been illustrated and described herein for purposes of description, a wide variety of alternate and/or equivalent embodiments or implementations calculated to achieve the same purposes may be substituted for the embodiments shown and described without departing from the scope of the present disclosure. This application is intended to cover any adaptations or variations of the embodiments discussed herein. Therefore, it is manifestly intended that embodiments described herein be limited only by the claims and the equivalents thereof.

EXAMPLES

Example 1 may include a method comprising: configuring beamformed Channel State Information Reference Signal (CSI-RS), wherein the CSI-RS is transmitted with a vertical narrow and horizontal wide sector transmitting (Tx) beam, and each Tx beam is considered as a virtualized sector.

Example 2 may include the method of example 1 or some other example herein, wherein the UE measures and reports the Reference Signal Receiving Power (RSRP) based on the beamformed CSI-RS to indicate the signal quality of one sector Tx beam.

Example 3 may include the method of example 2 or some other example herein, wherein the UE reports a receiving (Rx) beam indicator associated with the RSRP, where value 0 indicates the RSRP is measured from an active Rx beam and value 1 indicates the RSRP is measured from a candidate Rx beam, and wherein the UE cannot receive data from both active Rx beam and candidate Rx beam simultaneously, wherein the Rx beam is defined as an Rx beam used for data and control receiving and is initially set to be either active Rx beam and can be switched to candidate Rx beam.

Example 4 may include the method of example 1 or 3 or some other example herein, wherein the UE reports a digital beam selection Channel State Information (CSI), wherein a Precoder Matrix Indicator (PMI) for the active Rx beam and the PMI for the candidate Rx beam may be reported.

Example 5 may include the method of example 4 or some other example herein, wherein the PMI is measured using a codebook from the CSI-RS transmitted on sector beam, which is defined by the system.

Example 6 may include the method of example 4 or some other example herein, wherein the PMI is selected from a rank 1 codebook.

Example 7 may include the method of example 1 or some other example herein, wherein a UE-specific CSI-RS is transmitted as several groups and each group of the several groups is transmitted using a two dimensional narrow Tx beam.

Example 8 may include the method of example 7 or some other example herein, wherein each of the several groups use two antenna ports sent from both horizontal and vertical polarizations.

Example 9 may include the method of example 7 or some other example herein, wherein the UE measures the CSI-RS Receiving Power (CSIRS-RP) for each CSI-RS group.

Example 10 may include the method of example 9 or some other example herein, wherein the UE reports the CSIRS-RP comprising the value of CSIRS-RP, Rx beam indicator, CSI-RS group index and subframe index, wherein the Rx beam indicator is used to indicate whether this CSIRS-RP is measured from active Rx beam or candidate Rx beam.

Example 11 may include the method of example 10 or some other example herein, wherein the UE may report up to N CSIRS-RPs, where N is to be configured by the system or radio resource control (RRC) signaling.

Example 12 may include the method of example 11 or some other example herein, wherein only a valid CSIRS-RP may be reported and a valid CSIRS-RP is defined as a CSIRS-RP within the CSIRS-RP threshold, which is configured by the system or RRC signaling.

Example 13 may include an apparatus comprising means to perform one or more elements of a method described in or related to any of examples 1-12, or any other method or process described herein.

Example 14 may include one or more non-transitory computer-readable media comprising instructions to cause an electronic device, upon execution of the instructions by one or more processors of the electronic device, to perform one or more elements of

a method described in or related to any of examples 1-12, or any other method or process described herein.

Example 15 may include an apparatus comprising logic, modules, and/or circuitry to perform one or more elements of a method described in or related to any of examples 1-12, or any other method or process described herein.

Example 16 may include a method, technique, or process as described in or related to any of examples 1-12, or portions or parts thereof.

Example 17 may include an apparatus comprising: one or more processors and one or more computer readable media comprising instructions that, when executed by the one or more processors, cause the one or more processors to perform the method, techniques, or process as described in or related to any of examples 1-12, or portions thereof.

Example 18 may include a method of communicating in a wireless network as shown and described herein.

Example 19 may include a system for providing wireless communication as shown and described herein.

Example 20 may include a device for providing wireless communication as shown and described herein.

Example 21 may include an apparatus for use in an eNB in a wireless communication network, the apparatus comprising transmitter circuitry; and control circuitry coupled to the transmitter circuitry, the control circuitry to: configure a plurality of channel state information reference signals (CSI-RS), each CSI-RS associated with one of a plurality of virtualized sectors; and cause the transmitter circuitry to transmit the configured CSI-RS; wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

Example 22 may include the apparatus of example 21, wherein each of the plurality of virtualized sectors is associated with a different vertical downtilt angle.

Example 23 may include the apparatus of example 21 or example 22 example further comprising receiver circuitry coupled to the control circuitry, the receiver circuitry to receive an indication of a reference signal received power (RSRP) value associated with one of the virtualized sectors from a User Equipment (UE), the indication of RSRP value based on the CSI-RS associated with the one of the virtualized sectors.

Example 24 may include the apparatus of example 23, wherein the indication of RSRP value comprises an indication of a receiving beam associated with the RSRP value.

Example 25 may include the apparatus of example 24, wherein the indication of a receiving beam comprises a first value to indicate that the RSRP value was measured from an active receiving beam and a second value to indicate that the RSRP value was measure from a candidate receiving beam.

Example 26 may include the apparatus of example 23, wherein the control circuitry is further to select a virtualized sector beam for communicating with the UE based on the received indication of RSRP value.

Example 27 may include the apparatus of example 26, wherein the control circuitry is further to configure UE specific CSI-RS associated with the selected virtualized sector and cause the transmitter circuitry to transmit the UE specific CSI-RS to the UE in the selected virtualized sector.

Example 28 may include the apparatus of example 27, wherein the receiver circuitry is further to receive a digital beam selection channel state information (CSI) from the UE in response to the UE specific CSI-RS, the digital beam selection CSI comprising a first precoder matrix indicator (PMI) associated with an active receiving beam.

Example 29 may include the apparatus of example 28, wherein the digital beam selection CSI further comprises a second PMI associated with a candidate receiving beam.

Example 30 may include the apparatus of examples 28 or 29, wherein the PMI is selected from a rank 1 codebook.

Example 31 may include the apparatus of examples 28 or 29, wherein the PMI is measured using a codebook defined by the network.

Example 32 may include the apparatus of any of examples 8 to 10, wherein the control circuitry is further to generate a two dimensional narrow transmit beam within the selected virtualized sector based on a received PMI.

Example 33 may include the apparatus of any of examples 27 to 32, wherein the transmitter circuitry is further to transmit the US specific CSI-RS a plurality of CSI-RS groups, wherein each CSI-RS group of the plurality of CSI-RS groups is associated with a two dimensional narrow transmit beam within the selected virtualized sector.

Example 34 may include the apparatus of example 33, wherein each of the plurality of CSI-RS groups is associated with two antenna ports sent from both horizontal and vertical polarizations.

Example 35 may include the apparatus of example 33 or example 34, the receiver circuitry further to receive a CSI-RS report from the UE, the report comprising: CSI-RS receiving power (CSIRS-RP) value; a receiving beam indicator comprising a first value to indicate the CSIRS-RP value was measured using an active receive beam and a second value to indicate that the CSIRS-RP value was measured using a candidate receive beam; a CSI-RS group index; and a subframe index.

Example 36 may include the apparatus of example 35, the receiver circuitry further to receive a plurality of CSI-RS reports from the UE, each CSI-RS report associated with a CSI-RS group of the plurality of CSI-RS groups.

Example 37 may include the apparatus of example 36, wherein the plurality of CSI-RS reports may comprise N CSI-RP reports, where N is configured by the network or using radio resource control signalling (RRC).

Example 38 may include the apparatus of example 36 or example 37, wherein the plurality of CSI-RS reports comprises CSI-RS reports having a CSIRS-RP value greater than a threshold CSIRS-RP value.

Example 39 may include the apparatus of example 38, wherein the threshold CSIRS-RP value is configured by the network or using radio resource control signalling (RRC).

Example 40 may include an apparatus for use in a user equipment in a wireless communication network, the apparatus comprising receiver circuitry to receive a plurality of channel state information reference signals (CSI-RS) from an eNB, each CSI-RS associated with one of a plurality of virtualized sectors; controller circuitry coupled to the receiver circuitry, the controller circuitry to: obtain a plurality of reference signal receiver power (RSRP) values, each of the plurality of RSRP values associated with one of the received CSI-RS; and generate an indication of RSRP associated with one of the virtualized sectors; and transmitter circuitry to transmit the indication of RSRP to the eNB; and wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

Example 41 may include the apparatus of example 40, the controller circuitry further to determine a highest RSRP value of the plurality of RSRP values wherein the generated indication comprises an indication of the determined highest RSRP value and the associated virtualized sector.

Example 42 may include the apparatus of example 40 or example 41, wherein the receiver circuitry is operable to receive an active receiving beam and a candidate receiving beam; and wherein the generated indication of RSRP further comprises an indication of a receiving beam associated with the RSRP value, wherein the indication of

a receiving beam comprises a first value to indicate that the RSRP value was measured from the active receiving beam and a second value to indicate that the RSRP value was measure from the candidate receiving beam.

Example 43 may include the apparatus of example 42, wherein the receiver circuitry is operable to receive one of the active receiving beam and the candidate receiving beam at one time.

Example 44 may include the apparatus of any of examples 40 to 43, wherein the receiver circuitry is further to receive UE specific CSI-RS on a first virtualized sector of the plurality of virtualized sectors; and wherein the controller circuitry is further to generate a digital beam selection Channel State Information (CSI) in dependence on the received UE specific CSI-RS.

Example 45 may include the apparatus of example 44, wherein the UE specific CSI-RS comprises a plurality of CSI-RS groups, wherein each CSI-RS group of the plurality of CSI-RS groups is associated with a two dimensional narrow transmit beam within the selected virtualized sector.

Example 46 may include the apparatus of example 44 or example 45, wherein the digital beam selection CSI comprises a first precoder matrix indicator (PMI) associated with an active receiving beam.

Example 47 may include the apparatus of example 46, wherein the digital beam selection CSI further comprises a second PMI associated with a candidate receiving beam.

Example 48 may include the apparatus of example 44 to example 47, wherein the PMI is selected from a rank 1 codebook.

Example 49 may include the apparatus of example 45, the control circuitry to generate a CSI-RS report, the CSI-RP report comprising CSI-RS receiving power (CSIRS-RP) value; a receiving beam indicator comprising a first value to indicate the CSIRS-RP value was measured using an active receive beam and a second value to indicate that the CSIRS-RP value was measured using a candidate receive beam; a CSI-RS group index; and a subframe index.

Example 50 may include the apparatus of example 49, the control circuitry to generate a plurality of CSI-RS reports from the UE, each CSI-RS report associated with a CSI-RS group of the plurality of CSI-RS groups.

Example 51 may include the apparatus of example 50, wherein the plurality of CSI-RS reports may comprise N CSI-RP reports, where N is configured by the network or using radio resource control signalling (RRC).

Example 52 may include the apparatus of example 50 or example 51, wherein the plurality of CSI-RS reports comprises CSI-RS reports having a CSIRS-RP value greater than a threshold CSIRS-RP value.

Example 53 may include the apparatus of example 52, wherein the threshold CSIRS-RP value is configured by the network or using radio resource control signalling (RRC).

Example 54 may include a user equipment comprising an apparatus according to any of examples 20 to 33, the user equipment further comprising at least one of a display; a keyboard; and a touchscreen.

Example 55 may include a computer readable medium comprising computer program code that when executed implements the method of receiving a plurality of channel state information reference signals (CSI-RS) from an eNB, each CSI-RS associated with one of a plurality of virtualized sectors; obtaining a plurality of reference signal receiver power (RSRP) values, each of the plurality of RSRP values associated with one of the received CSI-RS; and generating an indication of RSRP associated with one of the virtualized sectors; and transmitting the indication of RSRP to the eNB; wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

Example 56 may include a computer readable medium comprising computer program code that when executed implements the method of configuring a plurality of channel state information reference signals (CSI-RS), each CSI-RS associated with one of a plurality of virtualized sectors; and transmitting the configured CSI-RS; wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

Example 57 may include the apparatus of example 21, wherein a transmit beam associated with a virtualized sector is transmitted using a first antenna port, the first antenna port associated with a first number of vertical antenna elements and a second number of horizontal antenna elements wherein the first number of vertical antenna elements is greater than the second number of horizontal antenna elements.

Example 58 may include the apparatus of example 57, wherein the first number of vertical antenna elements is greater than or equal to 8, and wherein the second number of horizontal antenna elements is less than or equal to 2.

The foregoing description of one or more implementations provides illustration and description, but is not intended to be exhaustive or to limit the scope of the example embodiments to the precise form disclosed. Modifications and variations are possible in light of the above teachings or may be acquired from practice of various implementations of the example embodiments.

CLAIMS

1. An apparatus for use in an eNB in a wireless communication network, the apparatus comprising:

transmitter circuitry; and

control circuitry coupled to the transmitter circuitry, the control circuitry to:

configure a plurality of channel state information reference signals (CSI-RS), each CSI-RS associated with one of a plurality of virtualized sectors; and

cause the transmitter circuitry to transmit the configured CSI-RS;

wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

2. The apparatus of claim 1, wherein each of the plurality of virtualized sectors is associated with a different vertical downtilt angle.

3. The apparatus of any preceding claim further comprising:

receiver circuitry coupled to the control circuitry, the receiver circuitry to receive an indication of a reference signal received power (RSRP) value associated with one of the virtualized sectors from a User Equipment (UE), the indication of RSRP value based on the CSI-RS associated with the one of the virtualized sectors.

4. The apparatus of claim 3, wherein the control circuitry is further to select a virtualized sector beam for communicating with the UE based on the received indication of RSRP value.

5. The apparatus of claim 4, wherein the control circuitry is further to configure UE specific CSI-RS associated with the selected virtualized sector and cause the transmitter circuitry to transmit the UE specific CSI-RS to the UE in the selected virtualized sector.

6. The apparatus of claim 5, wherein the receiver circuitry is further to receive a digital beam selection channel state information (CSI) from the UE in response

to the UE specific CSI-RS, the digital beam selection CSI comprising a first precoder matrix indicator (PMI) associated with an active receiving beam.

7. The apparatus of claim 6, wherein the digital beam selection CSI further comprises a second PMI associated with a candidate receiving beam.

8. The apparatus of claims 6 or 7, wherein the PMI is selected from a rank 1 codebook defined by the network.

9. The apparatus of any of claims 6 to 8, wherein the control circuitry is further to generate a two dimensional narrow transmit beam within the selected virtualized sector based on a received PMI.

10. The apparatus of any of claims 6 to 9, wherein the transmitter circuitry is further to transmit the US specific CSI-RS a plurality of CSI-RS groups, wherein each CSI-RS group of the plurality of CSI-RS groups is associated with a two dimensional narrow transmit beam within the selected virtualized sector;

wherein each of the plurality of CSI-RS groups is associated with two antenna ports sent from both horizontal and vertical polarizations.

11. The apparatus of any of claims 1 to 10, wherein a transmit beam associated with a virtualized sector is transmitted using a first antenna port, the first antenna port associated with a first number of vertical antenna elements and a second number of horizontal antenna elements wherein the first number of vertical antenna elements is greater than the second number of horizontal antenna elements.

12. The apparatus of claim 10 or claim 11, the receiver circuitry further to:

receive a CSI-RS report from the UE, the report comprising:

CSI-RS receiving power (CSIRS-RP) value;

a receiving beam indicator comprising a first value to indicate the CSIRS-RP value was measured using an active receive beam and a second value to indicate that the CSIRS-RP value was measured using a candidate receive beam;

a CSI-RS group index; and

a subframe index.

13. The apparatus of claim 12, the receiver circuitry further to receive a plurality of CSI-RS reports from the UE, each CSI-RS report associated with a CSI-RS group of the plurality of CSI-RS groups.

14. An apparatus for use in a user equipment (UE) in a wireless communication network, the apparatus comprising:

receiver circuitry to receive a plurality of channel state information reference signals (CSI-RS) from an eNB, each CSI-RS associated with one of a plurality of virtualized sectors;

controller circuitry coupled to the receiver circuitry, the controller circuitry to:

obtain a plurality of reference signal receiver power (RSRP) values, each of the plurality of RSRP values associated with one of the received CSI-RS; and

generate an indication of RSRP associated with one of the virtualized sectors; and

transmitter circuitry to transmit the indication of RSRP to the eNB; and

wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

15. The apparatus of claim 14, the controller circuitry further to determine a highest RSRP value of the plurality of RSRP values wherein the generated indication comprises an indication of the determined highest RSRP value and the associated virtualized sector.

16. The apparatus of claim 14 or claim 15, wherein the receiver circuitry is operable to receive an active receiving beam and a candidate receiving beam; and

wherein the generated indication of RSRP further comprises an indication of a receiving beam associated with the RSRP value, wherein the indication of a receiving beam comprises a first value to indicate that the RSRP value was measured from the active receiving beam and a second value to indicate that the RSRP value was measure from the candidate receiving beam.

17. The apparatus of claim 16, wherein the receiver circuitry is operable to receive only one of the active receiving beam and the candidate receiving beam at one time.

18. The apparatus of any of claims 14 to 17, wherein the receiver circuitry is further to receive UE specific CSI-RS on a first virtualized sector of the plurality of virtualized sectors; and

wherein the controller circuitry is further to generate a digital beam selection Channel State Information (CSI) in dependence on the received UE specific CSI-RS.

19. The apparatus of claim 18, wherein the UE specific CSI-RS comprises a plurality of CSI-RS groups, wherein each CSI-RS group of the plurality of CSI-RS groups is associated with a two dimensional narrow transmit beam within the selected virtualized sector.

20. The apparatus of claim 18 or claim 19, wherein the digital beam selection CSI comprises a first precoder matrix indicator (PMI) associated with an active receiving beam and a second PMI associated with a candidate receiving beam.

21. The apparatus of claim 19, the control circuitry to generate a CSI-RS report, the CSI-RP report comprising:

CSI-RS receiving power (CSIRS-RP) value;

a receiving beam indicator comprising a first value to indicate the CSIRS-RP value was measured using an active receive beam and a second value to indicate that the CSIRS-RP value was measured using a candidate receive beam;

a CSI-RS group index; and

a subframe index.

22. The apparatus of claim 21, the control circuitry to generate a plurality of CSI-RS reports from the UE, each CSI-RS report associated with a CSI-RS group of the plurality of CSI-RS groups.

23. A user equipment comprising an apparatus according to any of claims 20 to 33, the user equipment further comprising at least one of a display; a keyboard; and a touchscreen.

24. A computer readable medium comprising computer program code that when executed implements the method of:

receiving a plurality of channel state information reference signals (CSI-RS) from an eNB, each CSI-RS associated with one of a plurality of virtualized sectors;

obtaining a plurality of reference signal receiver power (RSRP) values, each of the plurality of RSRP values associated with one of the received CSI-RS; and

generating an indication of RSRP associated with one of the virtualized sectors; and

transmitting the indication of RSRP to the eNB;

wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

25. A computer readable medium comprising computer program code that when executed implements the method of:

configuring a plurality of channel state information reference signals (CSI-RS), each CSI-RS associated with one of a plurality of virtualized sectors; and

transmitting the configured CSI-RS;

wherein each of the plurality of virtualized sectors comprises a transmit beam beamformed to be vertically narrow and horizontally wide based on an associated vertical downtilt angle.

(54) **Title**: DOWNLINK CONTROL CHANNEL DESIGN AND SIGNALING FOR BEAMFORMED SYSTEMS

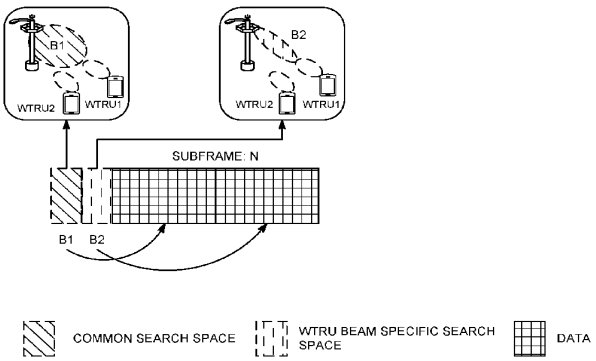

FIG. 22

(57) **Abstract**: Transmit and/or receive beamforming may be applied to the control channel transmission/reception, e.g., in mmW access link system design. Techniques to identify candidate control channel beams and/or their location in the subframe structure may provide for efficient WTRU operation. A framework for beam formed control channel design may support varying capabilities of mBs and/or WTRUs, and/or may support time and/or spatial domain multiplexing of control channel beams. For a multi-beam system, modifications to reference signal design may discover, identify, measure, and/or decode a control channel beam. Techniques may mitigate inter-beam interference. WTRU monitoring may consider beam search space, perhaps in addition to time and/or frequency search space. Enhancements to downlink control channel may support scheduling narrow data beams. Scheduling techniques may achieve high resource utilization, e.g., perhaps when large bandwidths are available and/or WTRUs may be spatially distributed.

WO 2017/083514 A1

DOWNLINK CONTROL CHANNEL DESIGN AND SIGNALING FOR BEAMFORMED SYSTEMS

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Patent Application No. 62/253,599, filed on November 10, 2015, the entire contents of which being incorporated by reference as if fully set-forth herein, for all purposes.

BACKGROUND

[0002] Small Cell mmW eNB (SCmB) deployment may be based on the 3GPP R12 small cell deployment. The mmW operation may be performed by one or more network nodes. A Small Cell mmW eNB (SCmB) may be an LTE small cell eNB capable of operating an mmW air interface, perhaps with an LTE air interface in the downlink.

[0003] An mmW WTRU (mWTRU) may be capable of operating in LTE and mmW air interface. The mWTRU may have one or more sets of antennas and/or the acccompanied Radio Frequency (RF) chains, perhaps one operating in the LTE band and/or in the mmW frequency band.

SUMMARY

[0004] Initial mmW access link system design may focus on cellular system procedures that enable add-on mmW data transmission (e.g., at least downlink transmission) to an existing network such as a small cell LTE network. Transmit and/or receive beamforming may be applied to the control channel transmission/reception, e.g., to overcome high path loss at > 6Ghz frequencies. Techniques to identify candidate control channel beams and/or their location in the subframe structure may provide for efficient WTRU operation. A framework for beam formed control channel design may support varying capabilities of mBs and/or WTRUs, and/or may support time and/or spatial domain multiplexing of control channel beams. Modifications to reference signal design may discover, identify, measure, and/or decode one or more, or each, control channel beam, for example for a multi-beam system, among other scenarios. Techniques may mitigate inter-beam interference. WTRU monitoring may consider beam search space in addition to time and/or frequency search space. Techniques to downlink control channel may

support scheduling narrow data beams. Scheduling mechanisms may achieve (e.g., high) resource utilization, e.g., perhaps when large bandwidths may be available and/or WTRUs may be spatially distributed.

[0005] For example, one or more beam specific control channels may be utilized. The beam specific control channels may utilize a fixed mapping in a frame structure. For example, a beam specific control channel may be mapped to a fixed symbol and/or a fixed subframe in the frame structure. For example, a flexible mapping may be used for the beam specific control channels within the frame structure.

[0006] For example, a WTRU-specific and/or beam-specific search space may be used for transmitting and/or receiving control channels. The WTRU-specific and/or beam-specific search space may be associated with serving control channel(s) assignments. The WTRU-specific and/or beam-specific search space may be utilized in a WTRU monitoring procedure. For example, the WTRU may be configured to determine a beam specific search space size (e.g., in terms of subframe and symbol location). A WTRU may be configured to determine a WTRU-specific search space within a beam and/or beam-specific search space.

[0007] A WTRU and/or based station may be configured to perform methods for resource allocation for sub-subframe scheduling. For example, sub-subframe scheduling may allow multiple allocations in a given subframe. For example, sub-subframe scheduling may be performed such that multiplexing (e.g., TDM) WTRUs with different downlink beams within a given subframe may be utilized.

[0008] A WTRU may be configured to identify the downlink data beam that an mB may use for the WTRU. For example, the WTRU may be configured to switch the receive beam used for downlink data based on one or more parameters. For example, the WTRU may be configured to switch the receive beam used for downlink data based on resource allocation information. For example, the WTRU may be configured to switch the receive beam used for downlink data independently from the received resource allocation information. For example, beam combining may be used for the DL and/or UL.

[0009] A wireless transmit/receive unit (WTRU) may be configured for wireless communication. The WTRU may comprise a memory. The WTRU may comprise a processor. The processor configured with at least one or more search spaces. The one or more search spaces may be configured to provide for at least one of: a monitor of one or more Downlink (DL) control channels, and/or a receipt of the one or more DL control channels. At least one search space of the one or more search spaces may correspond to at least one reference signal of one or more reference signals. The processor may be configured at least to monitor at least a part of a

control region for at least one reference signal of the one or more reference signals. The processor may be configured to detect the at least one reference signal in the at least part of the control region. The processor may be configured to monitor the at least one search space corresponding to the at least one reference signal for at least one DL control channel upon the detection of the at least one reference signal.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] FIG. 1 is an example of mmW Small Cell Deployment.

[0011] FIG. 2 is an example of Comparison of Frequency and Spatial Filtering.

[0012] FIG. 3 is an example of an OFDM Frame Structure.

[0013] FIG. 4 is an example of an mmW Downlink Logical, Transport and Physical Channel.

[0014] FIG. 5 is an example of an mWTRU Fully Digitized Beamforming.

[0015] FIG. 6 is an example of an mWTRU Analogue Beamforming with at least one PAA and at least one RF Chain.

[0016] FIG. 7 is an example of an mWTRU Analog Beamforming with at least one PAA and at least two RF Chains.

[0017] FIG. 8 is an example of an mWTRU Analog Beamforming with at least two PAAs and at least two RF Chains.

[0018] FIG. 9 is an example of an mWTRU Analogue Beamforming with at least two PAAs and at least one RF Chain.

[0019] FIG. 10 is an example of an Illustrative 2D and Realistic 3D Narrow Beam Pattern.

[0020] FIG. 11 is an example of a Realistic 3D Broadside Broad Beam Pattern.

[0021] FIG. 12 is an example of Physical Downlink Control Channel (PDCCH) Type 1a.

[0022] FIG. 13 is an example of PDCCH Type 1b.

[0023] FIG. 14 is an example of PDCCH Type 2.

[0024] FIG. 15 is an example of PDCCH Type 3a.

[0025] FIG. 16 is an example of PDCCH Type 3b.

[0026] FIG. 17 is an example of a Logical Architecture for Control Channel Beam Generation.

[0027] FIG. 18 is an example of a Subframe Structure and Placement for Control BRS.

[0028] FIG. 19 is an example of Resource Allocation in Two Dimension of Frequency and Time.

[0029] FIG. 20 is an example of a Subframe Structure and Placement for Control BRS for Parallel Beam Sweeping.

[0030] FIG. 21 is an example of Resource Allocation in Two Dimension of Frequency and Time.

[0031] FIG. 22 is an example of Common Control Channel Beam and Search Space.

[0032] FIG. 23 is an example of WTRU Beam Specific Search Space.

[0033] FIG. 24A is a System Diagram of an example Communications System.

[0034] FIG. 24B is a System Diagram of an example Wireless Transmit/Receive Unit (WTRU) that May be Used within the Communications System Illustrated in FIG. 24A.

[0035] FIG. 24C is a System Diagram of an example Radio Access Network and an Example Core Network that may be Used within the Communications System Illustrated in FIG. 24A.

[0036] FIG. 24D is a System Diagram of another example Radio Access Network and an Example Core Network that may be Used within the Communications System Illustrated in FIG. 24A.

[0037] FIG. 24E is a System Diagram of another example Radio Access Network and an Example Core Network that may be Used within the Communications System Illustrated in FIG. 24A.

DETAILED DESCRIPTION

[0038] A detailed description of illustrative embodiments will now be described with reference to the various figures. Although this description provides a detailed example of possible implementations, it should be noted that the details are intended to be examples and in no way limit the scope of the application.

[0039] An mmW deployment may be used, e.g., based on a 3GPP R12 small cell deployment perhaps with an extension of a LTE carrier aggregation scheme. An example is a Small Cell mmW eNB (SCmB) deployment. The SCmB may be based on the 3GPP R12 small cell deployment. The mmW operation may be performed by one or more of the following network nodes. A LTE small cell eNB may be capable of operating an mmW air interface, for example in parallel with a LTE air interface in the downlink. The SCmB may simultaneously transmit LTE downlink channels in a wide beam pattern and/or mmW channels in narrow beam

pattern(s), e.g., when it is equipped with advanced antenna configuration and/or beamforming technique(s). The SCmB may support features and/or procedures in a LTE uplink (UL) operation, e.g., to support mmW wireless transmit/receive units (WTRUs) without mmW uplink transmission. A wireless transmit/receive unit (WTRU) that is capable of operating an mmW air interface, possibly in parallel with a non-mmW LTE system, may be referred to as an mmW wireless transmit/receive unit (mWTRU) and/or an mmW user equipment (mUE). A mWTRU and/or a mUE may be used interchangeably herein. A WTRU may be used herein to refer to an mWTRU.

[0040] For example, an mWTRU may comprise antennas (e.g., two or more sets) and/or accompanied RF chains, some operating in a LTE band and/or some for operation in an mmW frequency band. The antennas and/or accompanied RF chains may perform independent baseband processing functions, although portions of the antennas and/or RF chains may share some hardware and/or functional blocks. For example, the baseband functions may share certain hardware blocks, e.g., when the mmW air interface bears similarity with the LTE system.

[0041] For example, mmW channels may be used as an extension of a LTE carrier aggregation scheme. One or more mmW channels may be a carrier type in the mmW frequency band. One or more mmW channels may apply a different air interface and/or legacy LTE. The one or more mmW channels may be of opportunistic use for high-throughput and/or low-latency traffic data application(s).

[0042] LTE channels may carry control signaling, e.g., system information update, paging, Radio Resource Control (RRC) and/or Non-Access Stratum (NAS) signaling (signaling radio bearers), and/or multicast traffic may be carried. LTE channels may be used to carry mmW Layer 1 (L1) control signaling.

[0043] The SCmB and/or mWTRU may employ narrow beamforming, e.g., in non-line of sight (NLOS) at mmW frequency band, perhaps for example due to relatively high propagation loss associated with mmW band. Employing narrow beamforming may provide for a (e.g., sufficient) link budget for high-throughput and/or low-latency data transmission.

[0044] Transmitting and/or receiving narrow beam pairing may be used. For example, at least a consistent coverage with a cell-radius of up to 200 meters may be achieved at 28 GHz and/or 38 GHz in urban areas by using a steerable 10°-beamwidth and/or a 24.5-dBi horn antenna for transmitting and/or receiving.

[0045] To meet the high data rate required for the next generation of cellular communication systems, the wireless industry and/or academia have been exploring ways to leverage the large bandwidths available at above-6 GHz frequencies, e.g. at cmW and/or mmW

frequencies. The large bandwidth available at these frequencies may provide capacity improvement for user-specific data transmission. One challenge of using these above-6 GHz frequencies may be characteristics related to their propagation which may be unfavorable for wireless communication, especially in an outdoor environment. For example, higher frequency transmissions may experience higher free space path loss. Rainfall and/or atmospheric gasses, e.g., oxygen, may add further attenuation and/or foliage may cause attenuation and/or depolarization. Narrow beam patterns which may be used to counter these losses may pose challenges for a base station (e.g., eNB), for example, in delivering cell-specific and/or broadcast information.

[0046] FIG. 1 depicts an example of a SCmB deployment. SCmB may use narrow beams for downlink transmissions. One or more mWTRUs may use receive-side narrow beams for receiving the downlink transmissions. SCmB and/or mWTRUs may apply broad beam pattern for the traditional LTE operation including cell search, random access, and/or cell selection/reselection etc.

[0047] FIG. 2 is an example of the mWTRU receive beamforming, for example, using narrow spatial filtering. FIG. 2 includes an example comparison with a frequency domain filtering to demonstrate the effect of a spatial and/or angular filtering.

[0048] The spatial filtering may allow an mWTRU to detect a channel impulse response at a distinct angular direction captured by the narrow receive beam, perhaps for example similar to a frequency filtering removing unwanted frequency components. This may result in a flat effective channel by excluding angular incoming paths outside of its beamwidth. An R12 LTE WTRU may be assumed to have an omni-directional receive beam pattern and/or may perceive a superimposed channel impulse response over the entire angular domain. An aligned mmW transmit and receive beam pair may provide a degree of freedom in the angular domain compared with the current LTE system.

[0049] An mmW system (e.g., a downlink system) design may focus on integrating directivity, e.g., the directivity of a narrow transmit and/or receive beam pair, into a celluar system which may include L1 control signaling, data scheduling, narrow beam pairing, beam measurement, and/or L1 control information feedback, etc.

[0050] Some examples of mmW system parameters and/or assumptions are described herein. The parameters and/or assumptions may change, for example, depending on the type of deployment. These parameters and/or assumptions are not intended to be limiting but serve to illustrate example set(s) of parameters and/or assumptions of an example mmW system. The parameters and/or assumptions may be utilized in various combinations.

[0051] For example, an example carrier frequency for mmW operation may be 28 GHz. This is an example system numerology. Similar designs may be extended to other mmW frequencies, e.g., 38 GHz, 60 GHz, 72 GHz, etc. A system bandwidth may be a variable (e.g., per carrier), for example up to a specific maximum system bandwidth. For example, 1 GHz may be used as the maximum system bandwidth with carrier aggregation perhaps being used to achieve higher overall bandwidth. An estimated RMS delay spread may be 100-200 ns with narrow beam pattern. A latency may be 1 ms. A waveform may be OFDM-based or broad-band-single-carrier-based. For example, dual connectivity may be based on LTE Small Cell eNB with mmW add-on channels and two separate antennas and/or RF chains connected to two different antenna solutions. A system design parameter may be to achieve DL data rates of 30 Mbit/s for at least 95% of mWTRUs, although other design goals may be used. A mobility may be optimized data connection at 3 km/h and/or maintain connection at 30 km/h. A coverage may meet data rate and/or mobility requirement with less than 100-m cell radius.

[0052] One or more waveforms such as broad-band Cyclic Prefixed Single Carrier (CP-SC), OFDM, SC-OFDM, MC-CDMA, Generalized OFDM, FBMC, and/or other may be used for the air interface of a system, e.g, an above-6 GHz system (e.g., cmW and/or mmW). Frame structure for the system may depend on the applied waveform. A Transmission Time Interval (TTI) length such as 100us may be used, e.g., to achieve low latency. A system bandwidth, e.g., one in the range of 50MHz to 2GHz may be used, for example, to achieve high data rates.

[0053] An mmW frame structure of an OFDM-based waveform may offer flexibility in coordination between the LTE and mmW channels and/or may enable common functional block sharing in a mWTRU device. For example, an mmW sampling frequency may be selected as an integer multiple of the LTE minimum sampling frequency of 1.92 MHz, which may lead to an mmW OFDM sub-carrier spacing Δf being an integer multiple of the LTE sub-carrier spacing of 15 kHz, e.g. $\Delta f = 15*K$ kHz. The selection of the integer multiple K and/or the resulting Δf may take into consideration the sensitivity to the Doppler shift, different types of frequency errors, and/or the ability to remove channel time dispersion, and/or the like. The orthogonality between sub-carriers may deteriorate and/or inter-sub-carrier interference (ISI) may increase, perhaps for example when the Doppler shift increases in proportion to the sub-carrier spacing.

[0054] For example, the maximum Doppler shift at 30 km/h and 28 GHz may be approximately 778 Hz. Example 28-GHz channel time dispersion measurements in dense urban area may indicate an RMS delay spread σ that may be between 100 and 200 ns for up to 200-m cell radius. The 90% coherence bandwidth may be estimated at $1/50\sigma$ of 100 kHz and the 50% coherence bandwidth at $1/5\sigma$ of 1 MHz.

[0055] A sub-carrier spacing Δf between 100 kHz and 1 MHz may be reasonable. A sub-carrier spacing of 300 kHz (K=20) may be robust against Doppler shift and/or other types of frequency error and/or reduce implementation complexity. The corresponding symbol length (1/ Δf) may be approximately 3.33 us.

[0056] A cyclic prefix (CP) length may be configured to span over the entire length of the channel time dispersion in order to eliminate the inter-symbol-interference. For example, a CP may or might not carry useful data, and/or in some scenarios a long CP may cause excessive system overhead. One example of CP length for a T_{symbol} of 3.33us may be selected at 1/14 of T_{symbol}, 0.24 us and/or the corresponding CP overhead may be 7% as calculated by T_{CP} / (T_{CP} + T_{symbol}).

[0057] The TTI length of the mmW transmission may be reduced compared to the 1-ms TTI length of the LTE system, perhaps for example to achieve low latency. In some scenarios, it may be beneficial to have an mmW sub-frame length of 1 ms to align with the LTE 1-ms sub-frame timing. The mmW sub-frame may contain multiple mmW TTIs whose length may be tied to other parameters, e.g., sub-carrier spacing, symbol length, CP length, and/or FFT size, etc.

[0058] Based on these and/or other considerations, an example with a conservative CP length (4x channel delay spread) is summarized in Table 1. It may be assumed that CP length selection is based on the delay spread over potential mmW frequency band of lower than 200 ns.

Table 1 Example mmW Downlink OFDM Numerology

OFDM Numerology Parameters				
System bandwidth (MHz)	125	250	500	1000

[0059] FIG. 3 depicts an example OFDM-based frame structure. In FIG. 3, the system bandwidth may be 1GHz and/or a sub-carrier spacing of 300 kHz may be used with a corresponding symbol length of 3.33 us. An example cyclic prefix (CP) length of 1/4 of T_{symbol} which equals 0.833 us may be used.

[0060] Some of the frame structure examples presented herein may be based on an assumption that an OFDM-based mmW waveform, which may be incorporated into the OFDM-based LTE small cell network. The system procedures described herein may be equally applicable to numerous types of frame designs and/or should not be interpreted to be bound by this specific frame structure and/or may be applied to other waveform candidates.

[0061] The SCmB and/or mWTRU deployments may employ one or more of the following mmW physical layer channels and/or reference signals, for example, rather than and/or in addition to the LTE physical channels.

[0062] An SCmB and/or an mWTRU may employ a unique sequence transmitted per transmit beam, e.g., a Beam-Specific Reference Signal (BSRS), used for beam acquisition, timing/frequency synchronization, channel estimation for a Physical Downlink Directional Control Channel (PDDCCH), beam tracking and/or measurement, etc. The BSRS may carry implicitly beam identity information including BSRS sequence index. There may be different types of BSRSs. The BSRS resource allocation may be pre-defined.

[0063] An SCmB and/or an mWTRU may employ a unique sequence scheduled and/or transmitted dynamically for the purpose of beam pair measurement specific for a given antenna port, e.g., an Adaptive Antenna Reference Signal (AARS). The AARS may embed implicitly the beam identity information in the sequence index and/or carry a small payload including the same information.

[0064] An SCmB and/or an mWTRU may utilize a Physical Downlink Directional Control Channel (PDDCCH). The PDDCCH may carry some or all data related control information for an mWTRU to identify, demodulate and/or decode an associated Physical

Downlink Directional Data Channel (PDDDCH) correctly. The PDDCCH may be carried in an mmW narrow beam and/or in a broad beam and/or may be applied for different multiple access. For example, there may be a common PDDCCH transmitted in downlink mmW broad beam covering a sector and/or cell and/or a dedicated PDDCCH transmitted (e.g., transmitted) in a narrow beam pair, for example, when mWTRU-specific data transmission is on-going. The dedicated PDDCCH may carry scheduling information for its associated PDDDCH on a per-TTI basis and/or may or might not carry beam specific information. A common PDDCCH may include cell-specific information including sector/segment identity and/or beam identity. In addition, an mWTRU may read the common PDDCCH to determine if it is scheduled for narrow beam pairing procedure in order to begin narrow beam data transmission subsequently.

[0065] An SCmB and/or an mWTRU may utilize a Physical Downlink Directional Data Channel (PDDDCH). The PDDDCH may carry payload information received in the form of MAC PDU from mmW MAC layer. The resource allocation of this channel may be determined by the downlink scheduling information carried in PDDCCH. The PDDDCH intended for a mWTRU may be transmitted in a narrow Tx beam and/or received in a properly paired narrow Rx beam, e.g., a narrow beam pair. Due to this spatial isolation, PDDDCHs for different WTRUs in different beam pairs may reuse a combination of one or more time, frequency, and/or code resource(s). Multiple PDDDCH may also operate in one beam pair using multiple access in one or more of the time, frequency, code domain, and/or the like. A common PDDDCH may be used to carry data in broad mmW antenna pattern associated with the common PDDCCH.

[0066] An SCmB and/or an mWTRU may utilize symbols embedded in a transmission for channel estimation for PDDDCH, e.g., a Demodulation Reference Signal (DMRS). For example, the DMRS may be placed in the time and/or frequency domain according to pre-defined pattern to ensure correct interpolation and/or reconstruction of the channel.

[0067] Some or all channels and/or reference signals in a narrow beam pair may be beamformed identically and/or considered to be transmitted via a specific and/or single physical antenna port. Although carrying broadcast and/or multicast information on a narrow beam can be utilized, given the directivity of the transmission of these channels, carrying broadcast, multicast, and/or other cell-specific information on the narrow beam may or might not be optimal application. The SCmB deployment with mmW downlink data transmissoin may adopt a channel mapping as illustrated in FIG. 4 and the mmW channels are marked in bolder line color.

[0068] An mWTRU may use a phase antenna array to achieve the beamforming gain, for example, in order to compensate the high path loss at mmW frequencies. At the mmW frequencies the short wavelength may allow a compact form factor of the device design. A large

spacing such as 0.7λ may be applied, for example. An element spacing of 0.5λ may be used in theoretical performance analysis.

[0069] The phase antenna may apply one or more different beamforming methods. For example, a fully digitized beamforming approach may have a dedicated RF chain. For example, the RF chain may include RF processing and/or analog-to-digital conversion (ADC) as depicted in FIG. 5 for an antenna element. The signal processed by an antenna element may be controlled independently in phase and/or amplitude to optimize the channel capacity.

[0070] The configuration may have the same number of RF chains and ADCs as that of antenna elements. The mWTRU antenna may offer (e.g., very) high performance. The mWTRU antenna configuration may impose costs and/or complexity in implementation. The mWTRU antenna configuration may cause high energy consumption in operation. Fully digitized beamforming may or might not be adopted in the initial 5G deployments and/or mWTRU implementations, but may be used in future releases.

[0071] FIG. 6 may be an example of analogue beamforming. In analog beamforming, an RF chain may be applied (e.g., only one RF chain) for a given phase antenna array (PAA). For example, an antenna element may be connected to a phase shifter. The phase shifter may be used to set the weight for beam forming and/or steering. The number of RF chains may be (e.g., significantly) reduced using analog beamforming (e.g., as compared to digital beamforming). The energy consumption may be significantly reduced.

[0072] The phase of the signal (e.g, only the phase) at an antenna element may be adjusted in the beamforming. FIG. 6 shows that the phase shifting and/or combining may be implemented in different stages, e.g., in RF, base-band (BB) analogue, and/or local-osciallator (LO). One or more of the techniaues described herein may be used to evaluate the effectiveness/efficiency of an approach, e.g., signal loss, phase error, and/or power consumption, and/or the like.

[0073] The mWTRU analogue beamforming methods may comprise one or more of the following. The mWTRU analogue beamforming algorithms may comprise a grid of beams having a set of fixed beams, e.g., a fixed codebook-based beamforming. A beam may be formed by the mWTRU applying a beamforming weight vector v chosen from a pre-defined codebook $v \in \{v_1, v_2, v_3 \ldots v_N\}$, where N denotes the number of fixed beams. A vector may comprise pre-calibrated phase shifts for certain (e.g., one or more, or all) phase shifters and/or may represent a unique analogue beam direction, e.g., "beam". The number of beams may depend on the Half-Power-Beam-Width (HPBW) of the beamforming and/or desired coverage. The mWTRU analogue beamforming algorithms may comprise a continuous phase shifting beamforming. For

example, the desired weight of a phase shifter may be calculated based on the estimated short-term channel information and/or converted using a high resolution digital-to-analogue converter (DAC) for the phase shifter. The continuous phase shifting beamforming may provide a continuous and/or adaptive beamforming to track the channel conditions. The algorithm may perform well in one or more scenarios, e.g., with increased multipath, high angular spread, and/or low WTRU mobility.

[0074] An mWTRU may employ a hybrid approach comprising the digitized and analogue beamforming. For example, the analogue beamforming may be performed over the phase array antenna elements where an antenna element is associated with a phase shifter and/or connected to one RF chain. The digitized beamforming may comprise a digital precoding applied on the baseband signal of a RF chain, e.g., when there is more than one RF chain. MIMO schemes may be implemented using digital precoding.

[0075] Examples for the basic system parameters of the hybrid beamforming may include one or more of a Number of data stream, N_{DATA}; Number of RF chain (TRX), N_{TRX}; Number of antenna ports, N_{AP}; Number of antenna elements, N_{AE}; and/or Number of phase antenna array, N_{PAA}, and/or the like. The configuration of these parameters may impact the system function and/or performance.

[0076] For example, perhaps when $N_{PAA} \leq N_{AP} \leq N_{TRX} \leq N_{AE}$, one or more of the following may occur. A PAA may comprise multiple antenna elements, e.g., a PAA of size 4x4 has 16 antenna elements. An antenna port may be defined, and/or the channel over which a symbol on the antenna port is conveyed may be inferred from the channel over which another symbol on the same antenna port is conveyed. There may be certain (e.g., one or more) resource grid per antenna port. One or more cell-specific reference signals may support a configuration of one, two, and/or four antenna ports and/or may be transmitted on antenna ports $p = 0$, $p \in \{0,1\}$ and $p \in \{0,1,2,3\}$, respectively. Multicast-broadcast single-frequency network (MBSFN) reference signals may be transmitted on antenna port $p = 4$. One or more WTRU-specific reference signals associated with PDSCH may be transmitted on antenna port(s) $p = 5$, $p = 7$, $p = 8$, or one or several of $p \in \{7,8,9,10,11,12,13,14\}$.

[0077] One or more demodulation reference signals associated with an enhanced Physical Downlink Control Channel (EPDCCH) may be transmitted on one or several of $p \in \{107,108,109,110\}$. Positioning reference signals may be transmitted on antenna port $p = 6$. CSI reference signals may support a configuration of one, two, four or eight antenna ports and/or may be transmitted on antenna ports $p = 15$, $p \in \{15,16\}$, $p \in \{15,16,17,18\}$, and $p \in$

{15,16,17,18,19,20,21,22}, respectively. An antenna port may carry beamformed reference signal(s) that may be uniquely associated with this antenna port and/or that can be used to identify the antenna port. The antenna configuration may become (e.g., fully) digitized as shown in FIG.5, e.g., perhaps when the number of TRX equals the number of antenna elements. An example may be one RF chain per antenna element. A PAA may be connected to a RF chain (as shown in FIG. 6) and/or multiple RF chains, e.g., depending on the system configuration. In FIG. 7, $N_{PAA} < N_{AP} = N_{TRX} < N_{AE}$, one PAA of size 4x4 is connected to two RF chains and/or one or more, or each RF, chain has a set of 16 phase shifters. The PAA may form two narrow beam patterns within a +45° and -45° coverage in azimuth plane. FIG. 8 is an example of two PAAs and/or one or more, or each, PAA may have a dedicated RF chain, e.g., $N_{PAA} = N_{AP} = N_{TRX} \leq N_{AE}$. The example in FIG. 8 may allow a spatial independence between the two simultaneous beams by placing the PAAs at different orientation e.g. in azimuth plane. An aligned PAA arrangement may provide an aggregated larger coverage compared to the configuration in FIG. 7. Both configurations with two RF chains may apply MIMO with two data streams.

[0078] For example, perhaps when $N_{AE} > N_{PAA} > N_{AP} = N_{TRX}$, multiple PAAs may be connected to a (e.g., single) RF chain by using a switch as depicted in FIG. 9. A PAA may form a narrow beam pattern covering from +45° to -45° in azimuth plane. They may be oriented separately. A single-beam solution may provide (e.g. a good) coverage by using a narrow beam at different direction at different time instances.

[0079] For example, when $N_{DATA} \leq N_{TRX} \leq N_{AE}$, the following may occur.

[0080] For example, when $N_{DATA} = N_{TRX} = 1$, a mWTRU may have a single-beam configuration and/or may operate one beam at a time. One or more of the following may occur. The mWTRU beamforming may form a narrow beam pattern. FIG. 10 is an example for a 16x16 PAA at the strongest angular direction, e.g., a line-of-sight (LOS) path obtained from beam measurement. The mWTRU may form a broad beam pattern, e.g. a wide main lobe. FIG. 11 is an example of a wide main lobe to cover a range of continuous angular directions including strong and/or weak ones in-between. The antenna gain may be reduced (e.g., considerably) with a broad beam pattern, and/or the link budget may worsen.

[0081] For example when $N_{DATA} = 1 < N_{TRX}$, an mWTRU may have simultaneous beam patterns. The beam patterns may be different and/or may be used for different applications. For example, when $N_{TRX} = 2$, an mWTRU may have two simultaneous beam patterns that are different and/or may be used for different applications. One or more of the following may apply. The mWTRU may place two narrow beam patterns at different angular

incoming directions to receive one data stream. For example, coherent beam combining may be used for spatial diversity and/or mitigate the blockage effect and/or weak LOS condition. The mWTRU may form one narrow beam and/or one broad beam for different application. For example, the narrow beam may be used for data transmissoin and/or the broad beam for control signaling.

[0082] For example, perhaps when $1 < N_{DATA} = N_{TRX}$, the transmission may apply MIMO to increase the capacity, e.g., in high SNR channel condition. The mWTRU may place two narrow beam patterns at different angular incoming directions to receive two data streams in parallel.

[0083] One or more of the SCmB beam forming schemes may include fixed beam, adaptive beam forming (e.g., codebook-based and/or non-codebook-based), and/or classical beam forming e.g. Direction-of-Arriaval (DoA) estimation. One or more schemes may use different approaches and/or may work well in certain scenarios. For example the DoA estimation may use smaller angular spread and/or a mWTRU may (e.g., need to) transmit a LTE uplink reference signal to ensure DoA accuracy. The fixed beam system may require beam cycling and/or switching.

[0084] One or more of the examples described herein may be explained in terms that assume an mWTRU antenna configuration and/or beamforming configuration. The mWTRU antenna configuration and/or beamforming configuration may be based on a single-beam mWTRU antenna configuration with analogue beamforming as illustrated in FIG. 6. The methods and/or techniques may also be applied using other beamforming methods such as digital beamforming and/or hybrid beamforming.

[0085] The LTE/LTE-A and/or E-PDCCH have evolved. In Rel-8, REs, REG, CCE and/or PDCCH may be the following. The smallest time-frequency unit for downlink transmission may be denoted a resource element (RE). A (e.g. one or more, or each) element in the resource grid for antenna port p may be called a resource element and/or may be uniquely identified by the index pair (k,l) in a slot where k and/or l may be the indices in the frequency and/or time domains, respectively. A PDCCH (Physical Downlink Control Channel) may carry scheduling assignments and/or other control information. A group of 4 consecutive resource elements may be called Resource Group Elements (REG). A physical control channel may be transmitted on an aggregation of one or several consecutive control channel elements (CCEs), where a control channel element corresponds to 9 REGs.

[0086] In Rel-11, EPDCCH WTRU-specific Search Space may be the following. The EPDCCH has been introduced in Rel-11 LTE-Advanced in order to achieve frequency domain ICIC and/or beamforming gain. Hereafter, EPDCCH, ePDCCH, and/or E-PDCCH may be used interchangeably. Also, EREG and/or ECCE may be interchangeably used as eREG and/or eCCE, respectively.

[0087] In Rel-11, PRB configuration may be the following. In Rel-11, the ePDCCH resources for WTRU-specific search space may be configured as a subset of PRBs in the PDSCH region. The ePDCCH resources may be configured in a WTRU-specific manner and/or up to two ePDCCH resource sets may be configured for a WTRU. An ePDCCH resource set may contain 2, 4, and/or 8 PRB-pairs according to the configuration and/or may be configured as a localized resource set and/or distributed resource set.

[0088] In Rel-11, eREG may be defined as the following. In a (e.g. one or more, or each) PRB-pair which is configured as ePDCCH resource, 16 eREGs may be defined regardless of normal CP and/or extended CP. The REs for eREGs may be allocated cyclically in a frequency first manner and/or may be rate-matched around for the demodulation RS such as antenna ports {107, 108, 109, 110}. Randomizing channel estimation performance across eREGS may occur as the channel estimation performance may be different according to the RE location in a PRB-pair. Since antenna port 107 and/or 108 are defined (e.g., only defined) for extended CP, the REs for eREGs may be allocated cyclically in a frequency first manner and/or may be rate-matched around for the demodulation RS such as antenna ports {107, 108}.

[0089] An eCCE may may be defined as the following. An eCCE may be defined as grouping of 4 and/or 8 eREGs within an ePDCCH resource set. Therefore, the number of eCCEs ($N_{eCCE,set}$) per ePDCCH resource set may be defined as a function of the number of PRB pairs ($N_{PRB,set}$) configured for the ePDCCH resource set and/or the number of eREGs grouped to form an eCCE (N_{eREG}) such as $N_{eCCE,set} = 16xN_{PRB,set}/N_{eREG}$. Two types of eCCE may be defined according to the mode of ePDCCH resource set such as localized eCCE (L-eCCE) and/or distributed eCCE (D-eCCE). To form an L-eCCE, the 4 and/or 8 eREGs located in the same PRB-pair may be grouped together. On the other hand, the eREGs in different PRB-pairs may be grouped to form a D-eCCE. C ertain (e.g., one or more, or all) eREGs in an ePDCCH resource set may be used to form L-eCCE and/or D-eCCE perhaps according to the ePDCCH transmission configured for the ePDCCH resource set. For instance, if an ePDCCH resource set may be configured as localized ePDCCH, then certain (e.g., one or more, or all) eREGs in the ePDCCH resource set may be be used to form L-eCCE. In other words, in an ePDCCH resource

set, there may be be L-eCCEs and/or D-eCCEs. For example, 4 eREGs may be grouped to form an eCCE in the case of normal subframe and/or special subframe configuration 3, 4, 8 in TDD perhaps for example since a (e.g, enough) number of REs may be available per eCCE so that a certain (e.g., required) effective coding rate may be used in one or more scenarios.

[0090] An antenna port mapping may be the following. The antenna ports {107, 108, 109, 110} and {107, 108} may be used for normal CP and/or extended CP, respectively. According to the ePDCCH transmission mode (e.g. localized ePDCCH and/or distributed ePDCCH), the antenna port mapping rules may be different as an (e.g., one or more, or each) ePDCCH transmission mode targeted for different system and/or channel environments. For instance, antenna port mapping for the distributed ePDCCH may be designed to maximize diversity gain as it has been introduced for open-loop transmission. On the other hand, antenna port mapping rules for localized ePDCCH may be defined to exploit WTRU-specific beamforming gain as well as multi-user MIMO gain.

[0091] For the distributed ePDCCH, two (e.g, only two, or more than two) antenna ports {107, 109} may be used out of {107, 108, 109, 110} in order to improve channel estimation gain while certain (e.g., one or more, or all) antenna ports may be used for localized ePDCCH. This may be due to the fact that WTRU-specific beamforming may use (e.g., require) larger number of antenna ports as one PRB-pair may be shared with up to 4 WTRUs. This may allow WTRU-specific beamforming of up to 4 WTRUs within a PRB-pair, for example.

[0092] A reference signal sequence may be the following. A predefined sequence (e.g., Pseudo-random (PN), m-sequence and/or etc.) may be multiplied with downlink RS so as to minimize inter-cell and/or intra-cell interference. This may improve channel estimation accuracy and/or increasing multi-user spatial multiplexing gain. For some (e.g., any) of the EPDCCH antenna ports {107, 108, 109, 110}, the reference signal sequence $r(m)$ may be defined by

$$r(m)=\frac{1}{\sqrt{2}}(1-2\cdot c(2m))+j\frac{1}{\sqrt{2}}(1-2\cdot c(2m+1)),\qquad m=\begin{cases}0,1,\ldots,12N_{\mathrm{RB}}^{\max,\mathrm{DL}}-1 & \text{normal cyclic prefix}\\ 0,1,\ldots,16N_{\mathrm{RB}}^{\max,\mathrm{DL}}-1 & \text{extended cyclic prefix}\end{cases},$$

where the $N_{\mathrm{RB}}^{\max,\mathrm{DL}}$ denotes the maximum number of RBs for the downlink system bandwidth and $c(i)$ denotes pseudo-random sequence. The pseudo-random sequence generator may be initialized with

$$c_{\mathrm{init}}=(\lfloor n_s/2\rfloor+1)\cdot(2n_{\mathrm{ID}}^{\mathrm{EPDCCH}}+1)\cdot 2^{16}+n_{\mathrm{SCID}}^{\mathrm{EPDCCH}}$$

at the start of a (e.g., one or more, or each subframe). The $n_{\mathrm{ID}}^{\mathrm{EPDCCH}}$ may be independently configured for a (e.g., one or more, or each) EPDCCH resource set and $n_{\mathrm{SCID}}^{\mathrm{EPDCCH}}=2$ may be used.

[0093] A WTRU-specific search space may be the following. In Rel-11, a WTRU-specific search space may be introduced (e.g., only introduced) for EPDCCH. Common search

space may be located at the PDCCH region. The WTRU monitoring behavior for downlink control signaling reception may be defined in a downlink subframe as one of following. A WTRU may monitor WTRU-specific search space in EPDCCH and/or common search space in PDCCH, e.g., where the EPDCCH monitoring subframe may be configured via higher layer signaling. A WTRU may monitor WTRU-specific search space and/or common search space in PDCCH. The WTRU-specific search space fallback may be used, perhaps even though a subframe is configured to monitor ePDCCH subframe, e.g., when ePDCCH is not available in that subframe. Some collisions between ePDCCH REs and/or other signals may occur. A WTRU may monitor PDCCH for WTRU-specific search space.

[0094] The aggregation level may increase to keep an effective coding rate, perhaps when the available number of REs may be smaller than a threshold ($n_{\text{EPDCCH}} < 104$). For instance, the supportable ePDCCH formats for localize transmission when $n_{\text{EPDCCH}} < 104$ may be $N_{\text{ECCE}} \in \{2,4,8,16\}$ while $N_{\text{ECCE}} \in \{1,2,4,8\}$ may be used in other cases. The set of aggregation levels may be different according to the ePDCCH transmission modes.

[0095] Collision handling may be performed. The ePDCCH REs may be defined as the REs in a PRB-pair not occupied by antenna port $\{107,108,109,110\}$. FIG. 1-24 may show an example of the ePDCCH RE definition in a PRB-pair according to the CP length without collission with other signals, resulting in 144 and/or 128 available REs for normal CP and/or extended CP, respectively. The ePDCCH resources may be configured in PDSCH region. The REs for ePDCCH may collide with other signals, e.g., CSI-RS, CRS, PRS, PBCH, SCH, and/or PDCCH. The WTRU behavior when the REs collide with other signals may be defined as one or more of the following. The coded bits for ePDCCH may be rate-matched around for the REs colliding with CSI-RS, CRS, and/or PDCCH. The PRB-pair used for PBCH and SCH in a subframe may or might not be used for ePDCCH. The available REs for ePDCCH may become smaller, e.g., when other signals are transmitted in the PRB-pair configured for ePDCCH.

[0096] Transmit and/or receive beamforming may be applied to the control channel transmission/reception, e.g., to overcome high path loss at > 6Ghz frequencies. The resulting beamformed link may be considered as a spatial filtering and/or limit the WTRU to receive incoming angular paths (e.g., only incoming angular paths) within the formed beam pair.

[0097] Legacy cellular systems may rely on Omni directional and/or cell-wide beams for control channel transmissions. From a WTRU's point of view, the placement of control channel may be well defined, e.g. in the control region. At higher frequencies, a (e.g., one or more, or each) base station may have plurality of control channel beams to cover the cell. A WTRU may

be able to (e.g., only be able to) receive a subset of those control channel beams. One or more techniques to identify candidate control channel beams and/or their location in the subframe structure may be defined for efficient WTRU operation.

[0098] One or more mBs and/or WTRUs in a beam formed system may have diverse set of capabilities, for example, different number of RF chains, different beam widths, and/or different number of PAAs, etc. One or more mBs with multiple RF chains may transmit control channel beam(s) in the same control symbol. One or more WTRUs with one or more, or multiple, RF chains may receive using receive beam pattern(s) same control symbol. One or more mBs with, for example, one RF chain may (e.g., need to) multiplex control channel beams in time domain (e.g. different symbols and/or different subframes). One or more mBs with RF chain(s) may multiplex control channel beams in time and/or spatial domains.

[0099] A framework for beam formed control channel design may be used to support varying capabilities of mBs and/or WTRUs and/or support time and/or spatial domain multiplexing of control channel beams.

[0100] The common reference signal design in LTE may assume cell wide transmission. For a multi-beam system, modifications to reference signal design may be used to discover, identify, measure, and/or decode a (e.g., one or more, or each) control channel beam. In a multi-beam system, interference between beams may degrade overall cell capacity, so additional mechanisms to mitigate inter-beam interference may be useful, e.g, for intra-cell and/or inter-cell scenarios.

[0101] WTRU monitoring may be defined to consider beam search space in addition to time and/or frequency search space.

[0102] Enhancements to downlink control channel may be useful to support scheduling narrow data beams. One or more mechanisms may be useful to achieve high resource utilization, e.g., perhaps when large bandwidths are available and/or WTRUs may be spatially distributed.

[0103] A mB, SCmB, mmW eNB, eNB, cell, small cell, Pcell, and/or Scell may be used interchangeably. The term operate may be used interchangeably with transmit and/or receive. Component carrier and/or mmW carrier may be used interchangeably with serving cell.

[0104] The mmW eNB may transmit and/or receive one or more mmW channels in a band (e.g., licensed band and/or unlicensed). The mmW eNB may transmit and/or receive one or more signals in a band (e.g., licensed band and/or unlicensed). One or more WTRUs may be substituted for eNB and still be consistent with the techniques described herein. An eNB may be substituted for WTRUs and still be consistent with the techniques described herein. UL may be

substituted for downlinke (DL) and still be consistent with the techniques described. DL may be substituted for UL and still be consistent with the techniques described herein.

[0105] A channel may refer to a frequency band which may have a center and/or carrier frequency and a bandwidth. Licensed spectrum may include one or more channels which may or might not overlap. Unlicensed spectrum may include one or more channels which may or might not overlap. Channel, frequency channel, wireless channel, and/or mmW channel may be used interchangeably. Accessing a channel may be the same as using (e.g., transmitting on and/or receiving on and/or using) the channel.

[0106] A channel may refer to an mmW channel and/or signal, e.g., an uplink physical channel and/or signal. A channel may refer to an mmW channel and/or signal, e.g., a downlink physical channel and/or signal. Downlink channels and/or signals may comprise one or more of the following: mmW synchronization signal, mmW broadcast channel, mmW cell reference signal, mmW beam reference signal, mmW beam control channel, mmW beam data channel, mmW hybrid ARQ indicator channel, mmW demodulation reference signal, PSS, SSS, DMRS, CRS, CSI-RS, PBCH, PDCCH, PHICH, EPDCCH, and/or PDSCH, and the like. Uplink channels and/or signals may include one or more of the following: mmW PRACH, mmW control channel, mmW data channel, mmW beam reference signal, mmW demodulation reference signal, PRACH, PUCCH, SRS, DMRS, and/or PUSCH, and the like. Channel and mmW channel may be used interchangeably. Channels and signals may be used interchangeably.

[0107] Data/control may mean one or more of the following: data, control signals, and/or channels, and the like. Control may comprise synchronization. The data/control may be mmW data/control. Data/control, data/control channels, and/or signals may be used interchangeably. Channels and signals may be used interchangeably. The terms control channel, control channel beam, PDCCH, mPDCCH, mmW PDCCH, mmW control channel, directional PDCCH, beamformed control channel, spatial control channel, control channel slice, and/or high frequency control channel may be used interchangeably. The terms data channel, data channel beam, PDSCH, mPDSCH, mmW PDSCH, mmW data channel, directional PDSCH, beamformed data channel, spatial data channel, data channel slice, and/or high frequency data channel may be used interchangeably.

[0108] Channel resources may be resources (e.g., 3GPP LTE and/or LTE-A resources), e.g., time, frequency, code, and/or spatial resources. Channel resources, e.g., at least sometimes, carry one or more channels and/or signals. Channel resources may be used interchangeably with channels and/or signals.

[0109] A mmW beam reference signal, mmW reference resource for beam measurement, mmW measurement reference signal, mmW channel state measurement reference signal, mmW demodulation reference signal, mmW sounding reference signal, reference signal, CSI-RS, CRS, DM-RS, DRS, measurement reference signal, reference resource for measurement, CSI-IM, and/or measurement RS may be used interchangeably. A mmW cell, mmW small cell, SCell, secondary cell, license-assisted cell, unlicensed cell, and/or LAA cell may be used interchangeably. A mmW cell, mmW small cell, PCell, primary cell, LTE cell, and/or licensed cell may be used interchangeably. Interference and interference plus noise may be used interchangeably.

[0110] A WTRU may determine the UL and/or DL directions of one or more subframes according to one or more received TDD UL/DL configurations. A WTRU may determine the UL and/or DL directions of one or more subframes according to one or more configured TDD UL/DL configurations. UL/DL and UL-DL may be used interchangeably.

[0111] The techniques described herein for beamformed control and data channels may be applicable to any system, perhaps irrespective of the frequency bands, usage (e.g. licensed, unlicensed, shared), antenna configuration (e.g. phased array and/or patch and/or horn etc.), RF configuration (e.g. single and/or multiple RF chains), beamforming methods used (e.g. digital, analog and/or hybrid, codebook based and/or otherwise), and/or deployments (e.g. macro, small cell, heterogeneous networks, dual connectivity, remote radio heads, carrier aggregation). A mmW (millimeter wave) may be substituted for cmW (centimeter wave) and/or LTE/LTE-A/LTE evolution and still be consistent with the techiques described herein.

[0112] A scheduling interval may refer to the subframe and/or slot and/or frame, and/or schedulable slice and/or control channel periodicity and/or any other pre-defined time unit. Gaps and/or guard periods and/or silence periods and/or switching periods and/or absence of transmission and/or DTX periods may be used interchangeably.

[0113] The terms channel, beam and/or channel beams may be used interchangeably. Antenna pattern, phase weights, steering vector, codebook, precoding, radiation pattern, beam pattern, beam, beam width, beam formed transmission, antenna port, virtual antenna port, transmission associated with a reference signal, directional transmission, and/or spatial channel may be used interchangeably.

[0114] The terms REGs and CCEs may refer to plurality of time, frequency, code and/or spatial resources generally and/or may or might not be limited by the LTE numerology/context (e.g., the LTE REGs and LTE CCEs may be considered types of REGs and CCEs in the context

of the techniques described herein). Radiation pattern may refer to the angular distribution of the radiated electromagnetic field and/or power level in the far field region.

[0115] A beam may be one of the lobes, e.g., main/side/grating lobes of the transmit radiation pattern and receive gain pattern of an antenna array. A beam may denote a spatial direction that may be represented with a beamforming weight vector. A beam may be identified and/or associated with one or more of a reference signal, an antenna port, a beam identity (ID), a scrambling sequence number, and/or the like. A beam may be transmitted and/or received at a specific time. A beam may be transmitted and/or received at a specific frequency. A beam may be transmitted and/or received at a specific code. A beam may be transmitted and/or received at specific spatial resources. A beam may be formed digitally and/or in an analogue manner (hybrid beamforming). The analogue beamforming may be based on fixed code-book and/or continuous phase shifting. A beam may comprise Omni directional and/or Quasi-Omni directional transmission. Two beams may be differentiated by direction of highest radiated power and/or by beam width.

[0116] One or more reference signals may be associated with one or more search spaces and/or one or more antenna ports. One or more search spaces may be associated with one or more beam search spaces and/or one or more antenna port search spaces.

[0117] In some scenarios, the WTRU may be configured to receive one or more search spaces from a wireless communication system network node, perhaps dynamically. In some scenarios, a WTRU may be configured such that the one or more search spaces are predefined on the WTRU.

[0118] A data channel beam may be used to transmit one or more of the following: data channel, data channel beam, PDSCH, mPDSCH, mmW PDSCH, mmW data channel, directional PDSCH, beamformed data channel, spatial data channel, data channel slice, high frequency data channel, and the like. A data channel beam may be identified and/or associated with one or more of the following: a reference signal, an antenna port, a beam identity (ID), a scrambling sequence number and/or a data channel number, and the like. A data channel beam may be transmitted and/or received at a specific time. A data channel beam may be transmitted and/or received at a specific frequency. A data channel beam may be transmitted and/or received at a specific code. A data channel beam may be transmitted and/or received at specific spatial resources.

[0119] A control channel beam may be used to transmit one or more of the following: control channel, PDCCH, mPDCCH, mmW PDCCH, mmW control channel, directional PDCCH, beamformed control channel, spatial control channel, control channel slice, high frequency control channel, and the like. The control channel may carry DCI for one or more

users. The control channel may carry PHICH and PCFICH in the downlink and PUCCH in the uplink. A control channel beam may be identified and/or associated with one or more of the following: a reference signal, an antenna port, a beam identity (ID), a scrambling sequence number, a control channel number, and the like. A control channel beam may be transmitted and/or received at a specific time. A control channel beam may be transmitted and/or received at a specific frequency. A control channel beam may be transmitted and/or received at a specific code. A control channel beam may be transmitted and/or received at specific spatial resources. A control channel beam may be cell specific and/or WTRU specific.

[0120] A common channel may be used to refer to transmission that carries information useful for plurality of WTRUs. The term common channel may be used interchangeably with shared channel.

[0121] Half Power Beam Width (HPBW) may refer to a radiation pattern cut containing the direction of the maximum of a lobe, the angle between two directions in which the radiation intensity is one-half the maximum value . The exact beam width for the beamformed control/data channel may or might not be specified and may depend on mB and/or WTRU implementation. A mB may support WTRUs with varying capabilities. WTRUs may work in an mB with varying capabilities.

[0122] A control channel beam duration may be a number of OFDM symbols in a scheduling interval occupied by a control channel beam.

[0123] A control region may be the number of OFDM symbols in a scheduling interval occupied by some or all of the control channel beams transmitted in the scheduling interval.

[0124] Fixed codebook-based analogue beamforming may refer to a grid of beams that may comprise a set of fixed beams. A beam may be formed by applying a beamforming weight vector v chosen from a pre-defined codebook $v \in \{v_1, v_2, v_3 \ldots v_N\}$ where N denotes the number of fixed beams. The number of beams may depend on the Half-Power-Beam-Width (HPBW) of the beamforming and desired coverage.

[0125] A continuous phase shifting analogue beamforming may provide a continuous and adaptive beamforming to track channel conditions. The desired weight of a phase shifter may be calculated based on the estimated channel information, e.g., angular information. The desired weight of a phase shifter may be converted using a high resolution digital-to-analogue converter (DAC) to apply to the phase shifter.

[0126] An antenna port may be defined. The channel over which a symbol on the antenna port is conveyed may be inferred from the channel over which another symbol on the same antenna port is conveyed. A time-frequency resource grid may be considered to be available per

antenna port. For example, a (e.g., one or more, or each) antenna port may be considered to be orthogonal to other antenna ports such that the time-frequency resources may be used for independent transmissions on a (e.g., one or more, or each) antenna port. Code multiplexing may also be used on one or more antenna ports.

[0127] The beamforming contains building blocks. An example subframe may have the following structure. A subframe and/or scheduling interval and/or slot and/or a predefined time unit may comprise plurality of symbols. One or more symbol(s) may be used to transmit and/or carry and/or include and/or map and/or be configured to receive the one or more control signal/channel/information. One or more symbol(s) may transmit/carry/include and/or be configured to receive one or more data channels.

[0128] Beamformed control and/or data channels may be one or more of the following. Control and/or data channels may be transmitted using a specific radiation pattern and/or beam. A control channel beam may be associated with one or more of the following: a unique reference signal, a steering vector, a scrambling code, an antenna port, time, code, spatial resource, frequency resource, and/or control channel identity, and/or the like. A data channel beam may be associated with one or more of the following: a unique reference signal, a steering vector, a scrambling code, an antenna port, time, code, spatial resource, frequency resource, and/or control channel identity, and the like. An mB and/or cell may transmit plurality of beamformed control and/or data channels. Beamformed control and/or data channels may be multiplexed in time.

[0129] Data region with one or more beamformed data channel(s) may work. One or more symbols within a subframe where the data channel is transmitted may be referred to as data region. Within a subframe, the data region may comprise multiple data channel beams multiplexed in time. For example, a data channel in a particular beam may occupy one more symbol(s). The remaining symbols within the same subframe may be used to transmit data channel in other beams. A data channel beam within the data region may be of variable beam widths. The maximum data channel beam width for a WTRU may be as wide as its control channel beam width. A WTRU may receive one or more data channels transmitted. A WTRU may use one or more beams and/or beam widths within a subframe and/or across different subframes. Plurality of WTRUs may be time multiplexed within a subframe, within same data channel beam and/or across different data channel beams. Minimum schedulable time resource within a subframe may be a symbol and/or group of symbols. Scheduling granularity may be less than a subframe, e.g., a new DCI format may carry allocation information at symbol level/symbol group.

[0130] The system may comprise a control region with one or more beamformed control channel(s). One or more symbols within a subframe where the control channel is transmitted may be referred to as cell specific control region and/or an overall control region. Within a subframe, the cell specific control region may comprise multiple control channel beams multiplexed in time. One or more symbols within a subframe where the control channel for a specific beam is transmitted may be referred to as beam specific control region. The term control region may mean cell specific control region and/or beam specific control region. Control region size may be fixed and/or be flexible. Control region and data region may overlap. One or more symbols may carry control and/or data channel. Control and/or data channel may be multiplexed in frequency and/or code and/or spatial domain.

[0131] The one or more search spaces may be configured to be used to monitor one or more Downlink (DL) control channels. The one or more search spaces may be configured to be used to receive the one or more DL control channels. At least one search space of the one or more search spaces may correspond to at least one reference signal of one or more reference signals. At least a part of a control region may be monitored for at least one reference signal of the one or more reference signals. At least one reference signal in the at least part of the control region may be detected. At least one search space corresponding to the at least one reference signal may be monitored for at least one DL control channel, perhaps for example upon the detection of the at least one reference signal.

[0132] The system may comprise gaps and/or switching periods. Gaps and/or guard periods and/or silence periods and/or switching periods and/or absence of transmission and/or DTX periods may be placed between two consecutive symbols. The two consecutive symbols may carry transmissions with different beam direction and/or radiation pattern and/or steering vector. Different gap types may be identified. One or more of the following examples may be identified, depending on the placement: gaps between two control symbols and/or group of control symbols, gaps between two data symbols and/or group of data symbols, and/or gaps between control symbols and data symbols (e.g. between the last control symbol and first data symbol and/or between the first control symbol and last data symbol), and/or the like.

[0133] Different gap types may be preconfigured with a different duration. Same gap type may be preconfigured with a different duration in different subframes. Gaps may be selectively placed between two consecutive symbols. The two consecutive symbols may be transmitted with a different radiation pattern. The two consecutive symbols may be transmitted with a different beam pattern. The two consecutive symbols may be transmitted with a different direction. The two consecutive symbols may be transmitted with a different channel type. Gaps

may be selectively placed between control and data symbols. Gaps within the same subframe may have different duration. Gaps may or might not be present in some or all of the subframes. Gaps may be placed between control symbols and may or might not be placed in the data symbols. Gaps may be placed between data symbols and may or might not be placed in the control symbols. Within the control and/or data region, gaps may be selectively placed between a subset of symbols.

[0134] The gaps may be defined from a WTRU point of view. A WTRU may or might not be required to receive on the DL during the gap periods (e.g., the gap between control symbols and data symbols for a WTRU). A WTRU may utilize the gap periods to decode the control channel, e.g., control channels received before the start of gap period. A WTRU may utilize the gap periods to switch its receive beam. A WTRU may utilize the gap periods to apply new steering vector to receive the downlink data channel. The downlink data channel may be different from the receive beam and/or steering vector used to receive the downlink control channel. A WTRU may utilize the gap periods (e.g. the gap between data symbols and/or group of data symbols for a WTRU) to switch its receive beam. A WTRU may utilize the gap periods (e.g. the gap between data symbols and/or group of data symbols for a WTRU) to apply new steering vector to receive the downlink data channel, which may be different from the receive beam and/or steering vector used to receive the previous downlink data channel in a subframe (e.g., same or different).

[0135] An mmW control channel may be designed, e.g., to facilitate control channel beam mapping to physical source. One or more control channels in a cell may be beamformed. One or more control channels in a cell may be placed in different control symbol and/or groups of control symbols in a subframe.

[0136] For example, an mB may utilize sweep operation to go through all or some of the control beams. An mB may transmit control channel beams in a subframe, e.g., one or more, or all, the control channel beams in every subframe. An mB may receive control channels in a subframe. For example, entire cell coverage may receive control channels in every subframe. An mB may utilize sweep operation, for example, starting from one control beam and going through some (e.g., one or more, or all) of the control beams in the cell in certain order. The sweep operation may go through selected (e.g., only specific) symbols in a subframe (e.g. only in the control region). The mB may utilize multiple subframes to transmit all or some of the control channel beams. For example, a subframe may comprise a partial sweep of control channel beams. One or more subframes may be used for a complete sweep of control channel beams to cover the entire cell. The mB may follow a certain order for the sweep operation. For example, it

may transmit control channel beams in a sequence based on control channel number and/or BRS sequence number. The mB may follow a random order for the sweep. The random order may be generated from a hashing function. The hashing function may use control channel number and/or subframe number etc.

[0137] The mapping between control channel beam(s) and/or control symbol(s) may be pre-defined and/or signaled via one or more of the following: broadcast channel(s) (e.g., MIB, SIB-x), higher layer signaling (e.g. RRC/MAC), L1 signal/channels, and/or any other common channel, and/or the like. The mapping between control channel beam(s) and control symbol group(s) may be pre-defined and signaled via one or more of the following: broadcast channel(s) (e.g., MIB, SIB-x), higher layer signaling (e.g. RRC/MAC), L1 signal/channels, any other common channel, and the like. WTRUs may determine the control channel beam to control symbol mapping by blind decoding. For example, WTRUs may search for pre-defined BRS sequence in the control region, and WTRUs may determine the control channel beam to symbol mapping, e.g., based on the received BRS signal quality (e.g. RSRP, SNR etc.).

[0138] An mB may select a subset of beams. The mB may transmit a subset of control channel beams in a subframe. The subset may be determined by one or more of the following criterias: distribution of WTRUs in a cell and/or beam, activity level of WTRUs in the cell and/or beam (e.g., buffer status of WTRUs, traffic pattern for WTRUs), WTRU grouping, WTRU service requirements, number of control channels with or without beamforming, scheduling algorithm, intra and inter cell interference, and/or type of control channel (e.g. common control and/or WTRU specific control), and the like. The mB may transmit a (e.g., only one) control channel beam in a subframe. The data region in the subframe may comprise transmissions using the same control channel beam and/or any other data channel beam related to the control channel beam, e.g, narrow data channel beam related to the control channel beam.

[0139] The mapping between a control channel beam and a symbol and/or a symbol group associated with a subframe (e.g., within a subframe and/or across subframes) may be fixed and/or flexible. The following may be applicable irrespective of control channel beam selection mode (e.g. subset transmission and/or full sweep transmission).

[0140] The mapping between a control channel beam and a symbol and/or a symbol group associated with a subframe, e.g., within a subframe and/or across subframes, may be fixed. In a fixed mapping, a control channel beam, e.g, every control channel beam, may be placed and/or transmitted in a pre-defined symbol and/or symbol group within a subframe. The mapping between the control channel beam and the symbol number may be same in certain (e.g., one or more, or all) subframes. For example, control channel beam 1 may be transmitted during symbol

number 1 in a (e.g., every) subframe. Symbol hopping may be used for control channel beams according to a pre-defined hashing function. For example, a function may use control channel number, cell ID, BRS sequence ID, subframe number, symbol number etc. WTRUs may determine the mapping between the control channel beam and the symbol/symbol group, e.g., implicitly based on the PBCH beam mapping. WTRUs may determine the mapping between control channel beam and the symbol/symbol group based on explicit configuration using one or more of the following: broadcast channel(s) (e.g., MIB, SIB-x), higher layer signaling (e.g. RRC/MAC), L1 signal/channels, and the like. WTRUs may determine the mapping between control channel beam and the symbol/symbol group based on a pre-defined function of cell-ID and/or beam-ID. Many to one mapping between control channel beams and control symbol/symbol group may be defined.

[0141] With a fixed mapping structure, control channel beams with no active WTRUs may have blank and/or empty control symbols. The blank and/or empty control symbols may be reclaimed and/or reused to map data channel beams, e.g., to improve resource utilization. The data channel beams may be scheduled by control channel beams occurring before the original blank and/or empty symbol. The data channel beams may be scheduled by control channel beams occurring after the original blank and/or empty symbol. WTRUs may buffer the complete subframe before the control channel decoding is complete. PDSCH may be mapped to the unused (e.g., empty and/or blank) control symbols. The unused control symbols may precede the associated PDCCH.

[0142] The mapping between a control channel beam and a symbol and/or a symbol group associated with a subframe, e.g., within a subframe and/or across subframes, may be flexible. In a flexible mapping, a control channel beam may be placed and/or transmitted in a (e.g., any) symbol and/or symbol group in a subframe. Multiple control channel beams in a subframe may be transmitted using different symbols, e.g., time multiplexed. The mapping between control channel beams and the symbol/symbol group may vary for different subframe. An mB may selectively transmit a subset of control channel beams in a subframe. The number of control channel beams transmitted may vary for different subframes. The number of control symbols occupied by a control channel beam may vary for different subframes. The number of control symbols occupied by different control channel beams in a subframe may vary.

[0143] The mapping between a control channel beam and a symbol and/or a symbol group associated with a subframe, e.g., within a subframe and/or across subframes, in a frame structure may be a hybrid of fixed and flexible mapping. The mB may use a fixed mapping for some beam types (e.g., common control beams and/or Omni beams, and/or WTRU specific

control beams). The mB may use a flexible mapping for other beam types (e.g., WTRU specific control beams, and/or common control beams and/or Omni beams). The mB may use a fixed mapping for some subframes and a flexible mapping for other subframes. The mapping format for different subframes may be explicitly signaled using one or more of the following: broadcast channel(s) (e.g., MIB, SIB-x), higher layer signaling (e.g., RRC/MAC), and/or L1 signal/channels, and the like. The mapping format for different subframes may be implicitly known by the presence of certain channels. For example, subframes with PBCH may use fixed mapping. A flexible mapping may be the default mode, and a fixed mapping may be applied in some (e.g., specific) subframes at a pre-defined periodicity.

[0144] For example, a fixed mapping between control channel beam RS and/or the control symbols may assist WTRU measurement at specific subframes. An mB may use a fixed mapping for a subset of beams for WTRUs in idle mode and a flexible mapping for WTRUs in connected mode. An mB may use a fixed mapping for WTRUs in connected mode and a subset of beams for WTRUs in idle mode. An mB may use a fixed mapping when the cell is lightly loaded (e.g. when the number of active WTRUs are small) switch to a flexible mapping when the cell is highly loaded. WTRUs may determine the mapping format for control channel beams from the configuration received in one or more of the following: broadcast channel(s) (e.g., MIB, SIB-x), higher layer signaling (e.g. RRC/MAC), L1 signal/channels, any other common channel, and/or the like. One or more WTRUs may determine the change/switch in control channel beam mapping from configuration received in one or more of the following: broadcast channel(s) (e.g., MIB, SIB-x), higher layer signaling (e.g. RRC/MAC), and/or L1 signal/channels, any other common channel, and/or the like.

[0145] An mmW control channel beam may have various control channel beams. The mmW control channel beam may carry plurality of control channels addressed to one or more WTRUs. The control channel beam may carry one of more of the following: the Downlink Control Information (DCI) [e.g., the DCI may include scheduling grant (UL and DL)], UL control channel assignment, beam switch command, power control commands and/or any other control information, higher layer messages (MAC, RRC), small payload (e.g. broadcast messages like SIB/Paging), cell and/or beam specific reference signals for demodulation, measurement for one or more WTRUs, and/or the like. The minimum time domain resource occupied by the control channel beam may be one symbol. The maximum time domain resource occupied by the control channel beam may be pre-configured (e.g., in MIB/SIB-x) and/or dynamically signaled using beam specific PCFICH. The dwell time of the control channel beam may be pre-configured (e.g. in MIB/SIB-x) and/or dynamically signaled using beam specific

PCFICH. The time domain resources (e.g. number of symbols) occupied by common control channel beam may be fixed (e.g., in MIB/SIB-x). The WTRU specific control channel beam may be dynamic (e.g., beam specific PCFICH).

[0146] The mmW control beam may carry one or more PDCCHs. The PDCCHs may be addressed for/to one or more WTRUs. A PDCCH may be transmitted on an aggregation of one or several CCEs (Control Channel Elements), e.g., where a control channel element may correspond to two or more REGs (Resource Element Groups). Different PDCCH formats may be defined, e.g., based on aggregation levels of CCEs. PDCCH may be transmitted, e.g., using a hierarchy of different groups of resource elements. The allocation of number of basic resource units for a level of resource group may be associated with PDCCH link adaptation scheme and/or other considerations. One or more characteristics/property of REs may be a function of beam ID and/or beam type. One or more characteristics/property of CCEs may be a function of beam ID and/or beam type.

[0147] Common control channel beams and/or WTRU specific control channel beams may use different PDCCH formats and/or aggregation levels. There may be a fixed aggregation level on the WTRU specific control channel beam. The number of REGs per CCE may vary for different beam type. For example, common control channel beam may have higher number of REGs per CCE. The resource block structure and/or subcarrier spacing may vary for different beam types. For example, symbols carrying common control channel beams and/or symbols carrying WTRU specific control beams may use different subcarrier spacings. Common control channel beams may be scrambled by a cell specific (e.g. cell ID) and/or beam specific (e.g. beam ID) identity. WTRU specific control channel beams may be scrambled by one or more of the following: a cell specific (e.g. cell ID), a beam specific (e.g. beam ID), a WTRU specific identity (e.g. C-RNTI), and/or the like. One or more modulation schemes and/or coding rates used for the control channel beam may be specific to beam type. For example, common control channel may use a fixed and/or preconfigured modulation scheme and/or coding rate. The WTRU specific control channel beam may use a dynamic MCS adaptation. The dynamic MCS adaptation may be signaled using beam PCFICH. Beam types may be WTRU specific. For example, a WTRU may use a common control channel beam. A WTRU may use a WTRU specific control channel beam. A WTRU may use a beam carrying common control channel scheduling and/or WTRU specific scheduling information. The part of the subframe where common control channel beams are transmitted may be referred as common control region. The part of the subframe where WTRU specific control channel beams are transmitted may be referred as dedicated control region.

[0148] The following examples are subframe configurations showing control channel beam placement and/or resource structure. The example figures for different control channel placement shown are not exhaustive and/or other control channel placements may be used. The figures are not meant to be exhaustive, e.g., all channels are not captured in the figure. For purposes of clarity and/or explanation, examples may be described in term of DL subframes and/or (e.g., only DL subframes are shown) UL subframes may be ignored. One or more techniques described in terms of DL operation may be equally applicable to uplink operation. The wide transmit beams at the mB may be referred here as B1, B2, B3, B4 etc. The narrow transmit beams may be referred to as B11, B12 (e.g., within B1), B21, B22 (e.g., within B2) etc.

[0149] In FIG. 12, the mB may transmit one or more wide beam control channels per subframe. For example, subframe 1 may carry the control channel beams B1 and/or B2, subframe 2 may control channel beams B3, etc. A (e.g., one or more, or each) control channel beam may carry DCI for one or more WTRUs. A (e.g., one or more, or each) control channel beam within a subframe may carry some unique content. For example, a DCI for a WTRU (e.g., a particular DCI for a WTRU) may be carried in a (e.g., only one) control channel beam. A control channel beam within the subframe may carry the same DCI content. The number of control channel beams per TTI may vary. For example, it may range from one control channel beam per TTI to the maximum available number of control channel beams in the cell. Length/duration of a (e.g., one or more, or each) control channel beam may vary (e.g. from one to more symbols). The data region within a subframe may carry PDSCH for one or more WTRUs, e.g., the PDSCH transmission for different WTRUs may be multiplexed in time, frequency, and/or spatial domain. For example, multiple PDSCH beams may be transmitted within the data region. The beam width of a data beam may be adjusted based on one or more of the following: WTRU location, throughput requirements, and/or interference consideration, and/or the like. The mapping between the control channel beam and the symbol number within the control region may be flexible. WTRUs may receive assistance information about the control channel configuration, e.g., from PBCH and/or from Omni PCFICH channel.

[0150] In FIG. 13, mB may transmit one (e.g., exactly one) wide beam control channel per subframe. For example subframe 1 may carry the control channel beam B1 and/or B2, subframe 2 may carry control channel beams B3 etc. WTRUs may be configured to monitor certain (e.g., only certain) subframes for a possible occurrence of the pre-selected control channel beam.

[0151] In FIG.14, mB may sweep some or all the control channel beams in a subframe. For example a (e.g., one or more, or each) subframe may carry the control channel beam B1, B2,

B3, and/or B4. A (e.g., one or more, or each) control channel beam may carry DCI for one or more WTRUs. WTRUs with lower SNR may have their DCIs repeated in certain (e.g., all) control channel beams. WTRUs with higher SNR may have their DCIs transmitted in a subset of control channel beams. The mapping between the control channel beam and the control symbol may be fixed. BRS for a control channel beam (e.g., rather than and/or in addition to control channels) may be swept.

[0152] In FIG. 15, the control channel beam may be predefined to symbol mapping, e.g., to reduce the blind decoding attempts for the WTRUs. The WTRUs may attempt to decode the symbols (e.g., only the symbols) carrying pre-selected control channel beams. mB may map/place/transmit data channel beams in some control channel symbols, e.g., control channel symbols that may or might not be occupied by control channel beams. The WTRUs may start to buffer the symbols, e.g., for a possible data channel until it decodes the pre-selected control channel beam at the appropriate control symbol.

[0153] In FIG. 16, many to one mapping may be utilized for control channel beam to control symbol mapping to reduce control overhead, e.g., when the number of control channel beams are high in a cell. In FIG. 16, B1 and/or B5 may be mapped to symbol 1. B1 and/or B5 may be transmitted in control symbol 1, e.g., when the assumption is that one RF chain may be for the mB. WTRUs having B1 control channel beam may be used (e.g., required) to decode control symbol 1. A hashing function may be used, e.g., to reduce blocking probability for control channel beams. The hashing function may avoid mapping the same set of control channel beams to the same control symbol. The hashing may be a function of one or more of the following: subframe number, system frame number, control channel beam ID, cell ID, the control symbol number, and/or the like.

[0154] FIG. 17 is an example of a logical architecture for control channel beam generation. FIG. 17 illustrates an example of the relation between the different mapping/selection functions.

[0155] A mmW PDCCH may use heterogeneous beam types. For WTRU specific control channel, wide beams may be configured and/or assigned for a group of users and/or one or more, or all, the users' control channels, e.g., PDCCHs that may carry user specific DL control information (DCI). One or more narrow beams may be configured and/or assigned for individual WTRU for WTRU-specific control channels. One or more beams may be configured, e.g., such that wide beam(s) may be used to cover a cluster of WTRUs and/or narrow beam(s) may be used for individual WTRUs. Table 2 is an example of some assignments and/or configurations for heterogeneous beam types. For common control channel, wide beam may be

used for individual WTRU and/or a WTRU group. Narrow beam may be used for individual WTRU (e.g., individual WTRU only). Narrow beam may be used as WTRU-specific beam for common control, e.g., depending on the beam configurations. Wide beams (e.g., only wide beams) may be used for a group of WTRUs for common control. For WTRU-specific control channel, narrow beam may be used as WTRU-specific beam for WTRU-specific control. Wide beam (e.g., only wide beams) may be used for a group of WTRUs for WTRU-specific control.

Table 2. Examples for Assignments and/or Configurations for Heterogeneous Beam Types

		Wide beam	Narrow beam
Common Control	Individual WTRU	May use wide beam for easy tracking of WTRUs, etc. WTRU-specific wide beam for common control.	May use narrow beam for high beamforming gain. WTRU-specific narrow beam for common control.
	WTRU group	May use wide beam for WTRU group	May or might not use narrow beam
WTRU-specific Control	Individual WTRU	May use wide beam for easy tracking of WTRUs, etc. WTRU-specific wide beam for WTRU-specific control.	May or might not use narrow beam for high beamforming gain. WTRU-specific narrow beam for WTRU-specific control.
	WTRU group	May use wide beam for WTRU group	May or might not use narrow beam

[0156] A wide beam may be configured and/or used as a WTRU-specific beam for control channels, e.g., to enable easy tracking of WTRUs. The control channels may be common control channels. The control channels may be WTRU-specific control channels, e.g., common DCI carried by PDCCH, and/or ePDCCH, and/or the like. This may enable easy tracking of WTRUs. This may sometimes lower beamforming gain. Easy tracking of WTRUs may be useful. Easy tracking of WTRUs may be useful where beamforming gain may be less of a concern. Beamforming gain may be less of a concern when WTRUs are near the eNB and/or AP. Narrow beam(s) may be configured and/or used (e.g., only used) as WTRU-specific beam(s) for control channels, e.g., to enable high beamforming gain. High beamperforming gain may be useful, e.g., when WTRUs are far away from eNB and/or AP. High beamperforming gain may be useful, e.g., when WTRUs are around the cell edge. The control channels may be common and/or WTRU-

specific control channels. The WTRU-specific control channels may be WTRU-specific DCI carried by PDCCH, and/or ePDCCH, and/or the like.

[0157] Beams with different beam widths may be used to cover different WTRU densities (e.g., the number of WTRUs in a given direction/area relative to the mB). The pairing for which beam with certain width to cover which WTRU density may depend on the density distribution of WTRUs in geography. For example, for high density area, beams with narrower beam width may be configured and/or used. For low density area, beams with medium and/or larger beamwidth may be configured and/or used.

[0158] Beams may be allocated to WTRUs, e.g., such that WTRU density per beam (e.g., number of WTRUs in a beam) may be uniform and/or constant. This may facilitate the use of digital beamforming within analog beam, e.g., to support a given number of active WTRUs. The number of analog beams may be reduced. The control overhead may be mitigated, e.g., when multiple control channels may be sent simultaneously in the same beam and/or frequency resource. Trade-off may occur between the number of OFDM symbols (e.g., for beam sweeping) for control and/or the number of OFDM symbols for data. Different compromises between overhead and throughput may be considered based on the specific deployment scenario.

[0159] Heterogeneous beam types with different beam widths may be configured and/or used, e.g., to improve network operation flexibility and/or to reduce the control overhead.

[0160] Heterogeneous beam types may support one or more of the following: heterogeneous beam types with different beam widths for common and/or WTRU specific channel, heterogeneous beam types with different beam widths for the same WTRU at different time instance, heterogeneous beam types with different beam widths for different WTRUs, and/or heterogeneous beam types with different beam widths for group of WTRUs depending on WTRU's locations, and/or the like. The heterogeneous beam types with different beam widths may be configured and/or used for common control and/or WTRU-specific control channel. Heterogeneous beam types with different beam widths may be configured and/or used for the same WTRUs at different time instance. Heterogeneous beam types with different beam widths may be configured and/or used for different WTRUs at the same and/or different time instances. Heterogeneous beam types with different beam widths may be configured and/or used for a group of WTRUs, e.g., a group of WTRUs with various WTRU's locations. The control overhead, e.g, the number of OFDM symbols for control with respect to the number of OFDM symbols for data and/or the number of beams needed for beam sweeping with respect to number of OFDM symbols for data, may be reduced.

[0161] One or more of the following beam configurations may be considered, e.g., when one RF chain and/or a (e.g., one) beam are formed at a (e.g., any) given time.

[0162] A beam sweeping may use homogeneous beam type (e.g., homogeneous wide beam). A (e.g., one or more, or each) beam may have the same beam width covering 360/N degrees where N is the number of OFDM symbols for control channel. For example, one or more, or each, beam will cover 120 degrees at a time for N=3. A beam sweeping cycle may cover 360 degrees. Homogeneous beam type may be for uniform angular distribution of WTRUs. Homogeneous beam type may become less efficient, e.g, for non-uniform angular distribution of WTRUs,

[0163] Heterogeneous beam type may be efficient, e.g., for non-uniform angular distribution of WTRUs. A beam sweeping may use heterogeneous beam type (e.g., heterogeneous wide beam). One or more, or each beam may have different beam width but still covering 360/N degrees where N is the number of OFDM symbols for control channel. One or more, or each beam may cover more or less than 120 degrees at a time and/or full beam sweeping cycle will cover 360 degrees. For example, for N=3 beams may have beam widths 60, 120 and/or 180 degrees. An eNB may keep the number of WTRUs per beam uniform and/or constant when it transmits control channel to a (e.g., one or more, or each) WTRU. Uniform search space for control channel may be maintained. Search space may avoid being over-utilized for some beams and/or under-utilized for other beams.

[0164] The number of WTRUs per beam may be kept constant and/or near constant, e.g., when two or more RF chains are utilized for hybrid beamforming. Within a beam (e.g., one or more, or each beam) the number of ranks for spatial multiplexing may be limited. Keeping number of WTRUs under such rank per beam may be performed to enable spatial multiplexing for future evolution.

[0165] Beam sweeping may use narrow beams. A beam may have narrow beam width but cover WTRUs within N OFDM symbols for control channel. For example, one or more, or each beam may have narrow beam width but cover one or more, or all WTRUs within N OFDM symbols for control channel. One or more, or each beam may cover a WTRU at a time and/or a full beam sweeping cycle may cover N WTRUs. For K WTRUs, if N>=K, one beam sweeping cycle may deliver control channel to K WTRUs within a TTI. If N<K, one beam sweeping cycle may or might not deliver one or more, or all control channels to one or more, or all K WTRUs within a TTI. Another TTI and/or TTIs may be used (e.g., required) to deliver control channel to remaining K-N WTRUs. How many TTIs may be used (e.g., required) for beam sweeping may depend on N and/or K. K/N beam sweeping cycles and/or TTIs may be required to deliver one

or more, or all control channel to all K WTRUs. This example may work for N>=K. This example may become less efficient when N<K. Overhead may increase, e.g., when the number of OFDM symbols for control increases. The number of WTRUs that may be supported may be limited, e.g., when the number of users and/or K decreases. Beam sweeping may be performed across multiple TTI, introducing latency (e.g., additional latency).

[0166] Beam sweeping may use heterogeneous beam type (e.g., heterogeneous wide/narrow beams). A beam may have a wide and/or narrow beam width but cover WTRUs within N OFDM symbols for control channel. For example, one or more, or each beam may have one or more, or each wide and/or narrow beam width but cover one or more, or all WTRUs within N OFDM symbols for control channel. One or more, or each beam may cover one or more WTRUs at a time and/or full beam sweeping cycle will cover N WTRUs. For K WTRUs, if N>=K, one beam sweeping cycle may deliver control channel to K WTRUs within a TTI. If N<K, one beam sweeping cycle may deliver one or more, or all control channels to one or more, or all K WTRUs within a TTI. For example, N-1 narrow beams may deliver control to N-1 WTRUs, and/or the last beam (wide beam) may deliver control to the remaining K-N+1 WTRUs. Another TTI and/or TTIs may or might not be used (e.g., required) to deliver control channel to remaining K-N WTRUs. How many narrow beams and/or wide beams may be used (e.g., required) may depend on design considerations and/or N and/or K. Using heterogeneous beam type may lower control overhead, lower latency, and/or increase the number of WTRUs that may be supported.

[0167] Heterogeneous beams may be considered. Heterogeneous beams may be s plularity of beams associated with one or more different characteristics and/or properties, e.g., beam width, transmit power, number of lobes, and/or number of active antenna elements, and/or the like. Beams with different beam widths and/or narrow beam may be used for the same cell and/or eNB. A narrow beam carrying control information and/or PDCCH may be used for individual WTRUs. Wide beams may be used for a group of control channels and/or PDCCHs. Heterogeneous beam types, e.g., wide and/or narrow beams, may be used. Heterogeneous beam widths for wide beam may be used. Different beam types and/or beam widths may be used, e.g., when beam sweeping is needed. For example, for three beams, beams 1, 2 and/or 3 may have beam width x, y and/or z respectively. For uniform settings beams 1, 2 and/or 3 may have beamwidth, x=y=z. For non-uniform settings x, y and/or z may or might not equal to each other. Depending on the settings of x, y and/or z, wide beam with different beam widths and/or narrow beam may be configured and/or formed.

[0168] To support beamforming reference signal (BRS), antenna ports may be designed to transmit BRS. Beam-specific antenna ports may be designed and/or allocated. Antenna port may be designed for beams that may be used for sending either common control and/or WTRU-specific control information. An antenna port may be associated with a reference signal called BRS. A BRS may be used to demodulate control channels. Antenna ports may be orthogonal to each other in time, frequency, code and/or any combination of them, e.g., to avoid mutual interferences among BRS. A design may use even/odd pattern for BRS. Even and/or odd BRS may be allocated in different frequency and/or time grid(s). Even BRS (E-BRS) may be placed in the same frequency and/or time grid(s). Odd BRS (O-BRS) may be placed in the same frequency and/or time grid(s). E-BRS and/or O-BRS may be allocated in different resources, e.g, resources that are orthogonal to each other. For control channel, control beam RS (CBRS) may be used. Even CBRS (E-CBRS) may be placed in the same frequency and/or time grid(s). Odd CBRS (O-CBRS) may be placed in the same frequency and/or time grid(s). E-CBRS and/or O-CBRS may be allocated in different resources, e.g., resources that are orthogonal to each other. For data channel, data BRS may be used.

[0169] In even beam, EAP may send E-CBRS for control channel. In odd beam OAP may send O-CBRS for control. EAP and/or OAP may be in orthogonal resources. E-CBRS and/or O-CBRS may be in orthogonal resources. Mutual interference between EAP and/or OAP or between E-CBRS and/or O-CBRS may be avoided.

[0170] One or more (e.g., only one) BRS (e.g., rather than and/or in addition to two BRS (E-CBRS, O-CBRS)) may be used. A (e.g., perfect) spatial separation may be achieved, e.g., to make one BRS more efficient than other designs. A BRS in even beam and/or E-CBRS may be active for control channel. BRS in odd beam and/or O-CBRS may or might not be active for control channel. BRS in odd beam and/or O-CBRS may be reused for data. O-CBRS may be active for control and/or E-CBRS may or might not be active for control. E-CBRS may be reused for data. CBRS in even and/or odd beam may or might not be reused for data, e.g, when perfect spatial separation may or might not be achieved. Side lobes of beams may be related to spatial separation. For example, side lobes of beams may prevent perfect spatial separation. Antenna patterns may be considered when designing antenna ports for BRS and/or CBRS. Side lobes may be considered when designing antenna ports for BRS and/or CBRS. Antenna ports and/or BRS design for data beam may be similar.

[0171] Spatial separation and/or resource reuse factor may be related to the efficiency of the channel design. For example, E-CBRS and/or O-CBRS may avoid mutual interferences between them, when resource reuse factor of two is considered. Resource reuse factor of two

may be considered efficient. Resource reuse factor Q=1 may be considered, e.g., when perfect spatial separation is achievable. Reuse factor Q may be set to two or higher, e.g. when perfect spatial separation may or might not be achieved. Reuse factor may be set to one, e.g., for sequential beam sweeping for control channel. Resource reuse factor may be set to two or higher, e.g., for parallel beam sweeping and/or transmission. Parallel beam sweeping and/or transmission may occur, e.g., when two or more beams transmitted in parallel simultaneously sweep through K WTRUs via N OFDM symbols for control. During parallel beam transmission, potential mutual interferences between beams may occur, e.g., when spatial separation is not perfect. Resource reuse factor may be set to two or higher.

[0172] For multi-layer beamforming, e.g., when wide beam and/or narrow beam may coexist, some offset in frequency/time grids may be applied to enable orthogonality between BRS for wide and/or narrow beams. Narrow beam may serve one WTRU among a WTRU group while a wide beam may serve the remaining WTRUs in the WTRU group, e.g., when they may (e.g., must) be served simultaneously, two (e.g., only two) beams are available, and/or the two beams may comprise a wide beam and/or a narrow beam. The narrow beam and/or wide beam may overlap. Narrow beam and/or wide beam may use FDM to enable coexistence, e.g., when spatial separation between them does not occur. BRS using FDM may be applied for narrow beam and/or wide beam.

[0173] One or more techniques associated with BRS may be applied to data BRS and/or control BRS. Control channel may be decoded. For example, channel estimation may be performed via CBRS to decode control channel.

[0174] Energy detection may be used for channel estimation and/or control channel demodulation, e.g., in even beam. For example, in even beam, E-CBRS may be on and/or O-CBRS may be off. No beam index may be decoded beforehand. Eenergy detection may be used to decide which antenna port to be used for channel estimation to decode control channel.

[0175] Channel estimation may be performed to decode data channel, e.g, when even/odd BRS is used. Beam index may already be decoded in control channel. Even/odd beam index may be obtained by one or more of the following. In even beam, even DBRS may be on, odd DBRS may be off, e.g., to avoid mutual interference between BRS at beam edge. Energy detection may be used to decide which antenna port may be used for channel estimation. It is similar for odd beam. In even beam, even DBRS may be on, odd DBRS may be on but may be used for data, redundant data may be for control and/or carry some short control message. Mutual interference between RS and/or data/else at beam edge may occur. It is similar for odd beam.

[0176] The WTRU may or might not be dependent on blind energy detection. The WTRU may decide between even/odd DBRS, perhaps for example even if a WTRU may or might not detect correct energy level. There may be an assumption that data demodulation may be performed after control channel decoding. One or more beam index may be (e.g., already) obtained in the control channel decoding.

[0177] A (e.g., one or more, or each) cell may have plurality of PDCCH regions, e.g. one for one or more, or each wide beam. A (e.g., one or more, or each) PDCCH may carry beam specific BRS sequence. The BRS REs mapping in the control channel symbols may be a function of PCI. The BRS REs mapping in the control channel symbols may be a function of beam index. The sequence carried in the BRS may be provided by the linked PBCH.

[0178] WTRUs may monitor PDCCH. WTRUs may detect BRS associated with the serving beam at control symbol location. The control symbol location may be fixed. WTRUs may perform BRS detection operation in certain (e.g., one or more, or all) control symbols defined by cell PCFICH, e.g., when the control symbol locations are not fixed and/or variable. WTRUs may perform BRS detection operation in the control symbols (e.g., only the control symbols) defined by beam-specific PCFICH. e.g., perhaps when the control symbol locations might not be fixed and/or variable. WTRUs may compare the measured BRSRP with an implementation dependent threshold. WTRUs may perform PDCCH decoding, e.g., when BRSRP is greater than the threshold. WTRUs may assume no DL/UL grant received in the current TTI, e.g., perhaps unless a semi-static grant is configured.

[0179] Subframe structure and/or placement for PDCCH BRS may be designed. For sequential beam sweeping, FIG. 18 may be an example subframe structure and/or placement for control BRS. The resources may be indicated in the FIG. 18. Example subframe in FIG. 18 shows three control symbols followed by some data symbols. Beams may be swept through three control symbols sequentially by the order of beams 1, 2 and/or 3 (e.g., B1, B2 and/or B3).

[0180] FIG. 19 may be an example resource allocation in two dimension of frequency and/or time. BRS may be used in a (e.g., one or more, or each) control symbol and/or may be placed uniformly (and/or non-uniformly) across frequency. FIG. 19 shows that BRS may have the same location in frequency across one or more, or all control symbols. Other allocations may be used, e.g., BRS may be in different locations in frequency across different control symbols. BRS may be in staggered patterns and/or designs.

[0181] FIG. 20 may be an example control BRS subframe structure and/or placement for parallel beam sweeping. The resources are also indicated in the block diagram. Example subframe in FIG. 20 shows three control symbols followed by some data symbols. One or more

beams may be swept through three control symbols sequentially by the order of beams 1&2, 3&4 and/or 5&6 (e.g., B1/B2, B3/B4 and/or B5/B6). Parallel beams may be used in a control symbol. Two parallel beams may be used simultaneously in a control symbol. For example, total six beams may be be swept through three control symbols. The number of users to be covered by the control channel may increase by using parallel beam transmission and/or sweeping. The capacity of system may increase.

[0182] FIG. 21 may be an example resource allocation in two dimension of frequency and/or time. BRS may be used in a control symbol and/or may be placed uniformly (and/or non-uniformly) across frequency. BRS may also be placed contiguously and/or non-contiguously. For example, O-BRS and/or E-BRS may be placed contiguously within a pair of O-BRS/E-BRS. Pairs of O-BRS/E-BRS may be placed uniformly and/or non-uniformly across frequency. O-BRS and/or E-BRS may be placed non-contiguously within a pair of O-BRS/E-BRS. Pairs of O-BRS/E-BRS may be placed uniformly and/or non-uniformly across frequency. Example may show that O-BRS/E-BRS pairs have the same location in frequency across one or more, or all control symbols. Other allocations may also be used, e.g. when BRS may be in different locations in frequency across different control symbols. A BRS may be in staggered patterns and/or designs.

[0183] Designs of mmW PCFICH may comprise, e.g., cell specific control region and/or beam specific control region. In a subframe, one or more beamformed control channel(s) may be transmitted during one or more control symbol(s) time multiplexed within a control region. The overall control region size/length/duration may be a function of one or more of the following: the number of control channel beams selected for transmission, the number of control symbols occupied by a (e.g., one or more, or each) control channel beam, a pre-defined max size/length/duration of beam specific control region, and/or a pre-defined max size/length/duration of cell specific control region, and/or the like.

[0184] The number of control channel beams and/or maximum number of control channel beams in a subframe may be fixed. The number of control channel beams may be less than or equal to the total number of control channel beams in the cell coverage. The number of control symbols may be a function of the number of control channel beams and/or the number of symbols per control channel beam. The number of control symbols and/or the maximum number of control symbols in a subframe may be fixed. The partial sweep function and/or a control channel beam subset selection function may select control channel beams based on one or more of the following: the number of control symbols in a subframe, and/or the number of control symbols per control channel beam, and the like. The ratio of control symbols to data symbols

may be configured to be less than or equal to a pre-defined value (e.g. control overhead percentage). The number of control symbols per control channel beam may be a function of number of WTRUs within the control channel beam and/or type of the control channel beam (e.g. common control beam and/or WTRU specific control beam).

[0185] At least a part of the control region may be one part of a number of parts of the control region. The number of parts of the control region may be a function of a number of symbols configured for the control region. The number of parts of the control region may be a function of a number of symbols used for the control region.

[0186] Cell specific control region configuration may be indicated. WTRUs may receive indication and/or configuration of cell specific control region from broadcast channel(s) (e.g., MIB, SIB-x) and/or any other common channel. The configuration may be WTRU specific. The configuration may be signaled using dedicated signaling (e.g. MAC and/or RRC message). A physical channel/signal (e.g., cell PCFICH) may be defined. A physical channel/signal may carry the configuration, e.g., for cell specific control region. A new physical channel/signal may be placed in one or more pre-defined symbol(s) in a subframe. Cell PCFICH may be transmitted with an Omni-beam and/or wide beam. Cell PCFICH may be transmitted with a narrow beam. Cell PCFICH may comprise two or more repetitions in wide beams. Cell PCFICH may comprise two or more repetitions in narrow beams. WTRUs may accumulate the energy from cell PCFICH repetitions to increase SNR. Cell PCFICH may be repeated in different directions, e.g., when transmitted using wide and/or narrow beam to provide coverage. Cell PCFICH may be repeated in different beam widths, e.g., when transmitted using wide and/or narrow beam to provide coverage. The beam used for cell PCFICH may be same as the beam used for one or more of synchronization channels (PSS and/or SSS and/or any other signal). The beam used for cell PCFICH may be the same as the beam used for PBCH. One or more WTRUs may determine the location of the cell PCFICH symbol by applying a pre-defined offset from symbol carrying PSS in the same beam.

[0187] At least one DL control channel may be communicated via one or more Orthogonal Frequency Division Multiplexing (OFDM) symbols. The one or more OFDM symbols on which the at least one DL control channel may be communicated may be located in the control region. A WTRU may obtain a number of the one or more OFDM symbols in the control region via a Physical Control Format Indicator Channel (PCFICH). In some scenarios the PCFICH may be obtained via a beam of a synchronization channel and/or via a beam of a Physical Broadcast Channel (PBCH).

[0188] WTRUs may determine the location of the cell PCFICH symbol by applying a pre-defined offset from symbol carrying SSS in the same beam. One or more WTRUs may determine the location of the cell PCFICH symbol by applying a pre-defined offset from symbol carrying PBCH in the same beam. The linkage (e.g., a pre-defined offset between two channel/beams) may be used to determine time and/or frequency location of a channel/beam when the time and/or frequency location of another channel/beam Cell PCFICH may be included in a subframe (e.g., every subframe). The linkage (e.g., a pre-defined offset between two channel/beams) may be used to determine time and/or frequency location of a channel/beam when the time and/or frequency location of another channel/beam Cell PCFICH may be included in n subframes and/or subframe (e.g., every n subframes and/or every subframe). Cell PCFICH may be transmitted in pre-defined locations within a subframe, e.g., first few symbols of a subframe.

[0189] At least one search space corresponding to at least one reference signal may be monitored for at least one data channel, perhaps for example upon the detection of the at least one reference signal. The at least one search space may have a duration. A time location of the at least one data channel may be determined, perhaps for example based on the at least one reference signal, or the duration.

[0190] The cell specific control region size may be fixed. The cell specific control region size may indicate the maximum size/length/duration of the cell specific control region. The cell specific control region size may be semi-static. The cell specific control region size may indicate the size/length/duration of the cell specific control region for n subframes. n may be greater than or equal to the periodicity of corresponding MIB/SIB-x and/or other common channels (e.g., any other common channel). The cell specific control region size may be a greater than or equal to the sum of beam specific control region size of certain (e.g., one or more, or all) control channel beams transmitted in that subframe. Cell specific control region size may be equal to the product of max beam specific control region size and/or max number of control channel beams in a subframe. The max beam specific control region size and/or max number of control channel beams in a subframe may be pre-defined in the standard. The max beam specific control region size and/or max number of control channel beams in a subframe may be configured in common/broadcast channels. One or more symbols within the control region may carry data channels, e.g., when the cell specific control region size is greater than the sum of beam specific control region size of certain (e.g., one or more, or all) of the control channel beams transmitted in that subframe. WTRUs may receive more than one configuration for cell

specific control region. For example one configuration may apply for subframes with flexible mapping. One configuration may apply for subframes with fixed mapping.

[0191] One or more WTRUs may receive configuration for flexible mapping (e.g., only for flexible mapping), and/or WTRUs may apply a pre-defined configuration (e.g. fixed and/or max length for cell specific control region) for fixed mapping. A configuration may apply for common control channels, and/or a configuration for WTRU specific control channel. The cell specific control region configuration, for example cell PCFICH, may be dynamic. The cell specific control region configuration, for example cell PCFICH, may vary for a (e.g., every) subframe. Cell PCIFCH may indicate presence of common control region within a subframe. Cell PCFICH may indicate the end and/or start of common control region within a subframe. WTRUs may assume that the rest of the control region not occupied by common control region may be dedicated control region.

[0192] Cell specific control region configuration may have contents. The configuration may include and/or identify the length of the cell specific control region size/duration/period. The length may be expressed in one or more of the following: a number of subframes, timeslots, and/or OFDM symbols, and/or the like. One or more WTRUs may assume the start of a cell specific control region as the first symbol in a subframe. WTRUs may receive explicit indication of the first and/or last symbol of the cell specific control region. The value transmitted in the cell specific control region configuration may be a logical value. The value transmitted in the cell specific control region configuration may have a pre-defined mapping to the actual duration/length/period of the cell specific control region. A WTRU may use the indications of a cell specific control region configuration to calculate and/or determine the end of the cell specific control region. A WTRU may use the indications of a cell specific control region configuration to calculate and/or determine start of the data region. The configuration may include/identify number of control channel beams transmitted in a subframe (e.g., in the current subframe and/or in n subsequent subframes and/or in some or all subframes). The configuration may include/identify the type of mapping applied for control channel beams (e.g., fixed and/or flexible mapping). The configuration may include beam identification (e.g., RS sequence ID, antenna port number, and/or control channel number) of certain (e.g., one or more, or all) control channel beams transmitted in a subframe. The subframe may be the current subframe, n subsequent subframes, and/or certain (e.g., one or more, or all) subframes.

[0193] Beam specific control region configuration may be indicated. One or more WTRUs may receive indication and/or configuration for beam specific control region size from broadcast channel(s) (e.g., MIB, SIB-x). WTRUs may receive indication and/or configuration for

beam specific control region size from any other common channel/signal. Beam specific control region size/length/duration may be pre-defined as a constant value. The constant value may be treated as a max value. Different beams in a cell may have different beam specific control region configurations. Beam specific control region size/length/duration may be semi-static. Beam specific control region configuration may vary for different beams in the cell. For example, common control channel beams may have a configuration different from the configuration for the WTRU specific control channel beams. Beam specific control region configuration for common control channel may be fixed and/or semi-static. Beam specific control region configuration for WTRU specific control channel beams may be dynamic.

[0194] The configuration may be WTRU specific and/or beam specific. The configuration may be signaled using dedicated signaling (e.g. MAC and/or RRC message). In the absence of dedicated signaling, WTRUs may apply the configuration in MIB/SIB-x and/or a pre-defined value. A physical channel/signal (for example beam PCFICH) may be defined. The physical channel/signal may carry the configuration for beam specific control region. A cell and/or mB may transmit multiple beam PCFICH in the same subframe. A beam PCIFCH may be transmitted with a specific beam pattern and/or beam width. A beam PCIFCH may carry the corresponding beam specific control region configuration. Beam specific control region configuration for a particular beam may vary across subframes. Beam PCFICH for a beam in a subframe may be transmitted conditionally based on the presence of corresponding (e.g., beam with similar properties and/or characteristics) control channel beam in that subframe. Beam PCFICH transmission may be coupled with control channel beam transmission. The control channel and/or the beam PCFICH, e.g., within a beam dwell time, may be transmitted. The beam used for beam PCFICH may be same as the corresponding control channel for which the configuration may be provided/signaled. Beam PCFICH may be time multiplexed (e.g., different symbol and/or first few symbols in a PDCCH). Beam PCFICH may be frequency multiplexed (e.g. CCEs, REs, and/or RBs) with the control channel transmission.

[0195] The mB may transmit certain (e.g., one or more, or all) the beam PCFICHs and/or transmit the control channel beams in certain order. The mB may multiplex beam PCFICH and/or cell PCFICH and/or control channel, e.g., when the cell PCFICH is transmitted with a wide and/or narrow beam. The mB may multiplex beam PCFICH and/or cell PCFICH and/or control channel, e.g., when the cell PCFICH is transmitted with a wide and/or narrow beam. The beam PCFICH may carry cell specific configuration and/or beam specific control region configuration. Beam PCFICHs may be transmitted with a different beam pattern from the beam pattern used by the control channel beams. A (e.g., one) beam PCFICH may carry the

configurations for multiple control channel beams. WTRUs may determine the presence of beam PCFICH. For example, WTRUs may determine the presence of beam PCFICH indicated by a bit and/or bitmap in cell PCFICH. WTRUs may determine the presence of beam PCFICH indicated by a bit and/or bitmap for a (e.g., one or more, or each) control beam in cell PCFICH.

[0196] Beam specific control region configuration may have contents. WTRUs may determine beam specific search space from the beam specific control region configuration. Beam specific control region configuration may include one or more of the following: a (e.g., single) beam specific control region size common for certain (e.g. one or more, or all) beams, a beam specific control region size for a (e.g., one or more, or each) beam separately, and/or a beam specific control region size as a group of beams with similar control region size, and/or the like. The configuration may include and/or identify the length of the beam specific control region size/duration/period. The size may be expressed in one or more of the following: a number of subframes, timeslots, and/or OFDM symbols, and/or the like. One or more WTRUs may receive explicit indication of the first and/or last symbol of the beam specific control region. The value transmitted in the beam specific control region configuration may be a logical value. The value transmitted in the beam specific control region configuration may have a pre-defined mapping to the actual duration/length/period of the beam specific control region. A WTRU may use the indications of a beam specific control region configuration, e.g., to calculate and/or determine the end of the beam specific control region. A WTRU may use the indications of a beam specific control region configuration, e.g., to calculate and/or determine start of the data region.

[0197] The configuration may include/identify the number of control symbols carrying the corresponding control channel beam in a subframe (e.g., in the current subframe and/or in n subsequent subframes and/or in certain (e.g., one or more, or all subframes)). The configuration may include/identify the type of mapping applied for a control channel beam (for example fixed and/or flexible). The configuration may also include beam identification (e.g., RS sequence ID and/or antenna port number and/or control channel number) of the corresponding control channel beam transmitted in a subframe (for example in the current subframe and/or in n subsequent subframes and/or in all subframes).

[0198] WTRU monitoring may be performed in idle mode. The monitoring may select a common control channel beam. WTRUs may or might not be involved in active data transfer (e.g. in idle mode). WTRUs may be in idle mode, e.g. when selecting one or more common control channel beam(s) to perform monitoring. WTRUs may monitor one or more common control channel beams. WTRUs may monitor one or more common control channel beams to receive system information. WTRUs may monitor one or more common control channel beams

to page messages. WTRUs may monitor one or more common control channel beams to perform coarse beam tracking/beam forming. WTRUs may monitor one or more common control channel beams to receive beam training. WTRUs may select one or more common control channel beam(s) for monitoring. WTRUs may perform measurements on beamformed RS. The RS may or might not be multiplexed with common control channel beams for beam evaluation purposes. Common control channel beams may be detected/measured/identified by reference signals that are different from WTRU specific beams. Certain (e.g., one or more, or all) common control channel beams may be associated with the same reference signal that may be cell specific.

[0199] A (e.g., one more, or each) common control channel beam may be associated with a different reference signal sequence. WTRU may select certain (e.g., one or more, or all) common control channel beams. WTRU may select certain common control channel beams whose measured signal quality (e.g. RSRP, SNR, SINR, RSRQ, etc.) may be above a threshold. WTRUs may select a beam (e.g. the best) based on measured signal quality for monitoring purposes. WTRUs may perform signal quality measurements on a restricted set of subframes, e.g., subframes where PBCH and/or Sync channels may be transmitted. WTRUs may perform signal quality measurements on the subframes, e.g., where there is fixed and/or pre-defined mapping between control channel beams and/or control symbols.

[0200] WTRUs may receive an explicit and/or implicit linkage between Sync beams and/or control channel beams, using heterogeneous control channel beams. One or more WTRUS may receive an explicit and/or implicit linkage between PBCH beams and/or control channel beams, using heterogeneous control channel beams. WTRU's cell selection and/or re-selection may be based on the PBCH beams. One or more WTRUs' cell selection and/or re-selection may be based on the sync beams. WTRUs may select control channel beams of certain type based on the linked serving PBCH to perform monitoring herein. WTRUs may select control channel beams of certain type based on the linked serving Sync beam type to perform monitoring herein. For example, a pre-configured offset may be defined between the PBCH/Sync beams and/or the corresponding control channel on the same beam. The offset may be in terms of time (e.g., subframe, symbols) and/or frequency.

[0201] One or more WTRUs may determine the presence of control channel beam by searching for PBCH on the same beam, e.g., at preconfigured locations in the frame structure. WTRUs may detect the presence of a beam type using the beam specific reference signals. Beam specific reference signals may be defined as a function of cell ID. One or more WTRUs may determine the cell ID from the discovery signal and/or the number of beams in the cell via

PBCH. WTRUs may determine the cell ID from the set of beam reference signals associated to the cell. The beam reference signals may be associated to the cell by a predefined function of cell ID and/or number of beams. Beam specific reference signals may identify beam types and/or beams. WTRUs may monitor the control channel beams associated with (e.g., belonging to) beams narrower than the current serving and/or detected PBCH beam type.

[0202] Common control channel beam may have a search space. Control region in a (e.g., one or more, or each) serving cell and/or mB may comprise one or more control symbols carrying one or more control channel beams. Control region of a (e.g., one or more, or each) control channel beam may comprise one or more symbols, where the number of symbols may be either fixed and/or variable. Control region of a (e.g., one or more, or each) control channel beam may comprise one or more symbols, where the symbols and/or symbol group (e.g., exact symbols and/or symbol group) may depend on the mapping function. Common search space may be a function of one or more of the following: number of common control channel beams transmitted by the mB, number of common control channels selected by the WTRU, beam specific control region size/duration, overall control region duration, bandwidth of the cell, and/or aggregation level, and/or the like. Within the symbols used for common control channel beam, frequency domain mapping may be explicitly provided for control channel, e.g., PDCCH candidates mapped to n number of carriers around the center frequency, even/odd RBs, hashing function, and/or any other pattern. The common search space with beamformed control channels may be defined as a set of PDCCH candidates on one or more common control channel beams, e.g., determined by control channel beam selection function. On a control channel beam, one or more WTRUs may monitor the corresponding beam specific control region for a set of PDCCH candidates defined by one or more aggregation levels.

[0203] FIG. 21 is an example of common control channel beam and/or associated search space. WTRUs may perform monitoring. WTRUs may monitor their common search space in idle mode. WTRUs may perform the monitoring on a set of pre-defined subframes, e.g., where the mapping between the common control channel beams may be known and/or configured in terms of control channel beam IDs and/or symbol mapping. WTRUs may search certain subframes (e.g., all subframes and/or preconfigured subframe(s)) for presence of common control channel beams at symbol locations within the control region. WTRUs may search the subframes by correlating a known reference signal sequence (e.g., signal sequences which may be cell specific and/or beam specific). Different reference signal sequences may be defined for common control channel beams and/or WTRU specific control channel beams. A (e.g., one or more, or each) beam may have its own reference signal sequence, perhaps within the common

control channel beams. Within the common control channel beams, one or more beams (e.g., all beams) may use the cell specific sequence. The WTRU may monitor the common search space within the beam specific control region, e.g., when the received reference signal power may be above a threshold. The reference signal sequence may be cell specific. Some or all of the common control channel beams in the cell may carry the same information. A WTRU may accumulate the energy received from some or all the common control channels to increase the SNR.

[0204] WTRUs may perform monitoring in connected mode. WTRU may perform monitoring in connected mode by assigning control channel beams. WTRUS may monitor one or more control channel beams to receive control information in connected mode. The control channel beams may be WTRU specific control channel beams and/or cell specific common control channel beams. The set of control channel beams that the WTRU may monitor may be referred to as serving control channel beams. One or more WTRUs may be assigned one or more serving control channel beam(s). WTRUs may consider some or all the control channel beams from the mB as serving control channels. WTRUs may consider the control channel beams selected during idle mode operation, e.g., as WTRU specific control channel beams for connected mode operation. WTRUs may receive the serving control channel beam(s) configuration using dedicated signaling (e.g. L1 and/or MAC and/or RRC message). One or more WTRUs may monitor one or more serving control channels in the connected mode for one or more of the following: UL and/or DL grants, Beam switch commands, handover commands, higher layer messages, and/or small payloads, and/or any other control information. One or more WTRUs may distinguish common control channel beams from the WTRU specific control channel beams by the presence of pre-defined beam reference signals.

[0205] WTRUs may monitor cell specific common control channel beams to receive common channels (e.g., Paging and/or SIB) while in connected mode. WTRUs may select common control channel beams autonomously. WTRUs may select common control channel beams based on dedicated signaling (e.g. L1 and/or MAC and/or RRC message) received in the serving control channel. WTRUs may monitor serving control channel beam for common channels (e.g. Paging and/or SIB). One or more WTRUs may select common control channel beam(s) that are implicitly and/or explicitly linked to current serving control channel beam(s).

[0206] WTRUs may have beam specific search space. Control region in a serving cell and/or mB may comprise one or more control symbols. Control symbols may carry one or more control channel beams. Control region of a (e.g., one or more, or each) control channel beam

may comprise one or more symbols. For example, the number of symbols may be either fixed and/or variable. The exact symbols and/or symbol group may depend on the mapping function.

[0207] WTRU specific search space may be a function of one or more of the following: the number of control channel beams transmitted by the mB, number of control channels selected by and/or assigned to the WTRUs, beam specific control region size/duration, overall control region duration, bandwidth of the cell, aggregation levels, WTRU ID, subframe number, and/or subframe, and/or the like. WTRU specific search space may be defined as the union of beam specific search space of certain serving control channel beams selected by /assigned to the WTRU. Beam specific search space may be defined as a set of PDCCH candidates in beam specific control region. Beam specific control region may be defined as one or more control symbols and/or symbol groups used to transmit and/or mapped to the corresponding beam. Number of symbols per control channel beam may be static, semi-static and/or dynamic. On a (e.g., one or more, or each) serving control channel beam, a WTRU may monitor the corresponding beam specific control region for set of PDCCH candidates defined by one or more aggregation levels. Within the symbols used for control channel beam, frequency domain mapping and/or restriction may be explicitly and/or implicitly defined for PDCCH candidates (e.g. mapped to n number of carriers around the center frequency and/or even/odd RBs and/or a hashing function and/or any other pattern). WTRUs may be configured with different set of aggregation levels for different control channel beams. WTRU specific search space within a beam may be a function of beam ID, WTRU ID, symbol number, subframe number etc.

[0208] FIG. 22 is an example for WTRU beam specific search space. WTRUs may perform monitoring. WTRUs may monitor their WTRU specific search space in connected mode. WTRUs may monitor common search space in connected mode. WTRUs may perform conditional monitoring, e.g., based on the presence of one or more serving control channel beams. One or more WTRUs may search certain subframes and/or one or more preconfigured subframes for the presence of WTRU specific control channel beam, by correlating one or more of the following: pre-configured beam specific reference signal sequence, cell specific reference signal sequence, and/or beam type specific reference signal sequence in the control region, and/or the like. One or more WTRUs may be configured with mapping between control channel beam and control symbol location. WTRUs may search for (e.g., only for) the configured control channel beams in a (e.g., one or more, or each) symbol location. The WTRUs may monitor PDCCH candidates within the detected beam specific search space, e.g., when the received reference signal power is above a threshold.

[0209] WTRUs may monitor beam specific search space in some or all the subframes and/or in the configured subframes where one or more serving control channel beams may be transmitted. WTRUS may monitor common search space in all or some of the subframes or in the configured subframes where one or more common control channel beams may be transmitted. For example, the control region in pre-configured subframes may comprise one more (e.g. two) parts, one for common control channel beams and/or the other for WTRU specific control channel beams, for example. One or more WTRUs may monitor common search space in the common control region and/or WTRU specific and/or beam specific search space in the dedicated control region.

[0210] WTRUs may perform monitoring using one or more techniques as described herein. WTRUs may determine WTRU specific control channel beam and/or common control channel beam by doing one or more of the following. WTRU specific control channel beam may be configured by the mB. WTRU specific control channel beam may be selected during the cell selection. WTRU specific control channel beam may be selected autonomously by the WTRU and/or indicated to the mB during the random access procedure. Common control channel beam may be selected by the WTRUs autonomously (e.g. linkage to PBCH/Sync beams). Common control channel beam may be selected by the WTRUs implicitly linked to current serving control channel beams (e.g., many to one mapping between WTRU specific beams and common control channel beams). An mB may override the common control channel beam for a WTRU in connected mode.

[0211] WTRUs may determine subframes to monitor, based on beam mapping function through one or more of the following. WTRUs may be preconfigured (in MIB/SIB-x and/or dedicated signaling) with the beam to subframe mapping. WTRUS may monitor those (e.g., only those) subframes, e.g, where one or more serving control channel beam and/or common control channel beams may be transmitted. WTRUs upon wake up from DRX mode may monitor those (e.g., only those) subframes, e.g., where the fixed mapping to the serving control beams may be pre-configured. WTRUs may assume and/or be configured a flexible mapping, e.g., any to any mapping between beams and subframes, with a (e.g., one or more, or each) subframe containing multiple control channel beams. One or more WTRUs may monitor certain (e.g. one or more, or all) the DL subframes for the serving control channel beams and/or common control channel beams. Upon wake up from DRX mode and/or receiving a valid allocation, WTRUs may continue monitoring certain (e.g., one or more, or all) subframes for the serving control channel beams. WTRUs may monitor specific subframes for common control channel beam and/or certain (e.g., one or more, or all) subframes for WTRU specific control channel beams.

[0212] WTRUs may determine overall control region in a subframe. WTRUs may determine the overall control region size/duration in a subframe from MIB/SIB-x. WTRUs may determine the overall control region size/duration in a subframe from a fixed parameter. WTRUs may determine the overall control region size/duration in a subframe dynamically signaled via a cell PCFICH.

[0213] WTRUs may determine beam specific search space by one or more of the following. Within the overall control region, WTRUs may assume one or more beam specific control region. For a (e.g., one or more, or each) monitored control channel beam, WTRUs may determine (e.g., first determine) the presence of those control beams and/or starting symbol for the control channel beams by explicit signaling in cell PCIFCH. For monitored control channel beams, WTRUs may determine the presence of those control beams and/or starting symbol for the control channel beams by detecting beam specific BRS above a threshold. For monitored control channel beams, WTRUs may perform blind decoding, e.g., when a cell specific BRS is used. WTRUs may assume no DCI received in that subframe, e.g, when BRS for certain (e.g., one or more, or all) serving control channel beams are below the threshold. WTRUs may identify the beams based on beam specific preambles added to a (e.g., one or more, or each) control symbol carrying the beam. The preambles may be a function of one or more of the following: beam ID, cell ID, and/or WTRU ID, and/or the like.

[0214] One or more WTRUs may utilize the measurements based on BRS to determine the characteristics/property of the control channel beam, e.g., the presence of a specific control channel type and/or beam, length of the control channel beam etc. For certain (e.g., one or more, or all) detected control channel beams, WTRUs may determine the beam specific control region size/duration and/or last symbol in the beam specific control region from MIB/SIB-x. For certain (e.g., one or more, or all) detected control channel beams, WTRUs may determine the beam specific control region size/duration and/or last symbol in the beam specific control region from a fixed parameter. For certain (e.g., one or more, or all) detected control channel beams, WTRUs may determine the beam specific control region size/duration and/or last symbol in the beam specific control region may be dynamically signaled via beam PCFICH. One or more WTRUs may be (e.g., explicitly) provided with a fixed mapping between the control channel beam and the symbol location of the beam specific control region. One or more WTRUs may be (e.g., explicitly) provided with a fixed mapping between the control channel beam and the size/duration of the beam specific control region. An overall control region may be split into common control region and/or a dedicated control region.

[0215] Within a (e.g., one or more, or each) detected beam specific control region, one or more WTRUs may do one or more of the following. A WTRU may apply the frequency and/or time domain restriction (e.g. central n carriers and/or specific RBs and/or any other pattern and/or remove non-PDCCH channels (e.g. PHICH, beam PCIFICH, sync/PBCH if present). Within the beam specific search space, some (e.g., additional), WTRU specific search space may be configured. For example, starting CCEs may be different for different WTRUs (e.g. based on WTRU ID, beam type, beam ID, subframe number, symbol number etc.). WTRUs may group the REGs within a (e.g., one or more, or each) beam specific control region into one set of CCEs. Within a (e.g., one or more, or each) set of CCEs, WTRUs may monitor one or more PDCCH candidates based on aggregation levels configured for a (e.g., one or more, or each) beam type and/or beam. DCI CRC may be scrambled with beam ID in addition to the WTRU ID (e.g. CRNTI) and/or common ID (e.g. SI_RNTI and/or Paging RNTI). When WTRU specific control channel beams, WTRU specific search space may be simplified (e.g., further simplified) by pre-configuring fixed starting CCEs, explicit indication of aggregation level used etc.

[0216] DL data may perform scheduling. WTRUs may, upon detection of PDCCH in some (e.g., at least one) of the serving control channel beams, indicate DL grant for data and/or some (e.g., any) other higher layer information intended for the WTRUs. WTRUs may attempt to decode the corresponding data channel beam in the resources indicated by the DCI. WTRUs may assume that the serving control channel beam may be used for data transmission, e.g., when no data beam specific identity is included in the DCI message. WTRUs may assume the last indicated data channel beam, e.g, if no data beam specific identity is included in the DCI message. WTRUs may assume the data channel indicated by the higher layer configuration, e.g., if no data beam specific identity is included in the DCI message. The scrambling initialization of the PDSCH may be a function of one or more of the following: control channel beam ID that carries the allocation, beam ID of the DL data channel beam, WTRU specific RNTI (e.g. C-RNTI and/or SPS-RNTI), a fixed RNTI (e.g. SI-RNTI and/or Paging RNTI), and/or beam type, and/or the like.

[0217] Sub-subframe scheduling may perform resource allocation by allowing multiple allocation in a subframe. Beamforming may be used (e.g., required) to compensate additional path loss at higher frequencies. Given the large bandwidths at higher frequencies and/or analog beamforming, one or more WTRUs may be multiplexed with different beams within a subframe and/or scheduling interval. One or more control channels may be transmitted with wide beams. A (e.g., one or more, or each) control channel beam may schedule one or more narrow data beams for one or more WTRUs within the same subframe.

[0218] Minimum schedulable time resource within a subframe may be symbol and/or group of symbols. Scheduling granularity may be less than a subframe and/or a scheduling interval. For example, a new (e.g., fresh and/or heretofore unused) DCI format may be defined to carry allocation information at symbol level/symbol group, to indicate a start offset (e.g., a symbol offset), repetition information (e.g. more than one data channel per WTRU per subframe), and/or spatial information (e.g. transmit beam ID), and/or the like.

[0219] Within a subframe, the data region may comprise multiple data channel beams multiplexed in time. For example, a data channel may occupy several symbols and/or the remaining symbols within the same subframe may be used by other data channel beams addressed to the same and/or different WTRUs. WTRUs may be allocated multiple data channel resources within the same subframe. A (e.g., one or more, or each) set of data channel resources may be associated with a different data beam.

[0220] Downlink data beam that an mB may use for the WTRU may be identified. WTRUs may use a receive beam pattern for downlink data channel reception. WTRUs may use different receive beam pattern for downlink control channel beam reception compared to the receiving beam pattern used for downlink data channel beam reception. An mB may comprise the transmit beam ID corresponding to the data channel beam to enable WTRU to switch receive beam accordingly. One or more WTRUs may use (e.g., require) gap and/or decoding period between the PDCCH carrying the grant and/or the actual data channel resource. Transmit beam ID may be implicitly determined by the WTRU, e.g., when WTRU specific control channel beam is used, as the data beam may be same as the WTRU specific control channel beam.

[0221] The data channel beam information may be coupled with resource allocation information. For example the DCI may include transmit beam identification in PDCCH that carries resource allocation in terms of time (e.g. symbol, symbol group) and/or frequency (e.g. RBs). An mB may explicitly provide a gap and/or guard period between the last symbol of PDCCH and the first symbol of PDSCH within the same subframe. The guard period may be defined from WTRU point of view. mB may use the symbols in the guard period to schedule other WTRUs. WTRUs may assume (e.g., always assume) an offset between PDCCH and PDSCH. For example PDCCH in subframe n may allocate PDSCH in subframe n+k. The value of k may be dynamic and/or may be configured by higher layer signaling (MAC and/or RRC) and/or may be included in DCI message and/or may be a pre-defined constant. WTRUs may assume k=0 for buffering the data in the current subframe. Depending on the value of k in the DCI, WTRUs may determine the PDSCH location in the current subframe (if k=0 and/or not included in DCI) and/or in subframe n+k (if k is included in the DCI).

[0222] At least one search space may include downlink control information (DCI). At least one data channel may be monitored, perhaps for example based at least in part on the DCI. At least one beam for receipt of the at least one data channel may be identified, perhaps for example based at least in part on the DCI.

[0223] The data channel beam information and/or spatial information may be separate from resource allocation (e.g. time, frequency, code) information. The spatial information (e.g., data channel transmit beam identification) may be derived from beam specific reference signal for the corresponding DL beam. The spatial information may be derived from beam specific reference signal for the corresponding antenna port. The spatial information may be derived from beam specific reference signal for the corresponding steering vector and/or codebook index. The spatial information may be signaled using RRC configuration/MAC CE/DCI, decoupled from the time and/or frequency resource allocation information. The spatial information may be acknowledged by the WRTU to prevent mismatch between an mB and the WRTU, before actual data transmission on the indicated data channel beam. The spatial information and/or resource allocation information (e.g. time and/or frequency) may have a pre-defined and/or configured offset to the allocated resources. The spatial information may be associated with a validity period and/or upon expiry of the validity period. WRTUs may perform (e.g., be required to perform) one or more of beam measurement and/or beam tracking and/or beam reporting (e.g. CSI).

[0224] The common channels may be scheduled using separate spatial information. The WTRU specific channels may be scheduled using the coupled spatial information. The common channels may be scheduled using coupled spatial information. The WTRU specific channels may be scheduled using the separate spatial information. Different WTRUs in the same cell may receive the scheduling information using different configuration (e.g. coupled and/or separate).

[0225] DCI may have format and/or contents. Downlink control information for a DL data channel grant may be include one or more of the following: spatial information, time, and/or frequency resource information, and/or the like. Spacial information may comprise one or more of the following: implicit data channel beam identity (e.g. associated Data channel RS sequence number, associated control channel RS sequence number and/or an index in the WTRU measurement report) and/or an explicit data channel ID which may map to a specific data channel beam, UL control channel beam configuration associated with a DL transmission, and/or set of control symbols to monitor for serving control channel beam(s), and/or the like. Time and/or frequency resource information may comprise one or more of the following: the resource allocation information corresponding to downlink data channel beam indicated in the spatial

information, Starting symbol location for PDSCH within the subframe, Duration (in terms of number of symbols), Frequency/Resource Block information, an index to a pre-configured symbol groups/resource groups in time and/or frequency, and/or the like.

[0226] Spatial information may be signaled using L23 signaling (e.g. RRC and/or MAC CE) and/or L1 signaling (e.g. in a DCI). WTRUs may consider the spatial information to be valid after transmitting an ACK corresponding to the DL PDSCH carrying the spatial information. WTRUs may assume that the spatial information valid until they receive RRC/MAC CE/DCI with a different spatial information. Time and/or frequency resource information may be signaled using L1 signaling (e.g. in a DCI). The scheduling information in the time and/or frequency resource information may be valid for (e.g., only for) the subframe where the resource information is received. Different DCI formats may be defined. For example, two different DCI formats may be defined, one with the time and/or frequency resource information and/or the other with time and/or frequency resource information and/or spatial information. A DCI format may contain the time and/or frequency resource information and/or the other(s) DCI format may contain the spatial information.

[0227] Beams may be combined for DL. Plurality of spatial information may be signaled to the WTRU using L23 signaling (e.g. RRC and/or MAC CE) and/or L1 signaling (e.g. in a DCI) for the downlink data transmission. The DCI and/or the L23 message may carry per spatial information, one or more of the following: symbol location, duration, resource block configuration, WTRU specific reference signal ID and/or beam ID, antenna port number, and/or HARQ information (e.g. redundancy version), and/or the like. Spatial information (e.g., one or more, or each spatial information) may identify the transmission direction and/or data channel beam to the WTRUs. WTRUs may receive a single transport block within a subframe and/or sequence of subframes multiplexed in time domain, using plurality of spatial configuration (e.g. multiple data channel beams). WTRUs may soft-combine the spatial repetitions of the transport block to improve the effective SNR. WTRUs may use same and/or different receive antenna configuration and/or receive beam pattern corresponding to the downlink spatial information signaled for beam combining.

[0228] UL data may be scheduled. WTRU upon detection of PDCCH in some (e.g., at least one) of the serving control channel beams in subframe/subframe n, indicating UL grant intended for the WTRU, may transmit PUSCH in subframe/subframe n+k, using the UL data channel beam indicated in the PDCCH., WTRUs may assume that the current UL control channel beam may be used for UL data transmission, e.g., when no data channel beam identity is included in the DCI message. One or more WTRUs may assume the last indicated UL data

channel beam and/or the data channel indicated by higher layer configuration for UL data transmission, e.g. when no data channel beam identity is included in the DCI message. The scrambling initialization of the PUSCH may be a function of control channel beam ID that carries the allocation and/or beam ID of the UL data channel beam and/or WTRU specific RNTI (e.g. C-RNTI and/or SPS-RNTI) and/or beam type.

[0229] Within a UL subframe, the data region may comprise multiple UL data channel beams from one or more WTRUs multiplexed in time. For example, a data channel may occupy one or more symbols and/or the remaining symbols within the same subframe may be used by other UL data channel beams addressed to the same and/or different WTRUs. WTRUs may be allocated multiple UL data channel resources within the same subframe. A (e.g., one or more, or each) set of UL data channel resources may be associated with a different UL data beam.

[0230] Uplink transmissions from multiple WTRUs within the same subframe and/or scheduling interval, may be multiplexed in time domain and/or frequency domain. Scheduling granularity may be less than subframe and/or scheduling interval. A new DCI format may carry UL allocation information at symbol level/symbol group, start offset, repetition information (e.g. more than one UL data channel per WTRU per subframe), spatial information (e.g. UL transmit beam ID).

[0231] One or more WTRUs may identify and/or signal the uplink data beam. One or more WTRUs may use a specific beam pattern for UL data channel transmission. One or more WTRUs may use different transmit beam pattern for uplink control channel compared to the transmit beam pattern used for uplink data channel beam. An mB may include the transmit beam ID corresponding to the UL data channel beam to enable WTRUs to switch transmit beam accordingly. One or more WTRUs may use (e.g., require) gap and/or decoding period between the PDCCH carrying the UL grant and/or the actual UL data channel resource.

[0232] The UL data channel beam information may be coupled with resource allocation information. For example the DCI may include transmit beam identification in PDCCH that carries resource allocation in terms of time (e.g. symbol and/or symbol group) and/or frequency (e.g. RBs). An mB may (e.g., explicitly) provide a gap and/or guard period between the last symbol of PDCCH and the first symbol of PUSCH. The guard period may be defined from WTRU point of view. An mB may use the symbols in the guard period to schedule other WTRUs. WTRUs may assume (e.g. always assume) an offset between PDCCH and PUSCH. For example PDCCH in subframe n may allocats PUSCH in subframe n+k. The value of k may be dynamic and/or may either be configured by higher layer signaling (MAC and/or RRC) and/or may be included in DCI message.

[0233] The UL data channel beam information and/or spatial information may be separate from resource allocation (e.g., time, frequency, code) information. The spatial information, e.g. UL data channel transmit beam identification, may be derived from SRS (e.g. SRS sequence ID and/or SRS configuration ID etc.), decoupled from the time and/or frequency resource allocation information. The spatial information may be derived random access procedure (preamble ID and/or subframe), decoupled from the time and/or frequency resource allocation information. The spatial information may be signaled using RRC configuration/MAC CE/DCI, decoupled from the time and/or frequency resource allocation information. The spatial information may be acknowledged by the WTRU to prevent mismatch between mB and the WTRU, e.g., before actual data transmission on the indicated data channel beam. The spatial information and resource allocation information (e.g. time and/or frequency) may have a pre-defined and/or configured offset to the allocated resources. The spatial information may be associated with a validity period. For example, upon expiry of the validity period, a WTRU may (e.g., be required to) perform one or more of sounding procedure and/or RACH etc.

[0234] The UL control channel beam may be scheduled using separate spatial information. The UL data channel beam may be scheduled using the coupled spatial information. One or more WTRUs in the same cell may receive the scheduling information using different configuration (e.g., coupled and/or separate).

[0235] DCI may have formats and/or contents. Downlink control information for a UL data channel grant may include one or more of the following: spatial information, time resource information, and/or frequency resource information, and/or the like. Spatial information may comprise one or more of the following: implicit data channel beam identity, and/or DL PHICH beam configuration, and/or the like. Implicit data channel beam identity may comprise one or more of the following: SRS sequence ID and/or SRS configuration ID etc., preamble ID, subframe and/or an explicit data channel ID which may map to a specific data channel beam, and/or explicit ID negotiated with the WTRU, and/or the like. Time and/or frequency resource information may comprise one or more of the following: information that may indicate the resource allocation information corresponding to downlink data channel beam indicated in the most recent spatial information, starting symbol location for PUSCH within the subframe, duration (e.g., in terms of number of symbols), frequency/resource block information, and/or an index to a pre-configured symbol groups/resource groups in time and/or frequency, and/or the like.

[0236] Spatial information may be signaled using Layer 2 and/or 3 (L23) signaling (e.g. RRC and/or MAC CE) and/or L1 signaling (e.g. in a DCI). A WTRU may consider the

scheduling information received in the spatial information to be valid after transmitting an ACK corresponding to the DL PDSCH carrying the spatial information. The WTRU may assume that the spatial information valid perhaps until it receives RRC/MAC CE/DCI with a different spatial information, for example. Time and/or frequency resource information may be signaled using L1 signaling (e.g. in a DCI). The scheduling information in the time and/or frequency resource information may be valid for the subframe (e.g., only for the subframe) where the resource information is received.

[0237] Different DCI formats may be defined. One or more (e.g. two) different DCI formats may be defined, perhaps one with the time and/or frequency resource information and/or another other with time and/or frequency resource information and/or spatial information. A DCI format may contain the time and/or frequency resource information and/or the other DCI format may contain the spatial information.

[0238] One or more beams may be combined for UL. A plurality of spatial information may be signaled to the WTRU using L23 signaling (e.g. RRC and/or MAC CE) and/or L1 signaling (e.g. in a DCI) for the uplink data transmission. The DCI and/or the L23 message may carry per spatial information, one or more of the following: symbol location, duration, resource block configuration, WTRU specific reference signal ID and/or beam ID and/or SRS configuration ID, antenna port number, and/or HARQ information (e.g. redundancy version) and/or the like.

[0239] A (e.g., one or more, or each) spatial information may identify (e.g., uniquely identify) the transmission direction and/or data channel beam from the WTRU. A WTRU may transmit a single transport block within a subframe and/or sequence of subframes multiplexed in time domain, perhaps for example using a plurality of spatial configuration (e.g. multiple data channel beams). An mB may soft-combine the spatial repetitions of the transport block, e.g., to improve the effective SNR. An mB may use a same receiving antenna configuration and/or receiving beam pattern corresponding to the uplink spatial information signaled for beam combining. An mB may use different receiving antenna configuration and/or receiving beam pattern corresponding to the uplink spatial information signaled for beam combining.

[0240] UL control channel information may be part of UL data scheduling. DCI may carry UL control channel information and/or the DL grant for data channels. The UL control channel information may include the resources used for feedback (e.g. ACK/NACK and/or CSI etc.). An mB may dynamically signal the WTRU UL control beam for feedback using the DCI carrying the corresponding DL resource allocation. One or more WTRUs may associate the UL control channel resources allocated in a DCI to the DL data channel allocation present in the

same DCI. The UL control channel information may include time (e.g. subframe offset or symbol offset from the current subframe) and/or frequency resources (e.g. Resource blocks). The UL control channel information may include the spatial information for the UL control channel. For example, the UL control beam for the WTRU may be identified by SRS configuration ID and/or SRS sequence and/or RACH identifier (RA-RNTI and/or preamble sequence number) used by the WTRU for the periodic/aperiodic transmission of the corresponding UL control channel beam.

[0241] A mB may pre-configure the mapping between DL control beam carrying the DL data allocation and the WTRU UL control beam carrying the feedback. The configuration may be WTRU specific. A mB may pre-configure the mapping between DL transmit control beam carrying the DL data allocation and the mB UL Rx control beam resources to receive the feedback. The configuration may provide WTRU specific resources within the mB UL Rx beam (e.g. frequency/time/code). A mB may schedule the uplink control beam semi-statically using higher layer signaling. A mB may schedule different uplink control beam for different feedback types (e.g. ACK/NACK vs CSI). In some or all the schemes discussed herein, a mB may configure more than one UL WTRU control beam for feedback (e.g. repetition and/or implicit HARQ retransmission).

[0242] FIG. 24A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, such as voice, data, video, messaging, broadcast, *etc.*, to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0243] As shown in FIG. 24A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, and/or 102d (which generally or collectively may be referred to as WTRU 102), a radio access network (RAN) 103/104/105, a core network 106/107/109, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be

configured to transmit and/or receive wireless signals and may include user equipment (UE), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0244] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to one or more communication networks, such as the core network 106/107/109, the Internet 110, and/or the networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0245] The base station 114a may be part of the RAN 103/104/105, which may also include other base stations and/or network elements (not shown), such as a base station controller (BSC), a radio network controller (RNC), relay nodes, *etc.* The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, *e.g.*, one for each sector of the cell. In another embodiment, the base station 114a may employ multiple-input multiple output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0246] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 115/116/117, which may be any suitable wireless communication link (*e.g.*, radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, *etc.*). The air interface 115/116/117 may be established using any suitable radio access technology (RAT).

[0247] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, such as CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 103/104/105 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 115/116/117 using wideband CDMA (WCDMA).

WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0248] In another embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 115/116/117 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0249] In other embodiments, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (*e.g.*, Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), and the like.

[0250] The base station 114b in FIG. 24A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, such as a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In another embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet another embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (*e.g.*, WCDMA, CDMA2000, GSM, LTE, LTE-A, *etc.*) to establish a picocell or femtocell. As shown in FIG. 24A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may or might not be used to access the Internet 110 via the core network 106/107/109.

[0251] The RAN 103/104/105 may be in communication with the core network 106/107/109, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106/107/109 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, *etc.*, and/or perform high-level security functions, such as user authentication. Although not shown in FIG. 24A, it will be appreciated that the RAN 103/104/105 and/or the core network 106/107/109 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 103/104/105 or a different RAT. For example, in addition to

being connected to the RAN 103/104/105, which may be utilizing an E-UTRA radio technology, the core network 106/107/109 may also be in communication with another RAN (not shown) employing a GSM radio technology.

[0252] The core network 106/107/109 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, such as the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include another core network connected to one or more RANs, which may employ the same RAT as the RAN 103/104/105 or a different RAT.

[0253] One or more of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, *e.g.*, the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 24A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0254] FIG. 24B is a system diagram of an example WTRU 102. As shown in FIG. 24B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment. Also, embodiments contemplate that the base stations 114a and 114b, and/or the nodes that base stations 114a and 114b may represent, such as but not limited to transceiver station (BTS), a Node-B, a site controller, an access point (AP), a home node-B, an evolved home node-B (eNodeB), a home evolved node-B (HeNB), a home evolved node-B gateway, and proxy nodes, among others, may include one or more of the elements depicted in FIG. 24B and described herein.

[0255] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a

microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the transmit/receive element 122. While FIG. 24B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0256] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (*e.g.*, the base station 114a) over the air interface 115/116/117. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In another embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet another embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0257] In addition, although the transmit/receive element 122 is depicted in FIG. 24B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (*e.g.*, multiple antennas) for transmitting and receiving wireless signals over the air interface 115/116/117.

[0258] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, such as UTRA and IEEE 802.11, for example.

[0259] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (*e.g.*, a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, such as the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-

access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In other embodiments, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, such as on a server or a home computer (not shown).

[0260] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (*e.g.*, nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), *etc.*), solar cells, fuel cells, and the like.

[0261] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (*e.g.*, longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 115/116/117 from a base station (*e.g.*, base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0262] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0263] FIG. 24C is a system diagram of the RAN 103 and the core network 106 according to an embodiment. As noted above, the RAN 103 may employ a UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 115. The RAN 103 may also be in communication with the core network 106. As shown in FIG. 24C, the RAN 103 may include Node-Bs 140a, 140b, 140c, which may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 115. The Node-Bs 140a, 140b, 140c may each be associated with a particular cell (not shown) within the RAN 103. The RAN 103 may also include RNCs 142a, 142b. It will be appreciated that the

RAN 103 may include any number of Node-Bs and RNCs while remaining consistent with an embodiment.

[0264] As shown in FIG. 24C, the Node-Bs 140a, 140b may be in communication with the RNC 142a. Additionally, the Node-B 140c may be in communication with the RNC142b. The Node-Bs 140a, 140b, 140c may communicate with the respective RNCs 142a, 142b via an Iub interface. The RNCs 142a, 142b may be in communication with one another via an Iur interface. Each of the RNCs 142a, 142b may be configured to control the respective Node-Bs 140a, 140b, 140c to which it is connected. In addition, each of the RNCs 142a, 142b may be configured to carry out or support other functionality, such as outer loop power control, load control, admission control, packet scheduling, handover control, macrodiversity, security functions, data encryption, and the like.

[0265] The core network 106 shown in FIG. 24C may include a media gateway (MGW) 144, a mobile switching center (MSC) 146, a serving GPRS support node (SGSN) 148, and/or a gateway GPRS support node (GGSN) 150. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0266] The RNC 142a in the RAN 103 may be connected to the MSC 146 in the core network 106 via an IuCS interface. The MSC 146 may be connected to the MGW 144. The MSC 146 and the MGW 144 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and land-line communications devices.

[0267] The RNC 142a in the RAN 103 may also be connected to the SGSN 148 in the core network 106 via an IuPS interface. The SGSN 148 may be connected to the GGSN 150. The SGSN 148 and the GGSN 150 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between and the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0268] As noted above, the core network 106 may also be connected to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0269] FIG. 24D is a system diagram of the RAN 104 and the core network 107 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 107.

[0270] The RAN 104 may include eNode-Bs 160a, 160b, 160c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 160a, 160b, 160c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 160a, 160b, 160c may implement MIMO technology. Thus, the eNode-B 160a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0271] Each of the eNode-Bs 160a, 160b, 160c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 24D, the eNode-Bs 160a, 160b, 160c may communicate with one another over an X2 interface.

[0272] The core network 107 shown in FIG. 24D may include a mobility management gateway (MME) 162, a serving gateway 164, and a packet data network (PDN) gateway 166. While each of the foregoing elements are depicted as part of the core network 107, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0273] The MME 162 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 162 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 162 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, such as GSM or WCDMA.

[0274] The serving gateway 164 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via the S1 interface. The serving gateway 164 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 164 may also perform other functions, such as anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0275] The serving gateway 164 may also be connected to the PDN gateway 166, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0276] The core network 107 may facilitate communications with other networks. For example, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and land-line communications devices. For example, the core network 107 may include, or may communicate with, an IP gateway (*e.g.*, an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 107 and the PSTN 108. In addition, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0277] FIG. 24E is a system diagram of the RAN 105 and the core network 109 according to an embodiment. The RAN 105 may be an access service network (ASN) that employs IEEE 802.16 radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 117. As will be further discussed below, the communication links between the different functional entities of the WTRUs 102a, 102b, 102c, the RAN 105, and the core network 109 may be defined as reference points.

[0278] As shown in FIG. 24E, the RAN 105 may include base stations 180a, 180b, 180c, and an ASN gateway 182, though it will be appreciated that the RAN 105 may include any number of base stations and ASN gateways while remaining consistent with an embodiment. The base stations 180a, 180b, 180c may each be associated with a particular cell (not shown) in the RAN 105 and may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 117. In one embodiment, the base stations 180a, 180b, 180c may implement MIMO technology. Thus, the base station 180a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a. The base stations 180a, 180b, 180c may also provide mobility management functions, such as handoff triggering, tunnel establishment, radio resource management, traffic classification, quality of service (QoS) policy enforcement, and the like. The ASN gateway 182 may serve as a traffic aggregation point and may be responsible for paging, caching of subscriber profiles, routing to the core network 109, and the like.

[0279] The air interface 117 between the WTRUs 102a, 102b, 102c and the RAN 105 may be defined as an R1 reference point that implements the IEEE 802.16 specification. In addition, each of the WTRUs 102a, 102b, 102c may establish a logical interface (not shown) with the core network 109. The logical interface between the WTRUs 102a, 102b, 102c and the core network 109 may be defined as an R2 reference point, which may be used for authentication, authorization, IP host configuration management, and/or mobility management.

[0280] The communication link between each of the base stations 180a, 180b, 180c may be defined as an R8 reference point that includes protocols for facilitating WTRU handovers and the transfer of data between base stations. The communication link between the base stations 180a, 180b, 180c and the ASN gateway 182 may be defined as an R6 reference point. The R6 reference point may include protocols for facilitating mobility management based on mobility events associated with each of the WTRUs 102a, 102b, 102c.

[0281] As shown in FIG. 24E, the RAN 105 may be connected to the core network 109. The communication link between the RAN 105 and the core network 109 may defined as an R3 reference point that includes protocols for facilitating data transfer and mobility management capabilities, for example. The core network 109 may include a mobile IP home agent (MIP-HA) 184, an authentication, authorization, accounting (AAA) server 186, and a gateway 188. While each of the foregoing elements are depicted as part of the core network 109, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0282] The MIP-HA may be responsible for IP address management, and may enable the WTRUs 102a, 102b, 102c to roam between different ASNs and/or different core networks. The MIP-HA 184 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices. The AAA server 186 may be responsible for user authentication and for supporting user services. The gateway 188 may facilitate interworking with other networks. For example, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and land-line communications devices. In addition, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0283] Although not shown in FIG. 24E, it will be appreciated that the RAN 105 may be connected to other ASNs and the core network 109 may be connected to other core networks. The communication link between the RAN 105 the other ASNs may be defined as an R4 reference point, which may include protocols for coordinating the mobility of the WTRUs 102a, 102b, 102c between the RAN 105 and the other ASNs. The communication link between the core network 109 and the other core networks may be defined as an R5 reference, which may include protocols for facilitating interworking between home core networks and visited core networks.

[0284] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element can be used alone or in any combination with the other features and elements. In addition, the methods described herein may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, and optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, UE, terminal, base station, RNC, or any host computer.

CLAIMS

What is claimed is:

1. A wireless transmit/receive unit (WTRU) configured for wireless communication, the WTRU comprising:

a memory; and

a processor, the processor configured with at least:

one or more search spaces, the one or more search spaces configured to provide for at least one of: a monitor of one or more Downlink (DL) control channels, or a receipt of the one or more DL control channels, at least one search space of the one or more search spaces corresponding to at least one reference signal of one or more reference signals, the processor configured at least to:

monitor at least a part of a control region for at least one reference signal of the one or more reference signals;

detect the at least one reference signal in the at least part of the control region; and

monitor the at least one search space corresponding to the at least one reference signal for at least one DL control channel upon the detection of the at least one reference signal.

2. The WTRU of claim 1, wherein the processor is further configured to monitor the at least one search space corresponding to the at least one reference signal for at least one data channel upon the detection of the at least one reference signal.

3. The WTRU of claim 2, wherein the at least one search space has a duration.

4. The WTRU of claim 3, wherein the processor is further configured to determine a time location of the at least one data channel based on at least one of: the at least one reference signal, or the duration.

5. The WTRU of claim 1, wherein the at least one search space includes downlink control information (DCI), and the processor is further configured to monitor the at least one DL control channel based at least in part on the DCI.

6. The WTRU of claim 2, wherein the at least one search space includes downlink control information (DCI), and the processor is further configured to monitor the at least one data channel based at least in part on the DCI.

7. The WTRU of claim 6, wherein the processor is further configured to identify at least one beam for receipt of the at least one data channel based at least in part on the DCI.

8. The WTRU of claim 1, wherein the processor is further configured such that the at least part of the control region is one part of a number of parts of the control region.

9. The WTRU of claim 8, wherein the processor is further configured such that the number of parts of the control region is a function of a number of symbols configured for the control region.

10. The WTRU of claim 8, wherein the processor is further configured such that the number of parts of the control region is a function of a number of symbols used for the control region.

11. The WTRU of claim 1, further comprising a transceiver, the transceiver being configured to receive the one or more search spaces from a wireless communication system network node.

12. The WTRU of claim 1, wherein the processor is further configured such that the one or more search spaces are predefined.

13. The WTRU of claim 1, wherein the processor is further configured such that the at least one reference signal of the one or more reference signals is at least one of: a beam reference signal, or an antenna port reference signal.

14. The WTRU of claim 1, wherein the processor is further configured such that the at least one search space of the one or more search spaces is at least one of: a beam search space, or an antenna port search space.

15. The WTRU of claim 1, wherein the processor is further configured such that the at least one reference signal in the at least part of the control region is detected upon a strength of the at least one reference signal crossing a predetermined threshold.

16. The WTRU of claim 1, wherein the processor is further configured such that the at least one DL control channel is communicated via one or more Orthogonal Frequency Division Multiplexing (OFDM) symbols.

17. The WTRU of claim 16, wherein the processor is further configured such that the one or more OFDM symbols on which the at least one DL control channel is communicated is located in the control region.

18. The WTRU of claim of 17, wherein the processor is further configured to obtain a number of the one or more OFDM symbols in the control region via a Physical Control Format Indicator Channel (PCFICH).

19. The WTRU of claim 18, wherein the processor is further configured such that the PCFICH is obtained via a beam of a synchronization channel.

20. The WTRU of claim 18, wherein the processor is further configured such that the PCFICH is obtain via a beam of a Physical Broadcast Channel (PBCH).

(54) Title: METHOD AND APPARATUS FOR CONFIGURING FRAME STRUCTURE FOR NEW RADIO ACCESS TECHNOLOGY IN WIRELESS COMMUNICATION SYSTEM

(57) Abstract: A frame structure for a new radio access technology (RAT) is configured by a network node. The network node configures a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and communicates with a user equipment (UE) by using at least one of the first frame and the second frame. The UE may be a one of a massive machine-type communication (mMTC) UE, an ultra-reliable and low latency communication (URLLC) UE or an enhanced vehicle-to-everything (eV2X) UE.

WO 2017/171398 A1

Description

Title of Invention: METHOD AND APPARATUS FOR CONFIGURING FRAME STRUCTURE FOR NEW RADIO ACCESS TECHNOLOGY IN WIRELESS COMMUNICATION SYSTEM

Technical Field

[1] The present invention relates to wireless communications, and more particularly, to a method and apparatus for configuring a frame structure for a new ratio access technology (RAT) in a wireless communication system.

Background Art

[2] 3rd generation partnership project (3GPP) long-term evolution (LTE) is a technology for enabling high-speed packet communications. Many schemes have been proposed for the LTE objective including those that aim to reduce user and provider costs, improve service quality, and expand and improve coverage and system capacity. The 3GPP LTE requires reduced cost per bit, increased service availability, flexible use of a frequency band, a simple structure, an open interface, and adequate power consumption of a terminal as an upper-level requirement.

[3] As more and more communication devices require more communication capacity, there is a need for improved mobile broadband communication over existing radio access technology. Also, massive machine type communications (MTC), which provides various services by connecting many devices and objects, is one of the major issues to be considered in the next generation communication. In addition, communication system design considering reliability/latency sensitive service/UE is being discussed. The introduction of next generation radio access technology considering enhanced mobile broadband communication, massive MTC, ultra-reliable and low latency communication (URLLC) is discussed. This new technology may be called new radio access technology (RAT) for convenience.

[4] In the new RAT, analog beamforming may be introduced. In case of millimeter wave (mmW), the wavelength is shortened so that a plurality of antennas can be installed in the same area. For example, in the 30 GHz band, a total of 100 antenna elements can be installed in a 2-dimension array of 0.5 lambda (wavelength) intervals on a panel of 5 by 5 cm with a wavelength of 1 cm. Therefore, in mmW, multiple antenna elements can be used to increase the beamforming gain to increase the coverage or increase the throughput.

[5] In this case, if a transceiver unit (TXRU) is provided so that transmission power and phase can be adjusted for each antenna element, independent beamforming is possible for each frequency resource. However, installing a TXRU on all 100 antenna elements

has a problem in terms of cost effectiveness. Therefore, a method of mapping a plurality of antenna elements to one TXRU and adjusting the direction of a beam using an analog phase shifter is considered. This analog beamforming method has a disadvantage that it cannot perform frequency selective beaming because it can make only one beam direction in all bands.

[6] A hybrid beamforming with B TXRUs, which is an intermediate form of digital beamforming and analog beamforming, and fewer than Q antenna elements, can be considered. In this case, although there is a difference depending on the connection method of the B TXRU and Q antenna elements, the direction of the beam that can be simultaneously transmitted is limited to B or less.

[7] For operating new RAT efficiently, various schemes have been discussed. Specifically, in perspective of using frequency/spectrum, some new features may need to be required. Further, new frame structure may also need to be required.

Disclosure of Invention

Technical Problem

[8] The present provides a method and apparatus for configuring a frame structure for a new ratio access technology (RAT) in a wireless communication system. The present invention discusses initial access procedure which can allow different use cases supported in the same spectrum, e.g. massive machine-type communication (mMTC) and enhanced mobile broadband (eMBB), for both below and above 6 GHz. The present invention discusses how to support multi/variable transmission time interval (TTI) operation for each channel including hybrid automatic repeat request acknowledgement (HARQ-ACK) operation.

Solution to Problem

[9] In an aspect, a method for configuring a frame structure for a new radio access technology (RAT) by a network node in a wireless communication system is provided. The method includes configuring a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and communicating with a user equipment (UE) by using at least one of the first frame and the second frame.

[10] In another aspect, a network node for a new radio access technology (RAT) in a wireless communication system is provided. The network node includes a memory, a transceiver, and a processor, coupled to the memory and the transceiver, that configures a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and controls the transceiver to communicate with a user equipment (UE) by using at least one of the first frame and the second frame.

Advantageous Effects of Invention

[11] New frame structure can be configured for new RAT.

Brief Description of Drawings

[12] FIG. 1 shows a wireless communication system.

[13] FIG. 2 shows structure of a radio frame of 3GPP LTE.

[14] FIG. 3 shows a resource grid for one downlink slot.

[15] FIG. 4 shows an example of subframe type for new RAT.

[16] FIG. 5 shows an example of a frame structure for a new RAT according to an embodiment of the present invention.

[17] FIG. 6 shows another example of a frame structure for a new RAT according to an embodiment of the present invention.

[18] FIG. 7 shows an example of nested frame structure for a new RAT according to an embodiment of the present invention.

[19] FIG. 8 shows an example of scheduling of multiple and different TTI via different TTI levels.

[20] FIG. 9 shows an example of overlapped short TTI in a nested frame structure for a new RAT according to an embodiment of the present invention.

[21] FIG. 10 shows another example of overlapped short TTI in a nested frame structure for a new RAT according to an embodiment of the present invention.

[22] FIG. 11 shows another example of a frame structure for a new RAT according to an embodiment of the present invention.

[23] FIG. 12 shows another example of a frame structure for a new RAT according to an embodiment of the present invention.

[24] FIG. 13 shows an example of a nested self-contained subframe according to an embodiment of the present invention.

[25] FIG. 14 shows another example of a frame structure for a new RAT according to an embodiment of the present invention.

[26] FIG. 15 shows another example of a frame structure for a new RAT according to an embodiment of the present invention.

[27] FIG. 16 shows an example of different subcarrier spacing between URLLC and eMBB which are multiplexed in a same carrier or frequency band.

[28] FIG. 17 shows an example of DM-RS sharing according to an embodiment of the present invention.

[29] FIG. 18 shows an example of PUSCH scheduling with DM-RS sharing according to an embodiment of the present invention.

[30] FIG. 19 shows an example of PUCCH scheduling without DM-RS sharing according to an embodiment of the present invention.

[31] FIG. 20 shows a method for configuring a frame structure for a new RAT by a network node according to an embodiment of the present invention.

[32] FIG. 21 shows a wireless communication system to implement an embodiment of the present invention.

Mode for the Invention

[33] Techniques, apparatus and systems described herein may be used in various wireless access technologies such as code division multiple access (CDMA), frequency division multiple access (FDMA), time division multiple access (TDMA), orthogonal frequency division multiple access (OFDMA), single carrier frequency division multiple access (SC-FDMA), etc. The CDMA may be implemented with a radio technology such as universal terrestrial radio access (UTRA) or CDMA2000. The TDMA may be implemented with a radio technology such as global system for mobile communications (GSM)/general packet radio service (GPRS)/enhanced data rates for GSM evolution (EDGE). The OFDMA may be implemented with a radio technology such as institute of electrical and electronics engineers (IEEE) 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802-20, evolved-UTRA (E-UTRA) etc. The UTRA is a part of a universal mobile telecommunication system (UMTS). 3rd generation partnership project (3GPP) long term evolution (LTE) is a part of an evolved-UMTS (E-UMTS) using the E-UTRA. The 3GPP LTE employs the OFDMA in downlink (DL) and employs the SC-FDMA in uplink (UL). LTE-advance (LTE-A) is an evolution of the 3GPP LTE. For clarity, this application focuses on the 3GPP LTE/LTE-A. However, technical features of the present invention are not limited thereto.

[34] FIG. 1 shows a wireless communication system. The wireless communication system 10 includes at least one evolved NodeB (eNB) 11. Respective eNBs 11 provide a communication service to particular geographical areas 15a, 15b, and 15c (which are generally called cells). Each cell may be divided into a plurality of areas (which are called sectors). A user equipment (UE) 12 may be fixed or mobile and may be referred to by other names such as mobile station (MS), mobile terminal (MT), user terminal (UT), subscriber station (SS), wireless device, personal digital assistant (PDA), wireless modem, handheld device. The eNB 11 generally refers to a fixed station that communicates with the UE 12 and may be called by other names such as base station (BS), base transceiver system (BTS), access point (AP), etc.

[35] In general, a UE belongs to one cell, and the cell to which a UE belongs is called a serving cell. An eNB providing a communication service to the serving cell is called a serving eNB. The wireless communication system is a cellular system, so a different cell adjacent to the serving cell exists. The different cell adjacent to the serving cell is called a neighbor cell. An eNB providing a communication service to the neighbor cell

is called a neighbor eNB. The serving cell and the neighbor cell are relatively determined based on a UE.

[36] This technique can be used for DL or UL. In general, DL refers to communication from the eNB 11 to the UE 12, and UL refers to communication from the UE 12 to the eNB 11. In DL, a transmitter may be part of the eNB 11 and a receiver may be part of the UE 12. In UL, a transmitter may be part of the UE 12 and a receiver may be part of the eNB 11.

[37] The wireless communication system may be any one of a multiple-input multiple-output (MIMO) system, a multiple-input single-output (MISO) system, a single-input single-output (SISO) system, and a single-input multiple-output (SIMO) system. The MIMO system uses a plurality of transmission antennas and a plurality of reception antennas. The MISO system uses a plurality of transmission antennas and a single reception antenna. The SISO system uses a single transmission antenna and a single reception antenna. The SIMO system uses a single transmission antenna and a plurality of reception antennas. Hereinafter, a transmission antenna refers to a physical or logical antenna used for transmitting a signal or a stream, and a reception antenna refers to a physical or logical antenna used for receiving a signal or a stream.

[38] FIG. 2 shows structure of a radio frame of 3GPP LTE. Referring to FIG. 2, a radio frame includes 10 subframes. A subframe includes two slots in time domain. A time for transmitting one transport block by higher layer to physical layer (generally over one subframe) is defined as a transmission time interval (TTI). For example, one subframe may have a length of 1ms, and one slot may have a length of 0.5ms. One slot includes a plurality of orthogonal frequency division multiplexing (OFDM) symbols in time domain. Since the 3GPP LTE uses the OFDMA in the DL, the OFDM symbol is for representing one symbol period. The OFDM symbols may be called by other names depending on a multiple-access scheme. For example, when SC-FDMA is in use as a UL multi-access scheme, the OFDM symbols may be called SC-FDMA symbols. A resource block (RB) is a resource allocation unit, and includes a plurality of contiguous subcarriers in one slot. The structure of the radio frame is shown for exemplary purposes only. Thus, the number of subframes included in the radio frame or the number of slots included in the subframe or the number of OFDM symbols included in the slot may be modified in various manners.

[39] The wireless communication system may be divided into a frequency division duplex (FDD) scheme and a time division duplex (TDD) scheme. According to the FDD scheme, UL transmission and DL transmission are made at different frequency bands. According to the TDD scheme, UL transmission and DL transmission are made during different periods of time at the same frequency band. A channel response of the TDD scheme is substantially reciprocal. This means that a DL channel response and a UL

channel response are almost the same in a given frequency band. Thus, the TDD-based wireless communication system is advantageous in that the DL channel response can be obtained from the UL channel response. In the TDD scheme, the entire frequency band is time-divided for UL and DL transmissions, so a DL transmission by the eNB and a UL transmission by the UE cannot be simultaneously performed. In a TDD system in which a UL transmission and a DL transmission are discriminated in units of subframes, the UL transmission and the DL transmission are performed in different subframes. In a TDD system, to allow fast switching between DL and UL, UL and DL transmission may be performed within a same subframe/slot in time division multiplexing (TDM)/frequency division multiplexing (FDM) manner.

[40] FIG. 3 shows a resource grid for one downlink slot. Referring to FIG. 3, a DL slot includes a plurality of OFDM symbols in time domain. It is described herein that one DL slot includes 7 OFDM symbols, and one RB includes 12 subcarriers in frequency domain as an example. However, the present invention is not limited thereto. Each element on the resource grid is referred to as a resource element (RE). One RB includes 12×7 or 12×14 resource elements. The number NDL of RBs included in the DL slot depends on a DL transmit bandwidth. The structure of a UL slot may be same as that of the DL slot. The number of OFDM symbols and the number of subcarriers may vary depending on the length of a CP, frequency spacing, etc. For example, in case of a normal cyclic prefix (CP), the number of OFDM symbols is 7 or 14, and in case of an extended CP, the number of OFDM symbols is 6 or 12. One of 128, 256, 512, 1024, 1536, and 2048 may be selectively used as the number of subcarriers in one OFDM symbol.

[41] 5th generation mobile networks or 5th generation wireless systems, abbreviated 5G, are the proposed next telecommunications standards beyond the current 4G LTE/ international mobile telecommunications (IMT)-dvanced standards. 5G planning aims at higher capacity than current 4G LTE, allowing a higher density of mobile broadband users, and supporting device-to-device, ultra-reliable, and massive machine communications. 5G research and development also aims at lower latency than 4G equipment and lower battery consumption, for better implementation of the Internet of things. Hereinafter, 5G technology may be referred to as new radio access technology (RAT).

[42] In new RAT, utilizing a subframe in which downlink and uplink are contained may be considered. This scheme may be applied for paired spectrum and unpaired spectrum. The paired spectrum means that one carrier consists of two carriers. For example, in the paired spectrum, the one carrier may include a DL carrier and an UL carrier, which are paired with each other. In the paired spectrum, communication, such as DL, UL, device-to-device communication, and/or relay communication, may be

performed by utilizing the paired spectrum. The unpaired spectrum means that that one carrier consists of only one carrier, like the current 4G LTE. In the unpaired spectrum, communication, such as DL, UL, device-to-device communication, and/or relay communication, may be performed in the unpaired spectrum.

[43] Further in new RAT, the following subframe types may be considered to support the paired spectrum and the unpaired spectrum mentioned above.

[44] (1) Subframes including DL control and DL data

[45] (2) Subframes including DL control, DL data, and UL control

[46] (3) Subframes including DL control and UL data

[47] (4) Subframes including DL control, UL data, and UL control

[48] (5) Subframes including access signals or random access signals or other purposes.

[49] (6) Subframes including both DL/UL and all UL signals.

[50] However, the subframe types listed above are only exemplary, and other subframe types may also be considered.

[51] FIG. 4 shows an example of subframe type for new RAT. The subframe shown in FIG. 4 may be used in TDD system of new RAT, in order to minimize latency of data transmission. Referring to FIG. 4, the subframe contains 14 symbols in one TTI, like the current subframe. However, the subframe includes DL control channel in the first symbol, and UL control channel in the last symbol. The remaining symbols may be used for DL data transmission or for UL data transmission. According to this subframe structure, DL transmission and UL transmission may sequentially proceed in one subframe. Accordingly, DL data may be transmitted in the subframe, and UL acknowledgement/non-acknowledgement (ACK/NACK) may also be received in the subframe. In this manner, the subframe shown in FIG. 4 may be referred to as self-contained subframe. As a result, it may take less time to retransmit data when a data transmission error occurs, thereby minimizing the latency of final data transmission. In the self-contained subframe structure, a time gap may be required for the transition process from the transmission mode to the reception mode or from the reception mode to the transmission mode. For this purpose, some OFDM symbols at the time of switching from DL to UL in the subframe structure may be set to the guard period (GP).

[52] Hereinafter, the present invention discusses transmission mechanism and resources used for synchronization signals, physical broadcast channel (PBCH), system information block (SIB) and physical random access channel (PRACH) related procedure for the new RAT, particularly considering forward compatibility in which different UEs are supported with different requirements in terms of radio frequency (RF)/baseband processing capability, latency requirements, power requirements, etc. For example, enhanced mobile broadband (eMBB) high data rate UEs with massive internet-of-things (IoT_ devices with relatively lower data rate and extremely limited

RF/baseband capability may be supported, compared to regular UEs or eMBB high data UEs. However, the present invention which will be described below may be applied to LTE technology wherever applicable.

[53] To allow coexistence of different use cases, at least one of the following aspects may be considered.

[54] - Different RF/baseband bandwidth capability: For example, an IoT device may support only very limited bandwidth such as M MHz of bandwidth or P*one subcarrier spacing. For another example, an IoT device may support 12*one subcarrier spacing (e.g. 12 * 7.5 kHz = 90 kHz).

[55] - Different processing capability in terms of encoding/decoding: For example, an IoT device may not support high processing decoding, such as turbo decoder or low-density parity-check (LDPC). If any common channel is shared among different UEs, this may be taken into account. For this manner, separate SIB may be transmitted per each UE. Alternatively, one main SIB or PBCH may be shared and different branch from the common channel may be allowed.

[56] - Different number of possible concurrent UEs attempting to access the cell: For example, though IoT device may not access the cell frequently, there may be many IoT devices attempting accessing the cell given a time duration. Handling massive UEs may require separate PRACH resource configuration or handling of RACH procedure differently.

[57] - Different synchronization requirement: For example, an IoT device may be supported by joint transmission from multiple cells to improve coverage. This may require larger CP overhead compared to other high data rate UEs.

[58] - Different subcarrier spacing: Due to different synchronization requirement or multiplexing capacity requirements, different subcarrier spacing may be used.

[59] - Different coverage requirement: Depending on use case, coverage and the required repetition numbers may be different.

[60]

[61] 1. Synchronization signal for the new RAT according to an embodiment of the present invention is described.

[62] For example, due to different subcarrier spacing and/or different RF/baseband requirement, synchronization signals, such as primary synchronization signal (PSS)/secondary synchronization signal (SSS), for eMBB and massive machine-type communication (mMTC) UEs may be different from the legacy synchronization signal. For example, synchronization signals for eMBB UEs may be transmitted over larger than M MHz of the lowest bandwidth supported UEs sharing the same spectrum. In this case, at least one of following approaches may be considered.

[63] (1) The common synchronization signals over the minimum system bandwidth (e.g.

M MHz) may be transmitted, and the same density of PSS/SSS may also be transmitted. The density may be determined by the coverage that the network intends to support.

[64] (2) Base sequence of synchronization signal may be transmitted in the minimum system bandwidth with the minimum density required for general UEs. For general UEs, repetition in frequency domain may be considered. And for high coverage requiring UEs, repetition in time domain may be considered. For example, minimum system bandwidth may be 180 kHz with 15 kHz subcarrier spacing with 12 subcarriers, and the bandwidth used for general UEs may be 1.4 MHz which may be repeated 6 times in frequency domain. On the other hand, for high coverage requiring UEs, repetition over multiple subframes may be considered. When repetition occurs in frequency domain, different root sequence may be used (which may affect overall peak-to-average power (PAPR)) or orthogonal cover code (OCC) may be applied over repetitions in frequency domain. Similar mechanism may be applied to repetition in time domain as well. From a UE perspective, if the network supports its UE type, appropriate repetition in either frequency domain or time (or both) domain may be used. In terms of repetition in frequency domain, the repetition may be done consecutively or discontinuously over the frequency.

[65] (3) Base sequence of synchronization signal may be based on synchronization signal system bandwidth designed for general UEs (e.g. 72 subcarriers * subcarrier spacing). For example, if the system bandwidth is K*M MHz, the base sequence may be mapped over k OFDM symbols for UE with lower bandwidth capability. In terms of mapping, M1, M2...Mk may be mapped over K OFDM symbols. Assuming a center frequency of a carrier where synchronization signal is transmitted, center frequency of the system bandwidth/carrier may be the same as the center frequency of synchronization signal for general UEs. Thus, if the channel raster is the same between different UEs, it means that center frequency of synchronization signals for low bandwidth UEs may be offset from the center of general UEs' synchronization signal. This offset may be prefixed. Alternatively, center frequency of system bandwidth/carrier may be the same as the center frequency of synchronization signal for low bandwidth UEs.

[66] (4) Separate synchronization signal may be configured between two types of UEs: In this case, to allow synchronization signal transmissions from different UEs, it is necessary to reserve some frequency regions for different types of UEs. This means that some signals/channels such as beam reference signal (RS) or PBCH or SIB may not be mapped to those reserved regions. At least a few potential regions may be reserved for future use of different system deployment or supporting different types of UEs.

[67] For the reserved regions, the following approaches may be considered. Within the

reserved time resource, any cell-common and/or group-common channels/RS/signals may not be transmitted.

[68] - Frequency resource(s) is reserved: For example, to allow different subcarrier spacing, frequency resource may be reserved. For the reserved frequency resources, the resources aligned with channel raster of low bandwidth UEs or future UEs may be considered. Generally, the same channel raster assumption may be used regardless of UE type. Thus, some frequency location which are aligned with channel raster may be reserved for future uses or supporting some different types of UEs.

[69] - Time resource(s) is reserved: For example, similar to legacy multicast-broadcast single-frequency network (MBSFN) subframe configuration, different types of future use subframes may be considered. In such subframes, one or a few symbols may be still used for control (DL and/or UL) transmissions. Within the reserved time resource, any cell-common and/or group-common channels/RS/signals may not be transmitted.

[70] - Time/frequency resource(s) is reserved: Both time and frequency domain may be considered for the reserved resources.

[71] - Beam direction(s) is reserved: Certain resources associated with a certain beam may be reserved. This implies that subcarrier spacing and/or CP length may be different per beam direction. In case below 6 GHz, this may be associated with a certain channel state information (CSI) RS and its associated virtual cell.

[72] If different subcarrier spacing is used, it may be necessary to fix synchronization signal (if they are common across UEs with different applications/subcarrier spacing values)

[73]

[74] 2. Empty frequency/time resources

[75] It is expected that some resources should be reserved for potential new services in future. The reason of reserving some frequency/time resource is to allow potentially different numerology (such as subcarrier spacing/CP length) and/or potentially different frame structure. In this sense, it is important to not allocate any available resources in frequency and time domain to one specific application. For example, the system bandwidth may not be entirely used for transmission of cell-specific signals, such as reference signals and channels. Also, it may be desirable to reserve some resources over the entire frequency domain rather than reserving some resources at the edge of system bandwidth. In this sense, it may be generally desirable to transmit any cell-specific RS and/or channel in rather discontinuous frequency resources. For example, PBCH may be transmitted in PRBs which are rather distributed over the system bandwidth, assuming minimum bandwidth. For example, if the minimum bandwidth is 20 MHz, and the number of PRBs are 20 with 75 kHz subcarrier spacing and PBCH uses 6 PRBs in one TTI, instead of placing PBCH in a contiguous 6 PRBs,

PBCH may be transmitted over 1 PRB in every 3 PRBs (or 2 PRBs excluding some PRBs used for synchronization signals). By this way, at least one or a few PRBs between PBCH PRBs may be reserved for some other future uses. Since additional RS and/or channels (cell-specific) may be transmitted in one TTI or one OFDM symbol, it may be also desirable to have discontinuous transmission of such RS/channels as well. Overall, the idea is to reserve at least one or a few subcarriers/RBs between two consecutive cell-specific RS/channels for future uses. The location of cell specific RS/channels may be determined based on cell ID and/or subframe and/or radio frame and/or frame index.

[76] Alternatively, signal system bandwidth may be signaled in synchronization signal where different frequency region can be used for different applications. For example, transmission of cell-specific RS may be different based on system bandwidth.

[77]

[78] 3. Frame structure

[79] It is expected that different frame structure may be necessary for the new RAT. Particularly, different frame structure in which UL and DL may be present in every subframe or may change very frequently in the same carrier may be necessary for the new RAT. Different application may require different minimum size of DL or UL portions to support different latency and coverage requirements. For example, mMTC for high coverage case may require relatively long DL and UL portion so that one transmission can be successfully transmitted. Furthermore, due to different requirement on synchronization and tracking accuracy requirements, different subcarrier spacing and/or different CP length may be considered. In this sense, it is necessary to consider mechanisms to allow different frame structures coexisting in the same carrier and be operated by the same cell/eNB.

[80] For the convenience, it is assumed in the description below that a frame structure type 1 (FS1) and a frame structure type 2 (FS2) are configured and coexist in the same carrier. The FS1 may be a baseline frame structure used for such as for eMBB use cases or typical use cases. The FS2 may be used for some other applications such as mMTC, ultra-reliable and low latency communication (URLLC), an enhanced vehicle-to-everything (eV2X) communication. The network or a cell may support one or multiple frame structures at the same time. For the convenience, the present invention may discuss relationship between two frame structures. However, more than two frame structures may be supported simultaneously.

[81]

[82] A. FS2 for mMTC/URLLC in FDD case

[83] In this case, one TTI of FS2 may consist of a few (e.g. 'm') TTIs of FS1. For example, if one TTI of FS1 is X ms, one TTI of FS2 may be 'm'*X ms. For de-

termining 'm', at least one of the following approaches may be considered.

[84] - 'm' may be predetermined. 'm' may be different per frequency or frequency range or frequency bands. To support variable coverage level or repetition level, it may be desirable to have different 'm' per repetition level. 'm' may be 2^N , where N=0,...P.

[85] - 'm' may be determined based on subcarrier spacing used for mMTC. For example, if 15*K1 kHz subcarrier spacing is used for FS1, and 15 kHz subcarrier spacing is used for FS2, 'm' may be same as K1 or multiple of K1.

[86] - Combination of the above two approaches may also be considered.

[87] FIG. 5 shows an example of a frame structure for a new RAT according to an embodiment of the present invention. Referring to FIG. 5, it is shown that FS1 is the same as the conventional frame structure, as one TTI includes 14 symbols. That is, one TTI of FS1 is 1 ms. On the other hand, one TTI of FS2 is 'm' ms. 'm' may be predetermined. Or, 'm' may be determined based on subcarrier spacing used for mMTC.

[88] If different subcarrier spacing is used, it may be necessary to have a gap between two different subcarrier regions. Also, for transmission of synchronization signals, collision between FS1 OFDM symbol carrying PSS and/or SSS and FS2 OFDM symbol carrying PSS and/or SSS should be avoided. For this, FS1 and FS2 may be configured by TDM manner. For this, in terms of system information or master information block (MIB) signaling, a set of subframes not usable may be configured. In other words, the set of available subframes for each FS may be signaled by each system information carried in each FS respectively. However, a set of available TTIs/subframes may not reflect the case where one or a few OFDM symbols within one TTI should not be used. For example, one OFDM symbol of FS2 colliding with synchronization signal(s) of FS1 may be excluded/punctured/rate matched. One or a few patterns of available OFDM symbols per TTI may be configured and signaled per each FS or to FS2. For example, patterns may be {all OFDM symbols available}, {the first symbol is not available}, {the first symbol in each slot is not available}, etc.

[89] Alternatively, CP length of FS2 may be configured smaller than m*CP length of FS1. The remaining portion may be used for gap or blank region between FS1 and FS2.

[90] FIG. 6 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. Referring to FIG. 6, like FIG. 5, one TTI of FS1 is 1 ms, and one TTI of FS2 is 'm' ms. However, CP length of FS2 is configured smaller than m*CP length of FS1, so gap occurs at the end of FS2. PSS/SSS of FS1 may be transmitted in gap of FS2, in order to avoid collision.

[91] Alternatively, when FS2 is constructed, additional gap may be considered, regardless of CP length, such that PSS/SSS (and also necessary system bandwidth wide signals such as CSI-RS, extended synchronization signal (ESS)) can be transmitted. In other

words, one or a few OFDM symbols may be reserved for some other purposes in FS2. For reservation, different CP may be configured so that the number of OFDM symbols within one TTI can be totally smaller than the size of one TTI (e.g. OFDM symbol size of 80 us*12 = 960 us in 1ms TTI leaves 40 us gap). Or, some OFDM symbols may be reserved for further uses. The future use or some other uses may include CSI-RS transmission, UL control transmission, DL control transmission, etc. Depending on reason of reservation, the gap may be formed in the beginning of each TTI (or multiple TTIs) or end of each TTI (or multiple TTIs). To support this, system bandwidth side signals of FS1, such as CSI-RS, ESS, PBCH, etc., may be transmitted in the beginning of TTI or ending of the TTI such that reservation on FS2 may be placed in the beginning or ending of TTI of FS2.

[92] Meanwhile, in order to reduce latency, short TTI which may be shorter than current TTI (i.e. 1ms) has been considered. For example, length of short TTI may be one of 1/2/3/4/7 symbols. When a short TTI is introduced for latency reduction in LTE, E-UTRAN may be configured with both normal TTI with 1ms and short TTI with a value less than 1ms, such as 1 symbol or 0.5ms. With keeping the current LTE frame structure, OFDM symbol length, subcarrier spacing, etc., reduction of TTI generally means smaller transport block size (TBS) contained in one TTI, and relatively larger control overhead if DCI size is kept as the same.

[93] When short TTI is adopted, and as a result, the number of OFDM symbols in reduced in one TTI (e.g. from 14 to 2) or subcarrier spacing increases (e.g. from 15 kHz to 60 kHz), a RB size may be different from the current RB size. For example, with subcarrier spacing of 60 kHz, one RB may include 12×8 resource elements, instead of 12×14 resource elements. For another example, when TTI length is 2 OFDM symbol length, one RB may include 12×2 resource elements. If short TTI is used, particularly with smaller number of OFDM symbols, larger RB size in frequency domain may be considered (e.g. one RB includes 48×2 resource elements).

[94] It is generally desirable to use short TTI for control. However, it may increase control overhead and thus decrease the overall performance benefit with short TTI operation. Thus, it may be desirable to support different TTI length per different application/packet.

[95] Hereinafter, as a proposal for FS2, a nested frame structure using short TTIs according to an embodiment of the present invention is described. It is assumed that "K" different levels (or lengths) of short TTIs is supported in the network. For example, level 1 may correspond to the legacy TTI length (e.g. 14 OFDM symbols with normal CP), which means 1 TTI in the network. Level 2 may correspond to 7 OFDM symbols, which means 2 TTIs in the network, and so on.

[96] FIG. 7 shows an example of nested frame structure for a new RAT according to an

embodiment of the present invention. Different TTI length may be used between FS1 and FS2. FIG. 7-(a) corresponds to level 1, in which one TTI includes 14 OFDM symbols. Level 1 may be called FS1. FIG. 7-(b) corresponds to level 2, in which one short TTI includes 7 OFDM symbols. That is, one TTI of FS1 includes two short TTIs of FS2. FIG. 7-(c) corresponds to level 3, in which one short TTI includes 3/4 OFDM symbols. That is, one TTI of FS1 includes 4 short TTIs of FS2. FIG. 7-(d) corresponds to level 4, in which one short TTI includes 1/2 OFDM symbols. That is, one TTI of FS1 includes eight short TTIs of FS2.

[97] Accordingly, depending on the needed number of short TTIs within one TTI (from 1 to 8, and 14), short TTIs may be placed. However, in FIG. 7-(c), instead of 4/3/4/3 OFDM symbols for short TTIs, 3/4/3/4 OFDM symbols or 3/4/4/3 OFDM symbols or 3/3/4/4 OFDM symbols or 4/4/3/3 OFDM symbols may be used. Similar rotation for 1/2 OFDM symbol may also be applied to FIG. 7-(d). In case of 1 OFDM symbol case, total of 14 short TTIs may be placed. Similar mechanisms may be applied to different OFDM symbols per TTI (e.g. 12 or 10). The proposed frame structure described above may allow that short TTI may be nested to the next level short TTI. In other words, one short TTI of one level may be divided to 2 short TTIs of the next level (except from 8 short TTIs to 14 short TTIs).

[98] In the proposed frame structure, the first one or two OFDM symbols of DL may be used for legacy control region, and the last OFDM symbol of UL may be reserved for sounding reference signal (SRS) transmission (or to minimize the impact by legacy SRS). In terms of SRS transmission for a short TTI supporting UE, the following two approaches may be considered.

[99] (1) If additional SRS configuration is given to short TTIs, a UE may transmit additional SRS according to short TTI configuration. If additional SRS transmission is considered, SRS may be transmitted in the last OFDM symbol of the configured short TTI for level 2 TTI structure. For level 3 and 4, the first OFDM symbol may be used for SRS except for the last short TTI in the legacy TTI. This additional SRS configuration may be cell-specific and may be configured per each TTI configuration. Thus, potentially multiple SRS configuration may be given. A UE configured with one level may perform rate matching or puncture in cell-specific SRS configuration of higher levels (i.e. shorter TTIs) to protect SRS. For example, if a UE is configured with level 2, and the cell also configures SRS for level 3, the UE may puncture or performing rate matching around SRS symbols of level 3.

[100] (2) Only legacy SRS configuration may be used, and additional SRS transmission in short TTI may not be used.

[101] More specifically, in FDD, option (2) above may be used. In TDD, option (1) may also be considered.

[102] With the nested frame structure, a UE supporting short TTI may be configured with multiple short TTI levels for control channel monitoring. For example, if level 4 is configured, the UE may monitor control channel in OFDM symbol 0 (possibly for legacy PDCCH), OFDM symbols 2, 4, 6, 7, 9, 11, and 14. In each short TTI, the multiple TTIs or variable TTI may schedule up to the maximum number of total short TTIs in the legacy TTI or multiple of the maximum short TTI numbers (e.g. 8 or 8*k in this example). For example, if a UE is scheduled with 4*sTTI in 2nd short TTI with level 2, PDSCH may be scheduled in 2nd, 3rd, 4th, 5th short TTIs, which in total of 7 OFDM symbols in length. The level may be determined by short TTI length used for control channel monitoring. More specifically, if the first short TTI schedules PDSCH, and the legacy PDCCH length is equal or larger than the size of short TTI, data may not be mapped to the fully overlapped short TTI. However, it may be counted for multiple TTIs scheduling. In other words, data may be rate matched, though it has been scheduled.

[103] It may be good to restrict the size of data channel only for a few cases (e.g. 1 symbol, 2 symbols, 4 symbols, 7 symbols and 12 symbols). It may be required by the network to schedule data properly not to vary the size of PDSCH in terms of OFDM symbols. For this, similar to ACK/NACK transmission, the timing from control channel to data channel may be considered. The timing from control channel to data channel may be signaled via number of short TTIs where short TTI length can be determined by sPDCCH TTI length (e.g. level 4). Alternatively, the basic short TTI length for ACK/NACK may also be determined by higher layer separately. In other words, a basic short TTI length or the level of short TTI used in DL and UL may be configured, respectively. Based on the basic short TTI length, multi/variable TTI scheduling which allows scheduling longer than the configured TTI length may be considered. If the first symbol is reserved for control channel in every short TTI, PDSCH may be rate matched in such OFDM symbols. Otherwise, data may be transmitted in the first control region of every short TTI as well, and data may be rate matched around its own scheduling DCI. Multi/variable TTI scheduling may be expanded to the next longer short TTI or level 1 TTI. If level 4 is used, data may not be scheduled in the same short TTI if the short TTI length is 1 OFDM symbol. For example, only 2 bits of 1, 2, 4, 8 multiple short TTIs may be scheduled in level 4 which allows PDSCH transmission ends aligned with the next higher level short TTI.

[104] FIG. 8 shows an example of scheduling of multiple and different TTI via different TTI levels. Referring to FIG. 8, legacy PDCCH may schedule PDSCH of level 1, 2, 3 and 4. PDCCH of each level may schedule PDSCH of each level. That is, PDCCH of level 2 may schedule PDSCH of level 2, PDCCH of level 3 may schedule PDSCH of level 3, and PDCCH of level 4 may schedule PDSCH of level 4.

[105] One drawback of the nested frame structure described above is that it leads different TTI lengths among short TTIs in the same level. To overcome this problem, partial overlap between two short TTIs may be considered.

[106] FIG. 9 shows an example of overlapped short TTI in a nested frame structure for a new RAT according to an embodiment of the present invention. That is, in the nested frame structure, short TTIs may be overlapped/shared to allow 2^N symbols per TTI. FIG. 9-(a) shows level 5 in which 16 short TTIs, instead of 14 short TTIs, are configured. In order to configure 16 short TTIs, fourth OFDM symbol are shared between TTI #3 and TTI #4, and eleventh OFDM symbol are shared between TTI #11 and TTI #12. FIG. 9-(b) shows level 4 in which 8 short TTIs are configured. In order to configure 8 short TTIs which has the same length, fourth OFDM symbol are shared between TTI #1 and TTI #2, and eleventh OFDM symbol are shared between TTI #5 and TTI #6. FIG. 9-(c) shows level 3 in which 4 short TTIs are configured. In order to configure 4 short TTIs which has the same length, fourth OFDM symbol are shared between TTI #0 and TTI #1, and eleventh OFDM symbol are shared between TTI #2 and TTI #3. 9-(d) shows level 2 in which 2 short TTIs are configured. In order to configure 2 short TTIs which has the length of 8 OFDM symbols, seventh and eighth OFDM symbols are shared between TTI #0 and TTI #1. The embodiment shown in FIG. 9 is only exemplary, and actual OFDM symbol which is shared between different short TTI may be changed. The idea is to allow some OFDM symbols overlapped among different short TTIs to align short TTI lengths.

[107] The drawback of the above approach is that control/data between two different short TTIs may be overlapped in the overlapped OFDM symbols, which may affect the overall FDM performance of control/data channels. However, if data and control is multiplexed by FDM, this overlap between control and data may be manageable if TDM between control and data is assumed. Alternatively, as the issue becomes more significant in level 2, overlap may not be considered in level 2.

[108] FIG. 10 shows another example of overlapped short TTI in a nested frame structure for a new RAT according to an embodiment of the present invention. Referring to FIG. 10, short TTI length may be configured as 7 actual OFDM symbols and fourth OFDM symbol may be mapped to #3 and #4 in each slot, respectively.

[109] The above approach may be applied to other levels as well. This may be explained that virtually there are 16 OFDM symbols which are mapped to physically 14 OFDM symbols. In this way, the design working for 16 OFDM symbols may be incorporated to 14 OFDM symbols cases (and vice versa). More specifically, in case from 16 OFDM symbols to 14 OFDM symbols, one OFDM symbol may be dropped between #3 and #4. In case from 14 OFDM symbols to 16 OFDM symbols, OFDM symbol #3 may be repeated. In terms of sharing OFDM symbol, at least in TDD, it is desirable to

use OFDM symbol #3 (in normal CP) in each slot may be preferable considering DM-RS position.

[110] When OFDM sharing is used, the number of OFDM symbols of multi/variable TTI scheduling may consider actual number of OFDM symbols in which multiple TTIs are spanning. In this sense, the total number of scheduled length may be smaller than multiple of short TTI length. This approach may allow that the number of OFDM symbols in each short TTI is 2^N, where N is 0, 1, 2...K depending on the necessity of latency and UE processing power requirement. In the overlapped short TTI with level 5 (e.g. TTI #3 and #4), it may be necessary to indicate which TTI is used for control and/or data channel, which may be differentiated via scrambling of control/data (some other means may also be considered). This may be particularly important when HARQ-ACK timing is determined based on 2^N number of OFDM symbols or the number of short TTIs in one the largest TTI size. For example, if TTI #3 schedules with gap of 2 TTI for sPDSCH, this may imply that PDSCH will be scheduled in TTI #5 (which is next OFDM symbol to TTI #3), thus, the gap may be in fact one short TTI. This may simplify the operation if system may require operating in multiple different levels of short TTI lengths. The similar concept may be used for UL as well. In UL, collision in the same resource between two short TTIs with level 5 may be considered as collision and transmission on one channel may be dropped per rule (if the network schedules collisions). For example, the rule may be configured based on uplink control channel information (UCI) priority or based on timing.

[111] For one example of the nested frame structure, if FS1 consists of 30 subframes, one subframe may be overlapped between two TTIs for FS2. If mMTC UE is scheduled in those overlapped TTIs, it may be counted only one as valid. Alternatively, instead of overlap of two TTIs, different TTI lengths may be configured. For example, level 2 of FS2 may have l TTIs with 2/2/2/2/1/2/2/2 in 1.5 ms range. Alternatively, reserve some resources may be reserved not used by mMTC devices. Those reserved resource blocks may be placed in any subframes consecutively or discontinuously. Alternatively, different levels may be defined by multiple of previous level's TTI length.

[112]

[113] B. Frame structure for mMTC in TDD case

[114] The above frame structure may be applied to a frame structure for mMTC in TDD. Additionally, in TDD, two different frame structures may be considered. One is a frame structure in which DL/UL switching may occur in a multiple TTI unit similar to current LTE TDD DL/UL configuration. The other is a frame structure that DL/UL switching may occur in every TTI to allow efficient DL and UL transmission and ACK/NACK transmission. For the latter case, DL control region and UL control region may need to be used for DL and UL, respectively, unless the network supports

full duplex capability. If the network does not support full duplex capability, thus, it may be necessary to align DL portions between FS1 and FS2. For this, the following two approaches may be considered.

[115] (1) FS1 configuration of DL/UL may be given to UEs of FS2, and UEs of FS2 may construct DL portion and UL portion according to DL/UL configuration of FS1. For example, if subcarrier spacing of FS2 is 2 times that of FS1, and the configuration of DL/UL configuration is DDDDDUUUUU (where D indicates subframes in which PDSCH may be transmitted, and U indicates subframes in which PUSCH may be transmitted), then DL and UL portion of FS2 may be constructed as DDSUU, where D indicates DL control and PDSCH portions can be used for DL and U indicates PUSCH portion and UL control portion can be used for UL.

[116] (2) FS2 configuration of DL/UL may be given to UEs of FS1, and UEs of FS1 may assume that subframe type (either PDSCH or PUSCH) may be determined by FS2 configuration, unless it's dynamically changed via scheduling or dynamic indication per each TTI. For example, assuming that the subcarrier spacing of FS2 is two times of that of FS1, FS2 may indicate DDDDDUUUUU. It may imply that default DL/UL configuration of FS1 is DDDDDDDDDDUUUUUUUUUU. More generally, a default DL/UL configuration of FS1 may be configured, and it may be overwritten by dynamic indication of subframe type change and/or via scheduling (e.g. DL grant or UL grant). Higher layer reconfiguration may also be considered.

[117] In terms of configuration of FS1 default DL/UL configuration type, a subset of TTIs/subframes with fixed D or U may be configured. Those fixed subframes may not change the subframe type either via dynamic singling or dynamic scheduling. For FS2, those fixed subframes may be at least used. For other subframes, additional configuration of subframe type and/or DL/UL configuration and/or availability for FS2 UEs' usage may be configured.

[118] Alternatively, In terms of configuration of FS1 default DL/UL configuration type, different types of subframe to FS1 UEs and FS2 UEs may be configured and FS1 UEs and FS2 UEs are multiplexed by FDM between DL and UL. FS1 UEs may be further classified between FS1 UEs with eMBB use cases and FS1 UEs with eV2X use cases. In other words, a subset of subframes with "D" type subframes may be fixed such that measurement signals and/or cell system bandwidth wide and/or cell specific signals/channels can be transmitted. For other subframes, the subframe type may be indicated as "U" from FS1 UE perspective such that sidelink resources can be configured/used in those resources, whereas the subframe type can be indicated as "D" from FS2 UE perspective. From the network perspective, the resource may be shared among FS1 and FS2 UEs and the network may transmit DL signals towards FS2 UEs. This may be applied to the same FS UEs depending on its communication/discovery types as well.

In other words, partial resources may be allocated for sidelink resources which can be multiplexed by FDM with DL resources in the same TTI. However, from a UE perspective, it may either perform DL or SL transmission.

[119]

[120] C. Frame structure for URLLC in TDD case

[121] The above frame structure with different subcarrier spacing may be applied to a frame structure for URLLC in TDD. If short TTI needs to be used for FS2, more DL/UL switching points within one TTI or different subframe type may be used. Or, if shorter OFDM symbol lengths are used for URLLC UEs for FS2, in one TTI of FS1, there may be different OFDM symbols used for DL and UL between FS1 and FS2.

[122] If the network does not support full duplex capability, it seems to be difficult to support different DL and UL in the same OFDM symbol duration. To minimize the impact, partial DL or UL transmission may be used in FS1. In partial DL or UL transmission, a UE may be scheduled with only one slot PDSCH or PUSCH transmission (if subcarrier spacing of FS2 is twice of FS1). In this case, the network may transmit data and then switch to UL and process URLCC uplink data. More generally, if FDM between FS1 and FS2 with different subcarrier spacing is used with potentially different UL/DL direction between FS1 and FS2, length of PDSCH or PUSCH scheduling and/or starting OFDM symbol index of PDSCH/PUSCH may be configured. Supporting partial PDSCH/PUSCH may be enabled by higher layer or dynamically indicated via common signaling or DCI or some signaling. Furthermore, FS2 needs to ensure DL control portion and UL control portion of FS1. Thus, first a few OFDM symbols may be used for DL control portion and last few OFDM symbols may be used for UL control portion. To minimize the DCI overhead, partial subframe length may be higher layer configured, and only starting position may be signaled. 0 or 1 may be used between partial and full TTI scheduling. Alternatively, it may also be combined with multiple TTI scheduling as well. Accordingly, partial TTI scheduling may be one of multi-TTI scheduling option.

[123] FIG. 11 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. FIG. 11 shows examples of frame structures when short TTIs are used in TDD. This may be treated similar to the above case with FDD, assuming that the last short TTI or first short TTI may not be used and gap symbol may be punctured or rate matched. FIG. 11-(a) corresponds to level 1, i.e. FS1. FIG. 11-(b) corresponds to level 2 of FS2, in which one short TTI consists of 6 OFDM symbols. 2 short TTIs are configured in one TTI of FS1. FIG. 11-(c) corresponds to level 3 of FS2, in which one short TTI consists of 3 OFDM symbols. 4 short TTIs are configured in one TTI of FS1. FIG. 11-(d) corresponds to level 4 of FS2, in which one short TTI consists of 1/2 OFDM symbols. For DL, short TTIs having 2/1/2/1/2/1/2/1

OFDM symbols are configured, and for UL, short TTIs having 1/2/1/2/1/2/1/2 OFDM symbols are configured. 8 short TTIs are configured in one TTI of FS1. FIG. 11-(e) corresponds to level 4 of FS2, in which one short TTI consists of 2 OFDM symbols. 6 short TTIs are configured in one TTI of FS1.

[124] Meanwhile, similar to FDD case, different layout may also be possible. For example, if guard period or switching from DL to UL takes more than one OFDM symbol, portioning of short TTIs may be changed. Depending on the network capability, short TTI of FS2 may have different direction from FS1.

[125] For both FDD and TDD, in terms of scheduling, FS1 UE may also be scheduled with FS2, and where only data portion may be mapped over multiple TTIs of FS2. In terms of resource mapping, UEs of FS1 may be configured with the size of FS2 (if any), and the bitmap may indicate the data mapping to a set of short TTIs of FS2. For example, if a case of FIG. 11-(e) is used, bitmap of 6 bits may be used to indicate to which short TTIs FS1 UE PDSCH can be mapped. For example, [1 1 1 1 0 0] may indicate that PDSCH is mapped to first four short TTIs, is not mapped to the last two short TTIs. Depending on the latency requirement, different level of short TTIs may be used for each packet. In terms of scheduling, a UE supporting short TTI may monitor DL control region in the lowest level that the network supports (which may be signaled by SIB or higher layer), or the level may be configured per UE or per session or per application. It is also possible that short TTI transmission may start in the middle of longer TTI transmission. In this case, preemption of longer TTI transmission may also be possible. To minimize the impact from this preemption, the network may send a common signal in short TTI control region which indicates whether there is any short TTI transmission or not. Alternatively, a longer TTI UE may perform blind search on data. Alternatively, in the next longer TTI control, the network may indicate whether there was interrupt in the previous transmission or not, and if so, the network may further indicate which short TTIs have been used.

[126] In summary, the proposed frame structure may allow that shorter TTIs can be nested to the next level of short TTI. In other words, one TTI of one level may be divided to 2 short TTIs of the next level (except from 4 short TTIs to 6 short TTIs and 6 short TTIs to 12 short TTIs if nested frame structure for 8 short TTIs is not used, and if the nested frame structure is used, only exception from 8 short TTIs to 12 short TTIs). Similar to FDD case, the order between 1/2 in 8 short TTIs case may be changed. This nested frame structure may allow multi-TTI scheduling a bit easier. For example, the shortest TTI may be configured to allow potentially many control possibilities with multi-TTI scheduling to [1...N], where N is the level of the configured short TTI level.

[127] FIG. 12 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. If DL and UL portion is equal within one TTI,

potentially limited number of levels may be supported for short TTIs. Referring to FIG. 12, only level 1, level 2, and level 3 are supported. FIG. 12-(a) corresponds to level 1, i.e. FS1. FIG. 12-(b) corresponds to level 2 of FS2, in which one short TTI consists of 6 OFDM symbols. 2 short TTIs are configured in one TTI of FS1. FIG. 12-(c) corresponds to level 3 of FS2. For level 3, short TTI size of 2 OFDM symbols may be considered (in total of 3 short TTIs per DL/UL) or 1/2/1/2 (or 2/1/2/1) short TTI lengths may be considered to support 4 short TTIs.

[128] UL switching symbol may be placed in any OFDM symbol in subframe with DL transmission. In other words, gap for DL to UL switching may be placed in any OFDM symbol which will be used by UE for switching. From DL perspective, the gap and UL symbols may be rate matched or punctured. From UL perspective, the gap and DL symbols may be rate matched or punctured.

[129]

[130] D. Frame structure for eV2X in FDD

[131] In this case, sharing among UEs transmitting towards the network needs to share UEs transmitting sidelink. The resource allocation mechanism or frame structure of eV2X UEs may be similar to other FS1 UEs. From a V2X UE perspective, if the same RF/ baseband capability of DL is used for both reception from the network and reception from other UEs, it may be necessary to separate DL resources between two transmission types.

[132] Similar mechanisms used in TDD case may be applied to FDD case as well, where sidelink resources may be configured in either DL or UL spectrum. The TTI length of sidelink may also be reduced to allow DL control reception and/or gap creation. Similar approach to place SL DL/UL control may be considered. In this case, if sidelink is only configured in UL spectrum, DL control may not be considered. If sidelink is configured in DL spectrum, UL control may not be considered. Alternatively, UL and DL spectrum may be used in a pair among different cells for different UEs. For example, a set of subframes may be fixed as DL or UL in each DL and UL spectrum. These configured subframes may not be configured as sidelink resources in either DL or UL spectrum. Other subframes in either DL or UL may be used for sidelink operation, like multi-carrier sidelink operation. Each UE may determine reception frequency and transmission frequency between DL and UL spectrum. Once it determines its direction, the UE will continue receiving or transmitting in one frequency and do opposite in the other frequency. In other words, other than fixed subframes, flexible subframes in either DL or UL may be used, like one carrier from a sidelink perspective similar to TDD case. More generally, TDD case may be applied in those flexible subframes, and DL carrier may include DL control in each TTI depending on configurations and UL carrier may include UL control in each TTI

depending on configuration.

[133]

[134] E. Frame structure for eV2X in TDD

[135] If TDD is used for eV2X, FS1 may be configured. Depending on its subframe type configuration of FS1, subset of UL portions may be used for sidelink operation (possibly except for UL control regions). Alternatively, a subset of subframes may be configured with subframe type, and the other subframes may be determined based on higher layer signaling and/or dynamic signaling. For example, non-DL subframe may be potentially allowed as sidelink capable subframes, then which subframes are usable for sidelink operation may be dynamically indicated by scheduling assignment (SA) transmission. In this case, to avoid any ambiguity, the SA may be transmitted in fixed UL subframe configured in MIB and/or SIB.

[136] IF DL control is potentially used in flexible subframes (i.e. flexible subframe is a subframe without configured subframe type via MIB and/or SIB), it may be desirable to avoid use of potential DL control portion in sidelink operation to minimize interference to other UEs, and potentially allow listening on DL control by eV2X UEs. In this case, DL control and potentially a gap to switch from DL to UL may be assigned in every flexible subframe. Alternatively, a subset of subframes with DL control may also be preconfigured, and a UE may assume that the first one or a few OFDM symbols may not be used for sidelink transmission in such subframes. To align resources among different cells, cells may be coordinated including DL control portions. Or, simply one or a few first OFDM symbols may always not be used for sidelink transmission in every TTI.

[137] Alternatively, subframe type for FS1 may be ignored and only sidelink resource information may be considered. For example, the network may perform FDM approaches between DL and UL between FS1 UEs receiving the data from the network and sidelink UEs.

[138] Whether to reserve DL control and UL control may be determined by at least one of the following approaches.

[139] - The network may configure the length of sidelink resource used in one TTI or the necessity of DL control and/or UL control region reservation. This may also allow flexible configuration of DL and UL control resource from network perspective. Only DL control portion may be reserved.

[140] - The UE may determine whether to reserve DL control and UL control depending on communication/discovery type. If the network controlled communication/discovery is used, DL control may be reserved. Otherwise, full TTI may be used for sidelink transmission. The gap may be used between DL and UL direction to minimize interference.

[141] - The resource may also include TTI size per each TTI in resource configuration.

[142] - It may be prefixed or follow a rule to determine the size.

[143] When each cell uses dynamic subframe type, different interference may be expected depending on subframe type on sidelink resources. In this sense, a subset of default UL subframes may be configured, and at least control channels of sidelink (such as SA) may be transmitted in those UL subframes. Those fixed UL subframes may be aligned among neighbor cells to minimize the interference among cells (similar concept may also be applied to DL as well).

[144] Also, ACK/NACK and control information for sidelink operations may be supported. Thus, sidelink DL control (configuration of sidelink resources, collision handling, etc., where all UEs except for the controlling UEs are supposed to listen) and ACK/NACK or feedback resource of sidelink (called sidelink UL control) should be placed somewhere. For this, at least one of the following options may be considered.

[145] - Option 1: Sidelink SL control may be multiplexed with DL/UL control by FDM (same direction): Or, the same OFDM symbol for DL control may be used for sidelink DL control and the same OFDM symbol for UL control may be used for sidelink UL control. It may follow the network configuration and the same configuration may be indicated to other UEs. This may be beneficial for relay nodes or UEs without network controlled operation. If this option is used, proper gap or interference mitigation between DL control and sidelink DL control may be assumed.

[146] - Option 2: Sidelink control FDM may be multiplexed with DL/UL control by FDM (opposite direction): Or, sidelink DL control may be placed in UL control region and sidelink UL control may be placed in SL DL control region to minimize the interference, assuming that interference from a UE to the network may be less significant to interference between UEs.

[147] - Option 3: Nested self-contained subframe

[148] FIG. 13 shows an example of a nested self-contained subframe according to an embodiment of the present invention. Referring to FIG. 13, sidelink DL control and/or sidelink UL control may be placed only in resources configured for sidelink operation. Depending on UE capability, gap from sidelink DL control to sidelink-transmit may be necessary. Depending on UE timing advance (TA) and other UL timing, gap between sidelink DL-receive to sidelink UL control may also be necessary. To allow a gap, it may be generally desirable not to use the last OFDM symbol for sidelink. In this case, either sidelink UL control or sidelink DL control may be placed in the second next to the last OFDM symbol.

[149] If the last OFDM symbol is used for UCI transmission toward to the network, it may not be used for the gap. To handle this case, a UE may create a gap by not receiving the next OFDM symbol if the next subframe is also used for sidelink. In this case,

sidelink UL control may be omitted and a UE may not receive sidelink DL control. To avoid such a case, if there is possibility of UCI transmission in the last OFDM symbol, it may be desirable to add one additional gap in the first OFDM symbol of the TTI.

[150] Overall, the followings may be considered for sidelink frame structure. TTI length of a sidelink may be at least 2 * gap OFDM symbols smaller than TTI length of host frame structure (e.g. if the gap size is 1 OFDM symbol, 2 OFDM symbols smaller than the FS1). Further, sidelink DL control and sidelink UL control may be placed in next to DL control and UL control (after and before) in the same TTI. If the gap is necessary to switch from sidelink DL/UL control to DL/UL control, the following order of priorities, UL control, sidelink DL/UL control, and DL control, may be used. If there is no sufficient gap is created by dropping lower priority, the next lower priority channel may be dropped.

[151]

[152] 4. Additional frame structure design for URLLC considering U-plane latency

[153] In the new RAT, scalable numerology may be considered. Some candidates of subcarrier spacing include 15 kHz, 30 kHz, 60 kHz, 120 kHz, etc. Among those, at least 15, 30, 60 kHz subcarrier spacing may be applied for under 6 GHz frequency band. Considering that the requirement of URLLC is 0.5ms for U-plane latency, some consideration on frame structure may be necessary. To minimize the overall U-plane latency, UL subframe boundary may be shifted. Assuming that data at L2/L3 queue may be scheduled to the next available subframe, the average latency may be 0.5*TTI. Assuming that UL subframe boundary is shifted by decoding latency of data channel, the latency to get the data at L2 at the destination side (without considering HARQ process) may be around 2*TTI.

[154]

[155] A. Frame structure for URLLC in FDD

[156] If HARQ process is considered, in FDD, since UL can be available anytime, the latency to encode ACK/NACK and TA may be added with HARQ retransmission latency. Overall, it may become 2.8*TTI (around 3*TTI).

[157] Table 1 shows an example of numerologies for normal CP and extended CP with 30 kHz spacing.

[158] [Table 1]

	eMBB - NCP	eMBB - ECP	URLLC - NCP	URLLC - ECP
OFDM symbol	33.34	33.34	33.34	33.34
Number of OFDM symbols in a TTI	14	12	4/3/4/3 in 0.5 ms	Option 1: 3 symbolsOption 2: 4 symbols
TTI length	0.5 ms	0.5 ms	0.1425/0.1075/0.1425/0.1075 ms	0.125 (with Option 1)0.16667 (with Option 2)
CP length	Half of LTE CP in NCP case	8.33us	Half of LTE CP in NCP case	8.33us

[159] Table 2 shows an example of numerologies for normal CP and extended CP with 15 kHz spacing.

[160] [Table 2]

	eMBB - NCP	eMBB - ECP	URLLC - NCP	URLLC - ECP
OFDM symbol	66.67 us	66.67 us	66.67 us	66.67 us
Number of OFDM symbols in a TTI	14	12	2	2 symbols
TTI length	1 ms	1 ms	0.143 ms	0.1667
CP length	Half of LTE CP in NCP case	Half of LTE CP in ECP case	Half of LTE CP in NCP case	Half of LTE CP in ECP case

[161] Table 3 shows an example of numerologies for normal CP and extended CP with 60 kHz spacing.

[162] [Table 3]

	eMBB - NCP	eMBB - ECP	URLLC - NCP	URLLC - ECP
OFDM symbol	16.67 us	16.67 us	16.67 us	16.67 us
Number of OFDM symbols in a TTI	14	10 (option 1)12 (option 2)	7	5 symbols (option 1)6 symbols (option 2)
TTI length	0.25 ms	0.25 ms	0.125 ms	0.125
CP length	Half of LTE CP in NCP case	8.33us (option 1)4.16 us (option 2)	Half of LTE CP in NCP case	8.33us (option 1)4.16 us (option 2)

[163] If 3 symbol short TTI is used (e.g. URLLC / 30 kHz / option 2), one short TTI may cross the slot boundary of eMBB subframe if slot is defined. More generally, short TTI may be defined over one or multiple subframes. One example is to aggregate two subframes and divide two subframe into multiple short TTIs (e.g. with 14 OFDM symbols of eMBB subframe, 4 OFDM symbol * 7 short TTIs may be constructed over two subframes for URLLC use case). In this case, where the short TTI starts (e.g. every even subframe or every odd subframe) needs to be clarified and may be defined in the specification or determined via initial access procedure.

[164]

[165] B. Frame structure for URLLC in TDD

[166] In TDD, since the ACK/NACK timing may be dependent on the availability of UL, if there is unavailable UL, the latency may be increased. Thus, to support low latency, in every short TTI, it is expected to have UL portion which can be dynamically created, whenever there is UL transmission. In TDD, if UL subframe boundary is shifted, UL transmission may occur in the middle of subframe. This may be handled by the network if the network and/or UE support (semi) full duplex capability. Or, larger delay budget may be assumed for TDD (e.g. 2 * TTI + TA without HARQ, 3 * TTI with HARQ). In TDD, even without subframe offset, as DL portion is relatively smaller compared to FDD, overall decoding latency may also be reduced (which in turn may lead less peak data rate with low latency). For TDD, the similar TTI length and the number of OFDM symbol per TTI may be considered.

[167] FIG. 14 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. In FIG. 14, 2 OFDM symbol length frame structure is supported in TDD. In order to support 2 OFDM symbol length with 15 kHz or other subcarrier spacing, one OFDM symbol may be assumed for DL portion, and

double subcarrier spacing for uplink portion may be assumed (e.g. 30 kHz with 15 kHz DL subcarrier spacing) with keeping the same CP overhead for UL. The remaining part may be used for guard period (GP) including TA and DL/UL switching time.

[168] FIG. 15 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. In FIG. 15, 3 OFDM symbol length frame structure is supported in TDD.

[169] For multiplexing of different use cases from the network perspective, different numerology or different subcarrier spacing may be used where the same CP may be still assumed between two different use cases. For this, 1 OFDM symbol for DL and 1 OFDM symbol for GP and 1 OFDM symbol for UL may be define in 3 OFDM symbol TTI length. Alternatively, similar to 2 OFDM symbol case, only UL portion may use different subcarrier spacing to allow more DL OFDM symbols available.

[170] More generally, this approach may be explained that URLLC can be utilized with extended CP with larger subcarrier spacing compared to eMBB to maintain the same level of CP. The remaining time may be applied towards GP between UL/DL switching and TA. Having larger GP in URLLC, TDD may be beneficial to allow more decoding time and UL transmission preparation. This case may be beneficial to reserve more processing time or allow larger GP which may be beyond one OFDM symbol length in 3 OFDM symbol short TTI case in TDD.

[171] FIG. 16 shows an example of different subcarrier spacing between URLLC and eMBB which are multiplexed in a same carrier or frequency band. From a UE perspective, each portion may be managed by individual transmission point or a cell such that initial access can be achieved separately per use cases. However, URLLC provided by shorter TTI with the same numerology with eMBB may also share the initial access procedure with host eMBB case. In this sense, via the initial access, whether to support short TTI or regular TTI may be informed.

[172] In determining UL portion for short TTI for URLLC, the portion or the number of OFDM symbol for UL portion in each short TTI may also depend on the necessity of demodulation RS (DM-RS) transmission. For example, if a UE requires to transmit DM-RS at least in one subframe in every 7 OFDM symbol, short TTIs within 7 OFDM symbol may not need to transmit DM-RS multiple times. In this sense, the first short TTI in every 7 OFDM symbol may have at least two OFDM symbols for UL portion and the remaining short TTIs may have one OFDM symbol for UL portion. Accordingly, dynamic determination of UL portion size may be supported depending on the necessity of DM-RS transmission in a given short TTI or not. This may also impact the behavior of DL reception, where a UE may puncture or not receiving the last DL OFDM symbol to shift UL portion one symbol forward. This may be restricted in case of 3 OFDM symbol short TTI. In this case, alternative approach is to transmit GP and

DM-RS in one OFDM symbol with different subcarrier spacing or by other means.

[173]

[174] 5. Above 6 GHz frequency

[175] The above description of the present invention may be applied for a frequency band below 6 GHz. The above description of the present invention may be applied for a frequency band above 6 GHz as well. In a frequency band above 6 GHz, analog beam may be used. In this case, the unit of beam switching may be used similar to one TTI mentioned for FS1 and FS2. However, the unit of beam switching for data transmission may be assumed for the unit size. For example, if beam switching occurs in every OFDM symbol for PSS/SSS or control channel transmission, whereas beam switching occurs only once per TTI for data transmission, the basic unit for beam switching may be 1 TTI. If beam switching for data transmission occurs in every 1/2 TTI, the basic unit for beam switching may be 1/2 TTI. When configuring sidelink resources, beam direction of each resource may be indicated such that UEs can communicate each other based on beam direction and based on each other's location information. The same size of subcarrier spacing among different applications may be used for frequencies above 6GHz.

[176]

[177] 7. DM-RS sharing

[178] For PUSCH, depending on coverage level, the network may configure the number of TTIs used for PUSCH transmission. As DM-RS for one OFDM symbol TTI in UL is very challenging (similar issue may be in DL as well, yet the problem may become more significant in UL due to SC-FDM characteristic and PAPR issue), the TTI of UL can be represented a bit differently in consideration of potentially DM-RS sharing among different TTIs.

[179] FIG. 17 shows an example of DM-RS sharing according to an embodiment of the present invention. FIG. 17-(a) shows a case of level 5 (i.e. 1 OFDM symbol short TTI) with discontinuous DM-RS. In this case, one symbol short TTIs share the DM-RS in the middle of legacy slot. Potentially different cyclic shift (CS) may be configured or preconfigured per each OFDM symbol to allow multiplexing of different TTIs. If a UE schedules more than one TTIs sharing the same DM-RS, it may continue using the first DM-RS scrambling/sequence of the first transmission among multiple TTIs. FIG. 17-(b) shows a case of level 4 (i.e. 2 OFDM symbols short TTI) with no DM-RS sharing.

[180] FIG. 17-(c) shows a case of level 4 (i.e. 2 OFDM symbols short TTI) for physical sidelink shard channel (PSSCH) with DM-RS sharing. FIG. 17-(d) also shows a case of level 4 (i.e. 2 OFDM symbols short TTI) for PSSCH with DM-RS sharing. For Level 4 with DM-RS sharing, there may be two different approaches.

[181] - Approach 1: DM-RS sharing does not occur between adjacent short TTIs with 2 OFDM symbols, and DM-RS sharing occurs between short TTIs with 1 OFDM symbol and 2 OFDM symbols. This approach corresponds to FIG. 17-(c).

[182] - Approach 2: DM-RS sharing occurs over all TTIs similar to level 5. One DM-RS symbol is shared by multiple short TTIs. This corresponds to FIG. 17-(d). Similar level 5, CS may be predefined or configured per OFDM symbol, and the first OFDM symbol mapped scrambling/CS/sequence is used if the short TTI size is larger than 1.

[183] FIG. 17-(e) shows a case of level 3 (i.e. 3/4 OFDM symbols short TTI) for physical uplink control channel (PUCCH) with no DM-RS sharing. FIG. 17-(f) shows a case of level 3 (i.e. 3/4 OFDM symbols short TTI) for PSSCH with DM-RS sharing. For level 3, if DM-RS sharing is considered, the fourth OFDM symbol in each slot may be used for DM-RS sharing.

[184] Additional DM-RS within a short TTI may be added which may or may not be shared among different short TTIs. For example, if PUCCH transmission is considered, with DM-RS sharing, additional DM-RS (the same DM-RS or with different CS) may be used in each TTI as well.

[185] FIG. 18 shows an example of PUSCH scheduling with DM-RS sharing according to an embodiment of the present invention. Referring to FIG. 18, PUSCHs of level 4 share DM-RS, and PUSCHs of level 3 with 2 short TTIs may also share DM-RS.

[186] FIG. 19 shows an example of PUCCH scheduling without DM-RS sharing according to an embodiment of the present invention. Referring to FIG. 19, there is no DM-RS sharing.

[187]

[188] 8. ACK/NACK transmission

[189] For ACK/NACK transmission or UCI transmission via PUCCH, the network may also indicate the number of TTIs used for ACK/NACK transmission or PUCCH transmission via DCI or higher layer signaling. As the coverage of ACK/NACK transmission may also be dependent on the number of ACK/NACK bits or UCI bits, it may be dynamically indicated by DL grant. For example, the timing and frequency offset of ACK/NACK transmission, and also the number of TTIs used for ACK/NACK transmission may be configured in DL grant. Or, the length may be determined by the number of UCI bits. The number of TTIs used for PUCCH may be semi-statically configured. In terms of baseline timing of ACK/NACK, (sPDSCH transmission duration + sPDSCH transmission duration (for decoding) or higher layer configured decoding latency + 2 * sTTI for UL for ACK/NACK preparation) may be assumed. If there is offset configured in the DL grant, the offset may be added to the baseline timing of ACK/NACK.

[190]

[191] 9. Short TTI indexing

[192] To indicate a short TTI within the largest TTI, assuming the largest TTI uses the subframe index, separate indexing of short TTI may be considered. In one subframe, K maximum short TTI may be placed. In terms of configuration of e.g. semi-persistent scheduling (SPS), CSI, etc., or any periodic configuration, periodicity may be represented by TTI length or multiple of TTIs. The periodicity may start from SFN=0 and subframe index = 0. Alternatively, periodicity may be represented in two level, i.e. periodicity in subframes and periodicity within a subframe.

[193]

[194] 10. Short TTI length for each channel

[195] There are a couple of aspects to determine right shot TTI length for each channel, e.g. the file size, system resource utilization, UE geometry, etc. Overall, smaller file size in a lighted loaded scenario for good coverage UEs may lead best performance gain, whereas very little or even worse performance may be expected with short TTI for poor coverage UEs with large file sizes. In this sense, it seems considerable to apply UE-specific TTI length at least based on UE geometry. However, the file size also impacts on the overall performance gain due to the associated protocol overhead and control overhead. In this sense, mechanisms to allow dynamic change of sPDSCH/sPUSCH may be beneficial to address the case where a UE has multiple transmission control protocol (TCP) sessions with different file sizes. As packets from different TCP sessions are not differentiable from the physical layer perspective, it may be beneficial to consider dynamic TTI length adaptation via DCI.

[196] To support this, the following overall approaches may be considered.

[197] (1) Dynamic TTI length for all channels: The TTI length of sPDCCH may be dynamically changed which are blindly monitored by a UE. Based on the scheduled sPDCCH, the UE may determine the TTI length for sPDSCH/sPUSCH. This approach however requires some mechanism to identify the length of sPDCCH. One approach is to assume that FDM between sPDCCH and sPDSCH is used such that sPDCCH is transmitted always over the entire short TTI. Or, explicit indication in DCI may be necessary.

[198] (2) Fixed TTI length for sPDCCH with dynamic indication via DCI: Alternatively, the TTI length used for sPDCCH may be higher layer configured, and the TTI length of scheduled sPDSCH or sPUSCH may be dynamically adapted by the signaling in DCI.

[199] The first approach may offer benefits to adapt sPDCCH resource in time domain (if sPDCCH and sPDSCH is multiplexed partially or fully by FDM). This however may be also achieved by different aggregation levels. Furthermore, it seems that both approaches may require potentially explicit indication via DCI. Thus, the clear benefits of

the first approach while it restricts the flexibility are not clear. In this sense, to simplify the UE blind decoding, refer the second approach may be preferred. In other words, supporting different TTI length for data channel may be supported by a multiple TTI scheduling manner.

[200] When variable/multi-TTI length scheduling is supported, the issue with multiplexing between sPDSCH with different TTI lengths may be also considered in terms of processing latency For example, if decoding latency is same as the length of sPDSCH, if longer TTI scheduling occurs before shorter TTI scheduling happens, the decoding or processing of following shorter TTI can be delayed (unless pre-emption is assumed). Thus, depending on the scheduling, the overall latency till ACK/NACK transmission can be changed. To address different cases, asynchronous HARQ-ACK feedback timing for sPDSCH may be considered as well where ACK/NCK timing can be signaled via DL scheduling DCI. Further, the shorter TTI of PUCCH transmission may reduce the overall coverage. This may be all right for good coverage UEs whereas it may impact on the cell edge UEs. In this sense, the TTI length for sPUCCH transmission may be semi-statically configured. Based on the semi-statically configured TTI length for sPDCCH and sPUCCH, timing of DL and UL may be respectively determined which are used for resources for DL and UL transmissions.

[201]

[202] FIG. 20 shows a method for configuring a frame structure for a new RAT by a network node according to an embodiment of the present invention. The present invention described above may be applied to this embodiment.

[203] In step S100, the network node configures a first frame which has one legacy TTI and a second frame which has multiple short TTIs. In step S110, the network node communicates with a UE by using at least one of the first frame and the second frame.

[204] The second frame may have the nested frame structure described above. The second frame may contain different number of short TTIs per a number of symbols in each short TTI. The number of symbols in each short TTI may be identical. In this case, at least one symbol may be shared between adjacent short TTIs.

[205] The second frame may contain at least one of a symbol for DL control, a symbol for UL control, a symbol for a sidelink DL control or a symbol for a sidelink UL control. The symbol for DL control may be placed in a first symbol of the second frame, and the symbol for UL control may be placed in a last symbol of the second frame. The symbol for sidelink DL control may be placed in a second last symbol of the second frame, and the symbol for sidelink UL control may be placed in a second symbol of the second frame. Further, a gap may be configured between the symbol for DL control and the symbol for sidelink UL control, or between the symbol for sidelink DL control and the symbol for UL control.

[206] A synchronization signal may be transmitted in a minimum system bandwidth with minimum density in the second frame. The synchronization signal may be shared among the first frame and the second frame. The synchronization signal may be repeated in a frequency domain or a time domain.

[207] The first frame and the second frame may be configured according to one of different baseband bandwidth capability, different processing capability, different number of possible UEs accessing a cell, different synchronization requirement, different subcarrier spacing or different coverage requirement. The UE may be a one of an mMTC UE, a URLL) UE or an eV2X UE.

[208] FIG. 21 shows a wireless communication system to implement an embodiment of the present invention.

[209] A network node 800 may include a processor 810, a memory 820 and a transceiver 830. The processor 810 may be configured to implement proposed functions, procedures and/or methods described in this description. Layers of the radio interface protocol may be implemented in the processor 810. The memory 820 is operatively coupled with the processor 810 and stores a variety of information to operate the processor 810. The transceiver 830 is operatively coupled with the processor 810, and transmits and/or receives a radio signal.

[210] A UE 900 may include a processor 910, a memory 920 and a transceiver 930. The processor 910 may be configured to implement proposed functions, procedures and/or methods described in this description. Layers of the radio interface protocol may be implemented in the processor 910. The memory 920 is operatively coupled with the processor 910 and stores a variety of information to operate the processor 910. The transceiver 930 is operatively coupled with the processor 910, and transmits and/or receives a radio signal.

[211] The processors 810, 910 may include application-specific integrated circuit (ASIC), other chipset, logic circuit and/or data processing device. The memories 820, 920 may include read-only memory (ROM), random access memory (RAM), flash memory, memory card, storage medium and/or other storage device. The transceivers 830, 930 may include baseband circuitry to process radio frequency signals. When the embodiments are implemented in software, the techniques described herein can be implemented with modules (e.g., procedures, functions, and so on) that perform the functions described herein. The modules can be stored in memories 820, 920 and executed by processors 810, 910. The memories 820, 920 can be implemented within the processors 810, 910 or external to the processors 810, 910 in which case those can be communicatively coupled to the processors 810, 910 via various means as is known in the art.

[212] In view of the exemplary systems described herein, methodologies that may be im-

plemented in accordance with the disclosed subject matter have been described with reference to several flow diagrams. While for purposed of simplicity, the methodologies are shown and described as a series of steps or blocks, it is to be understood and appreciated that the claimed subject matter is not limited by the order of the steps or blocks, as some steps may occur in different orders or concurrently with other steps from what is depicted and described herein. Moreover, one skilled in the art would understand that the steps illustrated in the flow diagram are not exclusive and other steps may be included or one or more of the steps in the example flow diagram may be deleted without affecting the scope of the present disclosure.

[213]

Claims

[Claim 1] A method for configuring a frame structure by a network node in a wireless communication system, the method comprising:
configuring a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs; and
communicating with a user equipment (UE) by using at least one of the first frame and the second frame.

[Claim 2] The method of claim 1, wherein the second frame contains different number of short TTIs per a number of symbols in each short TTI.

[Claim 3] The method of claim 2, wherein the number of symbols in each short TTI is identical.

[Claim 4] The method of claim 3, wherein at least one symbol is shared between adjacent short TTIs.

[Claim 5] The method of claim 1, wherein the second frame contains at least one of a symbol for downlink (DL) control, a symbol for uplink (UL) control, a symbol for a sidelink DL control or a symbol for a sidelink UL control.

[Claim 6] The method of claim 5, wherein the symbol for DL control is placed in a first symbol of the second frame, and
wherein the symbol for UL control is placed in a last symbol of the second frame.

[Claim 7] The method of claim 5, wherein the symbol for sidelink DL control is placed in a second last symbol of the second frame, and
wherein the symbol for sidelink UL control is placed in a second symbol of the second frame.

[Claim 8] The method of claim 5, wherein a gap is configured between the symbol for DL control and the symbol for sidelink UL control, or between the symbol for sidelink DL control and the symbol for UL control.

[Claim 9] The method of claim 1, wherein a synchronization signal is transmitted in a minimum system bandwidth with minimum density in the second frame.

[Claim 10] The method of claim 9, wherein the synchronization signal is shared among the first frame and the second frame.

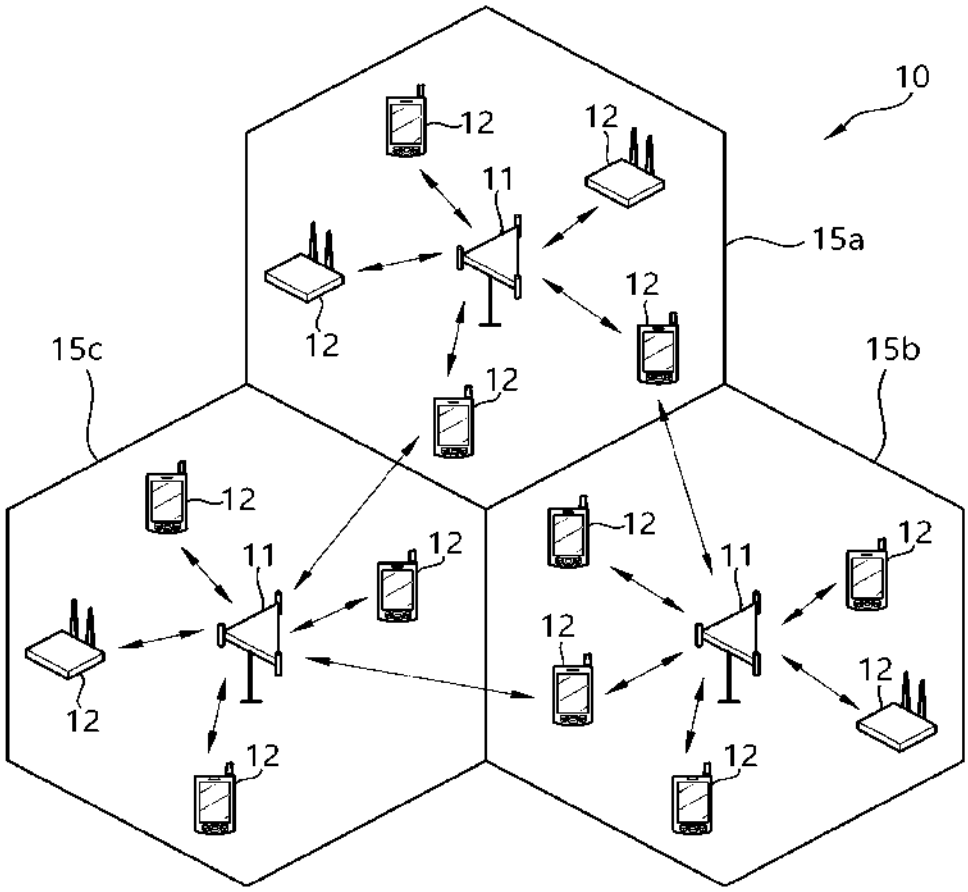
[Claim 11] The method of claim 9, wherein the synchronization signal is repeated in a frequency domain or a time domain.

[Claim 12] The method of claim 1, wherein the first frame and the second frame

are configured according to one of different baseband bandwidth capability, different processing capability, different number of possible UEs accessing a cell, different synchronization requirement, different subcarrier spacing or different coverage requirement.

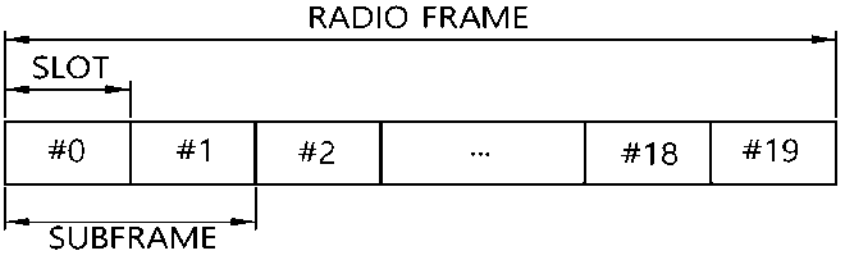
[Claim 13] The method of claim 1, wherein the UE is a one of a massive machine-type communication (mMTC) UE, an ultra-reliable and low latency communication (URLLC) UE or an enhanced vehicle-to-everything (eV2X) UE.

[Claim 14] A network node in a wireless communication system, the network node comprising:



a memory;

a transceiver; and



a processor, coupled to the memory and the transceiver, that:

configures a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and controls the transceiver to communicate with a user equipment (UE) by using at least one of the first frame and the second frame.

(54) Title: METHOD AND DEVICE FOR PAGING A MACHINE TO MACHINE DEVICE

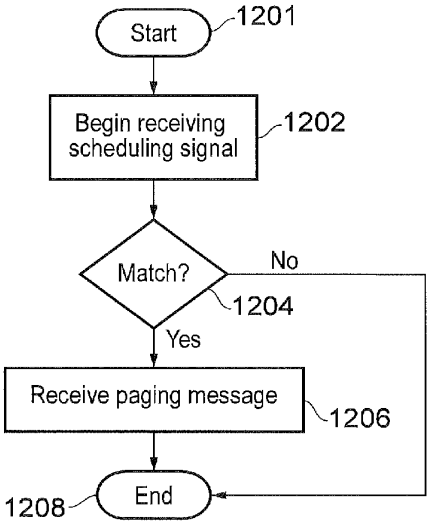

FIG. 12

(57) Abstract: A terminal device for use with a wireless telecommunications network comprising: a transceiver; and a controller. Receiving, during one of a plurality of periodic paging occasions associated with the terminal, a paging scheduling signal for one or more terminal devices, each paging occasion being associated with a value of a characteristic of the scheduling signal which is unique to that paging occasion. Determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the of periodic paging occasions associated with the terminal device; and control the transceiver to receive the paging message scheduled by the received scheduling message.

METHOD AND DEVICE FOR PAGING A MACHINE TO MACHINE DEVICE

BACKGROUND

Field of Disclosure

The present disclosure relates to a terminal device, infrastructure equipment, methods and integrated circuitry for use with a wireless telecommunications network.

Description of Related Art

The "background" description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description which may not otherwise qualify as prior art at the time of filing, are neither expressly or impliedly admitted as prior art against the present disclosure.

Third and fourth generation wireless communications systems, such as those based on the third generation project partnership (3GPP) defined UMTS and Long Term Evolution (LTE) architecture are able to support sophisticated services such as instant messaging, video calls as well as high speed internet access. For example, with the improved radio interface and enhanced data rates provided by LTE systems, a user is able to enjoy high data rate applications such as mobile video streaming and mobile video conferencing that would previously only have been available via a fixed line data connection. The demand to deploy third and fourth generation networks is therefore strong and the coverage area of these networks, i.e. geographic locations where access to the networks is possible, is expected to increase rapidly. However, whilst fourth generation networks can support communications at high data rate and low latencies from devices such as smart phones and tablet computers, it is expected that future wireless communications networks will need to support communications to and from a much wider range of devices, including reduced complexity devices, machine type communication devices, devices which require little or no mobility, high resolution video displays and virtual reality headsets. As such, supporting such a wide range of communications devices can represent a technical challenge for a wireless communications network.

A current technical area of interest to those working in the field of wireless and mobile communications is known as "The Internet of Things" or IoT for short. The 3GPP has proposed to develop technologies for supporting narrow band (NB)-IoT using an LTE or 4G wireless access interface and wireless infrastructure. Such IoT devices are expected to be low complexity and inexpensive devices requiring infrequent communication of relatively low bandwidth data. It is also expected that there will be an extremely large number of IoT devices which would need to be supported in a cell of the wireless

communications network. Furthermore such NB-IoT devices are likely to be deployed indoors and /or in remote locations making radio communications challenging.

SUMMARY OF THE DISCLOSURE

According to a first embodiment, the present technique provides a terminal device for use with a wireless telecommunications network, the terminal device comprising: a transceiver; and a controller operable: to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network; to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

According to the first embodiment, the present technique also provides infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising: a transceiver; and a controller operable: to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

According to a second embodiment, the present technique provides a terminal device for use with a wireless telecommunications network, the terminal device comprising: a transceiver; and a controller operable: to control the transceiver to begin receiving, during one of a plurality of periodic paging

occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

According to the second embodiment, the present technique also provides infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising: a transceiver; and a controller operable: to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

The foregoing paragraphs have been provided by way of general introduction, and are not intended to limit the scope of the following claims. The described embodiments, together with further advantages, will be best understood by reference to the following detailed description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete appreciation of the disclosure and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings wherein like reference numerals designate identical or corresponding parts throughout the several views, and wherein:

DETAILED DESCRIPTION OF THE EMBODIMENTS

Conventional Communications System

Figure 1 provides a schematic diagram illustrating some basic functionality of a mobile telecommunications network / system 100 operating in accordance with LTE principles and which may be adapted to implement embodiments of the disclosure as described further below. Various elements of Figure 1 and their respective modes of operation are well-known and defined in the relevant standards administered by the 3GPP (RTM) body, and also described in many books on the subject, for example, Holma H. and Toskala A [1]. It will be appreciated that operational aspects of the telecommunications network which are not specifically described below may be implemented in accordance with any known techniques, for example according to the relevant standards.

The network 100 includes a plurality of base stations 101 connected to a core network 102. Each base station provides a coverage area 103 (i.e. a cell) within which data can be communicated to and from communications devices 104. Data is transmitted from base stations 101 to communications devices 104 within their respective coverage areas 103 via a radio downlink. Data is transmitted from communications devices 104 to the base stations 101 via a radio uplink. The uplink and downlink

communications are made using radio resources that are licenced for exclusive use by the operator of the network 100. The core network 102 routes data to and from the communications devices 104 via the respective base stations 101 and provides functions such as authentication, mobility management, charging and so on. Communications devices may also be referred to as mobile stations, user equipment (UE), user device, mobile radio, terminal device and so forth. Base stations may also be referred to as transceiver stations / infrastructure equipment / NodeBs / eNodeBs (eNB for short), and so forth.

Wireless communications systems such as those arranged in accordance with the 3GPP defined Long Term Evolution (LTE) architecture use an orthogonal frequency division modulation (OFDM) based interface for the radio downlink (so-called OFDMA) and a single carrier frequency division multiple access scheme (SC-FDMA) on the radio uplink.

Figure 2 provides a simplified schematic diagram of the structure of a downlink of a wireless access interface that may be provided by or in association with the eNB of Figure 1 when the communications system is operating in accordance with the LTE standard. In LTE systems the wireless access interface of the downlink from an eNB to a UE is based upon an orthogonal frequency division multiplexing (OFDM) access radio interface. In an OFDM interface the resources of the available bandwidth are divided in frequency into a plurality of orthogonal subcarriers and data is transmitted in parallel on a plurality of orthogonal subcarriers, where bandwidths between 1.4MHz and 20MHz bandwidth may be divided into 128 to 2048 orthogonal subcarriers for example. Each subcarrier bandwidth may take any value but in LTE it is conventionally fixed at 15kHz. However it has been proposed in the future [2][3] to provide also a reduced subcarrier spacing of 3.75 kHz for certain parts of the LTE wireless access interface for the uplink. As shown in Figure 2, the resources of the wireless access interface are also temporally divided into frames where a frame 200 lasts 10ms and is subdivided into 10 subframes 201 each with a duration of 1ms. Each subframe is formed from 14 OFDM symbols and is divided into two slots each of which comprise six or seven OFDM symbols depending on whether a normal or extended cyclic prefix is being utilised between OFDM symbols for the reduction of inter symbol interference. The resources within a slot may be divided into resources blocks 203 each comprising 12 subcarriers for the duration of one slot and the resources blocks further divided into resource elements 204 which span one subcarrier for one OFDM symbol, where each rectangle 204 represents a resource element. More details of the downlink structure of the LTE wireless access interface are provided in Annex 1.

Figure 3 provides a simplified schematic diagram of the structure of an uplink of an LTE wireless access interface that may be provided by or in association with the eNB of Figure 1. In LTE networks the uplink wireless access interface is based upon a single carrier frequency division multiplexing FDM (SC-FDM) interface and downlink and uplink wireless access interfaces may be provided by frequency division duplexing (FDD) or time division duplexing (TDD), where in TDD implementations subframes switch

between uplink and downlink subframes in accordance with predefined patterns. However, regardless of the form of duplexing used, a common uplink frame structure is utilised. The simplified structure of Figure 3 illustrates such an uplink frame in an FDD implementation. A frame 300 is divided in to 10 subframes 301 of 1ms duration where each subframe 301 comprises two slots 302 of 0.5ms duration. Each slot is then formed from seven OFDM symbols 303 where a cyclic prefix 304 is inserted between each symbol in a manner equivalent to that in downlink subframes. In Figure 3 a normal cyclic prefix is used and therefore there are seven OFDM symbols within a subframe, however, if an extended cyclic prefix were to be used, each slot would contain only six OFDM symbols. The resources of the uplink subframes are also divided into resource blocks and resource elements in a similar manner to downlink subframes. More details of the LTE uplink represented in Figure 3 are provided in Annex 1.

Narrowband Internet of Things

As explained above, it has been proposed to develop an adaptation of a mobile communications network to accommodate narrow band communications within an existing wireless access interface which has been developed to provide broadband wireless communications. For example, in 3GPP a project relating to improvements to LTE wireless access interfaces to provide for a Narrowband Internet of Things (NB-IoT) was agreed [2]. This project is aimed at improved indoor coverage, support for massive number of low throughput devices, low delay sensitivity, ultra-low device cost, low device power consumption and (optimised) network architecture. An example of such a device is a smart meter. It has been proposed that an NB-IoT communications system supports a bandwidth of only 180 kHz and can have three operational modes:

1. 'Stand-alone operation' utilizing for example the spectrum currently being used by GERAN systems as a replacement of one or more GSM carriers
2. 'Guard band operation' utilizing the unused resource blocks within a LTE carrier's guard-band
3. 'In-band operation' utilizing resource blocks within a normal LTE carrier

Figure 4 provides an example schematic block diagram of a terminal device or UE 104 and an infrastructure equipment or eNB 101 according to embodiments of the present technique. As shown in Figure 4, the UE 104 includes a transmitter 401 and a receiver 402 (which together form a transceiver) which are controlled by a controller 403. The UE 104 also comprises a storage medium 420 for storing data. Correspondingly, the eNB 101 includes a transmitter 411 and a receiver 412 (which together form a transceiver) which are controlled by a controller 413 (which can also implement a scheduler function). The eNB 101 also comprises a storage medium 422 for storing data. As explained above, the UE 104 transmits and receives signals to and from the eNB 101 via a wireless access interface provided by the

eNB as part of the wireless communications network. Each of the UE 104 and eNB 101 are configured to exchange signals with each other using NB-IoT.

One of the objectives of NB-IoT is to provide extended coverage of up to 20 dB. The main mechanism to extend coverage is to perform numerous repetitions of a message to be received at a receiving device, such that the receiver can accumulate the signal energy over the repetitive samples in order for it to have an increased signal-to-noise ratio (SNR), which increases the likelihood of successful decoding of the message at the receiving device. Such a mechanism is known as coverage enhancement (CE).

Coverage enhancement (CE) may have several levels. For example, it may provide one of 5 dB, 15 dB and 20 dB additional coverage enhancement. In NB-IoT, the CE levels may be referred to as the targeted MCL (Max Coupling Loss, the achievable coupling loss (accounting for, for example, path loss, feeder losses and/or antenna gains) between transmitter and receiver) of, for example, 144 dB, 154 dB and 164 dB (so that the higher the targeted MCL, the greater the additional coverage enhancement).

As previously mentioned, repetitions of a signal so that a receiver can accumulate energy of the signal over numerous repetitive samples is the basic method used for coverage enhancement. The number of repetitions required is dependent upon the CE level. Thus, a UE at a lower CE level, such as at 144 dB, MCL requires less repetition compared to one at a higher CE level, such as at 154 dB MCL. The power spectral density, PSD (mW/Hz) of a transmission also affects the number of repetitions required, that is, the larger the PSD, the less the required number of repetitions.

The NB-PDCCH (Narrow Band Physical Downlink Control Channel) is a control channel that is used to schedule downlink resources (downlink grant) and uplink resources (uplink grant) for a NB-PDSCH (Narrow Band Physical Downlink Shared Channel) and a NB-PUSCH (Narrow Band Physical Uplink Shared Channel) that carry data traffic. An NB-PDCCH search space consists of multiple NB-PDCCH candidates wherein each candidate has a specific starting time, set of subcarriers, a defined number of repetitions and an aggregation level (the aggregation level relating to the number of frequency resources occupied by the candidate such that when the candidate occupies a higher number of frequency resources, the aggregation level is higher, and when the candidate occupies a lower number of frequency resources, the aggregation level is lower). Candidates that have a larger number of repetitions and a higher aggregation level are more robust and can reach a UE at poorer coverage compared to candidates that have a smaller number of repetitions and a lower aggregation level.

The eNB uses one of the candidates in the search space to carry the NB-PDCCH. The UE is not aware which candidate is used and so it must blind decode all the candidates in the search space in order to find the candidate used by the eNB for the NB-PDCCH. An example of a typical NB-PDCCH search space is

shown in Figure 5. Here, the search space has 4 repetition levels {R1, R2, R3, R4} where R4 = 2×R3 = 4×R2 = 8×R1. It should be appreciated that an NB-PDCCH search space with other repetition levels is also possible. As an example the eNB can use any of the 15 candidates (labelled as C1 to C15) to carry the NB-PDCCH and the UE has to blind decode for all 15 candidates. The max repetition R_{MAX} (in Figure 5, R_{MAX} = R4) of the search space is assigned to the UE based on the UE's radio condition. Thus, for example, if the UE is in a poorer quality radio coverage location, then the eNB can configure a search space with a larger value of R_{MAX}, and if the UE is in a better quality radio coverage location, then the eNB can configure a search space with a smaller value of R_{MAX}. Typically, a set of NB-PDCCH search spaces is predefined in which each NB-PDCCH search space of the set consists of a set of candidates and a value of R_{MAX}. The UE is then assigned one NB-PDCCH search space in the set of NB-PDCCH search spaces. The maximum repetition R_{MAX} of an NB-PDCCH search space can be selected from the set of values {1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048}, for example.

In NB-IoT, paging is performed when a UE is in idle mode. More specifically, when in idle mode, the UE monitors an NB-PDCCH CSS (Common Search Space) which, in the case that a paging message is to be transmitted to the UE, contains an NB-PDCCH that schedules that paging message (the paging message being carried by an NB-PDSCH). In order to reduce power consumption, the UE monitors the NB-PDCCH CSS during each of a plurality of periodic Paging Occasions (PO) rather than constantly monitoring the NB-PDCCH CCS. The PO occurs periodically for a particular UE (or particular group of UEs), wherein the period is configured by the network, for example. In an embodiment, the network can configure multiple POs in which the specific PO that a UE monitors depends on an identifier of that that UE (UE-ID), for example, the UE's International Mobile Subscriber Identifity (IMSI). This enables the network to spread the paging load. For example in Figure 6, the eNB configures four POs where each PO has a period T_{PO}. The UE thus wakes up every T_{PO} ms to monitor for possible paging. The PO is assigned to the UE based on the UE's ID, using a **MOD** function of the number of POs, for example (thus, in the case of Figure 6, the PO assigned to a particular UE is given by UE_ID **MOD** 4).

As described previously, repetition of the paging CSS can reach 2048. A problem with this is that a PO can overlap another PO, causing confusion for UEs reading the PO. For example in Figure 7, two POs are configured. PO 1 begins at time t_1, where UE 1 belonging to this PO will start monitoring for NB-PDCCH in the paging CSS. This paging CSS ends at time t_3. If the repetition of NB-PDCCH is very long (for example, if the paging CSS ending at time t_3 has the structure shown in Figure 5, and the NB-PDDCH is received via the candidate C15 with the largest number of repetitions) , it will overlap into PO 2 at time t_2. At time t_2 UE 2 belonging to PO 2 will start monitoring for NB-PDCCH and will start to accumulate repetition samples from the NB-PDCCH intended for UE 1 (belong to PO 1). If UE 2 is in a better radio condition than UE 1, it may decode the NB-PDCCH and start to accumulate and decode the corresponding NB-PDSCH containing the paging message. UE 2 will not find any paging indication in

this paging message and would waste battery power accumulating and decoding the NB-PDSCH. This is because the paging message contains an identifier of each UE to be paged. If a paging message is not intended for UE 2, then the identifier of UE 2 will not be included in the paging message and thus UE 2 will not be paged. However, since UE 2 has received the NB-PDCCH during its paging occasion, it will still attempt to read the paging message scheduled by the NB-PDCCH by accumulating and decoding the NB-PDSCH, thus wasting battery power. It should be noted that the NB-PDSCH is also repeated.

It should also be appreciated that if the PO period T_{PO} is shorter than the NB-PDCCH repetition, the PO may overlap itself, as shown in an example in Figure 8, in which the NB-PDCCH for PO 1 starts at time t_1 but the repetition doesn't end till time t_4. It overlaps the next PO 1 at time t_3. In this scenario, the UE belonging to PO 1 is confused as to whether to continue accumulating samples from the previous PO 1 (started at time t_1) or start a new accumulation starting at time t_3. Furthermore, in an embodiment, the NB-PDSCH starting subframe is indicated in the downlink control information (DCI) of the NB-PDCCH, this NB-PDSCH starting subframe being defined relative to the end of the NB-PDCCH that schedules this NB-PDSCH. In order to determine the end of an NB-PDCCH transmission, the repetition of the NB-PDCCH is indicated in the DCI of that NB-PDCCH. For example, in Figure 5, if candidate C11 is used to carry the NB-PDCCH (including the DCI), then the NB-PDSCH scheduled by the NB-PDCCH will start at k subframes after time t_6 (t_6 marking the end of the NB-PDCCH carried by candidate C11) where k is indicated in the DCI. Since the UE can decode a message with less repetition when it has a good radio condition, however, the UE may decode C11 at time t_5 and mistake candidate C11 for candidate C5. The UE will thereby use the wrong reference point for the start of the NB-PDSCH. To avoid this, the repetition of the NB-PDCCH is indicated in the DCI so that the UE will not mistake candidate C11 for C5. However, this does not solve the problem shown in Figure 8 in which the search space overlaps itself. In this case, although the UE will know the repetition of the NB-PDCCH from the DCI information, the UE does not know whether the NP-PDCCH repetitions started at time t_1 or at time t_3. This causes confusion at the UE regarding the candidates.

In LTE Release-13 eMTC (enhanced Machine Type Communication), the POs are separated far apart so that they do not overlap. This is possible because the repetition used in this case is not as large as that used in NB-IoT. Furthermore, eMTC can use different narrowbands for different groups of UEs and avoid overlapping. In contrast, only the anchor NB-IoT can contain the paging CSS and paging message, and therefore problem of overlapping of the NB-PDCCH between different POs requires a new solution.

In an embodiment of the present technique, an indicator is used to distinguish one PO from another. The UE belonging to a PO then uses this indicator to determine whether the NB-PDCCH belongs to it or to another PO.

In one embodiment, the said indicator is a PO index in the DCI (carried by the NB-PDCCH). A new field in the DCI would indicate which PO the DCI (that is, the NB-PDCCH) belongs to. The UE, after accumulating the NB-PDCCH, will then decode the DCI and check the PO index to see whether it matches the PO that the UE belongs to.

In another embodiment, different versions of the same PO are also indicated in the DCI. This is to help overcome the issue of uncertainty at the UE regarding when the search space starts when a NB-PDCCH repetition is larger than the PO period T_{PO} (as described in Figure 8). For example, in Figure 8, PO 1 at time t_1 can be version 1 and PO 1 at time t_3 can be version 2, these versions being distinguishable from each other by the PO identifier in the DCI so the UE is clear where the search space starts. This helps to avoid confusion of the candidates in the search space.

In another embodiment the starting time of the CSS is indicated in the DCI. This is similar to indicating the PO index (which indirectly indicates the starting time of the CSS). After decoding the DCI, the UE will determine whether the starting time of the decoded NB-PDCCH belongs to the CSS that starts at its PO or another PO. If the CSS starts at a time belonging to another PO, the UE can discard the decoded DCI.

In another embodiment, a different P-RNTI (Paging Radio Network Temporary Identifier) is used for one or more of each respective PO and each respective PO version. The P-RNTI of each respective PO and/or each respective PO version can be signalled either explicitly or implicitly (that is, derived from a reference P-RNTI). For example, in the case that a different P-RNTI is used for each respective PO, the eNB may signal a single reference P-RNTI and PO 1 will use this P-RNTI, PO 2 will use this reference P-RNTI + 1, PO 3 will use P-RNTI + 2, and so on.

In another embodiment, a scrambling applied to the NB-PDCCH is dependent upon the PO. The UE then applies a descrambler depending upon which PO it belongs to. A different scrambling may be applied to each respective PO (so as to distinguish, for example, PO 1 from PO 2, but not distinguish between different versions of PO 1 or PO 2). Alternatively, or in addition, a different scrambling may be applied to each respective PO version (so that different versions of, for example, PO 1 or PO 2 may be distinguished from each other).

It will be appreciated that various features of these embodiments may be combined as appropriate. For example, it may be the case that each respective PO is distinguished by a different scrambling, but then each version of that PO is further distinguished in the DCI.

In another embodiment of the present technique, two or more different NB-PDCCH search spaces (that is, Common Search Spaces) are configured wherein at least one of these search spaces has max repetition $R1_{MAX}$ greater than the time between two adjacent POs T_S (thus potentially causing the overlapping issue described in Figure 7) whilst the remaining search spaces have max repetition $R2_{MAX}$ smaller than T_S. In this way the search space with $R1_{MAX}$ can be segmented and interleaved with search spaces with $R2_{MAX}$. An example is shown in Figure 9, where each PO is associated with one of two types of NB-PDCCH Common Search Space (CSS) with $R1_{MAX}$ and $R2_{MAX}$, respectively. CSS1 belongs to PO1, starts at time t_1 and has a max repetition of $R1_{MAX}$ where $R1_{MAX} > T_S$, (meaning that, if measures are not taken, then CSS1 will overlap with the adjacent PO (that is, PO2)). Using the method of an embodiment, CSS1 (belonging to the first version of PO1) is segmented into 3 segments, wherein the 1st segment starts at time t_1 and ends at time t_2. The 2nd segment occupies the time t_3 to t_4, which avoids overlapping CSS2 (belonging to the first version of PO2) between time t_2 and t_3. The 3rd segment occupies time t_5 to t_6, which avoids overlapping CSS3 (belonging to the second version of PO1) between time t_4 and t_5. The segments of CSS1 are therefore interleaved with CSS2 and CSS3. CSS3 and CSS4 belong to PO1 (the second and third versions of PO1, respectively) but with a smaller maximum repetition, that is, $R2_{MAX} < T_S$, and therefore do not overlap with any adjacent PO. CSS3 and CSS4 are thus not segmented. CSS5 belongs to PO2 (in particular, the second version of PO2), and since its max repetition is greater that T_S, it is segmented and interleaved in a similar manner as that for CSS1. The example in Figure 9 shows two types of CSS (that is, with two different max repetition values). However, it should be appreciated this method is also applicable for more than two different max repetition CSSs. Also, the segments of CSS1 can be interleaved using a different pattern, for example, interleaved with different CSSs such as CSS3 and CSS4 (as shown in Figure 10).

In an embodiment, different POs have different max CSS repetitions. For example, the CSS for PO1 may have repetition $R1_{MAX} > T_S$ whilst the CSS for PO2 may have max repetition $R2_{MAX} < T_S$. In this embodiment, the CSS for PO1 is segmented and interleaved with the un-segmented CSS for PO2.

In another embodiment, all CSSs have $R1_{MAX} > T_S$. Each CSS (with $R1_{MAX}$) is segmented and the segment occupies multiple POs. That is, the CSS is spread among multiple POs. An example is shown in Figure 11, where CSS1 (belonging to PO1) has $R1_{MAX} > T_S$ and is segmented into two segments. The first segment occupies time t_1 to t_2 and the 2nd segment occupies time t_4 to t_5. Similarly, CSS5 (belonging to PO2) has $R1_{MAX} > T_S$ and is segmented into two segments. The first segment occupies time t_2 to t_3 and the 2nd segment occupies time t_6 to t_7. It should be noted that the 2nd segment length of each of CSS1 and CSS2 is less than T_S in this example.

In another embodiment, the overlapping problem shown in Figure 8 can be overcome by ensuring the Paging Occasion period $T_{PO} >$ R1max. Note that this is easier to achieve than to ensure that $T_S > R1_{MAX}$,

since T_{PO} can be much larger than T_S (for example, up to 2560 subframes) and multiple different POs may fit within the T_{PO}.

In embodiments, the segments of the NB-PDCCH search space can be defined by a predetermined pattern, this pattern being configured by the network and, for example, transmitted to the UE 104 from the eNB 101 as system information (in the System Information Block (SIB), for example). In an embodiment, the pattern may vary depending on the number of repeats of the NB-PDCCH, an identifier of the CSS which is used, or any other parameter which the UE may discern from the CSS or NB-PDCCH. The relationship between the predetermined pattern and the CSS or NB-PDCCH may be determined and transmitted to the UE 104 by the eNB 101 and may be in the form of a lookup table of the like. In another embodiment, the pattern may be fixed for the set of paging occasions associated with the UE (again, information indicative of this fixed pattern may be determined and transmitted to the UE 104 by the eNB 101).

It will thus be appreciated that, in a first embodiment, the present technique provides a terminal device 104 for use with a wireless telecommunications network. The terminal device comprises a transceiver 401, 402 and a controller 403. The controller is operable to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device (for example, the plurality of periodic paging occasions PO1 or PO2), a scheduling signal (carried by the NB-PDCCH, for example) scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network. Each periodic paging occasion associated with the terminal device is associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network. The controller is operable to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, and, if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

In one example, the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal. All periodic paging occasions associated with the terminal device may be associated with the same identifier of the scheduling signal (thus, for example, each paging occasion in the plurality of paging occasions PO1 may have the same index, each paging occasion in the plurality of paging occasions PO2 may have the same index, and so on). Alternatively, each periodic paging occasion

associated with the terminal device may be associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device (thus, for example, each paging occasion in the plurality of paging occasions PO1 may have a version number which distinguishes it from the other paging occasions in the plurality PO1, each paging occasion in the plurality of paging occasions PO2 may have a version number which distinguishes it from the other paging occasions in the plurality PO1, and so on). Any suitable identifier may be used as the paging occasion identifier, including, for example, an identifier comprising one or more of a PO index, PO version number or P-RNTI number, as previously discussed.

In another example, the characteristic of the scheduling signal is a scrambling of the scheduling signal. All periodic paging occasions associated with the terminal device may be associated with the same scrambling of the scheduling signal (thus, for example, each paging occasion in the plurality of paging occasions PO1 may be associated with the same scrambling of the scheduling signal, each paging occasion in the plurality of paging occasions PO2 may be associated with the same scrambling of the scheduling signal, and so on). Alternatively, each periodic paging occasion associated with the terminal device may be associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device (thus, for example, each paging occasion in the plurality of paging occasions PO1 may be associated with a different scrambling of the scheduling signal to the scrambling of the scheduling signal associated with the other paging occasions in the plurality PO1, each paging occasion in the plurality of paging occasions PO2 may be associated with a different scrambling of the scheduling signal to the scrambling of the scheduling signal associated with the other paging occasions in the plurality PO2, and so on).

In another example, the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space. For example, the radio search space may be a CSS and the scheduling signal may be the repeatedly transmitted NB-PDCCH. In this case the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a radio search space

with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

In this first embodiment, the present technique also provides infrastructure equipment 101 for use with a wireless telecommunications network. The infrastructure equipment comprises a transceiver 411, 412 and a controller 413. The controller is operable to control the transceiver to begin transmitting, during the one of the plurality of periodic paging occasions associated with the terminal device 104, the scheduling signal scheduling the paging message for paging the terminal device in the way as described.

It will also be appreciated that, in a second embodiment, the present technique provides a terminal device 101for use with a wireless telecommunications network. The terminal device comprises a transceiver 401, 402 and a controller 403. The controller is operable to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device (for example, the plurality of periodic paging occasions PO1 or PO2), a scheduling signal (carried by the NB-PDCCH, for example) scheduling a paging message for paging the terminal device. The scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods (in other words, the periodic repeats of the scheduling signal are segmented, as shown in Figures 9 to 11, for example), each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal. The controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

In one example, the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated. Scheduling signals with a duration of that of CSS1 or CSS 5 (shown in Figures 9 to 11) are examples of such scheduling signals.

In one example, the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network. This is shown, for example, in Figures 9 to 11, in which paging occasions belonging to the plurality PO1 are interleaved with paging occasions belonging to the plurality PO2.

In one example, the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods. In this case, for example, information indicative of the predetermined plurality of separate time periods (in other words, the segmentation pattern of the repeatedly transmitted scheduling signal) is stored in the storage medium 422 of the infrastructure equipment 101 and is signalled to the terminal device 104 using the transceiver 411, 412. The transceiver 401, 402 of the terminal device then receives the signal and the information indicative of the predetermined plurality of separate time periods is stored in the storage medium 420.

In one example, the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device. In this case, for example, there are at least two terminal devices in the wireless telecommunications network, wherein one terminal device is associated with the plurality of periodic paging occasions PO1 and the other terminal device is associated with the plurality of periodic paging occasions PO2, as shown in Figures 9 to 11. In another example, there may be no other terminal devices associated with a plurality of different periodic paging occasions (in which case, the only paging occasions present are those associated with the terminal device 104). It is noted that the present technique will still work in this case, in that if the terminal device knows the predetermined plurality of separate time periods over which the scheduling signal is repeatedly transmitted, the terminal device will know which paging occasion a particular set of repeats of the scheduling signal belongs to (thus avoiding the confusion arising from the situation shown in Figure 8, for example).

In this second embodiment, the present technique also provides infrastructure equipment 101 for use with a wireless telecommunications network. The infrastructure equipment comprises a transceiver 411, 412 and a controller 413. The controller is operable to control the transceiver to begin transmitting, during the one of the plurality of periodic paging occasions associated with a terminal device 104, the scheduling signal scheduling the paging message for paging the terminal device in the way as described.

Figure 12 illustrates a flow chart schematically showing a method according to the first embodiment of the present technique. The method starts at step 1201. At step 1202, the terminal device 104 begins receiving a scheduling signal during one of a plurality of periodic paging occasions associated with the terminal device. At step 1204, it is determined whether a value of a predetermined characteristic associated with each of the received scheduling signal and the one of the plurality of paging occasions matches. In the case that there is no match, the method ends at step 1208. On the other hand, in the case

that there is a match, the method moves on to step 1206, in which the terminal device receives a paging message scheduled by the scheduling signal. The method then ends at step 1208.

Figure 13 illustrates a flow chart schematically showing a method according to the second embodiment of the present technique. The method starts at step 1301. At step 1302, the terminal device 104 begins receiving a scheduling signal during one of a plurality of periodic paging occasions associated with the terminal device. At step 1303, the terminal device receives a predetermined number of repeats of the scheduling signal over a predetermined plurality of separate time periods. At step 1304, the terminal device receives a paging message scheduled by the scheduling signal. The method then ends at step 1305.

Features of various embodiments of the present technique are described by the following numbered clauses:

1. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

2. A terminal device according to clause 1, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

3. A terminal device according to clause 2, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

4. A terminal device according to clause 2, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

5. A terminal device according to clause 1, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

6. A terminal device according to clause 5, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

7. A terminal device according to clause 5, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

8. A terminal device according to any preceding clause, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

9. A terminal device according to clause 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space, wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a

radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

10. A terminal device according to any preceding clause, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

11. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

12. Infrastructure equipment according to clause 11, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

13. Infrastructure equipment according to clause 12, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

14. Infrastructure equipment according to clause 12, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

15. Infrastructure equipment according to clause 11, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

16. Infrastructure equipment according to clause 15, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

17. Infrastructure equipment according to clause 15, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

18. Infrastructure equipment according to any one of clauses 11 to 17, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate.

19. Infrastructure equipment according to clause 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, , wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, the starting time of the radio search space matching the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

20. Infrastructure equipment according to any one of clauses 11 to 19, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

21. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, controlling the transceiver to receive the paging message scheduled by the received scheduling message.

22. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

23. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver element to receive the paging message scheduled by the received scheduling message.

24. Integrated circuitry for infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

25. A wireless telecommunications network comprising a terminal device according to clause 1 and infrastructure equipment according to clause 11.

26. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

27. A terminal device according to clause 26, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

28. A terminal device according to clause 26 or 27, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

29. A terminal device according to any one of clauses 26 to 28, wherein the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods.

30. A terminal device according to any one of clauses 26 to 29, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

31. A terminal device according to any one of clauses 26 to 30, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

32. A terminal device according to any one of clauses 26 to 31, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

33. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

34. Infrastructure equipment according to clause 33, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the transceiver is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

35. Infrastructure equipment according to clause 33 or 34, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

36. Infrastructure equipment according to any one of claims 33 to 35, wherein the controller is operable to control the transceiver to transmit a signal to the terminal device indicative of the predetermined plurality of separate time periods.

37. Infrastructure equipment according to any one of clauses 33 to 36, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

38. Infrastructure equipment according to any one of clauses 33 to 37, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate..

39. Infrastructure equipment according to any one of clauses 33 to 38, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

40. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

transceiver is controlled to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

41. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the transceiver is controlled to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

42. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin receiving the scheduling signal; and

the controller element is operable to control the transceiver element to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

43. Integrated circuitry for operating infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller element is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin transmitting the scheduling signal.

44. A wireless telecommunications network comprising a terminal device according to clause 26 and infrastructure equipment according to clause 33.

Numerous modifications and variations of the present disclosure are possible in light of the above teachings. It is therefore to be understood that within the scope of the appended claims, the disclosure may be practiced otherwise than as specifically described herein.

In so far as embodiments of the disclosure have been described as being implemented, at least in part, by software-controlled data processing apparatus, it will be appreciated that a non-transitory machine-readable medium carrying such software, such as an optical disk, a magnetic disk, semiconductor memory or the like, is also considered to represent an embodiment of the present disclosure.

It will be appreciated that the above description for clarity has described embodiments with reference to different functional units, circuitry and/or processors. However, it will be apparent that any suitable distribution of functionality between different functional units, circuitry and/or processors may be used without detracting from the embodiments.

Described embodiments may be implemented in any suitable form including hardware, software, firmware or any combination of these. Described embodiments may optionally be implemented at least partly as computer software running on one or more data processors and/or digital signal processors. The elements and components of any embodiment may be physically, functionally and logically implemented in any suitable way. Indeed the functionality may be implemented in a single unit, in a plurality of units or as part of other functional units. As such, the disclosed embodiments may be implemented in a single unit or may be physically and functionally distributed between different units, circuitry and/or processors.

Although the present disclosure has been described in connection with some embodiments, it is not intended to be limited to the specific form set forth herein. Additionally, although a feature may appear to be described in connection with particular embodiments, one skilled in the art would recognize that various features of the described embodiments may be combined in any manner suitable to implement the technique.

Annex 1:

The simplified structure of the downlink of an LTE wireless access interface presented in Figure 2, also includes an illustration of each subframe 201, which comprises a control region 205 for the transmission of control data, a data region 206 for the transmission of user data , reference signals 207 and synchronisation signals which are interspersed in the control and data regions in accordance with a predetermined pattern. The control region 204 may contain a number of physical channels for the transmission of control data, such as a physical downlink control channel PDCCH, a physical control format indicator channel PCFICH and a physical HARQ indicator channel PHICH. The data region may contain a number of physical channel for the transmission of data, such as a physical downlink shared channel PDSCH and a physical broadcast channels PBCH. Although these physical channels provide a wide range of functionality to LTE systems, in terms of resource allocation and the present disclosure PDCCH and PDSCH are most relevant. Further information on the structure and functioning of the physical channels of LTE systems can be found in [1].

Resources within the PDSCH may be allocated by an eNodeB to UEs being served by the eNodeB. For example, a number of resource blocks of the PDSCH may be allocated to a UE in order that it may receive data that it has previously requested or data which is being pushed to it by the eNodeB, such as radio resource control RRC signalling. In Figure 2, UE1 has been allocated resources 208 of the data region 206, UE2 resources 209 and UE resources 210. UEs in a an LTE system may be allocated a fraction of the available resources of the PDSCH and therefore UEs are required to be informed of the location of their allocated resources within the PDCSH so that only relevant data within the PDSCH is detected and estimated. In order to inform the UEs of the location of their allocated communications resources, resource control information specifying downlink resource allocations is conveyed across the PDCCH in a form termed downlink control information DCI, where resource allocations for a PDSCH are communicated in a preceding PDCCH instance in the same subframe. During a resource allocation procedure, UEs thus monitor the PDCCH for DCI addressed to them and once such a DCI is detected, receive the DCI and detect and estimate the data from the relevant part of the PDSCH.

Each uplink subframe may include a plurality of different channels, for example a physical uplink shared channel PUSCH 305, a physical uplink control channel PUCCH 306, and a physical random access channel PRACH. The physical Uplink Control Channel PUCCH may carry control information such as ACK/NACK to the eNodeB for downlink transmissions, scheduling request indicators SRI for UEs wishing to be scheduled uplink resources, and feedback of downlink channel state information CSI for example. The PUSCH may carry UE uplink data or some uplink control data. Resources of the PUSCH are granted via PDCCH, such a grant being typically triggered by communicating to the network the amount of data ready to be transmitted in a buffer at the UE. The PRACH may be scheduled in any of the

resources of an uplink frame in accordance with a one of a plurality of PRACH patterns that may be signalled to UE in downlink signalling such as system information blocks. As well as physical uplink channels, uplink subframes may also include reference signals. For example, demodulation reference signals DMRS 307 and sounding reference signals SRS 308 may be present in an uplink subframe where the DMRS occupy the fourth symbol of a slot in which PUSCH is transmitted and are used for decoding of PUCCH and PUSCH data, and where SRS are used for uplink channel estimation at the eNodeB. Further information on the structure and functioning of the physical channels of LTE systems can be found in [1].

In an analogous manner to the resources of the PDSCH, resources of the PUSCH are required to be scheduled or granted by the serving eNodeB and thus if data is to be transmitted by a UE, resources of the PUSCH are required to be granted to the UE by the eNodeB. At a UE, PUSCH resource allocation is achieved by the transmission of a scheduling request or a buffer status report to its serving eNodeB. The scheduling request may be made, when there is insufficient uplink resource for the UE to send a buffer status report, via the transmission of Uplink Control Information UCI on the PUCCH when there is no existing PUSCH allocation for the UE, or by transmission directly on the PUSCH when there is an existing PUSCH allocation for the UE. In response to a scheduling request, the eNodeB is configured to allocate a portion of the PUSCH resource to the requesting UE sufficient for transferring a buffer status report and then inform the UE of the buffer status report resource allocation via a DCI in the PDCCH. Once or if the UE has PUSCH resource adequate to send a buffer status report, the buffer status report is sent to the eNodeB and gives the eNodeB information regarding the amount of data in an uplink buffer or buffers at the UE. After receiving the buffer status report, the eNodeB can allocate a portion of the PUSCH resources to the sending UE in order to transmit some of its buffered uplink data and then inform the UE of the resource allocation via a DCI in the PDCCH. For example, presuming a UE has a connection with the eNodeB, the UE will first transmit a PUSCH resource request in the PUCCH in the form of a UCI. The UE will then monitor the PDCCH for an appropriate DCI, extract the details of the PUSCH resource allocation, and transmit uplink data , at first comprising a buffer status report, and/or later comprising a portion of the buffered data, in the allocated resources.

Although similar in structure to downlink subframes, uplink subframes have a different control structure to downlink subframes, in particular the upper 309 and lower 310 subcarriers/frequencies/resource blocks of an uplink subframe are reserved for control signalling rather than the initial symbols of a downlink subframe. Furthermore, although the resource allocation procedure for the downlink and uplink are relatively similar, the actual structure of the resources that may be allocated may vary due to the different characteristics of the OFDM and SC-FDM interfaces that are used in the downlink and uplink respectively. In OFDM each subcarrier is individually modulated and therefore it is not necessary that frequency/subcarrier allocation are contiguous however, in SC-FDM subcarriers are modulation in

combination and therefore if efficient use of the available resources are to be made contiguous frequency allocations for each UE are preferable.

As a result of the above described wireless interface structure and operation, one or more UEs may communicate data to one another via a coordinating eNodeB, thus forming a conventional cellular telecommunications system. Although cellular communications system such as those based on the previously released LTE standards have been commercially successful, a number of disadvantages are associated with such centralised systems. For example, if two UEs which are in close proximity wish to communicate with each other, uplink and downlink resources sufficient to convey the data are required. Consequently, two portions of the system's resources are being used to convey a single portion of data. A second disadvantage is that an eNodeB is required if UEs, even when in close proximity, wish to communicate with one another. These limitations may be problematic when the system is experiencing high load or eNodeB coverage is not available, for instance in remote areas or when eNodeBs are not functioning correctly. Overcoming these limitations may increase both the capacity and efficiency of LTE networks but also lead to the creations of new revenue possibilities for LTE network operators.

CLAIMS

1. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

2. A terminal device according to claim 1, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

3. A terminal device according to claim 2, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

4. A terminal device according to claim 2, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

5. A terminal device according to claim 1, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

6. A terminal device according to claim 5, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

7. A terminal device according to claim 5, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

8. A terminal device according to claim 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

9. A terminal device according to claim 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space, wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

10. A terminal device according to claim 1, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

11. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

12. Infrastructure equipment according to claim 11, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

13. Infrastructure equipment according to claim 12, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

14. Infrastructure equipment according to claim 12, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

15. Infrastructure equipment according to claim 11, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

16. Infrastructure equipment according to claim 15, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

17. Infrastructure equipment according to claim 15, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

18. Infrastructure equipment according to claim 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate.

19. Infrastructure equipment according to claim 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, , wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, the starting time of the radio search space matching the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

20. Infrastructure equipment according to claim 11, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

21. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, controlling the transceiver to receive the paging message scheduled by the received scheduling message.

22. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the

plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

23. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver element to receive the paging message scheduled by the received scheduling message.

24. Integrated circuitry for infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from

a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

25. A wireless telecommunications network comprising a terminal device according to claim 1 and infrastructure equipment according to claim 11.

26. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

27. A terminal device according to claim 26, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

28. A terminal device according to claim 26, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

29. A terminal device according to claim 26, wherein the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods.

30. A terminal device according to claim 26, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

31. A terminal device according to claim 26, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

32. A terminal device according to claim 26, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

33. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

34. Infrastructure equipment according to claim 33, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the transceiver is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

35. Infrastructure equipment according to claim 33, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

36. Infrastructure equipment according to claim 33, wherein the controller is operable to control the transceiver to transmit a signal to the terminal device indicative of the predetermined plurality of separate time periods.

37. Infrastructure equipment according to claim 33, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

38. Infrastructure equipment according to claim 33, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate..

39. Infrastructure equipment according to claim 33, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

40. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the

plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

transceiver is controlled to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

41. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the transceiver is controlled to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

42. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin receiving the scheduling signal; and

the controller element is operable to control the transceiver element to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

43. Integrated circuitry for operating infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller element is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin transmitting the scheduling signal.

44. A wireless telecommunications network comprising a terminal device according to claim 26 and infrastructure equipment according to claim 33.

INTERNATIONAL SEARCH REPORT

International application No
PCT/EP2017/057758

A. CLASSIFICATION OF SUBJECT MATTER
INV. H04W68/00
ADD. H04W4/00 H04W68/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
H04W

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
EPO-Internal, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 2 999 280 A2 (APPLE INC [US]) 23 March 2016 (2016-03-23) paragraphs [0100] - [0159] ----- -/--	1-25

[X] Further documents are listed in the continuation of Box C.

[X] See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.
PCT/EP2017/057758

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

☒ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-25

   Identification of paging/scheduling signal for a given mobile terminal

   ---

2. claims: 26-44

   Avoiding interference for paging where paging signals are transmitted multiple times (Coverage Enhancement)

(54) Title: METHODS AND APPARATUSES FOR DOWNLINK CONTROL INFORMATION TRANSMISSION AND RECEIVING

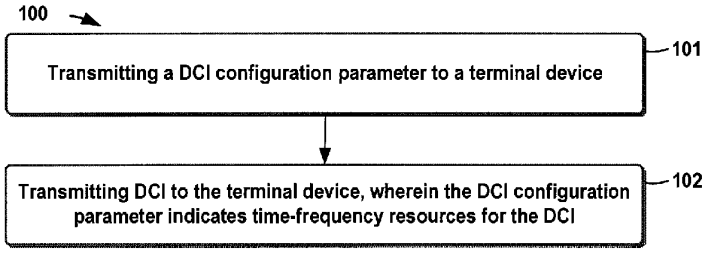

Fig. 1

(57) Abstract: Embodiments of the present disclosure relate to methods and apparatuses for downlink control information (DCI) transmission and receiving in a wireless communication system. A DCI configuration parameter can be first transmitted to a terminal device; and then DCI is transmitted to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI. With embodiments of the present disclosure, the UE could perform a flexible DCI monitoring according to the DCI configuration parameter and thus it may support the DCI monitoring occasion change due to numerology and scheduling unit size.

WO 2018/126401 A1

METHODS AND APPARATUSES FOR DOWNLINK CONTROL INFORMATION TRANSMISSION AND RECEIVING

FIELD OF THE INVENTION

[0001] The non-limiting and exemplary embodiments of the present disclosure generally relate to the field of wireless communication techniques, and more particularly relate to methods and apparatuses for downlink control information (DCI) transmission and receiving in a wireless communication system.

BACKGROUND OF THE INVENTION

[0002] New radio access system, which is called as new RAT (NR) system or network for short, is the next generation communication system. In Radio Access Network (RAN) #71 meeting for the third generation Partnership Project (3GPP) working group, study of NR system was approved. The NR system will consider frequency ranging up to 100Ghz with an object of a single technical framework addressing all usage scenarios, requirements and deployment scenarios defined in Technical Report TR 38.913, which include requirements such as enhanced mobile broadband, massive machine-type communications, ultra reliable and low latency communications.

[0003] Especially, in the NR network, different numerologies will coexist in the same carrier and a mini-slot will be introduced to carry Ultra-reliable low latency communication (URLLC) traffic. As a result, DCI monitoring may be performed per symbol based on the specific numerology. Thus, a terminal device like user equipment (UE) needs to know when to monitor the DCI for scheduling related operations.

[0004] In current LTE system, DCI monitoring is performed per subframe or per slot if the UE is in on duration of the discontinuous reception (DRX) active state. The DRX periodicity can be configured by higher layers.

[0005] However, with the current DCI monitoring solution in LTE, it cannot support the DCI monitoring occasion change due to numerology and scheduling unit size.

SUMMARY OF THE INVENTION

[0006] In patent cooperation treaty (PCT) application publication No. WO2016190970A1, there were proposed techniques for selecting data communications with shortened time duration wherein a two-stage grant for communication scheduling was introduced, the first stage grant could include an indication to activate/deactivate ultra-low latency (ULL) communication.

[0007] In US application US20160119969A1, there was proposed a solution for MAC enhancement for concurrent legacy and enhanced component carrier (ECC) operation, wherein a two stage Semi-Persistent Scheduling (SPS) solution was introduced and a first stage grant could contain parameters that may not change much over the course of a given SPS instance while the second stage grant could contain the actual resource for the SPS scheduling.

[0008] In another PCT application publication No. WO2016069270A1, there was proposed another two-stage PDCCH wherein a fast DCI could include a DCI flag and DCI format size indicator to indicate the existence and the size of the slow DCI in the same TTI.

[0009] However, none of the above solutions can address the problems as presented in the back ground.

[0010] To this end, in the present disclosure, there is provided a new solution for DCI transmission and receiving in a wireless communication system, to mitigate or at least alleviate at least part of the issues in the prior art.

[0011] According to a first aspect of the present disclosure, there is provided a DCI transmission in a wireless communication system. The method comprises transmitting a DCI configuration parameter to a terminal device; and transmitting DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

[0012] According to a second aspect of the present disclosure, there is provided a method of DCI receiving in a wireless communication system. The method comprises receiving a DCI configuration parameter at a terminal device; and receiving DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

[0013] According to a third aspect of the present disclosure, there is provided

an apparatus of DCI transmission in a wireless communication system. The apparatus comprises: a parameter transmission module and a DCI transmission module. The parameter transmission module may be configured to transmit a DCI configuration parameter to a terminal device. The DCI transmission module may be configured to transmit DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI

[0014] According to a fourth aspect of the present disclosure, there is provided an apparatus of DCI receiving in a wireless communication system. The apparatus comprises: a parameter receiving module and a DCI receiving module. The parameter receiving module may be configured to receive DCI configuration parameter at a terminal device. The DCI receiving module may be configured to receive DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

[0015] According to a fifth aspect of the present disclosure, there is provided a computer-readable storage media with computer program code embodied thereon, the computer program code configured to, when executed, cause an apparatus to perform actions in the method according to any embodiment in the first aspect.

[0016] According to a sixth aspect of the present disclosure, there is provided a computer-readable storage media with computer program code embodied thereon, the computer program code configured to, when executed, cause an apparatus to perform actions in the method according to any embodiment in the second aspect.

[0017] According to a seventh aspect of the present disclosure, there is provided a computer program product comprising a computer-readable storage media according to the fifth aspect.

[0018] According to an eighth aspect of the present disclosure, there is provided a computer program product comprising a computer-readable storage media according to the sixth aspect.

[0019] With embodiments of the present disclosure, a DCI configuration parameter can be first transmitted to the terminal device, and then the DCI is transmitted to the terminal device. Thus, the terminal device may monitor the transmitted DCI based on the received DCI configuration parameter, which means a flexible DCI monitoring solution and thus can support the DCI monitoring occasion change due to

numerology and scheduling unit size.

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] The above and other features of the present disclosure will become more apparent through detailed explanation on the embodiments as illustrated in the embodiments with reference to the accompanying drawings, throughout which like reference numbers represent same or similar components and wherein:

[0021] Fig. 1 schematically illustrates a flow chart of a method of DCI transmission according to an example embodiment of the present disclosure;

[0022] Fig. 2 schematically illustrates DCI occurrence occasions with different numerologies according to example embodiments of the present disclosure;

[0023] Figs. 3A to 3C schematically illustrate DCI occurrence occasions at different levels according to examples embodiments of the present disclosure;

[0024] Figs. 4A and 4C schematically illustrate DCI occurrence occasions with frequency hopping according to example embodiment of the present disclosure;

[0025] Fig. 5A schematically illustrates a two-DCI solution for enhanced mobile broadband (eMBB) and URLLC multiplexing in which control and data are multiplexed in time domain according to an embodiment of the present disclosure;

[0026] Fig. 5B schematically illustrates a two-DCI solution for eMBB and URLLC multiplexing in which control and data are multiplexed in frequency domain according to an embodiment of the present disclosure;

[0027] Figs. 6A to 6D schematically illustrate two-DCI solutions for eMBB and URLLC multiplexing according to an embodiment of the present disclosure, wherein control region and data are multiplexed in time domain and the eMBB and the URLL are multiplexed in TDM, in TDM by symbol, in FDM, and in both FDM and TDM, respectively;

[0028] Figs. 7A to 7D schematically illustrate two-DCI solutions for eMBB and URLLC multiplexing according to an embodiment of the present disclosure, wherein control region and data are multiplexed in frequency domain and the eMBB and the URLL are multiplexed in TDM, in TDM by symbol, in FDM, and in both FDM and TDM, respectively;

[0029] Fig. 8 schematically illustrates a two-DCI solution for eMBB and

URLLC multiplexing according to an embodiment of the present disclosure, wherein two segments are used and the second segment is punctured or not punctured without re-transmission;

[0030] Fig. 9 schematically illustrates a two-DCI solution for eMBB and URLLC multiplexing according to an embodiment of the present disclosure, wherein two segments are used and the second segment is punctured with retransmission;

[0031] Fig. 10 schematically illustrates an example two-DCI division solution according to an embodiment of the present disclosure;

[0034] Fig. 13 schematically illustrates a block diagram of an apparatus for DCI receiving according to an embodiment of the present disclosure; and

[0035] Fig. 14 further illustrates a simplified block diagram of an apparatus 1410 that may be embodied as or comprised in a serving node like a base station in a wireless network and an apparatus 1420 that may be embodied as or comprised in a terminal device like UE as described herein.

DETAILED DESCRIPTION OF EMBODIMENTS

[0036] Hereinafter, the solution as provided in the present disclosure will be described in details through embodiments with reference to the accompanying drawings. It should be appreciated that these embodiments are presented only to enable those skilled in the art to better understand and implement the present disclosure, not intended to limit the scope of the present disclosure in any manner.

[0037] In the accompanying drawings, various embodiments of the present disclosure are illustrated in block diagrams, flow charts and other diagrams. Each block in the flowcharts or blocks may represent a module, a program, or a part of code, which contains one or more executable instructions for performing specified logic functions, and in the present disclosure, a dispensable block is illustrated in a dotted line. Besides, although these blocks are illustrated in particular sequences for performing the steps of the methods, as a matter of fact, they may not necessarily be performed strictly

according to the illustrated sequence. For example, they might be performed in reverse sequence or simultaneously, which is dependent on natures of respective operations. It should also be noted that block diagrams and/or each block in the flowcharts and a combination of thereof may be implemented by a dedicated hardware-based system for performing specified functions/operations or by a combination of dedicated hardware and computer instructions.

[0038] Generally, all terms used in the claims are to be interpreted according to their ordinary meaning in the technical field, unless explicitly defined otherwise herein. All references to "a/an/the/said [element, device, component, means, step, etc.]" are to be interpreted openly as referring to at least one instance of said element, device, component, means, unit, step, etc., without excluding a plurality of such devices, components, means, units, steps, etc., unless explicitly stated otherwise. Besides, the indefinite article "a/an" as used herein does not exclude a plurality of such steps, units, modules, devices, and objects, and etc.

[0039] Additionally, in a context of the present disclosure, a user equipment (UE) may refer to a terminal, a Mobile Terminal (MT), a subscriber station, a portable subscriber station, Mobile Station (MS), or an Access Terminal (AT), and some or all of the functions of the UE, the terminal, the MT, the SS, the portable subscriber station, the MS, or the AT may be included. Furthermore, in the context of the present disclosure, the term "BS" may represent, e.g., a node B (NodeB or NB), an evolved NodeB (eNodeB or eNB), gNB (Node B in NR), a radio header (RH), a remote radio head (RRH), a relay, or a low power node such as a femto, a pico, and so on.

[0040] As mentioned hereinbefore, none of the prior arts can support the DCI monitoring occasion change due to numerology and scheduling unit size. Thus, in the present disclosure, there is proposed a new DCI transmission and receiving solution. In the proposed solution, a DCI configuration parameter can be first transmitted to the terminal device, and then the DCI is transmitted to the terminal device. Thus, the terminal device may monitor the DCI based on the received DCI configuration parameter, which means a flexible DCI monitoring solution and thus can support the DCI monitoring occasion change due to numerology and scheduling unit size.

[0041] Hereinafter, reference will be made to Figs. 1 to 14 to describe the DCI transmission and receiving solution.

[0042] Fig.1 schematically illustrates a flow chart of a method 100 of DCI transmission in a wireless communication system according to an embodiment of the present disclosure. The method 100 can be performed at a serving node, for example a BS, like a node B (NodeB or NB).

[0043] As illustrated in Fig. 1, first in step 101, a DCI configuration parameter is transmitted to a terminal device, and the DCI configuration parameter indicates time-frequency resources for a following DCI.

[0044] In an embodiment of the present disclosure, the DCI configuration parameter comprises at least one of: a numerology to be used; a valid duration for the DCI configuration parameter; a duration for a single DCI; and DCI occurrence occasions.

[0045] In NR system, different numerologies might be used, whereas different numerologies might use different transmission parameters, for example different subcarrier spacings. The different subcarrier spacings mean different symbol lengths. For example, for 15 kHz subcarrier spacing, its symbol will have a time length four times as that for 60 kHz subcarrier spacing, as illustrated in Fig. 2. Thus, the numerology to be used can be used to define a symbol.

[0046] The valid duration for the DCI configuration parameter indicates a duration in which the DCI configuration parameter is valid. The valid duration can be a number of symbols (for example, numerology specific) or a number of frames (for example numerology common). In an embodiment of the present disclosure, the values of the start of the valid duration can be an absolute value with respect to the reference numerology. For example, if the configuration signaling is received in symbol 7 of the subframe 2 of frame 6, the starting can be defined as symbol 0 of subframe 0 of frame 6. The definition of the absolute value can be predetermined or configured by a high layer signaling like RRC signaling. In another embodiment of the present disclosure, the first symbol carrying the configuration signaling can be used as the start of the valid duration no matter whether the configuration signaling is configured by DCI or by a RRC signaling.

[0047] The duration for a single DCI indicates the length of the DCI, it can be a number of symbols. Thus, parameter may indicate the length of DCI. It is also possible to use a predetermined length and in such a case, this parameter can be omitted.

[0048] DCI occurrence occasions indicate occasions at which DCI occurs in frames. In an embodiment of the present disclosure, the DCI occurrence occasions can be at a slot level, at subframe level (multi-slot), or at symbol level, as illustrated in Figs. 3A to 3C respectively.

[0049] The DCI occurrence occasions can be periodic. That is to say, the DCI monitoring will be performed periodically, for example every a predetermined number of slots, every a predetermined number of symbols. Fig 3A and Fig. 3B illustrate two examples of periodic DCI occurrence occasions. In Fig. 3A, the DCI occurrence occasions are per slot; in other words, the DCI monitoring is performed every slot, like in slots 0, 1,…,. In Fig. 3B, the DCI occurrence occasions are per multi-slot (e.g., 2 slots, a subframe); that is to say, the DCI monitoring can be performed per multi-slot. In such a case, the DCI occurrence occasions can be indicated by the periodicity and an offset of the DCI occurrence. The periodicity can be, for example, a predetermined number of symbols, slots, or frames.

[0050] Alternatively, the DCI occurrence occasions can also be aperiodic. Fig. 3C illustrates an aperiodic DCI occurrence occasion. In Fig. 3C, the DCI occurrence occasions are per symbol but aperiodic. In such a case, it may predefine a set of possible aperiodic patterns in specification or pre-configure the possible set of aperiodic patterns by a higher layer signaling. In the set of aperiodic patterns, each aperiodic pattern contains one or more symbols within a valid duration. In such a way, the network can inform the aperiodic pattern index to the terminal device in DCI configuration parameter.

[0051] It should be noticed that although the DCI occurrence occasions per slot and multi-slot in Fig.3A and 3B are periodic and the DCI occurrence occasions per symbol in Fig.3C is aperiodic, the present disclosure is not limited thereto. In fact, in each of the DCI occurrence occasions per slot, per multi-slot, per symbol, the DCI occurrence occasions can be periodic or aperiodic.

[0052] As another alternative, the DCI occurrence occasions can be a combination of periodic and aperiodic occasions. In other word, in a time period, it contains an aperiodic pattern including one or more symbols but the aperiodic pattern will repeat by the time period in the valid duration. In such a case, the DCI occurrence occasions can be indicated by the periodicity and the aperiodic pattern.

[0053] In another embodiment of the present disclosure, the DCI configuration parameter may comprise at least one of: frequency domain resource unit; and frequency hopping pattern.

[0054] The frequency domain resource unit indicates the resource unit to be used for DCI in the frequency domain, it could be a control channel element (CCE), a subband, a physical resource block (PRB), or physical resource group (REG). In addition, the frequency domain resource unit can be numerology common, which mean the frequency domain resource unit is same for all numerologies, or numerology specific, which mean that different numerologies might use different frequency domain resource units.

[0055] The frequency hopping pattern indicates a pattern in which the frequency hopping is used. This parameter is required when the frequency hopping pattern is used. An explicit signaling can be used to indicate the frequency resource in each DCI occurrence occasion. The hopping pattern can be a predetermined pattern which is known at both network and the terminal device, or a pattern configured by the network. The hopping pattern can be used to calculate the frequency resource position.

[0056] Figs. 4A to 4C illustrate use of frequency hopping in different DCI occurrence occasions according to embodiments of the present disclosure. DCI occurrence occasions as illustrated in Fig.4A to Fig. 4C are same with those in Fig. 3A to 3C in the time domain but in the frequency domain, the frequency hopping is used for the DCI occurrence occasions. It should be noticed that although the DCI occurrence occasions per slot and per multi-slot in Fig.4A and 4B are periodic and the DCI occurrence occasions per symbol in Fig.4C is aperiodic, the present disclosure is not limited thereto. In fact, in each of the DCI occurrence occasions per slot, per multi-slot, per symbol, the DCI occurrence occasions can be periodic or aperiodic.

[0057] Reference is made back to Fig. 1, in step 102, the DCI can be transmitted to the terminal device. With the DCI configuration parameter, the terminal device may learn the time-frequency resource for the DCI from the DCI configuration parameter and monitor the DCI within the time-frequency resource.

[0058] In an embodiment of the present disclosure, the DCI configuration parameter can be transmitted to the terminal device by a higher layer signaling like a

RRC signaling. That is to say, in the two-stage solution, for the first stage, the higher layer signaling can be used to transmit the DCI configuration indicating the time-frequency resource for the following DCI in the second stage.

[0059] In another embodiment of the present disclosure, the DCI configuration parameter can be transmitted to the terminal device dynamically by another DCI. In such a case, a first DCI is used to transmit the DCI configuration parameter for the following DCI. The actual data scheduling related information is located in the following DCI.

[0060] In addition, considering the payload size of the first DCI, it is also possible to use a combination of DCI and high layer signaling. That is to say, a part of DCI configuration parameter can be transmitted by DCI and another part of the DCI configuration parameter can be transmitted by a high layer signaling.

[0061] In the two stage DCI solution, the first DCI can be cell specific, beam specific, TRP specific, common for a UE group or UE specific. In an embodiment of the present disclosure, the DCI can be scrambled with a specific RNTI. The periodicity of the first DCI can be larger than the second DCI. The occurrence occasions of the first DCI can predetermined or configured by a higher layer signaling such a RRC signaling. The first DCI can be located in common search space. Or alternative, the first DCI can also be located in UE specific search space.

[0062] It shall be noted that there may be a valid duration for the DCI configuration parameter but there is no any restriction on DCI configuration parameter and scheduling unit size. For example, with slot-level DCI monitoring configuration, UE can also be configured with a scheduling unit starting and ending from the symbol boundary rather than a slot boundary. In such a case, the remaining blank symbols can be allocated to other UE with symbol level DCI monitoring configuration. Or alternatively, the remaining blank symbols can also be allocated to other UE with slot-level or multi-slot level DCI configuration.

[0063] In a further embodiment of the present disclosure, the DCI configuration parameter may comprise at least two sets of parameters, from which the terminal device can select a set of parameters based on its requested traffic types. In other words, DCI monitoring can be adapted at UE side after resource requirement by means of random access procedure/scheduling request (SR).

[0064] After a random access procedure, the terminal device starts DL/UL transmission/reception with the eNB. Thus, the DCI monitoring behavior can be based on the reason for random access. If URLLC scheduling request is the reason for random access, the DCI monitoring should be more frequent. If eMBB scheduling request is the reason for random access, the DCI monitoring can be less frequent. By providing two or more different sets of DCI configuration parameters predefined or configured by RRC signaling, the terminal device could choose the suitable parameter set based on its request traffic type. In such a way, it is possible for UE to perform DCI monitoring based on its required traffic type.

[0065] In another aspect of the present disclosure, there is also provided another two-DCI solution for different traffic type multiplexing. In these solutions, two DCIs are used, one of which can be called as prepositive control region (DCI), the other of which can be called as postpostive control region (DCI). The prepositive control region can be used to indicate resource that is allocated to a first traffic type (such as eMBB traffic) but is to be occupied by a second traffic type (such as URLLC traffic), the postpositive control region can be used to indicate resource that allocated to a first traffic type (such as eMBB traffic) but was already occupied by the second traffic type (such as abrupt URLLC traffic). Hereinafter, the URLLC traffic and the eMBB traffic will be taken as examples of different traffic types to describe the two-DCI solution; however, those skilled in the art can readily know that the present disclosure is not limited thereto.

[0066] In an embodiment of the present disclosure, the prepositive control region can include at least one of following fields:

- a field to indicate puncture or rate-matching around some time-frequency resource in a following pattern of time-frequency resource;
- a field to schedule on a following pattern of time-frequency resource (e.g. can be contiguous or non-contiguous symbols/frequency bands);
- a field to indicate re-transmission of previous punctured part;
- a field to indicate the end of one transmission block.

[0067] In an embodiment of the present disclosure, the postpositive region can include at least one of following fields:

- a field to indicate puncture or no puncture of some time-frequency

resources in the previous pattern of time-frequency resource

- a field to indicate re-transmission or no re-transmission of previous punctured part
- a field to indicate the end of one transmission block

[0068] It shall be noted that patterns of time-frequency resource in prepositive and postpositive control regions can be complementary. For example, the two patterns can compose a whole time-frequency resource of a region (subframe). Alternatively, the two patterns can be also partially overlapped.

[0069] Fig. 5A illustrates a two-DCI solution for different traffic type multiplexing according to an embodiment of the present disclosure. The resource of eMBB can be split into two parts as illustrated in Fig. 5, the first one is to be scheduled by the prepostive control region and the other one is to be scheduled by the postpostive control region. For some resources such as first several symbols, the scheduling of URLLC can be known, thus the eMBB UE can be indicated of rate-matching or puncture for the occupied resource in the prepositive control region if it is occupied by the URLLC. While, for some resources, for example when the URLLC occurs abruptly, the scheduling of URLLC cannot be known in the prepositive control region, and thus the eMBB UE can be indicated to puncture for the occupied resources in the postpositive control region.

[0070] In Fig. 5A, it is shown that the control regions and the data regions are multiplexed in the time domain. In another embodiment of the present disclosure, the control regions and data regions can be multiplexed in the frequency domain. Fig. 5B illustrates a two-DCI solution for different traffic type multiplexing according to an embodiment of the present disclosure. Fig. 5B is similar with Fig. 5A but differs in that in Fig. 5B, the control regions and data regions are multiplexed in the frequency domain.

[0071] It should also be noted that resource indicated to eMBB UE can be resource occupied by URLLC or resource reserved as empty for forward phase.

[0072] In addition, it shall also be noted that the split resource parts can also be multiplexed in many different ways, which will be described with reference to Fig. 6A to Fig. 7D.

[0073] Fig. 6A illustrates a two-DCI solution according to an embodiment of

the present disclosure, in which the control region and the data region are multiplexed in TDM and two split parts are multiplexed in time domain multiplexing (TDM). Fig. 6A is substantially same as that in Fig. 5A, and in the two DCI solution, the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region in TDM.

[0074] Fig. 6B illustrates another two-DCI solution according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in TDM and the two split parts are multiplexed in TDM by symbols. Compared with that illustrated in Fig. 6A, in Fig. 6B, the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region also in TDM but by symbol; that is to say, in Fig. 6B, the symbols belonging to each part are not continuous.

[0075] Fig. 6C illustrates a further two-DCI solution according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in TDM and the two split parts are multiplexed in frequency domain multiplexing (FDM). Different from that illustrated in Fig. 6A and Fig. 6B, in Fig. 6C the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region in FDM, i.e., they respectively occupy different frequency domain resources.

[0076] Fig. 6D illustrates a further two-DCI solution according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in TDM and the two split parts are multiplexed in TDM and frequency domain multiplexing (FDM). As illustrated in Fig. 6D, the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region in a combination of TDM and FDM.

[0077] Figs. 7A to 7D illustrate two-DCI solutions according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in FDM and two split parts are multiplexed in different manners respectively. In Fig. 7A, the two split parts are multiplexed in TDM; in Fig. 7B, the two split parts are multiplexed in TDM by symbol; in Fig. 7C, the two split parts are multiplexed in FDM; and Fig. 7D, the two split parts are multiplexed in TDM and FDM.

[0078] The two split parts can be decoded in any suitable manner. In an embodiment of the present disclosure, the two split part can be separately decoded. In another embodiment of the present disclosure, the two parts can be cascaded to decode, i.e. when UE receives the two parts, then it decodes them immediately or it decodes them after UE receiving the postpositive control region.

[0079] In a further embodiment of the present disclosure, the resource for eMBB can be split for several parts, wherein first parts are to be scheduled by the preposition control region and seconds parts are to be scheduled by the postpostive control region. The several parts are further divided into two segments in the time domain, i.e., segment 1 and segment 2. For some resources such as first several symbols, the scheduling of URLLC can be known, thus the eMBB UE can be indicated of rate-matching or puncture for the occupied resource in the prepositive control region if it is occupied by the URLLC. While, for some resources, for example when the URLLC occurs abruptly, the scheduling of URLLC cannot be known in the prepositive control region, and thus the eMBB UE can be indicated to puncturing or not puncturing for the occupied resources in the postpositive control region. For some resources in the second segment, they may be reserved for re-transmission or be punctured part of transmission in the first segment. This punctured part can be for example a subset of the first segment, and the remaining of the first segment can be used for new transmission. Fig. 8 illustrates a two-DCI solution wherein there is no re-transmission in the second segment; while Fig. 9 illustrates a two-DCI solution wherein, in the second segment, there is a re-transmission of punctured part of the first segment as indicated by blocks filled with cross lines.

[0080] In addition, similarly to solutions as illustrate in Figs. 6A to 7D, the first parts and the second parts can be multiplexed in time and/or frequency domain. Moreover, these parts can be cascaded to decode, i.e. when UE receives the two parts, then it decodes them immediately or it decodes them after UE receiving the postpositive control region.

[0081] In a further aspect of the present disclosure, one transmission block can also be split into several parts. The first part can be scheduled by, for example, prepositive control region, and the second part can be scheduled by, for example, postpositive control region. The UE can decode after receiving the whole transmission

block. The end of the transmission can be indicated in a control region. For example, UE may obtain frequency and time domain mapping for data, then obtain the mapping over resources preempted by URLLC, and after that it decodes the block.

[0082] In another embodiment of the present disclosure, preemption of URLLC can be indicated implicitly. For example, it is possible to use tracking RS to implicitly indicate preemption of URLLC. For example, if the tracking RS is interrupted on some symbols, this means these symbols are occupied by URLLC, and thus this can be used to indicate preemption of URLLC.

[0083] In a further embodiment of the present disclosure, DCI can be cascaded with K-stage DCI. For example, a first stage DCI contains resource allocation field; the second stage DCI contains information of MCS and other information for data transmission (which may also contain detailed information of resource allocation). In such a case, the UE can cascades the two-stage DCI for control information.

[0084] In addition, the first stage DCI can be shared by different UEs, e.g. URLLC UE and eMBB UE, as illustrated in Fig. 10. The URLLC UE could obtain the shared first stage DCI and the second stage DCI for control and/or data transmission. The eMBB UE could obtain the shared first stage DCI for the resource allocation for puncturing or rate-matching. The shared common DCI can be scrambled with shared RNTI, e.g. a resource allocation RNTI calculated considering the resource index.

[0085] In a further embodiment of the present disclosure, the first DCI can include full scheduling information; while the second DCI may include indication of the resource occupied by URLLC or not. In addition, the second DCI can be reduced for some cases. For example, when no MCS needed, the second DCI can be omitted. If the resource is semi-statically reserved for URLLC and known to eMBB UE, the resource allocation is no needed and the second DCI can be reduced as well. In another case, if the resource is known by eMBB UE, and the time-frequency of remaining resource is fixed, then only an indication is needed in the second DCI, which indicates whether the time-frequency resource is occupied. If yes, the resource is for re-transmission or just keeps punctured; if not, the resource will be used for new data transmission.

[0086] It shall be noted that although the aspects and embodiments are described separately, they can also be combined together to achieve more benefits.

[0087] Fig. 11 further schematically illustrates a flow chart of method for DCI receiving according to an example embodiment of the present disclosure. The method 1100 can be implemented at a terminal device, for example UE, or other like terminal devices.

[0088] As illustrated in Fig. 11, the method starts from step 11, in which the terminal device like UE receiving a DCI configuration parameter. The DCI configuration parameter indicates the time-frequency resources for the following DCI.

[0089] In an embodiment of the present disclosure, the DCI configuration parameter may comprise at least one of: numerology to be used; a valid duration for the DCI configuration parameters; a duration for a single DCI; DCI occurrence occasions.

[0090] In another embodiment of the present disclosure, the DCI configuration parameter may comprise at least one of: a frequency domain resource unit; and a frequency hopping pattern.

[0091] In a further embodiment of the present disclosure, the receiving DCI configuration parameter may comprise receiving the DCI configuration parameter in a higher layer signaling.

[0092] In a further embodiment of the present disclosure, the receiving DCI configuration parameter may comprise receiving the DCI configuration parameter in another DCI.

[0093] In addition, considering the payload size of the first DCI, it is also possible to use a combination of DCI and high layer signaling. That is to say, a part of DCI configuration parameter can be received by a first DCI and another part of the DCI configuration parameter can be transmitted by a high layer signaling.

[0094] The first DCI can be cell specific, beam specific, TRP specific, common for a UE group or UE specific. In an embodiment of the present disclosure, the DCI can be scrambled with a specific RNTI. The periodicity of the first DCI can be larger than the second DCI. The occurrence occasions of the first DCI can predetermined or configured by a higher layer signaling such a RRC signaling. The first DCI can be located in common search space. . Or alternative, the first DCI can also be located in UE specific search space.

[0095] Next, in step 1102, DCI is received within time-frequency resources indicated by the DCI configuration parameter at the terminal device. That is to say, at

the terminal device, the terminal device may perform DCI monitoring based on the DCI configuration parameter, which means a flexible DCI monitoring solution and thus can support the DCI monitoring occasion change due to numerology and scheduling unit size.

[0096] In a still further embodiment of the present disclosure, the DCI configuration parameter comprises at least two sets of parameters. In such a case, further in step 1103, the UE may select a set of parameters based on its requested traffic types. In other words, DCI monitoring can be adapted at UE side after resource requirement by means of random access procedure/SR.

[0097] After random access procedure, the terminal device starts DL/UL transmission/reception with the eNB. Thus, the DCI monitoring behavior can be based on the reason for random access. If URLLC scheduling request is the reason for random access, the DCI monitoring should be more frequent. If eMBB scheduling request is the reason for random access, the DCI monitoring can be less frequent. By providing two or more different sets of DCI configuration parameters predefined or configured by RRC signaling, the terminal device could choose the suitable parameter set based on its request traffic type. In such a way, it is possible for UE to perform DCI monitoring based on its required traffic type.

[0098] Besides, in the present disclosure, there are also provided apparatuses for DCI transmission and receiving at the serving node and terminal device in a wireless communication system respectively, which will be described next with reference to Figs. 12 and 13.

[0099] Fig. 12 schematically illustrates a block diagram of an apparatus 1200 for DCI transmission in a wireless communication system according to an embodiment of the present disclosure. The apparatus 1200 can be implemented at a serving node, for example a BS, like a node B (NodeB or NB).

[00100] As illustrated in Fig. 12, the apparatus 1200 may comprise a parameter transmission module 1201 and a DCI transmission module 1202. The parameter transmission module 1201 can be configured to transmit a DCI configuration parameter to a terminal device. The DCI transmission module 1202 can be configured to transmit DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

[00101] In an embodiment of the present disclosure, the sequence position information may comprise any of: a numerology to be used; a valid duration for the DCI configuration parameters; a duration for a single DCI; DCI occurrence occasions; a frequency domain resource unit; and a frequency hopping pattern.

[00102] In another embodiment of the present disclosure, the parameter transmission module 1201 may be configured to transmit the DCI configuration parameter to the terminal device by a higher layer signaling.

[00103] In a further embodiment of the present disclosure, the parameter transmission module 1201 is configured to transmit the DCI configuration parameter to the terminal device dynamically by another DCI.

[00104] In a still further embodiment of the present disclosure, the another DCI may have a larger periodicity than the DCI.

[00105] In a yet further embodiment of the present disclosure, the DCI configuration parameter may comprise at least two sets of parameters, from which the terminal device can select a set of parameters based on its requested traffic type.

[00106] Fig. 13 further schematically illustrates a block diagram of an apparatus 1300 for DCI receiving in a wireless communication system according to an embodiment of the present disclosure. The apparatus 1300 can be implemented at a terminal device, for example UE, or other like terminal devices.

[00107] As illustrated in Fig. 13, the apparatus 1300 may include a parameter receiving module 1301 and a DCI receiving module 1302. The parameter receiving module 1301 may be configured to receive DCI configuration parameter at a terminal device. The DCI receiving module 1302 can be configured to receive DCI within time-frequency resources indicated by the DCI configuration parameter at a terminal device.

[00108] In an embodiment of the present disclosure, the sequence position information may comprise any of: a numerology to be used; a valid duration for the DCI configuration parameters; a duration for a single DCI; DCI occurrence occasions; a frequency domain resource unit; and a frequency hopping pattern.

[00109] In another embodiment of the present disclosure, the parameter receiving module 1301 may be further configured to receive the DCI configuration parameter in a higher layer signaling.

[00110] In another embodiment of the present disclosure, the parameter receiving module 1301 may be further configured to receive the DCI configuration parameter in another DCI.

[00111] In a still further embodiment of the present disclosure, the another DCI may have a larger periodicity than the DCI.

[00112] In a yet further embodiment of the present disclosure, the DCI configuration parameter may comprise at least two sets of parameters. In such a case, the apparatus 1300 may further comprise a parameter set selection module 1303. The apparatus 1300 may be configured to select a set of parameters based on a traffic type requested by the terminal device and wherein the time-frequency resources are those indicated by the selected set of parameters

[00113] Hereinbefore, the apparatuses 1200 and 1300 are described with reference to Figs. 12 and 13. It is noted that the apparatuses 1200 and 1300 may be configured to implement functionalities as described with reference to Figs. 1 to 11. Therefore, for details about the operations of modules in these apparatuses, one may refer to those descriptions made with respect to the respective steps of the methods with reference to Figs. 1 to 11.

[00114] It is further noted that the components of the apparatuses 1200 and 1300 may be embodied in hardware, software, firmware, and/or any combination thereof. For example, the components of apparatuses 1200 and 1300 may be respectively implemented by a circuit, a processor or any other appropriate selection device.

[00115] Those skilled in the art will appreciate that the aforesaid examples are only for illustration not limitation and the present disclosure is not limited thereto; one can readily conceive many variations, additions, deletions and modifications from the teaching provided herein and all these variations, additions, deletions and modifications fall the protection scope of the present disclosure.

[00116] In addition, in some embodiment of the present disclosure, apparatuses 1200 and 1300 may comprise at least one processor. The at least one processor suitable for use with embodiments of the present disclosure may include, by way of example, both general and special purpose processors already known or developed in the future. Apparatuses 1200 and 1300 may further comprise at least one memory.

The at least one memory may include, for example, semiconductor memory devices, e.g., RAM, ROM, EPROM, EEPROM, and flash memory devices. The at least one memory may be used to store program of computer executable instructions. The program can be written in any high-level and/or low-level compliable or interpretable programming languages. In accordance with embodiments, the computer executable instructions may be configured, with the at least one processor, to cause apparatuses 1200 and 1300 to at least perform operations according to the method as discussed with reference to Figs. 1 to 11 respectively.

[00117] Fig. 14 further illustrates a simplified block diagram of an apparatus 1410 that may be embodied as or comprised in a serving node like a base station in a wireless network and an apparatus 1420 that may be embodied as or comprised in a terminal device like UE as described herein.

[00118] The apparatus 1410 comprises at least one processor 1411, such as a data processor (DP) and at least one memory (MEM) 1412 coupled to the processor 1411. The apparatus 1410 may further comprise a transmitter TX and receiver RX 1413 coupled to the processor 1411, which may be operable to communicatively connect to the apparatus 1420. The MEM 1412 stores a program (PROG) 1414. The PROG 1414 may include instructions that, when executed on the associated processor 1411, enable the apparatus 1410 to operate in accordance with embodiments of the present disclosure, for example the method 100. A combination of the at least one processor 1411 and the at least one MEM 1412 may form processing means 1415 adapted to implement various embodiments of the present disclosure.

[00119] The apparatus 1420 comprises at least one processor 1421, such as a DP, and at least one MEM 1422 coupled to the processor 1421. The apparatus 1420 may further comprise a suitable TX/ RX 1423 coupled to the processor 1421, which may be operable for wireless communication with the apparatus 1410. The MEM 1422 stores a PROG 1424. The PROG 1424 may include instructions that, when executed on the associated processor 1421, enable the apparatus 1420 to operate in accordance with the embodiments of the present disclosure, for example to perform the method 1100. A combination of the at least one processor 1421 and the at least one MEM 1422 may form processing means 1425 adapted to implement various embodiments of the present disclosure.

[00120] Various embodiments of the present disclosure may be implemented by computer program executable by one or more of the processors 1411, 1421, software, firmware, hardware or in a combination thereof.

[00121] The MEMs 1412 and 1422 may be of any type suitable to the local technical environment and may be implemented using any suitable data storage technology, such as semiconductor based memory devices, magnetic memory devices and systems, optical memory devices and systems, fixed memory and removable memory, as non-limiting examples.

[00122] The processors 1411 and 1421 may be of any type suitable to the local technical environment, and may include one or more of general purpose computers, special purpose computers, microprocessors, digital signal processors DSPs and processors based on multicore processor architecture, as non-limiting examples.

[00123] In addition, the present disclosure may also provide a carrier containing the computer program as mentioned above, wherein the carrier is one of an electronic signal, optical signal, radio signal, or computer readable storage medium. The computer readable storage medium can be, for example, an optical compact disk or an electronic memory device like a RAM (random access memory), a ROM (read only memory), Flash memory, magnetic tape, CD-ROM, DVD, Blue-ray disc and the like.

[00124] The techniques described herein may be implemented by various means so that an apparatus implementing one or more functions of a corresponding apparatus described with one embodiment comprises not only prior art means, but also means for implementing the one or more functions of the corresponding apparatus described with the embodiment and it may comprise separate means for each separate function, or means that may be configured to perform two or more functions. For example, these techniques may be implemented in hardware (one or more apparatuses), firmware (one or more apparatuses), software (one or more modules), or combinations thereof. For a firmware or software, implementation may be made through modules (e.g., procedures, functions, and so on) that perform the functions described herein.

[00125] Exemplary embodiments herein have been described above with reference to block diagrams and flowchart illustrations of methods and apparatuses. It will be understood that each block of the block diagrams and flowchart illustrations, and combinations of blocks in the block diagrams and flowchart illustrations, respectively,

can be implemented by various means including computer program instructions. These computer program instructions may be loaded onto a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions which execute on the computer or other programmable data processing apparatus create means for implementing the functions specified in the flowchart block or blocks.

[00126] While this specification contains many specific implementation details, these should not be construed as limitations on the scope of any implementation or of what may be claimed, but rather as descriptions of features that may be specific to particular embodiments of particular implementations. Certain features that are described in this specification in the context of separate embodiments can also be implemented in combination in a single embodiment. Conversely, various features that are described in the context of a single embodiment can also be implemented in multiple embodiments separately or in any suitable sub-combination. Moreover, although features may be described above as acting in certain combinations and even initially claimed as such, one or more features from a claimed combination can in some cases be excised from the combination, and the claimed combination may be directed to a sub-combination or variation of a sub-combination.

[00127] It will be obvious to a person skilled in the art that, as the technology advances, the inventive concept can be implemented in various ways. The above described embodiments are given for describing rather than limiting the disclosure, and it is to be understood that modifications and variations may be resorted to without departing from the spirit and scope of the disclosure as those skilled in the art readily understand. Such modifications and variations are considered to be within the scope of the disclosure and the appended claims. The protection scope of the disclosure is defined by the accompanying claims.

WHAT IS CLAIMED IS:

1. A method of downlink control information (DCI) transmission in a wireless communication system, the method comprising:

transmitting a DCI configuration parameter to a terminal device; and

transmitting DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

2. The method of Claim 1, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameter;

a duration for a single DCI; and

DCI occurrence occasions.

3. The method of Claim 1 or 2, wherein the DCI configuration parameter comprises at least one of:

a frequency domain resource unit; and

a frequency hopping pattern.

4. The method of any of Claims 1 to 3, wherein the transmitting DCI configuration parameter to a terminal device comprises transmitting the DCI configuration parameter to the terminal device by a higher layer signaling.

5. The method of any of Claims 1 to 4, wherein the transmitting DCI configuration parameter to a terminal device comprises transmitting the DCI configuration parameter to the terminal device dynamically by another DCI.

6. The method of Claim 5, wherein the another DCI has a larger periodicity than the DCI.

7. The method of any of Claims 1 to 6, wherein the DCI configuration parameter comprises at least two sets of parameters, from which the terminal device can select a

set of parameters based on its requested traffic type.

8. A method of downlink control information (DCI) receiving in a wireless communication system, the method comprising:

receiving a DCI configuration parameter at a terminal device; and

receiving DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

9. The method of Claim 8, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameters;

a duration for a single DCI;

DCI occurrence occasions;

a frequency domain resource unit; and

a frequency hopping pattern.

10. The method of Claim 8 or 9, wherein the receiving DCI configuration parameter comprises receiving the DCI configuration parameter in a higher layer signaling.

11. The method of any Claims 8 to 10, wherein the receiving DCI configuration parameter comprises receiving the DCI configuration parameter in another DCI.

12. The method of Claim 11, wherein the another DCI has a larger periodicity than the DCI.

13. The method of any of Claims 8 to 12, wherein the DCI configuration parameter comprises at least two sets of parameters, wherein the method further comprises selecting a set of parameters based on a traffic type requested by the terminal device and wherein the time-frequency resources are those indicated by the selected set of parameters.

14. An apparatus of downlink control information (DCI) transmission in a wireless communication system, the apparatus comprising:

a parameter transmission module configured to transmit a DCI configuration parameter to a terminal device; and

a DCI transmission module configured to transmit DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

15. The apparatus of Claim 14, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameter;

a duration for a single DCI;

DCI occurrence occasions;

a frequency domain resource unit; and

a frequency hopping pattern .

16. The apparatus of Claim 14 or 15, wherein the parameter transmission module is further configured to transmit the DCI configuration parameter to the terminal device by a higher layer signaling.

17. The apparatus of any of Claims 14 to 16, wherein the parameter transmission module is further configured to transmit the DCI configuration parameter to the terminal device dynamically by another DCI.

18. The apparatus of Claim 17, wherein the another DCI has a larger periodicity than the DCI.

19. The apparatus of any of Claims 14 to 18, wherein the DCI configuration parameter comprises at least two sets of parameters, from which the terminal device can select a set of parameters based on its requested traffic type.

20. An apparatus of downlink control information (DCI) receiving in a wireless

communication system, the apparatus comprising:

a parameter receiving module configured to receive DCI configuration parameter at a terminal device; and

a DCI receiving module, configured to receive DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

21. The apparatus of Claim 20, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameters;

a duration for a single DCI;

DCI occurrence occasions;

a frequency domain resource unit; and

a frequency hopping pattern .

22. The apparatus of Claim 20 or 21, wherein the parameter receiving module is further configured to receive the DCI configuration parameter in a higher layer signaling.

23. The apparatus of any of Claims 20 to 22, wherein the parameter receiving module is further configured to receive the DCI configuration parameter in another DCI.

24. The apparatus of Claim 23, wherein the another DCI has a larger periodicity than the DCI.

25. The apparatus of any of Claims 20 to 24, wherein the DCI configuration parameter comprises at least two sets of parameters, wherein the apparatus further comprises a parameter set selection module, configured to select a set of parameters based on a traffic type requested by the terminal device and wherein the time-frequency resources are those indicated by the selected set of parameters.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these record s.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

(54) Title: DEVICE AND METHODS FOR MULTIPLEXING TRANSMISSIONS WITH DIFFERENT TTI DURATION

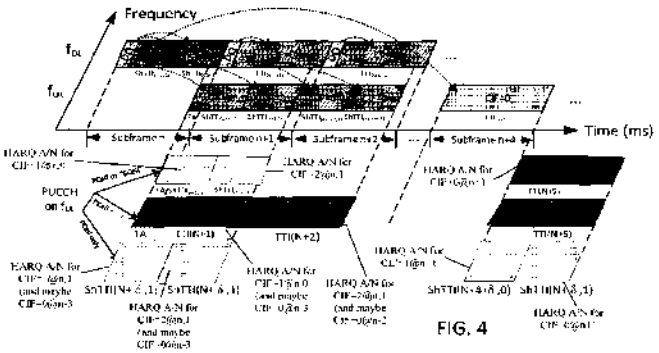

FIG. 4

(57) Abstract: A wireless transmit/receive unit, WTRU and methods of using a WTRU within a wireless communications network include communicating with a serving cell in the wireless communications network and determining, based on downlink control information whether the WTRU shall transmit with a first transmission time interval, TTI, length, using a first set of transmission resources, or a second TTI length, using a second set of transmission resources. Alternatively, determining based on said DCI, that the serving cell has indicated that the WTRU should use a first TTI on a physical uplink channel to communicate with the serving cell, or whether said DCI indicates that the WTRU should use a second TTI that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation.

WO 2017/079530 A1

DEVICE AND METHODS FOR MULTIPLEXING TRANSMISSIONS WITH DIFFERENT TTI DURATION

BACKGROUND

[0001] In a wireless communication network, such as a Long Term Evolution (LTE) system or New Radio (NR), a wireless transmit/receive unit (WTRU) device may access resources of the communication system. Latency associated with transmission of data in a communication system may have one or more latency components. A latency component may be the time to perform the transmission of a transport block, which time may be referred to as a Transmission Time Interval (TTI). Such TTI may be tied to a specific numerology associated with the transmission method and to a specific number of transmission symbols associated with the transmission. Other latency components may include processing time at a receiver, e.g., time decoding a transmission, transmission of feedback (e.g. ACK or NACK) and/or one or more retransmissions with one or more latency components.

SUMMARY

[0002] Systems, methods, and instrumentalities are disclosed for multiplexing transmissions with different durations, for example transmissions that are associated with different TTI lengths. Latency may be reduced (e.g., in an LTE system and/or in a NR system), for example, by multiplexing transmissions with different TTI durations or associated with different transmission numerologies. TTI duration may be modeled based on defining one or more cell(s) for a given carrier frequency, for example that may be associated with different TTI lengths and/or transmission durations. For example, the different transmission durations may be achieved by time-shifting one or more of the cells. In order to support signaling techniques that allow for concurrent and/or complementary scheduling of transmissions associated with different duration, a logical structure for the physical layer resources (e.g., a cell, a spectrum block, etc.) may configured to correspond to a secondary cell ("SCell"). A primary cell ("PCell") may logically maintain a first transmission duration (e.g., a first TTI length such as a legacy TTI length). The SCell may be configured with a second transmission duration (e.g., a second TTI length or a shortened TTI length). One or more of a PCell or an SCell may be configured with either the legacy or shortened TTI length (e.g., a shorter duration TTI (ShTTI).

[0003] By associating different TTI lengths with different cells, the LTE carrier aggregation framework can be utilized to support multiplexing of transmissions of different durations. For example, carrier aggregation signaling, including cross-carrier scheduling mechanisms, can be used to different scheduling grants and assignments of varying length. For example, a WTRU may determine a TTI duration (e.g., first or second TTI length) applicable to a transmission. For example, a WTRU may determine a TTI duration using cross-carrier scheduling. A WTRU may be configured to associate a given cell identity (e.g., servCellID) with a given transmission duration. Different cell identities (e.g., different servCellIDs) may be associated with different transmission durations/different TTI lengths. When a WTRU receives scheduling information applicable to a given cell identity, the WTRU may determine the associated TTI length based on the configuration received for that cell identity.

[0004] A WTRU may determine a TTI length and/or transmission duration based on one or more parameters and/or received fields. For example, a WTRU may associate a given TTI duration with a given transmission mode (TM). A TTI duration may be indicated by a Carrier Indicator Field (CIF), for example where certain values of the CIF are associated with SCells configured with a given TTI durations such as a ShTTI. The CIF may also be referred to as a Carrier Indicator Field (CIF). The TTI duration may be indicated by a field that indicates a set of resources such as a set of PRBs, a carrier, a serving cell of the WTRU's configuration, and/or a spectrum block. A TTI duration may be determined from an identity of a PRB subset associated with the transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using a medium access control (MAC) Activation/Deactivation control element. MAC Activation/Deactivation CE may be used to toggle between first and second TTIs (e.g. legacy TTI and ShTTIs) or between slot-based ShTTIs and/or may be used to determine zero, one or more TTI (e.g. ShTTI) period(s) within a subframe.

[0005] HARQ processing may be performed according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. An exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA) formats and/or (e.g. legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g. legacy) format, although, for example, interpretation of fields such as the CIF and/or fields that indicate the PRBs applicable for the transmission may be different than the interpretations of the first

(e.g. legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. Physical random access channel (PRACH) resources and/or physical downlink control channel (PDCCH) order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g. a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0006] A method of using a wireless transmit/receive unit within a wireless communications network that is capable of aggregating different sets of physical layer resources (e.g., such as carrier aggregation, for example) may include communicating with a serving cell in the wireless communications network and determining that the serving cell has indicated that the WTRU should use a first transmission time interval on a physical uplink channel to communicate with the serving cell. The method may also include determining whether downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel). The method may further include communicating with the wireless communications network using the second transmission time interval.

[0007] The method may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g, on the physical uplink channel) comprises determining based on a carrier indicator field in received downlink control information.

[0008] The method may include communicating with the wireless communications network using the second transmission time interval comprises communicating with the serving cell using the second transmission time interval.

[0009] The method may include wherein communicating with the wireless communications network using the second transmission time interval includes communicating with a secondary cell using the second transmission time interval.

[0010] The method may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a third

transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network. The shorten transmission time interval may correspond to at least one of at least one symbol or at least one resource block. The first transmission time interval may be one millisecond.

[0011] The method may include determining a time to transmit with the second transmission time interval based on the downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment). The time to transmit may defined by a time partition (e.g., a slot in a subframe and/or one or more time symbols, (e.g., OFDM symbols), an arrangement of symbols, a min-slot, or other time for a sub-carrier spacing).

[0012] The method may include determining whether a first downlink control information (e.g., using carrier aggregation fields such as the CIF) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel) or whether the WTRU should transmit using carrier aggregation comprises determining with cross-carrier scheduling.

[0013] A wireless transmit/receive unit (WTRU) for use within a wireless communications network that is capable of carrier aggregation may have a processor having executable instructions that communicate with a serving cell in the wireless communications network and determine that the serving cell has indicated that the WTRU should use a first transmission time interval on an uplink channel (e.g., physical uplink channel) to communicate with the serving cell. The processor instructions may include determining whether a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel). The WTRU processor instructions may include communicating with the wireless communications network using the second transmission time interval.

[0014] The WTRU processor instructions that determine that a first downlink control information (e.g, carrier aggregation field such as the CIF) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel) may comprise determining based on a carrier indicator field in received downlink control information.

[0015] The WTRU processor executable instructions that communicate with the wireless communications network using the second transmission time interval may comprise communicating with the serving cell using the second transmission time interval.

[0016] The WTRU processor executable instructions that communicate with the wireless communications network using the second transmission time interval may comprise communicating with a secondary cell using the second transmission time interval.

[0017] The WTRU processor executable instructions may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network. The shorten transmission time interval may correspond to at least one of at least one symbol or at least one resource block. The first transmission time interval may be one millisecond.

[0018] The WTRU processor executable instructions may include determining a time to transmit with the second transmission time interval based on the downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment). The time to transmit may be defined by a slot in a subframe.

[0019] The WTRU processor executable instructions that determine whether a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel).

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] FIG. 1A is a system diagram of an example communications system in which disclosed subject matter may be implemented.

[0021] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used in a communications system.

[0022] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0023] FIG. 1D is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0024] FIG. 1E is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0025] FIG. 2 shows an example of DL physical layer channels.

[0026] FIG. 3 shows an example of UL physical layer channels.

[0027] FIG. 4 is an example of scheduling with time-shifted cells.

DETAILED DESCRIPTION

[0028] A detailed description of illustrative embodiments will now be described with reference to the various figures. Although this description provides a detailed example of possible implementations, it should be noted that the details are intended to be exemplary and in no way limit the scope of the application.

[0029] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, for example voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, for example code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0030] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, and/or 102d (which generally or collectively may be referred to as WTRU 102), a radio access network (RAN) 103/104/105, a core network 106/107/109, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include a user equipment (WTRU), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0031] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to

one or more communication networks, for example the core network 106/107/109, the Internet 110, and/or the networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0032] The base station 114a may be part of the RAN 103/104/105, which may also include other base stations and/or network elements (not shown), for example a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In an embodiment, the base station 114a may employ multiple-input multiple output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0033] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 115/116/117, which may be any suitable wireless communication link (e.g. radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 115/116/117 may be established using any suitable radio access technology (RAT).

[0034] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, for example CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 103/104/105 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 115/116/117 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0035] In an embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 115/116/117 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0036] In an embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), New Radio (NR) and the like. The descriptions and example provided herein apply to any of the air interface and communications standards that have been implemented although the terminology may differ among them for the functional components.

[0037] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, for example a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In an embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet an embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (e.g. WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106/107/109.

[0038] The RAN 103/104/105 may be in communication with the core network 106/107/109, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106/107/109 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, for example user authentication. Although not shown in FIG. 1A, it will be appreciated that the RAN 103/104/105 and/or the core network 106/107/109 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 103/104/105 or a different RAT. For example, in addition to being connected to the RAN 103/104/105, which may be utilizing an E-UTRA radio technology, the core network 106/107/109 may also be in communication with a RAN (not shown) employing a GSM radio technology.

[0039] The core network 106/107/109 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The

PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, for example the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include a core network connected to one or more RANs, which may employ the same RAT as the RAN 103/104/105 or a different RAT.

[0040] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0041] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment. Also, embodiments contemplate that the base stations 114a and 114b, and/or the nodes that base stations 114a and 114b may represent, for example but not limited to transceiver station (BTS), a Node-B, a site controller, an access point (AP), a home node-B, an evolved home node-B (eNodeB), a home evolved node-B (HeNB), a home evolved node-B gateway, and proxy nodes, among others, may include some or each of the elements depicted in FIG. 1B and described herein.

[0042] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the

transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0043] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (e.g. the base station 114a) over the air interface 115/116/117. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In an embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet an embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0044] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (e.g. multiple antennas) for transmitting and receiving wireless signals over the air interface 115/116/117.

[0045] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, for example UTRA and IEEE 802.11, for example.

[0046] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (e.g. a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, for example the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In an embodiment, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, for example on a server or a home computer (not shown).

[0047] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (e.g. nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0048] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (e.g. longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 115/116/117 from a base station (e.g. base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0049] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0050] FIG. 1C is a system diagram of the RAN 103 and the core network 106 according to an embodiment. As noted above, the RAN 103 may employ a UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 115. The RAN 103 may also be in communication with the core network 106. As shown in FIG. 1C, the RAN 103 may include Node-Bs 140a, 140b, 140c, which may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 115. The Node-Bs 140a, 140b, 140c may each be associated with a particular cell (not shown) within the RAN 103. The RAN 103 may also include RNCs 142a, 142b. It will be appreciated that the RAN 103 may include any number of Node-Bs and RNCs while remaining consistent with an embodiment.

[0051] As shown in FIG. 1C, the Node-Bs 140a, 140b may be in communication with the RNC 142a. Additionally, the Node-B 140c may be in communication with the RNC142b. The Node-Bs 140a, 140b, 140c may communicate with the respective RNCs 142a, 142b via an Iub interface. The RNCs 142a, 142b may be in communication with one another via an Iur interface.

Each of the RNCs 142a, 142b may be configured to control the respective Node-Bs 140a, 140b, 140c to which it is connected. In addition, each of the RNCs 142a, 142b may be configured to carry out or support other functionality, for example outer loop power control, load control, admission control, packet scheduling, handover control, macro diversity, security functions, data encryption, and the like.

[0052] The core network 106 shown in FIG. 1C may include a media gateway (MGW) 144, a mobile switching center (MSC) 146, a serving GPRS support node (SGSN) 148, and/or a gateway GPRS support node (GGSN) 150. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0053] The RNC 142a in the RAN 103 may be connected to the MSC 146 in the core network 106 via an IuCS interface. The MSC 146 may be connected to the MGW 144. The MSC 146 and the MGW 144 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices.

[0054] The RNC 142a in the RAN 103 may also be connected to the SGSN 148 in the core network 106 via an IuPS interface. The SGSN 148 may be connected to the GGSN 150. The SGSN 148 and the GGSN 150 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between and the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0055] As noted above, the core network 106 may also be connected to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0056] FIG. 1D is a system diagram of the RAN 104 and the core network 107 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 107.

[0057] The RAN 104 may include eNode-Bs 160a, 160b, 160c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 160a, 160b, 160c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 160a, 160b, 160c may implement MIMO technology. Thus, the eNode-B 160a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0058] Each of the eNode-Bs 160a, 160b, 160c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1D, the eNode-Bs 160a, 160b, 160c may communicate with one another over an X2 interface.

[0059] The core network 107 shown in FIG. 1D may include a mobility management gateway (MME) 162, a serving gateway 164, and a packet data network (PDN) gateway 166. While each of the foregoing elements are depicted as part of the core network 107, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0060] The MME 162 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 162 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 162 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, for example GSM or WCDMA.

[0061] The serving gateway 164 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via the S1 interface. The serving gateway 164 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 164 may also perform other functions, for example anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0062] The serving gateway 164 may also be connected to the PDN gateway 166, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0063] The core network 107 may facilitate communications with other networks. For example, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 107 may include, or may communicate with, an IP gateway (e.g. an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 107 and the PSTN 108. In addition, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to

the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0064] FIG. 1E is a system diagram of the RAN 105 and the core network 109 according to an embodiment. The RAN 105 may be an access service network (ASN) that employs IEEE 802.16 radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 117. As will be further discussed below, the communication links between the different functional entities of the WTRUs 102a, 102b, 102c, the RAN 105, and the core network 109 may be defined as reference points.

[0065] As shown in FIG. 1E, the RAN 105 may include base stations 180a, 180b, 180c, and an ASN gateway 182, though it will be appreciated that the RAN 105 may include any number of base stations and ASN gateways while remaining consistent with an embodiment. The base stations 180a, 180b, 180c may each be associated with a particular cell (not shown) in the RAN 105 and may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 117. In one embodiment, the base stations 180a, 180b, 180c may implement MIMO technology. Thus, the base station 180a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a. The base stations 180a, 180b, 180c may also provide mobility management functions, for example handoff triggering, tunnel establishment, radio resource management, traffic classification, quality of service (QoS) policy enforcement, and the like. The ASN gateway 182 may serve as a traffic aggregation point and may be responsible for paging, caching of subscriber profiles, routing to the core network 109, and the like.

[0066] The air interface 117 between the WTRUs 102a, 102b, 102c and the RAN 105 may be defined as an R1 reference point that implements the IEEE 802.16 specification. In addition, each of the WTRUs 102a, 102b, 102c may establish a logical interface (not shown) with the core network 109. The logical interface between the WTRUs 102a, 102b, 102c and the core network 109 may be defined as an R2 reference point, which may be used for authentication, authorization, IP host configuration management, and/or mobility management.

[0067] The communication link between each of the base stations 180a, 180b, 180c may be defined as an R8 reference point that includes protocols for facilitating WTRU handovers and the transfer of data between base stations. The communication link between the base stations 180a, 180b, 180c and the ASN gateway 182 may be defined as an R6 reference point. The R6 reference point may include protocols for facilitating mobility management based on mobility events associated with each of the WTRUs 102a, 102b, 102c.

[0068] As shown in FIG. 1E, the RAN 105 may be connected to the core network 109. The communication link between the RAN 105 and the core network 109 may defined as an R3 reference point that includes protocols for facilitating data transfer and mobility management capabilities, for example. The core network 109 may include a mobile IP home agent (MIP-HA) 184, an authentication, authorization, accounting (AAA) server 186, and a gateway 188. While each of the foregoing elements are depicted as part of the core network 109, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0069] The MIP-HA may be responsible for IP address management, and may enable the WTRUs 102a, 102b, 102c to roam between different ASNs and/or different core networks. The MIP-HA 184 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices. The AAA server 186 may be responsible for user authentication and for supporting user services. The gateway 188 may facilitate interworking with other networks. For example, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. In addition, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0070] Although not shown in FIG. 1E, it will be appreciated that the RAN 105 may be connected to other ASNs and the core network 109 may be connected to other core networks. The communication link between the RAN 105 the other ASNs may be defined as an R4 reference point, which may include protocols for coordinating the mobility of the WTRUs 102a, 102b, 102c between the RAN 105 and the other ASNs. The communication link between the core network 109 and the other core networks may be defined as an R5 reference, which may include protocols for facilitating interworking between home core networks and visited core networks.

[0071] Systems, methods, and instrumentalities are disclosed for multiplexing transmissions with different durations, for example such as transmission that utilize different TTI lengths. Latency reduction for some transmissions may achieved, for example, by multiplexing transmissions with different TTI durations. Although examples may be described with respect to multiplexing of an LTE legacy TTI (e.g., 1 ms) with a shortened TTI length (e.g., less than 1 ms), the techniques described herein may be generally applicable to the multiplexing of other

types of transmissions that are of different/varying lengths. For example, the examples may be described with respect to transmissions that contain one transport block (TB), but the examples may be equally applicable to transmissions that include a portion of a TB, transmissions that contain multiple TBs, etc. Thus, as may be appreciated, although specific examples herein may be described with respect to multiplexing transmissions associated with a "legacy" 1 ms TTI with transmissions that are less than 1 ms, these examples are not limited to the specific embodiments described and may be applied to transmissions of varying length that include varying amounts of data. Additionally, although examples may be described with respect to multiplexing shorter than 1 ms transmissions into a legacy LTE system that utilizes a legacy TTI length of 1 ms, the techniques may be applied to other types of transmission configurations, for example such as the NR system that may be utilized for 5G cellular communications.

[0072] Transmissions of different length may be realized in multiple ways and be consistent with this disclosure. For example, multiple TTI lengths may be defined, and the system may be configured to multiplex transmissions associated with the different TTI lengths over a common set of transmission resources. In example, rather than or in addition to defining different TTI lengths, transmissions of different durations may be supported, for example where one or more of the transmissions durations may or may not correspond to a TTI. Transmission duration may be defined in a number of ways, for example an amount of time over which the transmission occurs, (e.g., a specific duration or a time partition), a number of symbols over which the transmission occurs (e.g., 14 OFDM symbols, 12 OFDM symbols, 1 OFDM symbol, etc.), a slot, a minislot, a time partition for a sub-carrier spacing, and/or in terms of a specific numerology associated with the transmissions. For example, the numerology may be defined based on one or more of a sub-carrier spacing (e.g., different sub-carrier spacing may lead to different time durations for a symbol), a symbol length, a waveform type, etc.

[0073] Examples may also be described with respect to one or more cells. However, the techniques described herein may be equally applicable to other types of resource partitions. For example, in LTE cells may be defined based on certain OFDM time-frequency resources that are defined for a certain operating band for the cell. However, the multiplexing techniques described herein may be applied to physical resources that may or may not be defined using the cell construct. For example, the techniques described herein may apply of a subset of the physical resources in a cell and/or to physical resources that are not defined using the cell construct.

[0074] In order to TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency, e.g. in an LTE system such as a legacy LTE system. A "logical" cell structure may correspond to an SCell (e.g., a legacy SCell). A PCell may logically maintain

a TTI (e.g., a first TTI such as a legacy TTI that may be 1 ms) or may be (e.g. also) configured with a second duration TTI (e.g., a shorter duration TTI (ShTTI) that may be less than 1 ms).

[0075] In an example, a WTRU may determine a TTI duration (e.g. first or second TTI) applicable to a transmission. A determination may be, for example, a function of one or more facts, factors, and/or parameters. For example, a WTRU may determine a TTI duration using cross-carrier scheduling information. A WTRU may associate a certain TTI duration with a certain cell identity (e.g. servCellID). A WTRU may associate a certain TTI duration with certain a transmission mode (TM). A TTI duration may be indicated by a CIF included in DCI. For example, a first cell identity (e.g., servCellID = 1) may be associated with a first TTI duration and a second cell identity (e.g., servCellID = 2) may be associated with a second TTI duration. When the CIF field indicates that the received DCI is applicable to the first cell identity (e.g., CIF = '001' - servCellID = 1), the WTRU may determine that the scheduled transmission is associated with the first TTI duration. When the CIF field indicates that the received DCI is applicable to the second cell identity (e.g., CIF = '010' - servCellID = 2), the WTRU may determine that the scheduled transmission is associated with the second TTI duration. In this matter, carrier aggregation signaling methods may be reused/reinterpreted in order to support multiple TTI length.

[0076] A TTI duration may be determined from an identity of a PRB subset associated with the transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using MAC Activation/Deactivation. MAC Activation/Deactivation may be used to toggle between first and second TTIs (e.g. between a legacy TTI and one or more ShTTIs). For example, a WTRU may utilize a first TTI length for a first cell prior to receiving MAC Activation/Deactivation control element. Upon receiving the MAC Activation/Deactivation control element for the first cell, the WTRU may toggle to a second TTI length. In an example, the MAC Activation/Deactivation control element may be used to toggle between different slots used for a ShTTI transmission in a legacy suframe. For example, the MAC Activation/Deactivation control element may be used to switch between the first and second slots for the shortened TTI transmission. MAC Activation/Deactivation may be used to determine zero, one or more ShTTIs period(s) within a subframe.

[0077] HARQ processing may remain according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. In an example, an exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA)

formats and/or (e.g., legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g., legacy) format, although, for example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different than the first (e.g., legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. PRACH resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g., a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0078] A device may access resources of a communication system. Latency associated with transmission of data may have one or more latency components. A latency component may be the time to perform the transmission of a transport block, which time may be referred to as a Transmission Time Interval (TTI). A latency component may be processing time at a receiver, e.g., time decoding a transmission. Receiver processing time may be tied to implementation complexity and may be accounted for using a fixed timing relationship between different events associated with the transmission of a data unit. A timing relationship may be fixed, for example, when time-division duplex (TDD) is used for a carrier and/or synchronous Hybrid ARQ (HARQ) operation (e.g., such as for LTE in the uplink).

[0079] There may be additional latency components, for example, when a transmission is not successfully decoded. For example, additional components may include transmission of feedback (e.g. HARQ ACK or NACK), processing time at the receiver and/or one or more retransmissions with one or more latency components.

[0080] Latency components may be measured in integer multiples of a basic time interval (BTI). For example, latency components may be measured in TTIs, e.g., in LTE.

[0081] Latency in wireless networks may be caused by multiple factors. Latency may be affected, e.g., at lower layers, by a need for highly reliable transmissions, which may be obtained using HARQ. One or more retransmissions may affect the latency of a transmission, for example, given that retransmissions may not be performed in adjacent time periods.

[0082] A WTRU may incur processing time, for example, for downlink (DL) transmission, to determine whether a transmission was decoded properly, which may lead to a time interval between reception of a DL transmission and transmission of an ACK or NACK. An eNB may

incur processing time, for example, to determine whether an ACK or NACK was transmitted by the WTRU and/or whether a retransmission is required. A similar consumption of processing time may occur for uplink (UL) transmissions. Processing times may be cumulative. There may be a tradeoff between latency and implementation complexity.

[0083] A system (e.g. LTE) may accommodate processing times in a timing relationship between a first transmission for a transport block and its corresponding ACK-NACK HARQ response for downlink and/or uplink operation and possible retransmission.

[0084] Time Division Duplex (TDD) and Frequency Division Duplex (FDD) DL scheduling timing may be the same, such that a WTRU may receive a scheduling grant for a DL transmission in the same subframe or transmission time interval (TTI).

[0085] A WTRU may transmit a corresponding Physical UL Shared Channel (PUSCH), e.g., in subframe n+4, for example, upon detection of a Physical DL Control Channel PDCCH or enhanced PDCCH (EPDCCH) with UL Downlink Control Information (DCI) format and/or Physical Hybrid ARQ Indicator Channel (PHICH) transmission in subframe n, e.g., in an FDD UL transmission intended for the WTRU. A HARQ ACK/NACK response for a DL or UL transmission in subframe n may be provided in subframe n+4.

[0086] A WTRU may transmit a corresponding PUSCH in subframe n+k, for example, upon detection of a (E)PDCCH with UL DCI format and/or PHICH transmission in subframe n, e.g., for a UL transmission in a TDD system intended for the WTRU. The value of k may depend on the TDD UL/DL configuration, the subframe where the UL DCI and/or PHICH was transmitted and/or the PHICH resource and the MSB or LSB of the UL index in the (E)PDCCH, e.g., in TDD UL/DL configuration 0. A HARQ ACK/NACK response for a DL or UL transmission in subframe n may be provided in subframe n+k, where k may depend on the value of n and the TDD UL/DL configuration. Bundling may be used to provide HARQ for multiple transmissions in one instance.

[0087] Processing time available to a WTRU may depend, for example, on the value of the timing advance or on the distance between the WTRU and the eNB. In an example, an LTE system may have a distance of 100km between a WTRU and an eNB, which may correspond to a (e.g. a maximum) timing advance of 0.67ms. In an example, there may be approximately 2.3 ms left for terminal processing. An eNB may have, for example, 3 ms processing time available, which may be on the same order as that of the terminal.

[0088] FIG. 2 shows an example of DL physical layer channels. In a DL example with reference to the example shown in FIG. 2, there may be three channel areas in a subframe to support DL Shared Channel (DL-SCH) and UL-SCH. Three channel areas may comprise a PDCCH (which may include Physical Control Format Indicator Channel (PCFICH) and PHICH),

a Physical DL Shared Channel (PDSCH) and an EPDCCH. An EPDCCH may include scheduling information for a WTRU while taking advantage of the benefits of the PDSCH region, such as beamforming gain and frequency domain Inter-Cell Interference Coordination (ICIC) and/or improving PDCCH capacity.

[0089] FIG. 3 shows an example of UL physical layer channels. In a UL example with reference to the example shown in FIG. 3, there may be two channel areas in a subframe to support DL-SCH and UL-SCH. Two channel areas may comprise a PUSCH and a PDSCH. These channel areas may be transmitted in different RBs in each time slot (e.g. frequency hopping of PUSCH), for example, to increase robustness in frequency selective channels.

[0090] A transmission time interval (TTI) duration may be based on and/or defined by one or more symbols. A TTI duration may be defined in terms of a number of OFDM symbols. For example, a TTI duration may be defined as an entire (legacy) subframe and/or a pair of physical resource blocks (PRBs). In the legacy 1 ms TTI length, there may be 14 OFDM symbols for normal cyclic prefix and 12 OFDM symbols for extended cyclic prefix. For example when multiplexing ShTTI transmissions with legacy TTI transmissions of 1 ms, a ShTTI may be made as short as a single ODFM symbol. Symbol-based categorization may be referred to as symbol-based TTI durations.

[0091] A TTI duration may be based on time-varying symbol duration. TTI durations may have a fixed number of symbols (e.g., 14 symbols) while symbol duration may vary in time. For example, variable time symbol-based TTI duration may be achieved by modifying subcarrier spacing. In an example, a first TTI duration may be achieved with a first subcarrier spacing and a second TTI duration may be achieved with a second subcarrier spacing. Different bandwidth portions (e.g. PRBs) of a carrier may support different subcarrier spacing, thus enabling different TTI duration for different bandwidth portions (e.g. PRBs). Multiplexing transmissions associated with different sub-carrier spacing and/or symbol duration may be applicable to 5G systems such as NR. Such techniques may also be used in LTE-Advanced.

[0092] A TTI duration may be based on a time slot. A TTI duration may be defined in terms of a time slot (e.g. 7 OFDM symbols for normal cyclic prefix and 6 OFDM symbols for extended cyclic prefix). For example, if a ShTTI is defined as the length of one slot, two ShTTI transmissions may be time multiplexed into a legacy 1 ms TTI length.

[0093] A TTI duration may be based on time. A TTI duration may be defined in terms of a time value (e.g. 1ms legacy TTI or a 100ms ShTTI).

[0094] A TTI duration may be based on a hybrid, such as a combination of forgoing TTI duration bases. In an example of a hybrid method of achieving variable TTI durations, a different number of symbols and different symbol durations may be used.

[0095] Latency may be improved. It may be beneficial to decrease the TTI duration of different channels. A decrease in TTI duration may enable a decrease in WTRU processing time and may permit a WTRU to begin processing data sooner. Such a scenario may enable a shorter HARQ timeline. Different channels may have different TTI durations. A TTI duration shorter than one subframe for one or more of the EPDCCH, PDSCH, PUCCH, PDSCH, etc. may be provided. Effective HARQ feedback for PDSCH and PUSCH transmissions using shorter than (e.g., legacy 1ms) subframe TTI durations may be provided. Shorter TTIs may be referred to as ShTTI.

[0096] ShTTI and/or a combination of TTI and ShTTI may be supported for a given WTRU, for example, to minimize the impact of other aspects related to WTRU transmissions, such as scheduling (e.g., formats of DCIs), HARQ (e.g., related processing/process identities), feedback formats and determination of an applicable TTI duration. For example, the configuration of ShTTIs and/or the signaling of DCI for ShTTIs may utilize certain signaling originally defined for purposes of carrier aggregation in order to limit the amount of complexity at the WTRU and/or facilitated TTI length multiplexing in a backwards compatible manner. One or more latency components may be reduced, for example, to minimize the impact on WTRU implementations.

[0097] A WTRU may (e.g., based on a determination) operate with a one or more TTI durations, such as subframe TTI duration (e.g., 1 ms), a timeslot TTI duration (e.g., 0.5 ms), a symbol-based TTI duration (e.g., one or more OFDM symbols in duration), and/or other shorter than 1 ms TTI durations. In an example, a WTRU may be configured to operate with specific but different TTI duration configuration in downlink and uplink. In an example, a WTRU may be configured to permit the same TTI duration configuration to be used in downlink and uplink for applicable transmissions. For example, if the WTRU receives a configuration that indicates a first cell is associated with a first TTI duration in the downlink, the WTRU may determine that the uplink TTI duration is also the first TTI duration unless the configuration indicates otherwise.

[0098] A TTI duration may be WTRU specific. A WTRU may operate with a TTI duration during a given period. A WTRU may be configured to operate according to one or more of a plurality of possible TTI durations and may operate with the one or more TTI durations for a specific period of time, e.g., based on an L3 (e.g., radio resource control (RRC)) reconfiguration. A TTI duration may be fixed (e.g. statically, semi-statically or dynamically) for a (e.g. every) transmission to and from a WTRU.

[0099] Multiple TTI durations may be concurrently configured and/or used. A WTRU may be configured to operate for transmissions of different TTI durations concurrently. Different TTI durations may be based on, for example, semi-static allocation (e.g. configuration of a subset of frames/subframes dedicated to different TTI durations based on a semi-persistent grant or assignment) and/or dynamic allocation (e.g. based on detection and/or reception of downlink control signaling).

[0100] A TTI duration may be cell/cell group (CG)-specific. Configuration may be applicable per cell of a WTRU's configuration, for a subset of cells of a WTRU's configuration, and/or for all cells of the same timing advance group (TAG) and/or all cells of the same cell group (CG). For example, upon adding a new cell, the TTI duration may be defined for the new cell. As an example, if the WTRU adds an SCell, the SCell configuration may indicated that the WTRU is to utilize a shortened TTI duration for the SCell. The HARQ instances associated with a specific MAC entity may be configured with a similar configuration for TTI duration. A similar or same configuration for TTI duration may be used, for example, for cells associated with the same channel(s) (e.g. PUCCH, PUSCH) for uplink control signaling.

[0101] TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency. Modeling may enable co-existence between WTRUs operating according to different TTI durations, e.g. in legacy LTE systems. A "logical" cell structure may correspond to the use of one or more serving cell(s). Serving cells may include secondary cells, such as an SCell type or a PSCell type defined for LTE CA. A PCell may logically maintain a first (e.g., legacy) TTI such as 1 ms or may be (e.g., also) configured as a ShTTI.

[0102] Multiple serving cells may be associated with a specific TTI duration. A WTRU may support multiple TTI durations based on one or more functions and/or characteristic associated to a serving cell.

[0103] A WTRU may determine the duration of a downlink control region, e.g., according to a first (e.g., legacy) behavior for LTE. A reception of PDCCH may be a first (e.g., legacy) behavior for downlink subframes. In an example, the first ShTTI in a subframe may include a control region, e.g., in case of slot-based operation, such as two slots of 7 symbols where the first slot include 1-3 symbols for PDCCH. In an example, the ShTTI duration may exclude the control region, e.g., in case of symbol-based ShTTIs. In an example, an offset in time or in symbol from the start of a subframe may be used to indicate the start of an ShTTI (e.g., in the DCI).

[0104] In an example, a WTRU may operate on a given carrier frequency (e.g., for downlink and/or uplink) according to at least one of the following: TTI duration per Transmission

Mode (TM), TTI duration per Serving Cell Identity (servCellID), and/or TTI duration per Serving Cell.

[0105] In an example of TTI duration per Transmission Mode (TM), a WTRU may be configured with multiple transmission modes (TM), e.g., one for each applicable TTI duration.

[0106] In an example of TTI duration per Serving Cell Identity (servCellID), a WTRU may be configured with multiple serving cell identities (e.g., servCellIDs), e.g., one for each applicable TTI duration.

[0107] In an example of TTI duration per Serving Cell, a WTRU may be configured with multiple serving cells for a given carrier frequency, e.g. one for each applicable TTI duration.

[0108] Combinations may be made using different types of serving cells. For example, a WTRU may be configured according to any of the following examples or other examples.

[0109] In a first case or example, a WTRU may be configured with one PCell and one SCell (or PSCell). A WTRU may perform a transmission associated with a PCell using a first ShTTI and a transmission associated with the SCell/PSCell using a second ShTTI. A WTRU may transmit Uplink Control Information (UCI) for a transmission associated with a specific cell using the uplink resources associated with the concerned cell (e.g., according to a first (e.g. legacy) behavior or processing time associated with the ShTTI), for example, when an SCell is configured with PUCCH resources or when the WTRU is configured with PSCell. A WTRU may perform the transmission of UCI using resources of the PCell (e.g., according to a first (e.g., legacy) behavior), for example, otherwise. In either case or other cases, a WTRU may transmit UCI using the TTI applicable to the uplink configuration of the concerned cell or according to the ShTTI applicable the received transmission.

[0110] In a second case or example, a WTRU may be configured with one PCell and two SCells. A WTRU may perform a transmissions associated with a PCell using a first TTI (e.g., a legacy 1ms TTI) and a transmission associated with an SCell using a second TTI (e.g., an ShTTI). A WTRU may transmit UCI for a transmission associated with a specific cell using the uplink resources associated with the concerned cell (e.g., according to a first (e.g., legacy) behavior or processing time associated with the ShTTI), for example, when an SCell is configured with PUCCH resources. A WTRU may perform the transmission of UCI using resources of the PCell (e.g., according to a first (e.g., legacy) behavior), for example, otherwise. In either case or other cases, a WTRU may transmit UCI using the TTI applicable to the uplink configuration of the concerned cell or according to the ShTTI applicable to the received transmission.

[0111] In a third case or example, a WTRU may be configured with one PCell and multiple SCells. A configuration may be a generalization of either of the first and second examples,

whereby more than two TTI durations may be supported (e.g., within a first (e.g., legacy) subframe).

[0112] In an example involving a PSCell, a different Cell Radio Network Temporary Identifier (C-RNTI) than that applicable for a PCell may indicate the duration of the TTI. Examples presented and other examples may be used separately or in combination. Other realizations and/or combinations are possible.

[0113] Examples for handling of downlink control region for case 1 with slot-based operation are described.

[0114] A WTRU may be configured with a (e.g., DL) control region of zero symbols for a serving cell used for the purpose of ShTTI, e.g., for the serving cell that corresponds to a second slot in case of slot-based operation. A WTRU may determine that a serving cell is configured for the purpose of ShTTI, for example, based on reception of signaling that indicates such value for the duration of the control region. A WTRU may determine that a serving cell is configured as an ShTTI for the second slot, for example, based on reception of signaling that indicates such value for the duration of the control region. A WTRU may determine that a PCell configuration is used for ShTTI for the first slot.

[0115] Different procedures or algorithms may be used to determine applicable TTI duration, e.g., independent of modeling. For example, a WTRU may determine the TTI duration (e.g. legacy duration such as 1ms or shorter (e.g., ShTTI)) applicable to a transmission as a function of one or more of the following: (a) a WTRU may determine TTI duration using cross-carrier scheduling; (b) a WTRU may associate a TTI duration with a serving cell identity; (c) a TTI duration may be indicated by a Carrier Indicator Field (CIF); (d) a TTI duration may be indicated by C-RNTI applicable to control signaling associated with the allocation of resources; (e) a TTI duration may be determined from the identity of a PRB subset applicable to the transmissions and/or to the time-shifted cell within the entire subset of PRBs for the carrier frequency; (f) a MAC Activation/Deactivation may be used to determine the applicable TTI duration and/or the identity of the slot/period applicable to a transmission within a subframe. A MAC Activation/Deactivation may be used, for example, to toggle between multiple TTIs (e.g. a legacy TTI and one or more ShTTIs), toggle between slot-based ShTTIs and/or to determine zero, one or more ShTTIs period(s) within a subframe.

[0116] HARQ processing may be used (e.g., according to a first (e.g., legacy) behavior) for time-shifted cell(s), although, in an example, timing-relationships may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may reuse LTE CA formats, first (e.g., legacy) subframe-based timing relationships and/or timing relationship associated with the HARQ

process. DCI signaling may reuse a first (e.g., legacy) format, although, in an example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with the HARQ process. Physical Random Access Channel (PRACH) resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted according to the shift applied to the TTI associated with a cell, for example, when such time shift is relative to the PCell timing (e.g., the PCell remains the DL timing reference for such SCell with the additional offset corresponding to the start of the ShTTI for those cells).

[0117] Any procedure or algorithm that may operate with or indicate a TTI duration may be applicable as a procedure or algorithm to operate with or to indicate a subcarrier spacing.

[0118] Support may be provided for transmissions with different TTI duration. A WTRU may be configured for operation with the LTE physical layer. A WTRU may be configured, for example, for operation according to a first (e.g., legacy) LTE behavior or for operation together with a 5gFLEX configuration, e.g., a configuration that supports a physical layer operating with other variants of potentially filtered OFDM transmissions, such as Universal Filtered OFDM (UF-OFDM), Filtered Based OFDM (FB-OFDM), etc.

[0119] In an example of LTE FDD, a radio frame may consist of 10 subframes of 1ms each with a TTI of 1ms. Each TTI may consist of two 0.5ms slots of 7 symbols for a configuration with a normal cyclic prefix. In the downlink, there may be 8 asynchronous HARQ processes numbered 0-7 that may be addressed by means of downlink DCI. In the uplink, there may be 8 synchronous HARQ processes per RTT, which identity may be tied to the subframe timing. A WTRU may be configured for 1 to 3 symbols at the beginning of the first slot used for control signaling (PDCCH). Control signaling may span the entire bandwidth for a given cell. A TTI duration may be fixed, e.g., at 1ms, as an aspect of the LTE physical layer.

[0120] Different cells of a WTRU's configuration may be (e.g. explicitly) associated with a TTI duration/offset shift. Support for different TTI durations may be realized, for example, by maintaining a unique association between a cell and a TTI duration in a WTRU's configuration. Timing associated with the cell (e.g. a cell of the LTE CA SCell type) may be shifted and/or offset in time with respect to the timing of a reference cell. A reference cell may be the PCell of the WTRU's configuration. The PCell may be considered to have a zero time shift, e.g., by default. In an example of dual connectivity, a PSCell may be considered to have a zero time shift (e.g., by

default), for example, when a secondary group of cells is configured and when the PSCell is used as the timing reference.

[0121] In an example, a time-shifted/TTI duration/offset shift may be associated with an identity. For example, a time-shifted cell may be configured with a serving cell identity, with an offset in time relative to the start of a cell-specific subframe (e.g. where timing may be based on the PCell used as a downlink timing reference) and with a TTI duration (e.g. shorter than a first (e.g. legacy) timing that may be referred to as a shorter TTI or ShTTI).

[0122] TTI duration may be a configuration aspect of a WTRU, such as part of a configured transmission mode associated with the physical layer configuration for the cell.

[0123] Cells using a timing relationship may be configured as part of the same timing advance group (TAG). Cells (e.g., SCells) in a secondary TAG (STAG) supporting ShTTIs may use one of the cells in the same TAG as a timing reference (e.g., a cell used may be a configuration aspect of a WTRU) or may use the PCell as the timing reference (e.g., otherwise).

[0124] Support may be provided for multiplexing transmissions in a cell and/or for a specific WTRU. Support for transmissions using different TTI duration may be for concurrent transmissions in the same cell. For example, transmission may correspond to a single TTI duration for each WTRU at any given time while some WTRUs may have different TTI duration than other WTRUs. Support may be for transmissions for a given WTRU within the same subframe (e.g., within a first (e.g., legacy) subframe such as 1 ms) where different transmissions may be performed according to different TTI durations by the concerned WTRU.

[0125] Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0126] An ShTTI-based transmission mode (TM) and cell timing configuration may be provided. For example, a WTRU may be configured with a PCell (e.g., according to first (e.g., legacy) behavior). For example, a WTRU may operate on a PCell carrier frequency using a first TM (e.g., a TM in the range of 1-10) associated with a first TTI duration (e.g., legacy 1ms). The WTRU may receive a RRC Connection Reconfiguration message that may reconfigure the WTRU according to at least one of the following: the WTRU may reconfigure the PCell and/or may configure at least one SCell.

[0127] In an example of reconfiguring a PCell, the WTRU may reconfigure the PCell such that a second TTI (e.g., ShTTI) of a duration shorter than previously used by the WTRU for the PCell is supported. For example, the WTRU may reconfigure (or add) a TM associated to the PCell. For example, a TM (e.g., TM = 11) may be associated with a TTI duration different than previously used by the WTRU for the PCell.

[0128] For example, a WTRU may configure a TTI duration according to one of the following. In an example, an ShTTI duration may be equal to 1 slot (0.5ms). This may be applicable, for example, to the first case. In another example, an ShTTI may be a duration expressed as an integer multiple of 1 symbol. A duration may include the control region, for example, when the configuration includes a start offset for the ShTTI and such offset is equal to zero. In another example, an ShTTI may be a duration expressed as an integer value in time, e.g. 100 μs or 125μs. Whether an ShTTI duration may include the control region may be determined as a function the value of a start offset for the ShTTI when applicable. A control region may be a separate aspect of a WTRU's configuration for a cell when an offset is equal to a non-zero value.

[0129] For example, a TM may support transmissions in (e.g., only in) the first slot of a first (e.g., legacy) subframe for the concerned ShTTI duration. A WTRU may determine an aspect as a function of the type of cell (e.g., PCell) associated with the TM. A TM may support WTRU-specific demodulation reference signals (e.g., DM-RS) such that their location and density may be better suited for ShTTI operation.

[0130] In an example of reconfiguring a PCell, transmissions on the PCell using a first (e.g., legacy) TTI such as 1ms may be enabled. This may be applicable, for example, in the second case, e.g., when a WTRU may be configured such that PCell operation supports transmissions using a first (e.g. legacy) 1ms TTI and one or more SCells support operation using ShTTI.

[0131] A WTRU may configure a PCell with an additional cell identity to the PCell in the PCell's configuration such that DCI may indicate, for example, "CIF=0" for a transmission on PCell using a first TTI (e.g., 1ms) and "CIF=1" for a transmission on PCell using a second TTI (e.g. a slot-based ShTTI of 0.5ms or similar). This may be applicable, for example, in the first case.

[0132] In an example of reconfiguring at least one SCell, the WTRU may configure an SCell such that an associated TTI duration (e.g., ShTTI) is less than that of a first (e.g., legacy) subframe duration (e.g., less than 1ms). For example, the WTRU may configure a TM associated with the SCell. For example, a TM (e.g., TM = 11) may be associated with a TTI duration similar to that of the PCell (e.g., ShTTI). For example, a ShTTI duration may be equal to 1 slot (0.5ms). This may be applicable, for example, in the first case. A TM (e.g., TM = 11+x) may be (e.g. alternatively) associated with a TTI duration different than that of the PCell, for example, when the TTI duration of such SCell may differ from that of the PCell.

[0133] Combinations of slot-based TTI (e.g., 0.5ms for a PCell) and non slot-based TTIs (e.g., 5 SCells of 100ms each) may be applicable for a given WTRU. Another example may be of a WTRU configured with symbol-based TTIs such that a different number of symbols may be used for each of the control regions (e.g,. 3 symbols), the TTI duration for the PCell (e.g., 5 symbols)

and for a number of SCells of x symbols in duration (e.g., 3 SCells each 2 symbols in TTI duration). Other combinations and/or other values are possible.

[0134] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0135] TTI duration may be determined as a function of a Carrier Indicator Field (CIF) in a DCI on PDCCH. A TTI duration may be signaled as a function of the indicated cell identity in the DCI (e.g., by CIF or similar for a given carrier frequency of the WTRU's configuration). A determination or indication may be achieved, for example, by associating a second identity with a cell of the WTRU's configuration or by duplication of a serving cell configuration for a given carrier frequency. The WTRU may determine that the DCI of a given transmission (e.g., PDDCH transmission, serving cell transmission, received downlink control information, or scheduling information) has indicated that the WTRU should use a first transmission time interval on a physical uplink channel to communicate with the serving cell. For example, the determination may be based on the CIF field of the DCI, as the CIF may refer to a serving cell identity that has been configured to utilize the first transmission time interval. In this manner, downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) may be re-used for scheduling of transmissions associated with the first TTI length. Similarly, the WTRU may determine that the DCI of a given transmission (e.g., PDDCH transmission, serving cell transmission, received downlink control information, or scheduling information) has indicated that the WTRU should use a second transmission time interval on a physical uplink channel to communicate with a second serving cell. For example, the determination may be based on the CIF field of the DCI, as the CIF may refer to the second serving cell identity and the second serving cell may have been configured to utilize the second transmission time interval. One or more of the first or second transmission time intervals may correspond a shortened TTI that is less than the legacy transmission time interval. The first and second serving cells may configured to utilize the same frequency band and/or carrier frequency.

[0136] In an example using slot-based TTI duration, a WTRU may be configured with a PCell with CIF=0, an SCell with CIF=1 and an SCell with CIF=2 for a given carrier frequency. Both SCells may be configured with carrier aggregation cross-carrier scheduling such that scheduling information for the associated resources may be received on the PDCCH associated with the PCell. A WTRU may receive signaling that schedules a transmission on such PDCCH. A WTRU may determine that a TTI duration is according to first (e.g., legacy) operation (e.g., 1ms), for example, when the WTRU determines that the CIF applicable to the transmission is that

of the PCell. The WTRU may determine that the transmission is applicable to the first slot of the concerned subframe, for example, when the WTRU determines that the CIF=1. The WTRU may determine that the transmission is for the second slot of the concerned subframe, for example, when CIF=2.

[0137] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0138] A start offset for ShTTI may be a function of CIF in the DCI on PDCCH. In an example, determination of the applicable location in time (e.g., slot in the subframe, applicable starting symbol and/or all applicable symbols or similar) may be enabled for a transmission, for example, when a TTI duration shorter than that of the subframe duration is configured for a given cell.

[0139] A start offset or applicable location in time may be based on signaling received by the WTRU. The WTRU may perform such determination as a function of the indicated cell identity in the DCI, e.g., by Carrier Indicator Field (CIF) or similar for a given carrier frequency of the WTRU's configuration. An indication or determination may be achieved, for example, by associating a specific offset in the subframe with an identity of a cell of the WTRU's configuration or by configuring multiple serving cells for a given carrier frequency each with a different identity and a different offset.

[0140] For example, an offset may indicate one of a first slot or a second slot of a cell-specific subframe or it may indicate an offset in terms of a starting symbol in a subframe or an offset in absolute time (e.g. 500ms). An offset may be applied from the start of a cell-specific subframe. An offset may implicitly indicate a TTI duration (or vice-versa).

[0141] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0142] A TTI duration may be a function of PRB(s) for a transmission. In an example, a WTRU may be configured such that a number of PRBs (e.g. a subset of the total set of system-specific PRBs for the concerned carrier frequency) may be associated with a cell of the WTRU's configuration for which the WTRU is operating with shorter than 1ms TTI duration e.g. configured with ShTTI.

[0143] A WTRU may determine an applicable TTI duration as a function of the PRB(s) indicated by the scheduling information. A PRB may correspond to the starting PRB for the resource allocation for the transmission. A set of PRBs may correspond to a range of PRBs. A

WTRU may use the TTI duration associated with a set of PRB(s), for example, when such range includes (e.g., only includes) PRB(s) associated with the concerned set. A WTRU may (e.g., otherwise) use a different TTI duration (e.g., a first (e.g. legacy) TTI duration, such as 1ms, or a configured duration), for example, when such range includes PRBs associated with different sets of PRBs or when such range does not include PRBs associated with any such sets. Sets of PRBs may be a configuration aspect of a WTRU's configuration. For example, a serving cell may be associated with a set of one or more PRBs, for example, when a serving cell is configured for ShTTI operation for a carrier frequency. A WTRU may use the TTI duration associated with such a cell or associated with the concerned PRBs. Scheduling information may be received dynamically in a DCI on PDCCH. Scheduling information may be semi-statically configured. For example, an entire (e.g., system-specific) set of PRBs for a PCell configured with a first (e.g., legacy) operation may be 110 PRBs. A WTRU may (e.g., alternatively) be configured with one or more subsets of PRBs, where each set may be associated with a specific TTI duration.

[0144] A WTRU may (e.g., first) determine the cell configured with ShTTI applicable to the transmission and/or the duration of the TTI (e.g., determining as described herein) and may determine the set of applicable PRBs therefrom (e.g., determining using a configuration of sets of PRBs as discussed herein).

[0145] Example procedures (e.g., operation) may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU. For example, a procedure may be associated with a transmission mode for downlink and/or uplink. For example, a procedure may be associated with a serving cell of the WTRU's configuration. For example, a WTRU may determine that a configuration is specific to a serving cell of a WTRU's configuration, e.g., a determination may be made that a TTI configuration applies to both DL and UL frequencies. For example, a WTRU may determine that a configuration is specific to a specific direction of a configuration for a given serving cell of the WTRU's configuration, e.g., a determination may be made that a TTI configuration is provided separately for the DL direction and for the UL direction.

[0146] A determination may be made about the start offset time for a transmission. Cell de-activation may control availability of ShTTI. In an example, a first (e.g., legacy) cell activation-deactivation mechanism (e.g., procedure or algorithm) may control the duration (e.g., first or second TTI such as a legacy TTI or an ShTTI duration) of a transmission, e.g., by activating and deactivating the transmission. A WTRU may associate an activation state with an ShTTI, a slot and/or a resource.

[0147] In an example, a WTRU configured using ShTTI cells may receive a first (e.g., legacy) MAC activation/deactivation control element. A WTRU may use the activation/deactivation element as a mechanism to determine the availability of the ShTTI. For example, a WTRU may use a first (e.g., 1ms) TTI duration, e.g., when the WTRU is configured with a single SCell with ShTTI and when the SCell is in a deactivated state when the WTRU determines that it needs to perform a transmission. A WTRU may (e.g., otherwise) use a second TTI duration (e.g., ShTTI) for a transmission, e.g., when the SCell is active. The WTRU may perform a transmission using the second TTI duration (e.g. ShTTI), for example, according to scheduling information independently of the scheduled slot. This example may be extended to apply to the case where a symbol-based TTI duration is used instead of a time duration such as transmission slots.

[0148] In an example where multiple SCells may be used to indicate slot-based transmissions, a WTRU may determine that a first TTI duration is applicable when all cells configured with ShTTI are in a deactivated state. A WTRU may determine (e.g., otherwise) the applicable slot based on the activation state associated with each SCell and associated with each slot. This example may be extended to apply to the case where a symbol-based TTI duration is used, e.g., instead of using time duration such as transmission slots.

[0149] A WTRU may transmit HARQ feedback and/or other Uplink Control Information (UCI) (e.g. CQI, PMI, RI or similar), for example, taking into consideration the configuration of the TTI duration.

[0150] A TTI duration applicable to the transmission of UCI may be a function of at least one of the following: scheduling information, configuration information, TTI applicable to a serving cell, a default configuration for UCI transmission, etc.

[0151] Scheduling information may indicate whether a WTRU has resources for a PUSCH transmission and (e.g., if so) the TTI duration associated with such transmission, which may be determined according to procedures described herein.

[0152] Configuration information may indicate whether a WTRU is configured for simultaneous PUSCH and PUCCH transmission.

[0153] A TTI may be applicable to a serving cell associated with a UCI transmission in the subframe for the concerned UCI transmission.

[0154] A TTI may be applicable (e.g., in duration and/or offset) to a serving cell associated with a UCI transmission in the subframe for a downlink transmission pertaining to the feedback (e.g., in case of HARQ A/N feedback).

[0155] A default configuration for the transmission of UCI may be, for example, for the transmission of UCI on PUCCH (e.g., always a first TTI such as 1 ms TTI on PCell).

[0156] Further examples are provided below.

[0157] An applicable resource may be a PUSCH or PUCCH resource. A WTRU may determine a physical channel to perform the transmission of UCI using any technique, procedure or algorithm. For example, a WTRU may determine that UCI may be included in a PUSCH transmission when the transmission is scheduled, when simultaneous PUSCH and PUCCH transmissions are not configured or on a PUCCH transmission (e.g., otherwise).

[0158] An applicable resource may be a PUSCH resource. A WTRU may perform the transmission of UCI on a PUSCH transmission according to a TTI duration associated with a PUSCH transmission, which may be determined using procedures described herein.

[0159] An applicable resource may be a PUCCH resource. A WTRU may determine that a PUCCH resource may be used for transmission of UCI according to any technique, procedure or algorithm applicable to LTE CA. For example, selection of a resource may be based on the first CCE of the DCI that scheduled a downlink transmission or based on a configuration (e.g. PUCCH format 3 or similar). Bundling and/or multiplexing may be applied, for example, when configured.

[0160] An applicable TTI may be function of the type of transmissions on the carrier frequency PUSCH or PUCCH. Transmission of UCI may use the principles of LTE CA whereby UCI corresponding to transmission on different cells, e.g., including time-shifted cells, maybe multiplexed on a single transmission using a format that supports the required number of information bits (e.g., PUCCH format 3).

[0161] A PUCCH transmission may be performed on a PCell with a first (e.g., 1 ms TTI), where the first TTI may be a fixed TTI. A WTRU may perform PUCCH transmission on resources of an applicable serving cell (e.g., a PCell) according to a TTI duration associated with a concerned (e.g., pertinent) PCell, which may be determined using procedures described herein. In an example, a WTRU may transmit HARQ feedback using a single PUCCH transmission, which may use resources associated with a PCell (e.g. using a 1ms TTI duration), for example, when a WTRU has HARQ A/N feedback to transmit for two slot-based time-shifted cells using PUCCH on the PCell according to a configuration for a given carrier frequency where the PCell uses a first (e.g., 1ms) TTI.

[0162] A PUCCH transmission may be performed on a PCell with alignment in time with TTI being reported. A WTRU may perform PUCCH transmission on resources of an applicable serving cell (e.g. a PCell) according to a TTI duration associated with transmission(s) for which feedback is transmitted. A WTRU may have, for example, HARQ A/N feedback to transmit for

two slot-based time-shifted cells using PUCCH on the PCell according to a configuration for a given carrier frequency. In an example, a WTRU may transmit in the first slot a HARQ feedback for a transmission associated with the first slot and may transmit the HARQ feedback for the other transmission in the second slot for the concerned subframe.

[0163] A PUCCH transmission may be performed on a PCell with TTI/ShTTI of the PCell. A WTRU may perform a PUCCH transmission on resources of an applicable serving cell (e.g. a PCell) according to a TTI duration associated with the PCell, which may be determined using procedures described herein. A PCell may be (e.g., otherwise) configured with a default TTI, such as a first (e.g., 1 ms) TTI or an ShTTI. A WTRU may have HARQ A/N feedback to transmit for two slot-based time-shifted cells using PUCCH on the PCell, e.g., according to a configuration for a given carrier frequency where the PCell uses ShTTI in the concerned subframe (e.g., based on a configuration aspect and/or an activation state such as ShTTI activated for a time-shifted SCell for the concerned subframe), In an example, a WTRU may transmit HARQ feedback using a single PUCCH transmission, which may use resources associated with the PCell using a ShTTI duration with an offset applicable to the PCell.

[0164] A WTRU may transmit HARQ A/N feedback, for example, based on an applicable WTRU processing time for a concerned (e.g., pertinent) HARQ process in a given subframe.

[0165] Processing time associated with a HARQ process may be specific to a TTI associated with a transmissions for a concerned process. Processing time may be specific to a serving cell, a transmission mode or may be indicated by DCI (e.g., from servCellID or CIF) associated with such transmissions for a concerned HARQ process. In an example, HARQ processing time may be the same for all HARQ processes associated with a serving cell configured with a specific TTI (e.g., an ShTTI). Processing time may be a fixed value (e.g., 1ms), a multiple of an ShTTI, etc. Processing time may be determined for a transmission using ShTTI in subframe, the first available occasion in subframe n+2, where an occasion may correspond to a PUCCH or a PUSCH transmission with duration according to a first TTI or second TTI (e.g., ShTTI).

[0166] Systems, methods, and instrumentalities have been disclosed for multiplexing transmissions with different TTI duration. Latency may be reduced (e.g., in an LTE system), for example, by multiplexing transmissions with different TTI durations. TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency. A "logical" cell structure may correspond to an SCell. A PCell may logically maintain a TTI (e.g,. a first TTI) or may be configured with a second duration TTI (e.g., a shorter duration TTI (ShTTI)).

[0167] In an example, a WTRU may determine a TTI duration (e.g., first or second TTI) applicable to a transmission. For example, a WTRU may determine a TTI duration using cross-

carrier scheduling. A WTRU may associate a TTI duration with a cell identity (e.g. servCellID). A WTRU may associate a TTI duration with a transmission mode (TM). A TTI duration may be indicated by Carrier Indicator Field (CIF). A TTI duration may be determined from an identity of a PRB subset applicable to transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using MAC Activation/Deactivation. MAC Activation/Deactivation may be used to toggle between first and second TTIs (e.g. legacy TTI and ShTTIs) or between slot-based ShTTIs and/or may be used to determine zero, one or more TTI (e.g. ShTTI) period(s) within a subframe.

[0168] HARQ processing may be performed according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. An exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA) formats and/or (e.g., legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g., legacy) format, although, for example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different than the first (e.g., legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. PRACH resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g. a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0169] A different TTI may be used in LTE R14 and NR. Multiple serving cells may be configured on the same carrier for a single WTRU. There may be an association between a serving cell and a TTI duration (or more generally – a numerology-related aspect). A WTRU can be configured with multiple such cells on a given carrier to support (*e.g.*, dynamically) a change in transmission duration. A field in downlink control signaling (DCI), *e.g.*, on a downlink control channel (*e.g.*, PDCCH), such as the CIF field in a DCI, may be used to dynamically schedule specific TTI durations for same or later subframes, for UL or DL transmissions.

[0170] The WTRU may be configured with a plurality of transmission methods, where at least two of the configured transmission methods differ in at least the applicable TTI duration.

[0171] A transmission may be associated with a transmission timing (start offset) relative to a timing reference.

[0172] A WTRU transmission mode may be indicated in downlink control information (DCI) signaling.

[0173] WTRU transmissions may be configured for each of a plurality of PRBs in the WTRU's configuration. Each of a plurality of PRBs may correspond to a serving cell of the WTRU's configuration. Each of a plurality of PRBs may correspond to a given carrier.

[0174] An applicable transmission duration/timing may be determined from a serving cell ID indicated in DCI signaling.

[0175] The WTRU may determine the set of resources, transmission duration, and/or uplink control information for a transmission based on a previous combination of received downlink signaling and received transmission duration.

[0176] A WTRU may determine whether a control region (*e.g.*, single control region) (*e.g.*, single level PDCCH) or multiple control regions (*e.g.*, multi-level PDCCH) are applicable and whether they are a function of the PDCCH configuration applicable to the concerned cell(s). A WTRU can determine the location of CCEs with respect to the timing reference (*e.g.*, in support of either self-scheduling or cross-TTI scheduling).

[0177] A WTRU may support mini-slots (*e.g.*, 125usec), slots (*e.g.*, 0.5ms), subframe (*e.g.*, 1ms) and multi-slots (*e.g.*, Multiples of other durations), and transmission durations and use different (*e.g.*, shortened) TTI's based on these time allocations. This may provide a low latency mode, a throughput mode and/or a coverage mode.

[0178] FIG. 4 depicts a scheduling example with time shifted-cells. As shown, there is a frequency axis and a time axis. In Fig. 4, the time is measured in milliseconds and divided into subframes. Other time units can be used such as slots, minislots, symbols, and PRB lengths. The frequency axis shows downlink (DL) and uplink (UL) transmissions. The time axis shows subframes. N, n+1, N=3, etc.... As shown for the DL frequency, for one or more subframes, the WTRU may receive DCI. For subframe n, the DCI may indicate two allocations, for example two ShTTI allocations (*e.g.*, $ShTTI_{DL(n,0)}$ and $ShTTI_{DL(n,1)}$). As an example, setting the CIF equal to 1 may indicate that the allocation is for $ShTTI_{DL(n,0)}$ and setting the CIF equal to 2 may indicate the allocation is for $ShTTI_{DL(n,1)}$. Other values of the CIF may be used to indicate no ShTTI transmissions and/or different transmission durations. For example, the DCI in Subframe

n+1 may indicate that for DL subframe n+1, the transmission has a duration corresponding to the entire subframe by using the value CIF=0 (*see e.g.*, a $TTI_{DL(N+1)}$).

[0179] A similar signaling mechanism can be used for indicating different durations of uplink transmissions. For example, DCI in DL subframe n may indicate that the WTRU has recieved two uplink grants. For example, a first grant for subframe n+1 may be indicate a CIF=1, which may be configured to correspond to $ShTTI_{(n+an\ offset,0)}$, while a CIF equal to 2 may indicate a grant for $ShTTI_{(n+an\ offset,0)}$. Similarly, a different value of the CIF (*e.g.*, CIF = 0) in this example may indicate that the transmissions duration spans an entire legacy TTI as illustrated in FIG. 4. Thus, by associating different CIF values with different transmission durations, the DCI may be used to indicate different transmission durations by referencing the different CIF values. Although the CIF field is used for purposes of illustration, other DCI fields may be used and may have values mapped to/associated with transmissions of different duration.

[0180] FIG. 4 also shows for an example of the PUCCH on the uplink frequency. For the PCell or SCell there may be a HARQ A/N for CIF = 1 at (n, 0) and a HARQ A/N for CIF = 2 at n, 1. For the PCell, (*e.g.*, PCell only), there may be a HARQ A/N for CIF = 0 at (n, 0) or CIF = 0 at n-3. Also, for the PCell, (*e.g.*, PCell only), there may be a HARQ A/N for CIF = 1 at (n, 0) or CIF = 0 at n-3 for the $ShTTI_{(n+?,\ 0)}$ and HARQ A/N for CIF = 2 at (n, 1) or CIF = 0 at n-3 for the $ShTTI_{(n+?,\ 1)}$.

[0181] FIG. 4 shows an example with time shifted cells with an offset of symbols. In this example, the symbol offset is based on CIF. FIG. 4 shows a single HARQ addressing space per TTI duration and start offset in a given subframe. MAC activation/deactivation may be applied by a HARQ process space or CIF value. FIG. 4 also shows a UCI example with time-shifted cells. The first CCE of the DCI on the example channel, PDCCH, may be used for legacy PUCCH resource allocation at TTI or ShTTI. Configured LTE CA PUCCH, PUCCH on an SCell, and/or ARI may be used for UCI using different TTIs. As shown, the WTRU interprets the DCI TTI indication differently in the FIG. 4 example for SCells and PCells to use ShTTI for the SCells. FIG. 4 also shows an example of the frequency being the same for the PCell and SCell. The FIG. 4 example dynamically varies the scheduled TTI for a WTRU and uses the appropriate HARQ signaling. Also, resource allocation for associated control information is resolved and there is flexibility to adapt different time offsets in a subframe and with different ShTTIs.

[0182] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element may be used alone or in any combination with the other features and elements. In addition, the methods described herein

may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, WTRU, terminal, base station, RNC, or any host computer.

CLAIMS

What Is Claimed:

1. A method implemented by a wireless transmit/receive unit (WTRU) for supporting transmissions of different durations, the method comprising:

receiving a first configuration associated with a first set of transmission resources, the first configuration indicating a first transmission time interval (TTI) length for use with the first set of transmission resources;

receiving a second configuration associated with a second set of transmission resources, the second configuration indicating a second transmission time interval (TTI) length for use with the second set of transmission resources;

receiving downlink control information (DCI), wherein the DCI comprises a field that indicates whether the DCI is applicable to first set of transmission resources or the second set of transmission resources; and

determining that a transmission associated with the DCI utilizes the first TTI length on condition that the field indicates that the DCI is applicable to the first set of transmission resources or that the transmission associated with the DCI utilizes the second TTI length on condition that the field indicates that the DCI is applicable to the second set of transmission resources.

2. The method of claim 1, wherein the first set of transmission resources correspond to a first serving cell and the second set of transmission resources correspond to a second serving cell.

3. The method of claim 2, wherein the field corresponds to a carrier indicator field.

4. The method of claim 2, wherein the first serving cell and the second serving cell are associated with the same carrier frequency.

5. The method of claim 2, wherein each of the first and second serving cells are configured as secondary cells (SCells).

6. The method of claim 2, wherein the first serving cell corresponds to a primary cell (PCell), the second serving cells is configured as a secondary cells (SCell), the first TTI length corresponds to 1 millisecond (ms), and the second TTI length corresponds to less than 1 ms.

7. The method of claim 1, wherein the DCI further comprises a physical resource block (PRB) assignment field, and the PRB assignment field is interpreted differently depending on whether the transmission is associated with the first TTI length or the second TTI length.

8. The method as in claim 1, wherein at least the second configuration is received via a radio resource control (RRC) message, and the DCI is received via a physical downlink control channel.

9. The method as in claim 1, wherein a hybrid automatic repeat request timing used for the transmission is dependent on whether the transmission is associated with the first TTI length or the second TTI length.

10. A method implemented by a wireless transmit/receive unit (WTRU) for supporting transmissions of different durations, the method comprising:

receiving downlink control information from a first serving cell in the wireless communications network;

determining that the received downlink control information indicates that the WTRU should use a first transmission time interval to transmit data information to the first serving cell;

determining whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is different than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation; and

communicating with the wireless communications network using the second transmission time interval.

11. The method of claim 10, wherein determining that the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel comprises determining based on a carrier indicator field in the received downlink control information.

12. The method of claim 10, wherein communicating with the wireless communications network using the second transmission time interval comprises communicating with the first serving cell using the second transmission time interval.

13. The method of claim 10, wherein communicating with the wireless communications network using the second transmission time interval comprises communicating with a secondary cell using the second transmission time interval.

14. The method of claim 10, further comprising determining that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network.

15. The method of claim 10, wherein the shorten transmission time interval corresponds to at least one of at least one symbol or at least one resource block.

16. The method of claim 10, wherein the first transmission time interval is one millisecond.

17. The method of claim 10, wherein the first transmission time interval is greater than the first transmission time interval.

18. The method of claim 10, wherein the first transmission time interval corresponds to a first sub-carrier spacing and the second transmission time interval corresponds to a second subcarrier spacing.

19. The method of claim 10, wherein the first transmission time interval corresponds to a first number of transmission symbols and the second transmission time interval corresponds to a second number of transmission symbols.

20. The method of claim 10, further comprising the WTRU communicating with the first serving cell and a second serving cell using the same carrier frequency.

21. The method of claim 10, further comprising determining a time to transmit with the second transmission time interval based on the received downlink control information.

22. The method of claim 21, wherein the time to transmit is defined by a slot in a subframe.

23. The method of claim 10, wherein determining whether the received downlink control information indicates that the WTRU should use a second transmission time interval that

is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation comprises determining with cross-carrier scheduling.

24. A wireless transmit/receive unit (WTRU) for use within a wireless communications network that is capable of carrier aggregation, comprising:

a processor having executable instructions that:

determine that downlink control information from a first serving cell in the wireless communications network has been received;

determine that the received downlink control information indicates that the WTRU should use a first transmission time interval to transmit data information to the first serving cell;

determine whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is different than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation; and

communicate with the wireless communications network using the second transmission time interval.

25. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine that the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel comprises determining based on a carrier indicator field in the received downlink control information.

26. The WTRU of claim 24, wherein the executable instructions that communicate with the wireless communications network using the second transmission time interval comprise communicating with the first serving cell using the second transmission time interval.

27. The WTRU of claim 24, wherein the executable instructions that communicate with the wireless communications network using the second transmission time interval comprise communicating with a secondary cell using the second transmission time interval.

28. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network.

29. The WTRU of claim 24, wherein the shorten transmission time interval corresponds to at least one of at least one symbol or at least one resource block.

30. The WTRU of claim 24, wherein the first transmission time interval is one millisecond.

31. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine a time to transmit with the second transmission time interval based on the received downlink control information.

32. The WTRU of claim 31, wherein the time to transmit is defined by a slot in a subframe.

33. The WTRU of claim 24, wherein the executable instructions that determine whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation comprise determining with cross-carrier scheduling.

34. The WTRU of claim 24, wherein the first transmission time interval is greater than the first transmission time interval.

35. The method of claim 24, wherein the first transmission time interval corresponds to a first sub-carrier spacing and the second transmission time interval corresponds to a second subcarrier spacing.

36. The method of claim 24, wherein the first transmission time interval corresponds to a first number of transmission symbols and the second transmission time interval corresponds to a second number of transmission symbols.

37. The method of claim 24, further comprising the WTRU communicating with the first serving cell and a second serving cell using the same carrier frequency.

(54) Title: TRANSMITTING A BEAM RECOVERY REQUEST

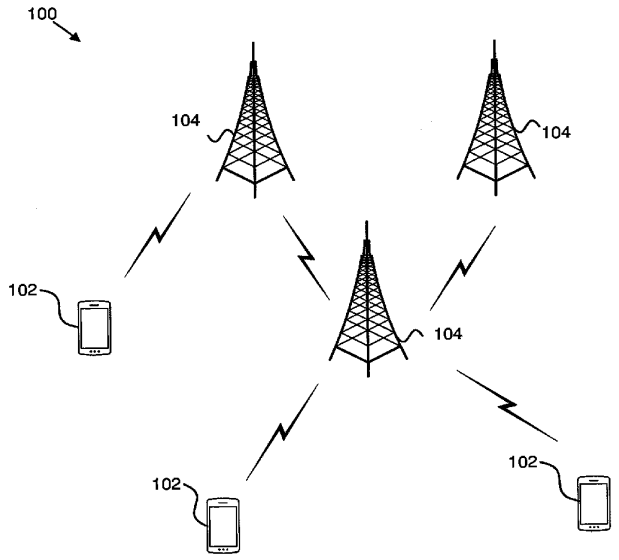

FIG. 1

(57) Abstract: Apparatuses, methods, and systems are disclosed for transmitting a beam recovery request. One apparatus (200) includes a receiver (212) that receives (402) information indicating a resource configured for a beam recovery request. The apparatus (200) includes a transmitter (210) that transmits (404) the beam recovery request on the resource in response to a first trigger condition.

TRANSMITTING A BEAM RECOVERY REQUEST

FIELD

[0001] The subject matter disclosed herein relates generally to wireless communications and more particularly relates to transmitting a beam recovery request.

BACKGROUND

[0002] The following abbreviations are herewith defined, at least some of which are referred to within the following description: Third Generation Partnership Project ("3GPP"), Positive-Acknowledgment ("ACK"), Binary Phase Shift Keying ("BPSK"), Clear Channel Assessment ("CCA"), Cyclic Prefix ("CP"), Cyclical Redundancy Check ("CRC"), Channel State Information ("CSI"), Common Search Space ("CSS"), Discrete Fourier Transform Spread ("DFTS"), Downlink Control Information ("DCI"), Downlink ("DL"), Downlink Pilot Time Slot ("DwPTS"), Enhanced Clear Channel Assessment ("eCCA"), Enhanced Mobile Broadband ("eMBB"), Evolved Node B ("eNB"), European Telecommunications Standards Institute ("ETSI"), Frame Based Equipment ("FBE"), Frequency Division Duplex ("FDD"), Frequency Division Multiple Access ("FDMA"), Guard Period ("GP"), Hybrid Automatic Repeat Request ("HARQ"), Internet-of-Things ("IoT"), Licensed Assisted Access ("LAA"), Load Based Equipment ("LBE"), Listen-Before-Talk ("LBT"), Long Term Evolution ("LTE"), Multiple Access ("MA"), Modulation Coding Scheme ("MCS"), Machine Type Communication ("MTC"), Multiple Input Multiple Output ("MIMO"), Multi User Shared Access ("MUSA"), Narrowband ("NB"), Negative-Acknowledgment ("NACK") or ("NAK"), Next Generation Node B ("gNB"), Non-Orthogonal Multiple Access ("NOMA"), Orthogonal Frequency Division Multiplexing ("OFDM"), Primary Cell ("PCell"), Physical Broadcast Channel ("PBCH"), Physical Downlink Control Channel ("PDCCH"), Physical Downlink Shared Channel ("PDSCH"), Pattern Division Multiple Access ("PDMA"), Physical Hybrid ARQ Indicator Channel ("PHICH"), Physical Random Access Channel ("PRACH"), Physical Resource Block ("PRB"), Physical Uplink Control Channel ("PUCCH"), Physical Uplink Shared Channel ("PUSCH"), Quality of Service ("QoS"), Quadrature Phase Shift Keying ("QPSK"), Radio Resource Control ("RRC"), Random Access Procedure ("RACH"), Random Access Response ("RAR"), Radio Network Temporary Identifier ("RNTI"), Reference Signal ("RS"), Resource Spread Multiple Access ("RSMA"), Round Trip Time ("RTT"), Receive ("RX"), Sparse Code Multiple Access ("SCMA"), Scheduling Request ("SR"), Single Carrier Frequency Division Multiple Access ("SC-FDMA"), Secondary Cell ("SCell"), Shared Channel ("SCH"), Signal-to-Interference-Plus-Noise Ratio ("SINR"), System Information Block ("SIB"), Transport Block ("TB"), Transport Block Size

("TBS"), Time-Division Duplex ("TDD"), Time Division Multiplex ("TDM"), Transmission Time Interval ("TTI"), Transmit ("TX"), Uplink Control Information ("UCI"), User Entity/Equipment (Mobile Terminal) ("UE"), Uplink ("UL"), Universal Mobile Telecommunications System ("UMTS"), Uplink Pilot Time Slot ("UpPTS"), Ultra-reliability and Low-latency Communications ("URLLC"), and Worldwide Interoperability for Microwave Access ("WiMAX"). As used herein, "HARQ-ACK" may represent collectively the Positive Acknowledge ("ACK") and the Negative Acknowledge ("NACK"). ACK means that a TB is correctly received while NACK (or NAK) means a TB is erroneously received.

[0003] In certain wireless communications networks, a beam quality may be degraded. In such configurations, a beam recovery may need to occur.

BRIEF SUMMARY

[0004] Apparatuses for transmitting a beam recovery request are disclosed. Methods and systems also perform the functions of the apparatus. In one embodiment, the apparatus includes a receiver that receives information indicating a resource configured for a beam recovery request. In some embodiments, the apparatus includes a transmitter that transmits the beam recovery request on the resource in response to a first trigger condition.

[0005] In one embodiment, the first trigger condition includes a medium access control layer receiving a number of out-of-sync indications from a physical layer. In a further embodiment, the number of out-of-sync indications is configured by radio resource control signaling. In certain embodiments, the resource configured for the beam recovery request is configured by radio resource control signaling. In various embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being configured by the radio resource control signaling. In some embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being activated by a medium access control control element.

[0006] In certain embodiments, the apparatus includes a processor that selects a first available resource to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being available for transmission of the beam recovery request. In some embodiments, the apparatus includes a processor that selects a physical uplink control channel resource to transmit the beam recovery request in response to a contention-free resource and the physical uplink control channel resource being available for transmission of the beam recovery request and in response to the physical uplink control channel resource having a channel quality greater than a predetermined threshold. In various embodiments, the apparatus includes a processor that selects a physical random access channel

resource to transmit the beam recovery request in response to the physical uplink control channel resource having the channel quality less than the predetermined threshold.

[0007] In one embodiment, the apparatus includes a processor that monitors for a response to transmission of the beam recovery request for a predetermined time in response to transmitting the beam recovery request using a physical random access channel resource and skips a physical uplink control channel resource for the beam recovery request during the predetermined time. In certain embodiments, the apparatus includes a processor that skips a physical random access channel resource for the beam recovery request in response to transmitting the beam recovery request using a physical uplink control channel resource. In some embodiments, the apparatus includes a processor that selects a contention based resource to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being unavailable for transmission of the beam recovery request. In various embodiments, the apparatus includes a processor that selects the resource to transmit the beam recovery request based on a measurement result and an association between a downlink transmission beam and a physical uplink control channel resource.

[0008] In some embodiments, the association between the downlink transmission beam and the physical uplink control channel resource is configured by radio resource control signaling. In certain embodiments, the measurement result is based on a channel state information reference signal in response to the channel state information reference signal being configured by a base unit. In various embodiments, the measurement result is based on a synchronization signal block in response to a channel state information reference signal not being configured by a base unit. In one embodiment, the apparatus includes a processor that performs a beam measurement to determine the measurement result in response to a second trigger condition. In some embodiments, the second trigger condition includes a quality of a serving beam being less than a predetermined threshold, a number of out-of-sync indications from a physical layer, or some combination thereof. In certain embodiments, the predetermined threshold and the number are configured by radio resource control signaling. In various embodiments, the apparatus includes a processor that starts a timer in response to the first trigger condition. In various embodiments, the processor enters radio link failure in response to the timer expiring. In one embodiment, the processor stops the timer in response to receiving a response to the transmission of the beam recovery request.

[0009] A method for transmitting a beam recovery request, in one embodiment, includes receiving information indicating a resource configured for a beam recovery request. In some

embodiments, the method includes transmitting the beam recovery request on the resource in response to a first trigger condition.

[0010] In one embodiment, an apparatus for receiving a beam recovery request includes a transmitter that transmits information indicating a resource configured for a beam recovery request. In some embodiments, the apparatus includes a receiver that receives the beam recovery request on the resource.

[0011] In certain embodiments, the resource configured for the beam recovery request is configured by radio resource control signaling. In various embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being configured by the radio resource control signaling. In some embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being activated by a medium access control control element.

[0012] In certain embodiments, a first available resource is selected to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being available for transmission of the beam recovery request. In some embodiments, a physical uplink control channel resource is selected to transmit the beam recovery request in response to a contention-free resource and the physical uplink control channel resource being available for transmission of the beam recovery request and in response to the physical uplink control channel resource having a channel quality greater than a predetermined threshold. In various embodiments, a physical random access channel resource is selected to transmit the beam recovery request in response to the physical uplink control channel resource having the channel quality less than the predetermined threshold.

[0013] In one embodiment, the transmitter transmits a response to the beam recovery request. In certain embodiments, a physical random access channel resource for the beam recovery request is skipped in response to the beam recovery request being transmitting using a physical uplink control channel resource. In some embodiments, a contention based resource is selected to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being unavailable for transmission of the beam recovery request.

[0014] In various embodiments, the resource to transmit the beam recovery request is selected based on a measurement result and an association between a downlink transmission beam and a physical uplink control channel resource. In certain embodiments, the association between the downlink transmission beam and the physical uplink control channel resource is configured by radio resource control signaling. In some embodiments, the measurement result is

based on a channel state information reference signal in response to the channel state information reference signal being configured by a base unit. In one embodiment, the measurement result is based on a synchronization signal block in response to a channel state information reference signal not being configured by a base unit.

[0015] In various embodiments, a beam measurement is performed to determine the measurement result in response to a second trigger condition. In certain embodiments, the second trigger condition includes a quality of a serving beam being less than a predetermined threshold, a number of out-of-sync indications from a physical layer, or some combination thereof. In some embodiments, the predetermined threshold and the number are configured by radio resource control signaling. In one embodiment, a timer is started in response to the first trigger condition. In various embodiments, radio link failure is entered in response to the timer expiring. In certain embodiments, the timer is stopped in response to transmitting a response to receiving the beam recovery request.

[0016] A method for receiving a beam recovery request, in one embodiment, includes transmitting information indicating a resource configured for a beam recovery request. In certain embodiments, the method includes receiving the beam recovery request on the resource.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] A more particular description of the embodiments briefly described above will be rendered by reference to specific embodiments that are illustrated in the appended drawings. Understanding that these drawings depict only some embodiments and are not therefore to be considered to be limiting of scope, the embodiments will be described and explained with additional specificity and detail through the use of the accompanying drawings, in which:

[0018] Figure 1 is a schematic block diagram illustrating one embodiment of a wireless communication system for transmitting and/or receiving a beam recovery request;

[0019] Figure 2 is a schematic block diagram illustrating one embodiment of an apparatus that may be used for transmitting a beam recovery request;

[0020] Figure 3 is a schematic block diagram illustrating one embodiment of an apparatus that may be used for receiving a beam recovery request;

[0021] Figure 4 is a schematic flow chart diagram illustrating one embodiment of a method for transmitting a beam recovery request; and

[0022] Figure 5 is a schematic flow chart diagram illustrating one embodiment of a method for receiving a beam recovery request.

DETAILED DESCRIPTION

[0023] As will be appreciated by one skilled in the art, aspects of the embodiments may be embodied as a system, apparatus, method, or program product. Accordingly, embodiments may take the form of an entirely hardware embodiment, an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodiment combining software and hardware aspects that may all generally be referred to herein as a "circuit," "module" or "system." Furthermore, embodiments may take the form of a program product embodied in one or more computer readable storage devices storing machine readable code, computer readable code, and/or program code, referred hereafter as code. The storage devices may be tangible, non-transitory, and/or non-transmission. The storage devices may not embody signals. In a certain embodiment, the storage devices only employ signals for accessing code.

[0024] Certain of the functional units described in this specification may be labeled as modules, in order to more particularly emphasize their implementation independence. For example, a module may be implemented as a hardware circuit comprising custom very-large-scale integration ("VLSI") circuits or gate arrays, off-the-shelf semiconductors such as logic chips, transistors, or other discrete components. A module may also be implemented in programmable hardware devices such as field programmable gate arrays, programmable array logic, programmable logic devices or the like.

[0025] Modules may also be implemented in code and/or software for execution by various types of processors. An identified module of code may, for instance, include one or more physical or logical blocks of executable code which may, for instance, be organized as an object, procedure, or function. Nevertheless, the executables of an identified module need not be physically located together, but may include disparate instructions stored in different locations which, when joined logically together, include the module and achieve the stated purpose for the module.

[0026] Indeed, a module of code may be a single instruction, or many instructions, and may even be distributed over several different code segments, among different programs, and across several memory devices. Similarly, operational data may be identified and illustrated herein within modules, and may be embodied in any suitable form and organized within any suitable type of data structure. The operational data may be collected as a single data set, or may be distributed over different locations including over different computer readable storage devices. Where a module or portions of a module are implemented in software, the software portions are stored on one or more computer readable storage devices.

[0027] Any combination of one or more computer readable medium may be utilized. The computer readable medium may be a computer readable storage medium. The computer readable storage medium may be a storage device storing the code. The storage device may be, for example, but not limited to, an electronic, magnetic, optical, electromagnetic, infrared, holographic, micromechanical, or semiconductor system, apparatus, or device, or any suitable combination of the foregoing.

[0028] More specific examples (a non-exhaustive list) of the storage device would include the following: an electrical connection having one or more wires, a portable computer diskette, a hard disk, a random access memory ("RAM"), a read-only memory ("ROM"), an erasable programmable read-only memory ("EPROM" or Flash memory), a portable compact disc read-only memory ("CD-ROM"), an optical storage device, a magnetic storage device, or any suitable combination of the foregoing. In the context of this document, a computer readable storage medium may be any tangible medium that can contain, or store a program for use by or in connection with an instruction execution system, apparatus, or device.

[0029] Code for carrying out operations for embodiments may be any number of lines and may be written in any combination of one or more programming languages including an object oriented programming language such as Python, Ruby, Java, Smalltalk, C++, or the like, and conventional procedural programming languages, such as the "C" programming language, or the like, and/or machine languages such as assembly languages. The code may execute entirely on the user's computer, partly on the user's computer, as a stand-alone software package, partly on the user's computer and partly on a remote computer or entirely on the remote computer or server. In the latter scenario, the remote computer may be connected to the user's computer through any type of network, including a local area network ("LAN") or a wide area network ("WAN"), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider).

[0030] Reference throughout this specification to "one embodiment," "an embodiment," or similar language means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one embodiment. Thus, appearances of the phrases "in one embodiment," "in an embodiment," and similar language throughout this specification may, but do not necessarily, all refer to the same embodiment, but mean "one or more but not all embodiments" unless expressly specified otherwise. The terms "including," "comprising," "having," and variations thereof mean "including but not limited to," unless expressly specified otherwise. An enumerated listing of items does not imply that any or all of

the items are mutually exclusive, unless expressly specified otherwise. The terms "a," "an," and "the" also refer to "one or more" unless expressly specified otherwise.

[0031] Furthermore, the described features, structures, or characteristics of the embodiments may be combined in any suitable manner. In the following description, numerous specific details are provided, such as examples of programming, software modules, user selections, network transactions, database queries, database structures, hardware modules, hardware circuits, hardware chips, etc., to provide a thorough understanding of embodiments. One skilled in the relevant art will recognize, however, that embodiments may be practiced without one or more of the specific details, or with other methods, components, materials, and so forth. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid obscuring aspects of an embodiment.

[0032] Aspects of the embodiments are described below with reference to schematic flowchart diagrams and/or schematic block diagrams of methods, apparatuses, systems, and program products according to embodiments. It will be understood that each block of the schematic flowchart diagrams and/or schematic block diagrams, and combinations of blocks in the schematic flowchart diagrams and/or schematic block diagrams, can be implemented by code. The code may be provided to a processor of a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the schematic flowchart diagrams and/or schematic block diagrams block or blocks.

[0033] The code may also be stored in a storage device that can direct a computer, other programmable data processing apparatus, or other devices to function in a particular manner, such that the instructions stored in the storage device produce an article of manufacture including instructions which implement the function/act specified in the schematic flowchart diagrams and/or schematic block diagrams block or blocks.

[0034] The code may also be loaded onto a computer, other programmable data processing apparatus, or other devices to cause a series of operational steps to be performed on the computer, other programmable apparatus or other devices to produce a computer implemented process such that the code which execute on the computer or other programmable apparatus provide processes for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

[0035] The schematic flowchart diagrams and/or schematic block diagrams in the Figures illustrate the architecture, functionality, and operation of possible implementations of

apparatuses, systems, methods and program products according to various embodiments. In this regard, each block in the schematic flowchart diagrams and/or schematic block diagrams may represent a module, segment, or portion of code, which includes one or more executable instructions of the code for implementing the specified logical function(s).

[0036] It should also be noted that, in some alternative implementations, the functions noted in the block may occur out of the order noted in the Figures. For example, two blocks shown in succession may, in fact, be executed substantially concurrently, or the blocks may sometimes be executed in the reverse order, depending upon the functionality involved. Other steps and methods may be conceived that are equivalent in function, logic, or effect to one or more blocks, or portions thereof, of the illustrated Figures.

[0037] Although various arrow types and line types may be employed in the flowchart and/or block diagrams, they are understood not to limit the scope of the corresponding embodiments. Indeed, some arrows or other connectors may be used to indicate only the logical flow of the depicted embodiment. For instance, an arrow may indicate a waiting or monitoring period of unspecified duration between enumerated steps of the depicted embodiment. It will also be noted that each block of the block diagrams and/or flowchart diagrams, and combinations of blocks in the block diagrams and/or flowchart diagrams, can be implemented by special purpose hardware-based systems that perform the specified functions or acts, or combinations of special purpose hardware and code.

[0038] The description of elements in each figure may refer to elements of proceeding figures. Like numbers refer to like elements in all figures, including alternate embodiments of like elements.

[0039] Figure 1 depicts an embodiment of a wireless communication system 100 for transmitting and/or receiving a beam recovery request. In one embodiment, the wireless communication system 100 includes remote units 102 and base units 104. Even though a specific number of remote units 102 and base units 104 are depicted in Figure 1, one of skill in the art will recognize that any number of remote units 102 and base units 104 may be included in the wireless communication system 100.

[0040] In one embodiment, the remote units 102 may include computing devices, such as desktop computers, laptop computers, personal digital assistants ("PDAs"), tablet computers, smart phones, smart televisions (e.g., televisions connected to the Internet), set-top boxes, game consoles, security systems (including security cameras), vehicle on-board computers, network devices (e.g., routers, switches, modems), or the like. In some embodiments, the remote units 102 include wearable devices, such as smart watches, fitness bands, optical head-mounted

displays, or the like. Moreover, the remote units 102 may be referred to as subscriber units, mobiles, mobile stations, users, terminals, mobile terminals, fixed terminals, subscriber stations, UE, user terminals, a device, or by other terminology used in the art. The remote units 102 may communicate directly with one or more of the base units 104 via UL communication signals.

[0041] The base units 104 may be distributed over a geographic region. In certain embodiments, a base unit 104 may also be referred to as an access point, an access terminal, a base, a base station, a Node-B, an eNB, a gNB, a Home Node-B, a relay node, a device, or by any other terminology used in the art. The base units 104 are generally part of a radio access network that includes one or more controllers communicably coupled to one or more corresponding base units 104. The radio access network is generally communicably coupled to one or more core networks, which may be coupled to other networks, like the Internet and public switched telephone networks, among other networks. These and other elements of radio access and core networks are not illustrated but are well known generally by those having ordinary skill in the art.

[0042] In one implementation, the wireless communication system 100 is compliant with the 3GPP protocol, wherein the base unit 104 transmits using an OFDM modulation scheme on the DL and the remote units 102 transmit on the UL using a SC-FDMA scheme or an OFDM scheme. More generally, however, the wireless communication system 100 may implement some other open or proprietary communication protocol, for example, WiMAX, among other protocols. The present disclosure is not intended to be limited to the implementation of any particular wireless communication system architecture or protocol.

[0043] The base units 104 may serve a number of remote units 102 within a serving area, for example, a cell or a cell sector via a wireless communication link. The base units 104 transmit DL communication signals to serve the remote units 102 in the time, frequency, and/or spatial domain.

[0044] In one embodiment, a remote unit 102 may receive information indicating a resource configured for a beam recovery request. In some embodiments, the remote unit 102 may transmit the beam recovery request on the resource in response to a first trigger condition. Accordingly, a remote unit 102 may be used for transmitting a beam recovery request.

[0045] In certain embodiments, a base unit 104 may transmit information indicating a resource configured for a beam recovery request. In certain embodiments, the base unit 104 may receive the beam recovery request on the resource in response to a first trigger condition. Accordingly, a base unit 104 may be used for receiving a beam recovery request.

[0046] Figure 2 depicts one embodiment of an apparatus 200 that may be used for transmitting a beam recovery request. The apparatus 200 includes one embodiment of the remote unit 102. Furthermore, the remote unit 102 may include a processor 202, a memory 204, an input device 206, a display 208, a transmitter 210, and a receiver 212. In some embodiments, the input device 206 and the display 208 are combined into a single device, such as a touchscreen. In certain embodiments, the remote unit 102 may not include any input device 206 and/or display 208. In various embodiments, the remote unit 102 may include one or more of the processor 202, the memory 204, the transmitter 210, and the receiver 212, and may not include the input device 206 and/or the display 208.

[0047] The processor 202, in one embodiment, may include any known controller capable of executing computer-readable instructions and/or capable of performing logical operations. For example, the processor 202 may be a microcontroller, a microprocessor, a central processing unit ("CPU"), a graphics processing unit ("GPU"), an auxiliary processing unit, a field programmable gate array ("FPGA"), or similar programmable controller. In some embodiments, the processor 202 executes instructions stored in the memory 204 to perform the methods and routines described herein. The processor 202 is communicatively coupled to the memory 204, the input device 206, the display 208, the transmitter 210, and the receiver 212.

[0048] The memory 204, in one embodiment, is a computer readable storage medium. In some embodiments, the memory 204 includes volatile computer storage media. For example, the memory 204 may include a RAM, including dynamic RAM ("DRAM"), synchronous dynamic RAM ("SDRAM"), and/or static RAM ("SRAM"). In some embodiments, the memory 204 includes non-volatile computer storage media. For example, the memory 204 may include a hard disk drive, a flash memory, or any other suitable non-volatile computer storage device. In some embodiments, the memory 204 includes both volatile and non-volatile computer storage media. In some embodiments, the memory 204 stores data relating to beam recovery requests. In some embodiments, the memory 204 also stores program code and related data, such as an operating system or other controller algorithms operating on the remote unit 102.

[0049] The input device 206, in one embodiment, may include any known computer input device including a touch panel, a button, a keyboard, a stylus, a microphone, or the like. In some embodiments, the input device 206 may be integrated with the display 208, for example, as a touchscreen or similar touch-sensitive display. In some embodiments, the input device 206 includes a touchscreen such that text may be input using a virtual keyboard displayed on the touchscreen and/or by handwriting on the touchscreen. In some embodiments, the input device 206 includes two or more different devices, such as a keyboard and a touch panel.

[0050] The display 208, in one embodiment, may include any known electronically controllable display or display device. The display 208 may be designed to output visual, audible, and/or haptic signals. In some embodiments, the display 208 includes an electronic display capable of outputting visual data to a user. For example, the display 208 may include, but is not limited to, an LCD display, an LED display, an OLED display, a projector, or similar display device capable of outputting images, text, or the like to a user. As another, non-limiting, example, the display 208 may include a wearable display such as a smart watch, smart glasses, a heads-up display, or the like. Further, the display 208 may be a component of a smart phone, a personal digital assistant, a television, a table computer, a notebook (laptop) computer, a personal computer, a vehicle dashboard, or the like.

[0051] In certain embodiments, the display 208 includes one or more speakers for producing sound. For example, the display 208 may produce an audible alert or notification (e.g., a beep or chime). In some embodiments, the display 208 includes one or more haptic devices for producing vibrations, motion, or other haptic feedback. In some embodiments, all or portions of the display 208 may be integrated with the input device 206. For example, the input device 206 and display 208 may form a touchscreen or similar touch-sensitive display. In other embodiments, the display 208 may be located near the input device 206.

[0052] The transmitter 210 is used to provide UL communication signals to the base unit 104 and the receiver 212 is used to receive DL communication signals from the base unit 104. In certain embodiments, the receiver 212 may be used to receive information indicating a resource configured for a beam recovery request. In various embodiments, the transmitter 210 may be used to transmit the beam recovery request on the resource in response to a first trigger condition. Although only one transmitter 210 and one receiver 212 are illustrated, the remote unit 102 may have any suitable number of transmitters 210 and receivers 212. The transmitter 210 and the receiver 212 may be any suitable type of transmitters and receivers. In one embodiment, the transmitter 210 and the receiver 212 may be part of a transceiver.

[0053] In some embodiments, transmitting a beam recovery request (e.g., a beam failure recovery procedure) may be performed using various steps that may be performed in any suitable order and/or some steps may not be performed.

[0054] In a first step, a base unit 104 may configure a remote unit 102 with various information. In one embodiment, in response to the remote unit 102 being configured with a channel state information reference signal ("CSI-RS"), the information may include that the CSI-RS is used to determine a beam failure. In another embodiment, in response to the remote unit 102 not being configured is a CSI-RS, the information may include that a synchronization signal

block ("SS-block") may be used to determine a beam failure. In some embodiments, resources for UL transmission of a beam recovery request may be configured by RRC signaling. In certain embodiments, the information may include a trigger condition to transmit a beam failure recovery request. In various embodiments, the trigger condition may be that a medium access control ("MAC") layer receives a number (e.g., "N") of out-of-sync indications from a physical layer. In one embodiment, the number of out-of-sync indications may be configured by RRC signaling. As used herein, an "out-of-sync indication" may refer to feedback, a response, an indication, and/or a signal that contains information indicating that there is no synchronization between data being received and a device decoding the data being received. In some embodiments, the information may include a trigger condition to identify a candidate DL TX beam. In various embodiments, the trigger condition may include that a serving beam quality becomes worse than a configured and/or predetermined threshold. In certain embodiments, the trigger condition may include that a number ("e.g., "M") of out-of-sync indications are received in a physical layer.

[0055] In a second step, the remote unit 102 may report measurement results periodically to the base unit 104. The report measurement results may include results corresponding to a serving beam.

[0056] In a third step, the base unit 104 may activate a dedicated UL resource for transmitting a beam recovery request based on the measurement results. In some embodiments, the dedicated UL resource may be activated by a MAC control element ("CE"). In one embodiment, the base unit 104 may configure the dedicted UL resource for the remote unit 102 to transmit the beam recovery request using RRC signaling. In such an embodiment, the remote unit 102 may be enabled to use the dedicted UL resource in response to receiving configuration information indicating the dedicated UL resource. In another embodiment, the remote unit 102 may be enabled to use the dedicated UL resource in response to the base unit 104 activating the dedicated UL resource via the MAC CE.

[0057] In a fourth step, an event that triggers a beam failure recovery request may be detected by the remote unit 102. In response to the event triggering the beam failure recovery request for a last active beam, the MAC of the remote unit 102 may start a timer ("T1"). In response to the timer expiring, the remote unit 102 may enter a radio link failure ("RLF") condition. In some embodiments, the timer may stop in response to the remote unit 102 receiving a response to the beam failure recovery request.

[0058] In a fifth step, the remote unit 102 may transmit a beam recovery request to the base unit 104. In some embodiments, a base unit 104 may configure an association between a

DL TX beam and a PUCCH resource. In certain embodiments, based on a measurement result associated to an SS-block or CSI-RS, only a PUCCH resource associated to a suitable beam may be used for a beam failure recovery request. As used herein, a "suitable beam" may mean that a measurement quality is better than a threshold quality configured by the base unit 104. In some embodiments, in response to a contention-free resource for a beam recovery request being available, the remote unit 102 may use the contention-free resource to transmit beam recovery request. In various embodiments, in response to a PUCCH resource such as scheduling request ("SR"), sounding reference signal ("SRS"), PUSCH, and/or PUCCH for a beam recovery request being available, the remote unit 102 may use a first available PUCCH resource to transmit the beam recovery request.

[0059] In certain embodiments, in response to both a contention-free resource and a PUCCH resource for beam recovery request being available, the remote unit 102 may select an UL resource for a beam recovery request based on certain criteria. In one embodiment, the criteria may include the remote unit 102 selecting a first available resource. In some embodiments, the criteria may include the remote unit 102 selecting a PUCCH resource based on a priority in response to a beam including a suitable PUCCH resource. In such embodiments, the criteria may include, in response to all beams associated with the PUCCH resource not being suitable, the remote unit 102 selecting a PRACH resource for transmitting the beam recovery request. As used herein, a beam "not being suitable" may mean that a measurement quality is less than a threshold quality configured by the base unit 104.

[0060] In various embodiments, in response to a beam recovery request being transmitted in a first selected resource, the remote unit 102 may handle other available resources according to certain criteria. In one embodiment, the criteria may include the remote unit 102 skipping other available resources for the beam recovery request. For example, in response to the beam recovery request being transmitted in a PRACH resource, the remote unit 102 may monitor for a response within a time window. During the time window, the remote unit 102 may skip a PUCCH resource for a beam recovery request. As another example, in response to the beam recovery request being transmitted in a PUCCH resource, the remote unit 102 may skip a PRACH resource for a beam recovery request. In some embodiments, the criteria may include the remote unit 102 retransmitting the beam recovery request using other available resources. For example, in response to the beam recovery request being transmitted in a PRACH resource, the remote unit 102 may monitor for a response within a time window. During the time window, the remote unit 102 may retransmit the beam recovery request using a PUCCH resource. As another example, in response to the beam recovery request being transmitted in a PUCCH

resource, the remote unit 102 may retransmit the beam recovery request using a PRACH resource. In various embodiment, in response to both a contention-free resource and a PUCCH resource for a beam recovery request not being available to the remote unit 102, the remote unit 102 may use a contention based resource to transmit a beam recovery request.

[0061] In a sixth step, the base unit 104 may transmit a response to the beam recovey request to the remote unit 102. For example, in response to the base unit 104 receiving the beam recovery request from the remote unit 102, the base unit 104 may transmit the response in a DL beam associated with the UL resource, or in a candidate DL beam signaled in PUCCH.

[0062] In a seventh step, the remote unit 102 monitors for a response from the base unit 104 after transmitting the beam recovery request. In response to the remote unit 102 failing to receive a response from the base unit 104 within a predetermined time window, the remote unit 102 may be enabled to transmit a beam recovery request again.

[0063] Figure 3 depicts one embodiment of an apparatus 300 that may be used for receiving a beam recovery request. The apparatus 300 includes one embodiment of the base unit 104. Furthermore, the base unit 104 may include a processor 302, a memory 304, an input device 306, a display 308, a transmitter 310, and a receiver 312. As may be appreciated, the processor 302, the memory 304, the input device 306, the display 308, the transmitter 310, and the receiver 312 may be substantially similar to the processor 202, the memory 204, the input device 206, the display 208, the transmitter 210, and the receiver 212 of the remote unit 102, respectively.

[0064] In certain embodiments, the transmitter 310 may be used to transmit information indicating a resource configured for a beam recovery request. In some embodiments, the receiver 312 may be used to receive the beam recovery request on the resource in response to a first trigger condition. Although only one transmitter 310 and one receiver 312 are illustrated, the base unit 104 may have any suitable number of transmitters 310 and receivers 312. The transmitter 310 and the receiver 312 may be any suitable type of transmitters and receivers. In one embodiment, the transmitter 310 and the receiver 312 may be part of a transceiver.

[0065] Figure 4 is a schematic flow chart diagram illustrating one embodiment of a method 400 for transmitting a beam recovery request. In some embodiments, the method 400 is performed by an apparatus, such as the remote unit 102. In certain embodiments, the method 400 may be performed by a processor executing program code, for example, a microcontroller, a microprocessor, a CPU, a GPU, an auxiliary processing unit, a FPGA, or the like.

[0066] The method 400 may include receiving 402 information indicating a resource configured for a beam recovery request. In some embodiments, the method 400 includes

transmitting 404 the beam recovery request on the resource in response to a first trigger condition.

[0067] In one embodiment, the first trigger condition includes a medium access control layer receiving a number of out-of-sync indications from a physical layer. In a further embodiment, the number of out-of-sync indications is configured by radio resource control signaling. In certain embodiments, the resource configured for the beam recovery request is configured by radio resource control signaling. In various embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being configured by the radio resource control signaling. In some embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being activated by a medium access control control element.

[0068] In certain embodiments, the method 400 includes selecting a first available resource to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being available for transmission of the beam recovery request. In some embodiments, the method 400 includes selecting a physical uplink control channel resource to transmit the beam recovery request in response to a contention-free resource and the physical uplink control channel resource being available for transmission of the beam recovery request and in response to the physical uplink control channel resource having a channel quality greater than a predetermined threshold. In various embodiments, the method 400 includes selecting a physical random access channel resource to transmit the beam recovery request in response to the physical uplink control channel resource having the channel quality less than the predetermined threshold.

[0069] In one embodiment, the method 400 includes monitoring for a response to transmission of the beam recovery request for a predetermined time in response to transmitting the beam recovery request using a physical random access channel resource and skipping a physical uplink control channel resource for the beam recovery request during the predetermined time. In certain embodiments, the method 400 includes skipping a physical random access channel resource for the beam recovery request in response to transmitting the beam recovery request using a physical uplink control channel resource. In some embodiments, the method 400 includes selecting a contention based resource to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being unavailable for transmission of the beam recovery request. In various embodiments, the method 400 includes selecting the resource to transmit the beam recovery request based on a measurement

result and an association between a downlink transmission beam and a physical uplink control channel resource.

[0070] In some embodiments, the association between the downlink transmission beam and the physical uplink control channel resource is configured by radio resource control signaling. In certain embodiments, the measurement result is based on a channel state information reference signal in response to the channel state information reference signal being configured by a base unit. In various embodiments, the measurement result is based on a synchronization signal block in response to a channel state information reference signal not being configured by a base unit. In one embodiment, the method 400 includes performing a beam measurement to determine the measurement result in response to a second trigger condition. In some embodiments, the second trigger condition includes a quality of a serving beam being less than a predetermined threshold, a number of out-of-sync indications from a physical layer, or some combination thereof. In certain embodiments, the predetermined threshold and the number are configured by radio resource control signaling. In various embodiments, the method 400 includes starting a timer in response to the first trigger condition. In various embodiments, the method 400 enters radio link failure in response to the timer expiring. In one embodiment, the method 400 stops the timer in response to receiving a response to the transmission of the beam recovery request.

[0071] Figure 5 is a schematic flow chart diagram illustrating one embodiment of a method 500 for receiving a beam recovery request. In some embodiments, the method 500 is performed by an apparatus, such as the base unit 104. In certain embodiments, the method 500 may be performed by a processor executing program code, for example, a microcontroller, a microprocessor, a CPU, a GPU, an auxiliary processing unit, a FPGA, or the like.

[0072] The method 500 may include transmitting 502 information indicating a resource configured for a beam recovery request. In certain embodiments, the method 500 includes receiving 504 the beam recovery request on the resource.

[0073] In one embodiment, the first trigger condition includes a medium access control layer receiving a number of out-of-sync indications from a physical layer. In a further embodiment, the number of out-of-sync indications is configured by radio resource control signaling. In certain embodiments, the resource configured for the beam recovery request is configured by radio resource control signaling. In various embodiments, the resource configured for the beam recovery request is enabled for use in response to the resource being configured by the radio resource control signaling. In some embodiments, the resource configured for the beam

recovery request is enabled for use in response to the resource being activated by a medium access control control element.

[0074] In certain embodiments, a first available resource is selected to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being available for transmission of the beam recovery request. In some embodiments, a physical uplink control channel resource is selected to transmit the beam recovery request in response to a contention-free resource and the physical uplink control channel resource being available for transmission of the beam recovery request and in response to the physical uplink control channel resource having a channel quality greater than a predetermined threshold. In various embodiments, a physical random access channel resource is selected to transmit the beam recovery request in response to the physical uplink control channel resource having the channel quality less than the predetermined threshold.

[0075] In one embodiment, the method 500 includes transmitting a response to the beam recovery request. In certain embodiments, a physical random access channel resource for the beam recovery request is skipped in response to the beam recovery request being transmitting using a physical uplink control channel resource. In some embodiments, a contention based resource is selected to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being unavailable for transmission of the beam recovery request.

[0076] In various embodiments, the resource to transmit the beam recovery request is selected based on a measurement result and an association between a downlink transmission beam and a physical uplink control channel resource. In certain embodiments, the association between the downlink transmission beam and the physical uplink control channel resource is configured by radio resource control signaling. In some embodiments, the measurement result is based on a channel state information reference signal in response to the channel state information reference signal being configured by a base unit. In one embodiment, the measurement result is based on a synchronization signal block in response to a channel state information reference signal not being configured by a base unit.

[0077] In various embodiments, a beam measurement is performed to determine the measurement result in response to a second trigger condition. In certain embodiments, the second trigger condition includes a quality of a serving beam being less than a predetermined threshold, a number of out-of-sync indications from a physical layer, or some combination thereof. In some embodiments, the predetermined threshold and the number are configured by radio resource control signaling. In one embodiment, a timer is started in response to the first

trigger condition. In various embodiments, radio link failure is entered in response to the timer expiring. In certain embodiments, the timer is stopped in response to transmitting a response to receiving the beam recovery request.

[0078] Embodiments may be practiced in other specific forms. The described embodiments are to be considered in all respects only as illustrative and not restrictive. The scope of the invention is, therefore, indicated by the appended claims rather than by the foregoing description. All changes which come within the meaning and range of equivalency of the claims are to be embraced within their scope.

CLAIMS

1. A method comprising:

receiving information indicating a resource configured for a beam recovery request; and

transmitting the beam recovery request on the resource in response to a first trigger condition.

2. The method of claim 1, wherein the first trigger condition comprises a medium access control layer receiving a number of out-of-sync indications from a physical layer.

3. The method of claim 1, wherein the resource configured for the beam recovery request is configured by radio resource control signaling.

4. The method of claim 3, wherein the resource configured for the beam recovery request is enabled for use in response to the resource being configured by the radio resource control signaling.

5. The method of claim 3, wherein the resource configured for the beam recovery request is enabled for use in response to the resource being activated by a medium access control control element.

6. The method of claim 1, further comprising selecting a first available resource to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being available for transmission of the beam recovery request.

7. The method of claim 1, further comprising selecting a physical uplink control channel resource to transmit the beam recovery request in response to a contention-free resource and the physical uplink control channel resource being available for transmission of the beam recovery request and in response to the physical uplink control channel resource having a channel quality greater than a predetermined threshold.

8. The method of claim 7, further comprising selecting a physical random access channel resource to transmit the beam recovery request in response to the physical uplink control channel resource having the channel quality less than the predetermined threshold.

9. The method of claim 1, further comprising monitoring for a response to transmission of the beam recovery request for a predetermined time in response to transmitting the beam recovery request using a physical random access channel resource and skipping a physical uplink control channel resource for the beam recovery request during the predetermined time.

10. The method of claim 1, further comprising skipping a physical random access channel resource for the beam recovery request in response to transmitting the beam recovery request using a physical uplink control channel resource.

11. The method of claim 1, further comprising selecting a contention based resource to transmit the beam recovery request in response to a contention-free resource and a physical uplink control channel resource being unavailable for transmission of the beam recovery request.

12. The method of claim 1, further comprising selecting the resource to transmit the beam recovery request based on a measurement result and an association between a downlink transmission beam and a physical uplink control channel resource.

13. The method of claim 12, wherein the association between the downlink transmission beam and the physical uplink control channel resource is configured by radio resource control signaling.

14. The method of claim 12, wherein the measurement result is based on a channel state information reference signal in response to the channel state information reference signal being configured by a base unit.

15. The method of claim 12, wherein the measurement result is based on a synchronization signal block in response to a channel state information reference signal not being configured by a base unit.

16. The method of claim 12, further comprising performing a beam measurement to determine the measurement result in response to a second trigger condition.

17. The method of claim 16, wherein the second trigger condition comprises a quality of a serving beam being less than a predetermined threshold, a number of out-of-sync indications from a physical layer, or some combination thereof.

18. The method of claim 1, further comprising starting a timer in response to the first trigger condition.

19. An apparatus comprising:

a receiver that receives information indicating a resource configured for a beam recovery request; and

a transmitter that transmits the beam recovery request on the resource in response to a first trigger condition.

20. An apparatus comprising:

a transmitter that transmits information indicating a resource configured for a beam recovery request; and

a receiver that receives the beam recovery request on the resource.

METHOD AND APPARATUS FOR MEASURING REFERENCE SIGNAL IN WIRELESS COMMUNICATION SYSTEM COMPRISING A PLURALITY BASE STATION USING A DISTRIBUTED ANTENNA

Abstract

Normally, a cellular wireless mobile communication system is organized by constructing a plurality of cells in a restricted area. Base station equipment which manages mobile communication within the corresponding cell is located at the center of the cell area. The base station equipment provides a mobile communication service to an antenna which transmits a wireless signal and terminals located at the center of the cell. The system is called as a centralized antenna system (CAS) and is a normal type of the mobile communication system. A contrasting system is a distributed antenna system (DAS), uniformly distributes antennas to service areas of the cells, and can provide the improved mobile communication service. The present invention proposes an interference measuring method and an interference measuring apparatus for effective communication in the distributed antenna systems (DAS) distributed in the service area of each base station. [Reference numerals] (700) Base station determines the feedback setup of a terminal;(710) Is it RI/PMI report unavailable setup?;(720) Transmitting PDSCH to a terminal based on the CSI of a terminal measured by CSH-RS;(730) Is it CRS allocation for CSI measurement?;(740) Notifying a RS switch bit to a terminal by setting Z as 0;(750) Notifying a RS switch bit to a terminal by setting Z as 1;(760) Transmitting PDSCH to a terminal based on the CSI of a terminal measured by CRS;(770) Transmitting PDSCH to a terminal based on the CQI of a terminal measured by CSI-RS

(54) 발명의 명칭 분산 안테나를 사용하는 복수 개의 기지국을 포함하는 무선통신 시스템에서 기준 신호 측정 방법 및 장치

(57) 요 약

일반적으로 셀룰러 무선 이동 통신 시스템은 한정된 지역에 복수개의 셀을 구축함으로서 이루어진다. 각 셀에는 해당 셀 내에서의 이동통신을 전담하는 기지국 장비가 셀 영역의 가운데에 위치하게 된다. 상기 기지국 장비로는 무선신호를 전송하는 안테나 및 신호처리 부분이 있으며 셀의 중앙에서 셀 내의 단말들에게 이동통신 서비스를 제공한다. 이와 같이 안테나가 셀의 중앙에 설치되는 시스템은 중앙 집중형 안테나 시스템 (Centralized Antenna System: CAS)이라고 하며 일반적인 이동통신 시스템이 이 형태이다.

이와 대비되는 시스템으로는 분산 안테나 시스템 (Distributed Antenna System: DAS)이 있으며 DAS의 경우 안테나들을 셀의 서비스영역에 골고루 분산함으로써 CAS와 대비하여 향상된 이동통신 서비스를 제공할 수 있다. 본 발명은 각 기지국의 서비스 영역에 분산되어 배치되어 있는 분산 안테나 시스템 (Distributed Antenna System: DAS)에서 효율적인 통신을 위한 간섭 측정 방법 및 장치를 제안한다.

특허청구의 범위

청구항 1

분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 기준신호 측정 정보를 기지국이 단말에 통보하는 방법에 있어서,

상기 단말의 RI/PMI 보고 불능 설정 여부를 결정하는 단계;

상기 단말의 RI/PMI 보고 불능 설정 시, CRS 또는 CSI-RS 중 단말이 측정할 기준 신호를 결정하는 단계;

상기 결정된 기준 신호를 상기 단말에게 통보하는 단계;

상기 결정된 기준 신호를 측정하여 단말이 생성한 제1 채널 정보를 상기 단말로부터 수신하는 단계; 및

상기 제1 채널 정보에 기반하여 상기 단말에게 데이터를 전송하는 단계를 포함하는 것을 특징으로 하는 방법.

청구항 2

제1항에 있어서,

상기 단말의 RI/PMI 보고 설정 시, 상기 단말이 CSI-RS를 측정하도록 통보하는 단계;

상기 단말이 상기 CSI-RS를 측정하여 생성한 제2 채널 정보를 수신하는 단계; 및

상기 제2 채널 정보에 기반하여 상기 단말에게 데이터를 전송하는 단계를 포함하는 것을 특징으로 하는 방법.

청구항 3

제1항에 있어서, 상기 통보 단계는,

상기 단말이 측정하도록 결정된 기준 신호 정보를 비트 형식으로 지시하는 기준 신호 측정 정보를 상기 단말에게 통보하는 것을 특징으로 하는 방법.

청구항 4

제3항에 있어서, 상기 기준 신호 측정 정보는,

상위 시그널링 또는 물리계층 시그널링을 통해 상기 단말에게 전송되는 것을 특징으로 하는 방법.

청구항 5

제1항에 있어서, 상기 통보 단계는,

간섭 측정 자원을 상기 단말에게 통보하거나 또는 복수 개의 피드백을 상기 단말에게 통보하는 단계; 및

상기 단말이 CSI-RS를 측정하여 생성한 제3 채널 정보를 상기 단말로부터 수신하는 단계를 더 포함하는 것을 특징으로 하는 방법.

청구항 6

제1항에 있어서, 상기 데이터 전송 단계는,

특정 프리코더가 적용된 데이터를 상기 단말에 전송하는 것을 특징으로 하며,

상기 프리코더는, 상기 프리코더가 속한 집합 및 각 서브밴드에 적용될 프리코더가 미리 결정된 것을 특징으로 하는 방법.

청구항 7

분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 단말의 하향링크 측정 방법에 있어서,

상기 단말의 RI/PMI 보고 불능 설정 여부에 대한 정보를 기지국으로부터 수신하는 단계;

상기 RI/PMI 보고 불능 설정 시, CRS 또는 CSI-RS 중 상기 단말이 측정하도록 결정된 기준 신호에 대한 정보를 상기 기지국으로부터 수신하는 단계;

상기 결정된 기준 신호를 측정하여 제1 채널 정보를 생성하고 상기 기지국으로 전송하는 단계; 및

상기 제1 채널 정보에 기반하여 전송되는 데이터를 상기 기지국으로부터 수신하는 단계를 포함하는 것을 특징으로 하는 하향링크 측정 방법.

청구항 8

제7항에 있어서,

상기 단말의 RI/PMI 보고 설정 시, 상기 CSI-RS를 측정하여 제2 채널 정보를 생성하는 단계; 및

상기 생성된 제2 채널 정보를 상기 기지국으로 전송하는 단계를 더 포함하는 것을 특징으로 하는 하향링크 측정 방법.

청구항 9

제7항에 있어서, 상기 기준 신호에 대한 정보 수신 단계는,

상기 단말이 측정하도록 결정된 기준 신호 정보를 비트 형식으로 지시하는 기준 신호 측정 정보를 수신하는 것을 특징으로 하는 하향링크 측정 방법.

청구항 10

제9항에 있어서, 상기 기준 신호 측정 정보는,

상위 시그널링 또는 물리계층 시그널링을 통해 상기 기지국으로부터 수신되는 것을 특징으로 하는 하향링크 측정 방법.

청구항 11

제7항에 있어서, 상기 기준 신호에 대한 정보 수신 단계는,

상기 기지국으로부터 간섭 측정 자원을 통보받거나 또는 복수 개의 피드백을 보고하도록 통보받는 경우, 상기 CSI-RS를 측정하여 제3 채널 정보를 생성하는 단계; 및

상기 생성된 제3 채널 정보를 상기 기지국으로 전송하는 단계를 더 포함하는 것을 특징으로 하는 하향링크 측정 방법.

청구항 12

제7항에 있어서, 상기 데이터 수신 단계는,

특정 프리코더가 적용된 데이터를 상기 기지국으로부터 수신하며,

상기 프리코더는, 상기 프리코더가 속한 집합 및 각 서브밴드에 적용될 프리코더가 미리 결정된 것을 특징으로 하는 하향링크 측정 방법.

청구항 13

분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 기준 신호 측정 정보를 단말에 통보하는 기지국에 있어서,

상기 기준 신호 측정 정보 또는 데이터를 상기 단말에 전송하고, 상기 단말로부터 전송되는 채널 측정 정보를 수신하는 송수신부; 및

상기 단말의 RI/PMI 보고 불능 여부를 결정하고, 상기 단말의 RI/PMI 보고 불능 결정 시 CRS 또는 CSI-RS 중 단말이 측정할 기준 신호를 결정하며, 상기 결정된 기준 신호를 상기 단말에게 통보하고, 상기 결정된 기준 신호를 측정하여 단말이 생성한 제1 채널 정보를 상기 단말로부터 수신하며, 상기 제1 채널 정보에 기반하여 상기

단말에게 데이터를 전송하도록 제어하는 제어기를 포함하는 것을 특징으로 하는 기지국.

청구항 14

제13항에 있어서, 상기 제어기는,

상기 단말의 RI/PMI 보고 결정 시 상기 단말이 CSI-RS를 측정하도록 통보하고, 상기 단말이 상기 CSI-RS를 측정하여 생성한 제2 채널 정보를 수신하며, 상기 제2 채널 정보에 기반하여 상기 단말에게 데이터를 전송하도록 제어하는 것을 특징으로 하는 기지국.

청구항 15

제13항에 있어서, 상기 제어기는,

상기 단말이 측정하도록 결정된 기준 신호 정보를 비트 형식으로 지시하는 기준 신호 측정 정보를 생성하여 상기 단말에 통보하는 것을 특징으로 하는 기지국.

청구항 16

제15항에 있어서, 상기 기준 신호 측정 정보는,

상위 시그널링 또는 물리계층 시그널링을 통해 상기 단말에게 전송되는 것을 특징으로 하는 기지국.

청구항 17

제13항에 있어서, 상기 제어기는,

간섭 측정 자원을 상기 단말에게 통보하거나 또는 복수 개의 피드백을 상기 단말에게 통보하고, 상기 단말이 CSI-RS를 측정하여 생성한 제3 채널 정보를 상기 단말로부터 수신하도록 제어하는 것을 특징으로 하는 기지국.

청구항 18

제13항에 있어서, 상기 제어기는,

특정 프리코더가 적용된 데이터를 상기 단말에 전송하도록 제어하며,

상기 프리코더는, 상기 프리코더가 속한 집합 및 각 서브밴드에 적용될 프리코더가 미리 결정된 것을 특징으로 하는 기지국.

청구항 19

분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 하향링크를 측정하여 보고하는 단말에 있어서,

기지국으로부터 전송되는 기준 신호 측정 정보 또는 데이터를 수신하고, 상기 단말이 측정한 채널 측정 정보를 상기 기지국으로 전송하는 송수신부; 및

상기 단말의 RI/PMI 보고 불능 설정 여부에 대한 정보를 기지국으로부터 수신하고, 상기 RI/PMI 보고 불능 설정 시 CRS 또는 CSI-RS 중 상기 단말이 측정하도록 결정된 기준 신호에 대한 정보를 상기 기지국으로부터 수신하며, 상기 결정된 기준 신호를 측정하여 제1 채널 정보를 생성하고 상기 기지국으로 전송하며, 상기 제1 채널 정보에 기반하여 전송되는 데이터를 상기 기지국으로부터 수신하도록 제어하는 제어기를 포함하는 것을 특징으로 하는 단말.

청구항 20

제19항에 있어서, 상기 제어기는,

상기 단말의 RI/PMI 보고 설정 시 상기 CSI-RS를 측정하여 제2 채널 정보를 생성하고, 상기 생성된 제2 채널 정보를 상기 기지국으로 전송하도록 제어하는 것을 특징으로 하는 단말.

청구항 21

제19항에 있어서, 상기 제어기는,

상기 단말이 측정하도록 결정된 기준 신호 정보를 비트 형식으로 지시하는 기준 신호 측정 정보를 수신하는 것을 특징으로 하는 단말.

청구항 22

제21항에 있어서, 상기 기준 신호 측정 정보는,

상위 시그널링 또는 물리계층 시그널링을 통해 상기 기지국으로부터 수신되는 것을 특징으로 하는 단말.

청구항 23

제19항에 있어서, 상기 제어기는,

상기 기지국으로부터 간섭 측정 자원을 통보받거나 또는 복수 개의 피드백을 보고하도록 통보받는 경우 상기 CSI-RS를 측정하여 제3 채널 정보를 생성하고, 상기 생성된 제3 채널 정보를 상기 기지국으로 전송하도록 제어하는 것을 특징으로 하는 단말.

청구항 24

제19항에 있어서, 상기 제어기는,

특정 프리코더가 적용된 데이터를 상기 기지국으로부터 수신하도록 제어하며,

상기 프리코더는, 상기 프리코더가 속한 집합 및 각 서브밴드에 적용될 프리코더가 미리 결정된 것을 특징으로 하는 단말.

기 술 분 야

[0001] 본 발명은 분산 안테나를 사용하는 복수 개의 기지국을 포함하는 무선통신 시스템에서 기준 신호 측정 방법 및 장치에 관한 것이다. 보다 구체적으로, 본 발명에서는 복수 개의 기지국이 존재하는 이동통신 시스템에서 각 기지국이 운용하는 안테나가 해당 기지국의 서비스 영역에 분산되어 배치되어 있는 분산 안테나 시스템(Distributed Antenna System: DAS)에서 하향링크에서 효과적인 통신을 위하여 단말에서 간섭측정을 수행하는 방법을 제안한다.

배 경 기 술

[0002] 이동통신 시스템은 초기의 음성 위주의 서비스를 제공하던 것에서 벗어나 데이터 서비스 및 멀티미디어 서비스 제공을 위해 고속, 고품질의 무선 패킷 데이터 통신 시스템으로 발전하고 있다. 최근 3GPP의 HSDPA(High Speed Downlink Packet Access), HSUPA(High Speed Uplink Packet Access), LTE (Long Term Evolution), LTE-A (Long Term Evolution Advanced), 3GPP2의 HRPD(High Rate Packet Data), 그리고 IEEE의 802.16 등 다양한 이동 통신 표준이 고속, 고품질의 무선 패킷 데이터 전송 서비스를 지원하기 위해 개발되었다. 특히 LTE 시스템은 고속 무선 패킷 데이터 전송을 효율적으로 지원하기 위하여 개발된 시스템으로 다양한 무선접속 기술을 활용하여 무선시스템 용량을 최대화한다. LTE-A 시스템은 LTE 시스템의 진보된 무선시스템으로 LTE와 비교하여 향상된 데이터 전송능력을 가지고 있다.

[0003] 상기 LTE는 일반적으로 3GPP 표준단체의 Release 8 또는 9에 해당하는 기지국 및 단말 장비를 의미하며 LTE-A는 3GPP 표준단체의 Release 10에 해당하는 기지국 및 단말 장비를 의미한다. 3GPP 표준단체에서는 LTE-A 시스템의 표준화 이후에도 이를 기반으로 하며 향상된 성능을 갖는 후속 Release에 대한 표준화를 진행하고 있다.

[0004] HSDPA, HSUPA, HRPD, LTE/LTE-A 등의 현존하는 3세대 및 4세대 무선 패킷 데이터 통신 시스템은 전송 효율을 개선하기 위해 적응 변조 및 부호(Adaptive Modulation and Coding, 이하 AMC) 방법과 채널 감응 스케줄링 방법 등의 기술을 이용한다. 상기의 AMC 방법을 활용하면 송신기는 채널 상태에 따라 전송하는 데이터의 양을 조절할 수 있다. 즉 채널 상태가 좋지 않으면 전송하는 데이터의 양을 줄여서 수신 오류 확률을 원하는 수준에 맞추고, 채널 상태가 좋으면 전송하는 데이터의 양을 늘려서 수신 오류 확률은 원하는 수준에 맞추면서도 많은 정보를 효과적으로 전송할 수 있다. 상기의 채널 감응 스케줄링 자원 관리 방법을 활용하면 송신기는 여러 사용자 중에서 채널 상태가 우수한 사용자를 선택적으로 서비스하기 때문에 한 사용자에게 채널을 할당하고 서비스해주는 것에 비해 시스템 용량이 증가한다. 이와 같은 용량 증가를 소위 다중 사용자 다이버시티(Multi-user

Diversity) 이득이라 한다. 요컨대 상기의 AMC 방법과 채널 감응 스케줄링 방법은 수신기로부터 부분적인 채널 상태 정보를 피드백(feedback) 받아서 가장 효율적이라고 판단되는 시점에 적절한 변조 및 부호 기법을 적용하는 방법이다.

[0005] 상기와 같은 AMC 방법은 MIMO (Multiple Input Multiple Output) 전송방식과 함께 사용될 경우 전송되는 신호의 spatial layer의 개수 또는 rank를 결정하는 기능도 포함할 수 있다. 이 경우 AMC 방법은 최적의 data rate를 결정하는데 단순히 부호화율과 변조방식만을 생각하지 않고 MIMO를 이용하여 몇 개의 layer로 전송할지도 고려하게 된다.

[0006] 최근 2세대와 3세대 이동 통신 시스템에서 사용되던 다중 접속 방식인 CDMA (Code Division Multiple Access)을 차세대 시스템에서 OFDMA(Orthogonal Frequency Division Multiple Access)으로 전환하려는 연구가 활발히 진행되고 있다. 3GPP와 3GPP2는 OFDMA를 사용하는 진화 시스템에 관한 표준화를 진행하기 시작하였다. CDMA 방식에 비해 OFDMA 방식에서 용량 증대를 기대할 수 있는 것으로 알려져 있다. OFDMA 방식에서 용량 증대를 낳는 여러 가지 원인 중의 하나가 주파수 축 상에서의 스케줄링(Frequency Domain Scheduling)을 수행할 수 있다는 것이다. 채널이 시간에 따라 변하는 특성에 따라 채널 감응 스케줄링 방법을 통해 용량 이득을 얻었듯이 채널이 주파수에 따라 다른 특성을 활용하면 더 많은 용량 이득을 얻을 수 있다.

[0007] 도 1은 LTE/LTE-A 시스템에서 시간 및 주파수 자원을 도시하는 도면이다.

[0008] 도 1에서 도시되는 바와 같이, eNB가 단말에게 전송하는 무선자원은 주파수 축 상에서는 RB (resource block) 단위로 나누어지며 시간 축 상에서는 서브프레임(subframe) 단위로 나누어진다. 상기 RB는 LTE/LTE-A 시스템에서 일반적으로 12개의 부반송파로 이루어지며 180kHz의 대역을 차지한다.

[0009] 반면 서브프레임은 LTE/LTE-A 시스템에서 일반적으로 14개의 OFDM 심볼구간으로 이루어지며 1 msec의 시간구간을 차지한다. LTE/LTE-A 시스템은 스케줄링을 수행함에 있어서 시간축에서는 서브프레임 단위로 자원을 할당할 수 있으며 주파수축에서는 RB 단위로 자원을 할당할 수 있다.

[0010] 도 2는 LTE/LTE-A 시스템에서 하향링크로 스케줄링 할 수 있는 최소 단위인 1 서브프레임 및 1 RB의 무선자원을 도시하는 도면이다.

[0011] 도 2에서 도시되는 바와 같이, 무선자원은 시간축 상에서 한 개의 서브프레임으로 이루어지며 주파수축상에서 한 개의 RB로 이루어진다. 이와 같은 무선자원은 주파수 영역에서 12개의 서브캐리어(subcarrier)(또는, 부반송파)로 이루어지며 시간영역에서 14개의 OFDM 심볼로 이루어져서 총 168개의 고유 주파수 및 시간 위치 갖도록 한다. LTE/LTE-A에서는 상기 도 2의 각각의 고유 주파수 및 시간 위치를 RE (resource element)라 한다.

[0012] 상기 도 2에 도시된 무선자원에는 다음과 같은 복수개의 서로 다른 종류의 신호가 전송될 수 있다.

[0013] 1. CRS (셀 특정 기준 신호, Cell Specific RS): 한 개의 셀(cell)에 속한 모든 단말을 위하여 주기적으로 전송되는 기준신호이며 복수개의 단말들이 공통적으로 이용할 수 있다.

[0014] 2. DMRS (복조 기준 신호, Demodulation Reference Signal): 특정 단말을 위하여 전송되는 기준신호이며 해당 단말에게 데이터를 전송할 경우에만 전송된다. DMRS는 총 8개의 DMRS 포트(port)들로 이루어질 수 있다. LTE/LTE-A에서는 port 7에서 port 14까지 DMRS port에 해당하며 port들은 CDM또는 FDM을 이용하여 서로 간섭을 발생시키지 않도록 직교성(orthogonality)을 유지한다.

[0015] 3. PDSCH (물리 하향링크 공유 채널, Physical Downlink Shared Channel): 하향링크로 전송되는 데이터 채널로 기지국이 단말에게 트래픽을 전송하기 위하여 이용하며 상기 도 2의 데이터 영역(data region)에서 기준신호가 전송되지 않는 RE를 이용하여 전송됨

[0016] 4. CSI-RS (채널 상태 정보 기준 신호, Channel Status Information Reference Signal): 한 개의 cell에 속한 단말들을 위하여 전송되는 기준신호를 채널상태를 측정하는데 이용됨. 한 개의 셀에는 복수개의 CSI-RS가 전송될 수 있음.

[0017] 5. 기타 제어채널 (PHICH, PCFICH, PDCCH): 단말이 PDSCH를 수신하는데 필요한 제어정보를 제공하거나 상향링크의 데이터 송신에 대한 HARQ를 운용하기 위한 ACK/NACK 전송

[0018] 상기 신호 외에 LTE-A 시스템에서는 다른 기지국의 전송하는 CSI-RS가 해당 셀의 단말들에게 간섭없이 수신될 수 있도록 뮤팅(muting)을 설정할 수 있다. 상기 muting은 CSI-RS가 전송될 수 있는 위치에서 적용될 수 있으며 일반적으로 단말은 해당 무선 자원을 건너뛰어 트래픽 신호를 수신한다. LTE-A 시스템에서 뮤팅은 또 다른 용어로 0 전력 CSI-RS((zero-power CSI-RS)라고 불리기도 한다. 뮤팅의 특성상 CSI-RS의 위치에 적용되며 전송전력이 송신되지 않기 때문이다.

[0019] 상기 도 2에서 도시되는 바와 같이, CSI-RS는 CSI-RS를 전송하는 안테나들 수에 따라 A, B, C, D, E, E, F, G, H, I, J로 표시된 위치의 일부를 이용하여 전송될 수 있다. 또한 뮤팅도 A, B, C, D, E, E, F, G, H, I, J로 표시된 위치의 일부에 적용될 수 있다. 특히 CSI-RS는 전송하는 안테나포트 수에 따라서 2개, 4개, 8개의 RE로 전송될 수 있다.

[0020] 안테나포트수가 2개일 경우 상기 도 2에서 특정 패턴의 절반에 CSI-RS가 전송되며 안테나포트수가 4개일 경우 특정 패턴의 전체에 CSI-RS가 전송되고 안테나포트수가 8개일 경우 두 개의 패턴을 이용하여 CSI-RS가 전송된다.

[0021] 반면 뮤팅의 경우 언제나 한 개의 패턴 단위로 이루어진다. 즉, 뮤팅은 복수개의 패턴에 적용될 수는 있지만 CSI-RS와 위치가 겹치지 않는 경우 한 개의 패턴의 일부에만 적용될 수는 없다. 단, CSI-RS의 위치와 뮤팅의 위치가 겹칠 경우에 한해서 한 개의 패턴의 일부에만 적용될 수 있다.

[0022] 두 개의 안테나포트에 대한 CSI-RS가 전송될 경우 CSI-RS는 시간축에서 연결된 두 개의 RE에서 두 안테나포트의 신호를 전송하며 각 안테나포트의 신호는 직교코드로 구분된다. 또한 네 개의 안테나포트에 대한 CSI-RS가 전송될 경우 두 개의 안테나포트를 위한 CSI-RS에 추가로 두 개의 RE를 더 이용하여 동일한 방법으로 추가로 두 개의 안테나포트에 대한 신호를 전송한다. 8개의 안테나포트에 대한 CSI-RS가 전송될 경우도 마찬가지이다.

[0023] 셀룰러 시스템에서 하향링크 채널 상태를 측정하기 위하여 기지국은 단말에게 기준신호 (reference signal, RS)를 전송해야 한다. 3GPP의 LTE-A (Long Term Evolution Advanced) 시스템의 경우 기지국이 전송하는 CRS 또는 CSI-RS (Channel Status Information Reference Signal)를 이용하여 단말은 기지국과 자신 사이의 채널 상태를 측정한다.

[0024] 상기 채널 상태는 기본적으로 몇 가지 요소가 고려되어야 하며 여기에는 하향링크에서의 간섭량이 포함된다. 상기 하향링크에서의 간섭량은 인접 기지국에 속한 안테나 의하여 발생되는 간섭신호 및 열잡음 등이 포함되며 단말이 하향링크의 채널 상황을 판단하는데 중요하다. 한 예로 송신안테나가 한 개인 기지국에서 수신안테나가 한 개의 단말로 전송할 경우 단말은 기지국에서 수신된 기준신호에서 하향링크로 수신할 수 있는 심볼당 에너지와 해당 심볼을 수신하는 구간에서 동시에 수신될 간섭량을 판단하여 Es/Io를 결정해야 한다. 결정된 Es/Io는 기지국으로 통보되어 기지국이 하향링크로 단말에게 어떤 데이터 전송속도로 전송을 수행할지를 판단할 수 있게 한다.

[0025] 일반적인 이동통신 시스템의 경우 각 셀의 중간 지점에 기지국 장비가 배치되며 해당 기지국 장비는 한정된 장소에 위치한 한 개 또는 복수개의 안테나를 이용하여 단말과 이동통신을 수행한다. 상기와 같이 한 개의 셀에 속한 안테나들이 동일한 위치에 배치된 이동통신 시스템을 CAS(Centralized Antenna System)이라고 한다. 반면 한 개의 셀에 속한 안테나(RRH: Remote Radio Head)들이 셀 내의 분산된 위치에 배치된 이동통신 시스템을 DAS (Distributed Antenna System: 분산안테나 시스템)이라고 한다.

[0026] 도 3은 일반적인 분산안테나 시스템에서 안테나의 분산된 위치에의 배치를 도시하는 도면이다.

[0027] 도 3에서 도시되는 바와 같이, 두 개의 셀 300과 셀 310은 분산안테나 시스템에 해당한다. 셀 300의 경우 다섯 개의 전송지점(transmission point)으로 이루어지며 한 개의 고출력 전송지점(320)과 네 개의 저출력 전송지점(340, 350, 360, 370)들로 이루어진다. 이 경우, 각각의 전송지점은 한 개 또는 복수개의 전송 안테나를 가질 수 있다.

[0028] 상기 고출력 전송지점은 셀영역 에 포함되는 전역에 최소한의 서비스를 제공할 수 있도록 하는 반면 분산된 저출력 전송지점들은 셀 내 제한된 영역에서 제한된 단말들에게 높은 데이터 속도를 기반으로 하는 서비스를 제공할 수 있다. 또한 저출력 전송지점들 및 고출력 전송지점은 330과 같이 모두 중앙제어기에 연결되어 중앙제어기

의 스케줄링 및 무선자원 할당에 따라 동작한다.

[0029] 상기 분산안테나 시스템에서 한 개의 지리적으로 분리된 전송지점 위치에는 한 개 또는 복수개의 안테나들이 배치될 수 있다. 분산안테나 시스템에서 동일한 전송지점에 배치된 안테나 또는 안테나들을 본 발명에서는 안테나 그룹 (RRH group)이라고도 한다. 상기 도 3과 같은 분산안테나 시스템에서 단말은 한 개의 지리적으로 분리된 안테나 그룹에서 신호를 수신하는 반면 나머지 안테나 그룹에서 전송되는 것은 간섭으로 작용한다.

[0030] 도 3과 같은 분산 안테나 시스템에서 CRS를 전송하기 위한 경우 한 개의 셀에 속한 모든 안테나들이 전송에 참여한다. 즉, 한 개의 셀에 속한 모든 안테나는 CRS를 위하여 CRS를 전송하거나 다른 안테나들이 CRS를 전송하는데 간섭을 발생시키지 않도록 CRS가 전송되는 RE 위치에서 다른 신호를 전송하지 않는다. 한 개의 셀에 속한 모든 안테나가 CRS를 위한 신호를 전송하는 경우 CRS를 기반으로 전송되는 데이터 신호는 셀에 속한 모든 안테나에서 전송된다.

[0031] 반면 한 개의 셀에 속한 일부 안테나들만 CRS를 위한 신호를 전송하는 경우 CRS를 위한 신호를 전송하지 않는 안테나들은 다른 안테나들에서 전송되는 CRS에 간섭을 발생시키지 않기 위하여 해당 CRS가 전송되는 RE 위치에서 다른 신호를 전송하지 않는다. 또한 CRS를 기반으로 전송되는 데이터 신호는 CRS를 전송하는 안테나들에서만 전송된다.

[0032] 반면 CSI-RS의 경우 한 개의 셀에 속한 안테나별로 다른 CSI-RS가 전송될 수 있다. 즉, 상기 도 3에서 동일한 CRS가 전송지점 320, 340, 350, 360, 370에서 전송되지만 CSI-RS는 전송지점 320, 340, 350, 360, 370마다 별도의 CSI-RS가 전송될 수 있다. 전송지점마다 다른 CSI-RS를 전송하는 방법으로는 상기 도 2에서 도시화된 복수개의 CSI-RS 전송위치 중 다른 것을 전송지점마다 할당하거나 동일한 전송위치를 이용하여 전송하되 전송지점마다 다른 scrambling을 적용하는 것이 있다.

[0033] LTE-A 시스템의 경우 단말은 하향링크의 채널상태에 대한 정보를 기지국에게 피드백하여 기지국의 하향링크 스케줄링에 활용할 수 있도록 한다. 즉, 단말은 하향링크로 기지국이 전송하는 기준신호를 측정하고 여기에서 추출한 정보를 LTE/LTE-A 표준에서 정의하는 형태로 기지국으로 피드백하는 것이다. LTE/LTE-A에서 단말이 피드백하는 정보로는 크게 다음의 세가지 정보가 있다.

[0034] - RI (랭크 지시자, Rank Indicator): 단말이 현재의 채널상태에서 수신할 수 있는 공간 레이어(spatial layer)의 개수

[0035] - PMI (프리코더 매트릭스 지시자, Precoder Matrix Indicator): 단말이 현재의 채널상태에서 선호하는 프리코딩 매트릭스(precoding matrix)에 대한 지시자

[0036] - CQI (채널 품질 지시자, Channel Quality Indicator): 단말이 현재의 채널상태에서 수신할 수 있는 최대 데이터 전송률 (data rate). CQI는 최대 데이터 전송률과 유사하게 활용될 수 있는 SINR, 최대의 오류정정 부호화율 (code rate) 및 변조 방식, 주파수당 데이터 효율 등으로 대체될 수 도 있음.

[0037] 상기 RI, PMI, CQI는 서로 연관되어 의미를 갖는다. 한 예로 LTE/LTE-A에서 지원하는 프리코딩 매트릭스 (precoding matrix)는 랭크(rank)별로 다르게 정의되어 있다. 때문에 RI가 1의 값을 가질 때 PMI 값 X와 RI가 2의 값을 가질 때 PMI 값 X는 다르게 해석이 된다. 또한 단말이 CQI를 결정할 때에도 자신이 기지국에 통보한 PMI와 X가 기지국에서 적용되었다는 가정을 한다. 즉, 단말이 RI_X, PMI_Y, CQI_Z를 기지국에 통보한 것은 랭크를 RI_X로 하고 프리코딩 을 PMI_Y로 할 때 CQI_Z에 해당하는 데이터 전송률을 해당 단말이 수신할 수 있다고 통보하는 것과 같다. 이와 같이 단말은 CQI를 계산할 때에 기지국에 어떤 전송방식을 수행할 지를 가정하여 해당 전송방식으로 실제 전송을 수행하였을 때 최적화된 성능을 얻을 수 있도록 한다.

[0038] LTE/LTE-A에서는 RI 및 PMI이 없이 CQI만을 피드백시키는 RI/PMI 불능 모드(이하, RI/PMI disabled mode)를 지원한다. 상기 RI/PMI disabled mode가 적용된 단말은 RI 및 PMI를 피드백하지 않고 CQI만을 기지국에게 피드백한다.

[0039] 도 4는 단말의 RI/PMI 보고(reporting)가 인에이블(enabled)된 상태와 RI/PMI reporting이 불능으로 설정(disabled)된 상태의 피드백을 도시하는 도면이다.

[0040] 도 4에서 도시되는 바와 같이, RI/PMI reporting이 enable된 상태에서 단말은 다음과 같이 RI, PMI, CQI를 전송한다.

[0041] - 400, 430의 위치에서 RI를 전송

[0042] - 410, 440의 위치에서 PMI를 전송

[0043] - 420, 450의 위치에서 CQI를 전송

[0044] 반면 RI/PMI가 disable된 상태에서 단말은 RI, PMI를 전송하지 않으며, 다만 CQI만을 460, 470의 위치에서 전송한다. RI/PMI를 disable시키는 것은 단말이 기지국으로 전송해야 하는 피드백 오버헤드를 감소시켜서 상향링크의 시스템 용량을 개선시키는 효과가 있으며 단말이 전송해야 하는 채널상태 정보량이 감소함에 따라 단말의 베터리 소모량을 감소시키는 효과도 있다.

[0045] LTE/LTE-A 시스템에서 RI/PMI reporting이 disable된 경우 단말은 언제나 CRS를 측정하여 CQI를 생성하게 되어 있다.

[0046] 상기에서 언급한 바와 같이 CQI를 생성하기 위해서 단말은 특정 전송방법을 가정해야 한다. LTE/LTE-A 시스템의 경우 RI/PMI가 disable될 경우 단말은 기지국이 두 개의 송신안테나를 가지면 SFBC (Space Frequency Block Code)에 따른 precoding이 적용된다는 가정하에서 CQI를 생성한다. 반면 기지국이 네 개의 송신안테나를 가지면 FSTD (Frequency Shift Time Diversity)에 다른 precoding이 적용된다는 가정하에서 CQI를 생성한다.

[0047] 상기와 같이 LTE/LTE-A에서 RI/PMI reporting이 disable된 경우 단말이 CRS를 측정하여 CQI를 생성하는 방법에는 두 가지의 주요 문제점이 있다.

[0048] <첫 번째 문제점>

[0049] CRS를 측정하기 때문에 상기 도 3과 같은 분산안테나 시스템에 적합하지 않다. CRS는 한 개의 cell내에 포함된 복수의 전송지점에서 동시 전송되기 때문에 CRS를 측정하여 얻어지는 CQI는 cell내의 모든 전송지점에서 동시에 단말에게 PDSCH를 전송하는 경우에만 정확하다. 일반적으로 분산안테나 시스템에서는 단말에게 상대적으로 가까운 전송지점에서만 PDSCH 전송을 수행한다. 이와 같이 가까운 전송지점에서만 PDSCH 전송을 수행할 경우 다른 전송지점들은 또 다른 단말에게 PDSCH 전송을 수행할 수 있기 때문에 시스템의 성능이 향상될 수 있다. 이와 같이 분산안테나 시스템에서 전송지점 별 하향 채널에 대한 정확한 CQI를 생성하기 위해서는 CRS가 아닌 CSI-RS를 측정해야 된다.

[0050] <두 번째 문제점>

[0051] CRS는 최대 4개의 송신안테나까지만 지원된다. 때문에 전송지점별 CRS 안테나 수가 2개 또는 4개일 때는 상기에서 언급한 바와 같이 SFBC 또는 FSTD에 따른 프리코딩 이 적용되지만 분산안테나 시스템에서 각 전송지점은 최대 8개의 안테나를 이용할 수 있다. 한 개의 전송지점이 8개의 안테나를 가질 경우 적용할 프리코딩이 정의되지 않았기 때문에 문제가 된다. 또한 상기의 SFBC 및 FSTD의 경우 CRS에 대해서만 정의되어 있기 때문에 CSI-RS에 적용하기에 어렵다.

[0052] 종래 기술에서 단말의 RI/PMI 보고가 불능(RI/PMI reporting이 disable)으로 설정된 경우에 CRS가 아닌 CSI-RS를 측정하여 CQI를 생성하는 방법으로 상기의 문제점을 해결할 수 있다.

[0053] 하지만 상기의 CRS를 측정하여 발생하는 문제는 종래 LTE/LTE-A 이동통신 시스템에서 언제나 발생되는 문제가 아닌 분산안테나 시스템이 구축되어 있을 경우에만 발생한다. 즉, 분산안테나 시스템이 구축되지 않았다면 단말은 RI/PMI reporting이 disable된 경우에 CRS를 측정하여 CQI를 생성하는 것이 시스템 성능관점에서 유리할 수 있다. 하지만 단말은 분산안테나 시스템이 구축되었는지 구축되지 않았는지 스스로 판단할 수 없기 때문에 독자적으로 CRS 또는 CSI-RS를 선택하여 측정할 수는 없다.

발명의 내용

해결하려는 과제

[0054] 본 발명의 목적은 LTE-A 시스템을 기반으로 하는 분산안테나 시스템에서 RI/PMI 보고가 불능으로 설정된 경우 정확한 CQI를 생성할 수 있도록 단말이 측정할 기준 신호를 기지국이 선택하여 단말에게 통보하는 방법 및 장치를 제공함에 있다. 또한 RI/PMI 보고가 불능으로 설정된 경우 단말이 CQI를 생성하기 위하여 가정하는 기지국의

전송방법을 정의한다.

과제의 해결 수단

[0055] 상기와 같은 문제점을 해결하기 위한 본 발명의 분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 기준신호 측정 정보를 기지국이 단말에 통보하는 방법은 상기 단말의 RI/PMI 보고 불능 설정 여부를 결정하는 단계, 상기 단말의 RI/PMI 보고 불능 설정 시 CRS 또는 CSI-RS 중 단말이 측정할 기준 신호를 결정하는 단계, 상기 결정된 기준 신호를 상기 단말에게 통보하는 단계, 상기 결정된 기준 신호를 측정하여 단말이 생성한 제1 채널 정보를 상기 단말로부터 수신하는 단계, 및 상기 제1 채널 정보에 기반하여 상기 단말에게 데이터를 전송하는 단계를 포함하는 것을 특징으로 한다.

[0056] 또한, 본 발명의 분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 단말의 하향링크 측정 방법은 상기 단말의 RI/PMI 보고 불능 설정 여부에 대한 정보를 기지국으로부터 수신하는 단계, 상기 RI/PMI 보고 불능 설정 시, CRS 또는 CSI-RS 중 상기 단말이 측정하도록 결정된 기준 신호에 대한 정보를 상기 기지국으로부터 수신하는 단계, 상기 결정된 기준 신호를 측정하여 제1 채널 정보를 생성하고 상기 기지국으로 전송하는 단계, 및 상기 제1 채널 정보에 기반하여 전송되는 데이터를 상기 기지국으로부터 수신하는 단계를 포함하는 것을 특징으로 한다.

[0057] 또한, 본 발명의 분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 기준 신호 측정 정보를 단말에 통보하는 기지국은 상기 기준 신호 측정 정보 또는 데이터를 상기 단말에 전송하고, 상기 단말로부터 전송되는 채널 측정 정보를 수신하는 송수신부, 및 상기 단말의 RI/PMI 보고 불능 여부를 결정하고, 상기 단말의 RI/PMI 보고 불능 결정 시 CRS 또는 CSI-RS 중 단말이 측정할 기준 신호를 결정하며, 상기 결정된 기준 신호를 상기 단말에게 통보하고, 상기 결정된 기준 신호를 측정하여 단말이 생성한 제1 채널 정보를 상기 단말로부터 수신하며, 상기 제1 채널 정보에 기반하여 상기 단말에게 데이터를 전송하도록 제어하는 제어기를 포함하는 것을 특징으로 한다.

[0058] 그리고 본 발명의 분산 안테나를 사용하는 복수 개의 기지국을 포함하는 이동통신 시스템에서 하향링크를 측정하여 보고하는 단말은 기지국으로부터 전송되는 기준 신호 측정 정보 또는 데이터를 수신하고, 상기 단말이 측정한 채널 측정 정보를 상기 기지국으로 전송하는 송수신부, 및 상기 단말의 RI/PMI 보고 불능 설정 여부에 대한 정보를 기지국으로부터 수신하고, 상기 RI/PMI 보고 불능 설정 시 CRS 또는 CSI-RS 중 상기 단말이 측정하도록 결정된 기준 신호에 대한 정보를 상기 기지국으로부터 수신하며, 상기 결정된 기준 신호를 측정하여 제1 채널 정보를 생성하고 상기 기지국으로 전송하며, 상기 제1 채널 정보에 기반하여 전송되는 데이터를 상기 기지국으로부터 수신하도록 제어하는 제어부를 포함하는 것을 특징으로 한다.

발명의 효과

[0059] 본 발명의 실시예에 따르면 LTE-A 시스템을 기반으로 하는 분산안테나 시스템에서 RI/PMI 보고가 불능으로 설정된 경우 단말이 측정할 기준 신호를 기지국이 선택하여 단말에게 통보해준다. 이에 따라, 단말은 종래 시스템에서보다 보다 정확한 채널 측정 정보를 생성하여 기지국으로 피드백해줄 수 있다.

도면의 간단한 설명

[0060] 도 1은 LTE/LTE-A 시스템에서 시간 및 주파수 자원을 도시하는 도면.

도 2는 LTE/LTE-A 시스템에서 하향링크로 스케줄링 할 수 있는 최소 단위인 1 서브프레임 및 1 RB의 무선자원을 도시하는 도면.

도 3은 일반적인 분산안테나 시스템에서 안테나의 분산된 위치에의 배치를 도시하는 도면.

도 4는 단말의 RI/PMI 보고(reporting)가 인에이블(enabled)된 상태와 RI/PMI reporting이 불능으로 설정(disabled)된 상태의 피드백을 도시하는 도면.

도 5는 CRS를 측정하여 얻어지는 무선채널에 대한 CQI와 전송지점별 CSI-RS를 측정하여 얻어지는 무선채널에 대한 CQI를 비교하는 도면.

도 6은 상기 도 5의 분산안테나 시스템에서 CRS를 이용하여 CQI를 측정할 경우 발생하는 부정확한 CQI의 문제를 도시하는 도면.

도 7은 본 발명에서 제안하는 분산안테나 시스템에서 RI/PMI reporting이 disable된 상태에서 단말에게 어떤 RS를 이용하여 하향링크를 측정할지를 통보하는 기지국의 동작 순서를 도시하는 순서도.

도 8은 본 발명에서 제안하는 분산안테나 시스템에서 RI/PMI reporting이 disable된 상태에서 단말이 어떤 RS를 이용하여 하향링크를 측정할지를 판단하는 동작을 순서도로 도시한 도면.

도 9는 단말과 기지국이 주파수 영역에서 복수개의 프리코딩이 번갈아 가며 적용되는 실시예를 도시하는 도면.

도 10은 프리코더 후보집합에 포함된 프리코딩 들이 한 개의 서브프레임 내의 한 개의 RB 내에서 번갈아가며 적용되는 것을 도시하는 도면.

도 11은 본 발명의 실시예에 따른 기지국의 내부 구조를 도시하는 블록도.

도 12는 본 발명의 실시예에 따른 단말의 내부 구조를 도시하는 블록도.

도 13은 본 발명에서 제안하는 공간 시간/주파수 블록 코드의 적용을 위한 단말 수신기에서의 안테나 가상화를 설명하기 위한 도면

발명을 실시하기 위한 구체적인 내용

[0061] 이하 본 발명의 실시예를 첨부한 도면과 함께 상세히 설명한다. 또한 본 발명을 설명함에 있어서 관련된 공지 기능 혹은 구성에 대한 구체적인 설명이 본 발명의 요지를 불필요하게 흐릴 수 있다고 판단된 경우 그 상세한 설명은 생략한다. 그리고 후술되는 용어들은 본 발명에서의 기능을 고려하여 정의된 용어들로서 이는 사용자, 운용자의 의도 또는 관례 등에 따라 달라질 수 있다. 그러므로 그 정의는 본 명세서 전반에 걸친 내용을 토대로 내려져야 할 것이다.

[0062] 또한, 본 발명의 실시예들을 구체적으로 설명함에 있어서, OFDM 기반의 무선통신 시스템, 특히 3GPP EUTRA 표준을 주된 대상으로 할 것이지만, 본 발명의 주요한 요지는 유사한 기술적 배경 및 채널형태를 가지는 여타의 통신 시스템에도 본 발명의 범위를 크게 벗어나지 아니하는 범위에서 약간의 변형으로 적용 가능하며, 이는 본 발명의 기술분야에서 숙련된 기술적 지식을 가진 자의 판단으로 가능할 것이다.

[0063] 도 5는 CRS를 측정하여 얻어지는 무선채널에 대한 CQI와 전송지점별 CSI-RS를 측정하여 얻어지는 무선채널에 대한 CQI를 비교하는 도면이다.

[0064] 도 5에서 도시되는 바와 같이, cell 500의 경우 단말 (UE1)은 CRS를 측정하여 CQI를 생성한다. CRS는 cell내에 속한 모든 전송지점에서 동시에 전송되는 신호이기 때문에 단말이 CRS를 측정하여 CQI를 발생할 경우 해당 CQI에 맞는 PDSCH를 전송하기 위해서는 PDSCH 역시 모든 전송지점에서 송신되어야 한다. 즉, 상기 도 5에서 CRS를 측정하여 얻은 CQI에 따라 PDSCH를 전송하면서 PDSCH를 전송하는 전송지점을 cell내에 있는 특정 전송지점으로 제한시키는 것은 PDSCH 수신 성능을 충분히 보장시키지 못하는 단점을 발생시킨다.

[0065] 도 6은 상기 도 5의 분산안테나 시스템에서 CRS를 이용하여 CQI를 측정할 경우 발생하는 부정확한 CQI의 문제를 도시하는 도면이다.

[0066] 도 6에서 cell 600의 UE1은 상기 도 5에서와 같이 CRS를 측정하여 CQI를 발생하여 기지국에 통보한다. 반면 PDSCH는 한 개의 전송지점으로부터 수신한다. 도 6에서 도시되는 바와 같이, 분산안테나 시스템에서 CRS를 측정하여 CQI를 생성하고, 이에 대응하여 PDSCH를 한 개의 전송지점으로부터 수신할 경우 기지국에 통보한 CQI가 PDSCH를 전송하는 전송지점과 단말 사이의 무선채널의 상태를 정확히 반영시키지 못하기 때문에 성능을 저하시키게 된다는 문제점이 있다.

[0067] 반면 cell 610의 UE3과 UE4는 분산안테나 시스템에서 CRS가 아닌 전송지점별 CSI-RS를 측정하여 CQI를 생성하였기 때문에 기지국에 통보한 CQI가 PDSCH를 전송하는 각각의 전송지점과 단말 사이의 무선채널의 상태를 정확히 반영시키고 있다.

[0068] 본 발명은 분산안테나 시스템에서 단말의 RI/PMI reporting이 disable된 상기 도 5의 cell 510과 같이 전송지점별 CSI-RS를 측정하도록 하는 방법을 제공한다. 상기에서 언급한 바와 같이 단말이 속한 cell에 분산안테나 시스템이 구축되었느냐 여부에 따라 RI/PMI reporting이 disable되었을 때 CRS 또는 CSI-RS를 선택하여 측정하는

것이 성능관점에서 유리하다.

[0069] 본 발명에서는 단말의 RI/PMI reporting이 disable된 상태에서 단말이 CRS 또는 CSI-RS 중 어느 것을 측정하여 CQI를 생성하여 보고할지 여부에 대한 정보를 기지국이 단말에게 통보하는 방법을 제안한다. 상기 통보 방법은 후술하는 바와 같이 명시적(explicit)으로 통보할 수도 있고, 또는 암묵적(implicit)으로 통보할 수도 있다. 이에 대한 구체적인 설명은 하기 및 해당 부분에서 설명하도록 한다.

[0070] 단말이 측정할 기준 신호의 종류를 명시적으로 통보하는 방법에 대한 일 실시예로, 본 발명에서는 'RS_Switch 비트' 라는 제어정보(이하에서는 기준 신호 측정 정보라는 용어와 혼용하여 사용하기로 한다)를 제안한다.

[0071] 상기 RS_Switch 비트의 값에 따라 단말은 RI/PMI reporting이 disable된 상태에서 CRS 또는 CSI-RS를 측정하여 CQI를 생성한다. 한 예로 RI/PMI reporting이 disable되었을 때 단말은 기지국이 통보한 RS_Switch 비트의 값이 '0' 일 경우 CRS를 측정하여 CQI를 생성하는 반면 RS_Switch 비트의 값이 '1' 일 경우 CSI-RS를 측정하여 CQI를 생성한다. 이와 같은 방법은 LTE/LTE-A 시스템의 릴리즈 10과 그 이후 릴리즈들에서 지원되는 TM9 (Transmission Mode 9)(전송 모드 9)에서 적용될 수 있으며 이후에 추가되는 전송 모드 들에서도 적용될 수 있다.

[0072] 도 7은 본 발명에서 제안하는 분산안테나 시스템에서 RI/PMI reporting이 disable된 상태에서 단말에게 어떤 RS를 이용하여 하향링크를 측정할지를 통보하는 기지국의 동작 순서를 도시하는 순서도이다.

[0073] 도 7에서 도시되는 바와 같이, 기지국은 과정 700과 같이 단말에게 어떤 종류의 피드백을 설정할지를 결정한다. 상기 과정 700에서 고려되는 것 중 하나는 단말의 RI/PMI 보고 불능 설정 여부를 결정(RI/PMI reporting을 disable할지)하는 것을 포함할 수 있다..

[0074] 해당 단말의 RI/PMI reporting을 disable시키지 않는 것으로 과정 710에서 판단할 경우, 기지국은 과정 720과 같이 단말이 CSI-RS를 측정하여 생성한 CSI(RI, PMI, CQI)를 기반으로 PDSCH 전송을 수행한다. 이를 위해, 본 발명의 일 실시예에 따르면, 기지국은 단말의 RI/PMI 보고 설정 시, 상기 단말이 CSI-RS를 측정하도록 통보하고, 이에 대응하여 단말이 상기 CSI-RS를 측정하여 생성한 제2 채널 정보를 수신할 수 있다. 그러면 기지국은 제2 채널 정보에 기반하여 상기 단말에게 데이터 즉, PDSCH를 전송할 수 있다.

[0075] 반면 해당 단말의 RI/PMI reporting을 disable시키는 것으로 과정 710에서 판단할 경우, 기지국은 과정 730에서 해당 단말이 CRS를 측정하여 CQI를 생성시킬지 아니면 CSI-RS를 측정하여 CQI를 생성시킬지를 판단한다.

[0076] 상기 과정 730에서 단말이 CRS를 측정하여 CQI를 생성하는 것으로 기지국이 판단할 경우, 기지국은 과정 740과 같이 RS_Switch 비트(또는, 기준 신호 측정 정보, 이하 동일하다)를 '0' 으로 설정하여 단말에게 통보한다. 그리고 기지국은 과정 760로 진행하여 해당 단말이 CRS를 측정하여 생성한 CQI를 기반으로 PDSCH 전송을 수행한다.

[0077] 반면, 과정 730에서 단말이 CSI-RS를 측정하여 CQI를 생성하는 것으로 판단할 경우, 기지국은 과정 750과 같이 RS_Switch 비트를 '1' 로 설정하여 단말에게 통보한다. 그리고 기지국은 과정 770로 진행하여 해당 단말이 CSI-RS를 측정하여 생성한 CQI를 기반으로 PDSCH 전송을 수행한다.

[0078] 참고로, 기지국이 결정한 기준 신호 종류에 따라 단말이 해당 기준 신호를 측정하여 생성한 CQI를 제1 채널 정보라고 일컬을 수 있다.

[0079] 도 8은 본 발명에서 제안하는 분산안테나 시스템에서 RI/PMI reporting이 disable된 상태에서 단말이 어떤 RS를 이용하여 하향링크를 측정할지를 판단하는 동작을 순서도로 도시한 도면이다.

[0080] 도 8에서 도시되는 바와 같이, 단말은 과정 800과 같이 기지국에서 피드백 설정에 대한 제어정보를 수신한다. 본 발명의 일 실싱예에 따르면, 상기 제어 정보는 상기 단말의 RI/PMI 보고 불능 설정 여부를 포함할 수 있다.

[0081] 과정 810에서, 상기 제어정보를 통해 단말의 RI/PMI reporting이 disable되지 않았을 경우, 단말은 과정 820로 진행하여 CSI-RS를 측정하고 RI/PMI/CQI(제2 채널 정보)를 생성한다. 그리고 단말은 상기 측정 결과인 RI/PMI/CQI를 기지국으로 전송할 수 있다.

[0082] 반면 단말의 RI/PMI가 disable된 경우, 단말은 CRS 또는 CSI-RS 중 상기 단말이 측정하도록 결정된 기준 신호에 대한 정보를 상기 기지국으로부터 수신할 수 있다. 그리고 기지국은 상기 기준 신호에 대한 정보에 포함된 RS_Switch 비트에 따라 어떤 RS를 측정하여 CQI를 생성할지를 결정한다.

[0083] 보다 구체적으로, 단말은 수신한 RS_Switch 비트가 '0' 으로 설정되어 있을 경우 과정 840과 같이 CRS를 측정하여 CQI를 생성한다. 반면 단말은 수신한 RS_Switch 비트가 '1' 로 설정되어 있을 경우 과정 850과 같이 CSI-RS를 측정하여 CQI를 생성한다.

[0084] 참고로, 기지국이 결정한 기준 신호 종류에 따라 단말이 해당 기준 신호를 측정하여 생성한 CQI를 제1 채널 정보라고 일컬을 수 있다.

[0085] 일반적으로 RI/PMI reporting을 enable 또는 disable시킬지 여부는 네트워크의 구현여부에 따라 결정되며 이때 고려될 수 있는 요소 중 하나는 상기에서 언급한 바와 같이 분산안테나 시스템의 구축여부이다. 기지국은 네트워크의 구현에 최선인 RS를 선택하여 그 선택결과를 상기의 RS_Switch 비트를 이용하여 단말에게 통보한다. 상기 RS_Switch 비트는 상위 시그널링 또는 물리계층 시그널링을 이용하여 기지국에서 단말에게 전송된다.

[0086] RS_Switch 비트가 상위 시그널링을 이용하여 단말에게 통보될 경우 시스템 정보의 일부에 포함되어 불특정 다수의 단말에게 방송되는 형태 또는 특정 단말에게만 통보되는 유니캐스트(unicast) 형태로 전송될 수 있다. RS_Switch 비트가 물리계층 시그널링을 이용하여 단말에게 통보될 경우 LTE/LTE-A에서 지원하는 PDCCH 또는 E-PDCCH에 실리어 단말에게 전송될 수 있다.

[0087] 상기에서는 기지국이 RS_Switch 비트를 단말에게 직접적으로 전송하여 어느 RS를 측정하는지를 직접적(명시적, explicit)으로 통보하는 방법에 대하여 설명하였다.

[0088] 본 발명에서 제안하는 또 하나의 방법은 RS_Switch 비트의 전달과 같은 직접적인 지시 정보 없이 다른 제어 정보 또는 시스템 설정 정보를 활용하여 기지국이 단말에게 어느 RS를 사용할지를 간접적(implicit)으로 통보하는 것이다. RS_Switch 비트와 같은 직접적인 지시 정보 없이 어느 RS를 사용할지를 통보할 수 있는 방법으로는 다음의 두 가지가 있다.

[0089] <측정할 RS 종류에 대한 간접통보 방법1>

[0090] LTE/LTE-A 시스템에서 특정 셀(cell)이 분산안테나 시스템으로 구축될 경우 간섭측정을 위하여 별도의 간섭측정 자원이 단말에게 통보된다. 분산안테나 시스템으로 구현되지 않은 종래의 LTE/LTE-A 이동통신 시스템의 경우 단말이 CRS를 이용하여 간섭측정을 수행하지만 분산안테나 시스템에서는 CRS를 이용하여 간섭측정을 수행할 경우 잘못된 간섭량을 측정하게 되기 때문에 기지국이 단말에게 별도의 간섭측정 자원을 통보한다.

[0091] 이와 같은 특징을 활용하여 RS_Switch 비트와 같은 별도의 제어정보를 단말에게 전송할 필요 없이 기지국과 단말은 간섭측정 자원이 단말에게 통보되면 RI/PMI reporting이 disabling되더라도 CSI-RS를 측정하여 CQI를 생성하는 것으로 가정하는 방법을 이용하면 된다.

[0092] 즉, 단말은 RI/PMI reporting이 disabling되더라도 간섭측정 자원에 대한 시그널링을 통보 받은 상태라면 CSI-RS를 측정하여 CQI를 생성하고 기지국인 이를 기반으로 PDSCH를 전송한다. 반면 단말은 RI/PMI reporting이 disable되었지만 간섭측정 자원에 대한 시그널링을 통보 받지 못한 상태라면 CRS를 측정하여 CQI를 생성한다. 이와 같은 방법은 상위 시그널링 오버헤드를 증가시키지 않으면서도 기지국이 단말에게 어떤 RS를 측정할지를 통보할 수 있는 수단을 제공한다.

[0093] < 측정할 RS 종류에 대한 간접통보 방법2>

[0094] LTE/LTE-A 시스템에서 특정 셀(cell)이 분산안테나 시스템으로 구축될 경우 분산된 전송지점들 사이의 협력통신을 위하여 복수개의 피드백을 단말에게 설정할 수 있다. 일반적으로 한 개의 피드백이라 함은 RI/PMI reporting이 disable되지 않은 상태에서는 별도의 RI/PMI/CQI를 의미하며 RI/PMI/CQI가 disable된 상태에서는 별도의 CQI를 의미한다.

[0095] 즉, RI/PMI reporting이 disable된 상태에서 복수개의 피드백이 단말이 설정될 경우 단말은 두 개 이상의 서로 다른 전송지점 또는 간섭상황에 대한 CQI를 기지국으로 통보하도록 설정된다. 이와 같이 분산안테나 시스템에서는 복수개의 피드백이 설정된다는 것을 이용하여 RI/PMI reporting이 disable된 상태에서 RS_Switch 비트와 같은 별도의 제어정보를 단말에게 전송할 필요 없이 단말에게 어떤 RS를 이용할 지를 통보할 수 있다. 즉, 단말은 RI/PMI reporting이 disable된 상태에서 자신에게 복수개의 CQI가 설정될 경우에는 CSI-RS를 측정하여 CQI를 생성한다. 반면 단말은 RI/PMI reporting이 disable된 상태에서 자신에게 한 개의 CQI가 설정될 경우에는 CRS를

측정하여 CQI를 생성한다. 이와 같은 방법은 상위 시그널링 오버헤드를 증가시키지 않으면서도 기지국이 단말에게 어떤 RS를 측정할지를 통보할 수 있는 수단을 제공한다.

[0096] RI/PMI reporting이 disable될 경우 CQI를 단말이 생성하기 위해서 해결해야 하는 또 하나의 문제는 어떤 프리코딩(precoding)을 가정하여 CQI를 계산할 것인가 이다.

[0097] 구체적으로 기지국이 RI/PMI reporting이 disable될 경우 CSI-RS를 측정하여 CQI를 계산하라고 통보하였을 때 복수개의 CSI-RS 안테나 포트들 사이에 적용할 프리코딩이 단말과 기지국 사이에 공유되어야 한다. 상기 프리코딩이 공유되어야 하는 이유는 기지국이 단말이 적용한 프리코딩을 알고 있어야 단말이 요청한 CQI에 해당하는 MCS로 PDSCH를 전송하기 위해서 자신이 어떤 프리코딩을 적용해야 하는지를 알아야 하기 때문이다. 이와 같이 단말이 적용할 프리코딩을 결정하는 방법으로는 다음의 두 가지 방법이 가능할 수 있다.

[0098] <프리코딩 방법1>

[0099] 첫 번째 방법은 특정 프리코딩을 이용할 것을 단말과 기지국이 사전에 약속하는 것이다.

[0100] 이와 같은 특정 프리코딩은 PMI가 지정할 수 있는 복수개의 프리코딩들 중 한가지일 수 있다. 한 예로 기지국과 단말은 CSI-RS가 네 개의 안테나 포트를 가질 경우 $[+0.5\ +0.5\ +0.5\ +0.5]^{T}$이라고 가정하는 것이다. 이외에 기지국과 단말은 복수개의 프리코딩이 주어진 시간 또는 주파수 영역 내에서 번갈아 가며 적용된다고 가정할 수도 있다.

[0101] 도 9는 단말과 기지국이 주파수 영역에서 복수개의 프리코딩이 번갈아 가며 적용되는 실시예를 도시하는 도면이다.

[0102] 도 9에서 도시되는 바와 같이, 단말은 서브밴드(Subband) 0에서 서브밴드(Subband) 4까지 서로 다른 프리코더(precoder)가 적용된다고 가정하고 있다.

[0103] 이와 같은 서브밴드별 프리코딩의 적용은 기지국도 공유하고 있는 것이다. 단말은 상기의 서브밴드별 프리코딩을 가정하고 CQI를 생성한다. 이와 같이 주파수 또는 시간 영역에서 프리코더를 번갈아 가며 적용된다고 가정하고 CQI를 생성하는 것은 특정 한 개의 프리코더만 적용된다고 가정했을 경우와 비교하여 다이버시티(diversity) 효과가 존재한다. 여기서 다이버시티 효과라 함은 복수개의 프리코더를 가정하여 CQI를 단말이 피드백 함으로써 좋지 않은 프리코더 에 대해서만 연속적으로 CQI를 피드백하는 것을 방지하는 것이다.

[0104] 이와 같은 프리코더 다이버시티(precoder diversity)는 실제로 시스템의 성능을 개선시키는 효과가 있다. RI/PMI reporting이 disabling된 상태에서 상기의 프리코더 다이버시티 가 동작하기 위해서는 단말과 기지국 사이에 어떤 집합의 프리코더를 가정할지와 어떤 프리코더를 각 서브밴드에 적용할지를 기지국과 단말에 약속되어 있어야 한다.

[0105] 한 실시예로 기지국은 별도의 시그널링 없이 사전에 약속된 프리코더 집합을 서브밴드 인덱스(subband index)에 따라 각 서브밴드별로 가정할 수 있다. 즉, 서브밴드에 CQI를 생성할 때 가정할 프리코더는 다음의 수학식으로 결정된다.

[0106] <수학식1>

[0107] $\text{precoder index} = \text{subband index modulo } N_{\text{precoder}}$

[0108] 상기 수학식 1에서 N_{precoder}는 프리코더 다이버시티(precoder diversity)에 활용할 프리코더의 개수이다.

[0109] <프리코딩 방법2>

[0110] 단말이 적용할 프리코딩을 결정하기 위한 또 다른 방법에서는 기지국이 상위 시그널링을 이용하여 단말에게 프리코더 집합을 통보하고 단말은 상기의 수학식 1을 이용하여 각 서브밴드별로 어떤 프리코딩을 가정하여 CQI를 생성할지를 결정할 수 있다.

[0111] 상기에서는 주파수 영역에서 프리코딩을 번갈아 가며 가정하는 경우에 대하여 설명하였지만 동일한 방법이 시간 영역에서도 적용될 수 있다.

[0112] <프리코딩 방법3>

[0113] 상기에서는 프리코더 후보집합에 포함된 프리코딩들이 시간 또는 주파수 영역에서 번갈아 가며 적용된다는 가정하에서 단말이 CQI를 생성하였다. 이와 같은 방법외에도 단말은 프리코더 후보집합에 포함된 프리코딩들이 한 개의 subframe의 일부 RE들에서 번갈이 적용된다는 가정하에서 CQI를 생성할 수 있다.

[0114] 도 10은 이와 같이 프리코더 후보집합에 포함된 프리코딩들이 한 개의 서브프레임 내의 한 개의 RB내에서 번갈아 가며 적용되는 것을 도시한 것이다.

[0115] 도 10에서와 같이 단말은 OFDM 심볼마다 프리코더가 번갈아 가며 적용된다는 가정하고 CQI를 생성한다. 상기 도 10에서는 OFDM 심볼마다 프리코더가 번갈아 가며 적용되는 경우를 도시하였지만 이와 같은 방법 외에 한 개의 RB내의 RE들을 임의의 방법으로 복수 개의 그룹으로 나누고 각 그룹마다 프리코더를 번갈아 가며 적용하는 것도 가능하다.

[0116] 상기 프리코딩 방법 3에서 단말은 사전에 설정되어 있는 프리코더 집합 또는 기지국이 통보한 프리코더 집합을 상기 수학식 1과 유사한 방법을 이용하여 한 개의 RB내의 RE들마다 어떤 프리코딩을 가정할지를 판단한다.

[0117] 상기 프리코딩 방법 1, 방법 2, 방법 3 외에도 단말이 각 RE마다 공간 시간/주파수 블록 코드(Space time/frequency block code)를 가정하고 CQI를 생성하는 방법도 가능하다. 공간 시간/주파수 블록 코드(Space time/frequency block code)를 가정하고 CQI를 생성하는 방법에 대해서는 이하에서 구체적으로 기술하도록 한다.

[0118] <프리코딩 방법4>

[0119] Space time/frequency block code를 가정하고 CQI를 생성하는 방법에서는 단말이 시간, 주파수, 안테나 영역에서 규격화되어 있는 부호화 방식을 가정하여 CQI를 생성한다. Space time/frequency block code는 복수 개 무선채널의 효과를 평균화시키는 효과를 얻을 수 있도록 한다.

[0120] 현재 LTE/LTE-A에서 정의하고 있는 space time/frequency block code로는 송신안테나의 개수에 따라 하기의 수학식 2 및 수학식 3에서 도시되는 두 가지 종류의 space time/frequency block code가 적용될 수 있다. 송신안테나의 개수가 두 개일 경우 하기의 수학식 2에서 정의되는 space time/frequency block code가 적용된다.

[0121] <수학식 2>

[0122]
$$\begin{bmatrix} y^{(0)}(2i) \\ y^{(1)}(2i) \\ y^{(0)}(2i+1) \\ y^{(1)}(2i+1) \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 0 & j & 0 \\ 0 & -1 & 0 & j \\ 0 & 1 & 0 & j \\ 1 & 0 & -j & 0 \end{bmatrix} \begin{bmatrix} \mathrm{Re}\left(x^{(0)}(i)\right) \\ \mathrm{Re}\left(x^{(1)}(i)\right) \\ \mathrm{Im}\left(x^{(0)}(i)\right) \\ \mathrm{Im}\left(x^{(1)}(i)\right) \end{bmatrix}$$

[0123] 상기 수학식 2에서 y는 부화화된 신호이며 x는 부호화기에 입력되는 신호이다. 또한 i는 부호화기에 입력되는 신호의 순서를 나타내는 인덱스이다. 또한 Re(Z)는 복소수 Z의 실수성분을 의미하며 Im(Z)는 복소수 Z의 허수성분을 의미한다. 또한 $x^{(k)}(i)$ 및 $y^{(k)}(i)$에서 k는 안테나 포트 인덱스에 해당한다.

[0124] 송신안테나의 개수가 네 개일 경우 하기의 수학식 3에서 정의되는 space time/frequency block code가 적용된다.

[0125] <수학식3>

$$\begin{bmatrix} y^{(0)}(4i) \\ y^{(1)}(4i) \\ y^{(2)}(4i) \\ y^{(3)}(4i) \\ y^{(0)}(4i+1) \\ y^{(1)}(4i+1) \\ y^{(2)}(4i+1) \\ y^{(3)}(4i+1) \\ y^{(0)}(4i+2) \\ y^{(1)}(4i+2) \\ y^{(2)}(4i+2) \\ y^{(3)}(4i+2) \\ y^{(0)}(4i+3) \\ y^{(1)}(4i+3) \\ y^{(2)}(4i+3) \\ y^{(3)}(4i+3) \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 0 & 0 & 0 & j & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & j & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & j & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & -j & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & j & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 0 & j \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & j \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & -j & 0 \end{bmatrix} \begin{bmatrix} \mathrm{Re}\left(x^{(0)}(i)\right) \\ \mathrm{Re}\left(x^{(1)}(i)\right) \\ \mathrm{Re}\left(x^{(2)}(i)\right) \\ \mathrm{Re}\left(x^{(3)}(i)\right) \\ \mathrm{Im}\left(x^{(0)}(i)\right) \\ \mathrm{Im}\left(x^{(1)}(i)\right) \\ \mathrm{Im}\left(x^{(2)}(i)\right) \\ \mathrm{Im}\left(x^{(3)}(i)\right) \end{bmatrix}$$

[0126]

[0127] LTE/LTE-A 시스템에서 단말이 상기 수학식2 또는 수학식3과 같은 space time/frequency block code를 가정하고 CQI를 생성하는 경우, 발생할 수 있는 문제점은 현재 LTE/LTE-A 시스템의 경우 space time/frequency block code가 두 개 또는 네 개의 송신안테나에 대해서만 정의가 되어 있다는 점이다. 때문에 CSI-RS가 8개의 안테나 포트를 가질 경우 상기와 같은 space time/frequency block code를 가정하고 CQI를 생성하기 위해서는 별도의 방안이 필요하다.

[0128] 상기와 같이 CSI-RS가 8개의 안테나 포트를 가지는 경우에도 space time/frequency block code를 가정하고 CQI를 생성하도록 하기 위해, 본 발명에서는 단말이 자체적으로 안테나 가상화(virtualization)를 수행하는 방안을 제안한다.

[0129] 즉, CSI-RS의 안테나 포트수가 가정해야 하는 space time/frequency block code가 지원하는 송신안테나 수보다 적을 경우, 단말은 안테나 가상화(virtualization)를 통하여 해당 space time/frequency block code에 적합하도록 CSI-RS를 결합할 수 있다. 이하에서는 구체적인 예시를 들어, 단말의 안테나 가상화 방법에 대해 설명하도록 한다.

[0130] 예를 들어, 단말이 상기 수학식 2에서 도시되는 바와 같은 두 개의 안테나를 위한 space time/frequency block code를 이용할 수 있고 CSI-RS는 안테나 포트수가 8개인 경우를 가정한다. 이 경우, 단말은 8개의 안테나 포트를 갖는 CSI-RS를 수신하여 이를 2개의 송신안테나에 대한 수신신호로 안테나 가상화를 수행한다. 단말에서 안테나 가상화를 수행하는 방법은 미리 정해진 규칙에 따라 CSI-RS 안테나포트 별로 수신한 신호를 더하는 것이다. 한 예로, 단말은 CSI-RS 안테나포트 1, 2, 3, 4, 5, 6, 7, 8에 대한 수신신호가 각각 있을 경우 단말은 CSI-RS 안테나포트 1, 2, 3, 4의 수신신호를 결합하여 송신안테나 1에 대한 수신신호를 생성하고 CSI-RS 안테나포트 5, 6, 7, 8의 수신신호를 결합하여 송신안테나 2에 대한 수신신호를 생성한다. 그리고 단말은 상기 수학식 2에 따른 space time/frequency block code를 가정하여 CQI를 생성할 수 있다.

[0131] 또는 단말과 기지국의 약속에 따라, 1, 3, 5, 7의 수신신호를 결합하여 송신안테나 1에 대한 수신신호를 생성하고 CSI-RS 안테나포트 2, 4, 6, 8의 수신신호를 결합하여 송신안테나 2에 대한 수신신호를 생성할 수 도 있다.

[0132] 상기에서 더하기를 수행할 경우 각 안테나별 신호에 단말과 기지국 사이에 약속된 상수 값을 곱한 후 더하기를 수행하는 것도 가능하다.

[0133] 도 13은 본 발명에서 제안하는 공간 시간/주파수 블록 코드의 적용을 위한 단말 수신기에서의 안테나 가상화를 설명하기 위한 도면이다.

[0134] 상기 도 13에서 단말은 8개의 안테나 포트에 대한 CSI-RS를 RE 위치 1300(P1, P2), 1310(P5, P6), 1320(P3, P4), 1330(P7, P8)을 통해 수신한다.

[0135] 단말이 CQI를 생성하기 위하여 가정해야 하는 space time/frequency block code가 두 개의 송신안테나를 지원한

다고 가정할 경우, 단말은 상기 8개의 안테나 포트에 대한 CSI-RS의 수신신호를 안테나 가상화(antenna virtualization)를 통하여 결합하여 두 개의 송신안테나에 대한 수신신호로 변환한다. 즉, 상기 도 13에서 1300, 1310, 1320, 1330의 수신신호를 임의의 규칙에 따라 더하여 두 개의 송신안테나에 대한 수신신호를 생성한다.

[0136] 이 경우, 8개의 안테나 포트에 대한 CSI-RS 수신 신호를 두 개의 송신안테나에 대한 수신신호로 변환하기 위한 일 예로, 수신 신호를 OFDM 심볼 별로 더하는 방법을 고려해볼 수 있다. 상기 도 13에서 1300, 1310, 1320, 1330의 수신신호를 OFDM 심볼 별로 더할 경우, 두 개의 RE에 대한 신호를 얻을 수 있으며 이에 대하여 송신단에서 안테나포트를 구분하기 위하여 이용한 직교코드 두 개로 correlation을 취함으로서 두 개의 안테나포트에 대한 신호를 얻을 수 있다.

[0137] 또한 단말이 CQI를 생성하기 위하여 가정해야 하는 space time/frequency block code가 네 개의 송신안테나를 지원할 경우, 단말은 상기 8개의 안테나 포트에 대한 CSI-RS의 수신신호를 안테나 가상화(antenna virtualization)을 통하여 결합하여 네 개의 송신안테나에 대한 수신신호로 변환한다. 즉, 상기 도 13에서 1300, 1310, 1320, 1330의 수신신호를 사전에 정해진 규칙에 따라 더하여 두 개의 송신안테나에 대한 수신신호를 생성한다.

[0138] 이 경우, 8개의 안테나 포트에 대한 CSI-RS 수신 신호를 네 개의 송신안테나에 대한 수신신호로 변환하기 위한 일 예로, 상기 도 13의 1300, 1310, 1320, 1330을 두 쌍씩 더하여 네 개의 송신안테나에 대한 수신신호를 얻는 방법을 고려해볼 수 있다. 이와 같이 두 쌍씩 더하여 네 개의 송신안테나에 대한 수신신호를 얻는 경우 기지국과 단말은 각 쌍이 어느 위치의 CSI-RS 수신신호를 더하여 얻어지는지를 사전에 약속한대로 수행해야 한다. 즉, 단말과 기지국이 1300과 1320을 더하고 1310과 1330을 더하기로 약속한 경우 단말은 언제나 이와 같은 조합으로 수신신호를 더해야 한다.

[0139] 도 11는 본 발명의 실시예에 따른 기지국의 내부 구조를 도시하는 블록도이다.

[0140] 상기 도 11에서 기지국의 장치 1100인 제어기는 다음의 사항을 결정한다.

[0141] - RI/PMI reporting disable 여부 및 이와 관련된 대한 설정 정보를 단말에게 통보

[0142] - RI/PMI reporting이 disable되었을 경우 CRS와 CSI-RS 중 어느 것을 단말에게 측정하도록 할지 및 이와 관련된 설정 정보를 단말에게 통보

[0143] - RI/PMI reporting이 disable되었을 경우 주파수 및 시간영역에서 어떤 프리코딩을 가정하여 CQI를 생성할지 및 이와 관련된 설정 정보를 단말에게 통보

[0144] 상기의 결정 사항이 이루어지면 제어기 1100은 RI/PMI reporting과 관련된 설정 정보, 어떤 RS를 이용할지에 대한 설정 정보, 어떤 프리코딩 집합을 가정할지 등에 대한 설정 정보를 결정하고 전송신호를 생성한다. 상기 장치 1100에서 생성된 전송신호는 CRS 신호 생성기 1110 및 CSI-RS 신호 생성기 1120에서 생성된 전송신호와 함께 장치 1130 멀티플렉서(multiplexor)에서 주파수영역 또는 시간영역에서 먹싱(muxing)되어 장치 1140의 OFDMA 신호발생기를 이용하여 전송된다.

[0145] 상기한 제어기 1100가 수행하는 동작을 정리하면, 제어기1100는 상기 단말의 RI/PMI 보고 불능 여부를 결정하고, 상기 단말의 RI/PMI 보고 불능 결정 시 CRS 또는 CSI-RS 중 단말이 측정할 기준 신호를 결정하며, 상기 결정된 기준 신호를 상기 단말에게 통보하고, 상기 결정된 기준 신호를 측정하여 단말이 생성한 제1 채널 정보를 상기 단말로부터 수신하며, 상기 제1 채널 정보에 기반하여 상기 단말에게 데이터를 전송하도록 제어할 수 있다.

[0146] 한편, 제어기 1100는 상기 단말의 RI/PMI 보고 결정 시 상기 단말이 CSI-RS를 측정하도록 통보하고, 상기 단말이 상기 CSI-RS를 측정하여 생성한 제2 채널 정보를 수신하며, 상기 제2 채널 정보에 기반하여 상기 단말에게 데이터를 전송하도록 제어할 수 있다.

[0147] 본 발명의 일 실시예에 따르면, 제어기 1100는 상기 단말이 측정하도록 결정된 기준 신호 정보를 비트 형식으로 지시하는 기준 신호 측정 정보를 생성하여 상기 단말에 직접적으로 통보할 수 있다. 이 경우, 제어기 1100는 상위 시그널링 또는 물리계층 시그널링을 통해 상기 기준 신호 측정 정보를 단말에게 전송할 수 있다.

[0148] 한편, 본 발명의 다른 실시예에 따르면, 제어기 1100는 간섭 측정 자원을 상기 단말에게 통보하거나 또는 복수개의 피드백을 상기 단말에게 통보하고, 상기 단말이 CSI-RS를 측정하여 생성한 제3 채널 정보를 상기 단말로부

터 수신하도록 제어할 수도 있다. 이는 단말이 측정할 기준 신호의 종류를 간접적으로 단말에게 통보해주는 실시예에 대한 기술이다.

[0149] 또한, 제어기 1100는 특정 프리코더가 적용된 데이터를 상기 단말에 전송하도록 제어할 수 있다. 이 경우, 상기 프리코더는, 상기 프리코더가 속한 집합 및 각 서브밴드에 적용될 프리코더가 미리 결정된 것일 수 있다.

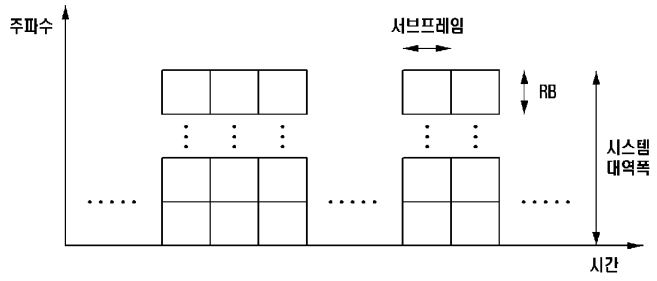
[0150] 도 12은 본 발명의 실시예에 따른 단말의 내부 구조를 도시하는 블록도이다.

[0151] 단말기는 장치 1200의 OFDMA 수신기를 통하여 기지국으로부터의 무선신호를 수신한다. 수신된 신호는 장치 1210의 디멀티플렉서(demultiplexor)에서 RI/PMI reporting관련 설정정보를 장치 1230의 제어기로 전달한다.

[0152] 상기 장치 1230의 제어기는 RI/PMI reporting이 disable될 경우 설정정보에 따라 어떤 RS를 이용할지, 어떤 프리코딩을 가정하고 CQI를 생성할지 등을 판단한다. 여기서 판단된 결과에 따라, RI/PMI reporting이 disable될 경우 제어기는 장치 1240의 CSI-RS 수신기에서 검출한 CSI-RS에 적절한 프리코딩을 가정하여 장치 1250(CQI 생성기)에서 CQI를 생성하거나 장치 1220의 CRS 수신기에서 검출한 CRS를 이용하여 장치 1250에서 CQI를 생성한다. 또한, RI/PMI reporting이 enable된 경우, 단말은 CSI-RS를 이용하여 장치 1240의 CSI-RS 수신기에서 검출한 CSI-RS를 이용하여 CQI를 장치 1250에서 생성한다.

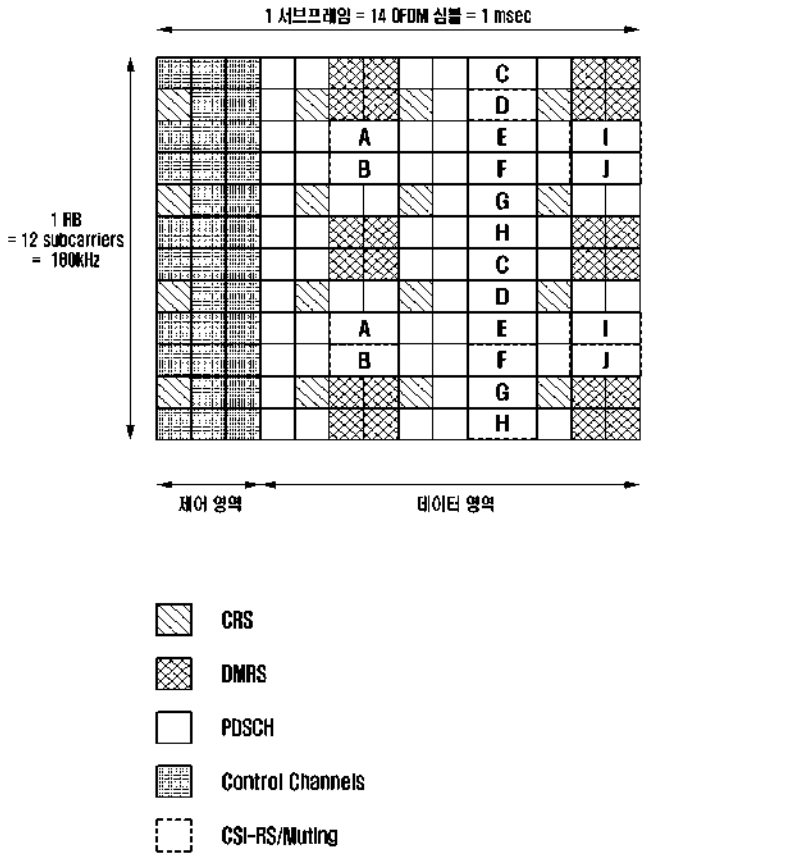
[0153] 상기한 제어기 1230가 수행하는 동작을 정리하면, 상기 제어기 1230는 단말의 RI/PMI 보고 불능 설정 여부에 대한 정보를 기지국으로부터 수신하고, 상기 RI/PMI 보고 불능 설정 시 CRS 또는 CSI-RS 중 상기 단말이 측정하도록 결정된 기준 신호에 대한 정보를 상기 기지국으로부터 수신한다. 그리고 제어기 1230는 상기 결정된 기준 신호를 측정하여 제1 채널 정보를 생성하고 상기 기지국으로 전송한다. 그리고 제어기 1230는 상기 제1 채널 정보에 기반하여 전송되는 데이터를 상기 기지국으로부터 수신하도록 제어한다.

[0154] 한편, 제어기 1230는 단말의 RI/PMI 보고 설정 시 상기 CSI-RS를 측정하여 제2 채널 정보를 생성하고, 상기 생성된 제2 채널 정보를 상기 기지국으로 전송하도록 제어할 수 있다.



[0155] 본 발명의 일 실시예에 따르면, 제어기 1230는 상기 단말이 측정하도록 결정된 기준 신호 정보를 비트 형식으로 지시하는 기준 신호 측정 정보를 기지국으로부터 명시적으로 수신할 수 있다. 이 경우, 상기 기준 신호 측정 정보는 상위 시그널링 또는 물리계층 시그널링을 통해 상기 기지국으로부터 수신될 수 있다.

[0156] 반면, 본 발명의 다른 실시예에 따르면, 제어기 1230는 기지국으로부터 간섭 측정 자원을 통보받거나 또는 복수개의 피드백을 보고하도록 통보받는 경우, 이를 CSI-RS를 측정하라는 간접적 통보방법으로 인지하고, 상기 CSI-RS를 측정하여 제3 채널 정보를 생성할 수 있다.



[0157] 본 명세서와 도면에 개시된 본 발명의 실시예들은 본 발명의 기술 내용을 쉽게 설명하고 본 발명의 이해를 돕기 위해 특정 예를 제시한 것일 뿐이며, 본 발명의 범위를 한정하고자 하는 것은 아니다. 여기에 개시된 실시예들 이외에도 본 발명의 기술적 사상에 바탕을 둔 다른 변형 예들이 실시 가능하다는 것은 본 발명이 속하는 기술 분야에서 통상의 지식을 가진 자에게 자명한 것이다.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C.

371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts where applicable. It serves as evidence of receipt similar to a Post Card as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

(12) INTERNATIONAL APPLICATION PUBLISHED UNDER THE PATENT COOPERATION TREATY (PCT)

(19) World Intellectual Property Organization
International Bureau

(43) International Publication Date
1 September 2016 (01.09.2016)

WIPO | PCT

(10) International Publication Number
WO 2016/136143 A1

(51) International Patent Classification:
H04W 68/08 (2009.01)

(21) International Application Number:
PCT/JP2016/000417

(22) International Filing Date:
28 January 2016 (28.01.2016)

(25) Filing Language: English

(26) Publication Language: English

(30) Priority Data:
15156154.5 23 February 2015 (23.02.2015) EP

(71) Applicant: **PANASONIC INTELLECTUAL PROPERTY CORPORATION OF AMERICA** [US/US]; 20000 Mariner Avenue, Suite 200, Torrance, California, 90503 (US).

(72) Inventors: **BASU MALLICK, Prateek**. **LOEHR, Joachim**. **SUZUKI, Hidetoshi**; c/o Panasonic Corporation, 1006, Oaza Kadoma, Kadoma-shi, Osaka, 5718501 (JP).

(54) **Title**: IMPROVED PAGING PROCEDURES FOR USER EQUIPMENTS REQUIRING COVERAGE EXTENSION

(57) **Abstract**: The present disclosure relates to a method for paging coverage extension UEs in a cell controlled by a radio base station. At least one regularly-occurring coverage-extension-specific paging possibility (CE-specific paging possibility), is defined for paging CE UEs. The CE-UEs in the cell regularly monitor the at least one CE-specific paging possibility. When the radio base station determines to page all the user equipments in the cell, it pages the CE user equipments in the cell at the CE-specific paging possibility, using a coverage extension technique. The present disclosure also relates to a method for paging a CE UE, which performs radio measurements by the CE-capable user equipment to determine whether coverage extension is necessary. The radio base station is informed about whether the CE-capable user equipment needs coverage extension or not and then pages the CE UEs applying or not applying a CE technique depending on whether coverage extension is necessary or not.

WO 2016/136143 A1

Description

Title of Invention: IMPROVED PAGING PROCEDURES FOR USER EQUIPMENTS REQUIRING COVERAGE EXTENSION

Technical Field

[0001] The present disclosure relates to methods for paging one or several user equipments in a cell of a radio base station, where the user equipment(s) do require coverage extension to be reliably paged. The present disclosure is also providing the user equipment and radio base station for participating in the methods described herein.

Background

[0002] Long Term Evolution (LTE)

Third-generation mobile systems (3G) based on WCDMA radio-access technology are being deployed on a broad scale all around the world. A first step in enhancing or evolving this technology entails introducing High-Speed Downlink Packet Access (HSDPA) and an enhanced uplink, also referred to as High Speed Uplink Packet Access (HSUPA), giving a radio access technology that is highly competitive.

[0003] In order to be prepared for further increasing user demands and to be competitive against new radio access technologies, 3GPP introduced a new mobile communication system which is called Long Term Evolution (LTE). LTE is designed to meet the carrier needs for high speed data and media transport as well as high capacity voice support for the next decade. The ability to provide high bit rates is a key measure for LTE.

[0004] The work item (WI) specification on Long-Term Evolution (LTE) called Evolved UMTS Terrestrial Radio Access (UTRA) and UMTS Terrestrial Radio Access Network (UTRAN) is finalized as Release 8 (LTE Rel. 8). The LTE system represents efficient packet-based radio access and radio access networks that provide full IP-based functionalities with low latency and low cost. In LTE, scalable multiple transmission bandwidths are specified such as 1.4, 3.0, 5.0, 10.0, 15.0, and 20.0 MHz, in order to achieve flexible system deployment using a given spectrum. In the downlink, Orthogonal Frequency Division Multiplexing (OFDM) based radio access was adopted because of its inherent immunity to multipath interference (MPI) due to a low symbol rate, the use of a cyclic prefix (CP) and its affinity to different transmission bandwidth arrangements. Single-carrier frequency division multiple access (SC-FDMA) based radio access was adopted in the uplink, since provisioning of wide area coverage was prioritized over improvement in the peak data rate considering the restricted transmit power of the user equipment (UE). Many key packet radio access techniques are employed including multiple-input multiple-output

(MIMO) channel transmission techniques and a highly efficient control signaling structure is achieved in LTE Rel. 8/9.

[0005] LTE architecture

The overall architecture is shown in Fig. 1 and a more detailed representation of the E-UTRAN architecture is given in Fig. 2. The E-UTRAN consists of an eNodeB, providing the E-UTRA user plane (PDCP/RLC/MAC/PHY) and control plane (RRC) protocol terminations towards the user equipment (UE). The eNodeB (eNB) hosts the Physical (PHY), Medium Access Control (MAC), Radio Link Control (RLC) and Packet Data Control Protocol (PDCP) layers that include the functionality of user-plane header-compression and encryption. It also offers Radio Resource Control (RRC) functionality corresponding to the control plane. It performs many functions including radio resource management, admission control, scheduling, enforcement of negotiated uplink Quality of Service (QoS), cell information broadcast, ciphering/ deciphering of user and control plane data, and compression/ decompression of downlink/uplink user plane packet headers. The eNodeBs are interconnected with each other by means of the X2 interface.

[0006] The eNodeBs are also connected by means of the S1 interface to the EPC (Evolved Packet Core), more specifically to the MME (Mobility Management Entity) by means of the S1-MME and to the Serving Gateway (SGW) by means of the S1-U. The S1 interface supports a many-to-many relation between MMEs/Serving Gateways and eNodeBs. The SGW routes and forwards user data packets, while also acting as the mobility anchor for the user plane during inter-eNodeB handovers and as the anchor for mobility between LTE and other 3GPP technologies (terminating S4 interface and relaying the traffic between 2G/3G systems and PDN GW). For idle state user equipments, the SGW terminates the downlink data path and triggers paging when downlink data arrives for the user equipment. It manages and stores user equipment contexts, e.g. parameters of the IP bearer service, network internal routing information. It also performs replication of the user traffic in case of lawful interception.

[0007] The MME is the key control-node for the LTE access-network. It is responsible for idle mode user equipment tracking and paging procedure including retransmissions. It is involved in the bearer activation/deactivation process and is also responsible for choosing the SGW for a user equipment at the initial attach and at time of intra-LTE handover involving Core Network (CN) node relocation. It is responsible for authenticating the user (by interacting with the HSS). The Non-Access Stratum (NAS) signaling terminates at the MME and it is also responsible for generation and allocation of temporary identities to user equipments. It checks the authorization of the user equipment to camp on the service provider's Public Land Mobile Network (PLMN) and enforces user equipment roaming restrictions. The MME is the ter-

mination point in the network for ciphering/integrity protection for NAS signaling and handles the security key management. Lawful interception of signaling is also supported by the MME. The MME also provides the control plane function for mobility between LTE and 2G/3G access networks with the S3 interface terminating at the MME from the SGSN. The MME also terminates the S6a interface towards the home HSS for roaming user equipments.

[0008] LTE RRC states

LTE is based on only two main states: "RRC_IDLE" and "RRC_CONNECTED".

[0009] In RRC_IDLE the radio is not active, but an ID is assigned and tracked by the core network. More specifically, a mobile terminal in RRC_IDLE performs cell selection and reselection — in other words, it decides on which cell to camp. The cell (re)selection process takes into account the priority of each applicable frequency of each applicable Radio Access Technology (RAT), the radio link quality and the cell status (i.e. whether a cell is barred or reserved). An RRC_IDLE mobile terminal monitors a paging channel to detect incoming calls, and also acquires system information. The system information mainly consists of parameters by which the network (E-UTRAN) can control the cell (re)selection process and also how the mobile terminal accesses the network. RRC specifies the control signalling applicable for a mobile terminal in RRC_IDLE, namely paging and system information. The mobile terminal behaviour in RRC_IDLE is specified in more detail e.g. in TS 36.304, current version 12.0.0(NPL 1), chapter 4 "General description of Idle mode" incorporated herein by reference.

[0010] In RRC_CONNECTED the mobile terminal has an active radio operation with contexts in the eNodeB. The E-UTRAN allocates radio resources to the mobile terminal to facilitate the transfer of (unicast) data via shared data channels. To support this operation, the mobile terminal monitors an associated control channel which is used to indicate the dynamic allocation of the shared transmission resources in time and frequency. The mobile terminal provides the network with reports of its buffer status and of the downlink channel quality, as well as neighbouring cell measurement information to enable E-UTRAN to select the most appropriate cell for the mobile terminal. These measurement reports include cells using other frequencies or RATs. The UE also receives system information, consisting mainly of information required to use the transmission channels. To extend its battery lifetime, a UE in RRC_CONNECTED may be configured with a Discontinuous Reception (DRX) cycle. RRC is the protocol by which the E-UTRAN controls the UE behaviour in RRC_CONNECTED.

[0011] The various functions of the mobile terminal in RRC Protocol for and including Connected Mode are described in 3GPP TS 36.331, current version 12.4.1(NPL 2), in

Ch. 4 "Functions", incorporated herein by reference.

[0012] Paging

The present application will differentiate between two types of paging, namely the paging initiated from the non-access stratum (NAS) (termed exemplarily in the following "Paging-NAS") and the paging initiated from the eNodeB (termed exemplarily in the following "Paging-eNB"). Paging-NAS relates to the paging of a particular UE e.g. when paging a UE in connection with an incoming data connection e.g. a mobile-terminating (MT) call. On the other hand, paging-eNB relates to the paging of all the UEs in the cell, and e.g. is used to inform them about a system information change, ETWS message (Earthquake and Tsunami Warning System), CMAS message (Commercial Mobile Alert System) etc. Furthermore, depending on whether the UE is in RRC idle or connected state, the actual paging messages are transmitted differently to the UE. However, the two paging procedures have a lot in common too.

[0013] In general, the UE in RRC_Idle state monitors for paging to detect incoming calls, system information change, for ETWS capable UEs, ETWS notification, and for CMAS capable UEs, CMAS notification. The UE in RRC_Connected state monitors for paging and/or System Information Block Type 1 contents to detect system information change, for ETWS capable UEs, ETWS notification, and for CMAS capable UEs, CMAS notification (see 3GPP TS 36.331, current version v12.4.1, subclause 4.2.1, incorporated herein by reference).

The general paging procedure for transmitting the paging message from EUTRAN to the UE is defined in TS 36.331, current version 12.4.1, subclause 5.3.2 incorporated herein by reference, describing that the purpose of the paging procedure is:

[0014] - to transmit paging information to a UE in RRC_IDLE (Paging-NAS) and/ or;

- to inform UEs in RRC_IDLE and UEs in RRC_CONNECTED about a system information change (Paging-eNB) and/ or;

- to inform about an ETWS primary notification and/ or ETWS secondary notification (Paging-eNB) and/ or;

- to inform about a CMAS notification (Paging-eNB).

[0015] The paging information received in the UE is provided to upper layers, which in response e.g. may the initiate RRC connection establishment to receive an incoming call.

[0016] E-UTRAN performs the paging procedure by transmitting the Paging message at the UE's paging occasion as specified in TS 36.304. E-UTRAN may address multiple UEs within a Paging message by including one PagingRecord for each UE.

[0017] To receive paging messages from E-UTRAN, UEs in idle mode monitor the PDCCH channel for an RNTI value used to indicate paging: the P-RNTI (Paging radio network

temporary identity) which is a common RNTI, i.e. not allocated to any UE explicitly. The UE only needs to monitor the PDCCH channel at certain UE-specific paging possibilities, i.e. at specific subframes within specific radio frames as will be discussed in more detail in the following. The E-UTRAN configures which of the radio frames and subframes can be used for paging in its cell. Each cell broadcasts a default paging cycle Tc, and in addition, upper layers may use dedicated signaling to configure a UE-specific paging cycle TUE; if both are configured, the UE applies the lowest value for the DRX cycle T of the UE.

[0018] In order to explain the procedure for paging as currently defined for LTE-A, the following exemplary cases A, B, and C are defined, as taken from the book LTE – The UMTS Long Term Evolution – From Theory to Practice, Edited by: Stefania Sesia, Issam Toufik, and Matthew Baker, Second Edition, ISBN 9780470660256, section 3.4(NPL 3).

[0019] [Table 1]

Case	UE_ID	T_C	T_{UE}	T	nB	N	Ns	PF	i_s	PO
A	147	256	256	256	64	64	1	76	0	9
B	147	256	128	128	32	32	1	76	0	9
C	147	256	128	128	256	128	2	19	1	4

[0020] The following parameters are used in said respect:

- "TC" is the cell-specific default paging cycle, and can be 32, 64, 128, or 256 radio frames,
- "TUE" is the UE-specific paging cycle of the UE, and can be 32, 64, 128, or 256 radio frames,
- "N" is the number of paging frames within the paging cycle of the UE, and is min (T, nB),
- Ns is the number of paging subframes in a radio frame that may be used for paging, and is max (1, nB/T),

[0021] - nB is the number of paging subframes per paging cycle (across all UEs in the cell), and can be 4T, 2T, T, T/2, T/4, T/8, T/16, T/32; the parameter determines to a large extent the paging capability of the eNB across all UEs in the cell. In general, if nB is set equal to or larger than T, all radio frames may be used for paging (see also parameter N), and there are nB/T POs per PF (see also parameter Ns). In turn, if nB is set lower than T, only a fraction nB/T of the radio frames may be used for paging (see also parameter N), and there is one PO per PF (see also parameter Ns).

[0022] - "T" is the DRX cycle of the UE (also termed paging cycle), is min of TC and TUE,

and specifies how frequently a UE monitors for paging, where a shorter DRX cycle decreases the time for paging but increases battery consumption.

[0023] For example, for cases A and B E-UTRAN has configured one out of every four radio frames and specifically one subframe in each of those radio frames, to be used for paging (see T, Ns, respectively). For case C, there are two subframes in each radio frame that can be used for paging, i.e. Ns=2, and 128 paging frames within the UE's paging cycle, i.e. N=128, available for paging the UEs in the cell. Furthermore, for case B, there are 32 paging frames within the UE's paging cycle (N=32). Across these generally-available paging opportunities configured by the eNB, the paging possibilities for paging the UEs are distributed based on the UE identity.

[0024] In said respect, the particular radio frame and subframe used for paging a particular UE is calculated as follows. A Paging Occasion (PO) is a subframe where there may be a P-RNTI (Paging radio network temporary identity) transmitted on PDCCH addressing the paging message. A Paging Frame (PF) is a radio frame, which may contain one or multiple Paging Occasion(s). In the context of this patent application, the term paging possibility shall refer to the combination of the paging frame and paging subframe.

[0025] The paging frames and paging occasions are defined for example in 3GPP TS 36.304, current version 12.0.0, subclause 7, incorporated herein by reference. Accordingly, the paging frame number (SFN) is calculated according to the following formula:

SFN mod T = (T div N)*(UE_ID mod N)

where UE_ID is IMSI mod 1024.

[0026] When assuming an UE_ID of 147 for all three cases A, B, and C, calculating the above formula results in the paging frame 76 for cases A and B, and paging frame 19 for case C. Furthermore, i_s would be calculated to be 0 for cases A and B, and be 1 for case C.

[0027] The paging occasion has values in the range of [0, 1, ... 9], as in LTE there are 10 subframes within one radio frame. The paging occasion number is selected from a preconfigured table based on the parameters Ns and i_s calculated according to the following formula:

i_s= floor(UE_ID / N) mod Ns.

[0028] The following table is taken from TS 36.304, current version 12.0.0, and is used to determine the Paging Occasion for a particular UE, based on the above parameters Ns and i_s. The following table is intended for FDD.

[0029]

[Table 2]

	PO when i_s=0	PO when i_s=1	PO when i_s=2	PO when i_s=3
1	9	N/A	N/A	N/A
2	4	9	N/A	N/A
4	0	4	5	9

[0030] Therefore, for case A and B, with Ns=1 and i_s=0, the table would yield the subframe number 9, such that the UE for cases A and B would be paged regularly in subframe 9 of radio frame 76 of every paging cycle; i.e. for case A next radio frame 332 and for case B next radio frame 204 etc. For case C, the UE would be paged regularly in subframe 4 of radio frame 19 of every paging cycle, i.e. next radio frame 147 etc.

[0031] The paging frame and paging occasion for the above-discussed cases B and C, is exemplarily depicted in Fig. 3.

[0032] Paging-NAS

For instance, in order to re-establish a connection towards a UE in idle mode, the MME - having been informed e.g. by the UE's P/SGW - sends a paging request message to all eNBs that are part of the so-called tracking area(s) to which the UE belongs and within which the UE can move without having to perform the Tracking Area Update (TAU) procedure (except the periodic TAU procedure).

[0033] When receiving the paging request, the eNodeB(s) of the tracking area(s) then broadcast(s) another paging message over the radio interface in the cells The UE is notified about the paging based on the P-RNTI on the PDCCH and then receives the paging message transmitted over the PDSCH, in the radio resources as indicated by the PDCCH paging notification. When the UE in RRC idle receives the paging message/ signal, it transfers from IDLE to CONNECTED state and establishes an RRC connection with that eNB where it is camped in IDLE mode (e.g. the UE initiates the RRC connection establishment procedure).

[0034] A system overview and message exchange is exemplarily illustrated in Fig. 4, assuming that the UE to be paged by the MME (as triggered by the SGW) is registered at tracking areas TAC1 and TAC3. Consequently, the MME will provide the S1AP paging request to the eNBs of those tracking areas, which in turn will transmit a page at the UE-specific paging possibility (i.e. the PDCCH notification) and then the paging message on the PDSCH resources. The UE is consequently notified about the paging, receives the paging message on the PDSCH, and after confirming its own identity in the paging message, processes the paging message and responds to the paging by e.g. by sending a service request to the MME.

[0035] In the current LTE system, the paging message transmitted from the MME to the eNB, and its content, are defined e.g. by 3GPP TS 36.413, current version 12.4.0(NPL 4), in sub-clauses 8.5 and 9.1.6, incorporated herein by reference. The paging message from the MME to the eNB contains amongst other the following information:

[0036] - UE_ID Index Value: known as UE_ID, which is calculated by (IMSI mod 1024). Correspondingly, the UE_ID may have values in the range of [0, 1 ... 1023].

[0037] - UE Paging Identity: can be the IMSI (as stored on the SIM card) or the SAE-Temporary Mobile subscriber ID (S-TMSI) assigned to the UE during the attach procedure. The UE Paging Identity is transmitted from the eNB to the UE in a paging message over the radio interface (i.e. Uu interface).

[0038] - Paging DRX cycle: is the Discontinuous Reception (DRX) cycle configured in the UE (using NAS signalling) or the default DRX cycle broadcast in the System Information Block (SIB). The default DRX cycle is also known as Paging Cycle in the RadioResourceConfigCommon SIB. The UE may use discontinued reception in IDLE mode in order to reduce power consumption. The DRX cycle is a time interval between monitoring Paging Occurrences for a specific UE. The values of the default DRX/paging cycle broadcast in the SIB are 32, 64, 128 or 256 radio frames.

- UE radio Capability for paging: including the radio access capabilities of the UE, including the coverage extension capability.

[0039] The paging message transmitted from the eNodeB is broadcast in a defined paging possibility as explained above. Paging possibilities are known to the eNodeB and the UE so that they send/listen to the paging message at the same time.

[0040] When Discontinues Reception (DRX) is used, the UE needs only to monitor one PO per DRX cycle.

[0041] As mentioned before, the paging initiated by the non-access stratum (NAS) is UE specific. Consequently, the UE is paged by using the IMSI (or S-TMSI) of the UE as paging identity in the paging message sent in the PDSCH. Therefore, for each UE a separate paging message has to be transmitted from the MME to the eNB(s), which has then to be broadcast from the corresponding eNB(s).

[0042] The paging message transmitted from the eNodeB to the UE is defined in TS 36.331, current version 12.4.1, subclause 6.2.2 Message definition, section "Paging", incorporated herein by reference. This message may contain the following:

[0043] - cmas-Indication: if present, indication of a CMAS notification

- cn-Domain: indicates the origin of paging

- eab-ParamModification: if present, indication of an EAB parameter (SIB14) modification

- etws-Indication: if present, indication often ETWS primary/secondary notification

- imsi: The International Mobile Subscriber Identity, a globally unique permanent

subscriber identity; can also be part of the Paging UE-Identity below
- systemInfoModification: if present, indication of a BCCH modification, other than SIB10-SIB12, SIB14
- ue-Identity: provides the NAS identity of the UE that is being paged

[0044] In the above description, it has been assumed that the UE is in an idle state when receiving the paging, such that the paging message is sent to the UE addressed to the P-RNTI on PDCCH at the UE-specific paging possibilities (based on IMSI of this UE) where the UE verifies that the paging message is indeed intended for it by checking the IDs in the included paging records.

[0045] However, also UEs in RRC connected state may be paged. In this case a downlink information transfer (DLInformationTransfer), containing the paging related information from the NAS, is sent to the UE addressed to the C-RNTI (Cell-RNTI, a unique ID used for identifying RRC connection and scheduling dedicated to a particular UE) on the PDCCH. The DLInformationTransfer message is used for the downlink transfer of NAS or non-3GPP dedicated information. The RRC layer is transparent for this information. For more information, reference is made to TS 36.331, current version 12.4.1, subclause 5.6.1 "DL information transfer" and 6.2.2 "Message definitions" section DLInformationTransfer, incorporate herein by reference.

[0046] Paging from eNB

One of the reasons for an eNodeB to page the UE is a change of system information. In general a change of system information only occurs at specific radio frames, thus implementing the concept of a modification period. System information may be transmitted a number of times with the same content within a modification period. When the network changes (some of) the system information, it first notifies the UEs about this change, which may be done throughout a modification period. In the next modification period, the network then transmits the updated system information. Upon receiving a change notification, the UE acquires the new system information immediately from the start of the next modification period. A paging message is used to inform the UEs in RRC idle and UEs in RRC connected state about a system information change (as mentioned e.g. in TS 36.304, current version 12.0.0, subclause 6.1). If the UE receives a paging message including the systemInfoModification, it knows that the system information will change at the next modification period and boundary. In said case, the UE does not need to check for the UE_ID (not included in the paging message), in view of the presence of the systemInfoModification. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.3, incorporated herein by reference.

[0047] Another reason for the eNodeB to page the UEs is an ETWS (Earthquake and Tsunami Warning system) notification, where the paging message is used to inform

ETWS-capable UEs in RRC idle and in RRC connected state about the presence of an ETWS primary/secondary notification. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.4, incorporated herein by reference. The paging message may also be used to inform CMAS-capable UEs in RRC idle and RRC connected state about the presence of one or more CMAS (Commercial Mobile Alert System) notifications. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.5, incorporated herein by reference. Still another reason for the eNB to page UEs in its cell relates e.g. to Enhanced Access Barring for MTC devices, EAB, as explained for example in TS 36.331, current version 12.4.1, subclause 5.2.1.6 incorporated herein by reference.

[0048] For UEs in both RRC connected and idle state the eNB sends a paging notification to the UE(s) addressed to the P-RNTI on the PDCCH at all possible paging occasions (e.g. at subframes 0, 4, 5, and 9) and at all possible paging frames (e.g. N different radio frames in total, calculated according to SFN mod T=T/N (UE_ID mod N) for every possible "UE_ID mod N" value) irrespective of the IMSI of a particular UE in the cell. By transmitting the paging message at all possible paging possibilities within a paging cycle, the eNB ensures that all the UEs receive the paging message. The detailed definitions for determining the paging occasions and paging frames are given above.

[0049] Machine Type Communication (MTC)

As LTE deployments evolve, operators strive to reduce the cost of overall network maintenance by minimizing the number of RATs. In this respect, Machine-Type Communications (MTC) devices is a market that is likely to continue expanding in the future.

[0050] Many MTC devices are targeting low-end (low cost, low data rate) applications that can be handled adequately by GSM/GPRS. Owing to the low cost of these devices and good coverage of GSM/GPRS, there is very little motivation for MTC device suppliers to use modules supporting the LTE radio interface.

[0051] As more and more MTC devices are deployed in the field, this naturally increases the reliance on GSM/GPRS networks. This will cost operators not only in terms of maintaining multiple RATs, but also prevent operators reaping the maximum benefit out of their spectrum (given the non-optimal spectrum efficiency of GSM/GPRS). With users and traffic becoming denser, using more spectral-efficient technologies, such as Long Term Evolution (LTE), allow the operators to utilize their spectrum in a much more efficient way.

[0052] Given the likely high number of MTC devices, the overall resource they will need for service provision may be correspondingly significant, and inefficiently assigned (for further details on objectives for MTC, see for example 3GPP, RP-111112, Vodafone:

"Provision of low-cost MTC UEs based on LTE"(NPL 5), section 4, available at http://www.3gpp.org and incorporated herein by reference).

[0053] Approaches to lower the cost of LTE presently regard the volume of products as the primary reason. The impact of volume can be seen in two possible ways, depending on how low-cost MTC is developed. Firstly, if low-cost MTC may be very similar to mainline LTE and included in LTE chipsets, MTC has the benefit of the volume of LTE. Secondly, a low-cost MTC based on LTE may have significantly lower cost than mainline LTE. Although it appears not to have the volume benefit of LTE, the volume of MTC devices can be even larger due to a potentially greater number of supported MTC applications and scenarios.

[0054] In this respect, the following approaches to lower the cost of LTE, i.e. defining low-cost MTC are discussed and found to have significant UE cost impact (for further details on low-cost MTC devices, see for example 3GPP, R1-112912, Huawei, HiSilicon, CMCC: "Overview on low-cost MTC UEs based on LTE"(NPL 6), section 4, available at http://www.3gpp.org and incorporated herein by reference):

[0055] - Reduction in supported bandwidth for the low-cost LTE: The low cost of 1.4 MHz (6 RB) downlink bandwidth could cover most application scenarios of MTC. However, 3 MHz (15 RB) or 5 MHz (25 RB) could be considered given that the complexity does not increase much. Given that the uplink may have a larger requirement for MTC services, the possibility of reduced transmit power, and small baseband complexity (relative to downlink reception), any reduction in minimum transmission bandwidth in the UE should be carefully justified.

[0056] - Modified PDCCH-related design for the low-cost LTE to simplify the PDCCH blind decoding and give efficient channel access for a large number of MTC devices. A reduction in maximum bandwidth (e.g., 1.4MHz) decreases PDCCH blind decoding naturally.

[0057] - Protocol simplification including HARQ consideration, MAC, RLC and RRC protocol. Signaling reduction between low duty cycle MTC devices and the base station.

- Transmission modes down-selection to maintain coverage and balance complexity.

[0058] Further considerations on low-cost MTC devices relate to an improved indoor coverage. A number of applications require indoor deployment of Machine Type Communication, MTC, devices, e.g. in an apartment basement, or on indoor equipment that may be close to the ground floor etc. These UEs would experience significantly greater penetration losses on the radio interface than normal LTE devices. This effectively means that indoor coverage should be readily available and reliable: i.e. should provide a significant improvement on existing coverage.

[0059] Additionally, regarding the power consumption of low-cost MTC devices it is noted

that many applications require devices to have up to ten years of battery life. In this respect, presently available Power Save Modes appear not sufficient to achieve the envisaged battery life. In this respect, it is anticipated that further techniques are proposed to significantly cut down the power usage of MTC devices e.g. by optimizing signaling exchanges in the system, in order to realize battery life of up to ten years.

[0060] Enhanced Coverage mode (EC mode)

For improving indoor coverage (for low-cost MTC devices), recent developments have focused on an Enhanced Coverage, EC, mode that is applicable to UEs e.g. operating delay tolerant MTC applications. Another term is "Coverage Extension". The corresponding Work Item in 3GPP Release 12 "Low cost & enhanced coverage MTC UE for LTE" came to the conclusion that further complexity reduction of LTE devices for MTC can be achieved if additional complexity reduction techniques are supported, as apparent from the study report TR 36.888. The study report TR 36.888 concluded that a coverage improvement target of 15-20 dB for both FDD and TDD in comparison to a normal LTE footprint could be achieved to support the use cases where MTC devices are deployed in challenging locations, e.g. deep inside buildings, and to compensate for gain loss caused by complexity-reduction techniques. MTC coverage enhancements are now expected to be introduced in 3GPP Release 13.

[0061] The general objective is to specify a new UE for MTC operation in LTE that allows for enhanced coverage and lower power consumption. Some of the additional objectives are given below:

- Reduced UE bandwidth of 1.4 MHz in downlink and uplink.

-- Bandwidth reduced UEs should be able to operate within any system bandwidth.

-- Frequency multiplexing of bandwidth reduced UEs and non-MTC UEs should be supported.

-- The UE only needs to support 1.4 MHz RF bandwidth in downlink and uplink.

-- The allowed re-tuning time supported by specification (e.g. ~0 ms, 1 ms) should be determined by RAN4.

[0062] - Reduced maximum transmit power.

-- The maximum transmit power of the new UE power class should be determined by RAN4 and should support an integrated PA implementation.

[0063] - Reduced support for downlink transmission modes.

[0064] - The following further UE processing relaxations can also be considered within this work item:

-- Reduced maximum transport block size for unicast and/or broadcast signalling.

-- Reduced support for simultaneous reception of multiple transmissions.

-- Relaxed transmit and/or receive EVM requirement including restricted modulation scheme. Reduced physical control channel processing (e.g. reduced number of blind

decoding attempts).

-- Reduced physical data channel processing (e.g. relaxed downlink HARQ time line or reduced number of HARQ processes).

-- Reduced support for CQI/CSI reporting modes.

[0065] A relative LTE coverage improvement - corresponding to 15 dB for FDD - for the UE category/type defined above and other UEs operating delay-tolerant MTC applications with respect to their respective normal coverage shall be possible. At least some of the following techniques, which shall be applicable for both FDD and TDD, can be considered to achieve this:

[0066] - Subframe bundling techniques with HARQ for physical data channels (e.g. PDSCH, PUSCH)

- Elimination of use of control channels (e.g. PCFICH, PDCCH)
- Repetition techniques for control channels (e.g. PBCH, PRACH, (E)PDCCH)
- Either elimination or repetition techniques (e.g. PBCH, PHICH, PUCCH)
- Uplink PSD boosting with smaller granularity than 1 PRB
- Resource allocation using EPDCCH with cross-subframe scheduling and repetition (EPDCCH-less operation can also be considered)

[0067] - New physical channel formats with repetition for SIB/RAR/Paging

- A new SIB for bandwidth reduced and/or coverage enhanced UEs
- Increased reference symbol density and frequency hopping techniques
- Relaxed "probability of missed detection" for PRACH and initial UE system acquisition time for PSS/SSS/PBCH/SIBs can be considered as long as the UE power consumption impact can be kept on a reasonable level.
- Spreading: Spreading refers to spreading of information across resources including time-frequency domain resources or even spreading using Scrambling (or Channelization) codes.

[0068] There can be also other techniques than those listed above.

The amount of coverage enhancement should be configurable per cell and/or per UE and/or per channel and/or group of channels, such that different levels of coverage enhancements exist. The different levels of coverage enhancement could mean different level of CE techniques being applied to support the CE-device transmission and reception. Relevant UE measurements and reporting to support this functionality should be defined.

[0069] For more details, see for example 3GPP RP-141865 "Revised WI: Further LTE Physical Layer Enhancements for MTC"(NPL 7) sourced by Ericsson, available at http://www.3gpp.org and incorporated herein by reference.

[0070] Notably, coverage enhancements of 15/ 20 dB for UEs in the Enhanced Coverage mode with respect to their nominal coverage means that the UEs have to be capable of

receiving extremely low signal strengths. This applies not only to the initial scanning operation, the cell search and the cell selection operation but also the subsequent communication scheme to be performed by the UE.

[0071] Early attempts to define the Enhanced Coverage mode have focused on modifications of the radio transmissions. In this respect, discussions have focused on repeated transmissions as being the main technique to improve the coverage. Repetitions can be applied to every channel for coverage improvement.

[0072] An exemplary implementation of these repeated transmissions prescribes that the same data is transmitted across multiple sub-frames. Yet, it will become immediately apparent that these repeated transmissions will use more resource blocks (time-frequency) resources than required for normal coverage UEs.

Summary

[0074] One non-limiting and exemplary embodiment provides an improved method for paging all user equipments in a cell, particularly involving user equipments which need coverage extension. Another non-limiting and exemplary embodiment provides an improved method for paging one user equipment in a cell, particularly a user equipment which needs coverage extension.

The independent claims provide non-limiting and exemplary embodiments. Advantageous embodiments are subject to the dependent claims.

According to a first aspect, the present disclosure improves the paging procedure by which a radio base station can page the user equipments in its cell, particularly for the case where the paging shall also reach user equipments which require coverage extension, i.e. user equipments that are in poor radio conditions but support coverage extension techniques as explained in the background section. The first aspect refers to the case were paging is initiated by the radio base station and shall reach all user equipments in the cell of the radio base station; in other words, the paging is not UE specific but cell specific, and can be for example used so as to broadcast a warning message or to inform UEs about an imminent system information change.

[0075] Consequently, the paging must reach user equipments that require coverage extension as well as "normal" user equipments which do not require coverage extension. One main idea of the first aspect is the definition of a coverage-extension-specific paging possibility, which is specifically defined for those user equipments that support coverage extension techniques, and more precisely which need coverage extension to be reliably reached. Correspondingly, the CE-UEs not only monitor the UE-specific paging possibility, calculated based on their identities, but additionally monitor a (at least one) different paging possibility dedicated to achieve coverage extension paging. Both CE-user equipments in idle and connected state can be configured to monitor this CE-specific paging possibility. Consequently, in order to reach those CE-UEs, the radio base station pages the CE-UEs at said CE-specific paging possibility, and uses one of the plurality of available techniques (e.g. repetition or increased transmission power) for extending the coverage of the paging and thus to reliably reach the CE-UE.

[0076] Like a usual UE-specific paging possibility, this CE-specific paging possibility is defined by a particular radio frame number and subframe number, and occurs regularly e.g. at every paging cycle.

[0077] Since the CE-specific paging possibility shall preferably only be monitored by CE-UEs, the radio base station still needs to reach the other non-CE-UEs and can thus, as described in the background section, perform the paging at all possible paging possibilities of a paging cycle, so as to reach all UEs in the cell. In this case the radio base station would not use a coverage extension technique, since the radio base station can be sure that the CE-UEs will be reached by the paging at the CE-specific paging possibility and not for all possible.

[0078] One advantage of the above-described first aspect is that, by providing one dedicated paging possibility for CE-UEs, downlink resources can be saved. The coverage extension techniques, which can be a heavy burden to the radio base station(s) are applied in a very limited manner, namely for just one paging possibility.

[0079] One set of variants of the first aspect differs as to how this CE-specific paging pos-

sibility is defined. In general, it can be said that the CE-specific paging possibility must be known to both the CE-UE(s) and the radio base station(s), so as to ensure that the paging can be successful. However, how exactly the CE-specific paging possibility is defined can vary. One solution is that the radio frame number and the subframe number of the CE-specific paging possibility is fixed beforehand such that corresponding information can be e.g. pre-stored at the radio base station and the CE-UE (e.g. in the USIM), or the radio base station can broadcast same in its cell. Another possible solution is that a plurality of possible paging subframes, generally configured for the system by the radio base station, is divided to be used either as a UE-specific paging subframe or as a CE-specific paging subframe. By correspondingly configuring the paging parameter(s) (e.g. nB) of normal UEs and CE-UEs it is possible that CE-UEs are assigned e.g. one normal UE-specific paging subframe and one CE-specific paging subframe. Still another solution is based on an additional CE-specific UE identity that is assigned exclusively to CE-UEs and which can be used for calculating the CE-specific paging possibility; in addition, as in the prior art, the UE-specific paging possibility is calculated based on the usual identity of the CE-UE (e.g. IMSI).

[0080] According to a second aspect, the paging procedure by which a radio base station pages a user equipment which requires coverage extension in its cell is improved. This second aspect refers to the case where the paging is initiated in the core network (NAS) and is destined to a single UE (or a very limited number of UEs), in contrast to the first aspect dealing with cell-wide paging initiated by the eNB. The paging which is directed at a particular CE-UE shall reliably reach the CE-UE, and thus the radio base station shall use one appropriate coverage extension technique for the CE paging. In order to avoid unnecessary CE paging from the radio base station, the CE-capable UEs will implement a measurement and reporting procedure according to which the radio base station is informed as to the current CE status of the UE. The radio base station will thus only perform a CE paging for a CE-capable UE that is indeed currently in the CE status, i.e. currently requiring coverage extension. CE-UEs, although CE capable, will not be paged with a coverage extension technique, if the status of the CE-capable UE, informed to the radio base station, indicates that no coverage extension is actually required by this CE-capable UE at the moment.

[0081] Appropriate radio measurements are regularly performed by the CE-capable UE(s) to determine whether coverage extension is necessary or not at the moment. The measurements could also be triggered by the radio base station or a core network entity when being interested in the current CE status. These measurements could include e.g. at least one of RSRQ, RSRP, channel quality, block error rate, or any other suitable measurement parameter. Appropriate threshold(s) can be defined to which the CE-capable UE(s) compare(s) the measurement results to determine whether it requires or

not coverage extension.

[0082] Consequently, a particular CE-capable UE can change it CE-status, i.e. toggle between being a CE-UE (i.e. indeed requiring coverage extension) and a non-CE-UE (i.e. supporting CE but not requiring CE at the moment).

[0083] The radio base station is kept updated on the current CE status of the CE-capable UE and thus (should) knows at the time of paging whether coverage extension is indeed necessary or not for the paging. In order to limit uplink traffic, the informing of the radio base station could be limited to the cases where the CE status of the CE-capable UE is changed, i.e. from non-CE-UE to CE-UE and vice versa. Of course it should also be possible for the CE-capable UE to measure and report such information/ measurements periodically even in the absence of said toggling. In this case, the eNB could, based on its implementation, perform some averaging of the received information including measurement reports and determine that a toggling of CE state is indeed helpful. The step of informing may be done, e.g. directly between the CE-capable UE and the radio base station, e.g. for CE-capable UEs that are in connected state and thus may provide the corresponding CE status to the radio base station. Alternatively, the CE-capable UE may report to a core network entity, which in turn may inform the radio base station, at the latest when triggering for paging; this may be done e.g. for those cases where the CE-capable UE is in idle state and thus has no active connection with the radio base station.

[0084] Correspondingly, the paging for CE-UE is performed by the radio base station by using a CE technique, whereas paging for a non-CE-UE is performed without using a CE technique. The CE-capable UE appropriately receives the CE paging or normal paging.

[0085] Correspondingly, in one general first aspect, the techniques disclosed here feature a method for paging all user equipments in a cell controlled by a radio base station in a mobile communication system. At least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment. The CE user equipments in the cell regularly monitor the at least one CE-specific paging possibility. When the radio base station determines to page all the user equipments in the cell, the radio base station pages the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0086] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities is defined for paging a specific user equipment in the cell of the radio base station. The

CE user equipments and non-CE user equipments each monitor a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities. The radio base station — upon determining to page all the user equipments in the cell - additionally performs paging at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension. According to a further example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0087] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and subframe number and is repeated every paging cycle. The at least one CE-specific paging possibility is only monitored by CE user equipments. For example, the at least one CE-specific paging possibility is monitored by CE user equipments in idle state and CE user equipments in connected state.

[0088] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the step of paging includes transmitting by the radio base station a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and includes transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification. For example, the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[0089] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the plurality of techniques for achieving the coverage extension comprise at least one of a repetition technique where a message is repeated by the radio base station for a pre-configured number of times, an increase in transmission power, where a message is transmitted by the radio base station with an increased transmission power, a bundling technique where a .same message is transmitted in a plurality of consecutive subframes, and a spreading technique where a message is transmitted by a larger resource, e.g. via a larger frequency-time resource or channelization code.

[0090] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the step of determining by the radio base station to page all user equipments in the cell is triggered by a change of system information applicable to the cell controlled by the radio base station or by the presence of a message, e.g. a warning message, to be broadcast in the cell controlled by the radio base station.

[0091] According to an advantageous variant of the first aspect which can be used in

addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. For example, information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment, or broadcast by the radio base station in the cell. Further exemplary, the pre-configured subframe number is 1, 2, 3, 6, 7, or 8.

[0092] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of paging possibilities are defined for paging in the cell of the radio base station, wherein a first value of at least one parameter for calculating the UE-specific paging possibility is different from a second value of the at least one parameter for calculating a CE-specific paging possibility such that the plurality of paging possibilities are divided to be used either as the CE-specific paging possibility or the UE-specific paging possibility. CE user equipments are configured to use the first value of the at least one parameter for calculating the UE-specific paging possibility and to use the second value of the at least one parameter for calculating the CE-specific paging possibility. Non-CE user equipments are configured to use the first value of the at least one parameter for calculating the UE-specific paging possibility and to not calculate the CE-specific paging possibility.

[0093] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, 6, wherein CE user equipments are assigned a CE-specific user equipment identity based on which the CE-specific paging possibility is calculated by the radio base station and the CE user equipments. For example, the CE-specific user equipment identity is the same for all CE-configured user equipments, and the CE-specific user equipment identity is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment or broadcast by the radio base station in the cell. Further for example, a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific user equipment identity is defined.

[0094] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, wherein a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific paging possibility is defined for paging the CE user equipments configured for that level of coverage extension.

[0095] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the radio base station determines whether there are CE user equipments in idle state in its cell by performing a counting procedure

where the CE user equipments in idle state inform the radio base station about their presence in the cell controlled by the radio base station. For example, the determination is only performed in case there are no CE user equipments in connected state in the cell.

[0096] Correspondingly, in one general first aspect, the techniques disclosed here feature a user equipment located in a cell controlled by a radio base station in a mobile communication system. The user equipment, in short CE user equipment, requires coverage extension, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for the CE user equipment. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE user equipment. A processor of the CE user equipment regularly monitors the at least one CE-specific paging possibility. A receiver of the CE user equipment receives a paging from the radio base station at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0097] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities is defined for paging a specific user equipment in the cell of the radio base station. The processor of the CE user equipment monitors a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities. In a further example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0098] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and subframe number and is repeated every paging cycle. In a further example, the at least one CE-specific paging possibility is monitored by the CE user equipment when in idle state and when in connected state.

[0099] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the receiver receiving the paging includes: receiving a first paging notification at radio resources of a control channel specific by the at least one CE-specific paging possibility, and includes receiving a second paging message at radio resources of another channel specific by the first paging notification. In a further example, the technique for achieving the coverage extension is used by the CE user equipment to both receive the first paging notification and receive the second paging message.

[0100] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging pos-

sibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. In a further example, a memory of the CE user equipment is adapted to store information to determine the pre-configured radio frame number and the pre-configured subframe number. Exemplarily, the memory is a Universal Subscriber Identity Module, USIM, of the CE user equipment. Or, the receiver of the CE user equipment receives information to determine the pre-configured radio frame number and the pre-configured subframe number, broadcast by the radio base station in the cell.

[0101] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the CE user equipment is assigned a CE-specific user equipment identity, wherein the processor of the CE user equipment is adapted to calculate the CE-specific paging possibility based on the CE-specific user equipment identity. Exemplarily, the CE-specific user equipment identity is the same for all CE-configured user equipments. In a further example, a plurality of different levels of coverage extension is defined. For each level of coverage extension a different CE-specific user equipment identity is defined.

[0102] Correspondingly, in one general first aspect, the techniques disclosed here feature a radio base station for paging all user equipments in a cell controlled by the radio base station in a mobile communication system. At least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment. A processor of the radio base station determines whether to page all the user equipments in the cell. A transmitter of the radio base station pages the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0103] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities are defined for paging a specific user equipment in the cell of the radio base station, wherein transmitter of the radio base station — upon the processor determining to page all the user equipments in the cell —additionally pages at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension. For example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0104] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the transmitter of the radio base station is

adapted to transmit a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and to transmit a second paging message at radio resources of another channel specified by the first paging notification. Exemplarily, the technique for achieving the coverage extension is applied to both the transmitting of the first paging notification and the transmitting of the second paging message.

[0105] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the processor determines to page all the user equipments in the cell when being triggered by a change of system information applicable to the cell controlled by the radio base station or by the presence of a message, e.g. a warning message, to be broadcast in the cell controlled by the radio base station.

[0106] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. Exemplarily, information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in the radio base station, wherein the transmitter of the radio base station broadcasts the information to determine the pre-configured radio frame number and subframe number.

[0107] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a CE-specific user equipment identity is assigned to the CE user equipments, wherein the processor of the radio base station is adapted to calculate the CE-specific paging possibility based on the CE-specific user equipment identity. Exemplarily, the transmitter of the radio base station is adapted to broadcast the CE-specific user equipment identity in the cell.

[0108] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the processor of the radio base station determines whether there are CE user equipments in idle state in its cell by performing a counting procedure. Exemplarily, the determination is only performed in case there are no CE user equipments in connected state in the cell.

[0109] Correspondingly, in one general second aspect, the techniques disclosed here feature a method for paging a user equipment in a cell controlled by a radio base station in a mobile communication system. The user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. Radio measurements are performed by the CE-capable user equipment, which determines whether coverage extension is necessary or not, based on the results of the

radio measurements. The radio base station is informed about whether the CE-capable user equipment needs coverage extension or not, based on the determination result. When paging the CE-capable user equipment, the radio base station applies or not applies one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[0110] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[0111] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of determining whether coverage extension is necessary comprises the step of comparing by the CE-capable user equipment the result of the radio measurements with a first threshold to determine whether coverage extension is necessary. For example, the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold. The step further comprises comparing by the CE-capable user equipment the result of the radio measurements with a second threshold to determine whether coverage extension is not necessary. For example, the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[0112] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of informing the radio base station about the CE-capable user equipment needing coverage extension or not, includes the steps of either transmitting by the CE-capable user equipment information about whether the CE-capable user equipment needs coverage extension or not to the radio base station. In this case, for example the CE-capable user equipment is in a connected state. In a further example, it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state. Alternatively, the step of informing includes the steps of transmitting by the CE-capable user equipment information about whether the CE-capable user equipment needs coverage extension or not to a core network entity. In this case, the core network entity provides the received information to the radio base station. For example, the CE-capable user equipment is in a connected state or in an idle state. In a further example, the core network entity is a mobility management entity.

[0113] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio base station is triggered to page the CE-capable user equipment by a core network entity that initiates and controls the paging,

preferably wherein the core network entity initiating the paging is a mobility management entity.

[0114] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the steps of performing the radio measurements and of determining whether coverage extension is necessary or not is performed regularly at a pre-configured time interval and/or triggered by the radio base station.

[0115] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of informing the radio base station is only performed when the result of the determination is different from the result of the determination previously informed to the radio base station.

[0116] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio base station determines whether the CE-capable user equipment needs coverage extension or not based on the radio resources selected by the CE-capable user equipment for initially attaching to the radio base station; for example, based on the selected preamble or access slot used for a random access procedure performed by the CE-capable user equipment when initially attaching to the radio base station.

[0117] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of paging the CE-capable user equipment comprises the steps of transmitting by the radio base station a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE-capable user equipment, and transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification. In a further example, the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[0118] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, upon successfully being paged by the radio base station, the CE-capable user equipment informs the radio base station about the successful paging, and the radio base station can inform a core network entity responsible for initiating the paging about the successful paging.

[0119] Correspondingly, in one general second aspect, the techniques disclosed here feature a user equipment located in a cell controlled by a radio base station in a mobile communication system. The user equipment, in short CE user equipment, supports coverage extension techniques. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. A processor of the CE user equipment performs radio measurements, and determines whether coverage extension is necessary or not, based on the results of the

radio measurements. A transmitter of the CE user equipment informs the radio base station about whether the CE-capable user equipment needs coverage extension or not, based on the determination result. A receiver of the CE user equipment receives paging from the radio base station, applying or not applying one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not.

[0120] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[0121] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the processor determines whether coverage extension is necessary or not by comparing the result of the radio measurements with a first threshold to determine whether coverage extension is necessary. For example, the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold. Furthermore, the result of the radio measurements is compared with a second threshold to determine whether coverage extension is not necessary. For example, the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[0122] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter informs the radio base station by transmitting information about whether the CE-capable user equipment needs coverage extension or not to the radio base station. For example, the CE-capable user equipment is in a connected state, and furthermore it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state. Alternatively, information about whether the CE-capable user equipment needs coverage extension or not is transmitted to a core network entity. The core network entity provides the received information to the radio base station, preferably wherein the CE-capable user equipment is in a connected state or in an idle state.

[0123] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the processor performing the radio measurements and determining whether coverage extension is necessary or not is performed regularly at a pre-configured time interval and/or triggered by the radio base station.

[0124] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter informs the radio base station

only when the result of the determination is different from the result of the determination previously informed to the radio base station.

[0125] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the receiver receiving the paging includes receiving a first paging notification at radio resources of a control channel specific by a paging possibility specific to the CE-capable user equipment, and receiving a second paging message at radio resources of another channel specific by the first paging notification. For example, the technique for achieving the coverage extension is used by the CE user equipment to both receive the first paging notification and receive the second paging message.

[0126] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter is further adapted to inform the radio base station about the successful paging.

[0127] Correspondingly, in one general second aspect, the techniques disclosed here feature a radio base station for paging a user equipment in a cell controlled by the radio base station in a mobile communication system. The user equipment supports coverage extension techniques. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. A receiver of the radio base station receives information about whether the CE-capable user equipment needs coverage extension or not. A transmitter of the radio base station, when paging the CE-capable user equipment, applies or not applies one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[0128] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the receiver receiving the information includes receiving from the CE-capable user equipment or from a core network entity the information about whether the CE-capable user equipment needs coverage extension or not.

According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter of the radio base station transmit a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE user equipment, and transmit a second paging message at radio resources of another channel specified by the first paging notification. For example, the technique for achieving the coverage extension is applied to both the transmitting of the first paging notification and the transmitting of the second paging message.

[0129] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, a receiver of the radio base station receives in-

formation about the successful paging of the CE user equipment, and the transmitter of the radio base station informs a core network entity responsible for initiating the paging about the successful paging.

[0130] Additional benefits and advantages of the disclosed embodiments will be apparent from the specification and Figures. The benefits and/or advantages may be individually provided by the various embodiments and features of the specification and drawings disclosure, and need not all be provided in order to obtain one or more of the same.

[0131] These general and specific aspects may be implemented using a system, a method, and a computer program, and any combination of systems, methods, and computer programs.

Description of Embodiments

[0133] A mobile station or mobile node or user terminal or user equipment is a physical entity within a communication network. One node may have several functional entities. A functional entity refers to a software or hardware module that implements and/or offers a predetermined set of functions to other functional entities of a node or the network. Nodes may have one or more interfaces that attach the node to a commu-

nication facility or medium over which nodes can communicate. Similarly, a network entity may have a logical interface attaching the functional entity to a communication facility or medium over which it may communicate with other functional entities or correspondent nodes.

[0134] The term "radio resources" as used in the set of claims and in the application is to be broadly understood as referring to physical radio resources, such as time-frequency resources.

The term "paging possibility" as used in the set of claims and in the application is to be broadly understood as referring to physical radio resources (frequency-time resources) of a control channel (e.g. the PDCCH), which are defined by a radio frame number (also termed paging frame, PF) and a subframe number (also termed paging occasion, PO).

[0135] The expression "coverage-extension UE" (or "CE UE") as used in the set of claims and in the application is to be broadly understood as referring to a UE which requires coverage extension, e.g. because it is in a bad radio condition. The expression "CE-capable UE" shall be used for a UE supporting the coverage extension techniques, irrespective of whether or not the UE indeed requires coverage extension, i.e. a UE can support coverage extension techniques but can still be understood as a "non-CE UE" in case that no coverage extension is currently necessary. From eNB-perspective, it may be unclear at any particular point in time whether a CE-capable UE indeed requires coverage extension or not. The second embodiment is directed at said drawback.

[0136] Correspondingly, the expression "non-CE-UE" as used in the set of claims and in the application is to be broadly understood as referring to a UE which either does not require coverage extension (even when actually supporting the corresponding CE techniques) or does not support coverage extension techniques.

[0137] The expression "UE-specific paging possibility" as used in the set of claims and in the application is to be broadly understood as that paging possibility which is calculated based on the UE-ID (e.g. IMSI), and should be understood in the context of the CE-specific paging possibility which is specific to only coverage extension. As described in the background section, there is only a limited amount of paging possibilities available, across which the UEs are then disposed depending on their IDs. Although a particular paging possibility may be monitored by several UEs, the paging possibilities are UE-specific in the sense that the paging possibility to be monitored by a UE is determined based on the respective UE-ID.

[0138] The terms "paging notification" and "paging message" are distinguished in the set of claims and in the application to respectively refer to the first PDCCH message (which is basically an indication notifying about a paging message e.g. by use of the common P-RNTI) and the subsequent PDSCH message with the actual paging information. The

term "paging" does not make this distinction and shall cover both.

[0139] The term "CE-page" or "CE-paging" as used in the application shall refer broadly to a paging where one out of a plurality of coverage extension techniques is used. For example, when considering the repetition technique as the CE-technique used by an eNB, the "CE-page" will involve repeating the transmission of both paging messages, i.e. the paging notification on the PDCCH and the actual paging message on the PDSCH, for a pre-configured number of times as defined for the repetition technique.

[0140] As explained in the background section, coverage extension techniques are to be implemented for (MTC) devices, and it is unclear how the coverage extension shall be achieved for the paging procedure. However, expenditure is quite high for any of these techniques, such that they should be only used when necessary. For the paging which is initiated by the eNB, and is directed to all UEs in the cell, the currently-implemented paging is applied to all possible paging possibilities so as to reach all UEs. In order to reach also the CE-UEs, a coverage extension technique may be applied to the paging at all possible paging possibilities, which however results in a high expenditure of resources.

[0141] For the paging which is initiated by the NAS, and is directed to one UE only (or a very limited number of UEs), the MME inform the eNB over the S1 interface about the capability of a RRC_Connected UE to allow coverage extension and thus to support the coverage enhancement techniques mentioned above. However, it is unclear whether the UE is actually requiring coverage extension at the time of the page, (e.g. the UE, e.g. MTC device, moved from the cellar to open terrain). Consequently, the eNB might page the UE at the UE-specific paging possibility by using one of the CE techniques, even though the UE is in a good radio condition and would not have needed a coverage extension page. Again, resources are wasted.

[0142] The following exemplary embodiments are conceived by the inventors to mitigate the problems explained above.

[0143] Some of these are to be implemented in the wide specification as given by the 3GPP standards and explained partly in the background section, with the particular key features as explained in the following pertaining to the various embodiments. It should be noted that the embodiments may be advantageously used for example in a mobile communication system, such as 3GPP LTE-A (Release 10/11/12/13) communication systems as described in the Technical Background section above, but the embodiments are not limited to its use in this particular exemplary communication networks.

[0144] The explanations should not be understood as limiting the scope of the disclosure, but as a mere example of embodiments to better understand the present disclosure. A skilled person should be aware that the general principles of the present disclosure as laid out in the claims can be applied to different scenarios and in ways that are not ex-

plicitly described herein. Correspondingly, the following scenarios assumed for explanatory purposes of the various embodiments shall not limit the present disclosure and its embodiments as such.

[0145] In the following a set of embodiments will be explained. Although in the following embodiment, the broad expressions UE, CE-UE, CE-capable UE, are used, the embodiments may be equally applied for MTC devices, i.e. a CE-MTC device or CE-capable MTC device etc.

[0146] First embodiment

According to a first exemplary embodiment, a paging procedure according to which the eNB can page all the UEs in its cell, including those UEs which require coverage extension (and of course also support coverage extension), is presented.

[0147] For this first embodiment it is assumed that the paging is initiated (i.e. triggered) by the eNB itself; in contrast to paging being initiated by the Non-Access-Stratum for which the second embodiment provides an improved paging procedure. As already explained in the background section, paging may be initiated by the eNB for several reasons. For example, system information applicable to the cell may change, and the eNB wants to notify the UEs in its cell such that the UEs may acquire the updated system information immediately from the start of the next modification period. Another reason is that a warning message shall be broadcast in the cell, such as a message from the ETWS or CMAS system, or a message in relation to EAB (Enhanced Access Barring for MTC devices). More detailed information is omitted here, and reference is made to the corresponding passages in the background section which equally apply to the first embodiment.

[0148] Consequently, due to nature of those reasons, the eNB wants to make sure that the paging reaches all UEs in the cell, including those UEs which need coverage extension to be successfully reached. According to the first embodiment, a paging possibility is established for specifically paging those CE-UEs, termed in the following CE-specific paging possibility. More precisely, a CE-specific paging frame and a CE-specific subframe are defined referring to radio resources of the PDCCH that can be used for the CE-paging. In a similarly manner as for the UE-specific paging possibilities defined in the current systems, the CE-specific paging possibility shall occur regularly, e.g. in a cyclic manner according to the paging cycle followed by the UE. The CE-specific paging possibility can be defined in addition to the normal UE-specific paging possibilities already established by the prior art, as discussed in the background section. The CE-specific paging possibility is independent from the UE's identity and shall be the same for a plurality of CE-UEs, e.g. CE-UEs of a particular cell or all CE-UEs in general (or at least all CE-UEs of a specific CE level as will be explained later); this is different from the normal UE-specific paging possibility which — even though

several UEs may monitor the same paging possibility - is specific to the UE due to being calculating based on the ID of the UE(s). This CE-specific paging possibility is known at least to the eNB and the CE-UEs; non-CE-UEs may or may not be informed about this CE-specific paging possibility; however, these non-CE-UEs shall not monitor the CE-specific paging possibility since they may be reached by "normal", i.e. non-CE, paging.

[0149] Furthermore, the paging initiated by the eNB shall reach both UEs in RRC-idle state as well as UEs in RRC-connected state. Consequently, the CE-specific paging possibility shall be monitored by UEs in RRC-idle state and UEs in RRC-connected state.

[0150] The CE-UEs regularly monitor the CE-specific paging possibility to receive the CE-paging, thereby ensuring that they can be successfully paged.

[0151] From the perspective of the eNB, when a page is triggered (e.g. by a system information change), in order to reach the CE-UEs, the eNB will wait for the corresponding paging opportunity given by the CE-specific paging possibility and will then perform a CE page at the CE-specific paging possibility which is monitored by all the CE-UEs in its cell. In a similar manner as for the UE-specific paging possibility, this particularly involves the transmission of the paging notification on the PDCCH at that radio frame and subframe of the CE-specific paging possibility and the corresponding transmission of the paging message on resources of the PDSCH as indicated by the paging notification on the PDCCH. This transmission of the two messages of the CE page is performed by using one appropriate technique of the plurality of CE techniques which are foreseen for achieving the coverage extension, e.g. a repetition technique or a technique where a significantly increased power is used for the transmission.

[0152] The CE-UE(s) in the cell of the eNB monitor the CE-specific paging possibility and thus will receive the paging notification on the PDCCH and subsequently the paging message on the PDSCH. Furthermore, since the eNB will use a coverage extension technique for the paging, which is known to the CE-UE(s), the CE-UE(s) will correspondingly react to the CE-paging by e.g. additionally receiving the repetitions of the paging notification and paging message.

[0153] The paging message will inform the CE-UE(s) about e.g. the system information change or a warning message etc. Depending on the content of the paging message on the PDSCH, the CE-UE will react accordingly, e.g. by acquiring the system information at the next modification period or by providing the warning message to the user of the CE-UE.

[0154] Of course, in a preferred first embodiment the eNB will also want to page the other (non-CE) UEs and for said purpose will page them at all possible paging possibilities, as discussed in the background section, i.e. this will be done without using any CE technique. The non-CE-UEs will each monitor their UE-specific paging possibility and

will thus receive one of the paging performed by the eNB.

[0155] In general, the CE-specific paging possibility may be different from any of the UE-specific paging possibilities, assignable for the UEs, although this is not strictly necessary for the functioning of the first embodiment. For example, only subframes 1, 2, 3, 6, 7, and 8 might be possible for the CE-specific paging possibility, considering that the other subframes 0, 4, 5, 9 are candidates for being selected/calculated as the UE-specific paging possibilities.

[0156] In one possible embodiment, the CE-UEs may keep on regularly monitoring their UE-specific paging possibility, calculated based on their identity as explained in the background section, in addition to the CE-specific paging possibility. Alternatively, the CE-UEs may not monitor the CE-specific paging possibility and the UE-specific paging possibility at the same time, but may only monitor the CE-specific paging possibility.

[0157] Fig. 5 shows, in a similar manner as Fig. 3, the paging possibilities monitored by two different CE-UEs, UE1 and UE2. As apparent from Fig. 5, it is assumed that CE-UE1 monitors a UE-specific paging possibility at radio frame number 76 and number 204 (76+128) etc., respectively at subframe 9 (see also Fig. 3, case B), and that CE-UE2 monitors a UE-specific paging possibility at radio frame number 19 and 147 (19+128) etc., respectively at subframe 4 (see also Fig. 3, case C). In addition, both CE-UE1 and CE-UE2 monitor the same CE-specific paging possibility, which in this exemplary illustration, is assumed to occur at CE-specific paging frames 36, 164 (36+128) etc. and at respective CE-specific subframe 1.

[0158] Fig. 6 shows a sequence diagram for the behavior of a CE-UE for an exemplary variant of the first embodiment. Particularly, it is assumed, in concordance with Fig. 5, that the CE-UE monitors both the CE-specific paging possibility as well as the UE-specific paging possibility, and when it receives the paging notification, the CE-UE will proceed to receive the corresponding paging message at the PDSCH resources indicated by the PDCCH paging notification, either applying or not applying a CE technique. Depending on the content of the paging message, the CE-UE will then react accordingly.

[0159] Fig. 7 shows a sequence diagram for the corresponding behavior of an eNB which wants to perform a paging. After the eNB decides to perform a paging of all UEs in its cell (e.g. due to system information change), it will proceed to perform the usual page at all possible UE-specific paging possibilities to reach all non-CE-UEs, without using any CE technique. On the other hand, to also reach the CE-UEs, the eNB will perform the CE paging at the CE-specific paging possibility, by using one appropriate CE-technique (e.g. repetition or increased transmission power).

[0160] The first embodiment as explained above has the advantage that the use of the

coverage extension technique(s) is limited to one particular CE-specific paging possibility, instead of having to be applied to all possible UE-specific paging possibilities. By using one paging possibility, all (or at least a plurality) of CE-UEs can be paged at the same time. Corresponding downlink resources can thus be saved. Furthermore, the CE-specific paging possibility is independent from the real IMSI of any CE-UE.

[0161] The CE-specific paging possibility can be defined in a number of different ways, but must always provide a CE-specific paging radio frame number and CE-specific paging subframe number, known to both the CE-UE(s) and the eNB(s).

[0162] According to a first variant of the first embodiment, the CE-specific paging possibility is fixed beforehand, e.g. not calculated but directly indicated. In one example, the numbers for the CE-specific paging radio frame and subframe are directly defined e.g. in the CE-UE (e.g. in its USIM, UICC etc) and the eNB; in other words, the CE-UE and the eNB would have information indicating particular radio frame and subframe numbers (such as radio frame number 36 and subframe number 1, as for the example of Fig. 4) for the CE-specific paging possibility. This information need not be pre-stored in the CE-UE (e.g. by use of the USIM) but could also be broadcast by the eNB in its cell, e.g. as part of the system information or indicated with a dedicated message when possible, such that the CE-UE(s) learn about the CE-specific paging possibility to be used for CE-paging from the eNB. This would allow different CE-specific paging possibilities to be used by different eNBs.

[0163] Alternatively, instead of directly indicating the CE-specific subframe number, the parameters Ns and i_s (already known from the calculation of the UE-specific paging possibility) could be reused in said respect. In particular, the following exemplary extended table can be used, which, in comparison with the table available from TS 36.304 as explained in the background section, includes at least one additional row for e.g. Ns= 5 (any other unused Ns number can be used of course) with the possible POs at subframes 1, 2, 3, and 6.

[0164] [Table 3]

Ns	PO when i_s=0	PO when i_s=1	PO when i_s=2	PO when i_s=3
1	9	N/A	N/A	N/A
2	4	9	N/A	N/A
4	0	4	5	9
5	1	2	3	6

[0165] For this alternative, Ns and i_s values would be pre-configured for the CE-specific paging possibility such that the CE-UE and eNB could determine, based on the exemplary table above, which CE-specific paging subframe to use. The CE-specific

paging radio frame would in this example still be directly indicated by a corresponding radio frame number.

[0166] The advantage of this first variant is that the CE-UE(s) would not need to calculate Ns and i_s, but may directly use the indicated numbers for the radio frame and subframe of the CE-specific paging possibility.

[0167] According to a second variant of the first embodiment to define the CE-specific paging possibility vis-a-vis the UE-specific paging possibility, the CE-specific paging possibilities are defined by providing different parameter values to the CE-UE(s) than to the non-CE-UEs. It is assumed, that the CE-specific paging subframe is calculated following the equations and principles explained for the UE-specific paging possibility in the background section. By using different parameter values for the same UE, the calculation of the UE-specific paging subframe yields different subframe numbers than the corresponding subframe numbers of the CE-specific paging possibility. As with the first variant explained above, the radio frame number for the CE-specific paging possibility is fixed.

[0168] In one example, the parameter with the different value is "nB", i.e. indicating the number of paging subframes per paging cycle (across all UEs in the cell), where one value is defined for CE-UEs and another value is defined for non-CE-UEs. There could however be another parameter broadcasted by the network for indicating rather directly the segregation of paging subframes between CE-UEs and non-CE-UEs.

[0169] According to a third variant of the first embodiment to define the CE-specific paging possibility, a CE-specific UE identity (e.g. CE-IMSI) is introduced. When considering the various CE levels a CE-UE can be configured for, a CE-level-specific UE identity can be introduced for each CE level. In any case, the CE-IMSI(s) is known to both the eNB and the CE-UE(s). The CE-specific UE identity(ies) can be provided to the CE-UEs beforehand, e.g. broadcast in the cell, or pre-stored in the SIM/ USIM or UICC or even in the Mobile Device, ME. A particular CE-UE and the network will use one of these identities corresponding to the required level of coverage extension support required e.g. one CE-UE deep down in bad radio and the network will use UE-identity1; whereas the same UE when coming back in relatively better radio, but still requiring CE support, will rather use UE-identity2 which is the corresponding use UE-identity for this level of Coverage Extension required. For this to work, it is important that the UE-identity to be used and the corresponding coverage extension required is known to both the network and the CE-UE e.g. by way of specification, or broadcasting etc. and there is a hand-shake between the CE-UE and the network about what level applies to the particular CE-UE at any given point in time. The hand-shake includes the measurement configuration and reporting as described previously.

[0170] It is assumed that basically the same calculation and principles are applied when cal-

culating the CE-specific paging possibility as explained for the UE-specific paging possibility in the background section. Both the eNB and the CE-UE(s) can calculate the same CE-(level)-specific paging possibility by the CE-(level)-specific IMSI instead of using the CE-UE's real IMSI.

[0171] As already mentioned in the background section, different coverage extension levels can be defined (e.g. 15dB, 13 dB etc.), where the respective coverage extension technique can be adapted appropriately to ensure achieving the corresponding coverage extension level. When e.g. considering the repetition CE technique, a coverage extension level to ensure 15dB might require 100 repetitions, whereas less or more repetitions may be necessary to ensure a different CE level. Similarly considerations apply to the other CE-techniques.

[0172] A particular CE-UE is configured for one of those coverage extension levels. Correspondingly, according to further examples of the first embodiment, one CE-specific paging possibility is defined per CE level, i.e. a CE-level-specific paging possibility, such that a CE-UE will only monitor the CE-level-specific paging possibility of the CE-level for which it is configured but not other CE-level-specific paging possibilities that are defined for other CE-levels.

[0173] A further improvement to the first embodiment is that CE-UEs which are in RRC-connected mode may try to read and receive paging at the UE-specific paging possibilities of other UEs. The UE_ID, which is IMSI mod 1024, can only take up to 1024 different values, and the radio frame is calculated based on "UE_ID mod N" such that only N different radio frames are used in each paging cycle. Consequently, a CE-UE could be configured to monitor some or all of the possible radio frames and subframes available for other UEs. This allows the network to not make as many repetitions as would otherwise be required if the UE was not receiving paging other than the UE-specific paging possibilities.

[0174] A further improvement to the first embodiment focuses on when to actually perform a CE page. Until now it has been (silently) assumed that there would be always a CE-UE in a cell, such that any eNB, at any time when paging is triggered, would perform the CE-paging at the CE-specific paging possibility(ies). The eNB is aware of all (CE-)UEs that are in RRC-Connected mode, since these have an active connection with the eNB, and thus the eNB determines whether a CE-UE that require coverage extension is in its cell or not. However, the eNB is not aware of which CE-UEs in RRC-Idle mode are currently in its cell. Consequently, assuming that no CE-UEs in RRC-Connected mode are in the cell of the eNB, the eNB is unaware of whether there is at least one CE-UE in RRC-Idle mode in its cell. To make sure that any possible CE-UEs in Idle mode are reached too, in these cases, the eNB will always have to performing the CE paging. This however may result in a waste of resources for the

case where no CE-UE(s) in RRC-Idle mode were in its cell either.

[0175] According to this improvement, this waste of resources shall be avoided by providing a procedure that allows the eNB to determine whether any CE-UEs are in its cell, be it in RRC-Idle or RRC-Connected state. To said end, the eNB might first determine whether there are any CE-UEs in RRC-Connected mode, which could be done e.g. by maintaining a table with UE-capability information received from the MME or UE. Subsequently, in case the eNB determines that there are no CE-UEs in RRC-Connected mode, a counting procedure is initiated which allows the eNB to determine/estimate the number of CE-UEs in RRC-idle state in its cell. In one example of a counting procedure the UEs in RRC-Idle on a more or less round robin fashion go to RRC-Connected state and inform the network about the presence of the CE UE in RRC-Idle mode (i.e. about itself). The round robin method can e.g. be implemented using a persistence check method wherein the Idle UEs compare a randomly drawn number against a number broadcasted by the network. Only the one(s) drawing a smaller value will transit to RRC Connected to inform the network. The network can keep the broadcasted value to be small enough so that only a very small percentage of UEs should really pass this test at a given time. This is similar to what is done in MBMS Counting procedure as depicted in RRC specification 3GPP TS 36.331, current version 12.4.1 incorporated herein by reference.

[0176] In consequence, the eNB will only perform the CE page when it has determined that there is at least one CE-UE in its cell, be it in RRC-Idle or RRC-Connected state. As a result, the additional resources for a CE-page are not used in vain.

[0177] Second embodiment

As explained above, the first embodiment relates to an improvement for a paging procedure initiated by the eNB, which then shall page all UEs in its cell. The second embodiment to be presented relates to an improvement for a paging procedure that is initiated by the NAS (Non-Access-Stratum), e.g. the MME, and which is dedicated to just a single UE, or a rather limited number of UEs.

[0178] In particular, for this second embodiment it is assumed that the paging is initiated by the NAS, for instance in order to establish a call with a particular CE-UE; details in said respect have already been provided in the background section (see also Fig. 4) and apply equally to the second embodiment. In this respect the "call" need not be just a voice call but can also refer to other terminating service like SMS, MMS or Pager etc. For instance, the MME — in response to a corresponding trigger from the SGW in the core network — sends a paging message to all eNBs that belong to the tracking area(s) for which the CE-UE is currently registered. Particularly, the MME does not know where a CE-UE in RRC idle is located. Each eNB belonging to one of the TAs in an associated TA-list, in turn, then has to perform paging so as to page this CE-UE to

which the call is destined. Finally, the CE-UE being paged can then establish a connection with the eNB where it is camped and then proceed to accept the incoming call (see also Fig. 4).

[0179] In the above-described scenario, the MME informs the eNBs (over the S1 interface) about the capability(ies) of a (CE-)UE, e.g. whether the UE is capable of supporting coverage extension (and optionally which level of coverage extension). As explained before, this general capability information however gives no information on whether a particular CE-capable UE indeed requires coverage extension at the moment or not; e.g. while a CE-capable UE might have been in a basement for a long time, i.e. thus requiring coverage extension for compensating the bad radio conditions, this very same CE-capable UE might in mean time have emerged from the basement and thus might no longer require coverage extension or still require coverage extension but corresponding to a less demanding coverage extension level.

[0180] Consequently, according to the second embodiment, a procedure is implemented according to which the eNB can learn whether a CE-capable UE is indeed requiring coverage extension or not at the time of paging. To said end, a new measurement and reporting procedure is implemented between the UE and the eNB as will be explained in detail below.

[0181] The CE-capable UE is configured to perform radio measurements that allow determining whether the CE-capable UE is currently indeed requiring coverage extension or not. The radio measurements could refer for example to one or more of the following: Reference Signal Received Power (RSRP), Reference Signal Received Quality (RSRQ), channel quality etc. e.g. as defined in Chapter 5 of 3GPP TS36.214 v10.1.0(NPL 8), or even current Block Error Rate (BLER) estimates or HARQ operating point and any other suitable measurement target. In any case, a skilled person is well aware of how to determine the current radio conditions of a CE-capable UE that allow, in a subsequent step, to determine whether coverage extension is indeed necessary or not.

[0182] After performing the appropriate radio measurements, the CE-capable UE shall then determine whether coverage extension is necessary based on the results of the measurements. In one example, two appropriate thresholds can be defined, to which the measurements results are compared by the CE-capable UE so as to determine the current CE status of the CE-capable UE. For example, an upper threshold can be defined, where if the measurements results (e.g. RSRP or RSRQ) exceed the upper threshold, the CE-capable UE would determine that it does not require coverage extension, i.e. that it currently is a non-CE-UE. Conversely, a different lower threshold can be defined, where if the measurement results (e.g. again RSRP or RSRQ) fall below the lower threshold, the CE-capable would conclude that it does require

coverage extension, i.e. that is currently is a CE-UE. Instead of using two thresholds, the determination of whether CE is required or not, could of course also be determined by simply using one threshold, where measurements results exceeding the threshold would mean that coverage extension is not necessary, and measurements results falling below the threshold would mean that coverage extension is necessary. The same technique can also be used for other measurement possibility like for HARQ operating point i.e. where HARQ operating point exceeding the corresponding HARQ operating point-threshold would mean that coverage extension is not necessary, and HARQ operating point falling below the HARQ operating point-threshold would mean that coverage extension is necessary.

[0183] The radio measurements and CE status determination can be performed regularly by the CE-capable UE, i.e. at specific, pre-configured, intervals, and/or event triggered (one even for exceeding the threshold in either direction as described above), e.g. , and/or triggered by the eNB. In addition to the absolute threshold for the corresponding measurement, the network might also provide the corresponding Hysteresis and Time to Trigger values as described in 3GPP TS 36.331, current version 12.4.1. Hysteresis basically gives a margin or allowance in breaching the threshold in either direction, and the Time to Trigger (TTT) indicates at least how long the said threshold should remain breached/ exceeded for the UE to trigger the corresponding event.

[0184] Which radio measurements shall be performed, at which intervals, against which threshold(s) the measurement results should be compared, and any other necessary information can be pre-configured in the CE-capable UE or provided to the CE-capable UEs from the eNB, e.g. within a corresponding control message which could be signaled by RRC or Layer2 (MAC) or Layer1 (Physical layer signal) and may contain additional parameters including Hysteresis, TTT and the target object like current/ serving and neighbor cell list.

[0185] The CE-capable UE has to make sure that the eNB is kept updated on the current CE status, i.e. on whether the CE-capable UE needs coverage extension or not. This may be done e.g. by reporting every change of CE status to the eNB, such that the eNB knows at the time of paging whether a coverage extension technique shall be applied to the paging or not. Of course the same information can be used for DL messages other than paging and also to UL messages including paging response and other non-paging related messages. Depending on whether the CE-capable UE is in idle mode or connected mode, the reporting of the CE status to the eNB may be different. If the CE-capable UE is in RRC connected state and thus has an active connection with the eNB, the CE-capable UE can directly transmit a CE-status report, e.g. RRC Measurement Report, to the eNB.

[0186] Since such a direct report is not possible for CE-capable UEs in RRC-IDLE (since no

active connection with the eNB is available), the CE-capable UE in idle will report the CE status to the MME, which thus knows whether coverage extension is indeed required or not (independent from the CE-capability of a UE). The MME may either keep the eNB(s) regularly up to date in said respect, or might only provide the corresponding information to the eNB(s) when also triggering the eNB for paging. Of course, also CE-capable UEs in RRC connected could inform the MME, instead of or in addition to the eNB.

[0187] In another alternative, the CE-capable UE in idle will report the CE status and UE NAS identity directly to the serving eNB where the UE is camped in currently e.g. upon cell Selection and Reselection(s), which thus knows whether coverage extension is indeed required or not by maintaining a new Table including the UE NAS identity and CE-requirement.

[0188] Alternatively, another improvement provides that the CE-capable UEs do not change into RRC-idle state and thus remain all the time in RRC-connected state, such that the CE-capable UE can always transmit the measurement report directly to the eNB. The eNB can ensure that the UE remains in connected state by never sending the RRC Connection Release message to the UE i.e. basically ignoring any inactivity timer in the eNB for this UE.

[0189] In any case, the eNB, when being triggered to page a particular CE-capable UE, will be informed about and will consider whether said CE-capable UE indeed requires coverage extension or not. Based on the thus known current CE status of the UE, the eNB will or will not apply an appropriate CE technique to the paging of the CE-capable UE. As explained in detail for the first embodiment already, applying the CE technique to paging involves applying the CE technique to both the paging notification transmitted on the PDCCH and the actual paging message transmitted on the PDSCH as addressed by the PDCCH.

[0190] In other words, two measurement events are defined, one referring to the case where the radio measurements indicate that coverage extension is required, and the other referring to the case where the radio measurements indicate that coverage extension is not required. When any of the two events occur, this is reported to the eNB (either directly or via the core network entity, e.g. MME).

[0191] Fig. 8 shows a message sequence diagram for an exemplary paging procedure according to the second embodiment. As apparent therefrom, a measurement control message is provided from the eNB to the UE, which is assumed to include all information necessary to configure the UE to perform the radio measurements and to determine the CE-status based on the measurement results. Fig. 8 also shows the measurement report message from the UE to the eNB, which is transmitted to the eNB to allow the eNB to update the CE status of the UE. This allows in consequence that the

eNB performs the paging of the UE by using or not using a CE technique depending on the CE status of the UE.

[0192] Fig. 9 shows a simplified sequence process diagram for the CE-capable UE for one particular exemplary second embodiment as explained above where the measurement and reporting procedure is depicted in parallel to the page monitoring procedure.

[0193] Fig. 10 shows a simplified sequence process diagram for the eNB as explained above including the reception and update procedure for the CE status of the UE, and the parallel paging procedure which depends on the CE status.

[0194] Fig. 8 additionally shows an optional determination of the initial coverage extension status of the UE, which can be done directly upon the initial access of the UE to the eNB (see dashed box). In particular, the UE when initially attaching to a cell (and to the corresponding eNB) usually performs a RACH procedure, which involves e.g. the selection of an appropriate preamble, access slot etc. The CE-capable UE would, during initial access, determine its CE status in order to appropriately select the RACH resources (e.g. preamble, access slot, etc). Now, the eNB can estimate the radio conditions of the UE, and thus the CE status of the UE, based on the parameters, like preambles, preamble format or even the physical resources that the UE selected to perform the RACH procedure.

[0195] Another improvement of the second embodiment, which is also illustrated in Fig. 8 by use of a dashed arrow, refers to a feedback message transmitted from the eNB to the UE about the successful reception of the measurement report, i.e. CE status update, and confirmation that the toggling (between CE and non-CE) is successfully applied at the network side and therefore the UE should also toggle and transmit/ receive according to the new toggled state. By e.g. sending back information on the current CE status, the eNB can make sure that the CE-capable UE and the eNB have the same understanding of the CE status, and behave accordingly in a same manner. For instance, if the measurement report is lost, or decoded incorrectly at the eNB, the eNB would not change the CE status, and the UE and eNB would have different CE status (e.g. until the next, successful, measurement report is received by the eNB). Also, even successful reception of the measurement report is not a guarantee that eNB is fine with the toggling for reasons like admission control or for independent toggling evaluation at the eNB side. In this respect, the triggering of a measurement event is just one of the input parameter for the eNB to decide about the said toggling of CE state, and eNB may take the final decision based on cell and System specific considerations. In absence of the feedback message transmitted from the eNB to the UE about the successful reception of the measurement report and confirming that the toggling (between CE and non-CE) is successfully applied at the network side, obviously, different CE status might lead to a waste of radio resources or to an unsuccessful

paging, which is avoided by providing a feedback on the successful CE status update.

[0196] Still a further improvement of the second embodiment is also illustrated in Fig. 8. As indicated by the dashed arrow, the UE can inform the eNB immediately when a CE page was successful. In particular, instead of waiting to receive e.g. all repetitions of the CE page, as soon as the CE page is successfully received (e.g. the actual paging message was successfully decoded/delivered to the higher layer), the CE-capable UE informs the eNB in said respect. In turn, the eNB can inform the MME in the core network, which may then abort the page in the other eNBs of all the tracking areas (not shown in Fig. 8) pertaining to a corresponding TA-list. Radio resources are thus not wasted by other eNBs.

[0197] Third embodiment

According to a third embodiment, the first embodiment and the second embodiments are combined such that CE devices can be paged both at the NAS level and the AS level (i.e. initiated by NAS and initiated by eNB). Thus, the separation of NAS and AS is maintained as in legacy systems. Furthermore, the first and second embodiments are simple to implement and have no impact on legacy procedures.

[0198] Hardware and Software Implementation of the present disclosure

Other exemplary embodiments relate to the implementation of the above described various embodiments using hardware and software. In this connection a user terminal (mobile terminal) and an eNodeB (base station) are provided. The user terminal and base station is adapted to perform the methods described herein, including corresponding entities to participate appropriately in the methods, such as receiver, transmitter, processors.

[0199] It is further recognized that the various embodiments may be implemented or performed using computing devices (processors). A computing device or processor may for example be general purpose processors, digital signal processors (DSP), application specific integrated circuits (ASIC), field programmable gate arrays (FPGA) or other programmable logic devices, etc. The various embodiments may also be performed or embodied by a combination of these devices.

[0200] Further, the various embodiments may also be implemented by means of software modules, which are executed by a processor or directly in hardware. Also a combination of software modules and a hardware implementation may be possible. The software modules may be stored on any kind of computer readable storage media, for example RAM, EPROM, EEPROM, flash memory, registers, hard disks, CD-ROM, DVD, etc.

[0201] It should be further noted that the individual features of the different embodiments may individually or in arbitrary combination be subject matter to another embodiment.

[0202] It would be appreciated by a person skilled in the art that numerous variations and/or

modifications may be made to the present disclosure as shown in the specific embodiments. The present embodiments are, therefore, to be considered in all respects to be illustrative and not restrictive.

Claims

[Claim 1] A method for paging all user equipments in a cell controlled by a radio base station in a mobile communication system, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment, the method comprising the steps of:
regularly monitoring by the CE user equipments in the cell the at least one CE-specific paging possibility,
determining by the radio base station to page all the user equipments in the cell, and
paging by the radio base station the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 2] The method according to claim 1, wherein a plurality of UE-specific paging possibilities are defined for paging a specific user equipment in the cell of the radio base station, wherein the CE user equipments and non-CE user equipments each monitor a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities,
wherein the radio base station — upon determining to page all the user equipments in the cell - additionally performs paging at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension,
preferably wherein each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[Claim 3] The method according to claim 1 or 2, wherein the step of paging includes:
transmitting by the radio base station a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and
transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification,
preferably wherein the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[Claim 4] The method according to one of claims 1 to 3, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility, preferably wherein information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment, or broadcast by the radio base station in the cell, and preferably wherein the pre-configured subframe number is 1, 2, 3, 6, 7, or 8.

[Claim 5] The method according to one of claims 1 to 3, wherein CE user equipments are assigned a CE-specific user equipment identity based on which the CE-specific paging possibility is calculated by the radio base station and the CE user equipments,
preferably wherein the CE-specific user equipment identity is the same for all CE-configured user equipments,
preferably wherein the CE-specific user equipment identity is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment or broadcast by the radio base station in the cell;
preferably wherein a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific user equipment identity is defined.

[Claim 6] A user equipment located in a cell controlled by a radio base station in a mobile communication system, the user equipment, in short CE user equipment, requiring coverage extension, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for the CE user equipment, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE user equipment, the CE user equipment comprising:
a processor adapted to regularly monitor the at least one CE-specific paging possibility,
a receiver adapted to receive a paging from the radio base station at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 7] The user equipment according to claim 6, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control

channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility, preferably wherein a memory of the CE user equipment is adapted to store information to determine the pre-configured radio frame number and the pre-configured subframe number, preferably wherein the memory is a Universal Subscriber Identity Module, USIM, of the CE user equipment, or
preferably wherein the receiver of the CE user equipment is further adapted to receive information to determine the pre-configured radio frame number and the pre-configured subframe number, broadcast by the radio base station in the cell.

[Claim 8] A radio base station for paging all user equipments in a cell controlled by the radio base station in a mobile communication system, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment, the radio base station comprising:
a processor adapted to determine whether to page all the user equipments in the cell, and
a transmitter adapted to page the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 9] A method for paging a user equipment in a cell controlled by a radio base station in a mobile communication system, wherein the user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the method comprising the steps of:
performing radio measurements by the CE-capable user equipment,
determining by the CE-capable user equipment whether coverage extension is necessary or not, based on the results of the radio measurements,
wherein the radio base station is informed about whether the CE-capable user equipment needs coverage extension or not, based on the determination result,

when paging the CE-capable user equipment, applying or not applying by the radio base station one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[Claim 10] The method according to claim 9, wherein the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[Claim 11] The method according to claim 9 or 10, wherein the step of determining whether coverage extension is necessary comprises the steps of:
comparing by the CE-capable user equipment the result of the radio measurements with a first threshold to determine whether coverage extension is necessary, preferably wherein the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold,
comparing by the CE-capable user equipment the result of the radio measurements with a second threshold to determine whether coverage extension is not necessary, preferably wherein the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[Claim 12] The method according to one of claims 9 to 11, wherein the step of paging the CE-capable user equipment comprises the steps of:
transmitting by the radio base station a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE-capable user equipment, and
transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification, preferably wherein the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[Claim 13] A user equipment located in a cell controlled by a radio base station in a mobile communication system, the user equipment, in short CE user equipment, supporting coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the user equipment comprising:
a processor adapted to perform radio measurements,

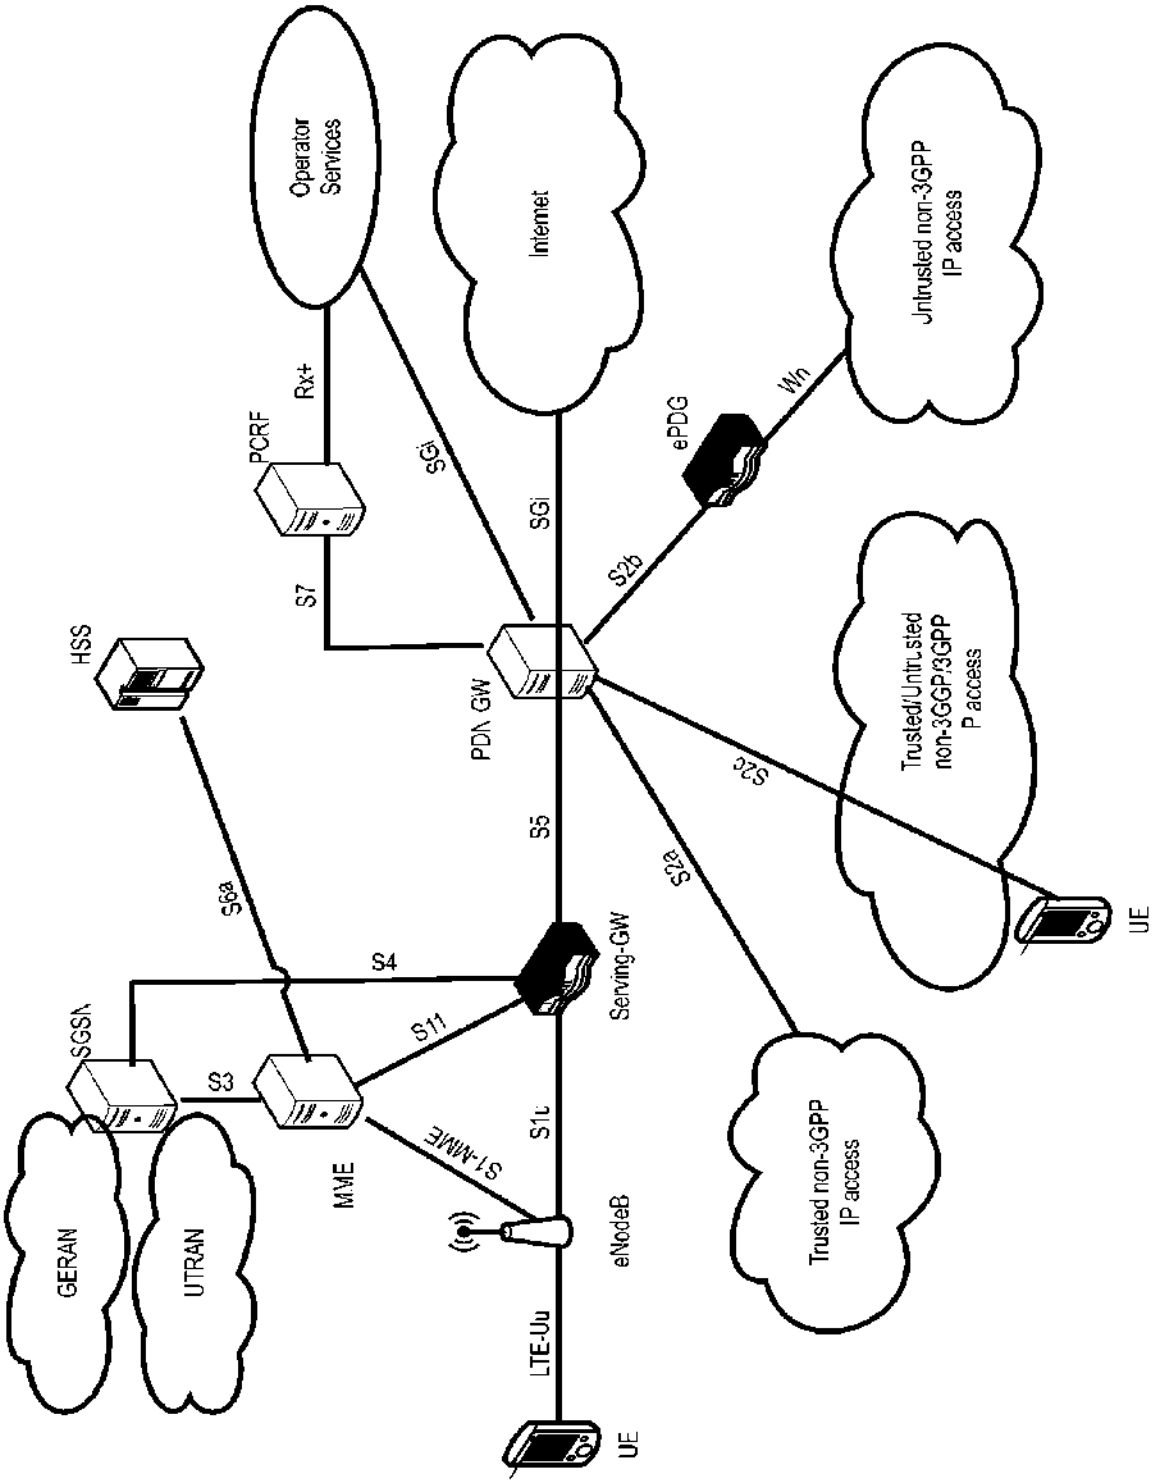
the processor being further adapted to determine whether coverage extension is necessary or not, based on the results of the radio measurements,

a transmitter adapted to inform the radio base station about whether the CE-capable user equipment needs coverage extension or not, based on the determination result,

a receiver adapted to receive paging from the radio base station, applying or not applying one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not.

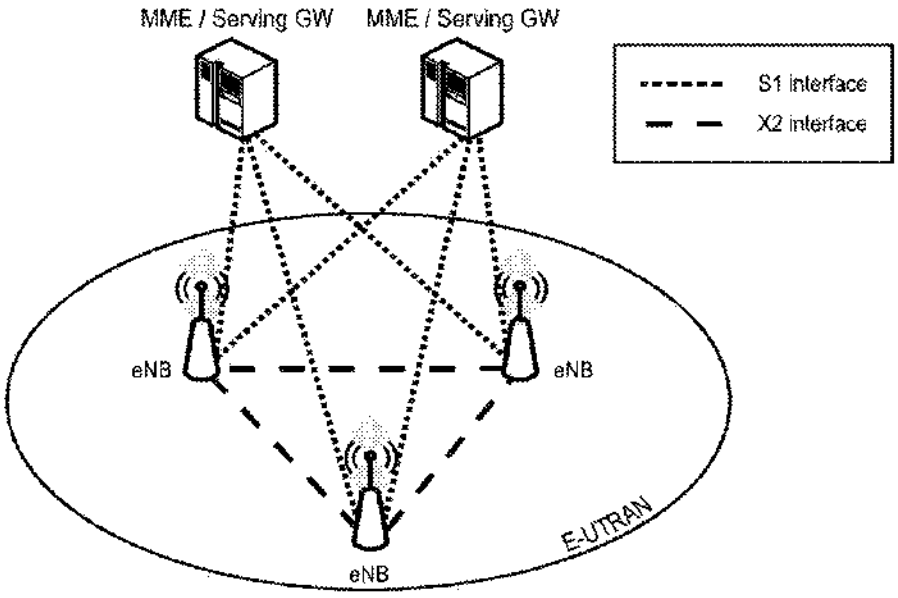
[Claim 14] The user equipment according to claim 13, wherein the transmitter informs the radio base station by:

transmitting information about whether the CE-capable user equipment needs coverage extension or not to the radio base station, preferably wherein the CE-capable user equipment is in a connected state, preferably wherein it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state, or



transmitting information about whether the CE-capable user equipment needs coverage extension or not to a core network entity, and wherein the core network entity provides the received information to the radio base station, preferably wherein the CE-capable user equipment is in a connected state or in an idle state.

[Claim 15] A radio base station for paging a user equipment in a cell controlled by the radio base station in a mobile communication system, wherein the user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the radio base station comprising:



a receiver adapted to receive information about whether the CE-capable user equipment needs coverage extension or not,

a transmitter being adapted to, when paging the CE-capable user equipment, apply or not apply one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

(54) **Title**: METHODS AND MACHINE TYPE COMMUNICATION, MTC, DEVICE, IMPLEMENTING PAGING PROCEDURES FOR REDUCED BANDWITH MTC DEVICES

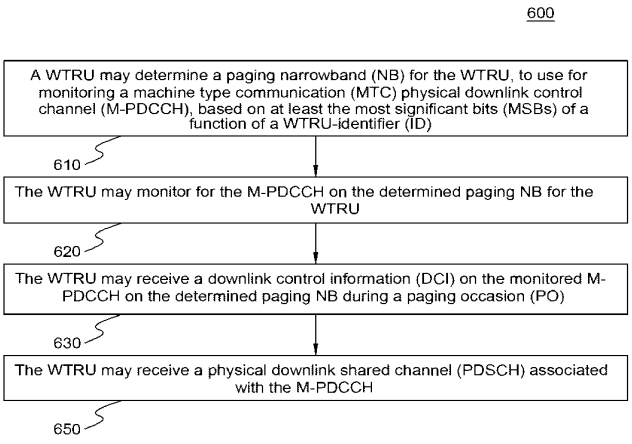

FIG. 6

(57) **Abstract**: Methods for paging for reduced bandwidth wireless transmit/receive units, WTRUs, in machine type communication, MTC, are provided. A WTRU determines (610) a paging narrowband, NB, for the WTRU, to use for monitoring an MTC physical downlink control channel, M-PDCCH, based on at least the most significant bits, MSBs, of a function of a WTRU-identifier, WTRU-ID. The WTRU monitors (620) for the M-PDCCH on the determined paging NB for the WTRU. The WTRU then receives (630) a downlink control information, DCI, on the monitored M-PDCCH on the determined paging NB during a paging occasion, PO.The WTRU then receives (650) a physical downlink shared channel, PDSCH, associated with the M-PDCCH. Alternatively, the WTRU monitors (420) the M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH has a starting enahnced control channel element, ECCE, index for a WTRU group containing the WTR, and wherein the M-PDCCH includes (430) the DCI.

METHODS AND MACHINE TYPE COMMUNICATION, MTC, DEVICE, IMPLEMENTING PAGING PROCEDURES FOR REDUCED BANDWITH MTC DEVICES

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Application No. 62/250,803 filed November 4, 2015, U.S. Provisional Application No. 62/290,790 filed February 3, 2016, and U.S. Provisional Application 62/308,042 filed March 14, 2016, the contents of which are hereby incorporated by reference herein.

BACKGROUND

[0002] As wireless communication systems such as Long Term Evolution (LTE) systems mature and their network deployment evolve, it may be beneficial for network operators to reduce the cost of the communication network, maintenance needs of the communication network or both. One technique to reduce the cost of the network may be to reduce the channel bandwidth and data rate used to communicate with devices.

[0003] For example, a portion of the channel bandwidth rather than the entire channel bandwidth may be supported by the devices in the network and/or the network itself when communicating with such devices. Current wireless communication systems, for example, LTE, have recently considered a bandwidth reduction for some devices including machine type communication (MTC) devices to some level, for example, 1.4 megahertz (MHz).

SUMMARY

[0004] Methods for paging for reduced bandwidth wireless transmit/receive units (WTRUs) in machine type communication (MTC) are provided. A WTRU may determine a paging narrowband (NB) for the WTRU, to use for monitoring an MTC physical downlink control channel (M-PDCCH), based on at least the most significant bits (MSBs) of a function of a WTRU-identifier (WTRU-ID). The WTRU may monitor for the M-PDCCH on the

determined paging NB for the WTRU. The WTRU may then receive a downlink control information (DCI) on the monitored M-PDCCH on the determined paging NB during a paging occasion (PO). The DCI may include a scrambled cyclic redundancy check (CRC). The CRC may be scrambled with a Paging Radio Network Temporary Identifier (P-RNTI). Also, the WTRU may receive a physical downlink shared channel (PDSCH) associated with the M-PDCCH.

[0005] In an example, the WTRU may determine the paging NB based on at least the 3 MSBs of a function of the WTRU-ID. In another example, the WTRU may determine the paging NB based on at least the 4 MSBs of a function of the WTRU-ID.

[0006] Further, the PDSCH may be scheduled by the DCI. In an example, the DCI may include a paging message. In another example, the DCI may include system information update related information. In a further example, the PDSCH may include a paging message. In an additional example, the PDSCH may include system information update related information.

[0007] In addition, a WTRU may monitor for a M-PDCCH in an M-PDCCH search space. The WTRU may receive an M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH has a starting enhanced control channel element (ECCE) index for the WTRU group containing the WTRU. Further, the WTRU may decode the M-PDCCH, wherein the M-PDCCH includes a DCI. In addition, the WTRU may receive a PDSCH associated with the M-PDCCH.

[0008] Further, the WTRU may receive, decode, and/or demodulate the PDSCH based on the DCI, wherein the PDSCH includes a paging message. The WTRU may then change operations based on the paging message. For example, the WTRU may change from idle mode to connected mode based on the paging message. In an example, the ECCE aggregation level may be 16.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] A more detailed understanding may be had from the following description, given by way of example in conjunction with the accompanying drawings wherein:

[0010] FIG. 1A is a system diagram of an example communications system in which one or more disclosed embodiments may be implemented;

[0011] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used within the communications system illustrated in FIG. 1A;

[0012] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used within the communications system illustrated in FIG. 1A;

[0013] FIG. 2 is an exemplary timing diagram which illustrates hyper frames and paging within hyper frames;

[0014] FIG. 3 is an exemplary diagram which illustrates WTRU group-specific starting enhanced control channel element (ECCE) indexes;

[0015] FIG. 4 is a diagram of an example flow chart showing a WTRU receiving a machine type communication (MTC) physical downlink control channel (M-PDCCH) with a starting ECCE index based on the WTRU group of the WTRU;

[0016] FIG. 5 is an exemplary diagram which illustrates WTRU group-specific random ECCE ordering;

[0017] FIG. 6 is a diagram of an example flow chart showing a WTRU using a WTRU-ID to determine a paging narrowband (NB) to use for monitoring an M-PDCCH;

[0018] FIG. 7 is a diagram illustrating an example of code-block segment multiplexing in a physical downlink shared channel (PDSCH), which may be scheduled by an associated physical downlink control channel (PDCCH) in a paging occasion (PO); and

[0019] FIG. 8 is a diagram illustrating an example of code-block segments transmitted via multiple PDSCHs, which may be scheduled by an associated PDCCH in a PO.

DETAILED DESCRIPTION

[0020] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, such as voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0021] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, 102d, a radio access network (RAN) 104, a core network 106, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include user equipment (UE), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0022] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to one or more communication networks, such as the core network 106, the Internet 110, and/or the other networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home

Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0023] The base station 114a may be part of the RAN 104, which may also include other base stations and/or network elements (not shown), such as a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In another embodiment, the base station 114a may employ multiple-input multiple-output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0024] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 116, which may be any suitable wireless communication link (for example, radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 116 may be established using any suitable radio access technology (RAT).

[0025] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, such as CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 104 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 116 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0026] In another embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 116 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0027] In other embodiments, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), and the like.

[0028] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, such as a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In another embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet another embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (for example, WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106.

[0029] The RAN 104 may be in communication with the core network 106, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, such as user authentication. Although not shown in

FIG. 1A, it will be appreciated that the RAN 104 and/or the core network 106 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 104 or a different RAT. For example, in addition to being connected to the RAN 104, which may be utilizing an E-UTRA radio technology, the core network 106 may also be in communication with another RAN (not shown) employing a GSM radio technology.

[0030] The core network 106 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, such as the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include another core network connected to one or more RANs, which may employ the same RAT as the RAN 104 or a different RAT.

[0031] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0032] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any

sub-combination of the foregoing elements while remaining consistent with an embodiment.

[0033] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0034] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (for example, the base station 114a) over the air interface 116. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In another embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet another embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0035] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (for example, multiple

antennas) for transmitting and receiving wireless signals over the air interface 116.

[0036] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, such as UTRA and IEEE 802.11, for example.

[0037] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (for example, a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, such as the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In other embodiments, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, such as on a server or a home computer (not shown).

[0038] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (for example, nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0039] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (for example, longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 116 from a base station (for example, base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0040] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0041] FIG. 1C is a system diagram of the RAN 104 and the core network 106 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 106.

[0042] The RAN 104 may include eNode-Bs 140a, 140b, 140c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 140a, 140b, 140c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 140a, 140b, 140c may implement MIMO technology. Thus, the eNode-B 140a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0043] Each of the eNode-Bs 140a, 140b, 140c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1C, the eNode-Bs 140a, 140b, 140c may communicate with one another over an X2 interface.

[0044] The core network 106 shown in FIG. 1C may include a mobility management entity gateway (MME) 142, a serving gateway 144, and a packet data network (PDN) gateway 146. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0045] The MME 142 may be connected to each of the eNode-Bs 140a, 140b, 140c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 142 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 142 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, such as GSM or WCDMA.

[0046] The serving gateway 144 may be connected to each of the eNode Bs 140a, 140b, 140c in the RAN 104 via the S1 interface. The serving gateway 144 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 144 may also perform other functions, such as anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0047] The serving gateway 144 may also be connected to the PDN gateway 146, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0048] The core network 106 may facilitate communications with other networks. For example, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 106 may include, or may communicate with, an IP gateway (for example, an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 106 and the PSTN 108. In addition, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0049] Other network 112 may further be connected to an IEEE 802.11 based wireless local area network (WLAN) 160. The WLAN 160 may include an access router 165. The access router may contain gateway functionality. The access router 165 may be in communication with a plurality of access points (APs) 170a, 170b. The communication between access router 165 and APs 170a, 170b may be via wired Ethernet (IEEE 802.3 standards), or any type of wireless communication protocol. AP 170a is in wireless communication over an air interface with WTRU 102d.

[0050] As wireless communication systems such as LTE systems mature and their network deployment evolve, it may be beneficial for network operators to reduce the cost of the communication network, maintenance needs of the communication network or both. One technique to reduce the cost of the network may be to reduce the channel bandwidth and data rate used to communicate with devices. For example, a portion of the channel bandwidth rather than the entire channel bandwidth may be supported by the devices in the network and/or the network itself when communicating with such devices. Current wireless communication systems, for example, LTE, have recently considered a bandwidth reduction for some devices including machine type communication (MTC) devices to some level, for example, 1.4 megahertz (MHz). The considered level may enable more compatibility with legacy systems and reduce the time and/or cost of a new design, since, for

example LTE may already support operation with a system bandwidth of 1.4 MHz. Further bandwidth reduction, however, may be desirable for some devices, for example, smart watches and alarms, for example to reduce costs even further. Further reduction of the bandwidth, for example, on the order of 200 kilohertz (kHz), has been suggested. Additional system design may be needed to support operation with a reduced bandwidth which may be less compatible with legacy system operation.

[0051] A reduced bandwidth (BW) WTRU may be a WTRU which may support or may only support a certain limited BW, for example, RF BW or a certain limited number of resource blocks (RBs) in the downlink (DL) and/or uplink (UL), which may be independent of the BW of the eNode-B or cell with which the WTRU may communicate. For example, a reduced BW WTRU, which may also be referred to as a limited BW WTRU, may support or may only support a certain number of RBs, for example, 6 RBs or 1 RB, or a certain BW, for example, 1.4 MHz or 180 kHz, for transmission and/or reception. Such a WTRU may communicate with an eNode-B or cell for which the BW may be larger, for example, 20 MHz or 100 RBs.

[0052] An enhanced machine type communication (eMTC) WTRU may be a limited BW WTRU which may support a first number of RBs and/or a BW of a first bandwidth. A first number may be represented by N1 and a first bandwidth may be represented by B1. N1 may, for example, be 6 and B1 may, for example be 1.4 MHz. In an example, 6 RBs may correspond to a BW of 1.4 MHz. An eMTC WTRU may be used to represent a non-limiting example of a limited BW WTRU. Another WTRU which may be referred to as a narrowband LTE (NB-LTE) or narrowband internet of things (NB-IoT) WTRU may be a limited BW WTRU which may support a second number of RBs and/or a BW of a second bandwidth. A second number may be represented by N2 and a second bandwidth may be represented by B2. N2 may be less than N1. B2 may be less than B1. N2 may, for example, be 1 and B2 may, for example, be 180 kHz. In an example, 1 RB may correspond to a BW of 180 kHz. An NB-LTE WTRU and/or NB-IoT WTRU may be used to represent a non-limiting example of a limited BW WTRU. A narrowband (NB) WTRU may be used to

represent a non-limiting example of a WTRU or limited BW WTRU. WTRU, limited BW WTRU, BW limited WTRU, reduced BW WTRU, limited capability WTRU, low cost-MTC (LC-MTC) WTRU, low-complexity WTRU, MTC WTRU, eMTC WTRU, NB-IoT WTRU, eMTC, NB-IoT, and NB WTRU may be used interchangeably herein. An RB may be a physical RB (PRB). The terms RB and PRB may be used interchangeably herein.

[0053] A limited BW WTRU may use or require special procedures to operate in a portion of the full BW of the cell. Reduced bandwidth, limited bandwidth, and bandwidth limited may be used interchangeably herein. A WTRU which may support the full BW of a cell may be referred to as a full BW WTRU. BW may include a number of RBs and/or a location in a band such as the center of the band.

[0054] A WTRU may at least sometimes communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent, with that of a full BW WTRU and may also at least sometimes, for example, some other times than when operating as a full BW WTRU, communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent, with that of a reduced BW WTRU. For example, a WTRU which may support the full BW of a cell may communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent with that of a reduced BW WTRU at certain times such as when it may be coverage limited or when it may operate in a coverage enhanced mode. A WTRU, such as this example WTRU, may be or may be considered a full BW WTRU at times and/or a reduced BW WTRU at times, for example at other times.

[0055] A WTRU may be or may be considered to be a reduced BW WTRU while it may, may need to, or may intend to behave or operate like, or for example, at least partially like, a reduced BW WTRU. A WTRU that may communicate, for example, with an eNode-B, behave, or operate in a manner which may be consistent, or for example, at least partially consistent with that of a reduced BW WTRU may be or may be considered to be a reduced BW WTRU, for example at least sometimes, such as when the WTRU may

communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent, with that of a reduced BW WTRU.

[0056] It should be noted that the terms eNB, eNode-B and cell may be used interchangeably herein. Embodiments and examples described for reduced BW WTRUs may be applied to coverage limited WTRUs and vice versa.

[0057] Coverage limited and reduced BW WTRUs are examples of WTRUs which may use the example methods and procedures described herein. These coverage limited and reduced BW WTRUs are non-limiting examples of such example WTRUs. Application to a WTRU of any kind, with any capabilities, or reduced capabilities may still be consistent with the example methods and procedures described herein.

[0058] The term physical downlink control channel (PDCCH) may be replaced by enhanced PDCCH (EPDCCH), machine type communication (MTC) physical downlink control channel (M-PDCCH), or another DL control channel, and vice versa and still be consistent with the example methods and procedures described herein. The terms component carrier (CC) and serving cell may be used interchangeably herein. The terms WTRU, WTRU medium access control (MAC) entity, and MAC entity may be used interchangeably herein.

[0059] The terms a WTRU, a certain WTRU or certain WTRUs may be replaced by at least a WTRU, at least a certain WTRU or at least certain WTRUs and still be consistent with the example methods and procedures described herein. The phrase intended for may be replaced by at least intended for or intended for at least and still be consistent with the example methods and procedures described herein.

[0060] The example methods and procedures described herein may be described for a random access response (RAR), paging channel (PCH), or physical downlink shared channel (PDSCH) carrying or which may carry a RAR or PCH. These are used as non-limiting examples. RAR may be replaced by PCH or PCH PDSCH and vice versa and still be consistent with the example methods and procedures described herein. The channel or other

contents which may be carried by the PDSCH may be replaced with any channel or contents and still be consistent with the example methods and procedures described herein.

[0061] Example methods and procedures involving coverage enhancement (CE) are disclosed herein. A coverage enhanced WTRU may be a WTRU which may require coverage enhancement or a WTRU which may employ coverage enhancement techniques or may support a CE mode. The terms coverage limited WTRU and coverage enhanced WTRU may be used interchangeably herein. CE may refer to extending or improving coverage, for example for low data rate applications. CE may refer to extending or improving coverage, for example to enable communication with devices with reduced capabilities such as devices employing a single receiver or devices using a reduced bandwidth. CE may refer to extending or improving coverage, for example to enable communication with devices for which communication may be hampered such as indoor devices or devices in basements where penetration losses may impede communication. In at least some examples, CE may involve extending or improving coverage by reducing the data rate. In at least some examples, CE may involve extending or improving coverage by employing repetition techniques. In at least some examples, CE may be used for MTC applications. In at least some examples, CE may be used for NB or NB-IoT applications. The terms CE operation and coverage enhanced operation may be used interchangeably herein.

[0062] A repetitive transmission of a physical channel may be used for CE. The CE level may be determined based on the number of repetitions, for example, that may be needed or used to achieve the intended coverage improvement. The terms repetition number, number of repetitions, repetition level, and CE level may be used interchangeably herein.

[0063] A CE mode may be used with one or more CE levels, or for example, repetition levels. The CE levels or repetition levels supported within a CE mode may be changed dynamically.

[0064] An eMTC WTRU may be for example, a low-cost WTRU. An eMTC WTRU may be for example, a WTRU with limited or reduced

capabilities. Limited or reduced capabilities may include at least one of a limited or reduced BW capability, for example a BW using 6 RBs , low throughput performance, and a single RF chain at the receiver. An eMTC WTRU may be delay tolerant. An eMTC WTRU may be served in an LTE network which may or may not have a system BW larger than the eMTC supportable BW that may for example be a BW of 1.4 MHz.

[0065] An eMTC WTRU may support coverage enhanced operation. For example, two CE modes of operation may be supported such as CE mode-A and CE mode-B. Normal and small CE levels may be supported in CE mode-A, and medium and large CE levels may be supported in CE mode-B. Normal CE may be the same as normal operation or no CE, which may involve for example, no use of repetitions for CE.

[0066] An NB-IoT WTRU may be, for example, a low-cost WTRU. An NB-IoT WTRU may be, for example, a WTRU with limited or reduced capabilities that may, for example, be more limited or reduced more than the capabilities of an eMTC WTRU in at least one aspect. For example an NB-IoT WTRU may support or use a further reduced BW, for example, a BW of 1 RB, that may be smaller than the supportable BW for an eMTC WTRU.

[0067] An NB-IoT WTRU may, or may be intended to, support CE, for example, with up to 20 decibel (dB) CE, with a battery life that may be longer than the intended or expected battery life of an eMTC WTRU. An NB-IoT WTRU may be intended or expected to support a battery life such as 10 years. The population of NB-IoT WTRUs in a cell may be significantly larger than for other types of devices.

[0068] Example methods and procedures of paging are discussed herein. As used herein, paging may refer to network initiated connection setup. As used herein, paging may refer to a mechanism that a network may use to provide information such as system information modification information or warning system information, for example Earthquake and Tsunami Warning System (ETWS) information, to one or more WTRUs that may, for example, employ techniques for battery saving such as discontinuous reception (DRX). In some examples, paging may be used when a WTRU is in idle mode. In other

examples, paging may be used when a WTRU is in connected mode. A WTRU may, for example periodically, monitor a PDCCH for a DL control information (DCI) or DL assignment on a PDCCH masked with a Paging Radio Network Temporary Identifier (P-RNTI), for example in idle mode and/or in connected mode. When a WTRU detects or receives a DCI or DL assignment using a P-RNTI, the WTRU may demodulate the associated or indicated PDSCH RBs and/or may decode a Paging Channel (PCH) that may be carried on an associated or indicated PDSCH. A PDSCH which may carry PCH may be referred to as a PCH PDSCH. The terms paging, paging message, and PCH may be used interchangeably herein. As used herein, the terms downlink control channel, DL control channel for NB WTRU, M-PDCCH, PDCCH, NB PDCCH (NB-PDCCH), internet of things PDCCH (IoT-PDCCH), and NB IoT-PDCCH (NB-IoT-PDCCH) may be used interchangeably.

[0069] The paging frame (PF) and subframe within that PF, for example, the paging occasion (PO), that a WTRU may monitor for the paging channel, for example in idle mode, may be determined based on the WTRU identifier (ID), for example, WTRU_ID or UE_ID, and parameters which may be specified by the network. The parameters may include the Paging Cycle (PC) length, for example in frames, which may be the same as a discontinuous reception (DRX) cycle and another parameter, for example, nB, which together may enable the determination of the number of PF per PC and the number of PO per PF which may be in the cell. The WTRU ID, in an example, may be the WTRU international mobile subscriber identity (IMSI) mod 1024. The terms WTRU ID, WTRU-ID, and WTRU_ID may be used interchangeably herein.

[0070] From the network perspective, there may be multiple PFs per paging cycle and multiple POs within a PF, for example, more than one subframe per paging cycle may carry PDCCH masked with a P-RNTI. Additionally, from the WTRU perspective, a WTRU may monitor a PO per paging cycle, and such a PO may be determined based on the parameters specified herein, which may be provided to the WTRU via system information, dedicated signaling information, and the like. POs may include pages for one

or more specific WTRUs, or they may include system information change pages which may be directed to each of the WTRUs, multiple WTRUs, or all WTRUs. In idle mode, a WTRU may receive pages for reasons such as an incoming call or system information update changes.

[0071] In connected mode, a WTRU may receive pages related to system information change, for example, and the WTRU may not receive WTRU-specific pages such as those that may be used for an incoming call. As such, a WTRU in connected mode may not monitor a specific PO. Additionally, for frequency division duplex (FDD), the PO subframes may be limited to certain subframes such as subframes 0, 4, 5 and 9 and/or for time division duplex (TDD), the PO subframes may be limited to certain subframes such as subframes 0, 1, 5 and 6.

[0072] As used herein, DRX may refer to a WTRU monitoring for DL control signaling or a DL control channel at certain times, for example only at certain times, during a cycle. For example, a WTRU using DRX may monitor for a DL control channel during certain time periods, for example only during certain time periods. During other time periods, the WTRU may switch off at least part of its receiver circuitry and reduce power consumption. A time period may, for example, be a subframe. Example methods for operation using DRX are discussed herein.

[0073] In idle mode, for example, radio resource control (RRC) idle mode and/or evolved packet system (EPS) connection management (ECM) idle mode, a WTRU may monitor for or listen to a paging message to know about one or more of: an incoming call, a system information change, an Earthquake and Tsunami Warning System (ETWS) notification for ETWS capable WTRUs, a commercial mobile alert service (CMAS) notification and an extended access barring (EAB) parameters modification.

[0074] A WTRU may monitor PDCCH for P-RNTI discontinuously, for example to reduce battery consumption when there may be no pages for the WTRU. DRX may be or may include the process of monitoring PDCCH discontinuously. In idle mode, DRX may be or may include the process of

monitoring PDCCH discontinuously for P-RNTI, for example to monitor or listen for a paging message during RRC idle state.

[0075] The terms idle mode, idle state, RRC idle mode, RRC idle state, and RRC_IDLE mode or state may be used interchangeably herein. The terms RRC idle and ECM idle may be used interchangeably herein. DRX may also be enabled and/or used in connected mode. When in connected mode, if DRX is configured, the MAC entity may monitor the PDCCH discontinuously, for example using DRX operation. The terms connected mode, connected state, and RRC_CONNECTED mode or state may be used interchangeably herein.

[0076] Examples of operation in idle mode DRX are discussed herein. A WTRU may use one or more DRX parameters that may be broadcast, for example in a system information block (SIB) such as a SIB2, to determine the PF and/or PO to monitor for paging. The WTRU may, for example, alternatively, use one or more WTRU specific DRX cycle parameters that may be signaled to the WTRU, for example by the MME through non-access stratum (NAS) signaling.

[0077] Table 1 provides examples of DRX parameters including example ranges and an example source of the DRX parameter, for example, an eNode-B or an MME.

Table 1. Example DRX Cycle Parameters.

DRX parameter	Notation	Value Range	Configuring Network Node
WTRU Specific DRX cycle	TWTRU	32, 4, 128 and 256 radio frames where each radio frame may be 10 milliseconds (ms)	MME, for example, via NAS signaling
Cell specific DRX cycle	TCELL	32, 4, 128 and 256 radio frames	eNode-B, for example, via system information such as a SIB2
Number of POs per DRX cycle, for example, DRX cycle across all users in the cell	nB	4T, 2T, T, T/2, T/4, T/8, T/16, T/32 where T may be the DRX cycle of the WTRU, for example, TCELL or the smaller of TWTRU, if provided, and TCELL	eNode-B, for example, via system information such as a SIB2

[0078] The DRX cycle T of a WTRU may indicate the number of radio frames in the paging cycle. A larger value of T may result in less WTRU battery power consumption. A smaller value of T may increase WTRU battery power consumption. A DRX cycle may be cell specific or WTRU specific.

[0079] A DRX cycle provided by an eNode-B may be cell specific and may be provided to at least some, or for example all, WTRUs in a cell. The DRX cycle that may be provided by the eNode-B may be the default paging cycle. A DRX cycle provided by an MME may be WTRU specific. The WTRU may use the smaller of the default paging cycle and the WTRU specific DRX cycle as its DRX or paging cycle. An MME may provide a WTRU specific DRX cycle to a WTRU using NAS signaling, for example as 'WTRU specific DRX cycle'. An MME may provide a WTRU specific DRX cycle to an eNode-B in a PAGING S1 AP message, as 'Paging DRX', for example, for an MME initiated paging message that may be intended for the WTRU.

[0080] The WTRU and/or eNode-B may use the minimum of the default and WTRU specific DRX cycle. For example, T = Min (T_{WTRU}, T_{CELL}) in radio

frames. A WTRU with a DRX cycle of N (for example, 128) radio frames may wake up or may need to wake up every N x frame time (for example, every 1.28 seconds for a frame time of 10 ms) and look for a paging message.

[0081] The parameter nB may indicate the number of paging occasions or POs in a cell specific DRX cycle. The parameter may be cell specific. Configuration of the nB value may depend on the paging capacity that may be desired or used in a cell. A larger value of nB may be used, for example to increase paging capacity. A smaller value of nB may be used, for example for a smaller paging capacity.

[0082] The eNode-B and/or WTRU may calculate the WTRU's PFs according to the following relation: a PF is given by the following equation or occurs when SFN mod T = (T div N)*(WTRU_ID mod N), where N = min (T, nB) and div may represent division. The WTRU specific PO within the PF may be determined from a set of paging subframes. The set may be a function of predefined allowed subframes for paging and/or the number of POs per PF which may be a function of at least nB and/or T. The system frame number (SFN) may have a range of values such as 0 through 1023.

[0083] Examples of connected mode DRX are discussed herein. In connected mode, a PF and PO may be determined in a similar manner as in idle mode. The DRX cycle parameters may be different for idle and connected modes. A WTRU may monitor a PO, for example, any PO, in a PC in connected mode, for example to obtain system information change information.

[0084] Extended DRX (eDRX) is disclosed herein. It may be desirable to have extended or longer DRX cycles, for example for devices such as MTC devices. Extended or longer DRX cycles may be useful for some devices such as delay tolerant devices and may, for example, reduce battery consumption and/or increase battery life for those devices. A new time unit, for example, a hyper frame (HF), may be used, for example, with, as an extension of, or on top of radio frames and/or SFN timing, for example, legacy SFN timing.

[0085] FIG. 2 is an exemplary timing diagram which illustrates HFs and paging within HFs. One HF may include an SFN cycle, for example, 1024 radio frames or 10.24 s. A HF may have a Hyper-System Frame Number (H-

SFN). An H-SFN cycle may be 1024 SFN cycles. An H-SFN cycle may last 1024*1024*10 ms, for example, 174.76 minutes. In an example shown in timing diagram 200, HF 210 may have H-SFN 0 and may contain an SFN cycle of 1024 radio frames, from radio frame 0 through radio frame 1023. Likewise, HF 220 may have H-SFN 1023 and contain its own SFN cycle of 1024 radio frames. H-SFN cycle 230 may contain 1024 HFs, including HF 210 through HF 220.

[0086] An idle mode extended DRX (I-eDRX) cycle may include up to 256 H-SFN cycles and may, for example, last 256*1024*10 ms, for example, 43.69 minutes. The H-SFN may be broadcast by the cell. The H-SFN may increment at SFN cycle boundaries.

[0087] The H-SFN in which a WTRU may become reachable for paging may be referred to as a paging hyper frame (PH) or as the WTRU's PH. The PH may be applicable, or only applicable, in ECM-IDLE. The PH may be computed as a function of the extended DRX cycle and/or WTRU ID, for example, IMSI mod 1024. Within a PH, the determination of the PF and/or PO may follow the regular DRX rules and/or formulas. A WTRU's paging window (PW) may be the window or time span corresponding to the set of PFs in the WTRU's PH during which the WTRU may monitor for paging and/or may be paged. The PW may include a subset of the available PFs in the PH. In an example shown in timing diagram 200, PW 250 may include PF 260, PF 270 and PF 280. PF 260, PF 270 and PF 280 may be PFs within PH 290. eDRX cycle 295 may include PH 290. The PW may be signaled to the WTRU, for example by the MME in a NAS message. In a PF, a WTRU may monitor or only monitor one PO. Paging to a WTRU may be repeated in one or more of a WTRU's PFs in its PW, for example if the WTRU does not respond to a previous page.

[0088] A cell's support of idle mode extended DRX may be implicitly indicated by the broadcast of H-SFN. For long DRX cycles, it may be useful for the MME to have some awareness of when the WTRU may be become reachable, for example to avoid storing paging requests at the eNode-B for a long time. In connected mode, the DRX cycle may be extended up to the SFN

limit, for example, by extending the range of values for long DRX cycles to 10.24 seconds.

[0089] A large population of NB WTRUs may be multiplexed within a limited number of paging resources. If the distribution of WTRUs among paging resources is based on WTRU-ID, for example IMSI or IMSI modulo 1024, there may, for example still be a large number of WTRUs sharing the same paging resources in time and/or frequency, for example sharing the same PO and/or paging NB.

[0090] A NB WTRU may monitor M-PDCCH in a PO or each of its POs. If the M-PDCCH, or a DCI in the M-PDCCH, indicates the scheduling of an associated PDSCH for paging message, the NB WTRU may receive the associated PDSCH, for example, to check if there may be a paging message targeted to the NB WTRU.

[0091] Since a large number of NB WTRUs may share the same paging resources, a NB WTRU may receive the associated PDSCH when the paging message may not be targeted to the NB WTRU. The reception of an associated PDSCH that may not be intended for the WTRU may, for example, increase the WTRU's battery consumption unnecessarily. If the NB WTRU is in a CE level that may use a large number of repetitions, the impact to the WTRU may be worse, and may be, for example, significantly worse.

[0092] A NB WTRU may monitor M-PDCCH, for example in a PO or in each PO, in a NB WTRU specific or a NB WTRU group specific manner. The M-PDCCH may implicitly or explicitly indicate the necessity of receiving and/or decoding the M-PDCCH and/or an associated PDSCH, for example by a WTRU or group of WTRUs. For example, the M-PDCCH may implicitly or explicitly indicate the intended recipient or recipients of the M-PDCCH, an associated PDSCH, a page, a paging message or a PDSCH carrying a paging message or channel. Further, an implicit indication of paging reception, the need for paging reception, or the intended recipient or recipients of a M-PDCCH, a PDSCH, a page, a paging message or a PDSCH carrying a paging message or channel may be employed which uses one or more of: a scrambling indication; a scrambling sequence such as a scrambling sequence for M-

PDCCH randomization, a WTRU group-specific or WTRU-specific scrambling sequence, an information type specific scrambling sequence, or a scrambling sequence for paging reception; a starting enhanced control channel element (ECCE) index for M-PDCCH randomization, a bit interleaver for M-PDCCH randomization; and/or one or more Radio Network Temporary Identifiers (RNTIs).

[0093] In an example, a scrambling sequence may be used to randomize a bit sequence of an M-PDCCH. A WTRU that may use the same scrambling sequence to descramble the received bits may receive or may be able to receive the M-PDCCH. In an example, only a WTRU that may use the same scrambling sequence to descramble the received bits may receive or may be able to receive the M-PDCCH.

[0094] The bit sequence of an M-PDCCH may be a bit sequence before the modulation of M-PDCCH. For example, the bit sequence of an M-PDCCH may be a bit sequence after rate matching. A coded bit sequence may be an input bit sequence of the rate matching and an output bit sequence of the rate matching may be the bit sequence of an M-PDCCH. A DCI with cyclic redundancy check (CRC) scrambled by an RNTI may be an input bit sequence of the channel coding block and an output bit sequence may be a coded bit sequence.

[0095] The bit sequence of an M-PDCCH may be a bit sequence before the channel coding. For example, a DCI with CRC scrambled by an RNTI may be the bit sequence of an M-PDCCH.

[0096] For the RNTI, one or more of following examples may apply. The RNTI may be a P-RNTI, for example, if the DCI may be used for the paging. In another example, the RNTI may be a group-specific P-RNTI which may be associated with a scrambling sequence. In a further example, the RNTI may be the N least significant bits (LSBs) of a WTRU-ID that may be used for paging. N may be the number of CRC bits, which may be referred to as NCRC. For example, the 16 LSBs of a WTRU-ID, for example, IMSI or System Architecture Evolution (SAE)-Temporary Mobile Subscriber Identity (s-TMSI), may be used. The N bits used for the RNTI may be the same N bits that

correspond to WTRU-ID modulo (2^N), for example, IMSI modulo (2^N), where N may be 16.

[0097] In an example, a bit sequence of M-PDCCH $b(0),\ldots,b(M_{\text{bit}}-1)$ may be scrambled with a certain scrambling sequence, $c(i)$, where M_{bit} may be the number of bits in the bit sequence of an M-PDCCH. The result of a WTRU-specific or a WTRU group-specific scrambling sequence may be referred to as $\tilde{b}(0),\ldots,\tilde{b}(M_{\text{bit}}-1)$.

[0098] In an example, the $\tilde{b}(0),\ldots,\tilde{b}(M_{\text{bit}}-1)$ bit sequence may be determined based on $\tilde{b}(i)=(b(i)+c(i))\text{mod}2$, where mod2 may be modulo-2 operation. Further, the scrambling sequence $c(i)$ may be a Pseudo-random sequence that may be determined based on an initialization value, c_{init}, where i may be a bit index of the bit sequence.

[0099] The certain scrambling sequence may be determined based on at least one of whether the M-PDCCH or scrambling sequence may be WTRU-specific or WTRU group-specific, information type in the associated DCI and information type in the associated PDSCH. The initialization value (c_{init}) may be determined based on at least the WTRU-ID, at least the associated WTRU group number, at least the information type in the associated DCI, at least the information type in the associated PDSCH and/or an RNTI.

[0100] In an example, a WTRU which may monitor or attempt to decode a bit sequence of M-PDCCH may use its associated scrambling sequence. The associated scrambling sequence may be determined based on at least one of whether the M-PDCCH or scrambling sequence may be WTRU-specific or WTRU group-specific, and/or information type in the DCI. For example, the associated scrambling sequence may be determined based on the type of the information in the DCI for which the WTRU may be monitoring, such as WTRU-specific or WTRU group-specific paging. In an example, the WTRU may perform descrambling with an input bit sequence of the channel decoder. Also, the WTRU may perform descrambling with an output bit sequence of the channel decoder. In an example, if the bit sequence of M-PDCCH received at the WTRU receiver is $d(0),\ldots,d(M_{\text{bit}}-1)$, the $\tilde{d}(0),\ldots,\tilde{d}(M_{\text{bit}}-1)$ sequence may be

referred to as a descrambled bit sequence with the associated scrambling sequence $c(i)$. As an example, the WTRU may perform descrambling with $\tilde{d}(i) = (d(i) + c(i)) \bmod 2$.

[0101] A WTRU-specific scrambling sequence and/or a WTRU group-specific scrambling sequence may be provided and/or used. In an example, a WTRU-specific or WTRU group-specific scrambling sequence, for example a first scrambling sequence, may be used to scramble a bit sequence of an M-PDCCH, for example in a PO or each PO. In an example, a WTRU or a WTRU group that may use the same scrambling sequence, for example the first scrambling sequence, may decode or may be able to decode the M-PDCCH. For example only a WTRU or a WTRU group that may use the same scrambling sequence, for example the first scrambling sequence, may decode or may be able to decode the M-PDCCH.

[0102] In an example of using a WTRU group-specific scrambling sequence, N_g scrambling sequences may be used for N_g WTRU groups for a PO and a bit sequence of M-PDCCH intended or targeted for a WTRU group, for example a first WTRU group, within N_g WTRU groups may be scrambled with the corresponding scrambling sequence, for example a first scrambling sequence. In an example, the WTRU group using the corresponding scrambling sequence, for example the first scrambling sequence, may receive or may be able to receive the M-PDCCH. In a further example, only the WTRU group using the corresponding scrambling sequence, for example the first scrambling sequence, may receive or may be able to receive the M-PDCCH. The WTRU group-specific scrambling sequence may be determined based on at least one of following: a modulo operation that may, for example, be based on at least N_g and the WTRU-ID; a hashing function that may, for example, be based on N_g and the WTRU-ID; and the WTRU group number that may, for example, be determined based on at least a CE level.

[0103] A modulo operation may be used where the modulo operation may be based on at least N_g and the WTRU-ID (N_{WTRUID}). The WTRU group number (N_{group}) may be determined by WTRU-ID modulo N_g (for example

$N_{group} = (N_{WTRUID}) \bmod N_g$). A subframe number and/or a frame number (for example SFN) may be used. For example, $N_{group} = (N_{WTRUID} \cdot N_{Frame}) \bmod N_g$.

[0104] A hashing function may be used where the hashing function may be based on N_g and the WTRU-ID. In this case, for example, $N_{group} = (A \cdot N_{WTRUID}) \bmod N_g$, where the A may be a prime number (for example A = 39,827), or $N_{group} = ((A \cdot N_{WTRUID}) \bmod D) \bmod N_g$, where the D may be a prime number which may be different from A (for example D = 65,537). The hashing function may be based on a subframe number and/or a frame number.

[0105] The WTRU group number may be determined based on at least a CE level. For example, WTRUs with a first CE level (for example CE level-1) may be grouped as a first WTRU group and WTRUs with a second CE level (for example CE level-2) may be grouped as a second WTRU group.

[0106] The WTRU-ID may be at least one of an RNTI allocated for a WTRU, IMSI, and s-TMSI, and/or a part of at least one of the allocated RNTI, IMSI, and s-TMSI. For example, WTRU-ID may be IMSI modulo M or s-TMSI modulo N. M and/or N may be 1024. A and/or D may be a function of N_g. A and/or D may be fixed and/or configured, for example, by the eNode-B via signaling. A N_{WTRUID} may be the WTRU-ID or a portion of or function of the WTRUs IMSI or s-TMSI. For example N_{WTRUID} for a WTRU may be IMSI-10, or IMSI modulo X, where X may be a number less than or equal to 1024.

[0107] In an example of using a WTRU specific scrambling sequence, a WTRU specific scrambling sequence may be used for a bit sequence of M-PDCCH intended or targeted for a WTRU, where the WTRU specific scrambling sequence may be determined based on at least a WTRU-ID or a part of a WTRU-ID. In MME initiated paging, the WTRU-ID may be provided by the MME to the eNode-B in an S1 paging message or request.

[0108] In an example, the scrambling sequence may be determined based on the specific information type which may be carried in the DCI. For example, a first scrambling sequence may be used for a bit sequence of an M-PDCCH in which the DCI may carry a first information type and a second

scrambling sequence may be used for a bit sequence of an M-PDCCH in which the DCI may carry a second information type.

[0109] The first information type may include, but not be limited to, at least one or more system information update indications such as system information modification indication, an ETWS indication, a CMAS indication, and an EAB parameter modification indication. One or more system information indications may be a single bit to indicate the system information update or multiple bits to indicate the system information update of multiple SIs, for example, SIBs or SI-messages. An additional indicator may be included, for example, a flag bit to indicate a DCI format or a DCI type. The scrambling sequence for the first information type may be based on at least one of cell-specific parameters, such as for example, a physical cell-ID.

[0110] The second information type may be at least scheduling information of the associated PDSCH. The scrambling sequence for the second information type may be based on at least one of WTRU-specific parameters, such as for example, a WTRU-ID.

[0111] In another example, the scrambling sequence may be determined based on the information type carried in a DCI and/or WTRU-ID. For example, a first scrambling sequence may be used for a bit sequence of an M-PDCCH in which the DCI may carry a first information type, and a second scrambling sequence may be used for a bit sequence of an M-PDCCH in a which the DCI may carry a second information type. The first scrambling sequence may be predefined. The second scrambling sequence may be determined based on a WTRU-ID.

[0112] In an example, the PO for the first information type and the second information type may the same. Further, a WTRU may monitor M-PDCCH for both the first information type and the second information type. Also, a WTRU may monitor M-PDCCH for the first information type in a subset of POs or all POs. A WTRU may monitor M-PDCCH for the second information type in a subset of POs or all POs.

[0113] In another example, the PO for the first information type and the second information type may be different. The time and/or frequency location

of the PO for the first information type may be determined based on at least one cell-specific parameter. The cell-specific parameters may include, for example, a physical cell-ID, a system bandwidth, a subframe number, a frame number such as an SFN and the like. The time and/or frequency location of the PO for the second information type may be determined based on at least one WTRU-specific parameter, such as, for example, a WTRU-ID.

[0114] Examples which include the use of a scrambling sequence for paging reception are disclosed herein. A WTRU may determine a bit scrambling sequence, for example, an M-PDCCH bit scrambling sequence according to one or more examples described herein. In an example, the WTRU may monitor for an M-PDCCH in a PO. The WTRU may descramble the received signal or M-PDCCH using the bit scrambling sequence. The WTRU may determine if the descrambled M-PDCCH may carry a DCI masked with an RNTI that the WTRU may use for paging. The RNTI may be, for example, a P-RNTI. If the WTRU determines the DCI is masked with the RNTI, such as, for example, the P-RNTI, the WTRU may read the contents of the DCI to obtain one or more of system information update information and/or PDSCH scheduling information. The WTRU may use the scheduling information to receive an associated PDSCH that may carry one or more paging records or paging messages.

[0115] Examples using a starting ECCE index for M-PDCCH randomization are disclosed herein. In an example, an M-PDCCH search space may be used for monitoring for an M-PDCCH or a DCI, where the starting ECCE index, for example for monitoring, may be determined based on at least one WTRU-specific parameter. For example, a WTRU may use an M-PDCCH search space for monitoring for a an M-PDCCH or a DCI, where the starting ECCE index, for example for monitoring, may be determined based on at least one WTRU-specific parameter. As used herein, control channel element (CCE), ECCE and NB-IoT control channel element (NCCE) may be used interchangeably.

[0116] FIG. 3 is an exemplary diagram which illustrates WTRU group-specific starting ECCE indexes. Diagram 300 shows an example of ECCEs in a

subframe 310 at ECCE aggregation level 16. In other examples, other ECCE aggregation levels such as 1, 2, 4, 8 and 32 may be used. In an example shown in FIG. 3, a WTRU may use a different starting ECCE index depending upon the group the WTRU is in. For example, the WTRUs may be divided among four WTRU groups, numbered WTRU group #1 through WTRU group #4. WTRUs in WTRU group #1 may use a starting ECCE index 330 with a starting ECCE of 1, WTRUs in WTRU group #2 may use a starting ECCE index 350 with a starting ECCE of 5, WTRUs in WTRU group #3 may use a starting ECCE index 370 with a starting ECCE of 9, and WTRUs in WTRU group #4 may use a starting ECCE index 390 with a starting ECCE of 12.

[0117] FIG. 4 is a diagram of an example flow chart showing a WTRU receiving a machine type communication (MTC) physical downlink control channel (M-PDCCH) with a starting ECCE index based on the WTRU group of the WTRU. In an example shown in chart 400, a WTRU may monitor for an M-PDCCH in an M-PDCCH search space 410. The WTRU may monitor for the M-PDCCH using a starting ECCE index for the WTRU group containing the WTRU. The WTRU may then receive the M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH may have a starting ECCE index for the WTRU group containing the WTRU 420. In an example corresponding to the WTRU groups shown in FIG. 3, the WTRU may be in WTRU group #2 and may therefore monitor for and/or receive an M-PDCCH with a starting ECCE index 350 of 5. Further, the WTRU may decode the M-PDCCH, wherein the M-PDCCH includes a DCI 430. The WTRU may receive a PDSCH associated with the M-PDCCH 440 or the DCI, for example a PDSCH scheduled by the M-PDCCH or the DCI. In an example, the WTRU may receive, decode, attempt to decode, demodulate, and/or attempt to demodulate the PDSCH based on the DCI, wherein the PDSCH may include a paging message. As a result, the WTRU may change its operation based on the paging message. For example, the WTRU may change from idle mode to connected mode based on the paging message. The WTRU may then begin to transmit and receive in connected mode. In another example, the WTRU may already be in connected

mode and may change its system operation based on system information change information in the page message.

[0118] In another example, an M-PDCCH search space may be used for a DCI monitoring, where the starting ECCE index and ordering (for example, an ascending order, a descending order, a random order and/or a predefined order) may be used to determine an M-PDCCH candidate. For example, if a number of ECCEs, $N_{ECCE,}$ is available in the search space and an ECCE aggregation level is the same as N_{ECCE} for an M-PDCCH candidate, one or more M-PDCCH candidates may be determined based on the starting ECCE index and/or ordering.

[0119] An M-PDCCH candidate may be defined or configured with N_{ECCE} ECCEs which may be aggregated in an ascending order, descending order, ascending order with a starting ECCE index, or descending order with a starting ECCE index. In an example, the starting ECCE index and/or ordering may be determined based on at least one WTRU-specific parameter. In a further example, the starting ECCE index and/or ordering may be determined based on at least information type carried in the DCI.

[0120] In another example, an M-PDCCH search space may be used for a DCI monitoring, where the ECCE aggregation may be based on a sequence. The sequence for the ECCE ordering may be determined based on at least one WTRU-specific parameter.

[0121] FIG. 5 is an exemplary diagram which illustrates WTRU group-specific random ECCE ordering. A sequence for the ECCE ordering may be determined based on at least one WTRU-specific parameter as shown in diagram 500. Similar to FIG. 3, FIG. 5 shows an example of ECCEs in a subframe 510, at ECCE aggregation level 16. In an example, a sequence may determine the ECCE ordering for ECCE aggregation. In a further example, the sequence for ECCE ordering may be determined based on at least one of: a WTRU-specific parameter, an information type carried in the DCI, an RNTI that may be used for CRC scrambling, a DCI format used and a CE level or repetition number such as, for example a repetition number of an M-PDCCH candidate.

[0122] In yet a further example, a set of random sequences may be predefined or configured, for example for a group of WTRUs. A sequence may correspond to a starting ECCE index. A sequence may correspond to ECCE aggregation ordering.

[0123] In an example shown in FIG. 5, a WTRU may use a different starting ECCE index depending upon a random sequence that may be defined, configured and/or used by or for the group the WTRU is in. For example, the WTRUs may be divided among four WTRU groups, numbered WTRU group #1 through WTRU group #4. WTRUs in WTRU group #1 may use a first random sequence 530 that may correspond to a starting ECCE index of 4, WTRUs in WTRU group #2 may use a second random sequence 550 that may correspond to a starting ECCE index of 5, WTRUs in WTRU group #3 may use a third random sequence 570 that may correspond to a starting ECCE index of 9, and WTRUs in WTRU group #4 may use a fourth random sequence 590 that may correspond to a starting ECCE index of 12. A random sequence, for example, within the set, may be determined based on at least one of: a WTRU-specific parameter, an information type carried in the DCI, an RNTI that may be used for CRC scrambling, a DCI format used, or a CE level or repetition number, such as, for example, a repetition number of an M-PDCCH candidate.

[0124] Examples using a bit interleaver for M-PDCCH randomization are disclosed herein. In an example, a bit sequence for an M-PDCCH may be interleaved with an interleaving sequence. The interleaving sequence may be a sequence with the length of the bit sequence. The bit positions may be interleaved based on the interleaving sequence. In an example, the interleaving sequence may be determined based on one or more of at least one WTRU-specific parameter, an information type carried in the DCI, an RNTI that may be used for CRC scrambling, a DCI format used, and a CE level or repetition number such as, for example a repetition number of an M-PDCCH candidate. In a further example, a WTRU may use the interleaving sequence to de-interleave the received bit sequence before it may attempt to decode the received bit sequence.

[0125] In an example, one or more RNTIs may be used for a DCI, for example to indicate to a WTRU whether to decode an associated PDSCH. For example, a cell-specific P-RNTI and one or more WTRU group specific P-RNTIs may be used. A WTRU may attempt to decode the M-PDCCH with the cell-specific P-RNTI and/or an associated WTRU group specific P-RNTI in a PO. In an example, a first P-RNTI may be used for a DCI carrying a first information type. In a further example, a second P-RNTI may be used for a DCI carrying a second information type. Also, in a PO, a WTRU may attempt to decode a DCI with the first P-RNTI and/or the second P-RNTI.

[0126] A first P-RNTI may be used for a DCI carrying a first information type. The first P-RNTI may be a cell-specific P-RNTI. The first information type may include but not be limited to at least one or more system information update indications such as a system information modification indication, an ETWS indication, a CMAS indication, and an EAB parameter modification indication. One or more system information indications may be a single bit to indicate the system information update or multiple bits to indicate the system information update of multiple SIs, such as, for example, SIBs or SI-messages. An additional indicator may be included, such as, for example a flag bit to indicate a DCI format or a DCI type. The first P-RNTI may be based on at least one cell-specific parameter, such as, for example a physical cell-ID.

[0127] A second P-RNTI may be used for a DCI carrying a second information type. A set of P-RNTIs may be predefined or configured for the second P-RNTI and one of the predefined or configured P-RNTIs may be determined in a WTRU-specific or a WTRU group specific manner. A modulo operation with a WTRU-ID and/or the number of P-RNTIs configured may be used to determine the associated P-RNTI. A hashing function may be used with a WTRU-ID and/or the number of P-RNTIs configured to determine the associated P-RNTI.

[0128] In a PO, a WTRU may attempt to decode a DCI with the first P-RNTI. The WTRU may also attempt to decode a DCI with the second P-RNTI which may be associated with the WTRU. If a WTRU may successfully decode a DCI with the first P-RNTI, then the WTRU may not monitor a DCI with the

second P-RNTI. If a WTRU may not successfully decode a DCI with the second P-RNTI, then the WTRU may assume that the associated PDSCH may not be scheduled.

[0129] An explicit indication of paging reception is disclosed herein including the use of: a paging occasion type; a monitoring indicator for a paging occasion, a paging type, a paging message, a paging window, among others; multiple monitoring indicators; and multiple monitoring indicators with explicit and implicit indications. In examples, one or more paging occasion types may be used, configured, or defined, for example for a RRC idle WTRU and/or a RRC connected WTRU.

[0130] A first paging occasion type may be used for a paging message transmission in which a WTRU may monitor for a paging message. The paging message may include one or more paging records and/or one or more system information update indications. In an example, the paging message may be carried in a DCI. In a further example, the paging message may be carried in a PDSCH and the scheduling information of the PDSCH may be provided in an associated DCI. Also, the paging message may be carried in a PDSCH without an associated DCI for the scheduling information. Further, the contents of the paging message may be indicated from the associated DCI. For example, a DCI may indicate the information type included in the paging message.

[0131] In an example, a second paging occasion type may be used for one or more system information update indications. In a further example, one or more paging occasion types may be located in a same time/frequency resource and monitored separately.

[0132] The time/frequency locations for one or more paging occasion types may be determined independently. A time/frequency location of a first paging occasion type may be determined based on at least one WTRU-specific parameter, such as, for example, a WTRU-ID. A time/frequency location of a second paging occasion type may be determined based on at least one cell-specific parameter, such as, for example, a physical cell-ID, (e)DRX cycle, system bandwidth and the like.

[0133] In an example, a DCI format or DCI contents may be different according to the paging occasion type. Further, an associated RNTI may be different according to the paging occasion type.

[0134] In an example, an indication for monitoring, for example, a monitoring indicator, of one or more of PO types may be transmitted in a broadcast channel, such as, for example, in a MIB, in a DCI in common search space and the like. For example, a broadcast channel may be transmitted in every x ms and one or more POs may be associated with a broadcast transmission. The broadcast transmission may indicate if a WTRU may need to monitor one or more POs associated with the broadcast transmission. A WTRU may attempt to decode or read a broadcast channel which may carry the monitoring indicator before it may monitor one or more POs. In an example, a monitoring indicator may be associated with one or more PO types. For example, the monitoring indicator may be associated with a first PO type. In a further example, the monitoring indicator may be associated only with a first PO type. In another example, the monitoring indicator may be associated with a second PO type. In a still further example, the monitoring indicator may be associated only with a second PO type. In an example, the monitoring indicator may be set to TRUE or FALSE. Based on the monitoring indicator, a WTRU may monitor a WTRU-group specific PO which may be determined based on at least one of a WTRU-specific parameter, such as, for example a WTRU-ID, or a cell-specific PO that may be determined based on at least one cell-specific parameter, such as, for example, a physical cell-ID.

[0135] A monitoring indicator may be associated with one or more POs. For example, a monitoring indicator may be associated with POs within a certain time window. If a WTRU receives the monitoring indicator, the WTRU may attempt to receive or monitor POs within the certain time window.

[0136] A monitoring indicator may indicate a WTRU group index and a WTRU group associated with the monitoring indicator may monitor the POs. In an example, the monitoring indicator may indicate which WTRU group may need to monitor POs. The WTRU group may include all WTRU groups for a system information update. In another example, the monitoring indicator

may have a number of states, such as four states and may indicate at least one of the states. The states may, for example include cell common paging, a first WTRU group, a second WTRU group, and a third WTRU group. In an example, the cell common page may be or occur in a cell-specific PO. A WTRU may monitor a PO or monitor for a page according to a monitoring indicator state.

[0137] A monitoring indicator may indicate a PO type and a WTRU may monitor POs corresponding to the PO type. In an example, a WTRU may receive a monitoring indicator which indicates a first PO type, and then the WTRU may monitor POs corresponding to the first PO type. Further, a WTRU may receive a monitoring indicator which indicates a first PO type, and then the WTRU may monitor POs corresponding to the first PO type only.

[0138] In another example, a monitoring indicator may be used with a WTRU group specific M-PDCCH scrambling sequence, a WTRU group specific RNTI, a WTRU group specific starting ECCE index, and/or a WTRU group specific interleaver. A monitoring indicator may be used to indicate if a WTRU may need to monitor POs associated with it and an implicit indication of paging reception schemes may be used in each PO. A WTRU may, for example, attempt to decode, receive, or monitor the monitoring indicator and, if the monitoring indicator indicates that the WTRU may need to monitor the POs, the WTRU may attempt to decode or monitor the POs, for an M-PDCCH, for example, with its associated scrambling sequence, starting ECCE index, RNTI, and/or interleaving sequence. Further, a WTRU may first attempt to decode, receive, or monitor the monitoring indicator and, if the monitoring indicator indicates that the WTRU may need to monitor the POs, the WTRU may attempt to decode or monitor the POs, for an M-PDCCH, for example, with its associated scrambling sequence, starting ECCE index, RNTI, and/or interleaving sequence.

[0139] In an example, one or more monitoring indicators may be used and a WTRU may determine if the WTRU may need to monitor, receive, or attempt to decode an M-PDCCH and/or a PDSCH carrying paging related information. A monitoring indicator may be used to determine if a WTRU

needs to monitor or attempt to decode a M-PDCCH in a PO, which may be referred to as a PO (paging occasion) monitoring indicator. A monitoring indicator may be used to determine if a WTRU needs to receive an associated PDSCH which may carry a paging message (PM), which may be referred to as a PM monitoring indicator. A monitoring indicator may be used to determine if a WTRU needs to monitor POs within a paging window (PW), which may be referred to as a PW monitoring indicator. A PW may include one or more POs for a WTRU. A PW may be defined or determined based on a number of POs. For example, a PW may be defined to include N_{PO} POs where N_{PO} may be a positive integer number.
